Job insecurity is a major work related stressor, which affects growing number of workers. Exposure to job insecurity has been linked to a number of negative health outcomes, particularly mental health. In recent years, job insecurity and a sustainable development growth has become more relevant for employees and organizations. The global situation and the world economy have undergone major changes in recent decades, which have affected organizations. These global changes have called for alterations in organizations and organizational practices in order for companies to be able to survive in this new context with increased competitiveness. There has been a decline in the use of long-term employment and thus in life-long tenure as well, which were the standard previously. Today, employees need to be able to deal with organizations need for flexibility, while loyalty to the organization, which formerly predominated employee’s behavior and attitudes, has taken a back seat. This also means that organizations are less likely to provide an opportunity for the organizational career, a life-long employment with one employer. In comparison to before, when organizations were more likely to provide security and sustainable development, employees today often need to ensure their own security by staying employable. Technology has advanced rapidly with the increasing and there have been some negative effects on working life from these new technologies; the boundaries between work and life outside work have been blurred, increasing the risk of working always and everywhere, especially in situations where working hours are unclearly regulated. When dealing with information overload, which can be caused by the new technologies and by the increased pace and amount of work employees have to accomplish, work stressors might spill more easily over into the non-work domain. It is well established that job insecurity affects both the individual and the organization. Job insecurity found relations between job insecurity and the aspects of
decreased job satisfaction, organizational commitment, trust, performance, job involvement, mental and physical health along with their sustainable development, and increased turnover intention. Outcomes of job insecurity may be  

Health related problems such as hypertension, anxiety and depression. In addition, mental health as well as family life may be affected negatively. It is also to be noted that their work life balance may fluctuate to the point of reaching unsteadiness.

**Literature Reviews**

1. Banu et al(2012), In this study the researcher found out that seasonal workers perceive higher job insecurity compared to permanent workers. They are also affectively less committed to their organizations than permanent workers. Furthermore, job insecurity does not mediate the relationship between contract type and affective commitment
2. Beatriz Sora et al (2010), In an innovative study the researchers attempted to measure the consequences of job insecurity for employees in the midst of liberation and globalization of the respective economies they argued that the job insecurity has tremendous impact over employees work attitude and intention. The results also revealed job insecurity adversely affects job satisfaction and organizational commitment. It perceived that work stressor and negatively creative over employees attitude
3. Bert Klandermans (2010), In this study the researcher finds that job insecurity has adverse affects on psychological well being and it also self esteem. It also reveals that job insecurity even leads to job loss.
4. Bert Klandermans et al (2010), In this study the researcher states that the impact of ones job loss depends upon the individual employment status. The job insecurity reflects health problems and the objective conditions, severity of job loss and depending upon employment status.
5. J.H. Buitendach, (2005), In this study the results revealed that there is small but significant relationships between job insecurity, extrinsic job satisfaction, job insecurity and affective organizational commitment. Job satisfaction was found to mediate the relationship between job insecurity and affective organizational commitment.
6. Claudia Bernhardet al (2011), the researcher in this study investigates job insecurity affects the individual well being. Job insecurity is negatively related to organizational outcomes and it is associated with lower affective organizational commitment and higher turnover intentions.

**Research Gap:** After investigating the national and international literature reviews regarding the job insecurity reflects health & stress problems and Job insecurity of employees and their sustainable development in the career growth in IT and ITeS companies, the researcher identified two predominant gaps which are still unaddressed at national and international level.

1. Are there any sufficient number of factors able to determine that job insecurity and perception towards sustainable development in their career growth of employees in the growing IT companies.
2. Is there any correlation between the employee’s perception and that job insecurity & sustainable development of their career growth in IT and ITeS companies.

These two predominant gaps are ventured by the researcher to find the solutions to fulfil them.

**Objectives of the Study**

1. To analyze the depth of job insecurity reflects health & stress problems and its perception towards sustainable development of their career growth affecting the employees in the study domain
2. To measure the influence of personal and organisational profile of the employees on their perception towards job insecurity & sustainable development in their career growth.

**Hypothesis:**

1. There is no significant difference among the employees perception towards job insecurity & sustainable development in their career growth in IT and ITeS companies.
2. The following Hypothesis were formulated:

Perceived Job insecurity is associated with reduced affective commitment and increased job related stress.

Methodology

The IMFL companies in Tamilnadu was selected as a suitable setting to test the proposed model. Mainly the focus was on the HRM practices in IMFL companies in Chennai. The main reasons for selecting this industry are:

(1) Availability of a higher number of IMFL companies
(2) availability of more number of employees working in these companies.

The unit of analysis in this study is the “Job insecurity”. So identifying the dyads that would provide the needed information is the key to this project. In order to ensure higher number of dyads, a total of ten companies five each in IT companies were focused for the study. The researcher circulated totally 572 questionnaires in IT companies and received 556 responses, among them 16 of them are found with flaws, hence the sample size of the research is 540.

Data Analysis: The application of K-means cluster analysis classified the employees concerned to HRM practices into three clusters namely perfection seekers, Unambitious employees and enthusiastic employees with respect to their perception towards HRM practices. Similarly, the employees concerned to job insecurity and trust are classified into three groups, security employees, attached employees and dedicated employees. The association between these two clusters was verified.

Analysis and Discussion

Classification of Employees Based on the Insecurity and Employee Trust: Result show that employees at risk of losing their jobs showed higher levels of perceived stress, anxiety, depression, and negative feelings and lower levels of positive feelings compared to employees not at risk of losing their jobs. The samples units into heterogeneous groups and their nature of heterogeneity are anatomically analyzed by the perceptual differences of Employees are identified through k-means cluster analysis by classifying the sample unit in the following way.

<table>
<thead>
<tr>
<th>Cluster</th>
<th>Job insecurity</th>
<th>Reliability</th>
<th>Organization caring</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3.79</td>
<td>2.79</td>
<td>2.45</td>
</tr>
<tr>
<td>2</td>
<td>3.97</td>
<td>3.97</td>
<td>3.02</td>
</tr>
<tr>
<td>3</td>
<td>2.92</td>
<td>4.92</td>
<td>4.73</td>
</tr>
</tbody>
</table>

Table 1: Final Cluster Centers

<table>
<thead>
<tr>
<th>Cluster</th>
<th>Number of Cases</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>204,000</td>
<td>37.78%</td>
</tr>
<tr>
<td>2</td>
<td>205,000</td>
<td>37.96%</td>
</tr>
<tr>
<td>3</td>
<td>131,000</td>
<td>24.25%</td>
</tr>
<tr>
<td>Valid</td>
<td>540,000</td>
<td>100.00%</td>
</tr>
</tbody>
</table>

Table 2: Number of Cases in each Cluster

The first cluster consists of 204 employees (37.78%) highly agree with job insecurity and disagree with reliability and organization caring. Therefore this group is known as Security seekers.

The second group 205 employees (37.96%) moderately agree with job insecurity, reliability and organization caring. Therefore they are called as Attached employees.

The third group 131 employees (24.25%) disagree with job insecurity and strongly agree with reliability and organization caring, hence they can be label as Dedicated employees.

Association between Job Insecurity and Employee Trust And existing Innovative Hr Practices in IT and ITeS: Factor analysis by principal component method derived the factors of job insecurity and employee trust in IMFL companies. These factors are considered as the basis to classify the employees into heterogeneous groups. Therefore it is essential to establish the Associations between the clusters of employee’s perception on job insecurity and employee trust and existing innovative HR practices in IMFL companies. In particular the existing innovative HR practices are 360 degree appraisal, performance based incentive, best employee award, attitude survey, competency mapping, higher studies for advancement at its expenses, flexible working hours, best suggestion award and work from home. Vice versa in the case of those who are all not performing well will lead to down grading of their status due to which psychology of the employee will lead to stress and stain resulting in mental illness.
Association between Job Insecurity and Employee Trust and 360 Degree Appraisal Systems: The existing innovative practice 360 degree appraisal system practiced in the organisation provide the employees job insecurity and trust in the IMFL companies they work. The association between clusters of job insecurity and employee trust and 360 degree appraisal practiced in IMFL companies is verified in the following table.

<table>
<thead>
<tr>
<th>Commitment</th>
<th>360 degree appraisal practices</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1.00</td>
<td>2.00</td>
</tr>
<tr>
<td>Security seekers</td>
<td>Count</td>
<td></td>
</tr>
<tr>
<td>Attached employees</td>
<td>Count</td>
<td></td>
</tr>
<tr>
<td>Dedicated employees</td>
<td>Count</td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>Count</td>
<td></td>
</tr>
</tbody>
</table>

From the above table, it is found that 77% of security seekers, 63.9% of attached employees and 41.2% of dedicated employees agreed towards their companies practicing 360 degree appraisal system and would provide job insecurity and employee trust among the employees working in IMFL companies. This leads to the computation of chi-square statistics as stated in the table below.

<table>
<thead>
<tr>
<th></th>
<th>Value</th>
<th>df</th>
<th>Asymp. Sig. (2-sided)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pearson Chi-Square</td>
<td>43.924(a)</td>
<td>2</td>
<td>.000</td>
</tr>
<tr>
<td>Likelihood Ratio</td>
<td>43.836</td>
<td>2</td>
<td>.000</td>
</tr>
<tr>
<td>Linear-by-Linear Association</td>
<td>42.601</td>
<td>1</td>
<td>.000</td>
</tr>
</tbody>
</table>

From the above table it is found that chi-square = 43.924, p=.000, therefore it can be concluded that there is association between job insecurity and employee trust and practice of 360 degree appraisal system in the IMFL companies. This implies the rigors 360 degree performance appraisal system is a very important factor as it determines the quality of the performance appraisal during the end of the year and recognizes the suitable rewards for the executive employees in the IMFL Company.

Findings and Conclusion

In IT and ITeS companies there is association between job insecurity and trust of the employees and practice of 360 degree appraisal system, performance based incentive system, best employee award, attitude survey, competency mapping, higher studies for advancement at its expenses, flexible working hours, best suggestion award, working at home.

The job insecurity reflects health problems and the objective conditions, severity of job loss and depending upon employment status. Whereas the job security companies’ results in developing core competencies and managerial capabilities by increasing the value of the workforce and provide career opportunities by the way of sustainable development of their career growth there by retaining quality employees. The employees prefer working for companies with full job security engaging them in challenging work involving cutting edge technology that is possible through effective HRM practices like sustainable development in their career growth. It also results to next generation job aspirants expecting to possess a positive attitude towards the profession and equip themselves with the required skills to enter the industry. In the case of the employees mentality of job insecurity, has adverse affects on psychological well being and it also self esteem. It also reveals that job insecurity even leads to job loss.

ABSTRACT

Introduction: Acne is a multifactorial inflammatory disease affecting the pilosebaceous follicles of the skin. Acne is a disorder resulting from the effect of hormones and other substances on the oil glands (sebaceous glands) and hair follicles present in the skin. The aim of this study was estimation of serum Fasting insulin in patients with acne vulgaris and compares these values with those in controls.

Methodology: This is the case control study which was carried out in the Departments of Biochemistry and Dermatology & Venereology of SGT Medical College Gurgaon. Fifty patients each of Mild (group I), Moderate (group II) and Severe Acne Vulgaris (group III) in age group 15-40 years were included as cases.

Result: In the present study, the level of serum insulin was significantly higher in moderate cases of acne as compared to controls. Therefore we suggest that insulin may also play an important marker for causing acne. Insulin stimulates the secretion of ovarian estrogen, androgen and progesterone which is consistent with our studies as increase in estrogen and testosterone has also been observed in moderate cases of acne.

Conclusion: Insulin was significantly higher in moderate cases as compared to controls. There by suggesting that insulin may play an important role to causation of acne.

Keywords: Insulin, acne vulgaris, multifactorial inflammatory disease

Introduction

Acne Vulgaris, chronic inflammatory dermatosis, insulin, hormonal misbalanced

Acne Vulgaris is a chronic inflammatory dermatosis notable for open or closed comedones (blackheads and whiteheads) and inflamatory lesions, including papules, pustules, or nodules (also known as cysts)¹.

The grading system of acne is based on the morphology of lesions. Acne was graded according to the Consensus Conference on Acne Classification convened by American Academy of Dermatology in Washington DC on 24-25 March, 1990².

According to these criteria:

- Mild acne is defined by the presence of comedones, without significant inflammation and a few or no papules
- Moderate acne, by the presence of comedones, with marked inflammatory papules and pustules
- Severe acne, by the presence of inflammatory nodules, in addition to comedones, papules and pustules.

The extra sebum or oil that is produced by the sebaceous glands mixes with dead skin cells and bacteria on the skin’s surface and blocks these pores. Within the blocked pore, bacteria multiplies and cause inflammation. All of this leads to the lesions that are associated with acne. The pathophysiology of acne vulgaris can be broken up into four different events:

1. Androgen-dependent overproduction of sebum
2. Follicular hyperkeratosis (closed and open comedones)
3. Increase in microbial flora (Propionibacteria acnes)
4. Immunological processes and inflammation

These events are not individual events, and are affected by each other. For example, the increase in proliferation of Propionibacteria acnes is a result of increased sebum production, as well as hyperkeratosis. However, the bacteria are responsible in part for producing factors such as bacterial lipases, proteases, hyalurinadases and chemotactic factors that stimulate inflammatory mechanisms. Follicular inflammation can also cause an increase in sebum production.

The acne develops predominantly in adult age; possible reasons for this are diet, lifestyle and more synthetic hormones in our environment (foods, water, plastics and medicatin). By early recognition, the etiology and treatment protocol of acne may prevent unwanted conditions. Since its first clinical description, acne has always been the subject of a great number of studies and research. But only very few of them dealt with the history of the disease focusing on semantic considerations. Therefore in the present work estimation of Fasting insulin in serum of patients with different grade of acne vulgaris patients will be analyzed and to compare with control groups.

**Material & Method**

This is the case control study which was carried out in the Departments of Biochemistry and Dermatology & Venereology of SGT Medical College Gurgaon. Fifty patients each of Mild (group I), Moderate (group II) and Severe Acne Vulgaris (group III) in age group 15-40 years were included as cases. All of them presented to the OPD of Departments of Dermatology & Venereology of SGT Medical College Gurgaon and students of SGT University of varies faculty. A detailed history was taken and clinical examination was done. Fasting sample for estimation of all parameters was taken on second day of menstruation after the diagnosis was confirmed. Fifty healthy age matched females were recruited for the study as controls (group IV). Controls consisted of healthy volunteers. None of them had any prior history of medical disorders. Fasting sample was taken for the controls also. Duration of this study was one year (01/06/2015 to 31/05/2016). Institutional ethical committee clearance was also taken on 1/05/2015.

**Selection of Cases: (Group I, II and III)**

**Inclusion criteria for group I:** Fifty clinically diagnosed females were taken with Mild Acne Vulgaris, consists of open and closed comedones and some papules and pustules, based on detailed clinical history and examination.

**Inclusion criteria for group II:** Fifty clinically diagnosed females were taken with moderate Acne Vulgaris, consists of more frequent papules and pustules with mild scarring, based on detailed clinical history and examination.

**Inclusion criteria for group III:** Fifty clinically diagnosed females were taken with severe Acne Vulgaris, contains all of the above, plus nodules and abscesses and more scarring, based on detailed clinical history and examination.

**Inclusion criteria for control group IV:** Fifty healthy age matched females were taken as controls.

**Exclusion criteria: (group I, II, III and IV)**

- Patients on immunosuppressive therapy like corticosteroids, regular analgesic intake and hormonal therapy.
- Patients with concomitant inflammatory or autoimmune disease
- Patients with acute or chronic infections.
- Patients with acute or chronic inflammatory disorder.
- Patients with Acne other than Acne Vulgaris

**Sample Collection and Storage:** The samples were collected on the second day of menstrual cycle of the patient and before the start of treatment. Written and informed consent was taken from all subjects in the cases and control groups after explaining about the details of the study.
5ml venous fasting blood samples were taken from all the four groups of our study subjects in plain vacutainer under sterile conditions. Samples were centrifuged and separated immediately. Then serums were stored at -20°C till the time of analysis.

**Estimation of Insulin**

**Reagents**
- **Insulin Bead Pack:** Coated with monoclonal murine anti-insulin antibody.
- **Insulin Reagent Wedge:** Alkaline phosphatase (bovine calf intestine) conjugated to polyclonal sheep anti-insulin antibody and alkaline phosphatase (bovine calf intestine) conjugated to monoclonal murine anti-insulin antibody in buffer.
- **Insulin Adjustors:** Two vial (low and High), lyophilized insulin in a nonhuman serum matrix, with preservative. At least 30 minutes before use, reconstitute each vial by adding 4.0ml distilled or deionized water. Mix by gentle swirling or inversion.
- **Insulin Controls:** Two vials of lyophilized insulin in a nonhuman serum matrix, with preservative. At least 30 minutes before use, reconstitute each vial by adding 4.0 ml distilled or deionized water mix by gentle swirling or inversion.

**Statistical Analysis:** Data was collected and mean and SD for all the parameter was calculated. Statistical analysis was performed by the SPSS program for Windows, version 17.0.

**Result**

**The Study Group:** A cohort of Fifty female patients each of Mild (group I), Moderate (group II) and Severe Acne Vulgaris (group III) in age group 15-40 years, seen from 01/06/2015 to 31/05/2016 formed the study group.

**The control group:** Fifty healthy age matched females were recruited for the study as controls.

**Table 1: Frequency of cases in Mild, Moderate, Severe and Control**

</tbody>
</table>

The difference of mean value of insulin was found to be significantly higher in moderate (P< 0.016) cases as compared to control and moderate with severe cases (P< 0.004). The mean values of serum insulin (fasting) were also found higher in mild acne (Mean ± SD 17.74 ± 7.67, P=0.196) as compared to controls (Mean ± SD 15.63 ± 8.36). However the difference was not found statistically significant (P= 0.196).

**Discussion**

Acne vulgaris is a common skin disease, affecting more than 85% of adolescents, women being affected more frequently than men. It is seen in nearly 100% of individuals at some time during their lives. Although it does not affect overall health, its impact on emotional well-being and function can be critical, especially active acne and its sequel, like permanent scarring, leaves psychological stress that do not always correlate with the clinician’s assessment of severity at one point in time. Our group I, I1, and I12 comprised of patients of Mild, Moderate and Severe Acne Vulgaris. Group IV consisted of healthy controls.

The age of the patients ranged from 15 to 35 years with 50(100%) of mild acne, 50(100%) of moderate acne and 50(100%) of severe acne and 50(100%) of control healthy.
In the present study, acne seems to be mostly found in 15-20 years of age group i.e 41(82%) cases of mild acne, 35 (70%) cases of moderate acnes and 10 (20%) cases of severe acne whereas 33 (60%) cases of control group. Only 6 (12%) cases have severe acne between 31 to 35 years of age group. This fact can be appreciated in Graph 2. The severe acne was found significantly in higher age group as compared to mild and moderate acne.

The mean values for age did not show significant variation in case when compared with control group and within the cases which is further supported by the work of Bassi et al. Rahman et al. and Rahman et al. who revealed that the mean values for age did not very much in obese and non-obese females with acne vulgaris when compared with control group.

**Insulin**

In the present study, the level of serum insulin was significantly higher in moderate cases of acne as compared to controls. Therefore we suggest that insulin may also play an important marker for causing acne. Insulin stimulates the secretion of ovarian estrogen, androgen and progesterone which is consistent with our studies as increase in estrogen and testosterone has been also observed in moderate cases of acne.

The work of Emiroglu et al. found that insulin resistance may have a role in the pathogenesis of acne and there exists a positive correlation between insulin resistance and severe acne vulgaris.

Shabir et al. observed that the serum fasting insulin was elevated in index patients and their family members and found a heritable component of β-cell dysfunction in the families of women with PCOS, which is likely to be a significant factor for the predisposition of metabolic syndrome in these families.

Pace insisted that Insulin resistance has been found to be a major component of PCOS; interaction can occur whereby hyperinsulinemia can promote hyperandrogenism and possibly also vice-versa.

**Conclusion**

Acne Vulgaris is mainly diseases of adolescent age where as severe acne is likely to be found in higher age group.

Level of LH, estradiol, testosterone and insulin may be studied in cases resistant to conventional treatment of acne in women and in those with history and clinical features suggestive of PCOD or hyperandrogenism and in obese women with acne. Any hormonal imbalance found may be correlated to help management of such cases.

Espousing Artificial Intelligence for Cataloguing of Tumors in the Brain

Ashwini Shivdas Shinde¹, Veena V Desai²

¹Research Scholar, Department of E & C GIT Belgaum, Karnataka, India; ²Professor and Head CSE, GIT Belgaum, Karnataka, India

ABSTRACT

Despite advantages in computer vision and machine learning its application in classification of Brain tumors and achieving optimal results is yet remains a challenge. The tumors appear at any location in the brain by nature and the tumors have any kind of dimensions, contour and contrast. This sources the motivation of our investigation of machine learning that adventures a high capacity deep learning algorithm being enormously effectual.

Deep learning has been used successfully in supervised classification tasks in order to learn complex patterns. The purpose of this research is to implement the machine learning technique to classify the tumors in the brain, with different classes of tumors such as benign and malignant. Training neural networks over the dataset is taken from the open f-MRI. There are 120 MRI datasets that are released to the public along as part of the materials for “Temporal interpolation alters motion in fMRI scans: magnitude and consequence for artifacts detection” Included for each subject is a T1-weighted anatomical image (MP-RAGE) and one or more T2 weighted scans (resting BOLD scans), legacy.openfmri.org. Every subject’s MRI is then split into 2D slices from the entire axis to increase the data volume, and then these images are preprocessed and fed into a 2D-CNN network. It is then trained for number of epoch cycle for a better processing speed and the resulted output of the weighted and biases are stored for the model to predict future inputs this has verified to be precise in its classifications with an average five-fold cross validation of 91.43%.

Introduction

About Brain Tumors: Brain is one of the supreme and delicate organ of human body; it functions as the coordinating center of intellectual, nervous activities and center of sensation. One of the most formidable diseases of mankind is the Brain tumor. The two major classes of tumor are primary brain tumors and secondary brain tumors. They are also known as low grade (Benign) and high grade (Malignant) tumors[1]. The tumor that origin within the brain and does not extent in other parts of the body are called the Primary brain tumors they are less aggressive whereas the tumors that are generated by cancer cells that rove from the tumors developed in other places are known as secondary tumors[2]. One of the significant clinical difficulty in brain metastatic management is the limitations of diagnosis due to ambiguity in imaging for identification of the etiology of contrast – enhancing lesions viewed on Magnetic Resonance Images (MRI) to plan treatment stratagem.

Imaging the Brain: Ever since the invention of the Magnetic resonance imaging in the 1980’s the MRI is been useful to perform imaging of the brain [3]. Magnetic resonant images are obtained from various sequences like the T1, T2, Fluid Attenuation Inversion Recovery (FLAIR) and the Diffusion Weighted Images (DWI), where these sequences provide texture and intensity information of the brain tumors[4][5].

Computer aided diagnosis: With the progress of technology many new trends come forward to give better results and maximum efficiency. Machine learning and Artificial intelligence is one of the state-of-the-art trends in computer aided diagnosis, it is also one of the most widespread scientific research trends these days.

The objective about this work is to cultivate a system for the radiologist to support them in classification of the tumors. Computer vision allows us to make broad use of medical imaging to provide better diagnosis, predication
and treatment for patients suffering from health disorders. Computer vision can exploit shape, texture, delineation and prior knowledge along with appropriate information from image sequence which are helpful for better understanding. Many dominant tools have to be developed through machine learning where quantitative information can be obtained.

The First generation Artificial Neural Network (ANN) composed of neural layers for perceptron but these were limited to simple computations and suffered high error rates, to overcome this limitation the back propagation technique were been used to update weights of neurons according to the error rates [6]. As research continued in this fields with more and various applications other techniques like the Feed forward Neural Network (FNN), the Recurrent Neural network (RNN) along with Deep belief network etc. got popular as the complexity in research gained success in different ways and purposes.

Deep learning is a multilayer, nonlinear repetition of simple architectures that helps to obtain output for high complex functions, Deep learning gained success in both the Supervised and the Unsupervised learning [7]. It was in the mid 1980’s the term deep learning was introduced to the concept of machine learning [8], here the features of the data are learnt by multiple layers of deep learning with multiple levels of abstraction [6]. The hierarchy of features is formed at different levels and the higher levels are well-defined from lower levels which in turn help in building many more higher levels [8]. The structure of deep learning is extended from the traditional neural network by adding more no of hidden layers.

Convolutional Neural Network (CNN): The CNN tries to imitate how the visual cortex of the brain recognizes images. To get better results with image classification image, feature extraction should be used [9]. Before CNNs existed, these feature extractors were designed by experts in each field of the images to be classified. However, with CNNs the feature extractor is involved in the training process.

The data set is normalized using Equation (1),

\[ Z = \frac{X - \mu}{\sigma} \]  

... (1)

Here X signifies the dataset features and \( \mu \) represents the mean value of each dataset feature. The feature extractors consist of several convolutional layers and pooling layers. The convolutional layer can be seen as a digital filter. The pooling layer reduces the dimension of the image by combining neighboring pixels into a single pixel [9]. CNN is the reasons for advances in image recognition. LeNet5 set that has now has become standard structure for CNN. The structure has stacked convolutional layers, which can be followed by contrast normalization and max-pooling layers, as shown in Fig 1. These are then followed by fully-connected layer(s). Compared to feed-forward network with similarly sized layers a CNN has fewer parameters and connections. This makes them easier to train, but theoretically their best performance is somewhat less than a feed-forward network. CNNs are computational heavy when applied on a large scale over high resolution images, but with the GPUs since 2012 and optimized versions of 2D convolution it is possible to do this with reasonable computational resources [10].

Structure of CNN: The CNN consist of multiple convolutional layers and between each consecutive convolutional layer there is a subsampling layers. Initially the kernel convolve the input image with the help of addable bias vectors. The feature maps are generated in the first convolutional layer and new feature maps are obtained by weighing and averaging the localized regions in the sub layer through a nonlinear activation function. The newly obtained feature maps are then convoluted with the trained filters of the next convolutional layer which are then fed to the next sub layer, this process continues till the final sub layer to obtain a feature vector which is given as an input to a traditional neural network for training [11].

![Fig. 1: Architecture of CNN](image-url)
**Deep Neural Network (DNN):** A Neural Network with multiple hidden layers is a deep neural network. The idea of DNN has been around for many years, but it is only recently that many of the problems associated with the technique have been solved. This is mainly because of new learning algorithms and an increase of compute power. The main problems for multilayer networks were: vanishing gradient, over fitting and computational load. Simplest way to improve a DNN is by increasing its size in both depth and width, but this simple solution comes with two drawbacks. Increased size will make the networks more prone to over fitting and it will also greatly increase the computer power required, which can be resolved by using Global processing units (GPU).

The Rectified Linear Unit (ReLU) acts as an activation function in each hidden layer, also used as a classifier in the final layer of the network.

**Methodology**

**Dataset:** The images used here come from multiple different open access sources; here we have taken 385x150 = 57,750 sequences of training data and 85x150 = 12,750 testing data which includes the T1, T2, DWI sequences. The taxonomy was then averaged to partition the individual diseases into training classes. This generated training classes with diseases that are clinically and visually similar since all training classes are descendants of the root nodes. Each training class was ensured to have a number of images so that the CNN would have sufficient training data for each class.

Convolutional neural networks have a high number of learnable parameters; the cutting edge neural networks have millions of learnable parameters relying on a large number of images in order to train the system. This can often happen due to small datasets. We applied several methods that prevent over-fitting including data augmentation, regularization through dropout, and parameter sharing implied through rotations and transformations of images mentioned below.

1. **Rotation:** Images were rotated with an angle between 0° and 360° that was randomly taken from a normal distribution.

2. **Shift:** Images were randomly shifted -4 to 4 pixels left or right and up or down. These minor shifts were taken from a normal distribute and kept brains in the center of the image but changed the location of the brains enough to avoid memorization of location in an image rather than relative to the brain itself.

3. **Scaling:** Images were randomly rescaled using the scaling between 1.3–1.4. Mirror: Each image was mirrored across its y-axis (horizontally) with a probability of 0.5. After these initial transformations, further augmentation was performed in order to increase the size of the training set each round. Each image was rotated 0° and 45° and flipped horizontally to create four images. These four images were cropped to a size of 45 x 45 taking the four corners of the images as edges to produce 16 different images. The above data augmentation was run on the training data every epoch of training in order to constantly introduce new images to the neural network every iteration. This augmentation affected training time very little.

This neural network represents taking only images as input. While many combinations of layers were tested, the best combination for this neural network was the following:

- Convolutional Layer of filters(64) with size 5x5 and stride = 1
- Max-pooling Layer with pool and stride of size 2 x 2
- Convolutional Layer with 64 filters of size 5 x 5 and stride of 1
- Max-pooling Layer with pool and stride of size 2 x 2
- Fully Connected Layer with 800 neurons
- Fully Connected Layer with 800 neurons
- Softmax Layer with 3 or 4 neurons depending on brain tumor only in training or tumor less brain inclusion in training respectively.

The softmax function postulates a discrete probability distribution given by

\[ \sum_{k=1}^{K} P_k \]  

...(2)

Each layer besides max-pooling applied the nonlinearity ReLU, and last three layers applied
dropout to help in regularization and over-fitting. [export.arxiv.org]

This neural network provides more information than one image input. There are two version of the neural network. Each version has a neural network synonymous to CNN from above. However, a second input layer exists representing the same image input or the maximum and minimum x and y to represent the location of the tumor. If we consider x as activation second last (penultimate) layer and $\theta$ is the weight parameter at the softmax layer we get as the input to the softmax layer:

$$\sigma = \sum_{i=1}^{n} \theta_i x_i \quad \ldots (3)$$

therefore $P_k = \frac{\exp(\sigma_k)}{\sum_{i=1}^{n} \exp(\sigma_i)} \quad \ldots (4)$

Hence the predictive class is $\hat{y} = \arg\max\ pi$ for $i = 1, \ldots N$

These have their own neural network path that eventually concatenates with the CNN from before. This second neural network path consists of the following layers:

- Fully Connected Layer with 800 neurons
- Fully Connected Layer with 800 neurons

The last layer of and the fully connected layer from CNN were concatenated together and connected to one last fully connected layer with 800 neurons before reaching the softmax layer. The patients data were randomly placed into three sets for training, validation, and test with 149, 21, and 21 patients respectively. A patient represents all of a patients images; this avoids mixing patient data in both training and test which allows for easier predictions since patient images are similar in structure. The mean picture from training was subtracted from the train, the validation, and the test in order to centralize the data.

Training data was used throughout the training of the neural networks the train data was used for updating weights while validation data gave a glimpse into how the neural network was improving over time. After completion, the test data was used to see how well the neural networks predicted types of tumors from new images. A variety of hyper parameters are available to alter. We list the hyper parameters that produced the highest accuracies.

**Data Analysis**

- Regularization constant: 0.014
- Learning rate: 0.0001 • Momentum constant: 0.9
- Batch size: 4 for non-augmented datasets, 128 for augmented datasets
- Epochs: 100 (and one 500) which was compensation between accuracy and training time

Rather than maintain a constant learning rate, a decaying learning rate was attempted in order to increase accuracies by decreasing the learning rate over time. However, each case of the decaying learning rate had significantly worse accuracies than without them.

**Performance Elevation/Findings:** The exploration in this study is carried out on a laptop with Intel CORE i5 processor and NVIDIA GeForce 960M 4GB Ram, Table 1 displays the results of the construction of the CNN. The last layer dense_2, used the softmax classifier and the ReLU classifier coding done in python (open source software) using the Jupyter note book, numpy.

**Conclusion**

In computer vision the state of the art is the Convolutional neural networks further introducing them into the medical field could greatly improve current practices of diagnosing patients. Training convolutional neural networks to detect types of tumors in brain images improves classification accuracy and provides initial steps into introducing deep learning into medicine. Neural networks also utilize a more general
methodology requiring only an image to understand brain tumor types. Furthermore, the accuracy per patient metric consistently remained at the levels of per image accuracy results, implying the neural network is providing consistent predictions for patient images.

ABSTRACT

Introduction: Obesity during pregnancy is one of the important risk factors for development of complications. This study is conducted to assess the association of body mass index with maternal complications in pregnancy.

Method: This was an observational study conducted retrospectively over a year comprised 300 pregnant subjects in second trimester. Incidence of gestational diabetes mellitus (GDM), pregnancy induced hypertension (PIH), Caesarean section and postoperative wound infection were compared in women with various Body Mass index (BMI). Analysis of the data was done using SPSS version 13 using chi square test and p ≤ 0.05 was considered statistically significant.

Results: Out of 300 participants, 62 (20.7%) subjects developed GDM out of which 88.7% were overweight/obese. 61 (20.3%) subjects developed PIH, out of which about 91.8% were overweight/obese. 162 (54%) subjects underwent C-section out of which 67 (41.4%) were in overweight/obese category. 82 subjects developed post-operative wound infection in which 41 (50%) cases were in overweight/obese category.

Conclusion: Normal body mass index at the time of incidence of pregnancy and proper antenatal care and careful monitoring of the maternal body weight can minimize the complications to a large extent. Obstetrician-gynaecologists could play a prime position to prevent it.

Keywords: Body mass index, Gestational Diabetes Mellitus, Pregnancy induced Hypertension, Caesarean section, Postoperative wound infection, Perinatal complications.
Obesity is a major contributor to the global burden of chronic disease and disability and has reached epidemic proportions globally with more than a billion adults being over-weight. The changing lifestyle has increased the prevalence of obesity worldwide including the women trying to become pregnant. It is now well recognized that maternal obesity during pregnancy increases the risks of complications for the mother and newborn. Adequate gestational weight-gain contributes for better pregnancy outcomes in both mother and infants for short and long-term health. Recognition of the importance of adequate weight gain during pregnancy has brought to light the lack of guidelines to establish proper weight gain during gestation. This study is conducted to assess the incidence and its possible association of BMI with maternal outcome of pregnancy.

Material and Method

This was an observational study conducted retrospectively in one year period with follow up being done for a period of 6 months post-delivery. 300 pregnant subjects in second trimester regularly attending the antenatal clinic at a tertiary health care center, Mangalore were taken in this study. Women in their second trimester and singleton pregnancy were selected. Women with multiple pregnancies and Pre-pregnancy complications like diabetes-mellitus, hypertension, cardiovascular and kidney diseases were excluded from the study. The study was approved by the Institutional Ethical committee (IEC), Kasturba Medical College (KMC), Mangalore, Manipal Academy of Higher Education (MAHE), Manipal, Karnataka, India. Prior permission was obtained from the hospital authority; all the pregnant subjects were briefed about the nature and purpose of the study, following which a written informed consent was taken. The study involved determination of height at the initial visit, weight at two separate occasions prior to the commencement of pregnancy and again during the second trimester. Body Mass index (BMI) was calculated and normal, underweight, overweight and obese groups were categorized based on their BMI.

Screening for GDM was conducted at (24-28) weeks of gestation using a 50 gram glucose test. After one hour of glucose intake blood sugar was measured. Levels >140 mg/dL were considered significant and diabetes confirmed on Glucose Tolerance Test (GTT). Pregnancy induced hypertension (PIH) was defined as persistently elevated blood pressure, systolic pressure >140 mm Hg and diastolic pressure > 90 mm Hg on more than two occasions with proteinuria or edema or both. Caesarean delivery defined as the birth of a foetus through incisions in the abdominal wall (laparotomy) and the uterine wall (hysterotomy). Post-operative wound infection could be either due to C-section or due to that of episiotomy.

**Statistical Analysis:** Analysis of the data was done using SPSS version 13, chi square test was done and $p \leq 0.05$ was considered statistically significant.

82 (27.3%) cases developed a postoperative wound infection. Out of these 82, about 50% were in the overweight/obese category and 31.7% were in the underweight group (Table 4).

Discussion

Gestation induced diabetes could be linked to a chain of exaggerated physiological changes that are known to occur in glucose metabolism. Another possible explanation is, gestation induced diabetes is very often type 2 diabetes which is unmasked by diabetogenic factors such as obesity, and known to aggravate by both pregnancy and impending insulinopenia. These findings of our study have been consistent with studies conducted by Catalano and associates who compared the endogenous glucose production, insulin response and changes in insulin sensitivity in subjects who had normal glucose tolerance with changes identified in subjects with gestation induced diabetes with the latter subjects having abnormal glucose metabolism that were characteristic of type 2 diabetes 10. The reason why obese women are at higher risk of developing GDM is likely to be related to a progressively increasing insulin resistance due to the continuous production of counter-regulatory, anti-insulin hormones by the growing placenta, which results in increased availability of lipids for fetal growth and development. No significant associations of GDM in our study were found in the underweight and control group.

Obesity which is regarded the most consistent risk factor for pregnancy induced hypertension, also had a highly significant association with BMI in our study population. These finding were similar to the studies conducted by Cedereng, Jensen, Sebire, Weiss and their colleagues who showed a strong correlation with maternal overweight and obesity in causing undesirable pregnancy outcomes particularly PIH11,12. A review of studies conducted by O’Brien and associates found that for every 5-7 kg/m² increase in prepregnancy BMI the occurrence of preeclampsia doubled 13. The pathophysiology of obesity, in causing PIH, can be linked to, the presence of low-grade inflammation and endothelial activation which would play a dominant role in causing the disease. Studies conducted by Wolf and co-workers have provided interesting evidence which might explain this inflammation in being associated with obesity and preeclampsia 14. The present study, however did not show any significance of PIH in the underweight and control subjects.

The present study had higher rates of caesarean section (CS) among the overweight/obese women, thus making the relationship between high maternal BMI and CS highly significant. These findings have been similar
to studies conducted by Barau et al who also described a linear association between maternal pre-pregnancy BMI and caesarean section particularly in term deliveries. Several studies have found an association between increased risk of CS following labour induction and high maternal BMI. In another study, obese and overweight women not only accounted for almost 20% of all post-term pregnancies and 45% of all CS following labour induction, in addition to adverse maternal and foetal outcome. Obesity is an independent risk factor for failed trial of labour after previous caesarean and also emergency C-section. Possible reasons for increased abdominal deliveries in case of obese patients could be cephalopelvic disproportion, failure to progress, intra-uterine growth restriction presenting as fetal distress or simply excess of fat deposition in the maternal pelvis. Studies have also postulated that leptin may exert a physiologic inhibitory effect on uterine contractility, leading to dysfunctional labour and increased operative delivery. The below normal group also had high percentage for CS compared to that of normal body weight group.

Post-operative wound infection, a bacterial infection is well known to occur in the obese and particularly who have had a caesarean section irrespective of whether it is an elective or emergency type, with or without coverage of prophylactic antibiotic. In this study, out of the subjects, who developed postoperative wound infections, about 50% were in the overweight/obese category and 18.3% were in the control group. The risk factors attributable in our study population includes pre-existing diabetes with concomitant immuno-suppression due to long term treatment of corticosteroids, previous history of C-section delivery, prolonged labour, prolonged operative period, poor hemostasis due to increase in the thickness of the subcutaneous tissue, lack of pre-incision antimicrobial care and hematoma formation. Hyperglycemia, however as such is known to cause a decrease in the cytokine expression by delaying re-epithelialization and enhancing the risks for wound infection.

**Conclusion**

Increased body mass index has been a potent risk factor for the perinatal complications. This has been well supported by evidences obtained in this study. Obesity is increasing in alarming rate and is the most important modifiable risk factor for development of pre and post-natal complications. Therefore, our study stresses that normal body mass index at the time of incidence of pregnancy and proper antenatal care and careful monitoring of the maternal body weight can minimize the complications to a large extent. Creating awareness programmes about obesity related maternal complication could be helpful to the society Obstetrician-gynaecologists could play a prime position to prevent it.

Static Balance and Dynamic Balance in Obese School Going Children Between 11 and 14 Years of Age: A Cross Sectional Study

J Andrews Milton¹, A Turin Martina²

¹Professor, Bethany Navajeevan College of Physiotherapy, Thiruvananthapuram; ²Associate Professor, PG & Research Department of Rehabilitation Science, Holy Cross College, Tiruchirappalli

ABSTRACT

Background: Childhood obesity is an epidemic. Childhood obesity leads to decreased balance.

Objective: The objective of the study is to determine the relationship between obesity and Static and Dynamic balance in school children aged 11 to 14 years.

Materials and Method: 100 school children between 11 and 14 years from the schools in Thiruvananthapuram city were included in the study using simple random sampling method. Students with musculoskeletal impairments, cardio respiratory disorders, neurological impairments and general weakness were excluded from the study. BMI percentile has been calculated for all the students. Stork balance stand test was used to measure the static balance. Modified Star Excursion Balance Test was used to measure the static and dynamic balance. The result of the study shows that there is a significant negative correlation between Body Mass Index and static and dynamic balance.

Conclusion: The result of the study shows that there is a significant negative correlation among Body Mass Index and static and dynamic balance. Thus the study concludes that obese school going children are having less static and dynamic balance.

Keywords: Childhood Obesity, Body Mass Index, Static balance, Dynamic balance.

Introduction

Childhood obesity is one among the most crucial health challenges the society is facing. Obesity is defined as “the excessive fat accumulation that presents a risk to health” (WHO). When the body weight is increased, it becomes much harder to shift the body weight and move from one place to another. Urbanization and digitalization of the society makes the children to involve more in indoor activities such as using smart mobile phones, social medias etc. In the ancient times, children go to school by walking, cycling etc. But nowadays majority of the children living in urban area are utilizing the transport facilities for going to school. More concentration on the academic activities and fear of the parents concerning the safety of their children force the children to spend most of the time indoor and live a passive lifestyle. Obesity in the childhood is the main source of non communicable diseases such as cardiovascular diseases and diabetes, musculoskeletal disorders etc in the adulthood. Obesity is associated with an increased risk of falls and subsequent injury. Excessive body weight increases the stress within the bones, joints and soft tissues resulting in abnormal musculoskeletal mechanics and function such as impaired balance, gait, strength, sensory function, neuromuscular function which ultimately leads to fall. Obesity alters the normal gait pattern. Obesity reduces the walking speed, cadence, step length; increased stance phase and double leg support duration. These gait

DOI Number: 10.5958/0976-5506.2019.01967.3
abnormalities represent the impairment of balance and result in abnormal musculoskeletal function, exhaustion and frequent falls. Balance is a state of equilibrium in which the sum of all internal and external forces acting on the body is zero. The ability of the body to maintain the balance in a certain static position is known as static balance and the ability of the body to maintain the balance during certain movement of dynamic posture is known as dynamic balance. Body Mass Index is a main determinant of performance of static and dynamic balance tests. Obesity increases the demand on the attention to maintain the balance and postural stability, hence when the obese individuals do multi task activities in their daily life the balance is disturbed. The purpose of the present study is to find out the relationship between Obesity and static and dynamic balance in obese school going children aged between 11 and 14 years.

Materials and Method

100 school children between 11 and 14 years from the schools in Thiruvananthapuram city were included in the study using simple random sampling method. Students with musculoskeletal impairments, history of lower extremity injury for the past 6 months, history of any surgery in the lower limb, cardio respiratory disorders, neurological impairments, general weakness, mentally retarded, were excluded from the study. BMI percentile has been calculated for all the students. They were divided into three BMI categories. i.e., Normal weight, Overweight and Obese. Stork balance stand test was used to measure the static balance. The subjects were asked to stand on the foot of the one leg and to place the ball of the foot of the other leg on the inner side of the supporting leg knee with the thigh rotated outward. The subjects were instructed to place the hands on the hip. The subjects were informed to stand on the ball of the foot by raising the heel from the floor. The stop watch was started as the subject raises the heel from the floor to maintain the balance as long as possible without moving the ball of the foot from the initial position. The stop watch was stopped as soon as the subject loses the balance by touching heel to the floor, the non supporting foot looses contact with the knee, the supporting foot moves in any direction, the hand(s) come off the hips. The total time in seconds were recorded. The best of the three trials was recorded. The procedure was repeated on the other leg. Modified Star Excursion Balance Test (SEBT) was used to measure the dynamic balance. The Modified Star Excursion Balance test directions were constructed by affixing three tape measures with a centimetre scale on the floor. The first reach direction was aligned anterior to the apex; the other two were oriented 135° to the first in the posteromedial and posterolateral directions. The subject’s starting foot was placed on the convergence of the reach directional lines of Y. The lateral malleolus was positioned at the intersection point of the three directions with the foot’s longitudinal axis oriented at the anterior direction. The starting position was bilateral stand. Subjects stood barefoot with their hands on their hips. Maintaining single leg stance, they were instructed to reach as far as possible with the non-stance leg along the marked tape, point to the most distal portion with their great toe and return their limb back to the starting position. The maximum reach distance was recorded. Subjects practiced each direction 4 times before the main test to minimise the learning effect. This was followed by recording of 3 successful trials of maximum reach distance in each direction for both legs, with 10 seconds rest between each test. The leg length of the subjects were measured from anterior superior iliac spine to the medial malleolus for normalization, the mean reach distance of 3 trials was divided by limb length(cm) and multiplied by hundred for a percentage score. The composite reach distance was calculated by using the sum of three normalized reach distances divided by 3 times the limb length, multiplied by 100. The results were recorded and statistically analyzed.

Statistical Analysis

The result was analyzed using SPSS software version 16. The statistical tool used was pearson correlation.

**Discussion**

100 school children between 11 and 14 years from the schools in Thiruvananthapuram city were included in the study using simple random sampling method. BMI percentile has been calculated for all the students. They were divided into three BMI categories, i.e., Normal weight, Overweight and Obese. The Stork Balance Stand Test was used to measure the static balance and the Modified Star Excursion Balance Test was used to measure the dynamic balance. The Pearson correlation for Stork Balance Test of Right side was -.931 and that of left side was -.930, P value was .000 which shows that there is a significant correlation at 0.01 level among Body Mass Index and Stork Balance Test score of right and left side. The Pearson correlation for right side anterior reach was -.811 and that of left side was -.860, P value was .000 which shows that there is a significant correlation at 0.01 level among Body Mass Index and Anterior Reach distance of Right and Left side. The Pearson correlation for right side Postero-medial reach was -.735 and that of left side was -.730, P value was .000 which shows that there is a significant correlation at 0.01 level among Body Mass Index and Postero-medial reach distance of right and left side. The Pearson correlation for right side Postero-lateral reach was -.805 and that of left side was -.805, P value was .000 which shows that there is a significant correlation at 0.01 level among Body Mass Index and Postero-lateral reach distance of right and left side. The Pearson correlation for right side Composite reach was -.836 and that of left side was -.824, P value was .000 which shows that there is a significant correlation at 0.01 level among Body Mass Index and Composite reach distance of right and left side. Also the value shows that the correlation is negative, i.e., as the Body Mass Index increases the static and dynamic balance decreases and vice versa. The increased abdominal fat shifts the body’s Centre of Mass and the Line of Gravity anteriorly, resulting in an increase in the magnitude of ankle torque that is required to stabilize the body in the upright position. Abdominal obesity decreases the angular movement of the thoracic segment and the range of motion of the thoracolumbar spine especially forward flexion. Obesity leads to gait abnormalities which
include decreased speed, cadence, stride length and an increase in the double leg support duration and the base of support. Gait abnormalities lead to poor muscular coordination, force production, decreased resistance to fatigue and functional impairments. Anterior tilt of the pelvis occurs during gait in obese persons impair the normal gait pattern. Obese persons have decreased ability to resist muscle fatigue that result in impairment in the balance control and requires more level of cognitive function for the coordination of the balance. Also excessive body fat increase the rate of perceived exertion during stresses resulting from balance and posture control. The balance is compromised in obese individuals while multitasking during the activities of daily living and needs greater attention to maintain the balance. In obesity there is an increased pressure in the plantar contact areas and pressure levels in the heel, midfoot and metatarsal areas. This increased pressure interferes with the function of the mechanoreceptors that is responsible for the maintenance of the body balance. Ambulatory stumbling and history of fall is more in obese individuals because of the impairment of balance. Body fatness is inversely associated with walking and balance abilities.

**Conclusion**

The result of the study shows that there is a significant negative correlation among the Body Mass Index and the static and dynamic balance in school children aged between 11 years and 14 years. Hence as the Body Mass Index increases the static and dynamic balance decreases and vice versa in school children. Thus the study concludes that obese school going children are having less static and dynamic balance.

Self–esteem and Psycho Social Impact of Dental Aesthetics among Children-Clinical Survey

Jincy V.V.,1 Suja M. K.2, Joshi K. C.3, Santhosh Kumar Caliaperoumal4

1PhD Scholar, 2Chairperson, Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India; 3Dentist and Dental Implantologist, Dar Al Hyath Medical Centre, Bahrain; 4Professor and Head, Department of Dentistry, Vinayaka Mission’s Medical College, Vinayaka Mission’s Research Foundation (Deemed to be university), Karaikal, Puducherry, India

ABSTRACT

Background: Self-esteem which is considered as one of the most important need to be satisfied by every individual during different stages of development. It is one of the major psychological concepts among children, especially during their transitional period. The self-esteem is related to the appearance, so the importance of dental aesthetics and related problems is a major element of self-esteem among children.

Aim: The aim of the study was to assess the level of self-esteem among the participants and to assess the Psychosocial Impact of Dental Aesthetics on self-esteem among the participant children, based on Clinical Survey.

Materials and Method: A total of 100 subjects aged 11-18 years were selected for study based on lottery method of Simple random sampling. The study was a clinical survey by Questionnaires pertaining to socio-demographic profile of age, gender, educational status, type of family, order of birth and nativity. The data collection was done in an interview schedule by answering the Questionnaires. The two standardised tools were used in the study, the Self-esteem scale developed by Rosenberg and the psychological Impact of Dental Aesthetics Questionnaire (PIDAQ) developed by Klages et al.

Statistical Analysis Used: Statistical tools used for the study ANOVA and independent sample T-test (T-test). Self-esteem and overall PIDAQ scale was compared with different variables of socio demographic profile.

Results: The result shows that there is no significant difference between any of the variables of both self-esteem and overall PIDAQ score.

Conclusions: The result led to a conclusion that both psychosocial impact of dental aesthetics and self-esteem has a common feature as both has difference in level of measurement among children by analysing its level through different socio demographic variables.

Keywords: Self-Esteem, psychological Impact of Dental Aesthetics Questionnaire (PIDAQ)

Introduction

The Self-esteem is the overall worth of a person that has to be formed and developed throughout his developmental stages. It’s one of the important personality traits that have an enduring and stable character from childhood. It starts to form as basement during childhood and get enriched during the later developmental milestones. The most important developmental milestones such as childhood to early and late adolescents are called as transitional period. In the transitional period, the appearance is an important matter of concern as it is considered as closely related to self-esteem or one of the important elements of self-esteem.

Aesthetic concern and related issues are the more common problems in these stages irrespective of

As face and smile is an essential factor of appearance it is one of the main concerns coming to aesthetics. Thus by considering the relevance of the topic present study was conducted about self-esteem and (PIDAQ) Psychosocial Impact of Dental Aesthetics by analysing various variables in relation with the same based on clinical survey. The aim of the study was to assess the level of self-esteem among the participants and to assess the Psycho-social Impact of Dental Aesthetics on self esteem among the participant children, based on Clinical Survey.

**Materials and Method**

**Design:** Clinic based survey design. This is a descriptive research Conducted among 100 patients who are under dental treatment in Dar Al Hayath Medical Centre in Kingdom of, Bahrain.

The samples selected for the study were under the age group of 11-18 years. The sampling technique adopted for the selection of the respondent subjects was by lottery method under Simple random sampling method.

The tool of data collection used for the study was an interview schedule that included questionnaires pertaining to socio-demographic profile. The data collection was done in an interview schedule by answering the Questionnaires. The two standardised tools were used in the study, the Self-esteem scale developed by Rosenberg and the psychological Impact of Dental Aesthetics Questionnaire (PIDAQ) developed by Klages et al.

**Statistical Analysis**

For comparing Self-esteeem and PIDAQ with the variables of age, educational qualification, type of family, order of birth and nativity ANOVA test was used. The independent sample T-test (T-test) was used to compare and find the statistical significance of self-esteeem and PIDAQ with gender of the children.

**Results**

The self-esteem score was compared by with age, educational qualification, type of family, order of birth and nativity by using ANOVA (Table-1). The independent sample T-test was used to compare self-esteem and gender (Table-2). There is no significant difference between any of the variables and self-esteem. But the self esteem score was high among 16-18 years, with no higher study, nuclear family, single child, rural background and male child.

Overall PIDAQ scale was compared with age, gender, educational qualification, type of family, order of birth and, nativity by using ANOVA (Table-3). The independent sample T-test (T-test) was used to compare overall PIDAQ and gender (Table-4). There is no significant difference between among any of the variables and overall PIDAQ score. But the PIDAQ score was high among 16-18 years, with no higher study, joint family, youngest child, sub-urban background and male child.

The table-5 shows that there is no correlation between self-esteem on social impact, psychological impact, dental self-confidence, aesthetic concern and Overall PIDAQ score.

Discussion

In this study we observed that 41% of the respondents are from rural area also only 16% of them have low self-esteem, in the study of Morris Rosenberg also it was stated that there was no association for self-esteem among children and their social classes.

The present study shows that there is no significant difference among respondents due to their age and self-esteem but the study done by Huajian Cai says that self-esteem is showing decrease with increase of age which means it is sensitive during development or age-related changes.

Frank M Biro et al in their study says that there is no significant difference found in self-esteem and gender difference same as like the present study. Margaret Zoller Booth in their study says that among 11-12 years student self-esteem was related to multiple indicators of later year academic achievements but in the present study it says that self-esteem has no significant difference based on their educational qualification even though it’s slightly high among children who are not doing their higher studies after higher secondary.

The present study states that psycho social impact of dental aesthetics is comparatively slightly high among males than females (64%) which is not agreeing with the study of Song Yi, C Zhang among young adults which shows the result among females the desire for orthodontic treatment is comparatively higher than males. Randa Abidia et al’s study among females also says that (89%) of them felt their teeth affected their attractiveness of their face which also influenced their quality of life.

Motloba in their study strongly agree that the age group 13-29 who are both male and female by showing the result significant negative impact on the psychological wellbeing of the patients due to malocclusion also the study enhance the patients general psychological wellbeing orthodontic treatment is showing an improved oral health-related quality of life, the same result is in the present study also as it is shown the psycho social impact of dental aesthetics is slightly high among 13-15 and 1-18 years old age group.

A study about self-esteem by and dental aesthetics among adolescents 13-16 years old is revealing that socio economic variability is playing an important role in self-esteem as it is seen when the dental aesthetics is high it comes and lowest level of self-esteem is among low socioeconomic status group which is somewhat agreeing with the present study the psycho social impact of dental aesthetics is slightly seen high among respondents from rural area who are considered as comparatively from low socioeconomic status. The correlation test also agrees that there is no positive correlation between self-esteem and any of the factors of psychosocial impact of dental aesthetics.

Conclusion

The research states that many of the socio demographic variables have influence on both self-esteem and psycho social impact of dental aesthetics among children even though it’s very slightly. The study also says that there is no correlation between self-esteem and any of the factors of psychosocial impact of dental aesthetics. Thus it can be concluded as both psychosocial impact of dental aesthetics and self-esteem has a common feature as both has difference in level of measurement among children by analysing its level through different socio demographic variables.

Effect of Electrical Stimulation along with Mendelsohn Maneuver in Muscles of Swallowing Function and Cognitive Function on Post-Stroke Dysphagia

K. Monica Blessy¹, A. Kumaresan², Jagatheesan Alagesan³
¹2nd Year, MPT (Neurology), ²Assistant Professor, ³Professor and Principal, Saveetha College of Physiotherapy, Saveetha Medical Technical Sciences, Thandalam, Chennai

ABSTRACT

Aim & Objectives: To find out the Effect of electrical stimulation along with Mendelsohn maneuver in muscles of swallowing function and cognitive function on post stroke dysphagia subjects. To analyze the characteristics of cognition through MMSE in patients with sub-acute post-stroke dysphagia subjects and to evaluate laryngeal elevation and closure during swallowing muscle activity by Surface EMG.

Methodology: In this study, 30 subjects with stroke were selected as per inclusion and exclusion criteria. All samples under pre measures were assessed by therapist using sEMG (surface electromyography) for masseter, infrahyoid, suprahyoid muscles and MMSE (mini mental state examination) for cognition. After the pre-test measures all samples were reviewed for electrical stimulation. These were performed in supine lying on treatment table. Mendelsohn maneuver is taught to the patient and they are requested to do for every 2hrs. This protocol consists of 1 session/day; 6days/week for 2 weeks. Similarly outcome measures were re assessed for post test measurements of movement for swallowing recovery after 12 sessions.

Results: Statistical analysis of pre-test and post test values of group showed the significant changes with the p values of FOIS, MMSE and Surface EMG were p≤0.001, p≤0.001 and p≤0.001 respectively.

Conclusion: This study shows the significant improvement by using electrical stimulation with mendelsohn maneuver can improve the function of swallowing muscles and cognitive function was improved by treating dysphagia in subjects with post stroke dysphagia. Patient with severe dysphagia and decreased cognition had been improved when compared to the pre test assessment.

Keywords: electrical stimulation; cognition; mendelsohn maneuver; post stroke dysphagia; surface EMG; deglutation.

Introduction

Dysphagia is the common symptom in patients with stroke, with up to 50-70% of all cases of swallowing problems in their acute phase¹. Impaired swallowing is a common complication with the prevalence to be approximately between 42 and 67% after stroke². Dysphagia can lead to a deterioration of activities of daily living (ADL) and quality of life, leading to malnutrition, dehydration, aspiration pneumonia and increased mortality. Therefore, it is important to assess the presence of dysphagia in the early stages of post-stroke rehabilitation³-⁴. Stroke is one of the leading causes of death and disability in India. The estimated adjusted prevalence rate of stroke range, 84-262/100,000 in rural and 334-424/100,000 in urban areas. The incidence rate is 119-145/100,000 based on the recent population based studies⁵. The swallowing muscles are asymmetrical in both motor cortex⁶-⁷. Swallowing is defined as the semi-automatic motor action of the muscles of the respiratory and gastrointestinal tract that propels food from the
oral cavity into the stomach. Swallowing is also a complex phenomenon involving breathing, phonation and swallowing occurring at the same anatomical location requiring coordination between them, for a safe swallow and appropriate gas exchange. Although many stroke patients recover swallowing spontaneously, 11–50% still have dysphagia at six months. Patients have significant facial weakness, a high arched palate, micrognathia, and weak masseter and pterygoid muscles. The pharyngeal and laryngeal muscles may be affected such as palatopharyngeus muscle, superior constrictor muscle, middle constrictor muscle and inferior constrictor muscle, levator veli palatini. However, it is still controversial as to which of the two hemispheres plays a more important role in swallowing, and which injured hemisphere is more likely to cause the specific patterns of dysphagia seen in stroke patients. Both hemispheres play a larger role in swallowing, and which wounded hemisphere is more likely to cause specific patterns of dysphagia in stroke patients, the left hemisphere is associated with the oral phase, and the right hemisphere is the pharyngeal phase. The entire voluntary oral phase is mainly controlled by the medial temporal lobes and the limbic system of the cerebral cortex with contributions from the motor cortex and other cortical areas where cognition is affected. Several studies have shown that dysphagia is associated with other neurological conditions related to stroke, such as cognitive dysfunction and neglect. However, most of these studies investigated the relationships between post-stroke dysphagia and cognitive deficits by using simple cognitive screening tests, such as the Mini-Mental State Examination (MMSE). Although MMSE is commonly used in clinical practices, it does not assess frontal lobe functions and mainly evaluates. The left hemisphere involves cognitive functions, including language, verbal memory, and calculation.

The FOIS is an ordinal scale reflects the functional oral intake of patients with dysphagia is levels (1 to 7). Although a standard clinical examination of dysphagia in stroke patients has recently been published, Electrical stimulation, when applied in this way, accelerates muscle building, accelerates cortical reorganization (especially after stroke), and increases the effectiveness of exercise therapy. The Mendelsohn maneuver, or the voluntary extension of the hyolaryngeal elevation to the swallow’s spike, has been used to treat patients with pharyngeal dysphagia for many years - sometimes as a compensatory strategy to help the bolus pass more efficiently in the pharynx. Some studies provide data on dysphagic patients who used the Mendelsohn maneuver as part of a series of exercises to rehabilitate them, but none used the maneuver alone and reported a change in the physiology of swallowing. Surface electromyography (sEMG) provides information on the temporal and amplitude characteristics of muscle contraction during swallowing. It is a non-invasive and inexpensive technique for studying muscle activity. It has been used to study the function of swallowing. Surface electromyography (sEMG) is useful for monitoring performance of the effortful swallow and can be used to collect and display information regarding performance of these maneuvers in treatment; such performance-contingent information can enhance motivation, compliance and task performance.

**Methodology**

**Participants:** The sample will be drawn from Physiotherapy department OPD and IP at Saveetha Medical hospital. The subjects will sign an informed consent form after elaborate education about the study purpose, duration and other aspects by the researcher. The subjects who fulfill the criteria’s of inclusion will be selected for the study. Inclusion criteria: Age group: 30-75 years, both genders, Patients must be conscious and comprehensive, Ischemic/haemorrhagic stroke patients leading to admission to the SMCH, Post stroke subjects with difficulty in swallowing. Subjects confirmed swallowing difficulty with Functional oral intake scale. Exclusion criteria: Individuals with current/history of tracheotomy or other structural alteration to the swallowing mechanism, Individuals with unconsciousness, Patients with histories of diseases related to swallowing, severe cognitive impairment (MMSE≤9), or severe aphasia preventing thorough evaluation of neurocognitive function, Recent trauma, unstable vital signs, recent surgeries around the neck.

**Procedure:** Subjects who are willing to participate in this study were screened for inclusion and exclusion criteria. They were explained about the safety and simplicity of the procedure and informed consent were obtained. Thirty post stroke dysphagia patients were selected from Saveetha Physiotherapy and rehabilitation centre (SPARC), Saveetha Institute of Medical and Technical Sciences (SIMATS) after concern referral for the study by using convenient sampling method. Informed consent was been obtained from each patient before the intervention. All the 30 samples were taken for confirmatory test FOIS (Functional oral intake scale) level of 1-4 to assess the level of swallowing inability and were selected for the study. The subjects under pre measures were done by using two scales as an outcome measure they are Semg by placing Patient position was sitting and three muscle groups were investigated and muscle activity recorded. Three muscle locations were examined in the study: (1) masseter (2) submental (3)
Infrahyoid its frequency, amplitude and duration are noted and MMSE scale (mini mental state examination) for cognition it is a diagnostic test to assess the cognition.

After the pre-test measures all 30 samples reviewed for electrical stimulation. Patient position is in supine lying and pillow is placed under the head, inactive electrode placed on the nape of neck and active pen electrode over the pharyngeal muscles and the current is surged faradic, intensity is minimum. Palpable, observable, contractions of minimum of 90/session and should be done as 1 session/day; 6days/week for 2 weeks. Mendelsohn maneuver is taught to the patient by asking the patient to take a small bit of food or sip of water then hold it in mouth, position index finger and thumb around Adams apple (thyroid notch) when they swallow and when the adams apple reaches the highest point of elevation then made to hold it with muscles for 5 seconds, then release. And make them to repeat it with each swallow. This was advised to do for every 2 hours in ward.

Result

Results of this study show that electrical stimulation with mendelsohn maneuver to swallowing muscles improves the muscle activity and simultaneously cognition also improves along with it in subjects with post stroke dysphagia.

Discussion

The purpose of the study is to determine the effect of electrical stimulation with Mendelsohn maneuver in swallowing function muscles and Cognitive function on Post-stroke dysphagia. To investigate characteristics of the post-stroke dysphagia and to determine the relationships between swallowing dysfunction and cognitive functions in patients with stroke and to determine whether any lasting physiologic changes in swallowing function can occur from utilizing the Mendelsohn maneuver as an exercise.

One of the aims of the present study was to evaluate the long-term effect of electrical stimulation on swallowing performance, including involuntary and voluntary swallowing. Cognitive function tests revealed lower performance in all measured subtests for the dysphagia. Earlier work for example revealed that low MMSE scores and neglect were associated with dysphagia. For the current investigation, we hypothesized that duration of superior and anterior maximal hyoid movement would be prolonged, as well as duration of UES opening.

Over a period of 4 weeks of treatment session, the result of the present study found that there is an extremely significant improvement in swallowing muscles and cognition with mendelsohn maneuver and electrical stimulation.

Conclusion

The study result showed that electrical stimulation with mendelsohn maneuver is effective to effective in promoting the activity of palatopharyngeal muscles during swallowing and cognitive functions might contribute to the severity of dysphagia in stroke patients.

Limitations & Recommendations

Limitations are less number of RCT’s was enrolled in the study. The study did not use dysphagia severity scale to assess the severity of stage. In this study only qualitative outcomes were performed. Recommendations are Further studies including a larger patient cohort were needed to fully verify the results. Dysphagia severity can be used for the assessment. Quantitative outcome can be used to assess for the effectiveness of cortical reorganization.

Ethical Clearance: The study was approved by Institutional Ethics Committee (Number 020/15/2018/IEC/SU on 15/02/2018) and was done in accordance with Ethical Guidelines for the Human Participants. This study protocol was approved by institutional ethical committee.

ABSTRACT

Background: Heart Rate variability (HRV) is a powerful non-invasive tool which can be used to detect the status of cardio-autonomic function. Its analysis gives information about the cardiac health status. In this study we tried to find out what is impact of different sleep patterns of healthy individuals on their respective heart rate variability.

Objectives: To assess the relationship between sleep duration along with its quality and autonomic function in healthy adult individual. The Pittsburgh Sleep Quality Index (PSQI) was used to assess sleep duration & its quality. Heart Rate Variability (HRV) was used as non-invasive indicator of autonomic function to examine the influence of sleep.

Design: Cross-sectional and experimental study on the effect of sleep duration along with its quality on autonomic nervous activity.

Participants: Apparently healthy individuals without any systemic and sleep disorder were included. Individual divided on the basis of sleep duration and its quality into 3 groups: Normal sleepers with good quality (N=20), Short sleepers with poor quality(N=20), & Long sleepers with good quality(N=20).

Method: We examined the subjective sleep duration and quality (efficiency, latency, awakening, medication) by the Pittsburgh Sleep Quality Index (PSQI). Time, Geometric and Frequency domain measures were calculated on supine 5-minute measurements of ECG.

Results: Time domain measures like STDHR, SDNN, TINN and RRTri significantly reduced in the long and short sleepers as compared to the normal sleepers. Frequency domain measures VLF, HF, Total power were also reduced in short & long sleepers.

Conclusion: From this study we conclude that the sleep duration along with its quality is associated with the autonomic nervous function. HRV was significantly altered in individuals with long and short sleep duration. This shows alteration in autonomic nervous system activity found in long and short sleepers in healthy individuals.

Keyword: PSQI, Sleep duration and quality, STDHR, TINN, RRTri, VLF, HF, Total power, ECG, Autonomic Nervous System.

Introduction

Sleep plays a crucial role in our well-being. It is a vital healing process which helps in repairing and rejuvenating our body. States of brain activity during sleep and wakefulness is a result of different activating & inhibiting process that are generated within brain.

Sleep is important for our general wellbeing but it should be for an optimum duration and quality. As evident from the literature, sleep duration in human being can be categorized into: Short sleep duration (≤6 hours) (1-4), Normal sleep duration (7 or 8 hours.) (5-8), Long sleep duration (≥9 hours). (9-11) Sleep quality is also important predictor for autonomic development in childhood than the sleep duration. (12) Subjective sleep quality, (13,14) and duration is assessed by a reliable tool i.e. The Pittsburgh Sleep Quality Index (PSQI).
HRV examines the tonic baseline of autonomic activity. Low HRV values usually indicate a relative sympathetic dominance. On the other hand, high HRV values indicate a shift of the sympathetic/parasympathetic balance toward increased vagal activity. All the parameters of HRV decrease with the age increases, especially of parasympathetic cardiac activity due to aging\textsuperscript{15}. Conversely, there is developing confirmation that unfavourable psychosocial factors might also be connected with a fall in HRV and different measures of irregularity in sympathetic\textsuperscript{16}.

There are two approaches to measuring HRV: Time domain and frequency domain measures. In time domain, the standard deviation of NN intervals (SDNN) represents the general measurements of the nervous system\textsuperscript{17} and the root mean square of successive differences (RMSSD) reflects the parasympathetic activity of the nervous system. Geometric time-domain methods are obtained through the conversion of the NN intervals data into geometric forms like histograms or the HRV triangular index (RRTri) and Triangular interpolation of RR intervals (TINN) that is a valuable estimate of overall HRV\textsuperscript{18,19}.

In frequency domain, spectral analysis of R-R intervals can detect two major components: called high frequency component (HF) of physiologic HRV (spectral band from 0.15 to 0.4 Hz), and the low frequency (2). Component (spectral band from 0.04 to 0.15 Hz). The HF component represents predominantly parasympathetic activity of the nervous system and LF component represents both sympathetic and parasympathetic activity of the nervous system. The total power represents overall HRV. The ratio LF and HF is used to assess the fractional distribution between the two systems and is an important marker of sympatho-vagal balance\textsuperscript{20}.

In this study we focused on understanding the link between sleep and autonomic function. Our Intention is to explore phenotype-phenotype link between sleep and autonomic function as measured through HRV.

**Methodology**

A written consent was taken from all participants in the study. All the Parameters of the group were collected between 9:00 am to 5:00 pm at room temperature (20-22°C). Subjects were told to report 15 minutes before screening. They were asked to have light breakfast at least two hour before and allowed to have relaxed for half an hour before the HRV test.

The study was conducted at Amity University, Noida. Subjects were recruited from the faculties and students from the campus

**Sample Design:** On the basis of sleep duration, individuals categorized into 3 groups-

- Short Sleepers (≤ 6 hours)\textsuperscript{1-6}
- Normal sleepers (7 or 8 hours)\textsuperscript{7-8}
- Long sleepers (≥ 9 hours)\textsuperscript{9-11}

Each category consists of Poor and Good quality of sleep.

**Study Design:** Cross-sectional and experimental study.

**Inclusion Criteria:** Age group of 18-44 years, both males and females, regular night time of sleep, body mass index (range 18-24 kg/m²), Individuals without any eating disorders (on a regular diet).

**Exclusion Criteria:** Individual unwilling to participate, Presenting any feature of systemic and/or sleep disorders, Any sleep disturbances, Shift workers (rotating or night schedules), Pregnancy or any hormonal dis balance, Habit of regular day time sleep or prolonged deviated sleep schedule.

**Questionnaire/Instruments**

**Sleep Assessment:** Sleep duration along with its quality was assessed through “The Pittsburgh Sleep Quality Index (PSQI)”. **Heart Rate Variability Assessment:** HRV is phenomenon with the beat to beat variation in the time interval. It can be termed as RR variability or cycle length variability PHYSIOBAC (KUBIOS 2.1) MATLAB Software system for Heart Rate Variability Test. The first 5 min. resting (supine) phase ECG data was analyzed in this study.

**Experimental Design**

Out of 100 screened volunteers, 87 were found free from any systemic and sleep disorders.

On the basis of PSQI, the subjects with normal, short & long duration of sleep having poor and good quality were grouped in 3 categories i.e. Group I- Normal with good quality; Group II- Short with poor quality; Group III- Long with good quality. It was intended to
To assess HRV of 30 volunteers of each group but due to low prevalence and slow turn up rate of volunteers, the numbers of HRV done in each group are as follows:

**No. of Volunteer**
- Group I: 20
- Group II: 20
- Group III: 20

**HRV Procedure:** HRV was assessed as per the HRV protocol. After PSQI screening a set of instruction (i.e. to remain nil orally 2 hours prior to test) was conveyed to the selected subjects.

**Analysis of HRV Data:** The first 5 min. resting (supine) phase ECG data was analyzed. The analysis of the data is done by using a sophisticated tool, Kubios HRV software package. The variability of heart beat intervals can be easily measured by using Kubios HRV.

**Statistical Analysis**
Statistical analyses were performed using IBM SPSS statistics (v.21). All data are presented as mean ± SD values.. Shapiro Wilk test was used to check the normal distribution. For comparison among the groups, One Way ANOVA was used to compare the normally distributed parameter and Independent Kruskal Wallis test was used for non-normally distributed parameter. Further, Independent t-test and Mann Whitney test were used to check the differences in two groups. P<0.05 was considered statistically significant.

**Results**
A total of 100 individuals were screened, but 87 healthy subjects provided sufficient sleep information on sleep duration & quality (with PSQI). Participants were categorized according to their sleep duration & quality into three groups out of which autonomic activity of 60 subjects was assessed with HRV for further analysis.

</table>
Values expressed in Mean ± S.D. * shows statistical difference in Group I and Group III (p<0.05). # shows statistical difference in Group I and Group II (p=0.05).

VLF, Very Low Frequency; LF, Low Frequency power; HF, High Frequency power; LF/HF, Sympatho-Vagal balance; nu, normalized value; ms, millisecond.

While comparing the parameters of frequency domain in Group I, Group II and Group III, VLF and total power was reduced in Group II and Group III and was found significant differences in the Group I and Group III (Table 4). The HF was found significantly reduced in Group II as compared to Group I. LF was found lowered in Group II and Group III as compared to Group I but not significantly different. LF/HF ratio was not significantly different in between the Groups. LFnu was found increased whereas HFnu was decreased in Group II & Group III as compared to Group I but differences were not statistical significant. This shows the sympathetic activity is more and parasympathetic activity is less in the individuals with long and short sleeping hours in comparison of normal sleepers. Overall HRV that denoted by the total power was also reduced in the long and short sleepers.

**Conclusion and Discussion**

It was concluded from this study that sleep duration along with its quality is associated with the autonomic nervous function. HRV was significantly altered in individuals with long and short sleep duration. Alteration in autonomic activity denotes reduced physiological flexibility & mal-adaptation to internal and external stressors. Phenotype to phenotype correlation such as association between sleep & autonomic function accentuate essentiality of optimum sleep duration & quality health. Moreover, bidirectional association of sleep and autonomic activity would not only be helpful to assess risk and severity of disease but also modulate life style changes as therapeutic intervention.

**Strengths & Limitations of the Study**

**Strengths:** It was a novel approach to explore association between both sleep duration and quality with the autonomic nervous system activity through heart rate variability (HRV) in healthy population. Though the subjective assessment of sleep was performed with PSQI but thorough history & pattern of sleep phenotype was studied in detail.

**Limitations:** Our study had a small sample size due to low prevalence and slow turn up rate of volunteers. Also gender regression was not attempted due to small sample size.

**Conflict of Interest:** Nil.

**Source of Funding:** Self.

**Ethical Clearance:** Taken from IEC of Amity University, Noida.

Serum Lipid Profile among the Patients of Various Cardiac Diseases Admitted in Intensive Cardiac Care Unit (ICCU)

ABSTRACT

Introduction: Cardiovascular disease (CVD) is one of the leading cause of morbidity and mortality globally. Hypertension is a major risk factor for CVD and account for more than 80% of deaths. Increased total cholesterol, triglycerides, LDL and decreased HDL are risk factors in CVD patients. As various types of cardiac diseases are differentially changes the metabolic patterns, hence the current study was undertaken to evaluate serum lipid profile of the patients suffering from various cardiac diseases.

Methodology: Cross-sectional study conducted on 278 CVD patients. Anthropometric, physiological and lipid profile parameters were recorded by using standard techniques. Statistical analyses were done by using SPSS software version 23.0.

Results: SBP, DBP, MAP and PP show a significant increase in hypertensive heart disease, myocardial infarction and ischemic heart disease as compared to other groups. Serum triglycerides, cholesterol and LDL were found to be statistically significant among hypertensive heart disease, myocardial infarction and ischemic heart disease groups.

Discussion: Results from present study revealed that there were serious changes in cardiovascular physiological parameters and lipid profile parameters among various types of CVD.

Conclusion: Results concluded that cardiovascular risk factors like blood pressure and lipid profiles are closely associated with each other and these risk factors are very specific in manifestation of different types of CVD especially linked with cardiovascular stress.

Keywords: lipid profile, dyslipidaemia, hypertension, cardiovascular diseases

Introduction

Cardiovascular disease (CVD) is one of the leading causes of death globally. Among the various types of CVD, coronary heart disease (CHD) is the most important cause of morbidity and mortality in both developed countries as well as in developing countries. Cardiovascular disease is regarded as a multifactorial disease, which is affected by the environment and genetic factors. Traditional cardiovascular risk factors, such as smoking, drinking, diabetes, dyslipidemia and advanced age, can increase the risk of cardiovascular disease. Hypertension is also a major risk factor for CVD and account for more than 80% of deaths. It is widely accepted that CVD is associated with hypertension and dyslipidaemia. Various epidemiological studies have established a strong association of hypertension and coronary artery diseases. In general, hypertension doubles the risk of cardiovascular disease and accelerates significantly the development of atherosclerosis.
Apart from many traditional cardiovascular disease risk factors, dyslipidaemia is considered as the most important factor which is a strong predictor for cardiovascular malfunction. Increased total cholesterol (TC), triglycerides (TG), low-density lipoprotein-cholesterol (LDL-C) and decreased high-density lipoprotein-cholesterol (HDL-C) are risk factors in myocardial infarction (MI) patients. Interestingly some other observations revealed that, baseline LDL-C was not associated with CVD events.

There are several contradictory findings on lipid profile in association with CVD. The contradiction on lipid profile in some cases on LDL-C or TG and some cases in HDL-C or TC/HDL-C ratio in relation to different types of CVD.

As there are several contradictory reports on dyslipidemia among the cardiac patients, hence current study has been undertaken to evaluate serum lipid profile of the patients suffering from various types of cardiac diseases admitted in ICCU of a tertiary hospitals in north Karnataka.

### Methodology

This cross-sectional study was conducted on 278 [With 95% confidence level, anticipated prevalence of cardiovascular diseases is 3% and desired precision as ± 5. the minimum sample size is 45 per group] cardiovascular disease patients with age range from 40-70 years who were admitted in ICCU of Shri B.M. Patil Medical College, Hospital and Research Centre, Vijayapur (Karnataka). The patients with all cardiovascular diseases diagnosed for myocardial infarction, MI (group1), ischemic heart disease, IHD (group2), angina (group3), hypertensive heart disease (group4), rheumatic heart disease, RHD (group5), congestive cardiac failure, CCF (group 6), cardiomyopathy (group7), admitted in ICCU were included in the study. Patients suffering from hyperthyroidism, antihypertensive drugs, chronic kidney disease, supplementation with drugs that are known to alter biochemical parameters, metabolic and malignant bone diseases were excluded from the study.

Institutional ethical clearance was obtained (IEC No-111/2015-16, dated 10/04/2015), purpose of study was explained and informed consent in local language (Kannada) was taken from all the patients. A data collection sheet was designed to gather all the necessary information of the patients. The written official permission was also taken from the hospital administrator. Detail clinical history from all the patients was noted.

Physical anthropometry: Body mass index (BMI): All the study participants were weighed barefoot with minimum clothing using an electronic weighing machine. Body weight was recorded to the nearest of 0.1 kg. Height was measured to the nearest of 0.1 cm using standard measuring tape. BMI was calculated using the formula BMI=Weight (kg)/Height² (m).

Physiological parameters : respiratory rate (RR), pulse rate (PR) systolic blood pressure (SBP), diastolic blood pressure (DBP), pulse pressure and mean arterial pressure (MAP) were recorded immediately after their hospitalization by using standard techniques.

Lipid profile: serum triglyceride, serum cholesterol, low-density lipoprotein (LDL), high-density lipoprotein (HDL), very low-density lipoprotein (VLDL) were also measured in all study subjects by using standard laboratory kits method (random blood samples were collected immediately after their hospitalization on day 1).

Statistical analyses were done by using SPSS software version 23.0. All characteristics were summarized descriptively. For continuous variables, the summary statistics of mean ± standard deviation (SD) were used. Chi-square ($\chi^2$) test was used for association between two categorical variables. The difference of the means of analysis variables between two independent groups was tested by unpaired t test. The difference of the means of analysis variables between more than two independent groups was tested by ANOVA and F test of testing of equality of Variance. Tukey’s post-hoc test was used for multiple comparison.

### Results

Table 1 shows mean age and anthropometric parameters of various cardiovascular disease patients. BSA shown significant difference in different cardiac disease groups although the values remain within the normal range.

Results from physiological parameters like blood pressures depict a significant changes between the groups (p<0.05). (table 2). Results clearly shows a higher blood pressure values in all the components of blood pressure in case of group 1, 2 and 3 as compared to normal blood pressure values. Similarly results from lipid profiles from CVD patients also showed a significant changes between the groups (p<0.05). A higher cholesterol level from normal range has been observed in case of group 1 and 2. Similarly in case of triglycerides, groups 1,2 and 3 also shows higher triglyceride limit from normal range. LDL levels in groups 1,2,3 and 6 showed statistically significant higher levels. Though HDL and VLDL levels showed statistically significant difference among cardiac patient groups but values are within normal range.

Discussion

Results from present study revealed that there were serious changes in cardiovascular physiological parameters among all the types of CVD where all components of BP were found to be higher than normal. Haque et al (2016) in their study found that 54% of the patients had hypertension (SBP>140 mmHg) which contributes to more than one third of premature mortality due to CHD and a greater proportion due to stroke. Our results also indicate a higher BP as compared to normal range in most of the types of CVD patients admitted in ICU which may be a possible reason behind dyslipidemia in group 1, 2, 3 of CVD patients admitted in ICU.

Conclusion

Results concluded that cardiovascular risk factors like blood pressure and lipid profiles are closely associated with each other and these risk factors are very specific in manifestation of different types of CVD especially linked with cardiovascular stress.

Research on Strategic Transformation of Marketing Organic and Herbal Products with Respect to Chennai City

M. Anbarasi¹, S. Praveen Kumar²
¹Research Scholar, Dept of MBA, Bharath University, Chennai; ²Professor & Head, Dept of Management Studies, Bharath University, Chennai, India

ABSTRACT

Organic and herbal products marketing and their production of all-natural health food is not new phenomenal process. But during recent year’s interest in the buying and selling organic and herbal products, industry has increased incredible growth and transformations. Organically grown health food has created a solid niche for itself it’s a knowledge of people knowing anonymously. Indeed with the growth of organic products, among the utility of stakeholders an increased concern over the effects of organic and herbal crucially began to make a serious bid for control of the various industry particularly in field of marketing. Indian brands like Dabur India, Himalaya, Herbalife, Patanjali, Eco Farms, Khadi and 24 Mantra organic etc., are using MLM (Multi Level Marketing) techniques and strategies for marketing and distributing the products. Organic and herbal marketing is growing rapidly and consumers are willing to pay for organic products. Companies that integrate organic strategies into product development, operational process and marketing activities find new opportunities for competitive advantages. Organic products are more preferred by our people in the market today because of natural ingredients. In contrast it has drawn attention of more and more consumers and retailers even to sell the products from street to stations and from supermarkets to online stores with different enclaves. As a result, the work is focused on the analysis of competitive dynamics (inter-firm rivalry, pricing and non-price policies, barriers to entry, regulatory conditions, etc.) within the sector, and draws lessons for competition policy and to overcome the new strategic transformation model of the small scale organic and herbal products in Chennai City.

Keywords: Marketing, Organic, Herbal, Strategic, Transformations.

Introduction

Although Asia has a very active organic movement, the area under organic cultivation remains relatively small. Herbal and organic markets highly depend on consumers buying behavior. Change in the buying behavior leads to change in the market demand. Today the organic products are becoming popular, which lead towards a transformation in the market demand and consumer behavior [1] [2]. As India is considered to be rich in heritage for organic agricultural and farming, it helps towards the growth and design of strong market development. Rapid increase in organic products and herbal (ayurvedic) products has created more market opportunities and challenges. Market development requires different marketing techniques and efforts to increase consumer awareness.

Many researchers have attempted to explain the motivations and marketing issues relevant in various studies and articles, to the topic as we discussed earlier focuses on the analysis of competitive dynamics (inter-firm rivalry, pricing and non-price policies, barriers to entry, regulatory conditions, etc.) within the sector, and draws lessons for competition policy and to overcome the new strategic transformation model of the small scale organic and herbal products in Chennai City [3] [4]. In contrast, this study is organized as follows: (i) Investigation of the data on the structure of the organic and herbal products retail market in Chennai city, (ii) Summarizes recent changes in the Chennai markets

(market dynamics), (iii) Drawing on the survey and the analyzed data (describes the conduct of retailers and suppliers, and analyzes the implications for competitive conditions), (iv) Discussion about the changes that can be observed in the future and (v) Finally, Competition policy issues.

Investigation of the data on the structure of the organic and herbal products retail market in Chennai city:
The retail sector in Chennai sold $1.3 billion worth of goods in 2016-2017. Its contribution to GDP amounted to $5.1 billion. The value of goods sold declined sharply in 2018 (10.2 billion). The retail sector employed 130 thousand people, and the number of people engaged in the sector (paid workers plus owners, self-employed and unpaid family workers) was 320 thousand in 2018. The retail sector, together with the wholesale sector, provides employment for 560 thousand people. In other words, it is one of the leading employment generation sectors in Chennai.

Even, the retail sector provides households essential consumption goods under the organic and herbal products in name of lemon grass, aloevera, botanical herbs etc. However, these same products are consumed by households as services provided by hotels and camping sites and restaurants, bars and canteens (that also includes activities and take-out activities). These services purchase as FMCGs from wholesale and/or retail trade outlets and substitute for consumption at home. These two sectors’ sales for private domestic consumption were about $15 billion in 2018.

An analysis of the market structure in supplier industries is necessary to understand the performance of the retail sector. In order to determine the degree of concentration in domestic supply, we need to check the level of concentration in imports, and the share of imports in domestic supply as well.

Recent changes in the Chennai markets (market dynamics) among various organic and herbal products: The market dynamics is to a large extent determined by the regulatory framework. In this part, we use the database of certain products to compare Chennai with various categories of economies because it covers a large number of countries and summarizes regulations in index form.

i. Patanjali Product:

Patanjali’s sales volumes grew 7% during October-March 2018 and 22% in April-September 2017, according to data from Kantar World panel, a global consumer research firm. That’s a sharp fall from 52% growth in October-March 2017 and 49% during April-September 2016.

Pedagogical Objectives in Chennai

- Product portfolio management, brand extension and market segmentation of patanjali reached 82% in Chennai market.
- Analysing product innovation strategies of Britannia as its competitive advantage
- Built its consumer-facing ayurveda business almost from scratch in a few years and gained market share and shelf space rapidly, challenging established multinational brands in all categories it has forayed in.

ii. 24 mantra product: Organic produce is an emerging market in India, clocking a turnover of Rs3,350 crore in 2016, and is expected to treble it by 2020. According to N. Balasubramanian, CEO of 24 Mantra Organic, among the largest organic food companies in India, rising consumer preference for safe food and emergence of companies who are working directly with farmers is driving this growth.

Pedagogical Objectives in Chennai

- To understand use of low-budget marketing techniques to market new-product offering
- To understand the concepts of viral marketing and below-the-line promotions
- To analyze the international expansion plans of a small family firm.

iii. Farm2Kitchen: Farm2kitchen is building the first technology platform of its kind for the Food Supply Chain- which will be a Global Food Marketplace, A Farmers Network while providing food traceability along the whole supply chain.

Pedagogical Objectives in Chennai

- To understand the global food market industry
- To discuss the core competence of farm to kitchen brands
- To analyze the probable synergies of the acquisition.
iv. Lever Ayush: Riding on a growing wave of interest in natural products and ingredients, Vaidya has, over the past couple of years, evolved the brand Dr Vaidya’s into much more. With 35 products, including those for hangovers and Chyawanprash-in-a-capsule, Dr Vaidya’s wants to latch onto the trend of first building a national and then an international business around natural products and ayurveda.

**Pedagogical Objectives in Chennai**

- To analyze the global and Indian ayurvedic medicine
- To illustrate effect market segmentation
- To understand growth strategies of natural products.

v. Dabur India: Dabur India Ltd. is one of India’s leading FMCG Companies with Revenues of over Rs 7,680 Crore & Market Capitalisation of over Rs 48,800 Crore. Building on a legacy of quality and experience of over 133 years, Dabur is today India’s most trusted name and the world’s largest Ayurvedic and Natural Health Care Company.

**Pedagogical Objectives in Chennai**

- To understand the diversification strategies followed by Dabur India
- To understand the efforts of other organic societies to emulate Dabur India.

**Drawing on the Survey and the Analyzed Data:** We have conducted interviews with about 20 large retailers, and on the basis of our findings, designed two surveys, one for retailers and the other one for FMCG-suppliers to get information about retailers’ conduct and retailer-supplier relations. We received responses from 51 retailer and 79 from suppliers. The responses rates were 50 percent and 40 percent, respectively. These comparisons suggest that our sample (the above mentioned products) firms provide a good coverage of large retailers. The coverage ratio for organic FMCG-supplier industries is also quite satisfactory (17.4 percent of sales in 2018).

The survey questionnaire included questions that define the “relevant market” for retailers. Three aspects of the market, consumers’ socio-economic status, retail format, and geo- graphical market, are used to define the “relevant market”. There are 10 retailers in our sample that are a member of a business group that also owns supplier firms. When asked about the relations with suppliers in the same group, 6 retailers said that they provide preferential access to shelf space for their sister suppliers, and 4 of them get lower prices and/or better payment conditions.

Although the number of vertically related retailers/ suppliers is small, these findings suggest that retailers (and suppliers) tend to favor their sister companies. This practice could be a concern for competition policy if any one of the vertically-related companies has a dominant position in the market. However, in our sample, it seems that medium-sized companies, not the large ones, have a stronger tendency to establish preferential relations with their other companies. In other words, the relations between vertically-related suppliers and retailers is not, at least for time being, likely to distort competitive conditions in the retail sector.

**Discussion about the Changes that Can be Observed in the Future:** There is no specific law regulating the retail market in Chennai for selling the organic and herbal products. A draft law prepared last year initiated an intense debate on a number of issues. It is obvious that almost all retailers and suppliers are in favor of having a law regulating the retail market. Suppliers are also strongly in favor of restrictions on payment conditions and exclusivity agreements whereas small and medium-sized retailers are indifferent and large retailers are weakly against these restrictions. While retailers, especially large ones, are against restrictions on promotions, suppliers are somewhat in favor of these restrictions, too. Overall, suppliers seem to be worried that retailers could pass on the costs of fierce competition in the market on their shoulders.

The issue of imposing restrictions on private label sales by retailers is a contested area where suppliers and retailers, and small and large firms disagree each other. Large retailers who can capitalize on the reputation they establish in the market by selling more private label products are against restrictions on private label sales, whereas medium-sized and large suppliers, who consider private label as a threat to their national brands, are in favor of these restrictions. Small and medium-sized retailers, who may not benefit much from private label products, are somewhat in favor of restrictions, and small suppliers, whose position may not differ under private label production, are indifferent. Private label products seem to be a tool that may shift the benefits of brand name advantages in favor of large retailers.
Competition Policy Issues: FSSAI issues draft regulations for organic food products as on Jan 12, 2018, New Delhi, stated, Food regulator FSSAI has come out with a draft regulation for organic food products, seeking to ensure that these food items are actually organic. Organic foods will have to comply with the provisions under the National Programme for Organic Production (NPOP) administered by the government or the Participatory Guarantee System for India (PGS-India) run by the Agriculture Ministry or any other standards notified by the food authority.

The Food Safety and Standards Authority of India (FSSAI) has sought public comments of the draft regulations, which has been prepared in view of rising demand for organic food products, being considered as healthy, in the country. “Organic food products are either those grown under a system of agriculture without the use of chemical fertilizers and pesticides or made from organically produced raw materials ... Currently, a number of food products are being marketed as organic,” the FSSAI said. However, the regulator said that consumers do not have any way to check the authenticity of organic food products due to lack of a regulatory framework. “The draft regulation on organic food is aimed at overcoming this problem and ensuring that what is sold as organic food is really organic,” FSSAI said. The draft regulation mandates that labeling of organic foods should convey full and accurate information on the organic status of the product.

Organic food products should also carry a certification mark or a quality assurance mark given by any of the notified certification bodies. The FSSAI’s draft has exempted organic food marketed through direct sale by the original producer or producer organization to the end consumer from verification compliance. However, this exemption does not apply to processed organic products. The FSSAI has defined ‘organic agriculture’ as a system of farm design and management to create an eco system of agriculture production without the use of synthetic external inputs such as chemicals, fertilizers, pesticides and synthetic hormones or genetically modified organisms. Organic farm produce means the produce obtained from organic agriculture, while organic food means food products that have been produced in accordance with specified standards for organic production, as per the draft.

Conclusion

Organic food has truly exploded in the Chennai city market, but there are still many challenges plaguing the small scale industry that an entrant should be aware of, yes as an authorized merchant or retailer or distributor or stakeholder or even the consumer or customer, 5 things to keep in mind while venturing into organic and herbal products business in India

1. Market opportunity
2. Understanding your target audience
3. Growth opportunity
4. Challenges and policy changes, and
5. Selection of good quality of organic and herbal products

Overall to conclude, all in all, all the players, who are present as well as those who plan to enter this sector need to work mutually and in a cohesive manner to build a sustainable ecosystem and growth opportunities to build up a strategic transformations among the other markets.

Discussion

Organic products have brought change in the current Chennai city market. Consumers have also diverted more towards organic and herbal products, which has brought change in the current market scenario. By analyzing this study, it shows that consumer behavior plays an important role in buying organic and herbal products. By conducting a systematic questionnaire for the retailers, it can be said that organic products have brought change in the retailer, distributor and stakeholders business, even they are aware about organic and herbal products and its business. They also have a positive attitude towards it since the city people are more aware of the healthy lifestyle and some go green anthems. The study brought out the fact that distributors consider the importance of the product they sell to the customers and reflect the change in customer’s attitude to the preference of organic products. Earlier organic products were new to the market but now a days due to change in the customer’s behavior and attitude has brought some good result in their business and profit has been also considerably raised with a lower investment and appropriate registration in micro and small scale industries at the same time due these business the government has lifted up several
people lives in building their own interest of selling homemade and handmade organic and herbal products.

**Ethical Clearance:** Since the article studies about online promotion on herbal products there is no need of clearance.

Mindfulness Training for Adolescents with Attention Deficit Hyperactivity Disorder

Mahesh M M1, Vinod Kumar S2
1Research Scholar, 2Head of the Department, School of Behavioural Sciences, Mangattuparamba Campus, Kannur University, Kannur

ABSTRACT

Attention Deficit/Hyperactivity Disorder (ADHD) is one of the most common childhood psychological disorders which are characterized by hyperactive/impulsive and inattentive symptoms. Mindfulness training is one of the emerging intervention programs for the treatment of ADHD. Current study aimed at examining the influence of mindfulness training on ADHD. 10 adolescents were recruited based on inclusion and exclusion criteria using purposive sampling method. The study included experimental single group Pre-Post design and intervention was based on mindfulness training consisting of 10 sessions. The participants were assessed with ADHD Rating Scale-V, at before and after the intervention. Descriptive statistics and Wilcoxon signed ranks test were used. Significant reduction in ADHD symptoms was observed after the intervention.

Keywords: Attention Deficit/Hyperactivity Disorder; Mindfulness; Adolescents; Experimental single group Pre-Post design

Introduction

Attention Deficit Hyperactivity Disorder (ADHD) is a common childhood psychological disorder, characterized by hyperactive-impulsive and inattentive symptoms with a prevalence rate of 5% which vary by community, and in Indian scenario it was 8 to 17%. It’s a physiological condition which may be found to be present at birth but noticeable symptoms was observed early in childhood. Due to the highly energetic, easily distractible, and impulsive behaviour in children it is difficult to diagnose ADHD before the age of five. So the diagnosis is done at the age of 7-8 years. However the severity of symptoms decreases as children grow older. But it has serious effects on academics, careers and increase vehicle accidents.

The most common treatments for ADHD includes stimulant medication (42%) and psychosocial interventions (32%) these treatment modalities had various limitations, so professionals believed a combined intervention to be effective and should be routinely employed. Short term improvements was provided by pharmacological Interventions; however these exhibited adverse side effects in children (insomnia, appetite reduction, and irritability), continuous use showed growth suppression in children.

Non stimulant medication does not provide any data regarding its short-term safety and also there is no evidence of long-term benefits. Combined approaches (behaviour therapy and medications) have shown to be effective with several limitations, behavioural approaches focuses on attentional enhancement without considering other domains-impulsivity. Recent studies revealed the effectiveness of mindfulness therapies in children and adolescents which involves comprehensive management of ADHD.

Mindfulness is a type of attention training, evolved from Buddhist tradition and Western knowledge of psychology, which focus on the awareness of the present moment and increases non-judgmental observation while automatic responding is reduced. Mindfulness in children is acceptable and feasible research in this area ‘has barely begun’ highlighted a number of areas where differences may occur after mindfulness training, in terms of attentional, cognitive and interpersonal functioning. Accordingly, the delivery of mindfulness teaching to children and adolescents should be developmentally appropriate.

Due to the limitations of the current treatment procedures, researchers are trying to develop other treatment modalities. A study assessed the effects
of mindfulness training on children with ADHD and reported that parent-rated ADHD symptoms of both the children and themselves were significantly reduced. Another study conducted for analyzing the effectiveness of mindfulness training for adolescents with ADHD and found improvements in attention.

The rationale for using a mindfulness approach in ADHD is built on several levels of potential impact, including symptoms like inattention and impulsivity, associated neuro cognitive deficits of attention and inhibition. During mindfulness training, participants learn to reduce arousal through breathing and relaxation exercises and they develop an openness and acceptance to their emotional experiences. It teaches engagement in emotional states in a way that is avoidance, flooding, nor dissociation but rather “mindfully observing and being with the emotion.” Reduction in negative affective reactivity and volatility in response to aversive visual stimuli or emotionally provocative events have been reported with the induction of a mindfulness state. Based on these results, the mindfulness training for adolescents with ADHD is an effective approach and current study assess the influence of Mindfulness training on adolescents with ADHD.

Method

The study design used was experimental single group pre – post design. The independent variables used were mindfulness and dependent variables as attention, hyperactivity – impulsivity and total ADHD symptoms. 10 adolescents sample were selected from schools in Kannur district, those who met the criteria for ADHD by means of purposive sampling method.

The inclusion and exclusion criteria were followed as the age between 12 -14 years, diagnosis of ADHD and able to comprehend English/Malayalam instructions. The exclusion criteria were the children with Mental Retardation, Pervasive Developmental Disorder, Seizure Disorder, children who have undergone any Psychological/ pharmacological treatment in the last 6 months.

The intervention was in a group format and through homework regular practice was confirmed. Post assessments were repeated after completing the 10 sessions of training. The data was treated using the Statistical Package for Social Sciences (SPSS version 16.0). Descriptive statistics and Wilcoxon signed ranks test were used.

Result and Discussion

The main objective of the study was to find out the influence of mindfulness training on symptoms of children with ADHD. The results are presented in table No 1, 2 and 3.

**significant at 0.01 levels

The tools were ADHD Rating Scale – V: Parents version. Age range 4–20 years, comprises 18 items of 4 point scale. It has a standardized norm and gave percentile score for attention, Hyperactivity and impulsivity and total score. Test’s coefficient alpha were 0.92 (total score), 0.86 (inattention) and 0.88 (hyper activity- Impulsivity) in home version. The test has good predictive and discriminant validity and Standard Progressive Matrices for assessing intellectual functions; it is intended for adults and children from 12 years, including 60 items grouped into five sets. Test has a split half reliability of 0.84 and factorial validity of .83.
Result presented in table: 1 shows the mean, Standard Deviation and Z score of the Pre-Post assessment of inattention before and after the intervention. In pre assessment the mean and standard deviation (SD) score of the participants were 14.300 and 4.595 respectively and in post assessment it was 8.200 and 3.705 respectively. The Z score was -2.814 and it was significant at 0.01 levels. The result revealed that the mindfulness training was effective in improving attention of adolescents with ADHD. The basic purpose for incorporating mindfulness-based approach in ADHD is based on different potential impact (e.g. behavioral symptoms of inattention and impulsivity). The mindfulness practice involves three steps. Bringing attention to an “attentional anchor” is the first step; identifying the distractions and letting go of it is considered as the next step and finally redirecting focus of attention back to the attentional anchor. These steps are repeated many times and this creates an open awareness or hovering attention which is stabilized in the primary practice and other aspects of attention was emphasized.\(^{19}\) In continuing sessions the participants were instructed to pay attention to attention and bring it to the present moment. It helps to decrease the inattention symptoms of adolescents with ADHD.

Result presented in Table: 2 show the mean, Standard Deviation and Z score of the Pre-Post assessment of hyperactive–impulsive before and after the intervention. In pre assessment the mean and standard deviation (SD) score of the participants were 13.400 and 5.985 respectively and in post assessment it was 8.700 and 5.207 respectively. The Z score was -2.818 and it was significant at 0.01 levels. The result revealed that the mindfulness training was effective in improving hyperactivity-impulsivity symptoms of adolescents with ADHD. Breathing and relaxation exercises in mindfulness training help the participants to reduce arousal and develop an openness and acceptance during emotional situations. Mindfulness training teaches the participants to engage themselves in emotional states not by avoidance, flooding or dissociation but by mindfully observing and being with the present emotions. Disengagement from intense emotional states is done by shifting attention to a neutral focus. Through this process the child acquire the capacity to regulate the emotions and reducing the impulsive behaviours. The improvement in impulsive behaviour was also presented in a study.\(^ {33} \)

Result presented in Table: 3 show the mean, Standard Deviation and Z score of the Pre-Post assessment of ADHD total symptoms before and after the intervention. In pre assessment the mean and standard deviation (SD) score of the participants were 27.700 and 8.807 and in post assessment it was 16.600 and 8.501 respectively. The Z score was -2.807 and it was significant at 0.01 levels. The result revealed that the mindfulness training was effective in adolescents with ADHD. Internal and external stimuli (for example thoughts and sounds) have a great effect on children with ADHD when they are bored or is doing any difficult tasks and they fail to bring back their attention to the previous activities.\(^ {1} \) In mindfulness practice, an attention anchor (body or breath) is given so that the child focuses their attention on it to observe the wandering of their mind and through this their ability to control and sustain attention was increased.\(^ {38, 21, 32} \) They are also taught to observe and become aware of the internal and external stimuli without any automatic signals. These aspects target on symptoms like hyperactivity and impulsivity. In mindfulness sessions children are observed to get
distracted easily due to their curiosity to know how other children are doing and these impulses are beyond a child’s control. However, the children’s attention is directed to the impulses and they realize their automatic behaviors and they can develop the capacity to select how to respond to the internal or external stimulus. This develops their skill to regulate the impulsivity-hyperactive behavior. Mindfulness is used as a treatment option in ADHD due to its increased capability of controlling attention and improving self-regulation.

Even though the result in various studies showing the inconsistency in the results, the researchers suggest mindfulness reduces primary symptoms of ADHD (inattention and hyperactivity). Current study also shows the reduction in ADHD symptoms after the mindfulness training.

**Conclusion**

Mindfulness training involves the practice of creating awareness of their attention as well as decreasing the automatic responses among children which helps them to focus their attention when distracted and have a control over their hyperactive and impulsive responses. This aids them to sustain their attention for a longer period. Results from the current study demonstrated that mindfulness is an effective approach and may have a potential for treating ADHD symptoms among adolescents.

Development and Validation of a Neck Pain Risk Factor Questionnaire

Neha Gupta¹, Aparna Sarkar², Deepak Kumar³
¹Assistant Professor; ²Professor, Amity Institute of Physiotherapy, NOIDA; ³Head of Department, Capri Institute of Manual Therapy, New Delhi

ABSTRACT

Background: Neck pain is the second most prevalent musculoskeletal symptom but is not given its due importance and is being assessed mostly with other musculoskeletal symptoms. The purpose of the current study was to develop a questionnaire for assessing factors associated with increased incidence and prevalence of non-specific neck pain.

Method: A questionnaire for evaluation of risk factors associated with Non-Specific Neck Pain” (QERNP), has fifty-nine items designed by a detailed literature review and comprehensive collaboration with two academicians and neck pain participants. The questionnaire was tested on 200 participants. The two sections of the questionnaire assess the demographic characteristics, previous relevant history and four domains of the hypothesised risk factors, being occupation, personal electronic device usage, physical activity/inactivity, sleep and stress. Further additional questions are regarding presence and influence of neck pain on the individual. The psychometric properties were analysed by establishing validity and reliability through Principal Component Analysis with varimax rotation, calculation of Cronbach’s alpha and item-total correlations.

Results: Twelve factors came into existence explaining 30-40% of the total variance. Lack of redundancy of items and reliability was provided by calculation of Cronbach’s alpha and cross validation.

Conclusion: QERNP has satisfactory validity and reliability and is capable of being used in documenting the risk factors associated with neck pain.

Keywords: Neck pain, risk factors, questionnaire, validity, reliability

Introduction

The global yearly prevalence for neck pain is ranging from 16% to 75%¹. However, in the recent decade the incidence and prevalence has been on the rise. It could partly be hypothesised because of increased use of computers²,³,⁴,⁶,⁷,⁸,⁹, mobile phones⁵,¹⁰,¹¹ and tablets³ for communication, entertainment, education and work¹⁰,¹¹. The economic growth and ready availability of these electronic devices has led to a compromise of physical fitness and a more sedentary lifestyle¹², especially in the urban parts of India. Other factors contributing to the increase prevalence are the extensive, inactive job demands of the modern culture⁶,⁸,¹³, which include awkward static postures³,⁶,⁷, and repetitive activities⁸,¹⁴. Neck pain further has serious economic consequences¹⁵.

In the current study through review of literature we have identified four domains which have the potential of being a risk factor for development of non-specific neck pain. These include occupation, personal electronic device usage, physical activity, sleep and stress. Demurring the above risk factors, it is rational to hypothesise that, the evaluation of the association of the various lifestyle modifiable risk factors with the intensity and impact of neck pain, would contribute towards a better understanding and development of preventive neck pain strategies. Although, remarkable battery of tests

DOI Number: 10.5958/0976-5506.2019.01974.0
and scales are available to measure and assess neck pain. However, we were incapable of finding a reliable and valid tool which could help us study the association of the above-mentioned risk factors with non-specific neck pain. Thus, the aim of the current study is development of a valid and reliable questionnaire which will help us understand the association of modifiable risk factors the urban, technological, sedentary Indians are subjected to with non-specific neck pain.

Materials and Method

Instrument: “A questionnaire for evaluation of risk factors associated with Non-Specific Neck Pain” (QERNP) is intended to evaluate the possible risk factors for neck pain. The QERNP is a self-administered tool, made in English language, for which multiple choice and dichotomous questions were chosen as pattern

Phase I: The original questionnaire is composed of two sections. The first phase of development included a thorough literature review (described elsewhere) and a detailed interaction with two other academicians and two neck pain participants, leading to the structure and frame of the instrument. The panel was asked to rate the significance each of the items on a three-point scale. Items which were rated as not significant by two or more in the panel were deleted.

Phase II: The questionnaire was pilot tested on 50 participants. Based on the feedback of the participants and principle component analysis the suitable modifications and refinements were made. An online link for the questionnaire was developed on “Google forms”, an obligatory informed consent check box was added in the same link. The online link was tested on ten participants to check for the feasibility of getting responses. It was observed that the participants took approximately fifteen mins to complete the online questionnaire as opposed to twenty minutes in the hard copy. It also gave an option of using section-based responses, thus was more flexible and saved time.

Phase III: The Final QERNP: After the modifications the final QERNP was tested on 200 participants. Neck region was demonstrated using picture of pre-shaded manikin picture. Participants were asked to ignore pain in any other region. Section A of QERNP has nineteen items which record the demographic details. All items are compulsory to be answered. It also includes questions regarding any chronic medical diseases, previous trauma/injury/surgery of neck and shoulders. Section B of QERNP has forty items which record work, computer/mobile/tablet/iPad usage, sleep, stress physical activity and neck pain. The “Questionnaire for evaluation of risk factors associated with non-specific neck pain” is registered for copyright with the Government of India by the registration number L-70226/2017 on 15/11/2017.

Participants: As the development QERNP is a part of another study, the participants were in the age group of 18 to 35 yrs., could read and write in English language and cleared class tenth. Also, any participants with history of smoking, diseases affecting the musculoskeletal system, any previous surgical procedure involving the spine or upper musculoskeletal extremity, severe neck/shoulder trauma, medical history chronic diseases and pregnancy were not included. The study was approved by the ethical committee of Amity University, Uttar Pradesh. The online link of QERNP was alive from March 2017 till May 2017.

Data Analysis

The QERNP validity and reliability was established in three courses. The first course involved assessment of content validity, which was established by thorough discussion and item ratings with two other academicians with excellent knowledge in the domain and two neck pain patients. The second course comprised of establishment of construct validity by exploratory factor analysis. Also, item-total correlations were calculated for all factors identified above, a value between 0.2 and 0.5 was accepted. The third course involved calculation of reliability, by calculation of Cronbach’s alpha [16]. The data was entered in MS EXCEL spreadsheet and analysis was done using Statistical Package for Social Sciences (SPSS) version 21.0.

Results

Characteristics of the sample: We received 209 completed online responses, from which 9 responses were not included as they did not meet the selection criteria. As the link of the questionnaire was circulated via social media and mail, we could not determine the response rate of it. Total of 200 responses were evaluated. Table 1 shows the demographic details of the participants. The mean age of the participants was 24.04 (± 4.97) and the mean Body mass Index was 22.89(± 3.94).

</table>

Validity: Exploratory factor analysis was preferred as it allows the investigation of the interrelations between large number of items, explaining at the same time the mutual primary proportions within the four domains. Principal Component Analysis with varimax rotation was used to split the items into factors. Kaiser’s eigenvalue rule (>1), extracted percentage of variance, item content and resulting factors interpretability was used to decide the number of factors that will be retained. Also, items with a factor loading <0.5 on all factors were excluded. We have exemplified the factors and the loaded items on them. The factors are interpreted by the content of the items.

Cross validation: Absence of redundant items and reliability was further provided by cross validation. It revealed that the factors identified, their edifice, and loadings were comparable for the greater part among the first randomly formed sub-sample (n=50) and complete sample (n=200). Contrasts were identified found in personal electronic device usage. That may be due to decrease in sample size in subset. Apart from this no variations originated between the sub-sample and complete sample.

Reliability: Cronbach’s alpha coefficients were calculated as a measure of internal consistency, to represent whether the items in the domain appraise the same notion and are inter-related or not. The alpha value in the twelve factors ranged from 0.1 to 0.9. In addition, inter-item correlations are also calculated for all the twelve factors (Table 2).

### QERNP – Psychometric Properties

#### Occupation
Occupation domain constituting the first group with four items was split in two factors by factor loadings and orthogonal VARIMAX rotation. The Factor loadings on all four items were more than 0.7 in either factor 1 or factor 2, thus were retained. The occupation domain met Kaiser’s eigenvalue rule (>1). The extracted percentage of variance was 30.92 for Factor 1 and 29.358 for Factor 2.

#### Use of Personal Electronic Items
Twelve items of the second domain loaded satisfactorily on five factors. Items loaded on Factor 3 included type of computer used and posture adopted while using computer with a rotated factor loading value >0.7. Hrs/day of computer usage, hrs/session spent on sitting in front of computer without moving much and hrs/day of Tablet/iPad usage loaded on Factor 4 with a value >0.6. Factor 5 has height of monitor and height of the keyboard and mouse loaded onto it with a value of >0.59. Factor 4 included hrs/day of computer usage, hrs/session spent on sitting in front of computer without moving much and hrs/day of Tablet/iPad usage with values > 0.65. Two items height of monitor and height of the keyboard and mouse constituted Factor 5 the factor loading value being >0.59. Factor 6 had hrs/day of mobile usage, posture adopted while using mobile phone and posture adopted while using the Tablet/iPad loaded on to it, with value >0.46. Distance between chin and chest while using Tablet/iPad and mobile phone loaded on Factor 7 with value >0.59. The use of personal electronic devices domain also met the Kaiser’s eigenvalue rule (>1). The extracted percentage of variance ranged from 10.20 to 16.14%.

#### Physical activity/inactivity
The physical activity/inactivity was investigated by seven items. The orthogonal VARIMAX rotation, indicated that indulgence in physical exercise, frequency of physical exercise/week and average duration of exercise/session loaded on Factor 8 with a value more than 0.79. Factor 9 had hrs/day of Television/movie watching and posture adopted while watching Television/movie loaded satisfactorily on it with value >0.5. Self-fitness rating and increase in sweating and breathing during the physical activity session were also found to be loaded on to factor 9, but with less than 0.5 values. Overall the physical activity/inactivity domain had met the Kaiser’s eigenvalue rule (>1). The extracted percentage of variance ranged from 16.06 to 32.14%.

#### Sleep and stress
Ten items investigated the relationship of sleep and stress on young individuals. Factor 10 had position while habitually going to sleep, position while habitually going to sleep, position maintained mostly while sleeping, no. and type of pillows used, troubled by difficulties in falling asleep, troubled by repeated awakenings with difficulties going back to sleep, troubled by feeling of stress, tension, restlessness, work/personal pressure, anxiety or nervousness which makes falling asleep difficult, feeling of depression, average duration of sleep and getting sufficient sleep.
maintained mostly while sleeping number and type of pillows used loaded satisfactorily on it with a value more than 0.5. Troubled by difficulties in falling asleep, troubled by repeated awakenings with difficulties going back to sleep, troubled by feeling of stress, tension, restlessness, work/personal pressure, anxiety or nervousness and feeling of depression load with a value of >0.69 on Factor 11. The last Factor 12 had average duration of sleep and getting sufficient sleep loaded on to it with a factor loading value >0.73. But in totality the overall sleep and stress domain had met the Kaiser’s eigenvalue rule (>1). The extracted percentage of variance ranged from 12.219 to 26.819%.

Discussion

We endeavoured to inspect accurately the validity and reliability of our newly developed tool QERNP. This tool will help in collection of data about the hypothesized risk factors associated with non-specific neck pain, in the contemporary Indian population. The present day urban Indian population is being subjected to, immense exposure to the technology\textsuperscript{17}, physically indolent lifestyle\textsuperscript{18}, psychological work pressure and sleep disturbances\textsuperscript{19}. The present tool tries to incorporate these issues.

Conclusion

We developed a risk assessment tool QERNP to assist is assessment of risk factors associated with non-specific neck pain. The designed tool has acceptable validity and reliability for urban young adults and shows promising capability to be used as a screening inventory by ergonomists, employers, colleges and schools for assessment of various risk factors and later in designing preventive protocols for neck pain.

Conflict of Interest: The developed tool “Questionnaire for evaluation of risk factors associated with non-specific neck pain” is registered for copyright with the Government of India by the registration number L-70226/2017 on 15/11/2017. But we are not receiving any royalties for it.

Source of Funding: The study was funded and supported by the authors.

Influence of Jacobson’s Progressive Muscle Relaxation Technique among Primipara Women with Postpartum Blues

Prachiti Bhore¹, Srinivasan Anandh²
¹Intern, ²Department of Community Health Sciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences ‘Deemed To Be’ University, Karad, Maharashtra, India

ABSTRACT

Introduction: In the first few days after delivery, mothers can present symptomatology of postpartum blues (PPB): fatigue, anxiety, insomnia, and mood swings. Depression during the PPB is accountable for 80% of all postpartum depression. Women commonly report an increase in fatigue during postpartum which may contribute to depression.

Aim & Objective: To find the influence of Jacobson’s progressive muscle relaxation technique (JPMRT) among primipara women with postpartum blues. To assess the pre-test and post-test measures with Blue’s Questionnaire (BQ) and Vertical Numerical Fatigue Rating Scale (NFRS) among primipara women screened for postpartum blues and to assess the difference between pre-test and post-test values of BQ and Vertical NFRS resulting out of JPMRT

Method: A total of 54 primipara women who delivered normally within the age group of 20-30 years, were selected and pre-test assessment was done using both the outcome measures and Jacobson’s progressive muscle relaxation technique was incorporated for 2 weeks. The later post-test assessment was done to find if any significant difference was seen.

Result: A total of 54 primipara mothers within age groups of 20-25 years (22.27 ± 1.78) & 25-30 years (27.30 ± 1.26) participated in the study. Statistically, this study shows that there was a considerable change in the outcome measures used, with significant difference seen in the postpartum blues (p-value <0.0001) and fatigue levels (p-value <0.0001).

Conclusion: As per the results of this study, we conclude that, Jacobson’s progressive muscle relaxation technique was significantly effective in reducing postpartum blues.

Keywords: childbirth, postpartum blues, postpartum depression, primipara women, fatigue, relaxation technique.

Introduction

The postpartum or postnatal period is about a total of 6-8 weeks, it begins right from an hour after the childbirth. It is mainly divided into, an early postpartum period which is the three weeks after childbirth and the later postpartum which is the four to six weeks after childbirth.¹ During this time, three psychiatric disorders can arise namely, PPB/maternity blues, post-partum depression (PPD) and also post-partum psychosis.¹,²

PPB are usually denoted as a brief psychological disturbance in mothers during the first few days after childbirth as the mother is in the stage of puerperium and trying to adapt to the new surrounding around her.³ It’s defined as, “a brief mood disorder, occurring within first day to 6 weeks after delivery, and it’s characterized by episodes of sudden mood swings, unexplained crying, irritability, impatience, insomnia, feeling of being vulnerable, loneliness, mild depression, anxiety, fatigue, and labile emotion.¹,⁴,⁵,⁶,⁷” It has a global occurrence of 300-750 per 1000 mothers.⁴ Its prevalence was found...
to be 58.5%.[6] Depression during the PPB is accountable for 80% of all PPD. [1] The precise reason for PPB is unknown, but various factors associated may include, economy, socio-cultural factors, relationship conflicts and hormonal changes. [3]

PPD usually starts between 2 weeks to a month after the delivery. [1] Prevalence of PPD is 22% with an incidence of 100-150 per 1000 births. [3] Post-partum psychosis is that which occurs within 4 weeks of post-partum and hospitalization may be required; it has a global occurrence between 0.89 to 2.6 per 1000 births, which occurs within four weeks of postpartum and requires hospitalization. [3] The neuro-chemical etiologies of the blues are not certain; only two small studies were found to have an association between low serum progesterone (including allopregnanolone) levels at day 2–3 and the maternity blues. [7]

A common symptom of all types of depression is fatigue; it’s extremely prevalent in postpartum women (Pugh & Milligan, 1995). Aaronson et al. has defined fatigue as “the awareness of a decreased capacity for physical and/or mental activity due to an imbalance in the availability, utilization, and/or restoration of resources needed to perform activity”. In particular postpartum fatigue, is often viewed as a normal result of the physical alterations and urge of motherhood. Amount of fatigue has increased from 20% presumptuously to 50% - 64% among women in immediate postpartum (Lee & Zaffke, 1999; Whiffen, 1992). Women on their own have rated exhaustion in the top 4 contributing factors to postpartum depression (Small et al., 1994). Fatigue was recorded to be enormous in majority of women experiencing postpartum depression (Caltabiano, 1996; Whiffen, 1992). [8,9,10]

JPMRT includes the method of sequentially tensing and relaxing the main group of skeletal muscle. It decreases arousal of the central and autonomic nervous system and to increase parasympathetic activity. They last commonly for about 20 to 30 minutes. [1,11]

Moreover, no study is done to date to check the influence of JPMRT among primipara women with PPB, hence this study is being done.

Materials & Method

This experimental study was conducted at the Physiotherapy department of Krishna Hospital and Research Centre in Karad city. The research study was done for a period of 3 months from 12th November 2018 to 12th February 2019. The study population included were 54 primipara women screened for postpartum blues who were selected by purposive sampling method.

Sample size and sampling: A sample size of 54 was calculated by the statistician with the reference of the mean and standard deviation of a study done using relaxation exercises. [1] Data was collected and the overall procedure of the treatment was supervised by the faculty in charge. The data collected and the proforma was checked by the faculty in charge of quality assurance.

Inclusion Criteria: 1) Age group: 20-30 years. 2) A postpartum female who has undergone normal delivery. 3) Primipara mothers.

Exclusion Criteria: 1) Mothers whose babies are in the neonatal intensive care unit. 2) Postpartum hemorrhage. 3) Mothers of babies with birth trauma. 4) Mothers with stillbirth. 5) Mothers with past psychiatric history.

Outcome Measures:

1. Blue’s Questionnaire: It is a well-known questionnaire for the screening of postpartum blues during the postpartum period. It comprises 28-questions, each having a score of 0-3, with minimum of 0 and maximum of 28 points respectively. This scale is validated in many countries and its reliability is found to be 0.84-0.94. [12]

2. Vertical Numerical Fatigue Rating Scale: It is a well-known tool for the screening of fatigue. It comprises of a vertical scale with numerical marking of 0-10, with minimum score of 0 and maximum of 10 respectively. The inter-rater and intra-rater reliability of Vertical Numerical Fatigue Rating Scale is 0.92 and 0.96 respectively. Hence it has an excellent validation and can be used to assess fatigue in postpartum blues. [13]

After the Ethical clearance was approved, subjects were approached and those fulfilling the inclusion criteria were selected. Procedure of the study was explained and written informed consent was taken from those willing to participate. General Data of the subjects was taken; they were informed about the treatment. Each of them underwent a pre-test assessment for postpartum blues and fatigue with the outcome measures before JPMRT was given later post-test assessment was done using both the same outcome measures. Both the data were recorded. Statistical analysis was done to find the results.
Results

A total of 54 primipara mothers within age groups of 20-25 years (22.27 ± 1.78) & 25-30 years (27.30 ± 1.26) participated in the study [Table 1]. Statistically, this study shows that there was a considerable change in the outcome measures used, with significant difference seen in the postpartum blues (mean diff= 10.87, p-value <0.0001) and fatigue levels (mean diff= 5.54, p-value <0.0001) [Table 2]

Discussion

The riskiest time for mental and psychological disorders is the postnatal period; it includes sadness, depression, and psychosis. It’s associated with intense physical and emotional changes as the mother is going through puerperium which leads to fatigue and mood disturbances, in more than 60-80% cases of PPB they can evolve into PPD as time progresses mostly after 2 weeks of postpartum. In a review given by Upadhyay et al. (2017) showed a higher prevalence of PPD in Indian mothers of 22%, quoting more resources are needed for a capacity-building of maternal mental health care in India. A systematic review of done in 11 high-income countries showed the prevalence to be around 12.9% of mothers depressed at 3 months of postpartum. PPD is the most common and it can disturb the relationship of the mother with her baby and family, in the absence of required attention and treatment may lead to irreparable damages. Henshaw et al. (2004) confirmed that the earlier work and establishes that severe PPB can independently predict PPD in time mothers.

In this study, 54 primipara women subjects between the age group of 20-30 years fulfilling the inclusion criteria were included [Table 1]. They were screened for PPB and the amount of fatigue associated with it. Kennerley and Gath(1989) mentioned in their study that, PPB are been commonly reported in primipara women (Yalom et al. 1968; Nott et al. 1976). A study was conducted to determine the effect of relaxation exercises on PPD among 30 postpartum women aged 20-35 years, it concluded that relaxation exercises are easy to perform, safe, have no side effects on reducing PPD and elevating female mood and enhancing the coping up skills for stressful conditions.

A study reviewed that PPB and fatigue go hand in hand. Fatigue is one of the most common complaints experienced during the postpartum period. NANDA defined fatigue as; “experiencing a constant feeling of exhaustion that never gets over by resting and decreases the physical and mental working capacity” (Thompson et al. 1989; Carpenito 1999).

The treatment of JPMRT in this study consisted of a 2-week protocol which was given to the mother from day 2 of her postpartum, in which the outcome assessment was done before and after the treatment. Karbandi et al. (2017) did a study at 24-72 hours of postpartum to check the effect of Jacobson’s PMRT in mother’s having difficulty in breastfeeding; was given for 30-45 mins, the results were found to be statistically significant, whereas to have a positive influence and an inexpensive technique to improve the mother’s health, particularly mothers with pre-term infants.

Our study showed that there were considerable changes with significant difference seen in PPB symptoms and fatigue levels in primipara women, as we analyzed that the changes in blue’s questionnaire and vertical numerical fatigue rating scale for screening PPB, before and after incorporating JPMRT [Table 2].
In a study done by Nasiri, progressive muscle relaxation and guided imagery were used to see its effect on stress, anxiety, and depression (76.9%) in pregnant women referred to health centers, the results showed a significant difference in the mean scores after and before the intervention in stress, anxiety, and depression in pregnant women at 4 and 7 weeks through these exercises. Akbarzadeh et al. (2013) in Shiraz studied the effect of relaxation and attachment behavior training on anxiety in the nulliparous women, for 4 weeks, at the end the results showed a significant difference between anxiety scores. A study done by Chambers showed that relaxation and self-care act in reducing the negative mood in women with high stress in the gestational age of 14-28 weeks. The study of Urech et al. found that both guided imagery and progressive muscle relaxation can help reduce the heart rate, it was found that a variety of relaxation techniques can have different effects on the biological systems and psychological stress of individuals.

This study showed has a positive influence among primipara women with postpartum blues. And results were found to be statistically significant by the use of both the blue’s questionnaire as well as vertical the numerical fatigue rating scale.

**Limitation:** The limitation of this study was that it evaluated the effect of JPMRT within a short period of 2 weeks of postpartum.

**Recommendations:**
1. Studies with larger sample size.
2. A comparative study between normally delivered and c-section delivered mothers.
3. Increase in the treatment duration to find further results.
4. Long term follow up may prove the efficiency of the treatment.

**Conclusion**

The present study provided enough proof supporting the use of Jacobson’s Progressive Muscle Relaxation Technique in reducing the postpartum blues and the fatigue associated with it among primipara women. In addition, results supported that it was statistically significantly effective in reducing the number of postpartum blue symptoms and fatigue in improving their quality of life.

**Acknowledgment**

We acknowledge the guidance and support from faculty of physiotherapy. Also express my most humble and profound gratitude to my respected Dean Dr. G. Varadharajulu, Dean, Faculty of Physiotherapy, KIMSDTU for his inspiration, motivation, valuable guidance and suggestions throughout this project.

**Ethical Clearance:** Taken from the Institutional Ethical Committee of KIMSDTU.

Antimicrobial Profile and Antibiotic Susceptibility of Neonatal Sepsis in Neonatal Intensive Care Unit of Tertiary Care Hospital of North India

Rahul Chauhan¹, Surbhi Gupta², Jagjit Singh Dalal³, Sandeep Jhajra⁴, Geeta Gathwala⁵
¹Fellow Neonatology, Department of Neonatology, ²PG Student, Department of Pediatrics, ³Associate Professor, ⁴Assistant Professor, Department of Neonatology, ⁵Senior Prof & Head, Department of Neonatology and Pediatrics, Pt. B. D. Sharma University of Health Sciences Rohtak, Haryana

ABSTRACT

Background: Neonatal septicemia is the cause for 20% of neonatal deaths in the world and is more prevalent in developing nations. The main cause of concern is the development of multiple drug resistance strains in Neonatal intensive care units (NICU). The mainstay of treatment for both empirical and definitive therapy is based on rapid identification of these MDR strains and their antibiotic susceptibility that helps the clinicians in further successful management of septicemia in these patients.

Objective: To determine the antimicrobial profile of culture-positive neonatal sepsis and its antibiotic susceptibility patterns.

Material & Method: The blood culture and relevant data of newborns with culture positive neonatal sepsis were reviewed retrospectively. The data were collected from records of babies admitted in NICU of a tertiary health setup.

Results: There were a total of 882 neonatal admissions, of which 141 neonates with culture positive sepsis were reviewed retrospectively. The average gestational age of newborns was 34.5 ± 3.4 weeks and the average birth weight was 1849 ± 665 gms. Most common organism isolated was Enterobacter Spp. 61 (43.3%), Klebsiella pneumoniae (28.4%), Acinetobacter baumanii (14.9%) and Pseudomonas Spp. (7.1%). Among the least common microorganism was Salmonella typhi, Staph aureus and Citrobacter spp. was 0.7%, 2.1% and 2.1% each respectively. Early onset culture positive sepsis was 44.6% and late onset sepsis was 55.0%. The frequency of pathogens isolated was similar for both early and late onset sepsis. The resistance patterns of antibiotics to pathogens were also similar between early versus late onset sepsis.

Conclusion: Gram negative organisms particularly Enterobacter Spp., Klebsiella Pneumoniae and Acinetobactor baumanii are now predominant organisms causing neonatal septicemia in NICU both in early as well as late onset sepsis. Gram positive organisms are not the common cause of sepsis in our centre.

Keywords: Antimicrobial profile, Antibiotic susceptibility, Neonatal sepsis, Tertiary Care Hospital, onset of sepsis

Introduction

20 % of Neonatal deaths are linked to neonatal sepsis throughout the world. It is far more common in developing countries. Emergence of Methicillin-resistant Staphylococcus aureus (MRSA) and extended spectrum beta-lactamases (ESBLs) and multiple drug resistant strains are a significant threat in Neonatal Intensive Care Units (NICU) in the entire world¹. Septicemia is broadly classified as early onset septicemia (EOS) and late-onset septicemia (LOS).² Most common isolates
associated with EOS include Group B Streptococcus (GBS), E. coli, coagulate negative Staphylococcus species (CONS), Haemophilus influenzae and Listeria monocytogenes. and that with LOS are coagulate negative Staphylococcus aureus, S. aureus, E. coli, Klebsiella spp., Pseudomonas spp., Enterobacter spp., Candida spp., Group B Streptococcus, Serratia spp., Acinetobacter spp. and Anaerobes. The recent studies suggest increasing trends in no of isolates of CONS 3.

In the India it appears in case of Gram negative bacilli such as Escherichia coli, Klebsiella pneumoniae and Acinetobacter spp. Sepsis is the most important factor in the morbidity and mortality associated with NICU patients. For prompt management of sepsis appropriate antibiotic therapy can be started either in culture guided way or as empirical therapy. To avoid deterioration of inherent or heath care related infection, cultures are sent and empirical therapy on the basis of environmental and hospital significance is instituted. We want to determine the prevalence of culture-positive neonatal sepsis, its antibiotic susceptibility profile in the NICU of PGIMS, Rohtak, Haryana.

Material and Method

The study was conducted in the Neonatal intensive care unit of PGIMS, Rohtak, Haryana as retrospective study and data was collected regarding micro-organism profile and their antibiotic sensitivity pattern. Data was collected from neonates admitted in NICU during past six months.

This was a retrospective study conducted in the Neonatal intensive care unit of PGIMS, Rohtak, Haryana.

Inclusion Criteria:

- All blood culture positive neonates with proven sepsis.
- Age ≤ 28 Days.

Exclusion Criteria:

- Newborns with sterile blood culture.
- Neonate with Contaminated culture

Data of total 141 culture positive neonates with septicemia were reviewed retrospectively to get their micro-organism profile and antibiotic susceptibility patterns. Neonatal septicemia was present when one or more of the following signs and symptoms were present: convulsions, respiratory rate >60/min, severe chest indrawing, nasal flaring, grunting, bulging fontanels, pus draining from the ear, redness around umbilicus, temperature ≥37.5°C or ≤36.4°C, lethargy, unconsciousness, reduced movements, not able to feed, unable to attach breast, not suckling, crepitations in lungs, cyanosis and capillary refill time.

The blood culture samples were collected under proper aseptic conditions and before administration of antibiotics as a standard protocol. The culture bottles were transported immediately to the microbiology laboratory of the hospital. They were then further analyzed according to the standard microbiological guidelines and the isolated organisms are identified.

As per Clinical Laboratory Standard Institute guidelines, antibiotic susceptibility testing was performed on Mueller-Hinton agar plates by modified Kirby- Bauer disk diffusion method. Newborn demographics, onset of sepsis and bacteriological profile, antimicrobial susceptibility and their outcome were recorded and analyzed

Statistical Analysis

Statistical analysis was performed using SPSS 20.0 (Statistical Package of Social Sciences, Chicago, IL, USA) software. Data were expressed as the mean ± standard deviation. Data were normally distributed, and paired comparisons were performed by Chi-Square test. The significance level was set at p-value at 5%.

Results

During the six months of the study period, total 141 neonates which were culture positive were further evaluated and studied for antibiotic susceptibility patterns. From the selected 141 neonates, 88 (62.4%) were preterm and 53 (37.6%) were full term.

Mean gestational age was 34.5 ± 3.4 weeks, range 27 to 41 weeks and mean birth weight was 1849 ± 665 gm, range 680 gm to 3500 gm. A majority of neonates were low birth weight (80.1%) and 19.9 % were of normal Birth weight babies.

Table 1 shows 72 (51.1%), 69 (48.9%) male and female respectively of 141 neonates.

Early onset and culture positive sepsis were 63 (44.6%) and late onset sepsis were 78 (55.0%)

When we compared the onset of sepsis and antibiotic susceptibility pattern of major antibiotics. The resistance pattern, resistance as well as sensitivity of organisms to all antibiotics were similar between early and late onset sepsis.

Figure 1 Distribution of Microorganisms

Figure 1 shows the isolates of microorganism found in the decreasing frequency. The most common microorganism was Enterobacter Spp. 61 (43.3%) followed by Klebsiella pneumoniae (28.4%) and Acinetobacter baumannii (14.9%). Least prevalent microorganism was Salmonella typhi (n=1), Staph aureus (n= 3) and Citrobacter spp.(n=3) was 0.7, 2.1 and 2.1% each respectively.

Early onset sepsis and late onset sepsis shows similar pathogen profile as listed in Table 2.

In Early onset sepsis (EOS), sensitivity of Carbenepems were (38.3%) and Polymixin B were (100%) whereas in Late onset sepsis, Carbenepems had sensitivity of 46.6%. The most commonly isolated organism in both early onset sepsis and late onset sepsis was Enterobacter spp, that shows maximum sensitivity to Polymixin B and Carbenepems. Klebsella Pneumonae was second most common organism isolated. It shows maximum sensitivity to Polymixin B and Carbenepems.

**Discussion**

Neonatal sepsis remains a major cause of morbidity and mortality in the neonates. The clinical diagnosis of neonatal sepsis is difficult as it presents with non-specific signs and symptoms. An early diagnosis of neonatal septicemia is important to initiate appropriate and prompt treatment. The correct and timely identification of infectious agents and their antibiotic sensitivity patterns are essential to guide the clinicians regarding both the empirical and definitive treatment. The bacteriological profile of septicemia keeps changing with the passage of time from region to region and hospital to hospital, in the country. The emergence of resistant bacteria in NICU settings leads to failure in the treatment of neonatal sepsis. For management of sepsis in neonates, we need to do longitudinal survey of the NICUs and make periodic guidelines for empirical treatment. In recent years, there has been a lot of improvement in medical care and as a result, the survival rate of the preterm and LBW babies has shown improvement. But at the same time, these neonates with immature immune mechanisms are exposed to NICU flora for longer periods. Most of the neonatal sepsis cases are either LBW or preterm. In the present study, 88 (62.4%) were preterm neonates which has led to more LOS as compared to EOS. Mhada et al. reported 23% of preterm neonates, in their study. The difficult delivery (32%) in the form of Caesarean, forceps or vacuum was found as a risk factor (14.88%) by Tallur et al.6

Mostly as per literature, the common pathogens of early onset sepsis are E coli, group B streptococci, Listeria monocytogenes and enterococcus spp. In Contrast our study showed Enterobacter Spp. (43.3%) and klebsella pneumoniae (28.4%) as the most common Gram-negative organisms of early onset sepsis which is quite high as compared to studies conducted by Agnihotri et al. and Sundaram et al. In our study early onset sepsis and late onset sepsis organism profile was similar in both group as also reported by other recent study from India (DeNIS collaboration). It may be possible that the pregnant women in South Asia are colonized with pathogens found in the hospitals (such as enterobactor, Klebsiella), also it may be more probable that the source of infection in early onset sepsis is the unhygienic practices in the labour rooms and neonatal intensive care units.

**Conclusion**

Successful management of neonatal sepsis depends upon quick identification of the causative organism following the environmental and hospital trends and initiation of empirical therapy. Gram negative organisms particularly Enterobacter spp., Klebsella Pneumoniae and Acinetobacto Baumanii. are predominant organisms causing neonatal sepsis in our neonatal intensive care unit. The resistance pattern and bacteriological profile is similar in early as well as late onset sepsis. Gram positive organisms are not the common cause of sepsis in our centre. There is urgent need to control growing microbial resistance by judicious use of antibiotics and continued surveillance.
Conflict of Interest: We declare that we have no conflict of interest.

In Vitro Evaluation of Shear Bond Strength of Orthodontic Brackets Cemented to Natural Teeth Treated with Various Soft Drinks

Ravi Gupta¹, Arun Prakash C², Amith M Singh¹, Amith M Singh³

¹Assistant Professor, Department of Conservative Dentistry, Faculty of Dentistry, Melaka Manipal Medical College (Manipal campus), Manipal Academy of Higher Education, Manipal, Karnataka India; ²Consultant Prosthodontist, Vellore, India; ³Assistant Professor, Department of Prosthodontics, Manipal College of Dental Sciences, Manipal Academy of Higher Education, Manipal, Karnataka India

ABSTRACT

Introduction: The common problem during the orthodontic treatment is debonding of brackets which leads to failure of orthodontic treatment. The purpose of this study was to determine the effects of four soft drinks (Coca-Cola, 7Up, Tropicana orange, minute maid apple juice) on the shear bond strength of orthodontic brackets.

Aim: To evaluate shear bond strength of orthodontic brackets cemented to natural teeth treated with various soft drinks

Materials and Method: A total of 50 extracted human premolars were collected and stored in normal saline solution. They were cleaned and cemented with edge wise stainless steel brackets using composite. Then they were cycled in the said four soft drinks for 2 hours up to 7 days. The samples were tested for their shear bond strength using Universal testing machine (INSTRON) with a cross head speed of 0.5mm/min. The values were tabulated and analyzed statistically using ANOVA.

Results: The lowest mean resistance to shearing forces was shown by control group (18.74 ± 5.15 Mpa) followed by 7Up group (20.17 ± 6.76 Mpa), orange juice group (21.79 ± 5.15 Mpa), Coca Cola group (24.58 ± 11.68 Mpa) and highest resistance to shearing forces by apple juice group (26.04 ± 1.31 Mpa). There was no statistically significant difference among the groups.

Conclusion: No significant differences were observed in bond strength of the teeth among the different groups suggesting that consumption of soft drinks after cementation of orthodontic brackets do not significantly affect in de-bonding the brackets.

Keywords: microleakage, shear bond strength, soft drinks

Introduction

In developing countries, there is increasing trend of consumption of Soft drink, especially among young people.¹ This habit often continues into adulthood. Soft drinks contain high sugar content and a pH of < 5.5 which is below the critical level that will cause enamel demineralization leading to dental erosion and also microleakage beneath the orthodontic brackets in patients undergoing orthodontic treatment.³⁴ This is a matter of concern among dental practitioners.
Debonding of brackets during orthodontic treatment is commonly seen. Hence, patients receiving orthodontic care need proper attention.

The causative factor for bond failure is due to acidic foods and drinks with the low pH in the diet of the patient which increases treatment time. This might also have an erosive influence on the hydroxyapatite component of teeth. Coca-cola is categorized as the most carbonated drink (50%) which contains high levels of citric acid and phosphoric acid that should be seen as a true hazard for patients with orthodontic appliances. Very few studies have been conducted in the past to evaluate the effect of soft drinks on the bond strength. Coca-cola, 7-Up, Orange juice and Apple juice are widely available in the market and is very popular among adolescents undergoing orthodontic treatment. The purpose of this study was to determine the effects of these four soft drinks (Coca-cola, 7-Up, orange juice and apple juice on the shear bond strength of orthodontic brackets in vitro.

Materials and Methodology

This in vitro study was conducted at the department of conservative dentistry and prosthodontics, Melaka Manipal Medical College, Manipal. Ethical clearance was obtained from Institutional Ethical committee.

1. Sample Selection: The software G*Power 3.0.10 was used to estimate the required sample size for the study. A total of 50 extracted human premolars were collected and stored in normal saline solution. The teeth selected for the study were free from enamel cracks, caries, and fillings. These teeth were fixed in self-cure acrylic blocks using aluminum tubes (Figure 1). Fifty 0.022” stainless-steel edgewise orthodontic brackets (Centrino Standard MBT ®) with a base surface of 12.2 square mmm were used in this study. (Figure 2)

Figure 1: Extracted premolars mounted in aluminum rings using acrylic resin

Figure 2: Stainless steel Edgewise Orthodontic brackets

2. Bonding of brackets: All 50 teeth were cleaned and polished thoroughly using pumice slurry before the bonding procedure. The teeth were etched using 37% phosphoric acid gel (DETREY Conditioner 36, Dentsply, UK) for 30 seconds as per manufacturer’s instructions. The teeth were rinsed with water spray and air dried until a frosty white appearance was seen on the etched buccal surface.

A thin uniform layer of Spectrum® bond- Nano-Technology Dental Adhesive (DENTSPLY, UK) was applied using a brush on the buccal surfaces of each tooth and also onto the base of the orthodontic brackets following manufacturer’s instruction and the bonding agent was cured. A flat-ended composite filling instrument was used to apply the required amount of Spectrum® dental composite (DENTSPLY, UK) onto the buccal tooth surface as well as the base of orthodontic brackets.

The bracket was then pressed firmly into the center of the crown of the tooth mesiodistally and along the long axis of the tooth immediately (Figure 3). Excess (composite) was removed from the bracket using a sharp scaler.
The composite was light-cured using Densply LED light curing unit on all four sides of the bracket edge, 10 seconds per side at a distance of 1-2mm.

3. Immersion and Storage: The samples were then immersed in 5 different groups of beverages once daily for 2 hours. This process continued for seven days. Then they were washed with water and stored in distilled water at a temperature of 37 degree Celsius until the testing.

4. De-bonding testing: The samples were tested for their shear bond strength using the Universal testing machine (INSTRON) with a cross head speed of 0.5mm/min. The values were obtained in Newton. The values which were obtained in Newton were converted to Megapascals by dividing the total area with 12.2 square mm which is the area of the single bracket. (Figure 4)

Statistical Analysis: Anticipating an effect size of 0.6 and to test the null hypothesis at 5% level of significance with 80% power the required sample size was 40. It was increased to 50 (10 per group), anticipating 20% failure during testing. Mean of the debond testing was compared applying Welch Anova followed by Post Hoc Games-Howell test using software SPSS version 15. P<0.05 was considered statistically significant.

Results

Table 2 shows the group wise summary (mean and SD) and result of group mean comparison. Considering unequal variance (Levene test of homogeneity of variance (P<0.001)) group means were compared applying Welch Anova (Robust test of equality of means). Welch Anova indicated significant difference in the group means (F (4,11.37)=3.61, P=0.038). Post Hoc Games-Howell test for pair-wise comparison did not show any significant difference in the group means. Mean resistance was maximum for Distilled water (mean=26.04) and was least for Apple juice (mean=18.74). The difference in mean of these two groups were not significant (P=0.08).

Among the selected values, the lowest mean resistance to shearing forces was shown by apple juice group (18.74 ± 5.15 Mpa) followed by 7Up group (20.17 ± 6.76 Mpa), orange juice group (21.79 ± 5.15 Mpa), Coca-Cola group (24.58 ± 11.68 Mpa) and highest resistance to shearing forces by control group (26.04 ± 1.31 Mpa).

A considerable amount of intergroup variation was seen in the coca-cola group. All the other groups showed lesser inter group variation.

Discussion

Several studies have reported that consumption of acidic beverages like cold drinks leads to debonding of orthodontic brackets due to decrease retention.1-6
This is an in vitro study, designed to reproduce in vivo situation. In the experiment, different drinks that are commonly consumed by target groups which are Coca-Cola, 7Up, Orange Juice, Apple Juice, and also distilled water (control) are used as manipulative variables.

The immersion times and schedules used in the many past studies varied widely. In our study, 50 specimens divided equally were kept for 2 hours, in respective drink groups daily for seven days. The remaining time it was kept in distilled water to mimic the normal oral environment. In this way, we can assume that these drinks were consumed 3 – 4 times a day considering 45 minutes to consume one drink.5

Coca-Cola was the most acidic drink followed by 7 UP. The apple and orange juices were also acidic. Both Coca-Cola and 7 UP contains citric acid which gives the acidity to the drink. The apple and orange juices contain calcium citrate and ascorbic acid. All these soft drinks have demineralizing effects on teeth surface.

The cementing of brackets under one operator minimizes the error and standardize the cementing force. During debond testing using Instron machine with a shear head speed of 0.5 mm/min,

Also, it is noteworthy to note that the inter group variations obtained in Coca-Cola group were higher compared to the other groups.

The results obtained are similar to the results of Navaro’s et al 5 study who reported that bond strength values for teeth treated in Coca-Cola and Schweppes Limon were not significantly different from those in their control group. Also, our results were in consistent with a study done by Suparssara et al10

This result contradicts with some of the studies conducted1,12 that found Coca-Cola showing a reduction in shear bond strength of orthodontic brackets. Based on the study, the teeth were immersed in Coca-Cola thrice a day, while our study only immersed the teeth once daily in respective drink groups. Hence, the study might have a better imitation of soft drink consumption by target groups. Coca-Cola is an acidic media, and it can decalcify tooth (Borjan a Ferrari). Calcium may leach out from the teeth, thus soften and erodes the dental hard tissues. This will then facilitates abrasion. Furthermore, the structure of bisphenol A glycidyl methacrylate-based composite resins which is the main composition of the adhesive used in the study will be degraded with acid and acidic drink consumption as mentioned as suprssra et al.12 The matrix of the adhesive will soften which leads to filler leaching out, thus lowering the bond strength of the brackets (Hobson RS).

The limitation of this study was an unexpected increase in the failure rate of teeth (lesser sample size) could be one of the reason for insignificant difference in the group means. Hence further study may be required by increasing the sample size.

There are many factors that may affect the results. For example, the experiment done is an in vitro study, which the teeth used are extracted from different patients, at different times, of different age. Hence, the mineralization level of each tooth differs as it is affected by their lifestyles, oral hygiene and age factor. Also, the biggest disadvantage in these studies is that the data of beverages consumed by the individual before the bonding is often unknown, which could be a major factor while comparing the results.

Furthermore, the teeth used are premolars, which have a convex surface. The bonding position of the brackets is not always consistent between different teeth. Thereby, affecting the force applied during debonding process might vary. Therefore studies are required.

**Conclusion**

No significant differences were observed in bond strength of the teeth after debonding among the different groups suggesting that consumption of soft drinks after cementation of orthodontic brackets do not significantly affect debonding of orthodontic brackets.

ABSTRACT

An image segmentation method uses dynamic shape models (ACM) executed by methods for level set systems have been successfully used as piece of picture division. essential idea of ACM is to undeniably address shapes zero level game plan of higher dimensional level set limit, & figure progression of frame through improvement of level set.since they always produce sub-regions with continuous boundaries. However, traditional edge-based active contour models have been applicable to only relatively simple images whose sub-regions are uniform without internal edges. A partial solution to the problem of internal edges is to partition an image based on the statistical approach i.e. Information of image intensity measured and active contour model based on level set and Singular Value Decomposition may be applied to improve the efficiency and accuracy in poor quality images. In this paper an Improved Active Contour Method for medical image segmentation is based on active appearance models, active shape models, level set,PCA and Linear Discriminant Analysis are analyzed with intent to produce an inhomogeneous environment using SVD for segmentation of real world images in the presence of intensity in-homogeneity and noise.

Keywords: Medical Image Segmentation, Level Set, Active Contour, Singular Value Decomposition, Linear Discriminant Analysis, Intensity homogeneity, Noise etc.

Introduction

Image Segmentation: Image segmentation is the problem of partitioning an image in a semantically meaningful way. This vague definition implies the generality of the problem - segmentation can be found in any image-driven process, e.g. fingerprint/text/ face recognition, detection of anomalies in industrial pipelines, tracking of moving people/cars/airplanes, etc. For many applications, segmentation reduces to finding an object in an image. This involves partitioning the image into two classes of regions - either object or background. Segmentation is taking place naturally in the human visual system. Human kinds are experts in detecting patterns, lines, edges and shapes, and making decisions based upon the visual information. At the same time, we are overwhelmed by the amount of image information that can be captured by today’s technology. It is simply not feasible in practice to manually process all the images (or it would be very expensive and tiresome. Instead, we design algorithms\textsuperscript{[1]} which look for certain patterns and objects of interest and put them to our attention. For example, a recent popular application is to search and match known faces in your photo library which makes it possible to automatically generate photo collections with a certain person. An important part of this application is to segment the image into “face” and “background”. This can be done in a number of ways, and it is well accepted that no general purpose segmentation algorithm exists, or that it ever will be invented. Thus, when designing a segmentation algorithm, the application is always of primary focus: based on edges, lines, shapes, colors etc.

Active Shape Models: Dynamic shape appearance (ASM) \textsuperscript{[6]}, is champion among most standard show based strategies for remedial picture division. It can be considered as advancement of deformable models while converging earlier shape data. shape earlier is worked by Point Distribution Model (PDM) which models shape varieties from arranging set. In PDM, shape is tended to by approach of spotlights appropriated on limit.
Numerically, it can be portrayed by \( n \times d \) dimensional vector interfacing each point’s headings, where \( n \) is measure of focuses & \( d \) is estimation of point organizes. For instance, 2D state of \( n \) focuses is depicted as:

\[
X = (x_1, y_1, x_2, y_2, \ldots, x_n, y_n)^T \tag{1}
\]

Given training set, each shape is represented by \( n \) points referring to same coordinate system (order) throughout entire training set. Then, these shapes have to be aligned into same coordinates system to filter out shape variations caused by translation, rotation & scaling. This procedure is commonly accomplished using Generalized Procrustes Analysis\(^6\), which minimizes least squared error between points. Once correspondences have been established, Principal Component Analysis (PCA) is used to build statistical shape model. mean shape of training set of \( N \) samples is calculated using:

\[
\overline{X} = \frac{1}{N} \sum_{i=1}^{N} X_i \tag{2}
\]

A covariance matrix \( S \) is computed by:

\[
S = \frac{1}{N} \sum_{i=1}^{N} (X_i - \overline{X})(X_i - \overline{X})^T \tag{3}
\]

An eigen decomposition of \( S \) yields eigenvectors \( \{P_i\}_{i=1}^{nd} \) (representing principle modes of variation) & corresponding eigenvalues \( \{\lambda_i\}_{i=1}^{nd} \) (indicating their importance in construction of model). Sorting all modes from largest to smallest variance, first \( k \) modes are employed to model observed variability of training set. Then, shape instances of this population can be expressed by linear combination of \( k \) significant modes of variation.

\[
\overline{X} = X + P_b \tag{4}
\]

where \( P = (P_1, P_2, P_3, \ldots, P_p) \) is matrix of first \( k \) eigenvectors, & \( b = (b_1, b_2, b_3, \ldots, b_k)^T \) is vector of weights, refereed to as shape parameters. We note that number \( k \) is significantly smaller than number of dimension \( n_d \). Varying parameters \( b \) can generate new examples of shape. interval values of \( b \) are imposed to constrain resulting new shape to be valid. Now given image, instance \( y \) of model in image is defined by similarity transform \( T \) & shape parameter vector \( b \).

\[
y = T(X + P_b) \tag{5}
\]

In order to find both transform \( T \) (also called as pose parameters) & shape parameters \( b \), iterative method is used given initial model state. At each iteration, current model state \( y \) is known in image space. First, optimal displacement of each model point is calculated according to image observations. This leads to vector of suggested movement of model dy in image space. Second, pose \( T \) is adjusted by Procrustes match of model to \( y + dy \) leading to new transformation \( T \) & new residual displacements \( dys \). Next, \( dys \) is transformed into model space & then projected into parameter space to give optimal parameter updates:

\[
db = P\hat{T}^{-1} \tag{6}
\]

where \( \hat{T} \) is equal to \( T \) but without translation part. In wake of reviving \( b \), another model case is made & used to invigorate state of model in photo. Thusly, just distortions that resemble shapes in readiness set are allowed. This technique is reiterated until movements of stance & shape parameters wind up observably irrelevant.

Remembering true objective to upgrade photo appearance, varieties of ASM use different features going past clear reasoning on constrain.\(^9\) uses Gabor wavelets & models part apportionment by Gaussian mix models.\(^10\) uses steerable features to address inquiry appearance. Beside Gaussian mix models, other nonlinear models are in like manner used for showing appearance course.\(^4\) proposes non-parametric appearance show which is set up on both honest to goodness & counterfeit instances of cutoff profiles & probability of given picture profile being bit of point of confinement is obtained using \( k \) nearest neighbor (kNN) probability thickness estimation.

Correspondingly,\(^6\) uses non-guide kNN classifier\(^2\) to evaluate if truth is inside or outside of dissent.\(^3\) use Adaboost estimation to fabricate appearance models.

Parallel to component space, attempts have been made on ASM look designs.\(^6\) merges PDM with biggest likelihood shape acceptance, where perfect course of action can be found using particle isolating in iterated likelihood estimating plan. usage of innumerable makes division by shape atom filtering energetic to close-by maxima & free of prologue to burden of growing computational cost.\(^7\) is extension work of dividing multi-objects using atom channels. Another heading of improving chase plot is to intertwine MRF regularization.\(^4\) joins regularization constraint rebuffing oddity
plans that is restricted using dynamic programming figuring.\(^9\) proposes procedure that unites MRF-based neighborhood shape show for guided candidate decision with PCA-based overall shape exhibit for regularization.

Given another photo, shape estimation incorporates trading design: beginning MRF deduction technique picks best contender for each point, by then they are used to revive parameters of overall stance & shape illustrate.

Related Work

**Linear Discriminant Analysis (LDA):** Straight Discriminant Analysis has been enough utilized as social event technique for various issues including face assertion. While PCA takes entire arranging information as one substance’s, will probably perceive intense method to address face vector space by mishandling class data. ace needs to perceive quick change from vital picture space to diminished estimation consolidate space. PCA gives initiate vectors which best address information perceptions by extending refinement of predicted information. Notwithstanding, these initiate vectors give no optimality to segregation among unmistakable classes. Fisher’s straight discriminant examination (LDA)\(^3,4,5,6\) portrays best direct subspace as course of action of present vectors which best seclude among classes once information is normal onto subspace.

In particular, objective has been to see strategy of initiate vectors which control refinement of predicted information inside each class while broadening change among different classes. PCA point of view does not give any data to class separation yet rather estimation lessen. Actually, PCA paradigm\(^8\) does not provide any information for class discrimination but dimension reduction. Accordingly, FLD has been applied to projection of set of training samples in eigen space \(X = (X_1, X_2, X_3, \ldots, X_n) \subseteq \mathbb{R}^{r \times n}\). paradigm finds optimal subspace for classification in which ratio of between-class scatter & within-class scatter is maximized. Let between class scatter matrix be defined as \(^3\).

\[
S_B = \sum_{i=1}^{C} n_i (\bar{X}_i - \bar{X})(\bar{X}_i - \bar{X})^T \quad \ldots(1)
\]

and with in-class scatter matrix be defined as

\[
S_W = \sum_{i=1}^{C} \sum_{x_i \in C} n_t (x_i - \bar{X})(x_i - \bar{X})^T \quad \ldots(2)
\]

Where \(X = (1/n) \sum_{j=1}^{n_C} X_j\) is mean image of ensemble, 
& \(\bar{X} = (1/n) \sum_{j=1}^{n_C} X_j^t\) is mean image of ith class & \(c\) is number of classes. optimal subspace \(E_{\text{optimal}}\) by FLD is determined as follows

\[
E_{\text{optimal}} = \arg \max_i \left[ \frac{E^T S_B E}{E^T S_W E} \right] = [e_1^T, e_2^T, \ldots, e_{c-1}] \quad \ldots(3)
\]

where \(e_1, e_2, e_3, \ldots, e_{c-1}\) is set of generalized eigenvectors of \(S_B\) and \(S_W\) corresponding to largest generalized eigen values \(\lambda_1, 2, 3, \ldots, c\) i.e.

\[
S_B E_i = \lambda_i S_W E_i \quad \ldots(4)
\]

Thus feature vectors \(P\) for any query face image \(Z\) in most discriminant sense can be calculated as follows:

\[
P = E_{\text{optimal}}^T U^T Z \quad \ldots(5)
\]

Figure 1: Segmentation using PCA & LDA
As opposed to properties of eigen features which are not unfaltering too there are most extraordinary chances of data disaster with low pixel regards & subsequently gathering precision with LDA can’t be ordinary.

The other technique for using PCA is with higher dimensional regards called Specific Values which are enduring by its inclination. Thus instead of using EVD [10] to update course of action precision of feature request & division SVD can be used.

Specific Value Decomposition: The specific regard deterioration is after effect of straight factor based math. It has entrancing & vital influence in various applications. On such application is in cutting edge picture planning. SVD in electronic applications gives intense technique for securing huge pictures as smaller, more sensible square ones. This is capable by imitating principal picture with each succeeding nonzero singular regard. In addition, to decrease limit measure considerably further, pictures may be approximated using less specific regards.

Singular regard crumbling of structure of m x n organize shape has been as given hereunder,

\[ A = U\Sigma V^T \]  
\[ \text{Where } U \text{ is m x m orthogonal matrix; } V \text{ n x n orthogonal matrix, & } \Sigma \text{ is m x n matrix containing singular values of } \sigma_1 \geq \sigma_2 \geq \ldots \geq \sigma_m \geq 0 \text{ along its main diagonal.} \]

A similar technique, known as eigenvalue decomposition [11] (EVD), is diagonal to matrix A, but with this case, must be square matrix. EVD diagonal [12] to as

\[ A = VDV^{-1} \]  
\[ \text{Where } D \text{ is diagonal matrix } \sigma_i \text{ comprised of eigenvalues, & } V \text{ is matrix columns of which comprise corresponding eigenvectors. Where Eigen value decomposition may not be possible for all facial images where SVD is result.} \]

Proposed Algorithm in Inhomogeneous Environment using SVD.

1. Input Image
2. Preprocess Image (de-noise Image)
3. Find mean of obtained value de-noised dataset ‘S’.
4. Subtract mean value from S. From these values new matrix ‘A’ is obtained.
5. Compute covariance ‘C’ from ‘A’ using

\[ C = AA^T \text{ Where, if data } 1,\ldots,l \in R^n \text{ \& division SVD covariance matrix will be: } c = \frac{1}{l} \sum_{i=1}^{l} A_i A_i^T \]

6. eigenvalues (Singular Values) are obtained from covariance matrixes, where are \[ [V_1, V_2, \ldots, V_n] \]
7. Finally, eigenvectors which uses singular features are calculated for covariance matrix C.

8. Any vector S or S − S can be written as linear combination of eigenvectors as:

a. \[ S = b_1u_1 + b_2u_2 + b_3u_3 + \ldots = b_r u_r \]

b. lower dimensional dataset is obtained from largest eigenvalues only are kept to form \[ S = \sum_{i=1}^{l} b_i u_i, l < N \]

c. Apply LDA for further feature Processing to obtain distinct features.

\[ S_b = \sum_{i=1}^{c} n_i (\bar{X}_i - \bar{X})(\bar{X}_i - \bar{X})^T \]

\[ S_w = \sum_{i=1}^{c} n_i (\bar{X}_i - \bar{X})(\bar{X}_i - \bar{X})^T \]

\[ E_{\text{optimal}} = \arg \max_{E} \frac{E^T S_b E}{E^T S_w E} = [e_1, e_2, \ldots, e_c] \]

\[ p = E_{\text{optimal}} U^T \]

9. Project obtained features in image space & cluster features & reconstruct image I

/* Apply variational Level Set method for segmentation*/

10. Let I be image, & g be edge indicator function defined by,

\[ g = \frac{1}{1 + ||\nabla G_{\sigma} * I||} \]

Then find coefficient of internal energy term that help contour to outside object boundary.

11. contour (or level set) C(t) is curve described by set of points where function has similar features. zero level set can be given as
\[ C(t) = \{(x, y) \in \Omega : \phi(x, y, t) = 0\} \]

where \( t \) is variable that indicates time step in evolution of contour.

inside \( (C) = \Omega_1 = \{(x, y) \in \Omega : \phi(x, y, t) < 0\} \) &
inside \( (C) = \Omega_2 = \{(x, y) \in \Omega : \phi(x, y, t) > 0\} \)

10. Classify Features according properties also known as segmentation.

Approach- State Of The Art and Analysis

Effect of Ice Pack Application on Pain During Venipuncture among the Children Admitted in Selected Pediatric Units of Sangli, Miraj, Kupwad Corporation Area

Rohini Dani¹, Aparna Kale², Pravin Dani³

¹Clinical Instructor; ²Assistant Professor; ³Professor, College of Nursing, Bharati Vidyapeeth (Deemed to be University) Sangli

ABSTRACT

“A study to assess effect of ice pack application on pain during venipuncture among the children admitted in selected pediatric units of Sangli, Miraj, Kupwad corporation area”. Background: Pain as “an unpleasant sensory and emotional experience associated with actual or potential tissue damage. Intrusive procedures such as venipuncture are really a stressful event for children. Venipuncture in the paediatric population can be the most distressing event associated with medical encounters. A nurse has to help the children through such procedure. The nurse caring the child during procedure has a double task. One is helping the child and parents effectively and the other is ensuring the effectiveness of procedures. Objectives: 1.To assess the level of pain during venipuncture in control group. 2. To assess the effect of Icepack application on pain during venipuncture in experimental group. Methodology- Research design selected for the present study was quasi experimental- post test only control group design to assess the effect of ice pack application on pain during venipuncture among the children. The sample comprised of 50 children in experimental and 50 children in control group. Sample was selected using Non probability purposive sampling technique. The pain during venipuncture was assessed using FLACC pain scale. Data was analyzed using descriptive and inferential statistics. Result: The mean pain score of control group was 7.96 and mean score of experimental group was 5.4 with a P value of 0.000 which was significantly high. This shows that severe pain is less in experimental group compared to control group. Conclusion: The results of this study proved that the use of ice pack application prior to venipuncture is effective intervention for reducing venipuncture-related pain. It was concluded from the statistical tests that practicing ice pack application prior to venipuncture was effective in reduction of pain during venipuncture in children. Ice pack application has a significant effect on pain during venipuncture.

Keywords: Effect, Ice pack Application, pain during venipuncture.

Introduction

Pain is a universal, complex and subjective experience. Children experiences more distress during hospitalisation. Painful medical procedures are the major sources of distress among children; and for those with acute and chronic diseases, the procedure-related pain can be worse than that of the illness itself. Illness and hospitalization expose children to unfamiliar and unpleasant feelings.¹

Since children have little experience with and comprehension of the pain and disease process, such negative feeling can cause intimidation and anxiety for them. Millions of children experience these procedures which cause considerable distress.²

Children requiring needle stick such as injections, IV catheters and blood sampling view these procedure as frightening and is a significant source of pain. Non-pharmacological procedures or technique to reduce procedure related pain can be performed independently.

by a nurse. A number of non-pharmacological techniques such as distraction, relaxation, guided imagery and cutaneous stimulation provides coping strategies that may help to reduce pain perception, make pain more tolerable, decrease anxiety and enhance the effectiveness of analgesics.

One of these measures is proper use of cutaneous stimulation which can reduce pain perception. Cutaneous stimulation is performed by several methods such as simple rhythmic rubbing, use of pressure or electric vibrator, application of cold and hot at site before injection, which has been significantly valued in various sites. Cold application relieves pain by slowing the ability of pain fibres to transmit pain impulse.

**Materials and Method**

A quantitative research approach was adopted to conduct this study. Quasi experimental research design was used. The study was carried out at Sangli, Miraj and Kupwad Corporation area. Data collection was done using standardized FLACC pain assessment scale. The sample comprised of 50 children in experimental and 50 children in control group. Non probability purposive sampling technique was used for sample selection.

**Criteria for Sample Selection:**

**Inclusion Criteria:**
- Child with age group of 1 - 6 years.
- A child admitted to paediatric unit and requiring venipuncture procedure.

**Exclusion Criteria:**
- A Child who was on ventilator
- A child with skin allergies/burn at the venipuncture site
- A child who was on sedation during venipuncture.

**Procedure for data collection:** The data was collected in three phases.

**Pre intervention phase:** Phase I: Demographic data was collected from parents of samples in the experimental and control group.

**Intervention phase:** Phase II: In experimental group, ice-application was done for 3 minutes prior to venipuncture at venipuncture site. In control group, hospital protocol was carried out for venipuncture procedure.

**Post intervention phase:** Phase III: The level of pain was assessed with the help of FLACC scale in both experimental and control group during venipuncture.

**Hypothesis:** H$_0$: There is no significant effect of ice pack application on pain during venipuncture among children admitted in paediatric units.

**Results and Discussion**

In this study maximum children were in age group of 4 to 6 years in both the group that is 40% in control group and 44% in experimental group. Gender wise 66% were male in control group and 64% were male in the experimental group.

<td>41</td>
<td>82</td>
</tr>
</tbody>
</table>
Above table shows that in the criteria of face and legs compared to control group, experimental group had low pain score. 44% had clenched jaw in experimental group than 74% in control group. 2% had score legs drawn up in experimental group, compared to 38% in control group. There was not much difference in both the groups in activity, because it had almost similar frequency. 36% children not cried in experimental group during venipuncture. In Consolability 82% children were difficult to consol in control group and experimental group it was only 8%.

The grading of pain was categorised into three that is mild (1 - 3 score), moderate (4 - 7) and severe (8 - 10 score). Not a single child was in mild pain category in both the groups. 74% children were in severe pain where as only 6% children had severe pain in experimental group. This shows that severe pain intensity was very less in experimental group compared to control group.

**Comparison of pain in control and experimental group:** Table number 2 shows that in comparison of pain there were highly significant differences in Face, Legs, Cry, and Consolability except Activity. Total mean of control group was 7.96 and mean of experimental group was 5.4 with t value 15.849 and a \( P \) value of \( 0.000 \) which is significantly high because it was less than 0.05.

This shows that severe pain is less in experimental group compared to control group. According to the tested values Null hypothesis was rejected. That means there is significant change in level of pain after application of ice pack in experimental group.

**Discussion**

The effect of icepack on pain suggests that it may act like sensory stimuli on pain gate mechanism. Since cold stimuli are quite intense they may lead to the release of endorphins and encephalin by the same mechanism. The fact that cold will effectively relieve pain, at least temporarily, has been supported by many studies. Following this principle in present study, the researcher decided to select children between the age group of 1 to 6 years. This age group accounts for maximum % of hospitalisation. In one of the study conducted on hospital admission patterns among the children showed that 36% children admitted among the age group 1 to 5 years. Also in the UNICEF systematic review on common childhood infections and gender inequalities it is reported that children below 6 years had maximum admissions for pneumonia, diarrhoea and malaria.\(^5\)

In this study maximum children were in the age group of 4 to 6 years in the both group that is 40% in control group and in experimental group 44%. According gender 66% were male in control group and 64% male in experimental group. 34% Females in control group and 36% female were in experimental group.\(^6\) In this study pain was assessed using FLACC scale. FLACC score was low in experimental group than the control group.

Result from the study showed that in control group 74% children were in severe pain whereas only 6% children had severe pain in experimental group. This shows that severe pain is less in experimental group compared to control group. Several studies support that the application of cold is effective in reducing pain associated with puncture. Also in the study which was done on pain during arterial puncture by Bastam M in (2015) showed that icepack was effective in reducing the pain associated even with arterial puncture. This experimental study was undertaken among patient admitted to emergency ward in a public educational centre, Iran. The mean and slandered deviations of
pain score immediately after the arterial puncture for treatment and control groups were 3.12 (1.68) and 4.6 (1.56), respectively. (p<0.001) This difference was statistically significant.7

A similar kind of study was conducted to assess the effectiveness of local cold application on pain response during intravenous procedure among children in selected hospital at Mangalore. (2010) In quasi experimental study they were taken 60 samples and used DAN scale was 3.52 for the experimental group and it was 6.78 for the control group, indicating a significant lower pain score for experimental group (p=0.001).8

In present study total mean of control group was 7.96 and mean of experimental group was 5.4 with t value 15.849 and a P value of 0.000 which is significantly high because it was less than 0.05. This shows that severe pain is less in experimental group compared to control group. According to the tested values Null hypothesis is rejected. Means there is significant change in level of pain after application of ice pack in experimental group. In comparison of pain there were highly significant differences in Face, Legs, Cry, and Consolability except Activity.

The above findings were supported by Navjot kiran et al(2013) who conducted study on effect of icepack application at the prior to venipuncture on intensity of pain among children in Chandigarh. Total 100 sample was assessed by using FLACC scale. In experimental group the mean pain score was 2.98 and in control group mean pain score was 4.7. The result had shown that, there was significant lesser mean pain score during venipuncture in experimental as compared to control group.9

Conclusion

In the present study effect of icepack application on intensity of pain was assessed. In the experimental group icepack was applied at the site of prior to venipuncture for three minutes and pain was assessed using FLACC pain scale. Finding of the study clearly indicate that intensity of pain was significantly lesser in experimental group than control group. Hence null hypothesis was rejected at 0.05 level of significance. Ice pack application helps in reducing pain during venipuncture among children admitted in paediatric units.

Recommendations

1. Comparative studies can be done for testing both pharmacological and non pharmacological measures.
2. More studies may be conducted with large sample to make generalisation.
3. Studies can be done by taking other age group like 7 years onwards.
4. Studies can be conducted on effect of icepack application on pain by using different pain scales.
5. A comparative study can be conducted to assess the effect of icepack application verses cutaneous stimulation by tapping.
6. A similar study can be conducted for IM injections.
7. A study can be done to assess the effect of distraction or diversion as a technique for pain control during venipuncture.

Conflict of Interest: Nil

Comparison of Conventional and Lateral Approach to Supraclavicular Brachial Block

Shaik Zebaish Zamir¹, Suresh Y V², Shaila S Kamath³
¹Post Graduate, ²Professor, ³Professor and HOD, Department of Anesthesiology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal

ABSTRACT

Background: The conventional approach is many a time associated with complications such as vascular puncture, inadequate analgesia etc. The lateral approach is hypothesized to be equipotent and much safer than the conventional approach. We aim to evaluate this hypothesis.

Method: After Institutional ethics committee clearance, the patients, after consenting, through computer generated block randomization, were allocated to either of the two groups – Group L or C. After the block, the duration for onset of sensory and motor blockade, the total duration of sensory & motor blockade and any complications were noted.

A total of 60 patients were analyzed, 30 patients for the lateral approach and 30 patients for conventional approach. ASA 1 and 2 patients who were undergoing the surgeries of the upper limb were included in the study.

Results: The incidence of complications was much higher in conventional approach as compared to the lateral approach with a p value of 0.041. In conventional approach, in 2 (6.7%) of the patients the block failed to act completely, inadequate block was seen in 7 (23.3%) of the patients of which vascular puncture was seen in 4 (13.3%) patients. In lateral approach, inadequate blockade was seen in 1 (3.3%) patient but there was no vascular puncture.

Conclusion: Lateral approach is a much safer and reliable technique of supraclavicular brachial block.

Keywords: Anesthesia conduction, Nerve Block, Brachial Plexus, Bupivacaine, Analgesia

Introduction

The supraclavicular brachial block is used to block the brachial plexus. It is one of the most commonly performed blocks all over the world. It can be used to anesthetize a patient for surgeries from the mid-arm down. It rightly has been called the “Spinal of the Upper Limb”. It helps avoid the administration of general anesthesia and, hence, the plethora of problems associated with it. It provides faster recovery and lesser in-hospital days.

The advent of ultrasound and nerve stimulators further improved the efficacy and the safety profile of the block [¹,²]. However, numerous places in our country are yet to be equipped with this technology and, hence, rely on the classical anatomical approach which utilizes paresthesia to locate the brachial plexus [³]. Though effective, the classical approach is laden with an increased frequency of complications such as vascular puncture, inadequate blockade or even a complete failure to act. In our study, we aim to evaluate the lateral approach as an alternate safer approach to administer the supraclavicular brachial plexus block [⁴,⁵].

Material and Method

After the approval of the institutional scientific and ethics committee, Patients aged between 18-65 years
of ASA 1 & 2 status posted for any elective surgery of the upper limb below the mid-arm such as A-V fistula, orthopedic surgeries and emergency cases with no known co-morbidities were included. Patient refusal, hypersensitivity to local anesthetics and adjuvants, heart block, dysrhythmia, uncontrolled hypertension, or any other severe systemic disease, ASA 3 and 4 patients with coagulation disorders, psychiatric illness that would interfere with perception of and assessment of pain, pregnancy and emergency cases with any co-morbidities were excluded from the study.

Using computer generated block randomization, the patients were distributed into two groups- 30 patients in each group

Group L: Brachial block was given by the lateral approach

Group C: Brachial block was given by the conventional approach

Each patient underwent a thorough pre-anesthetic evaluation including patient’s history, complete physical examination and appropriate investigations were done. The patients were explained about the nature, scope, procedures of the study and the risks involved and then a written informed consent was taken. The patients were educated about the VAS score (Visual analog scale) for assessment of intra operative and postoperative pain [6].

<table>
<thead>
<tr>
<th>VAS Score</th>
<th>Description</th>

<td>Severe pain, unbearable</td>
</tr>
<tr>
<td>10</td>
<td>Most severe pain, unbearable</td>
</tr>
</tbody>
</table>

The patients were kept on nil per oral from 6 hours before surgery. No premedication was given before surgery. An 18G cannula was secured in the opposite arm and a crystalloid was started – Ringer’s Lactate for non-diabetic patients and normal saline for diabetics.

Once the patient was shifted into the OR, The baseline blood pressure, heart rate, saturation and ECG were noted.

In both lateral and conventional approach paraesthesia in the arm, forearm or hand were sought for. Once the nerve plexus was identified, an assistant administered a mixture of 2% lignocaine with adrenaline (1:200000) 7 mg/kg and 0.5% Bupivacaine 2 mg/kg. After administering the block, a gentle pressure was given at the area of the block to help uniform spread of the drug.

During the procedure and after, the signs for complications are vigilantly looked for such as pleural puncture, vascular puncture, hematoma formation, Horner’s syndrome, phrenic nerve palsy, local anesthetic toxicity and post-operative nausea and vomiting etc [7].

The time for onset of sensory and motor block was measured and the quality of analgesia was assessed using VAS scores. Intra-op blood pressure, pulse rate and SpO2 are measured.

A successful sensory block was defined as the subjective feeling of loss of pain, heaviness, tingling and numbness. The motor block was defined as the paresis of the upper arm in the form of inability to lift or abduct the forearm.

After completion of surgery, patients were shifted to the recovery room. All analgesics and sedatives were withheld in the postoperative period, unless the patient complained of pain. Postop analgesia was recorded for 24 hours. When patients complained of pain (>3 VAS), parenteral analgesic (Inj.Diclofenac Sodium 50 mg in 100ml infusion over 10 min) was given.

SAMPLE SIZE was calculated using the following formula

\[
N = \frac{Z_{\alpha}^2 \times \sigma^2}{d^2}
\]

Where, \(Z_{\alpha} = 1.96\) at 95% confidence interval
\[
\sigma = \text{Standard Deviation}
\]
\[
d = 15\% \text{ of mean difference}
\]

The sample size of 60 patients has been arrived at with 85% of power and 95% confidence level, 30 patients for the lateral approach and 30 patients for conventional approach.

**Statistical Analysis:** Data was analyzed by student’s unpaired ’t’ test and chi-square test.

A statistical package SPSS 17.0 was used to do the analysis. P<0.05 was considered as significant.

**Findings**

Among the 60 patients in Group C, 17 were males and 13 were females, whereas in Group L, 16 were males and 14 were females as shown in table 1.
The time for onset of sensory block in Group C was \(5.893 \pm 2.132\) minutes, in Group L was \(5.667 \pm 2.057\) minutes. Statistically insignificant with \(p\) value 0.682 as shown in table 2.

The time for onset of motor block in Group C was \(10.643 \pm 2.215\) minutes and in Group L was \(9.400 \pm 2.207\) minutes with a \(p\) value 0.037 (\(p<0.05\)) and statistically significant as shown in table 2.

The duration of sensory block in Group C was \(282.286 \pm 30.252\) minutes and in Group L was \(300.500 \pm 41.029\) minutes. The \(p=0.061\) (\(p>0.05\)) statistically insignificant as shown in table 3.

The duration of motor block in Group C was \(172.500 \pm 24.664\) minutes and in Group L was \(179.500 \pm 32.599\) minutes. The \(p=0.363\) (\(p>0.05\)) statistically insignificant as shown in table 3.

Among the 30 patients in Group C, 30% had complications like vascular puncture and inadequate blockade in 13.3%. Inadequate blockade alone in 10% of the patients. In 6.7% of the cases, the block failed to act completely.

Among the 30 patients in Group L, 3.3% had inadequate blockade. There was no vascular puncture in any of the patients as shown in table 4. In both the groups, no serious complications such as pleural puncture or pneumothorax were observed.

The \(p\) value for complications among the two groups was 0.041 (\(p<0.05\)) and statistically significant.
Discussion

The results of our study have proved that the lateral approach to the supraclavicular brachial plexus block is indeed a safer technique. Since the needle is passed parallel to the clavicle, away from the pleura, the chances of pneumothorax occurring are virtually nil. As for the vascular puncture, the subclavian artery lies away from direction of the needle.[5]

In the study done by Dr. Dilip Kothari, he was able to elicit paresthesia in all 250 patients [9]. Onset of sensory block was reported to occur within 3 minutes and motor block in 6-8 minutes. We achieved the sensory block in 5.667 ± 2.057 minutes and motor block in 9.400 ± 2.207 minutes. The faster onset may be attributed to the higher ratio of lignocaine used in his study. The duration of sensory block was 180-200 minutes and motor block was 120-150 minutes as reported by him. A longer duration of motor block 179.500 ± 32.599 minutes and sensory block of 300.500 ± 41.029 minutes in our study could be attributed to the higher amount of bupivacaine used in our study. He reported an incidence of vascular puncture of 6% which is higher than in our study. No other serious complications such as pleural puncture, pneumothorax etc occurred in either of the studies.

DK Sahu and Anjana Sahu reported that they had a success rate of 92% whereas we had a success rate of 96.667% [4]. The average time for sensory block in their study was 7.61 ± 2.82 minutes (mean ± SD), while it is 5.667 ± 2.057 minutes in our study. The duration for complete motor blockade was reported as 11.70 ± 2.50 minutes (mean ± SD), while it was 9.400 ± 2.207 minutes in our study. The faster onset of sensory and motor block can be due to the higher concentration of lignocaine used in this study 2% lignocaine with adrenaline against 1.5% lignocaine used by DK Sahu. The total duration of action of sensory block was 127.87 ± 14.57 minutes while it is 179.500 ± 32.599 minutes in our study. The total duration of sensory block was reported to be 2-12 hours in their study, whereas, it is 300.500 ± 41.029 minutes in our study. The longer duration of sensory block can be attributed to the usage of 0.5% bupivacaine instead of the 0.325% bupivacaine used in their study. Vessel puncture occurred in 20 patients in their study while we had no such occurrence.

A Kumar et al. reported the onset of sensory block of 7.33 ± 4.17 minutes similar to that of ours of 5.667 ± 2.057 minutes [3]. The analgesia lasted for about 180 ± 38.43 minutes in their study but we achieved a block lasting 300.500 ± 41.029 minutes. Also, they reported a duration of motor block of 176.57 ± 33.92 minutes similar to that achieved by us of 179.500 ± 32.599 minutes. Vascular puncture occurred in 3 cases in their study. The difference in duration of sensory block in between the two studies could be due to differences in drug manufacturing, cold chain maintenance etc.

In the study done by Pothula Krishna Prasad et al. the onset of sensory block took 8.5 ± 1.25 minutes and of motor block took 12.94 ± 1.72 minutes [10]. The faster onset in our study of 5.667 ± 2.057 minutes for sensory and 9.400 ± 2.207 minutes for motor block could be attributed to the higher amount of 2% lignocaine with adrenaline at 7mg/kg against the 1.5% lignocaine 10ml used by them. Total duration of action of sensory block was 192.65 ± 22.54 minutes and motor block was 186.25 ± 25.67 minutes as reported in above study. The motor block in our study for 179.500 ± 32.599 minutes was comparable to that reported by them but the higher duration of sensory block of 300.500 ± 41.029 minutes could be due to the higher amount of drug used in our study. Vessel puncture was reported in one case by them whereas we did not have any such incidence.

The above results demonstrate that the lateral approach is indeed safer. It has significantly lower rates of failed blocks, inadequate blockade, vascular puncture, pleural puncture etc. these all lead to a reduction in conversion rates to general anesthesia.

It has been successfully demonstrated that the addition of additives such as Dexamethasone [11], Dexmedetomidine [12], Hyaluronidase [13, 14], Fentanyl [15, 16], Morphine [15], Nalbuphine [17] etc. improve the duration and success rates of the block. Multiple studies have reported excellent degree of analgesia during intra-operative and post-operative period for up to 24hrs.

Newer studies using an indwelling catheter to provide continuous intra-op and post-op analgesia have yielded promising results and are set to bring in the next revolution in peripheral nerve blocks and regional anesthesia [18].

Conclusion

The lateral approach to supraclavicular brachial block is a safer and reliable alternative to the classical
approach. It has significantly lower rates of complications with the same efficacy in onset and duration of action as the classical approach. The lateral approach technique can be practiced more widely in developing countries where due to the economic constraints, the nerve stimulators and ultrasound are not available at most of the centers.

1Associate Professor, Department of Physiology, 2Professor and Head, Department of Pathology, 3Professor and Head, Department of Physiology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India; 4Professor and Head, Department of Yogic Sciences, Mangalore University

ABSTRACT

Background: Medical education is perceived as being stressful, and a high level of stress may have a negative effect on cognitive functioning and learning of students in a medical school.

Aims and Objectives:
1. To assess the stress levels in first year MBBS students.
2. Evaluate the effects of yogic techniques on their stress levels.

Materials and Method: This cross-sectional study was conducted among first year medical undergraduates. Institutional ethics committee clearance was obtained before beginning the experiments. A total of 100 1st year medical students from Kasturba medical college Mangalore were the participants in this study. Stress levels were assessed using perceived stress scale questionnaire. Yogic techniques were given for a period of 6 weeks and post intervention stress levels were assessed using student t test. Statistical package SPSS version 17.0 was used to do the analysis. Significance of the test was set at P<0.05.

Results: The overall response rate was 95%. The mean perceived stress score was 20.5 ± 3.36. In the high stress group average score was 22.84 ± 2.39 where as in the low stress group they had an average score of 15.8 ± 2.56. The stress levels were significantly higher in the high stress group. Yoga intervention significantly(p<0.0001) decreased the stress levels in the high stress groups from mean perceived stress scale score of 23.69(pre intervention) to 19.72 (post intervention) when compared to the low stress groups.

Conclusion: From the present study it is concluded that yogic intervention helps in reducing stress in medical students

Keywords: Yoga intervention, Medical students, Mental health.

Introduction

Educational stress emerges as a significant mental problem globally in recent years1. Around one third of the students experience stress that affect their scholastic performance, psychosocial adjustment along with their overall emotional and physical well being1. Poor academic performance, low peer admiration, psychosomatic symptoms, substance abuse are commonly seen among the students of academic stress without having any knowledge of techniques to overcome it.
In the first year of our MBBS curriculum we get students from all over the world. They come from different background and culture. They do have a lot of stress trying to settle in a new place and making friends. All this adds to the academic stress of the MBBS curriculum. The rate at which they learn things differ from one individual to another. This stress could have a role in their academic performance. Some perform well in the sessional exams whereas others do not.

Practice of Yoga has become increasingly popular in India as well as in western countries as a method for coping with stress and improving the quality of life. Yoga is one of the methods by which a goal of positive health can be achieved. Yoga plays a significant role in augmenting one’s mental health, which is instrumental for their fruitful performance in all domains of life.

This study is aimed at providing Yogic sessions to see effect in reducing the stress levels in First year medical students and improving their academic performance.

**Aims and Objectives**

1. To assess the stress levels in first year MBBS students.
2. Evaluate the effects of yogic techniques on the stress levels.

**Methodology**

This was a cross-sectional study conducted on first year MBBS students studying in a private medical college. Students (n=100) who have scored less in their sessional examination were taken for the study. They were then given the Perceived stress scale Questionnaire to get a baseline data. The perceived stress scale is a globally accepted test for measurement of stress which is a ten-item questionnaire that poses general questions allowing users to respond according to their personal stressors. Questions are based on a five point Likert scale. Scores range from zero to forty with higher scores indicating higher levels of perceived stress. Based on their scores students are divided into high stress group (Score ≥20, n=70) and low stress group (Score <20, n=30). Students in each of these groups are equally divided by simple randomization into the control group (n=50, 35 high stress and 15 low stress) who were not given any intervention on yoga, and the intervention group (n=50, 35 high stress and 15 low stress) who were given yogic intervention.

**Intervention Detail:** Students were given daily yoga sessions by a qualified yoga teacher in the Department of Physiology. Yogic sessions were given 3-4 hours after meals which was at 5:00 pm. Sessions were conducted for a period of 40 minutes in the evening for 5 days a week for a duration of 6 weeks. The yoga module consisted of Asanas, Bandha Mudra, Pranayama, Meditation and relaxation for a duration of 40 min. Intervention was given to the students which was for 6 weeks (12th March 2018-20th April 2018).

The pre and post interventional data of both control group and Intervention group were collected in the following way:

Self-assessed reduction in Stress levels will be assessed using Perceived stress scale questionnaire.

**Statistical Method:** Comparison between high stress group and low stress group was done using Student’s unpaired t test and paired t test by SPSS(version 16) software.

**Results**

**Table 1: Comparison of PSS scores of students**

</tr>
</tbody>
</table>

The response rate was 95%. Of 105 students 100 completed and returned the questionnaire giving an overall response rate of 95.32%. The results of the following study showed that in the slow learners, the high stress group had an average score of 22.84 ± 2.39, where as in the low stress group they had an average score of 15.8 ± 2.56 after analyzing the PSS questionnaire. On comparison of high stress group with low stress group there was significant increase in stress score in high stress group(p<0.0001) Yoga intervention significantly(p<0.0001) decreased the stress levels in the high stress groups when compared to the low stress groups. (Table 2)

Discussion

The first part of my study has given a lot of insight about the stress levels in medical undergraduates. The first year medical undergraduates do have a lot of stress which was reflected in their perceived stress scale scores. Previous studies have shown that academic curriculum, increased number of examinations, competition with fellow mates were sources of anxiety among medical undergraduates. [5,6,7,8,9,10]. This could exaggerate the already existing problems such as the stress of new place and friends.

Our results have shown that there is significant reduction in the stress levels after 6 weeks of Yogic intervention. This is in accordance to another case control study conducted by Lona Prasad et al. Yoga is gaining prominence in boosting the mental health and in the treatment of psychiatric and psychosomatic disorders. This has a direct effect on the quality of their life. As medical students are the footing of the medical profession, they ought to be be aware of this complementary therapy of yoga for the enhancement of their own mental health and that of their patients.

Limitations

This a cross-sectional study conducted only in one medical college and lacks generalization of results. Since the information was obtained from a self-administered questionnaire, information bias cannot be ruled out.

Conclusion

From the present study it is concluded that yogic intervention helps in reducing stress in medical undergraduates.

Implications: The high stress in medical undergraduates could be a reason for their poor performance in the sessional exams and addressing them by some measures may boost up their confidence and mental health and give the society better doctors in the long run.

Optimization Techniques to Solve Waste Management Problem: A Review

Snehal Sagar Kolekar¹, Poorva Agrawal²

¹Postgraduate Student, ²Assistant Professor, Department of Computer Science, Symbiosis Institute of Technology, Symbiosis International (Deemed University), Pune

ABSTRACT

With the development of advanced technology in the recent years there is an enlargement in the generation of waste. There are different sources of waste generation such as industries, hospitals, etc. This paper provides a review on different type of waste management problems such as biomedical waste management, Solid waste management, Hazardous waste management etc. There is a need to manage this waste properly within short time period because it affects the people lives and environment. Therefore, the waste management problems have become more and more complex in today’s life. To dispose the waste within short time there is need to optimize some factors like distance, time and number of vehicles used for the collection and transportation of waste. This paper focuses on the different optimization techniques such as Genetic Algorithm (GA), Ant Colony Optimization (ACO) and Modified multi-Objective Ant Colony Optimization (MOACO), etc. to solve the waste management problems using Vehicle Routing problem (VRP).

Keywords: Vehicle Routing Problem, Genetic Algorithm, Biomedical Waste Management, Ant Colony Optimization, Modified multi-Objective Ant Colony Optimization.

Introduction

Waste Management is a global issue that has become a serious concern in people lives because there is an increment of new problems which indirectly influences the society/environment. The waste generated from the different sources like hospital, industries, etc. can be hazardous. It may cause the dreadful effects if it is not managed properly. Hence, it is very important to dispose the biomedical waste or hazardous waste as early as possible because there are many issues such as vehicle failure, road accidents; traffic problems, Lack of infrastructure and many more during transportation of waste.

In last few years, researchers⁴,⁵ mainly focused on the transportation of waste but they have not considered the risk associated with transportation of waste. Risks associated with transportation of wastes are traffic problem, road accident, etc. Sudden vehicle failure or accident leads in to dumping of waste anywhere on the road and it turns into the environment pollution. So in such situation there is need to work. On path planning approach using some advanced technology.

In recent years, researchers⁵,¹² focused on waste management method by using different optimization techniques. They applied different optimization techniques to minimize the risk, cost and to optimize the distance so waste will dispose in short time at the disposal site. This paper mainly focused on different reviews and different optimization techniques used for the waste management.

The outline of the paper is organised as follows: In the section II, different waste management categories has been discussed. Section III explains research in the field of waste management using different optimization techniques. The related research work is divided further into three different categories. First category includes optimization techniques used for the BMW management. The second category includes different optimization techniques used for the hazardous waste management and the third category is related to the solid waste management using optimization techniques. Section IV discusses about the conclusion and the future scope and Section V includes the overview of some important research papers.

Waste Management: It is significantly essential to manage the waste generated within the hospitals properly so as to avoid health problems and environmental
It includes soil, water and air pollution where as humans have to fight with infectious diseases like HIV, hepatitis etc. essential to manage the biomedical waste properly. In last few years, many researchers worked on issues related to biomedical waste and they focused on collection, separation, treatment of biomedical waste in hospital by using bins. There is a need to focus on safe transportation of biomedical waste. In the year of 2016, author 12 works on network optimization in the field of BMW. Then in the year of 2018, Radhika and Ajay1 introduced, modified Multi-Objective Ant Colony System (MOACS) technique supported by clustering algorithm to obtain optimum and safe routes for biomedical waste complex transportation (BMWCT) problem. In this paper, the MOACS algorithm is used in BMW management to solve the complex transportation issues. The multiple depot and disposal facility are considered to optimize the transportation risk associated with the collection and transportation of waste.

Hazardous material generated from industries or any other sources are dangerous. It includes wastes from electroplating, metal finishing operations, chemicals, etc. There are different techniques proposed by different researcher2,3 to manage the hazardous waste collection. Vehicle routing and scheduling technique is used for the planning of hazardous waste collection and disposal. This technique is also used to optimize the route for the hazardous waste collection 3. Genetic Ant Colony Optimization Algorithm (GACO) is proposed by a researcher6 which is used for the real time garbage collection study. A fuzzy bi-level programming model is developed by researchers2 to minimize the total transportation risk of delivering products of hazardous materials from multiple depots. Disposal of solid wastes is major problem in both urban and rural areas of many developed and developing countries. To solve this problem, some researchers have worked on some policies to define the rules for the MSW13. One of the major environmental problems is the collection, management and disposal of the MSW in the urban areas. The sources of solid waste include residential, commercial, institutional, and industrial activities. Lack of MSW management and disposal is leading to significant environmental problems. This includes soil, air water, and aesthetic pollution. Such environmental problems are associated with human health disorder. Many researchers 10,11 worked on the municipal solid waste collection using vehicle routing problem to minimize the transportation risk.

The main problem related to the waste management is the improper transportation of waste at disposal site. In this paper, authors1-13 mainly focused on waste management problem using different optimization techniques. These optimization techniques are used to optimize the distance between collection point and the disposal site using vehicle routing problem2. Fig 1 shows the scenario of various depots and hospitals. Fig 2 shows the group of nearby depot and hospital to collection of waste2. In this scenario, distance between depot and hospital is calculated based on Euclidean distance method31. Then the vehicle starts from one of the depot based on calculated distance search for nearby hospital then collects the waste from different hospitals till the capacity of vehicle and come back to the depot to dump the waste. This method helps to proper management of biomedical waste within time and also optimizes the distance, time and cost associated with the collection and transportation of waste. In this figure, depot and disposal site have been considered at the same location.

![Fig. 1: Scenario for depot and hospital](image1)

![Fig. 2: Group of depot and hospitals](image2)
Related Research Work: In this paper, comparative analysis of various optimization algorithms for the waste management problem have been studied.

Biomedical Waste Management: This section focuses on the research in the field of BMW management and the problems within the field of BMW, faced by individuals and the environment due to improper management of BMW.

Need for Biomedical Waste Management: In the year 2012, Mathur et.al. focused on the basic issues of BMW Management. In this paper authors discussed about improper management of waste generated in health care facilities, how it impacts on the community, health care workers and the environment. Large amount of infectious and hazardous waste are generated in the health care hospitals. Unplanned disposal of BMW or hospital waste and exposure to such waste possess serious threat to environment and human health. In this paper researchers explained the classification of BMW such as General Waste, Pathological, Radioactive, Sharps, Pharmaceuticals, etc. Researcher also defined the major sources of generation of BMW such as Govt. hospitals, private hospitals, nursing homes, primary health centres. Mainly researchers explained the need for the BMW, the BMW management process, rules and benefits of BMW management.

Healthcare Waste Management: In the year 2016, Ankur Chauhan et.al. focused on numerous future research directions towards BMW management in healthcare. In this paper, researchers worked on the requirement of more in-depth application of operations management tools and techniques in the field of BMW. Researchers were worked on the unaddressed issues related to a healthcare waste management i.e. inventory management, warehousing, bins allocation, routing and transportation. Also explained the importance of effective management of healthcare waste.

Vehicle Routing Problem: This paper, focused on distance optimization using network optimization strategy. The main model of the network optimization is VRP. The medical waste generated from small hospitals and clinics can be transported to the nearby bigger hospitals because bigger hospitals have enough space to accommodate the medical waste generated from nearby clinics. So, it helps to optimize the distance and the cost associated with the collection and transportation of medical waste generated from small clinics. In this paper, two-three hybrid networks are designed by researchers to cluster the bigger hospital and nearby small clinics. These networks are helped to transport the waste generated in small clinics to the bigger hospital. Through this network strategy, author worked on path optimization to decrease the total travel distance.

Modified multi-Objectives Ant Colony System: In the year 2018, paper discussed the development of a modified ACS-based approach to determine the optimal and safest route for (BMW) collection and transportation. In this problem, researcher considered the number of vehicles, multiple depot, disposal site and hospitals. Vehicle starts from depot, collect the biomedical waste from respective hospitals and dumps to the disposal site by satisfying the defined constraints like vehicle capacity and time window. The objectives considered by the researchers are route selection of vehicles, risk associated with the collection and transportation of BMW, total scheduling time of vehicles and number of vehicles. In this method, clusters of the hospital nodes are comprised based on their distance from the nearest depot and late time window associated with the hospital node. The distance is calculated by Euclidian Distance Method. This algorithm was tested on real time data as well as on standard data. The results obtained using MOACO algorithm gives good results with deviation less than 5% compared to the standard best solutions.

Hazardous waste/material Management: This section explains the different issues in the management of hazardous waste. Many researchers are worked on various optimization techniques. In this section, different optimization techniques for the hazardous waste management are explained by the authors.

Vehicle routing and scheduling technique: In paper, the authors have introduced a vehicle routing and scheduling technique for the planning of hazardous waste collection and disposal. In this method clients requests for waste withdrawal in order to find shortest distances, maximization of amount of collected waste and maximization of commercial value of withdrawals. It considers constraints on vehicles capacity and availability, lunch break requirements, working hour’s limits, the need to keep the different type of hazardous waste separated and the time restrictions. The short computational time approach is used which is suitable for evaluating alternative plans, as well as managing late
orders or urgencies. This study has more computational complexity while handling very large number of requests to service.

**Genetic Ant Colony Optimization Algorithm (GACO):** In this paper\(^7\), the researchers worked on capacitated vehicle routing problem with fuzzy demand to solve the garbage collection case study. The GACO algorithm is developed by the researchers to improve the performance of ACO and the GA. This algorithm is used for the real time study of garbage collection. The proposed GACO algorithm is compared with other existing algorithms for solving CVRP. The proposed method improves initialization of typical ACO by employing Prims algorithm. The crossover and mutation steps are integrated in ACO to accelerate the local and global exploration. The proposed GACO algorithm is able to handle the CVRP with fuzzy demand using fuzzy credibility measurement theory.

**Multi-Depot Vehicle Routing Problem (MDVRP):** In paper\(^2\), four fuzzy simulation-based heuristic algorithms are designed by the authors for obtaining the optimal solution to the proposed model. For modelling MDVRP for hazardous materials transportation, the authors have concentrated on the goal of minimizing transportation risk. To calculate the risk, the problem is divided into two levels of formulations. The upper level formulation allocates customers to depots under the constraints of depot capacities and customer demands, while the lower level determines the optimal path for each group of depots and customers. Comparative analysis was done to evaluate their performances for searching the optimal routing and allocation strategy. Incorporating the historical information of road accidents from urban transportation systems is used to find the risk associated with the transportation of hazardous materials. Risk is difficult to define accurately that’s why researcher does the formulation of the MDVRP for transportation of hazardous materials. In this study, number of depot and the location are not fixed.

**Municipal solid waste:** Municipal solid waste is the emerging issues because amount of waste generated from the society is more. So to manage the municipal solid waste different optimization techniques are explained by the different researchers.

**Vehicle Routing Problem:** In the year 2012, Katja Buhrkal\(^10\), worked on the Waste Collection Vehicle Routing Problem with Time Windows (WCVRPTW) in a city logistics context. In this paper, researchers worked on the cost optimization with finding of optimal route for garbage collection. Researchers proposed an adaptive large neighbourhood search algorithm for solving the waste collection problem. The objective of the WCVRPTW is to find a set of routes for the vehicles, minimizing total travel cost and satisfying vehicle capacity such that all customers are visited exactly once and within their time window.

**Optimization of solid waste systems:** In this paper\(^11\), researchers worked on the municipal solid waste management using optimization technique. Mathematical model has been developed and tested it by using the real data from Ilala Municipal in Dares Salaam Tanzania. The formulated model resulted into lower cost of transporting solid waste from sources to collection points.

**Conclusion and future scope:** In this paper author review the literature on waste management using VRP with different optimization techniques. It also explains about different waste management types and the research related to waste management using different optimization techniques. It also gives idea about previous and current waste management scenarios. Researchers focused on to find the optimal path for the transportation of waste but they are not focused on vehicle failure problem. In future researchers may work on some advanced technology like artificial intelligence to solve waste management problem. It will help for safest transportation of hazardous and non-hazardous.

**Ethical Clearance:** Not required as it is a review article.

Risk Factors and Clinical Characteristics of Stenotrophomonas Maltophilia Infections

Suyash Jha¹, Ashwini Hegde²
¹Intern, Kasturba Medical College, Mangalore, ²Associate Professor, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education

ABSTRACT

Stenotrophomonas maltophilia is a non-fermenting, aerobic, gram-negative bacillus that shows multi-drug resistance and is an opportunistic and nosocomial pathogen.

It causes infections like pneumonia, bacteremia, endocarditis, meningitis, bone and gastrointestinal infections, which may lead to septic shock.

This study was undertaken to evaluate the clinical and microbiological profile of this emerging pathogen since not many studies about this organism have been done in India.

This retrospective study was conducted at a tertiary care hospital of Karnataka, India for two years (2014-2015).

Demographic and clinical data of patients was collected from medical records section and then analyzed using SPSS 11.0

**Keywords:** Stenotrophmonas maltophilia, antibiotic resistance, immunocompromised, critical care, antibiotic therapy, opportunistic infections, infectious diseases

Introduction

Stenotrophomonas maltophilia is an aerobic, non-fermenting, gram negative bacterium. First isolated in 1943, it was classified as Bacterium bookeri and later renamed to Pseudomonas maltophilia in 1961. It was also grouped under Xanthomonas in 1983 before being finally classified as Stenotrophomonas maltophilia in 1993. It is motile due to presence of polar flagella and grows well on MacConkey Agar producing pigmented colonies. S. maltophilia is catalase positive, oxidase negative and has a positive reaction for extracellular DNase. S.maltophilia is found in the environment and frequently colonizes humid surfaces like catheters and endoscopes.¹

It is known to produce beta lactamases which make it resistant to beta lactam antibiotics such as carbapenems. Many strains are sensitive to ticarcillin and trimethoprim-sulfamethoxazole, but antibiotic resistance has been increasing. It is emerging as a global multi -drug resistant organism and can cause nosocomial infections in immunocompromised patients². Of these, the most common are respiratory tract infections. Risk factors include mechanical ventilation, diabetes mellitus, tuberculosis, surgery, trauma, catheterization and prolonged hospitalization³

S.maltophilia does not produce any significant virulence factor and is therefore considered to be an organism with low virulence. It is generally regarded as an opportunistic pathogen, especially in immunocompromised hosts. Its ability to survive and colonise on humid surfaces, to form biofilm and its resistance to a number of antimicrobial agents by virtue of possessing several mechanisms that confer resistance to a number of antimicrobial agents help it to cause infections.⁴

Malignancy especially hematologic, transplantation, human immunodeficiency virus (HIV) infection, cystic fibrosis, prolonged hospitalization, intensive care unit
(ICU) admission, mechanical ventilation, indwelling catheters, corticosteroid or immunosuppressive therapy, and recent antibiotic treatment are some of the risk factors associated with \textit{S.maltophilia} infections.\[^5\]

\textit{S.maltophilia} causes a wide range of infections including respiratory tract infections (RTI), bloodstream infections (BSI) and, less commonly, skin and soft tissue infections (SSTI), bone and joint infections, biliary tract infections, urinary tract infections, endophthalmitis, endocarditis, and meningitis.\[^6\]

\textit{S. maltophilia} pneumonia is usually hospital-acquired and most frequently occurs in mechanically ventilated patients. Compared with pulmonary colonization, infection is associated with underlying immunosuppression.\[^7\]

Most cases of \textit{S. maltophilia} bacteremia are associated with indwelling catheters.

In a study conducted on 207 oncology patients with a central venous catheter and \textit{S.maltophilia} bloodstream infection, 73 percent of infections were found to be catheter-related, 22 percent were secondary (mainly from a pulmonary source), and 5 percent were thought to be primary and non-catheter related. Most of the catheter-related \textit{S. maltophilia} bloodstream infections are polymicrobial.\[^8\]

Our study was a retrospective study of two years duration between January 2014 and December 2015. The study was conducted in a 850 bed referral hospital in South India after approval from the institutional ethics committee. All clinical samples which were culture positive for \textit{S.maltophilia} from January 2014 to December 2015 were included in this study.

\textbf{Materials and Method}

This study was conducted in a tertiary care hospital of Karnataka taking into account cases for two years:2014-2015. Demographic and clinical details of the patients which include age, gender, clinical presentation, associated risk factors and comorbidities, radiological findings, use of antimicrobial therapy and prognostic outcomes was collected from the medical records. Culture reports of the patients were collected to study bacteremia due to \textit{S.maltophilia}. Clinical and radiological findings of the patient were correlated and compared to assess the clinical significance of \textit{S.maltophilia} isolates. Lower respiratory tract samples including sputum, endotracheal aspirates or bronchoalveolar lavage fluid (BAL) from patients’ with symptoms and signs of LRTIs were processed by microscopy and culture. Microscopy was done according to Bartlett’s grading system. Culture for all the respiratory samples was done on sheep blood agar, MacConkey agar and chocolate agar and incubated at 37°C for 18-24 hours in 5-10% CO2. Culture for ET aspirates and BAL specimens were done quantitatively.

The obtained data was subjected to statistical analysis by SPSS version 11.0

\textbf{Results}

\textit{S. maltophilia} was isolated from a total of 40 samples

Maximum number of patients (15) presented with fever as the chief complaint. Trauma and respiratory distress with breathlessness and cough were reported as complaints by 10 and 11 patients respectively.

Maximum number of patients belonged to the age group of 51-60 (8;20%). Patients aged 41-50 and 61-70 accounted for 7 cases (17.5%) each of the studied population.

26(65%) of the studied cases were males while 14(35%) were females.

Of the total 40, 30 cases resolved the infection and 10 deaths were reported.

The presence of risk factors in the patients was as shown in following figure:

\textbf{Figure 1: Presence of risk factors in Patients}

As seen in the chart above, hypertension and Diabetes emerged as major risk factors. They were reported in 14(23.7%) and 12 (20.3%) cases respectively.

A significant correlation was found between the age and death as a outcome in patients with p value of 0.032

25%(10) cases succumbed to infection whereas 75% (30) resolved the infection successfully.

Discussion and Conclusion

A retrospective study conducted in Southern India by Gupta, Chawla and Vishwanath [9] in 2014 found *S.maltophilia* to be an important nosocomial pathogen in Lower Respiratory Tract infections. The study showed a predisposition to infection amongst elderly males (>55 ys of age). 72% of the patients in this study were diagnosed with pneumonia. In our study, *S.maltophilia* was more commonly isolated from males (65%) than females (35%). Our study showed the mean age of patients who resolved the infection was 45 and those who died was 65 indicating that age has an important role in outcomes. Immunosuppressed status and invasive procedures performed in the hospital were identified as major risk factors for acquiring the infection. Diabetes and hypertension have emerged as the major risk factors for *S.maltophilia* infections. Of those infected, 35% had diabetes and 30% had hypertension.

Mechanical ventilation was performed on 30% of the cases studied. 25% of the patients studied underwent tracheostomy and endoscopy. *S.maltophilia* may be present as a surface organism that gains access when invasive procedures are performed. It is noteworthy that the most common chief complaint was fever(37.5%) followed by respiratory distress/COPD(27.5%).

A study carried out by J. Brooke found immunocompromising conditions, malignancy, indwelling catheters and long term ICU stay to be one of the important risk factor. This study has implicated beta lactamase production and intrinsic genetic mechanisms to be the cause of antibiotic resistance. This study showed good sensitivity to trimethoprim-sulfamethoxazole and ticarcillin [10]. In our study the isolates of *S.maltophilia* showed sensitivity to Gentamicin (85%) and Piperacillin/Tazobactam (82.5%). *S.maltophilia* in our study showed significant resistance to amoxiclav (70%), cefotaxime (72.5%) and ceftazidime. (75%). Trimethoprim-sulfamethoxazole is an effective antibiotic for the treatment of *S. maltophilia* infections but it’s adverse effects have caused limitations in use [11]. Trimethoprim/sulfamethoxazole (used in 12.5% cases) and piperacillin/
tazobactam (used in 20%) cases were the most effective antibiotics. Of those treated 72.5% showed resolution of infections whereas 27.5% cases ended in death. Presence of sul1 and sul2 genes on plasmids, integrons and transposons may cause antibiotic resistance. Resistance to beta lactamase resistance is due to low membrane permeability.[12][13]

A study conducted by Mehmet Mutlu et al in Turkey on neonates found ventilator associated pneumonia to be the main cause of *S.maltophilia* in neonates. In our study, two neonatal cases were encountered, one of the neonates had mechanical ventilation and one had congenital abnormality namely patent foramen ovale.[14]

Our results showed old age, immunocompromised status and long standing chronic illnesses to be a major risk factor for *S.maltophilia* infections. The mean age for those with resolved infection was found to be 45 whereas the age of those who died was found to be 65 on statistical analysis. In our study the isolates of *S.maltophilia* showed good sensitivity to Gentamicin (85%) and Piperacillin/Tazobactam (82.5%).

From this study we conclude that *S.maltophilia* can cause serious infections in in patients with underlying risk factors. It is essential to utilize the available antimicrobials appropriately, use novel agents to which the organism is susceptible, and to strictly apply infection control measures in order to decrease the incidence of infections caused by *S. maltophilia*.

Attempts to identify this organism in the laboratory must be done and should be Sensitivity reports must be taken into consideration for treatment options. More studies should be done to establish a regimen for *S. maltophilia* infections.

ABSTRACT

The present study was undertaken to observe the status and regional variations in acute respiratory infections (ARI’s) among the children below 5 years age group in coastal and tribal regions of the state Odisha, India. Hospital-based cross-sectional study. Fisher’s exact test using Graph Pad Prism 5.0 was used for comparison of different risk factors associated with ARI’s

Prevalence of ARI was 20.9% (3513/16769), in tribal region and its 26.8 % (1988/7401) in coastal region 16.2 % (1524/9368). Out of 303 coastal cases 64.6% were males and from 300 tribal cases, 58.6% were females (p<0.0001, OR=2.600). Low birth weight children suffered severe forms of ARI were more in tribal region 59.3% compared to coastal region 36.6% (P=0.0001, OR=0.3962). Bivariate analyses indicated that overcrowding (OR=0.613), cross ventilation (OR=1.403); low birth weight and mother’s age were significantly associated with ARI. Fever (73.2%) and cough (73.8%), were the most frequently reported clinical symptoms.

Keywords: Pneumonia, Morbidity, Infant, Social Class, Maternal Age, Respiratory Tract Infections.

Introduction

Acute Respiratory Infection (ARI) appears as a single largest contributor of under-five childhood morbidity and mortality [1, 2]. World Health Organization (WHO), states that the ARI is 10 major diseases and one of the most common causes of death in infants. In developing countries ranges from 30-70 times higher than developed countries and allegedly 20% of infant mortality each year are caused by ARI. According to the World Health Organization (WHO) estimates, in 2012, globally 15% of the 6.5 million deaths in children <5 years of age were because of ARI In India, 14% of 1.4 million deaths in this age group in 2012 were attributed to ARI[3]. The potential threat of ARI has been recognized as one of the major challenges for its prevention and control in reproductive and child health programs in India [4].

There are both biological and social reasons that epidemiology of ARI differs across geographic and climatic zones. High morbidity for ARI has been encountered among under-five children admitted or treated in different pediatric hospitals in state of Odisha. The present study is envisaged to determine and assess the risk factors that affect the prevalence of ARIs in under-five in the tribal and coastal populations of Odisha.

Material and Method

Study Design and Ethics: According to the geographical pattern, Odisha can be divided into two distinct regions
viz., coastal and other hilly region. The current cross-sectional study was undertaken among under-five children presenting with ARI admitted or attained to Sardar Vallabhbhai Patel (SVP) Pediatric Hospital at Cuttack district, and District Headquarter Hospital (DHH), Rayagada, Odisha during the period from August 2015 to July 2016. A written consent for participation in the study was obtained from legal guardians of all patients. The study was approved by institute ethical committee. Pediatric patients (≤5 years old) presented with at least two of the following symptoms like cough, pharyngeal discomfort, nasal obstruction, sneeze and respiratory distress. Patients with a history of chronic respiratory infections or whose parents'/guardians refused to give consent were excluded from the study. The relevant socio-demographic and epidemiological information of the cases were collected by interviewing the parents/guardians of the children.

Statistical Analysis: Fisher’s exact test was conducted to compare the different associated risk factors between coastal and tribal children using Graph Pad Prism 5.0. Probability values of P<0.05 were considered significant.

Findings
A total 16,769 of admissions were made during the study period, of which 3513(20.9%) suffered from ARI. Occurrence of ARI was more in tribal region 1988/7401 (26.8%) as compared to coastal region 1525/9368 (16.2%). Out of 3513 ARI children, 603 (303 coastal and 300 tribal) cases were included in the study. About half (54.3%, n=328) were below 1 year of age, 39.9% (n=241) were between 1-4 yrs of age and 5.6% (n=34) were in 4-5 yrs of age group. The comparison of ARI patients between tribal and coastal region demonstrated that 70.6% children of below 1 year age with ARI belonged to the coastal region. Sex wise distribution found a significant difference in coastal and tribal children (p=0.0001, OR=2.600) (Table 1).

Out of 303 coastal cases 196 (64.6%) were males and out of 300 tribal cases, 176 (58.6%) were females (Fig 2). On the basis of clinical manifestations, the children were found to be associated with Bronchopneumonia 55.8%, severe pneumonia 19.5%, Pneumonia 16.7%, and any ARI 7.8%. Significantly more cases from the tribal facility had fever, 300 (100%) compared with 141 (46.6%) from the coastal facility (p=0.0001). Other characteristics that were common were wheezing 76 (25%) and high pulse rate 61 (20.2%) cases from the tribal site and dyspnoea was reported in 58 (19.2%) from the coastal health facility (as displayed in Table 2).

Out of 603 cases, low birth weight (≤2.5 kg) children were 289 (47.9%). In tribal region low birth weight children (59.3%) were more as compared to coastal region (36.6%). The severity of ARI was very high in low birth weight baby (≤2.5, 36%) as compared to normal birth weight baby (≥2.5, 17.3%) (Fig.-1). In this study, low birth weight was significantly related to ARI (p=0.001). Based on Table 1 shows that 300 coastal cases risky birth weight (<2,500 g) of 36.6%, while the tribal of 303 cases whose birth weight risk as much as 59.3%. Statistical test results obtained p value = 0.001, OR = 0.396, i.e., meaning that infants born with the weight does not normally have the chance 0.396 times sufferer of acute respiratory infections compared with infants with normal birth weight. Birth weight is an important indicator of a child’s vulnerability to the risk of childhood illness and chances of survival.

Out of 303 coastal cases 196 (64.6%) were males and out of 300 tribal cases, 176 (58.6%) were females (Fig 2). On the basis of clinical manifestations, the children were found to be associated with Bronchopneumonia 55.8%, severe pneumonia 19.5%, Pneumonia 16.7%, and any ARI 7.8%. Significantly more cases from the tribal facility had fever, 300 (100%) compared with 141 (46.6%) from the coastal facility (p=0.0001). Other characteristics that were common were wheezing 76 (25%) and high pulse rate 61 (20.2%) cases from the tribal site and dyspnoea was reported in 58 (19.2%) from the coastal health facility (as displayed in Table 2).

Majority (66.9%) of the mothers belonged to the age group between nineteen to twenty-four years in tribal region where as in coastal its 49.8%. However, a positive correlation was found between mothers age, child birth weight and occurrence of ARI as well as mothers education and ARI in the coastal region (p<0.001) (Fig.-1).

Overall, 26.56% of ARI cases were prevalent in low social classes (III, IV and V). Male children (60%) were more affected than female children (40%), children below 1 year (69%), overcrowded houses (28.5%) and low birth weight babies (≤2.5 kg) (36.18%). Maximum 64% and 40% of ARI cases were low socioeconomic groups (IV) in tribal and coastal regions respectively and remaining ARI cases were distributed among middle
and upper socioeconomic groups (I, II and III) in both the region. Among 603 cases of ARI, overcrowding was associated in 408 (67.6%), and history of tobacco smokers in family in 335 (55.5%). Occurrence of ARI was 73% in overcrowding families in tribal as compared to the 63% in coastal (p=0.0054). Prevalence of ARI was more among children having an illiterate mother (70%) in comparison to the primarily educated mother (17%) in the tribal region. In contrast to this result, more prevalence of ARI was found among children having primary educated mother (49%) in comparison to the illiterate mother (25%) in the coastal region. The age of the mother and indoor smoking by any family member was also significantly associated with ARI (p<0.001) (Table-1).

**Seasonality of ARI case enrolment:** Month wise patient admission with ARI indicated two peaks in a year one between July-August (34.7%), September-October (21.3%) in coastal region, in tribal’s (22.8%) during August-September in both consecutive years. In brief, most of the specimens were collected (84.3%) between July and February in coastal patients, whereas in tribal region, cases were reported throughout the year with only a single pick between August-September.

**Discussion**

ARI in young children is responsible for 3.9 million deaths worldwide each year. The incidence of pneumonia in developing countries is high due to increased prevalence of malnutrition, low birth weight and indoor air pollution in developing countries [2]. The prevalence of ARI under-five children was reported to be 34.3% in Delhi [5] while 22% in Gujarat [6]. In the present study, the overall prevalence of ARI was 20.9% that is comparable with the study done in Kenya [7], Delhi [8], and Bangladesh [9]. Results from our study suggested that the present rate of ARI was more than the reports of NFHS-3 [10] and much less than the prevalence rate in Delhi, 2011. Prevalence of ARI in Greeneland increased from less than 1 year age and decreased there after [15]. Severe underweight was another predictor of pneumonia; low birth weight has been reported to be associated with the development of pneumonia [11, 12]. Several studies describe an association of cigarette smoking or exposure to environmental tobacco smoke with the occurrence and severity of ARI [13, 14, 15, 16, 26]. Smoking is believed to exacerbate respiratory diseases by harming respiratory defense mechanisms [17]. Living in poor economic conditions are more likely to suffer from acute lower respiratory infections than children living in better-off households. This finding is common around the world [24].

In our study, the pattern of all ARI involves maximum 56.7% Bronchopneumonia, 19% severe pneumonia and 17.2% pneumonia. It has been reported that respiratory diseases contribute 10% of pneumonia in Lucknow [18] and Delhi [20]. Pneumonia among ARI cases was reported to be 4% in Bangladesh [22] that stayed less than the Indian counterpart. This incidence of pneumonia and severe pneumonia is a contrast to the reports available in another part of the country and neighboring country [19].

The present study perhaps the first cross-sectional study investigating the role of risk factors for ARI in the tribal and coastal populations of Odisha. In our study, the most affected age group were below 1 year including Bronchopneumonia, severe pneumonia and pneumonia that declined with increasing age.

Globally, poor living conditions present risk factors for illness and are associated with inadequate utilization of primary health care [23]. The findings of the present study clearly reveals that low-economic status (wealth index) is an indicator of high prevalence (51%) of ARI among under-five children as reported in Gujarat [7]. Our results revealed 64% tribal and 40% coastal ARI cases were among low socioeconomic class under-five children’s. This association of ARI with low socioeconomic factor is significantly associated in both the region. Still, children from poor households face a problem of healthcare utilization [22].

Mother education has a strong positive influence on child survival in most of the developing country [23, 27]. Educated mothers have better knowledge of nutrition, illness of children and treatment. There is direct relationship exists between education and health seeking behaviors. In our study, 73% tribal families with the history of overcrowding had high risk of ARI compared to the families 63% in coastal (p=0.0054, OR=0.613). In addition, we found that the environmental variables, inadequate ventilation (P=0.0417, OR =1.4), exposure to indoor air pollution in form of smoking by any family member (p<0001, OR=0.206) were significant risk factors for ARI.

**Conclusion**

Based on this research can be concluded that the age of children under 1 years, male gender and low birth weight, low-economic status, inadequate ventilation and
indoor air pollution toddlers has a chance to experience acute respiratory infections is greater than the toddlers aged over 1 years, female gender, birth weight normal, adequate ventilation and no indoor air pollution. The tribal’s residing in remote areas got distinct disadvantages for attaining good health as compared to the coastal population of the state. This hospital-based study documents the importance of ARI associated with the infants and provides baseline data to develop preventive methods depending on the risk factors.

Effectiveness of Training on Postural Stability in Mild to Moderate Diabetic Neuropathy Patients

T. M. Vishnu Priya¹, A. Rajarajeswari², R. Sivakumar³

¹MPT (Neurosciences)–Postgraduate, ²Associate Professor, ³Professor & Principal, Faculty of Physiotherapy, Sri Ramachandra Medical College & Research Institute, Porur, Chennai, Tamil Nadu

ABSTRACT

Background and Purpose: Diabetic neuropathy is a well-known micro vascular complication of type 2 diabetes mellitus attributed to chronic hyperglycemia with peripheral nerve dysfunction. Postural instability is the major clinical impairment which leads to increased risk of falls. Therefore this study aims to retrain the postural stability and to reduce risk of falls by means of prescribed exercise training program in mild to moderate diabetic neuropathy patients.

Research Design and Method: This Quasi experimental - pretest/posttest design included 34 subjects who fulfilled inclusion criteria. Outcomes were measured using Clinical neurological examination-Valk score, Tinetti falls efficacy scale, Multi directional reach test and Unipedal stance test. Patients were given a prescribed training program of 3 weeks at home with a regular follow up.

Result: The results showed that there is a significant difference in Clinical neurological evaluation, Falls efficacy scale and unipedal stance time (p<0.000),Multi directional reach forward and right (p<0.000), backward (p<0.001) and left (p<0.002) shows significant changes.

Conclusion: Training postural stability have beneficial effects in improving the unipedal stance time, Multidirectional reach and Falls efficacy scale. Clinical neurological examination score is significant but not highly significant as expected. Training may not have a greater influence and effectiveness in clinical symptoms but beneficial in improving one’s stability limits. Early assessment and training program to be considered to reduce the risk of falls in the disease progression state.

Keywords: Diabetic neuropathy, fall risk, postural stability, training

INTRODUCTION OR BACKGROUND

Diabetic neuropathy is a well-known microvascular complication of type 2 diabetes mellitus attributed to chronic hyperglycemia, and is defined as the presence of peripheral nerve dysfunction in diabetics after exclusion of other causes¹.

The typical diabetic peripheral neuropathy is a chronic, symmetrical, length-dependent sensorimotor polyneuropathy and is thought to be the most common variety. It develops on a background of long-standing hyperglycemia, associated metabolic derangements (increased polyol flux, accumulation of advanced glycation end products, oxidative stress, and lipid alterations among other metabolic abnormalities) and cardiovascular risk factors².

According to the Diabetes Atlas 2012 published by the International Diabetes Federation, the number of diabetes in India is currently around 40.9 million, and is expected to rise to 69.9 million by 2025 unless urgent preventive steps are taken. It is estimated that 60% to 70% of individuals with diabetes have mild to severe forms of nervous system damage.
The common clinical manifestations include pain, numbness or tingling sensation, distal sensory loss such as pin prick, temperature, proprioception and vibration, distal weakness, foot ulceration, subjective feeling of unsteadiness and history of fall.

Postural instability can be defined as inability of an individual to maintain the position of body, or more specifically the centre of mass within specific boundaries of space referred to as stability limits and in relation to the surrounding environment, in static and dynamic conditions.

Individuals with diabetes and peripheral neuropathy have greater postural sway in quiet standing and greater difficulty in integrating sensory information for balance control than healthy subjects.

Postural instability in diabetic neuropathy may be influenced by factors such as distal sensory loss mainly proprioception and vibration, decreased tactile and thermal sensitivity, impairments such as loss ankle motor function, impaired weight transfers and decreased unipedal stance time, increased whole body reaction time, different onset and cessation of muscle activity and abnormal gait patterns over irregular surfaces which predispose to falls.

Postural instability is greatest when visual or vestibular cues are absent or degraded. Even with vision, the postural stability of diabetic neuropathic patients is impaired when performing more challenging daily tasks. The sensory loss associated with diabetic neuropathy contributes to impaired balance and gait.

Patient with even mild neuropathy and clinically normal ankle strength have a marked impairment in distal motor function characterized by a decrease in ability to develop strength about ankle rapidly.

A fall is often defined as inadvertently coming to rest on the ground, floor or other lower level, excluding intentional change in position to rest in furniture, wall or other objects. Many studies shows that, compared to patients with diabetes but no peripheral neuropathy, patients with diabetic peripheral neuropathy are more likely to report an injury during walking or standing, more frequent on irregular surfaces. There is growing evidence that foot and ankle neuropathy leads to difficulty with balance and possibly increases the risk of falling.

Diabetic neuropathy is a true risk factor for falls in the elderly.

The expected functional limitations could be postural instability and falls. Neuropathy may remain undetected, and progress over time leading to serious complications. So, this subclinical impairment needs an early assessment and intervention. But there is lack of definite exercise protocol for treating such diabetic neuropathy with postural instability. An exercise program may be designed to target on the components such as ankle strategy, multi directional reaching, muscle force & strength and rapid reaction strategies.

Only few studies have evaluated treatments, which aimed to improve gait and balance and decrease fall risk. A 2010 update of a Cochrane database systematic review states that there is “lack of high-quality evidence to evaluate the effect of exercise in people with peripheral neuropathy”. And also in a systemic review which says there is (Grade B) fair evidence for clinical recommendation of lower limb exercise for diabetic neuropathy (level of evidence II-1).

The more severe the stage of diabetic polyneuropathy the patients were unable to walk. Hence this study included the patients with mild to moderate forms of diabetic neuropathy.

This study aims to retrain the postural stability and to reduce risk of falls by means of prescribed exercise training program in mild to moderate diabetic neuropathy patient.

**MATERIALS AND METHOD**

This Quasi experimental - pretest/posttest design was conducted in out patient department of Diabetology, Sri Ramachandra hospital using convenient sampling.

Inclusion criteria were patients diagnosed as diabetic neuropathy with Valk score mild to moderate >2-18, Normal standing balance ability to participate, Duration of type 2 diabetes (>5 years), Age 50-75, Both genders, Able to walk household distance without any assistance and Able to understand and obey simple commands.

Patients with other neurological & musculoskeletal disorders & cardiovascular problems,Non-diabetic neuropathy, Presence of plantar ulcer, 4)Signs of vestibular dysfunction, Visual impairment and Medically unstable patients were excluded in the study.
Procedure: The subjects was recruited according to the eligibility criteria. A total of 60 diabetic patients was examined for neuropathy using clinical neurological evaluation (valk score). In which, Sensory components such as light touch, pin prick, vibration sense, proprioception of first toe and motor components such as strength of extensor hallucis longus and gastrocnemius, and ankle jerk was examined. Neuropathy score was given, and patients who fall under >2-18(mild to moderate) score was selected. Out of 60 patients, 39 patients had mild to moderate diabetic neuropathy. Two patients was excluded with the presence of foot ulcer and one was not willing to participate. Informed consent was obtained from the included subjects.

Subjects were assessed initially using following outcome measures.

1. Clinical neurological examination (CNE)- Valk score
2. Tinetti falls efficacy scale (FES)
3. Multi directional reach test (MRT)
4. Unipedal stance time (UPS)

Fear of fall was evaluated & scored by questionnaire method, Multi directional reach test was performed and measured in inches, Unipedal stance test was performed and the time was noted in seconds.

After the initial evaluation, 36 patients were trained for exercise program. The protocol was explained and demonstrated individually to all patients initially, and then group training was given. Initial supervised exercise program was given for 2 sessions. And the patients was advised to follow the protocol at home. Safety measures was also advised. A pamphlet of prescribed exercises was made and given to all the patients and advised to follow the same. Also a month calendar was attached with the pamphlet, a date mark made in the start of session and at the end of 3 weeks. Then the patients was asked to mark over the calendar as they do exercise daily for confirmation. Regular follow up was also made through telephone.

Training Protocol:

1. Wall slides
2. Bipedal (Standing) heel & toe raises
3. Stepping practice (Ankle strategy training)- participants needs to lean, pivoting at their ankles until they need to take protective step(s) to stop themselves from falling (lean forward or backward)
4. Step over 4-square exercise
5. Single leg stance
6. Single leg heel raise – chair assisted
7. Stepping over blocks
8. Resistance exercises
9. Turning 360
10. Reaching forward

Training was prescribed for 3 weeks, everyday 3 sets, 10 repetitions each exercise. Patients were allowed to use their hands for support wherever they need for safety purpose.

After the training program, re assessment was made using the same outcome measures and post test values were recorded.

FINDINGS

This study was a Quasi experimental study design (pre and post test). The paired t-test was used to test the differences. The measures such as clinical neurological evaluation, falls efficacy scale, multi directional reach test and unipedal stance time pre and post test conditions were analyzed for results. P values of <0.05* was considered to be statistically significant. Patients was analyzed for results. The software used for analysis of data was SPSS version 20.

Paired t test, N=34  *Significant P<0.05

CNE-Clinical neurological evaluation, FES - Falls efficacy scale, MRT - Multidirectional reach test, UPS - Unipedal stance time ( EO- Eyes open, EC- Eyes closed)

Clinical Neurological Examination (CNE): Clinical neurological examination included following components such as pin prick and light touch sense(cotton wool), strength of extensor hallucis, gastrocnemius and ankle jerk. There is no such significant improvement as expected in the total score of neuropathy following a training program.

In Length-dependent diabetic polyneuropathy LDDP, more than 80% of patients with clinical diabetic neuropathy does not show any trend towards improvement may require a longer duration of therapy to show any improvements especially sensory deficits13.

These evidences could be the reason for the lack of expected significant improvements in clinical symptoms in this short duration study.

Postural Instability And Multi Directional Reach: Ankle strategy, multidirectional reach, muscle force & strength and rapid reaction strategies play an important role in postural stability. Hence the training program was designed to target these components.

According to the results, there was a significant positive impact of training program on improving functional balance.

Ankle strategy training had enhanced muscle strength of foot and ankle and thereby enhancing the patients ability to balance. It also increased the rapidly available torque in the ankle14 and it recruits type II motor units.

Decreased ankle strength will impair balance recovery, which has been prospectively identified as a risk factor for falls15. Training was also focused on retraining ankle strength, which showed significant improvement.

Reaching activities will improve dynamic stability16. Some studies says that there is lack of stability in anteroposterior direction which might be due to weakness of the leg and back muscles, primarily controlling balance strategies during movement. Based this background, this study focused training antero-posterior stability using ankle, hip strategies. Of all the scores obtained in multidirectional reach, there was a greater improvement in forward reach and right side reach.

Unipedal Stance time test: Significant improvements in unipedal stance time were found with both eyes open and closed conditions. In this study unipedal stance exercise with eyes open and closed with hands support were also trained.

In diabetic neuropathy there will be decreased unipedal stance time10 due to reduced plantar sensation, reduced proprioception and unequal weight transfers. The severity of these components might increase with reduced vision17.

Unequal weight transfers between right and left lower extremities will contribute to increased risk of falls18. Unipedal standing will improve proprioception and equal weight transfers. So, In the training protocol unipedal stance exercises were included.

Falls Efficacy Scale: Fear of fall is a common subjective feeling in diabetic neuropathy. Results shows a greater reduction in fear of falls.
There is a strong association between falls/loss of balance and decreased ankle strength. So any postural training program will improve muscle force and associated function.

This training program improved the subjective confidence towards fear of fall and reduced the risk of fall.

CONCLUSION

The study analysis concludes that training postural stability in mild to moderate diabetic neuropathy patients had beneficial effects in improving the unipedal stance time and Multidirectional reach and in reducing risk of Falls. Clinical neurological examination score was significant but not highly significant as expected. Training may not have a greater influence and effectiveness in reducing other clinical symptoms. Exercise training is beneficial in improving one’s stability limits which reduces the risk of falls. Early assessment and training program should be considered in diabetic neuropathy to reduce the risk of falls in the disease progression state.

Baseline Wander Removal from ECG Using Multiband Structured Sub band Adaptive Filter LMS Algorithm

B. Bhaskara Rao¹, B. Prabhakara Rao²
¹Research Scholar, ECE Dept., JNT University, Kakinada, Kakinada; ²Program Director, School of Nanotechnology, IST, Kakinada, India

ABSTRACT

This paper investigates the new detailed adaptive noise canceller (ANC) system for Electrocardiogram (ECG) enhancement with robustness based on multiband structured sub band adaptive filter (MSAF). The proposed design is probably a new realization form of algorithm which guaranteed a more stable transformation and solves the structured problems in conventional sub band adaptive filter (SAF). The objective of the examination is to give arrangement keeping in mind the end goal to improve the execution of ANC as far as filter parameters which are procured with the assistance of uniform filter banks (UFB) and non uniform filter banks (NUFB) structured MSAF’s using LMS algorithm. Computer simulation demonstrates that the proposed system gives improved performance and achieves good adaptation. NUFB structured MSAF algorithms are applied on ECG records obtained from standard MIT-BIH data base and the performance is compared with UFB structured MSAF algorithms in terms of parameters SNR, MSE, RMSE and distortion. The SNR for various NUFB structured MSAF’s was found to be higher than the UFB structured MSAF’s. The five channel NUFB structures with decimation factors (16,16,8,4,2) has on average SNR of 17.67064 dB is obtained using LMS algorithm which is superior to existing algorithms.

Keywords: ANC, ECG, MSAF, SAF, UFB, NUFB, LMS

BACKGROUND

The Electrocardiogram (ECG) record is a procedural electrical activity of the heart which is noninvasive recording and is acquired by surface electrodes at designated locations on the skin of patient’s body. The ECG is a bioelectric signal, which statistics the electrical pastime of coronary heart as opposed to time. Therefore, it is a vital diagnostic device for assessing coronary heart function. Usually the band of the graphical record signal is 0.05 to 100 Hz. In order to investigate the ECG record of the patient in real-time, there is a chance that the ECG may be corrupted with noise. The main noise(artifact) available in the ECG contains: power-line interference (PLI), baseline wander (BW), muscle artifacts (MA) and motion artifacts (EM), that are generated by patient breathing, movement, power line interference, bad electrodes and improper electrode position. In these artifacts Baseline wander is a low frequency artifact in the ECG that arises from breathing, electrically charged electrodes, or subject movement and can hinder the detection of these ST changes because of the varying electrical isoline.. The observation of those changes becomes difficult if the ECG baseline is not constant. BW is extraneous and strongly influences the ST section, degrades the sign first-rate, frequency resolution, produces huge amplitude indicators in ECG that can resemble PQRST waveforms and mask tiny capabilities which might be important for clinical tracking and diagnosis. Hence, baseline drift must be removed using a standard signal processing algorithms. Most types of artifacts which affect ECG record are eliminated by band pass filters which may not give good result. To enhance the accuracy and reliability for refine diagnosis the artifacts in ECG need to be decreased. Many methods have been implemented to eliminate the noise from noise contaminated ECG using static filters. To overcome the restrictions of static filters, various Adaptive filtering methods have been developed.¹²

Fig. 1 defines the essential downside and noise cancelling answer. A signal s(n) is communicated over a channel to a detector that also collects a interference n₁(n) unrelated with the signal. The first input to the ANC

DOI Number: 10.5958/0976-5506.2019.01986.7
is noise contaminated signal \( d(n) \) i.e. \( s(n) + n_1(n) \). The second detector accepts a noise signal \( n_2(n) \) unrelated with the reference input to the ANC that is filtered to produce the estimate signal \( y(n) \) that’s a detailed duplicate of reference input. The output signal \( y(n) \) is subtracted from signal \( d(n) \) to produce the error signal as shown in equation (1). This adaptive filter can be realized using various structures; the most frequently used structure is transversal finite impulse response (FIR).

\[
e(n) = d(n) - y(n) \quad \text{ ...(1)}
\]

**Fig. 1: Block diagram of Adaptive Noise Canceller**

Traditional filters such as adaptive filters\(^3\), sign based normalised adaptive filters\(^4\) were proposed in the literature to minimise artifacts. Different methodologies for ECG denoising include new variable step size NLMS\(^5\) and EEMD-BLMS methods\(^6\). Promising performance are acquired by non linear adaptive algorithms\(^7\), recently hybrid techniques have been proposed to eliminate noise from ECG signals using cascaded adaptive filters\(^8\). Filter banks (FB) decompose a digital signal into different frequency bands. Different methods of decomposing signals in to sub bands have become prominent and were proposed in the literature\(^10, 11, 12, 13\).

Sub band adaptive filter (SAF) structures have been proposed to overcome these problems of adaptive filters. Recently different noise cancellation methods are proposed using SAFs include variable step size sign SAF\(^14\), Variable individual step size SAF\(^15\), New normalised SAF\(^16\). An optimised cosine modulated NUFB design approach has been proposed by Kumar,A.,G K Singh et., al\(^17\). To solve these structured problems a multiband structured SAF (MSAF) are developed in which the full band adaptive filter’s tap weight vectors are updated by a single adaptive algorithm using sub band signal\(^11, 18\). The non-uniform filter bank SAF (NUFBSAF) is developed to achieve a better convergence performance by adapting the band width of analysis filters through proper selection of decimation factors. The objective of this paper is to develop non uniform multi band structured sub band adaptive filter which can improve the performance of the traditional ANC system, to analyse the application of SAF to noise cancellation problem in ECG.

**PROPOSED DESIGN**

A general objective is to create one arrangement of preprocessing filters which is useful in a noise cancellation tasks for ECG signal. The concept of multiband structured-sub band adaptive filter (MSAF) is presented in this section. In the proposed design the noise contaminated ECG record i.e primary input signal denoted as \( d(n) \) given to the upper FB in Figure.2. Secondary (reference) signal is given to SAF (lower FB with adaptive filter) is noise signal \( n_2(n) \) denoted as \( u(n) \).

The full band input signal \( u(n) \), primary input signal or desired response signal \( d(n) \) and filter output signal \( y(n) \) are decomposed into \( N \) sub bands by means of analysis filters \( H_i(z) \); for \( i=0,1,2...(N-1) \). In this Fig.2 \( H_0, H_1, H_2,...., H_{N-1} \) and \( F_0, F_1, F_2,....F_{N-1} \) are analysis & synthesis filters of \( N \) channel perfect reconstruction (PR) filter bank respectively. These sub band signals are decimated to a lower rate using same factor and are processed by individual sub band adaptive sub filters \( W(z) \)^\(^{11}\).

**Fig. 2: Block diagram of a multiband structured sub band adaptive filter (adapted from Reference [11])**
Non uniform filter banks have non uniform frequency partition. One method of building NUFB is to cascade UFB in a tree structure using a two channel FB as basic building blocks. As an example of this method, NUFB with decimation factors (16,16,8,4,2) is illustrated. The proposed tree-structured non uniform filter bank’s analysis section is shown in Figure.3.

![Fig. 3: Proposed block diagram of a tree structured NUFB](image)

The proposed structure make use of low pass FIR prototype Parks-McClellan optimal equiripple filter design in both analysis and synthesis FB that give near perfect reconstruction by permitting little measure of distortion at the output. The generalized structure of N-channel NUFB based on tree structured approach having decimation N_0, N_1, N_2, ..., N_{N-1} for each band then the decimation factors must fulfill the accompanying condition_12_.

\[ \sum_{k=0}^{N-1} \frac{1}{N_k} = 1 \] ...
(2)

In N-channel NUFB the PR is possible if

\[ \sum_{k=0}^{N-1} |H_k(e^{jw})|^2 = 1 \text{ for } 0 \leq w \leq \frac{\pi}{N} \] ...
(3)

Where \( H_k(e^{jw}) \) is frequency response of \( k \) th filter in equivalent NUFB parallel form

For tree structured NUFB design having decimation factors (16,16,8,4,2) the PR condition can be achieved by using following equation

\[ |H_0(e^{jw})|^2 + |H_2(e^{jw})|^2 + |H_4(e^{jw})|^2 = 1 \text{ for } 0 \leq w \leq \frac{\pi}{5} \] ...
(4)

Here \( H_0(z), H_2(z), H_4(z) \) analysis filters with the following relations_12_.

\[ H_0(z) = H_{11}(z) \quad H_2(z) = H_{21}(z) \quad H_4(z) = H_{41}(z) \] ...
(5)

\[ H_1(z) = H_{11}(z) \quad H_3(z) = H_{21}(z^2) \quad H_5(z) = H_{41}(z^2) \] ...
(6)

\[ H_2(z) = H_{11}(z) \quad H_4(z) = H_{21}(z) \quad H_6(z) = H_{41}(z^2) \] ...
(7)

Where \( H_{11}, H_{21}, H_{31}, H_{41} \) are low pass filters in the first, second, third and fourth stages respectively and \( H_{12}, H_{22}, H_{32}, H_{42} \) are high pass filters in the first, second, third and fourth stages respectively.

**Proposed NUFB-MSAF algorithm:** The traditional ANC shown in Figure.1 incorporates filter whose input parameters are \( d(n) \) and \( u(n) \). Here \( u(n) \) is the time delayed input vector values, \( u(n) = [u(n), u(n-1), u(n-2), \ldots, u(n-M+1)] \). The vector \( w(n) = [w_0(n), w_1(n), w_2(n), \ldots, w_{M-1}(n)] \) represents the coefficients of the filter at time index \( n \). The \( N \) sub band signals of MSAF algorithms require particular computational steps in every emphasis as takes after_11_.

It is important to note that \( n \) refers to the time index of original sequence and \( k \) denotes the time index of decimated signal.

**Summary**

For \( s = 1, 2, \ldots, N \) where \( s \) is stages

Analysis filters \( H_i(z) \)

for \( i = 0, 1, 2, \ldots, N-1 \)

\[ H(z) = H_{s,j}(z^s), H(z^s), H(z^s) \ldots, H_{s,j}(z^s) \]

\[ H_{s,j}(z) = H_{s,j}(z^s), H(z^s), H(z^s) \ldots, H_{s,j}(z^s) \]

For \( k = 0, 1, 2, \ldots, kN \) where \( kN = n \)
Error estimation:
\[ e_D(k) = d(k) - U^T(k)w(k) \]

Normalization matrix:
\[ \Lambda(k) = \text{diag}[U^T(k)U(k) + \alpha] \]

Tap-weight adaptation:
\[ w(k+1) = w(k) + \mu U(k)\Lambda^{-1}(k)e_D(k) \]

Input signal Band partitioning:
\[ U_1^T(k) = H^T A(kN) \]

Desired signal Band partitioning:
\[ d_D(k) = H^T A(kN) \]

Synthesis:
\[ e(kN) = Fe_D(k) \]

Parameters:
- \( l \& h \) - Basic Low pass filter & high pass filter notation
- \( M \) - Number of adaptive tap weights
- \( N \) - Number of sub bands
- \( L \) - Length of the analysis and synthesis filters

Variables:
\[ U^T(k) = [U_1^T(k), U_2^T(k-1)] \]
\[ U_2^T(k-1) \text{ - first } M-N \text{ columns of } U^T(k-1) \]
\[ A(kN) = [a(kN), a(kN-1), a(kN-2), \ldots, a(kN-N-1)] \]
\[ a(kN) = [u(kN), u(kN-1), u(kN-2), \ldots, u(kN-L-1)]^T. \]
\[ d(kN) = [d(kN), d(kN-1), d(kN-2), \ldots, d(kN-L-1)]^T. \]

MSAF using LMS Algorithm
\[ w(k+1) = w(k) + \mu \left\| e_D(k) \right\| + \alpha U(k) \]

Where \( \mu \) is learning rate parameter and it should be selected in the stability bound i.e. \( 0 < \mu < \frac{2}{N \cdot P_u} \), here \( P_u \) is average power of the reference signal \( u(n) \) calculated as \( P_u = u^T(n)u(n) \). And \( \alpha \) is a small positive constant used to avoid possible division by zero.

RESULTS AND DISCUSSION

In this simulation the benchmark Massachusetts Institute of Technology-Beth Israel Hospital (MIT-BIH) arrhythmia database \(^{19,20}\) ‘mat’ file recordings (100m, 105m, 108m, 203m and 228m) were used to test the execution of various UFB & NUFB structured MSAF’s adaptive algorithms for ECG denoising. The recordings were sampled at 360 samples per second per channel with 11-bit resolution over a 10 mV range. The simulations were done by collecting 3600 samples of ECG recordings. In this simulation the proposed methodology has been implemented using Parks-McClellan optimal equiripple linear phase (real, symmetric coefficients) low pass FIR filter design with length 32, cut off frequency 50 Hz and sampling frequency 360 Hz. The secondary noise signal \( n_2(n) \) shown in Figure 1 is taken from noise generator. In order to test the filtering capability in non-stationary environment artificial BW with 2 mv amplitude and 3600 samples were simulated for BW cancellation. The proposed UFB and NUFB structured MSAF-ANC are compared quantitatively by quality assessment parameters Signal-to-Noise Ratio Before Filtering (SNRBF) and Signal-to-Noise Ratio After Filtering (SNRAF) are

\[ \text{SNRBF} = 10 \log_{10} \frac{\sum_{n=0}^{N-1} [S(n)]^2}{\sum_{n=0}^{N-1} [d(n) - s(n)]^2} \]
\[ \text{SNRAF} = 10 \log_{10} \frac{\sum_{n=0}^{N-1} [S(n)]^2}{\sum_{n=0}^{N-1} [e(n) - s(n)]^2} \]

Baseline Wander Cancellation using MSAF-LMS algorithm: In this proposed design 3600 samples of clean ECG signal records from MIT-BIH database which are corrupted with BW noise with frequency 0.5 Hz and the sampling frequency of 360Hz is applied as primary input signal to the ANC shown in Figure 1. The following figures 5-6 show the BW Noise elimination. The NUFB structured MSAF’s achieve good SNR; MSE and RMSE values over UFB structured MSAF’s adaptive algorithms. Table 2 presents ‘quantitative parameter values for five record numbers from MIT-BIH data base. The simulation results state that NUFB structured MSAF’s adaptive algorithms has greater efficiency than UFB structured MSAF’s adaptive algorithms. These results for MIT-BIH data base record number 105 are shown in Figures 5-6.

</tbody>
</table>

The performance of UFB structured MSAF’s and NUFB structured MSAF’s using LMS algorithms in terms of SNR are shown in Table.2. The simulation results state that NUFB structured MSAF algorithms has greater efficiency than UFB structured MSAF algorithms. As shown in Table.1 three channels UFB has on average SNR of 7.29346 dB for 5 records and three channels NUFB has on average SNR of 9.37192 dB. Similarly for four channel UFB has on average SNR of 6.81944 dB for 5 records and four channels NUFB has on average SNR is 11.93572dB, for five channel UFB has on average SNR is 7.10056dB for 5 records and five channel NUFB has on average SNR is 17.67064 dB. It is clear from Table.1 that NUFB structured MSAF’s adaptive algorithms outperform UFB structured MSAF algorithms in approximating the ECG noises. The peak reconstruction error (PRE) is reduced appreciably. The average PRE obtained for three channel, four channel and five channel UFB’s are 0.08169 dB, 0.0414 dB and 0.0454 dB respectively. The average PRE obtained for three channel, four channel and five channel NUFB’s are 0.03583 dB, 0.0238393 dB and 0.0288 dB respectively.

**CONCLUSIONS**

This research paper presents the new comprehensive ANC system of ECG signals with robustness based on UFB &NUFB structured MSAF’s using LMS algorithm. The proposed model is potentially a new realization structure form of ANC which guaranteed a more stable transformation in response to variants in input signal power. The theoretical analysis of NUFB structured MSAF system is carried out and simulations are performed using MATLAB. In order to analyze the performance of the proposed design a comparison has been made between six different ECG denoising schemes i.e three channel, four channel and five channel UFB & NUFB structured MSAFs using LMS algorithm. Better filtering performance results are obtained by NUFB structured MSAF using LMS algorithm and also this algorithm guarantee the better estimation of noise. Computer simulation demonstrated that the proposed system gives improved performance and achieves good adaptation. The SNR for various NUFB structured MSAF’s was found to be higher than the UFB structured MSAF’s. The NUFB structured MSAF’s using LMS algorithm performs better SNR values than UFB structured MSAF using LMS algorithms.

Abstract

We conducted this study among 100 nurses who were working in the maternity ward of Hosahalli referral Hospital, and Sagar hospital in Bangalore, India, by using non-probability purposive sampling technique. The data was collected by using self-administered questionnaire. The study revealed that there is a significant relationship between knowledge level of respondents and their experience in the procedure of oxytocin induction as evidenced by P value 0.0422< alpha value 0.05. The test is Statistically Significant at 95% confidence level. Area wise analysis of knowledge score of staff nurses regarding oxytocin induction of labour has made the impression in five areas (1) the knowledge score of the samples about information of induction of labour were 70%. (2) General information about oxytocin induction (64.57%). (3) Information related to indications and contra indications of oxytocin induction (65%). (4) Information about induction of oxytocin (68.53%). (5) Nursing management during oxytocin induction (66.14%).The overall knowledge score of the participants (100 samples) is (65.50%), overall mean (28.82), median (23) SD (20.32) which revealed that only 31% of the participants have adequate knowledge on oxytocin induction during labour. A new protocol was developed for the maternity nurses on the oxytocin induction, based on the statistical findings of self-administered questionnaire for the two hospitals where the study was conducted.

Keywords: Knowledge, Staff nurses, Oxytocin Induction, Protocol

Introduction

Ensuring safe childbirth is the responsibility of a maternity nurse by promoting and preserving the health of the mother and foetus from conception to childbirth. To ensure safe delivery, various measures have been used when needed to induce labour ¹ namely, medical induction and surgical induction. Medical induction is administration of oxytocin drug intravenously which is more commonly used during the first stage of labour for the purpose of progression of labour process².

The use of oxytocin for induction of labour has been studied in the United States since 1993.³ This method is effective for cervical ripening and has relatively few adverse effects. Patients will often progress to spontaneous labour in eight to 12 hours. At the same time health care professionals should bear in mind the serious adverse reaction of oxytocin drugs if they are misused ⁴. Nurses often must assess the safety of mother and foetus during an oxytocin induction without a protocol based on research findings. The perinatal team can develop
strategies to minimize risk of maternal-foetal injuries related to oxytocin administration consistent with safe care practices used with other high-alert medications.\(^5\)

An incidental study was done among 75 mothers in Mumbai on oxytocin for ripening of cervix in induction of labour and most of them had a ripped cervix. Majority (92\%) of the patients went into spontaneous labour and 8\% required re-instillation and the study has shown that the proper and safe administration of oxytocin can produce active result but the staff nurse should have through knowledge on the induction.\(^6\) Initiation of induction or augmentation of labour with oxytocin is the responsibility of primary health care providers, although the medication is often administered by a nurse. A written protocol for the preparation administration of oxytocin should be established by the obstetrics department in each institution.\(^7\)

A Randomized Control Trial on concurrent oxytocin with a sustained-release dinoprostone vaginal insert for labour induction at term to determine whether the concurrent administration of oxytocin with sustained-release dinoprostone resulted in shorter induction times when compared with oxytocin after the removal of the dinoprostone insert. The proportion of deliveries within 24 hours was higher (90\% vs 53\% \(P = .002\)) in the immediate group.\(^8\)

Lack of protocols in the hospitals, lack of knowledge about administration of oxytocin drugs, its monitoring and serious adverse reactions and inadequate provision for in-service education for the technically qualified nurse lead to improper oxytocin administration.\(^9\)

Oxytocin induction protocol can also be useful in securing the maternal and foetal well-being, prevention of maternal and foetal complications, ensuring safe delivery and to safeguard the nursing personnel.\(^10\)

Objectives

1. To assess the level of knowledge of staff nurses in maternity ward on oxytocin induction during labour.
2. To find out the association between selected demographic variables of staff nurses working in maternity ward with their knowledge level regarding oxytocin induction
3. To develop a protocol for staff nurses regarding oxytocin induction during labour.

Materials and method

Research design: Descriptive research design was used.

Research approach: Survey approach, using self-administrated questionnaire.

Research setting: The setting of the study was 150 bedded Hosahalli referral hospital and 400 bedded Sagar Hospital in Bangalore.

Independent and dependent variable: Oxytocin induction knowledge level of staff nurses on oxytocin induction.

Extraneous variable: Age of the staff nurses, gender, religion, education, type of family, marital status, family income, year of experience in maternity ward, number of performance of oxytocin induction, designation, previous seminars attended, and source of information etc.

Study population: Staff nurses who are working in maternity ward. The Assessable population are staff nurses who are working in the maternity ward of Hosahalli referral Hospital, and Sagar hospital in Bangalore.

Sample size: The sample size of the study consists of 100 staff nurses who are working selected hospitals

Sampling technique: Non-probability purposive sampling

Sampling criteria

Inclusion criteria

1. Staff nurses who are working in maternity ward.
2. Staff nurses who are willing to participate in the study.
3. Staff nurses who are available at the time of study.
4. Staff nurse who can read and write English.

Exclusion criteria

1. Staff nurse working in maternity ward who are not ready to consent in the study.
2. Staff nurses working in maternity ward that are not available during study period.
3. Staff nurses who had the qualification of ANM or multipurpose workers.

Tool for data collection: Self-administered questionnaire was used to assess the knowledge of staff nurses on oxytocin induction during labour. Content validity was done by 10 experts in obstetrics and gynaecology and one statistician. Internal consistency was assessed by using split half with row score and deviation method and spearman brown prophesy formula. The reliability of the tool was found to be 0.9.

Data collection process: The study data collection was done from 1\(^{st}\) October 2016 to 30\(^{th}\) of October 2017. The total sample of the main study consists of 100 staff nurses those who working in maternity ward. Data
was collected from the sample by administering self-administered questionnaire, after obtaining consent from the participants. per day 10 samples (5 in the morning and 5 in the afternoon) were assessed from the both hospitals. 30 staff nurses from Hosahalli referral hospital, and 70 staff nurses from Sagar hospital were assessed the knowledge on oxytocin induction by SAQ.

Figure 1 depicts the source of information for nurses about oxytocin induction which shows 49% of nurses gained information about oxytocin induction through in-service education (49%) followed by academic education (39%). Mass media and colleagues were the least information sources (6%) for nurse about oxytocin induction.

Table 1: Level of knowledge percentage of scores among the participants

</table>

There is a significant relationship between knowledge level of respondents and their experience in the procedure of oxytocin induction as evidenced by P value 0.0422 < alpha value 0.05. The test is Statistically Significant at 95% confidence level. There was no association between knowledge and other demographic details of subjects participated in the study.

Out of 44 questions, 4 questions are information related to induction of labor, the knowledge score of the samples were 70%, the second session consists of general information about oxytocin induction, the samples knowledge score were 64.57%. Third session contains the information related to indications and contra indications of oxytocin induction, the knowledge score of the samples were 65%. Fourth session includes the information about induction of oxytocin, the knowledge score of the staff was 68.53%. Fifth session consists of nursing management during oxytocin induction. Knowledge score of the participants were 66.14%. The overall knowledge score of the participants was 65.50%, overall mean 28.82, median 23, SD 20.32, which reveals that the participants got moderate knowledge on oxytocin induction during labour.
Figure 2: Overall knowledge score of participants on oxytocin (OXT) induction

Overall knowledge score of participants on OXT induction which Shows that (20%) participants having inadequate knowledge on oxytocin induction, (49%) were having moderate knowledge and the remaining (31%) were having adequate knowledge about oxytocin induction during delivery of pregnant women.

Discussion

Majority 51(51%) were 21-30 years age group, 29 (29%) were 31-40 years of age, 14 (14%) were 41-50 years of age, 6(6%) were 50-58 years of age. Majority of samples were 73 (73%) qualified with diploma in nursing, 10 (10%) were B.Sc. nursing, 12 (12%) were post B.Sc. nursing, and the remaining 5 (5%) were M.Sc. nursing.

A pre experimental design was conducted at ESI Hospital, Bangalore among 60 samples, using non-probability convenient sampling technique, to assess the effectiveness of self-instructional module on knowledge regarding maternal and neonatal outcome of induction of labour among staff nurses structured questionnaire was used. Majority of staff nurses attained were 31-35 years age (37%) had GNM education (83%). About 39% of subjects had above 6 years experiences.

Majority 59 (59%) have done nursing training from private institutions, 38 (38%) were from Government institutions, 3 (3%) were done from the military institution. This inference was supported by Malek-Khosravi.S in her study out of 30 subjects 26(43.33%) of the subjects were done nursing training from private institution.

Majority of samples 53 (53%) were having an experience of below 5 years, 23 (23%) were having an experience of 6-10 years, 18 (18%) were having an experience of 11-15 years, and the remaining 6 (6%) were having more than 16 years’ experience in the maternity ward.

Majority 97 (97%) of the staff nurses got the chance of administering the oxytocin in their carrier, remaining 3 (3%) were not done the oxytocin administration procedure in their carrier.

This study is supported by Rajatee.M and Rezaee.M, shows that among the total sample 13 (40%) of the subject performed oxytocin induction more than 10 times during their working experience in the maternity ward.

Almost half 49 (49%) of the staff nurses got information from in service education, 39 (39%) were got OXT information from the academic education, 6 (6%) were got through mass media and the remaining 6 (6%) were got it from friends and colleagues.

Knowledge score of participants on OXT induction reveals that the mean knowledge score obtained by the participants were 28.82, median were 23 and the SD were 20.32, the mean percentage of the participants were 65.50%, which was supported by a study conducted in Vellore.
Government Hospital, on knowledge of staff nurses on oxytocin induction that showed overall mean percentage was 60.20% with the mean 20, median 19.8 and SD.

Result of our study showed that there was a significant relationship between knowledge level of respondents and their experience in the procedure of oxytocin induction as evidenced by P value 0.0422< alpha value 0.05. The test is Statistically Significant at 95% confidence level.

The above findings are supported by a study conducted in Tamilnadu, South India, which found that there was an association between some of the demographic variables like age, designation, experience in the obstetric department, with the knowledge level of the nurses, and no association with the marital status and monthly income.

Area Wise Analysis of Knowledge score of staff nurse regarding Oxytocin induction during Labour with the help of mean, median and standard deviation.

The present study reveals that out of 44 questions the 4 questions belong to information related to induction of labor, the knowledge score of the samples were 70%, the second part of the knowledge question belongs to general information on oxytocin induction, there were 7 questions and the samples knowledge score were 64.57%. Third part of the knowledge area belong to indications and contra indications of oxytocin induction, there were 4 questions and the knowledge score of the samples were 65%. Next part include induction of oxytocin, there were 13 questions, and the knowledge score of the staff was 68.53%. Next part consists of nursing management during oxytocin induction, there were 7 questions, the knowledge score of the participants were 66.14%. The overall knowledge score of the participants (100 samples) is 65.50%, Mean 28.82, median 23, SD 20.32, which reveals that the participants have moderate knowledge on oxytocin induction during labour.

The findings of the study supported by a study conducted in Vellore Government Hospital to assess the level of knowledge of staff nurses regarding oxytocin induction in which there was an association between some of the demographic data like age, designation, experience in the obstetric department, with the knowledge level of the nurses, and found that only 2.6% had inadequate knowledge, 52.7% had moderate knowledge and 47.7% had adequate knowledge on labor induction.

Conclusion

In order to ensure safe practices of performing oxytocin induction during labour, we prepared a protocol on oxytocin induction and its management on the basis of significant results of self-administered questionnaire and criteria rating scale that showed that the staff nurses had moderate knowledge on oxytocin induction during labour. We distributed the protocol to the selected maternity ward of hospitals for the better understanding of the oxytocin induction during labour, thus by reducing complications of improper knowledge and practice of oxytocin induction.

A Comparative Study of Effectiveness of Psychological Intervention on Menstrual Distress among College Students

C. S. Sowndaram
Professional Counsellor, Amrita School of Engineering, Coimbatore

ABSTRACT
A Package of relaxation, systematic desensitization and an education program was developed and evaluated to determine its efficacy in decreasing the severity of Menstrual Distress. This study had involved both pretest and posttest as well a control group was also used to compare with. But still it’s not purely an experimental design as there is no randomization. It is a quasi-experimental design. Seventy unmarried undergraduate college students were taken for the study. Extraneous variables such as age, family, monthly income, and health status were methodologically controlled. Moos Menstrual Distress Questionnaire, Spielberger’s State and Trait Anxiety Inventory were administered. Among the sample, thirty five comprise the experimental group who were given the package of psychological intervention with grape juice and the other thirty five remained the control group to whom only grape juice was given without psychological intervention. The statistical analysis of the data was carried out with the paired t test technique to reveal significant positive impact of the intervention on the alleviation of menstrual distress which is seen in the group to whom the intervention was given and not in the other group. No significant differences were found in the control group on pretest and posttest menstrual distress which suggest that the intervention program have been the source of reduction in the menstrual distress of the experimental group.

Keywords: Menstrual distress, systematic desensitization, quasi-experiment, intervention.

INTRODUCTION
Menstruation is of reproductive function in the human adult female. It is the discharge of blood periodically and also the sign of disintegration of the endometrium after a normal ovulatory cycle. According to the Society of Menstrual Cycle Research (SMCR, 1986), the reference point for all Menstrual phases is menses that is all days when menstrual blood flows. The length of menses varies between and within women. In India most of the adolescent girls lack knowledge in the menstruation, sex and reproduction. Even today there is a myth existing not only among the rural people, but also among the urban people that menstruation is considered as a curse on women which results in contamination and a feeling of unholy. This makes the girl to feel as if she is too impure and dirty during her time of menstruation. Though it has been found that the mean age of menarche of a normal Indian girl is 13.4 yrs., it is found that half the populations of the adolescent girls who belong to the age of 12-15yrs still have nil information about their menstrual cycle as per the Nutrition Foundation of India’s report. (U.S. Agency for International Development 2001).

Female children are always seems to be underprivileged in India and hence it’s quite natural that these adolescent become vulnerable. During the period of Menstruation they are considered as untouchables. This shows clearly the people do not have proper scientific awareness about fertility and related areas. These responses and attitudes that the girl experience will certainly bring about an aversion towards her sign of maturity. Because of misconceptions about menstruation-a natural process, sometimes result in adverse health issues.

Common Physical Menstrual Complaints Include (Abraham, G.E. 1978)
- Headache
- Backache
- Edema
- Abdominal bloating
- Breath tenderness
- Ache
- Constipation or diarrhea
Common Behavioral Complaints:
- Increased tension or irritability
- Depression
- Aggression
- Decreased energy
- Disruptions in eating, sleeping, work and interpersonal relationships.

Tension and irritability seems to be the one universal Menstrual Complain (Hoes, 1980; Reid & Yen, 1981; Widholm, 1979).45,6

Psychology of the Menstrual Distress: The woman who is ashamed of menstruating is particularly vulnerable to menstrual complaints. Her mother may have coped poorly with menstruation. (Whitehead et al, 1986)7. Her family may have reinforced her avoidant coping with menstruation (Golub, 1981)8. She may also have lacked the education and medical care that counteract unhealthy cultural influences (Reid, 1985)9. Ylikerkala and Dawood (1978)10 suggested that menstrual irritability is a state of conditioned anticipatory fear that reduces tolerance for any environmental event. When Menstrual complaints and such avoidant behavior have become well established, the vulnerable women is likely to be subject to high chronic levels of stress which increase the production of endogenous uterine prostaglandins which in turn could cause more pain during menstruation (Tigranian et al, 1980)11. Premenstrual stress was calculated through their stress score, menstrual discomfort and menstrual blood flow. (Cutts T, Evans T, Christoff K 1983)12. Although most women rate their symptoms as mild, approximately 2% - 10% report severe symptoms, one fourth of the women folk undergo some sort of menstrual distress. (Moos R H 1985)13. Relaxation technique stimulate the sympathetic and parasympathetic nervous system, which balance the physiological functions like heart rate, blood pressure, respiration, temperature, muscle tension and sweating .This exercise helps to eliminate irrelevant muscular tension, brings down the individual’s stress, improve the quality of sleep and calms down the individual to get rid of anxiety and other affective symptoms.(Anice George, 2011;Jyoti Dvivedi, 2007)14,15.

Nidhi Gupta, Shveta Khera, Vempati, Ratna Sharma, and Bijlani (2005)16 conducted a study to assess the impact of short-term and brief lifestyle intervention, applying yoga, on anxiety levels in normal and diseased people at All India Institute of Medical Sciences, New Delhi, India. The intervention package includes yoga Sana, pranayama, relaxation techniques, support group, individual counselling, some audio lectures and videos on yoga, the role of yoga in daily life, meaningful meditation, stress management, and knowledge in nutrition and physical illness. On the first and last day of the course anxiety was measured. Anxiety scores, both state (study group pretest mean 39.6 and posttest mean 34.1 and control group pretest mean 35.0 and posttest mean 36.4) and trait anxiety (Study group pretest mean 43.1 and posttest mean 38.5 and control group pretest mean 36.1 and posttest mean 37.1) were significantly reduced.

HOME REMEDIES
(Source: http://healthruns.com/25-grape-fruit-diet-tips)

1. Grapes and especially black grapes is one of the most effective home remedy for handling menstrual distress. Regular intake of grape juice can perfect the menstruation cycle. However, in summer months, stick to one glasses a day.

2. Make some radish seed paste and mix it with one glass of buttermilk. Drinking one glass every day is one of the effective home remedies for delayed menstruation.

3. Bitter gourd juice twice a day is the solution to all your” periods” problems. There are also other benefits of bitter gourd.

4. Regular intake of aloe Vera juice helps the body maintain regular menstruation cycle.

5. Painful cramp can be overcome by grape juice daily during periods .Grapes juice is unavoidable for dysmenorrhea /painful menstruation and irregular periods.

OBJECTIVES OF THE STUDY
- To assess the trait anxiety and menstrual distress level of the sample
- To employ psychological intervention in decreasing the menstrual distress of the selected sample
- To study the effectiveness of psychological intervention in decreasing the menstrual distress of the selected sample in the experimental group and compared with that of the control group.
DESIGN AND BACKGROUND OF THE STUDY

- A quasi Experimental Pretest- posttest Control group design was used to determine the efficacy of the intervention.
- Seventy unmarried undergraduate college students were taken for the study. Extraneous variables such as age, family, monthly income, health status were matched and hence methodologically controlled. The sample was divided into two groups and they were randomly assigned as experimental and control groups, each constituting thirty five students.
- Initial assessment was made using the scales Moos Menstrual Distress Questionnaire and Spielberger’s Trait Anxiety inventory. Their friends, mothers were interviewed and it was concluded that there was a marked qualitative menstrual distress and moods off during their menarche.
- Administration of relaxation, grape juice and psychological intervention:
  - Relaxation through deep breathing exercise.
  - Systematic desensitization where the hierarchical scenes concerning menstruation has been used for psychological management of menstrual distress. It was based on the findings of Cox and Meyer (1978).
  - Here the subjects were also instructed to practice auto-genic suggestion. And to take grape juice a glass/day.

METHOD

Sample: The researcher used Purposive Sampling method in this study. Total of seventy students were chosen of which thirty students are in the experimental group and thirty students in the control group randomly. Purposive sampling is the sampling technique which assumes that with good judgment the researcher can select the sample units that are satisfying the requirements (Das, 2008).

Purposive Sampling

Sample is chosen with a particular purpose
1. The Sample helps in gaining insights into the particular issue taken for study
2. Number is determined by the availability (Alston & Bowels, 2003)

TOOL

Menstrual Stress Questionnaire was used before and after the intervention. Trait inventory from Spielberger (1983) State-Trait inventory was used where a four point scale is the method of rating on 20 items. The inventory includes eleven anxiety present statements.

The anxiety inventory was used in the study to rule out one of the confounding factors of individual differences in the interpretation of threatening situation among experimental and control groups.

INTERVENTION PROCEDURE

Session I:

A health education package was developed based on extensive review of the literature content outline
- Review the structure and function of female reproductive system
- The physiology of menstruation was explained
- Myths and traditional misconceptions about menstruation were discussed and their doubts were cleared.

Session II:

- Discussion on stress and information on sources of stress were provided
- Discussion on relationship between stress and menstruation
- Deep breathing exercise to induce relaxation.
- Practice the same regularly
- Systematic – desensitization – hierarchical scenes concerned with menstrual distress
- The researcher encouraged the students to relax and then exposed them to imagine an increasingly intense series of experiences. That is enabling them to stay calm and relaxed, even when they were in the most painful menstrual distress
- They were also asked to drink a glass of grape juice daily
- All the above were applied only to the group which is taken as experimental and for the control group only grape juice was provided.
DATA ANALYSIS

Table 1: shows the comparison of trait anxiety among experimental and control group

<table>
<thead>
<tr>
<th>Variable</th>
<th>Experimental group</th>
<th>Control group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trait anxiety</td>
<td>mean</td>
<td>S.D</td>
</tr>
<tr>
<td></td>
<td>1.67</td>
<td>1.4</td>
</tr>
<tr>
<td></td>
<td>1.53</td>
<td>1.8</td>
</tr>
</tbody>
</table>

The results showed that the mean difference was not significant with t = 1.12 indicating that the trait anxiety was not a confounding variable in the study.

Table 2: shows the comparison of pretest, posttest menstrual distress of the experimental group

<table>
<thead>
<tr>
<th>Menstrual Distress</th>
<th>Mean</th>
<th>S. D.</th>
<th>t</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pretest</td>
<td>9.22</td>
<td>6.4</td>
<td>3.02</td>
</tr>
<tr>
<td>Posttest</td>
<td>6.91</td>
<td>5.1</td>
<td>p &gt; 0.05</td>
</tr>
</tbody>
</table>

The p value demonstrated significant difference which implies that the intervention package has certainly benefited the experimental group.

Table 3: shows the comparison of pretest posttest menstrual distress of the control group

<table>
<thead>
<tr>
<th>Menstrual Distress</th>
<th>Mean</th>
<th>S. D.</th>
<th>t</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pretest</td>
<td>1.98</td>
<td>1.3</td>
<td>1.02</td>
</tr>
<tr>
<td>Posttest</td>
<td>2.27</td>
<td>1.3</td>
<td>p &lt; 0.05</td>
</tr>
</tbody>
</table>

The p value demonstrated no significant difference which implies the control group remains with the same level of menstrual distress.

DISCUSSION

- This study support for the multi intervention approach where biological and psychological factors were addressed (Ussher, 1992). Also the experimental group reported less menstrual distress after the intervention
- It was also confirmed through the interview with the mothers and peer group of the experimental group that they showed improved social and familial interaction which was not seen initially before the intervention

Our study corroborated findings that our study corroborated findings that At the minimum, girls need to be educated about menstruation much before they attain menarche, and also to have a basic understanding on secondary sex characteristics that will happen during puberty. Research has shown that ignorance and lack of knowledge on puberty and menstruation intensifies the existing myths stronger and the girls are vulnerable to feelings of shame, and anxiety of something which they must be proud of because menarche is the step which finally leads to motherhood of every girl.

CONCLUSION

Results of this study suggest that this package of educating and psychological intervention is necessary to develop a positive self-concept and also a positive attitude towards the normal physiological function, the menarche. It has certainly helped in overcoming the menstrual distress. It is not the nutritive diet alone but also the psychological support had helped in overcoming menstrual distress which was not seen in the control group where the effect of grape juice alone was taken into consideration.

Evaluation of Peak Expiratory Flow Rate (PEFR) in Pet Owners

Chris Noel Timothy¹, Gayatri Devi R², Jothi Priya A²
¹Graduate Student, ²Assistant Professor, Department of Physiology, Saveetha Dental College, Saveetha Institute of Medical and Technical Science, Saveetha University, Chennai

Abstract

Introduction: Lung function tests have been gradually used in evaluating the harshness of obstructive airway disease and also in assessing the outcome of various healing routines and providing an improved understanding of pulmonary physiology. The main aim of this study is to assess the pulmonary function in pet owners.

Materials and Method: People were selected randomly. The subjects were of varying age groups. Then individuals were divided into 2 groups. One group of individuals were pet owners while the other group consisted of individuals who do not own any pets. Each group consists of 30 individuals. The readings were obtained using peak flow meter. Readings were recorded and calculated.

Result: The mean and standard deviation were calculated for both pet owners and healthy individuals. In the control group, the values of the males were found to be 440±15.51. In females the value was found to be 414.70±23.25. In the pet owners group the value of male pet owners were found to be 425.38±59.38. In females the value was found to be 377.64±64.64. The values of pet owners were significantly less compared to the control group consisting of non- pet owners.

Conclusion: Although this research was not significant due to certain factors, further research could be done on this topic to further establish the relation between humans and pets.

Keywords: PEFR, pet owners, respiratory disorders, airflow, peak flow meter.

Introduction

Peak expiratory flow rate (PEFR) is one of the simplest ways to check lung function. It shows the vital signs of airway obstruction. Peak expiratory flow rate is measured using mini wright peak flow meter. It has a great analytic and predictive value in subjects with respiratory diseases and disorders. It is extensively used in general medicine in the European nations and in the USA with demonstrated reputation in assessing and observing patients with asthma [1,2].

The Mini-Wright Peak Flow Meter is portable and can easily be used in an office setting or lent to patients for home use. Some patients may benefit by purchasing the meter themselves and self-adjusting the time and dose of their medication based on objective measurements of airway obstruction [3].

Widely used standard peak flow rates have not been established for pet owners and the PEFR tables in use are based on studies in the Western countries [4,5]. Numerous factors can influence the reading of peak expiratory flow rate (PEFR). The height, weight, gender and age are vital factors upon which peak expiratory flow rate rest on [6]. Other features include the racial variances.

The level to which equally the tutor and the subject understand the technique of using the flow meter is vital and can significantly influence the outcome [7,8]. The associations of peak expiratory flow rate with pulmonary indications and other indices of long-lasting illness raise the likelihood that peak expiratory flow rate will predict death in an ageing population [9]. The aim of this study is...
to determine whether owning pet animals brings about change in Peak expiratory flow rate.

Materials and Method

People were randomly selected and were divided into 2 groups with age group ranging from 15 to 50 years old. One group of individuals was pet owners while the other group consisted of individuals who do not own any pets. Each group consists of 30 individuals each. The readings were measured using mini Wright peak flow meter. First the subject must slide the marker all the way to zero on the scale. He/she should be seated or has to stand up straight. The subject should take in a deep breath. The mouthpiece is then placed in the patient’s mouth which is then followed by a fast and forceful expiration. The marker will move on the scale indicating the peak expiratory flow rate. The best reading from 3 repeated attempts is taken and used. Subjects should not average several attempts as the lower readings usually represent faulty technique or poor effort. This was recorded on the table along with subject’s name, age, pet owned, time period the pet was owned for and the 3 peak flow meter readings. Results were calculated.

Results

Totally 15 individuals were enrolled in this study of both sexes. The results were expressed in mean ± SD. The collected data was compared to normal PEFR values and was assessed by unpaired ‘t’ test. The results were non-significant between control and pet owners.

<table>

Discussion

Calculation of lung functions both qualitatively and quantitatively in both hale and hearty and sickly individuals has become vital in the ground of Respiratory medicine. Measurement of PEFR has achieved worldwide reputation in clinical practice for assessment of patients with obstructive and restrictive airway sicknesses [14].

In the table 1, the relation between males and females were made. The value of control group for males and females were found to be 440±15.51 and 414.70±23.25 respectively. The value of pet owners for males and females were found to be 425.38±59.38 and 377.64±64.64 respectively. The values of pet owners is lesser compared to the control group. In table 2, the relation between the individual’s age and the PEFR values. Taking age as the factor, the value for the control group was found to be 35.28±16.38. The value for the pet owners was found to be 38.26±16.38. Taking the PEFR values as the factor, the value for the control group was found to be 423.66±43.58. The value for the pet owners was found to be 404.66±90.35. In this case also the values of pet owners is lesser compared to the control group. Among the Indian population, racial variances have been revealed to account for the dissimilarities in the pulmonary functions [15]. Obstruction of the airways is associated with daytime sleepiness, poor quality of life, road traffic accidents, and an increased risk of cardiovascular disease, systemic hypertension, type 2 diabetes, depression, cognitive impairment, and cor pulmonale, left ventricular dysfunction, cardiac arrhythmias, stroke and premature death [18]. COPD manifests as inflammation of the lung connective tissue caused by irritants such as smoking and dust particles, resulting in narrowing of the airway [19].

The factors affecting this study were, the difference in the age groups of the patients. The study was taken randomly and there was no particular age group, so it could affect the accuracy of the data. Also there is no equality among the number of males and females owing to the randomness of the study. Sensitization to domestic pets, particularly cats and dogs, is an important risk factor for allergic diseases, such as asthma and allergic rhinitis. Although cat and dog allergens are known asthma triggers and can influence disease severity among sensitized individuals, their role in the development of sensitization and allergic disease is less clear and has remained a subject of debate. Recent studies propose
that pet exposure, particularly in early childhood, may have valuable effects and may actually avert the advance of atopic disorders. Although the complicated relationships between pet exposure and development of allergic sensitization and sickness are not completely understood, potential biological mechanisms that may underlie the protecting effect of pets have been projected. Considerable proof has arisen to prove that opinion.

Many authors have also found a noteworthy positive association of PEFR with age, height, and weight, out of which height has been highly correlated with PEFR. The individual’s age was taken as a factor and the value for the control group was found to be 35.28±16.38. The value for the pet owners was found to be 38.26±16.38. Since height has been maximally correlated with PEFR, the age wasn’t a significant factor. The p value was found to be 0.30 (p < 0.05). The peak flow meter has some limitations. Results are sometimes not reproducible over a long period and there may be inter-model variation in the values of readings obtained. Asthma affects people of all ages and the most common trigger is continuous exposure to allergens. Allergic asthma is characterized by increased mucus production, reversible airway obstruction, infiltration of eosinophils and nonspecific airway hyper responsiveness.

Conclusion

Even though this research was considered insignificant, this opens a wide range of opportunities for further research. Future research could help to discover new medications for allergies caused by pets. This is a field with potential and can very well be utilized to improve the coexistence of man with pet animals.

A Survey Study on Causes, Treatment and Prevention of Onychocryptosis

Prabhav Kumar Iyer¹, Gayatri Devi R², Jothi Priya A²
¹Graduate Student, ²Assistant Professor, Department of Physiology, Saveetha Dental College, Saveetha Institute of Medical and Technical Science, Saveetha University, Chennai

Abstract

Introduction: An ingrown toenail, also called as onychocryptosis, is one of the most common disorders of the toe. It is described as the extension of the side of the nail inside the nail bed which causes bleeding, sharp pain and possible infection can occur. The main causes of this condition are any injury to the nail, bacterial infection of the nail bed or wearing tight fitting shoes on a daily basis. The aim of this research is to check the status of ingrown toenails in an area.

Materials and Method: 26 people ranging from the age 12 to 60 who have had ingrown toenail in the past or had ingrown toenail during the time of data collection were included. Their preferred type of footwear, occupation, treatment taken, places visited often before the condition developed were recorded and the cause of their disorder was deduced. Based on these data, the methods to prevent ingrown toenails were deduced.

Result: Teenagers are more prone to ingrown toenails than any other age groups. Stage 1 was the most common type of ingrown toenail. Out of the people who had ingrown toenails, most of them wore poorly fitting shoes. Trauma to the nail was the most common cause of ingrown toenail. Conservative Therapy was the most common type of treatment for ingrown toenails.

Conclusion: Ingrown toenail is one of the most common nail disorders. Since teenagers are the most agile group, they are more prone to the disease. This disease can be easily avoided by maintaining the hygiene of the feet and by wearing proper fitting shoes.

Keywords: Ingrown, trauma, shoes, matricectomy, hygiene

Introduction

Onychocryptosis also has known as ingrown toenailis a common nail disease. Ingrown toenails are common worldwide and diverse treatment options are available [7]. It is the most common in teenagers and young adults during the second and third decades of their life [1]. The condition most commonly involves the great toes [8]. Many factors have been theorised to contribute to the formation of ingrown toenails, such as improper trimming of the nail, repetitive or inadvertent trauma, genetic predisposition, and poor foot hygiene [3]. The commonest symptom is pain in the affected nail which, if left untreated leads to infection, discharge and difficulty in walking, greatly hampering the quality of life of the individual. Diagnosis is apparent and several treatment approaches exist, ranging from a conservative medical approach to extensive surgical treatment options. The therapeutic approach chosen is dictated by the severity and formstage of the ingrown toe nail [1].

Various theories have been proposed to explain the aetiology of the ingrown toenail and they can be broadly classified according to whether the primary fault is the nail itself or the soft tissues at the side of the nail. One theory is that the nail is not the real culprit, and it is
actually the excess skin surrounding the nail which is the real problem. The person who develops this condition has an unusually wide area of tissue which spreads medially and laterally to the nail. Over time, with weight bearing, this tissue tends to bulge up around the nail which leads to pressure necrosis. A prospective study by Pearson and colleagues failed to demonstrate any abnormality of the nail in patients with symptomatic ingrown toenails, and suggested that treatment should not be based on the correction of a non-existent nail deformity. Although it is still believed that the real defect lies in the nail, the controversy of whether there is a nail plate abnormality or overgrown nail folds still exists[1].

Although an ingrown toenail can occur in any age group, teenagers are usually most prone to this disease. In teenagers, increased perspiration causing the nail fold to become soft and participation in sports result in the production of nail spicules, which can pierce the lateral skin fold of the nail apparatus. In older persons, spicules can be formed by reduced ability to care for their nails which can be caused due to reduced mobility or impaired vision. In addition, the natural aging process causes the toenails to increase in thickness which making them more difficult to cut and more inclined to exert pressure on the lateral skin at the sides of the nail plate, which leads to increase in the severity of the condition[2]. The aim of this study is to find the causes, treatment taken and the possible ways to prevent ingrown toenails.

**Method and Materials**

Patients, aged between 12 and 60 years with a clinical diagnosis of an ingrown toenail were included. The affected toe and foot were evaluated at baseline for the stage and type of ingrown toenail and the condition of the nail structures using the following criteria: Stage 1 was defined as the presence of only mild erythema or edema, with pain on applying pressure, Stage 2 as significant erythema or edema with sero-purulent drainage from the affected nail fold and Stage 3 as significant drainage, formation of granulation and lateral wall hypertrophy. At baseline, a potassium hydroxide (KOH) mount of the nail clipping was examined to rule out fungal infection for all patients with nail thickening, distal onycholysis, or subungual debris[5].

The patient’s age, sex, the types of their footwear and the places which are frequently visited by them were recorded. This was done to help analyse the cause of their condition. The records taken ranged from fresh to old cases. The treatment they sought (if any) was also recorded. Based on these records, the causes for the condition were also deduced.

Ingrown toenails are not difficult to diagnose. Usually self-diagnosis can identify the condition. Since this condition is so easy to diagnose, many patients try to cure it themselves. This complicates the condition as the severity of the disorder cannot be self-diagnosed. It is best for the patients to consult a specialist before trying to treat it themselves.

**Result**

53.8% of teenagers were affected from ingrown toenails. Most of the subjects wearing shoes were having this problem than others wearing sandals, slippers and barefoot. According to this survey, stage 1 was the most common among this study population. Trauma is the primary cause for this type. 38.5% of subjects felt conservative treatment plan is the remedy for ingrown toenails.

**Graph 1: Age Group most prone to ingrown toenails**

**Graph 2: Type of footwear worn by patients**
Discussion

The data confirmed that the most common age group who are affected by onychocryptosis are teenagers (graph 1). Another thing that came to light was that the most common cause of ingrown toenail was trauma to any side of the nail. This backs up the hypothesis that teenagers are more prone to ingrown toenail rather than adults because teenagers are more agile, flexible and energetic than adults. So, it is more likely for them to suffer trauma in their foot (graph 4). The second most common reason for occurrence of ingrown toenail is wrong size of footwear. Another thing was found out was that the most common treatment for Stage 1 and Stage 2 onychocryptosis is Conservative Therapy (graph 5). The data also shows that in some cases, no treatment was done. One other thing to be seen was that people who go to places which has a dusty environment or to places where physical activity is done (eg. Places like the football ground and the badminton court) are more prone to ingrown toenails via bacterial infection or excess sweating than other people if they don’t take care of their feet.

This is so because most of the time, Stage 1 and Stage 2 ingrown toenails do not show complexities that requires surgical corrections. One of the techniques in conservative therapy includes soaking the affected toe and foot for 10 to 20 minutes in warm, soapy water. After each soak, apply Neosporin or a mid-potency steroid cream to the affected area several times daily for a few days\(^3\). The most popular conservative therapies techniques include warm water soaks, antibiotic therapy, proper nail trimming, and elevation of the corner of the nail with a cotton wick \(^{15}\). The second most common reason for occurrence of ingrown toenail is wrong size of footwear. People often compromise on their footwear when it comes to compatibility. This puts a lot of pressure on the toenails which often leads to a wound in the skin below the nail as it was already under pressure. The data also shows that in some cases, no treatment was done. In the cases were the patient did not take any treatment, the patient let the wound heal itself without any interference from the outside. The condition can recur if proper care is not taken. Recurrences are reduced when some form of matricectomy is used. If meticulous attention is paid to technique and good advice is given to the patient, recurrences can be minimised \(^9\). There are various types of matricectomy techniques and it should be selected on the basis of patient preference \(^4\).

Sometimes, surgical methods are used. Total matricectomy is done for stage IV onychocryptosis in adult patients, onychogryphosis and chronic hypertrophy of the distal and lateral folds. Nail excision and total matricectomy with phenol is performed \(^{18, 19}\). Phenol-Alcohol technique is a procedure which comes under chemical matricectomy. The phenol-alcohol technique is safe in diabetic patients who have no vascular risk and have good control of their diabetes \(^6\). The nail splinting technique is a successful, simple and non-invasive therapeutic method for treating ingrown nails. \(^{8}\) Simple excision of the matrix using
mechanical procedures is most effective, leading to fewer complications and infections and with a shorter healing time. Trichloroacetic acid matricectomy showed a low recurrence rate with minimal side effects and was easy to perform in outpatient clinic. The aesthetic reconstruction technique involves complete removal of the nail plate and debridement of the granulomatous tissue, after which wedge-shaped ellipsis of skin and subcutaneous tissue, lateral to the affected nail fold, is removed. The gutter treatment consists of introducing a small guard along the side of the toenail and requires only three sittings. The gutter is left in place for eight to twelve weeks and then removed. The gutter treatment requires little skill and can be carried out in general practice. Electrocautery, radiofrequency, and carbon dioxide laser ablation of the nail matrix are also options for removal of an ingrown toenail. Local anaesthesia should be performed cautiously to avoid vascular complications as toe necrosis has been reported as a rare serious complication of ingrown toenail surgery. A study done by Grover et al showed that Phenol-Alcohol technique was an effective way of treating the disorder should the patient undergo chemical matricectomy. Similarly, a study done by Wallace et al showed that gutter splint technique can be a reliable treatment for ingrown toenail.

**Conclusion**

This study concluded that 1) Teenagers were mostly affected by this disorder. 2) The most common type of ingrown toenail was Type I. 3) The most common type of treatment for ingrown toenail was conservative therapy. 4) People who do a lot of physical activity or work in a dusty environment are more prone to ingrown toenails. 5) The disorder in these cases could have been prevented if proper care of the nails were taken. Things like wearing shoes of proper size and cleaning of the toe are the main prevention methods to prevent ingrown toenails.

Effect of Cooperative Learning on off Task Behaviour: An Action Research Approach for Better Academic Performance

Kalpana Sawane¹, Sheela Upendra², Sheetal Barde¹
¹Asst. Prof., ²Assoc. Prof., Symbiosis College of Nursing, Symbiosis International University

Abstract

Background: Disruptive off-task behaviour can interfere with the continuity of an average classroom performance. Learning in groups and teams can help equip students to brainwave their critical thinking skills that will prepare them to enter today’s workforce.

Objective: The main objective of the study was to implement Cooperative learning and to see the effect on off task behaviour of students in the view to improve the academic performance of students.

Material and Method: One group pertest post-test design was adopted to implement Cooperative learning on 40 Baccalaureate Nursing students. The sample were selected by purposive sampling technique. Checklist was used to assess the off task behaviour and academic performance test were conducted to measure academic performance.

Results: Day wise academic performance was assessed and it was found that there is reduction in off task behaviour of students from day one to day seven. Cooperative learning has positive effect on good academic performance evident by Wilcoxon Sign rank test.

Keywords: Off task behaviour, Cooperative learning, Academic performance

Introduction

Disruptive off-task behaviour can interfere with the continuity of an average classroom performance. One of the greatest challenges of the teacher is to maintain order in the classroom to assist students so they can achieve academic objectives Frequency of misbehaviour, including off-task behaviour, talking without permission, moving without permission, aggression, daydreaming, inattentiveness, and playing with something or someone are all common concerns of educato today¹. Rathvon (1990) defines off-task behaviour as students doing anything not appropriate to the task at hand. Off task behaviour interfere with academic growth as it creates distraction in the class and affects the concentration.²

Cooperative learning means method which learners work in a small group members or teams which contain 3 to 6 students with heterogeneous capacities work together until attain goal that both whole group get it. Group work is highly appreciated by students as a means of learning and preparing for future work

Cooperative learning in universities is based on the theories of cognitive development, behavioural learning and social interdependence. Cooperative learning has been linked to a range of positive social, effective and psychological outcomes, including social support, the quality of students’ relationships, attitude to learning, learning skills and self-esteem. Cooperative learning is based on the theories of cognitive development, behavioural learning and social interdependence. Cooperative learning has been linked to a range of positive social, effective and psychological outcomes, including social support, the quality of students’ relationships, attitude to learning, learning skills and self-esteem.³

Cooperative learning has changed classrooms from being “teacher-centred,” where the focus is on the
teacher imparting knowledge to the students, to “student centred,” where the students are expected to take a more vigorous part in their own learning.4

Teachers have seen an increase in the lack of social skills being taught to students which has amplified the students’ lack of control in their behaviour and respect for others. Often, students feel little respect from teachers and do not have the skills themselves to respect others or to control their behaviour. One of the greatest challenges of the teacher is to maintain order in the classroom to assist students so they can achieve academic objective.5

**Purpose of the study:** The off-task behaviour typically begins with one person who does not want to focus on his work and his behaviour becomes distractive, which disrupts and gathers wind with some of the other students in my class.

As a teacher in the college, I have observed a large amount of disruptions in my class whenever I discuss or ask questions in class, a great majority have to do with students speaking out of turn, having side conversations. Only few students used to participate in discussion. Those who are not participating they keep busy in their own conversations and when asked for response they usually have nothing to say or participate superficially. This results in bad performance at the time of assessment. As a teacher I was thinking to overcome this problem for the better achievements of students. I want to see whether the cooperative learning is really impacting them to be more creative rather than distracting. Also I want to see whether there is any change in the academic performance and that change is by chance or it is associated with cooperative learning. Based on these factors in my mind I set the following objectives for my action research.

**Objectives**

1. To implement the cooperative learning technique
2. To assess the effect of cooperative learning on off task behaviour of students
3. To assess changes in academic performance after cooperative learning
4. To find the association between cooperative learning and academic performance

**Material and Method**

**Design:** The research design selected for the study was one group pertest and post-test design

**Setting:** Setting of the research study was Symbiosis College of Nursing, Senapati Bapat Road, Pune, India.

**Target population:** Target Population for the present research is BSc Nursing 2nd year of Symbiosis College of Nursing who have joined in the year 2015-16.

**Tool:** A Checklist was developed to observe off task behaviour and Academic test in the form of Multiple choice questions were prepared in order to assess the off task behaviour and academic learning of the students

**Procedure for Data Collection:** Prior information was given to the Head of Department of research at Symbiosis college of Nursing Pretest in the form of Academic test was taken on 30 July before the implementation of cooperative learning.

The cooperative learning was implemented. 8 groups were framed. There were 5 students in each group. I informed about the cooperative learning to the students. Groups were made keeping in mind the diversity of the group. The instructions were given and task was explained to the students every time when the class has been conducted. The cooperative learning was implemented from 2 Aug to 8 Aug 2016. The timing of the class was same for all same days. I tried to maintain the environment as smooth and conducive as possible to conduct. Cooperative learning. A comfortable classroom was selected and the participants were made comfortable and relaxed. Time taken for one session was 1 hour.

I took additional assistance of Dr. Sheela Upendra, Assoc. Prof. at Symbiosis College of Nursing to observe the off task behavior. A separate session was conducted to explain her about the details, objectives, purpose of the research before the implementation of Cooperative learning. The Post test in the form of academic test was taken on 8th day of the implementation of the cooperative learnin

**RESULTS**

**Section 1:** Demographic characteristics calculated by percentage where maximum students were in the age group pf 17 to 18. 9 were male and 31 were female students.
Section 2: The effect of cooperative learning on off task behaviour of students

The off task behaviour was marked in the checklist as either yes (if present) or No (if not present).

Day wise the score that is number of Yes (= 1) is decreasing. So graph show decreasing pattern of off task behaviour all together for 8 groups. This is a good change in academic performance after implementing cooperative learning.

Section 3: Changes in academic performance after implementing cooperative learning: There is sufficient evidence to reject the null hypothesis (p < 0.05). The population median is statistically different from 0. Here estimated median is 1. So using this, I can conclude that there is positive effect of cooperative learning on academic performance of students.

Section 4: Association between cooperative learning and off task behaviour: Chi-square test for association between the questions response of pre-test and post-test. All the p-values are less than 0.05, Hence shows there is association between cooperative learning and academic performance.

Discussion

The present work emphasised on the off-task behaviour in nursing students during the class and to investigate the relationship between cooperative learning to reduce the off task behaviour and its effect on academic performance of students. Specifically, we examined whether this pedagogy of group work is really effective in reducing the off task behaviour or not. Our findings indicated that cooperative learning is having a positive effect in reducing the off task behaviour among students as students are utilising same destructive energy into the constructive group work of learning and problem solving.

This pedagogy engage the students in the goal oriented activity. Instructional activities that are more motivational are in turn increase students’ on-task behaviour. A state of focused attention is raised when instruction consists of team work and cooperative behaviour.

“A Phenomenological Study: The Experience of Mental Health Nurse in Managing Violent Behaviour of Psychiatric Patient”

Nirmala Adsul¹, Sheela Upendra²

¹M.Sc. Nursing Second Year; ²Assoc. Professor, Symbiosis College of Nursing, Symbiosis International (Deemed University), Pune

Abstract

Introduction: Patient violence against health care personnel at work is a widespread global concern, particularly in the fields of mental health care. The present study would add on to the existing data on the managing violent behaviour experience by the nurse in psychiatric ward.

Research question: What are the lived experiences of nurses, in managing violent behaviour of psychiatric patients?

Material and Method: Qualitative research approach was adopted. The phenomenological approach was selected as it provides the nurses with the opportunity to give a detailed account of the ‘lived experiences’ from their perspective on violent behaviour of psychiatric patients. The samples size was 05 Nurses from Psychiatric Hospital of Pune city. A purposive sampling technique was used. The researcher collected the data regarding the lived experiences of nurses, who manage violent behaviour of psychiatric patients, through in-depth interviews. The quality of the data collected was significant and determined by addressing the authenticity (triangulation and member checking done) Dependability and transferability.

Findings: Themes that were emerged includes Divergent Selfcare, High expectations, Action in violence and Safety and Security.

Conclusion: Violent behaviour of psychiatric patients against nurses working in psychiatric hospitals is a serious consequence of nursing work in a mental health care setting. The anguish caused by the violent behaviour of patients on Nurses is manifested through a range of emotional reactions in nurses.

Keywords: Experience; Mental Health Nurse; Violent Behaviour; Psychiatric Patient; Manage

Introduction

Patient violence against health care personnel at work is a widespread global concern, particularly in the fields of mental health care.¹ Most psychiatric patients are not violent, from various long studies have determined that serious mental illnesses such as schizophrenia are associated with an augmented risk of aggression and violence. Aggressive behaviour can range from irritability and anger to verbal aggression, progressing to physical acts of violence. Aggression has been defined in different studies using different terms like agitation, violence, dangerousness, violent crime, and hostility, with each of them classifying it differently.² Violent events may also have an impact on nurses’ well-being in the form of, for example, post-traumatic symptoms, fear, work-related stress, anxiety, blame, and the feeling of being insulted.³ A high prevalence of violent events may also impair the overall ward climate and thereby erode the quality of patient care.⁴

Need of the Study: Regardless of relatively thin body of research literature regarding the experiences of Mental Health Nurse in managing violent behaviour, searches indicated that there is dearth of studies in the field and is needed on occupational support provisions that reduce the risk of staff experiencing verbal and physical violence and the stress that is associated with it. There is scarcity of Indian data towards this facet. Therefore the present study would add on to the existing data on the managing violent behaviour experience by the nurse in psychiatric ward.

Purpose of the study: To explore the lived experiences of Nurses in managing violent behaviour of psychiatric patients.

Research Question: What are the lived experiences of nurses, in managing violent behaviour of psychiatric patients?

Operational definitions:

Experience: Mental Health Nurse who is working in the psychiatric hospital and involved in providing care to violent and aggressive patients, those who are admitted in the hospital.

Mental Health Nurse: Registered Nurses with minimum five years of experience in psychiatric ward and involved in direct patient care in Psychiatric hospital

Violent behaviour: Behaviour of psychiatric patient that threatens or harmful to self, other patients in the ward, health care professionals or destroys property in the psychiatric ward/hospital.

Psychiatric patient: Patient with mental illness predominately with violent behaviour that causes significant distress or impairment of personal functioning and is admitted in the psychiatric hospital in Pune city.

Inclusion Criteria:

- Nurses who have more than five years of experience in psychiatric ward.
- Nurses who are involved in providing mental health care to mentally sick patients.
- Nurses who will explore all answers genuinely and with openness.

Exclusion Criteria:

- Nurses will be on leave at the time of data collection.
- Nurses who will be unwilling to participate

Material and Method

Qualitative research approach was adopted. The phenomenological approach was selected as it provides the nurses with the opportunity to give a detailed account of the ‘lived experiences’ from their perspective on violent behaviour of psychiatric patients. The samples size was 05 Nurses from Psychiatric Hospital of Pune city. Data saturation was reached after the fourth interview as no new themes emerged from the interviews. A purposive sampling technique was used. The researcher collected the data regarding the lived experiences of nurses, who manage violent behaviour of psychiatric patients, through in-depth interviews, which lasted between 30 to 60 minutes. The researcher took field notes encompassing of observations made during the interview and due importance was given to nonverbal expressions. An interview guide with open-ended questions, relating to nurses’ experiences, was used. The Nurses were asked to share their experiences without disruption. Each Nurse were given time to speak comprehensively. Probing questions were asked, to obtain clarity or redirect the interview.

A pilot study was conducted and found to be reliable and feasible for the study. Qualitative rigor was done, Investigator ‘Bracketed’ her own feelings and experiences about the topic under investigation and through. The quality of the data collected was significant and determined by addressing the authenticity (triangulation and member checking done) Dependability and transferability. Transferability was ensured by the presentation of a dense narration of the participant’s research context and setting.

Seven steps of Colaizzi’s phenomenological method of data analysis were followed for data analysis process.

Findings

Description of Demographic Variables: All nurses were female registered nurses and are registered with State Nursing Council. The ages of the participants were ranged between 30-42 years. Professional experience for the participant group was ranged from 5 -18 years working in Psychiatry ward.

Themes That Emerged

Theme 1: Divergent Selfcare: Controverting experiences from the nurses was noted. While caring for violent patient and aggression, self-care remained secondary for the Nurses. Nurses have preferred nursing care for the patients than self-care and self importance. One sub-theme that fall under this theme is
fascination. Nurses being having experiences of violent behaviour, they continued to perform work in a normal way in wards.

“I really don’t bother much, even when my patient shows aggression or violent behaviour towards me. (P 04).

Another Nurse has accepted that no alternative is left to overcome when it came for patient caring. As described by the participants:

“… don’t have an alternative, while on duty … I consider and take as part of my job’ (P02).

**Theme 2: Action in violence:** Under this theme, nurses labelled a variety of Physical violence and emotional responses at the hands of the patients. Sub-themes that emerged under this theme was Physical violence and emotional trauma. Physical violence covered pushing, slapping, swelling etc.

…..I experienced numbed when I was first hit in the mid of the ward in presence all patients and relatives”(P04).

Nurses feel sometimes helpless and they felt at not being able to protect themselves, when patients show anger on them. Some nurses realised that retribution was not an option, as the patients were mentally ill, as expressed by the participant:

“……..At times feel I should react but soon realized that these are the symptoms and I should present cool and show professionalism” (P01)

**Theme 3: High Expectations:** This theme reveal that inspite of proper caring, the responsibility seeks more demands in all domains to the management of patients’ negative behaviour. This lead to unhappiness amongst them during job. Subthemes emerged as managing aggressive behaviour. All time demanding is a difficult task to manage the patient or else show aggression. The following statement refers:

“..........do it now, I am asking and you are attending other patients” (P03).

**Theme 4: Safety and Security:** This theme refers to the backing service expressed by the nurses; at times it is difficult to handle too much. Subtheme emerged under this theme is Felt need welfare facility and safe working environment. As it is risk to work in the ward where both male and female to be equally taken care and to keep records update and lapses leads to loss in nurses side. Insecurity during night is a safety concern to be taken care.

“… my mother in law is against of night duties in the ward even I fell insecure at times due to aggressive behaviour of few patients.” (P02).

**Discussion**

Physical assault of nurses was significant in this study, as the nurses reported being physically assaulted by patients.

Similar findings have been reported by Bilgin (2009), who found that 53% (n = 162) of the participants of the study were physically assaulted by patients, who had been diagnosed with severe mental disorders[5]

**Conclusion**

Violent behaviour of psychiatric patients against nurses working in psychiatric hospitals, is a serious consequence of nursing work in a mental health care setting. The anguish caused by the violent behaviour of patients on Nurses is manifested through a range of emotional reactions in nurses. Violence against nurses is under-reported, the challenge that remains is,

‘How can nurses be sustained in distressed environment, if the magnitude of the problem is unknown?’

**Implications**

**Nursing service:** Nurses should be involved in decision-making around patient care, which would lead to a sense of self-empowerment. Health care personnel should be encouraged and supported to report incidents of violence in a supportive environment.

**Nursing Education:** Skill development workshops on the management of aggression to equip health care team with skills to manage aggressive patients. The findings of the study will be very beneficial for nursing education because it will motivate the nursing scholars to conduct further studies on violent behavior of psychiatric patients.

**Nursing Administration:** Specific policies relating to the processes of incident reporting should be formulated and implemented, so that Nurses can be assured that their
well-being is important. Findings of the study will help nurse administrator in organizing short term courses for nurses regarding violent behavior of psychiatric patients in hospital and nursing colleges.

**Nursing Research:** The findings of the study are beneficial for the researchers for extensive research in violent behavior of psychiatric patients. The findings of the study will serve as a basis for the professional and student nurses to conduct further studies on violent behavior of psychiatric patients.

**Limitations**

- The study population was purposively selected to fulfill particular inclusive criteria and, therefore, not all the nurses, employed at the hospital, could be selected to participate in the study, which resulted in a small number of samples.
- The findings could also not be generalized, as the study was conducted at only one psychiatric hospital with a limited sample, which is not representative of all nurses at the participating hospital.
- The study was limited to Phenomenological research design.

**Conflict of Interest:** Nil

**Source of Funding:** Self-Funded

**Ethical Clearance:** Ethical approval to conduct the study was obtained during the Institute ethical committee presentation. Written permission to conduct the study at the hospital was also obtained from the administrative department of the hospital. Informed consent was obtained from each sample. Confidentiality was also maintained in the study by concealing the names of the samples, as different codes were allotted to each sample during the interviews and when the results were made.

Impact of Yoga on Coping Styles of Mid-Level Managers–An Experimental Study

Nirmala Raghavan¹, S. Panboli²

¹Research Scholar, ²Associate Professor, Department of Management Studies, B S Abdur Rahman Crescent Institute of Science and Technology, Vandalur, Chennai, TamilNadu, India

Abstract

Recently, the daily news is overloaded with reports of human atrocities in the society due to the presence of uncontrolled emotions in human life. This is because of high degree of anger and frustration caused by the manifestation of emotional weaknesses which leads individuals in adopting negative coping styles. Research studies have shown that yoga has played a constructive role in enhancing emotional intelligence which in turn leads to adaptation of positive coping style. But how far yoga impacts one’s coping style on mid-level managers has not been dealt so far and hence the current study is undertaken to explore the research gap. For this purpose an experimental study on 105 mid-level managers belonging to HTC Global Services, Chennai was undertaken. The mid-level managers were divided into 70 and 30 mid-level managers under experimental and control group respectively. The Simplified kundalini yoga training was imparted for 25 sessions, each session consisting of 1 hour 15 minutes. Data was elicited through multi-dimensional coping inventory (Carver et al., 1989) from both the groups before and after Simplified kundalini yoga training. Paired ‘t’ test was used to analyze the collected data and the results has shown significant improvement in emotion focused coping and significant decrease in avoidance focused coping in the experimental group after Simplified kundalini yoga training in comparison to the control group. Though increased mean scores for problem focused were observed after yoga training in comparison to control group, the results were not statistically significant. Therefore, the present study has revealed that regular practice of yoga can have an impact in making individuals adopt a positive coping style and reduces maladaptive coping to an extent to face challenges in their career and attain success in life.

Keywords: Simplified kundalini yoga, mid-level managers, problem focused, emotion focused, avoidance, impact

Introduction

For almost a decade, organizational stress and workplace health have become an issue of concern for employees in general and managers in particular. Owing to the fact, that managers’ are considered as the key persons, their efficient performance highly influences the overall success of the project. The stress is even more among the mid-level managers because they tend to face multitude of stressors with the limited authority and resources. Consequently, the workplace stress affects their physical and mental health tremendously ¹. Research studies has shown that mere work load cannot mount pressure on the employees but it may also arise due to lack of individual’s control on stressors which may cause disappointment, low motivation, instability and disabling pressure ².

Research evidence has proved that individuals employ coping strategies whenever they are exposed to stressful conditions. These coping strategies or a style very often leads in enhancing their adaptation with the environment and help in preventing negative outcomes of overload. Various techniques are employed to control or lower stress, and to amend stress coping strategies and behavior. Yoga is one such technique which is used as both preventive and recovery method to control stress and amend stress coping strategies/styles ³. The current study focuses on three coping style viz problem, emotion and avoidance coping styles. Problem focused style focuses on the stressor or altering the problem. Emotion focused emphasize more on emotions rather than problem but avoidance focused style totally ignores or avoids the stressor.
Yoga and Coping–Literature review: Over the last decade, yoga, one of the six foundations of Indian philosophy has become a popular subject for the researchers. Patanjali, popularly known as ‘Father of yoga’ defined yoga as ‘Chitta Viritti Nirodha’ – a state of complete control over fluctuations of mind- the intellect and the ego. Research studies have shown that yoga has a positive impact on both physical and mental health such as *Musculoskeletal Disorders*[^4], *Chronic Bronchitis and Asthma*[^5], *chronic insomnia*[^6], *Post menopausal problems*[^7] and *Hypercortisolemia*[^8].

Apart from research studies on physical and mental health, evidence has also shown that several studies on yoga have proved its dominance in the field of management. Yoga has played a phenomenal role in *Transformational leadership*[^9], *Organizational Citizenship Behavior*[^10], *Emotional Intelligence & Empathy*[^11], *Personality development*[^12]. A recent quasi experimental study on coping styles conducted on 34 nurses working in intensive care units for 8 weeks has revealed significant difference of stress focus; emotion focus and state-trait focus strategies among experimental group in comparison to the control group. The study has shown increase in mean scores of emotion focus and decrease in mean scores of state-trait focus strategy[^3]. Similarly yoga intervention has led to better problem focused coping style among nurses[^13] and among informal caregivers[^14].

The above reviews have revealed that no systematic attempt has been established so far to study the impact of yoga on coping styles of mid-level managers. Hence, Simplified Kundalini yoga (SKY), one of the popular yoga style developed by Shri. Vethathiri Maharishi is used for the current study to explore the research gap.

Inclusion criteria:

i. Participants should be in the category of mid-level managers.

ii. Participants should have not prior experience in yoga practice and should not have participated in any yoga program/research program.

iii. The participants should not suffer from major ailments or undergone surgery in the recent past.

iv. The participants were requested to maintain minimum of 80% attendance. However, attendance on *kayakalpa* session, *agna* and *shanthi meditation* was made compulsory.

Duration: Simplified Kundalini Yoga training program was conducted for 3 days in a week i.e., Tuesday, Thursday and Friday for 8 weeks from 5.pm to 6.15 pm. (25 sessions). The training period was from July 11th 2017 to September 7th 2017.

Training procedure: Simplified kundalini yoga popularly known as SKY yoga is a holistic approach consisting of 4 components such as

-Kayakalpa yoga exercise–for strengthening life force

- Simplified physical exercises–for physical fitness

- Meditation practice–to reduce the frequency of mind

- Introspection courses–To create in-depth awareness about one self and others emotions.

The training imparted to the mid-level managers was conducted in 3 phases which are as follows:

I phase–Exercises (1 to 8 sessions): In the initial stage, focus was given to the physical exercises and asanas, so that, the participants are ensured of physical fitness to prepare themselves for meditation process.

II Phase–Meditation (9 to 17 sessions): Three levels of basic meditation steps are imparted such as *Agna, Shanthi and Thuriya* meditation

III Phase–Introspection courses (18 to 24 sessions): After the second phase, Introspection courses, such as analysis of thoughts, moralization of desires, neutralization of anger, eradication of worries, importance of emotional intelligence and auto-suggestions were imparted to the mid-level managers as a part of training programme.
Data collection and analysis: Data was collected through multi dimensional coping inventory developed by Carver et al., (1989) to both the groups before and after yoga training. Data analysis was carried out with the help of SPSS application software version 23 and AMOS version 23.

Results & Implications:

** denotes significant at 1% level

Inference: From the above Table -1, for the experimental group, the mean scores for all the factors except suppression of competing activities show increase in the mean scores after SKY yoga training. But the difference in the mean scores is statistically significant at 1% level only for two factors i.e., active coping and planning. For ‘Active coping’, the mean scores has increased from 15.34 to 16.19 and is found to be significant at 1% level (p = .009 < 1). Similar results are found for ‘Planning’, where the mean scores has increased to 16.50 from 15.67 and p value (.005 < 1) is found to be significant. However, the overall scores for Problem focused coping style, though show increased mean scores from 73.52 to 75.48, after SKY yoga training, is not significant ( p > 0.05).

In the control group, though the mean scores for all the factors show mild increase or decrease after yoga training but overall, the results are not significant (p > 0.05).

</tr>
</tbody>
</table>

** denotes significant at 1% level, * denotes significant at 5% level
**Inference:** From the above table – 2, for the experimental group, the mean scores for all the factors of emotions focused coping style has increased except for the factor ‘Acceptance’ where the p value is > 0.05 and hence not significant. For the factors ‘Seeking support for emotional reasons and ‘Religion’, the increase in mean scores from 13.33 to 14.16 and 14 to 14.86 respectively are found to be significant at 1% level after yoga training. For the factor ‘Positive reinterpretation & growth’, the increase in mean scores from 17.01 to 17.27 after yoga training shows that p value (0.43 < 0.05) are significant at 5% level. Moreover, the overall scores for Emotion focused coping showed increase in the mean scores from 59.57 to 61.61 after SKY yoga training and this increase is found to be significant at 1% level.

Comparatively, for the Control Group, the results are not significant. In fact the overall mean scores in Emotional focused coping show a decrease in mean scores from 59.46 to 59 though not statistically significant.

<td>.000**</td>
</tr>
<tr>
<td>Post_ Avoidance coping style</td>
<td>42.47</td>
<td></td>
</tr>
</tbody>
</table>

** denotes significant at 1% level, * denotes significant at 5% level

**Inference:** From the above Table – 3, In the experimental group, except for the factor ‘Denial’, the decrease in scores for the factors ‘Venting of emotions’ from 13.46 to 13.21, ‘Behavioral disengagement’ from 10.96 to 10.40 and overall scores for avoidant Focused coping style is significant at 1% level. For the factor ‘Mental disengagement’ the decrease in mean scores from 10.11 to 8.41 is significant at 5% level (p value - 0.045 < 0.05).

For the control group, the results are not significant and in fact, the overall ‘Avoidance Coping shows increase in mean scores from 45.20 to 46.10, but the increase is not significant.

### Results and Discussion

The 8 weeks Simplified kundalini yoga training on 70 mid-level managers has proved that yoga can impact the coping styles of mid-level managers. Analysis of data has shown that overall problem focused coping mean scores has increased from 73.52 (8.58) to 75.48 (10.04) after yoga intervention but is not statistically significant. The result seems to vary with the research findings of Puymbroeck (2000), Lim, (2008) and Mehrabi et al.,(2012) in which the increase in mean scores of problem focused coping are significant. With regard to emotion focused coping, the increase in mean scores before and after yoga intervention shows increase from 59.57 (7.69) to 61.61(7.12) and is significant (<0.01). The results are contradictory with the findings of Mehrabi et al.,(2012) where there is a significant decrease in emotion focused coping of nurses after yoga intervention. This holds good for the current study because in an IT Organization completion of task within the professional deadline may act as stressor to the employees. Since the respondents in the present study are mid-level managers whose decision making capacity is limited and may not possess the required authority to alter any task or professional deadline, choosing emotion focused coping style by mid-level managers would be more appropriate to overcome
the situation than adopting problem focused coping. As far as avoidance coping focus is concerned, the results from table-3 clearly shows that there is a decrease in the overall avoidance coping from 45.37 (7.93) to 42.47(7.34). The results are significant at 1 % level (<0.01) which are similar to the findings of Mehrabi et al.,(2012). Sometimes individuals tend to adopt avoidant coping style to escape from difficult situations. Though it is advantageous at times, may prove disadvantageous when used in a long run (Carver et al., 1989). Hence this finding has more relevance in the present scenario where stressed people often use avoidance style to escape from the stressor and therefore, it can be concluded that yoga has a significant and positive impact on the coping style of mid-level managers. So, yoga training/workshops should be given due importance in Organizations’ like any other corporate programs to aid corporate employees in adopting effective coping styles. This would enable the Organizations to achieve maximum goals with minimum stress among the employees.

**Suggestions for future research:** Among the various forms or styles of yoga, Simplified Kundalini Yoga (SKY) is used for the present experimental study to explore the impact of coping style of mid-level managers. To what extent other forms/styles of yoga impact the coping style of different respondents and whether the duration of the yoga training programme will have a differential impact on the coping style could be taken as a gap for future research.

**Note:**

1. The total no. of words in the manuscript is 3000 including references.
2. The references have been converted to Vancouver style and references are quoted in superscript.

**Ethical Clearance:** The bonafide certificate issued by the HTC Global Services, a mail feedback on yoga training program from Human performance coordinator and sample photographs are attached for your reference.

**Source of Funding:** Basically, I am a Simplified kundalini yoga trainer and completed my masters in yoga from the University of Madras. Simplified Kundalini Yoga practice has enhanced both my physical and mental health. As a token of gratitude, the entire training programme was self funded. I spent more than Rs.30,000/- for the training session which includes payment to the World Community Service Centre and Rs.15000/- to the volunteers (25 sessions x average of 6 volunteers per session x Rs.100 per head).

Role of Oral Appliances in Obstructive Sleep Apnea as a Treatment Modality

Manisha Kulkarni¹, Sabita M Ram²

¹PhD Scholar; Saveetha Institute of Medical and Technical Sciences, (Associate Professor; Department of Prosthodontics. YCMM and RDS’S Dental College, Ahmednagar); ²Dean, HOD; Professor Department of Prosthodontics. MGM Dental College, Navi Mumbai

Abstract
Mandibular repositioning splints (MRSs) and continuous positive airway pressure (CPAP) are used to treat the sleep apnea/hypopnea syndrome (SAHS). There are some data suggesting that patients with milder symptoms prefer MRS, but there are few comparative data on outcomes. The main morphological feature of OSA is upper airway narrowing during sleep, which is associated with snoring, excessive daytime sleepiness, hypertension, increased risk of cardiovascular diseases etc. Some evidence links OSA to an increased risk of mortality but the pathogenesis of this relationship is still not entirely clear. It has been postulated that upper airway dilator muscle activity is crucial for counter-acting the negative intraluminal pharyngeal pressure. Diminution of this activity during sleep is the major reason for pharyngeal collapse and obstruction in patients with obstructive sleep apnoea.

Keywords: Obstructive sleep apnea, Oral appliance, CPAP, Mandibular advancement device

Introduction
Obstructive sleep apnea is due to repeated arousals during sleep. Day time sleepiness is one of the characterized by pauses in breathing during sleep, micro-arousals and daytime sleepiness. These symptoms are caused by repeated episodes of obstruction at one or more upper airway levels during sleep.

Oral appliances that advance the mandible forward during sleep have been suggested as an appropriate and non-invasive treatment for mild to moderate obstructive sleep apnea. The purpose of this article is to create awareness about the efficacy of mandibular advancement devices as a treatment for mild to moderate obstructive sleep apnea¹. There has always been increase in the interest of knowing about the sleep apnea. OSA is characterized mainly by the recurrent complete or incomplete upper airway obstruction which makes difficulty to breathe. OSA is a sleep disorder which shows symptoms such as irritability, neurocognitive deficits, snoring, daytime tiredness, frequent awakening from sleep, depression in adults². The prevalence of OSA is reported to be around 2% for women and 4% for men³, wherein 3% to 12% of the total world population is affected by habitual snoring⁴,⁵.

The OSA is mainly caused by collapse of upper airway that leads to upper airway constriction. The three major areas of obstruction include: the nose, palate, and hypopharynx. Additional factors that may contribute this collapse include: soft tissue hypertrophy, obesity, and craniofacial characteristics such as retrognatia⁶. anatomical abnormalities are not always the main causative factors leading to OSA and in fact, in some cases, the etiology can be due to failure of the central nervous system to signal the pharyngeal dilator muscles to dilate and maintain an open pharynx . Environmental and genetic factors related to obstructive sleep apnea are, increasing age, family history, obesity, ethnicity, alcohol, smoking, and cranio-facial abnormalities and nasal obstruction⁷.

Diagnosis and Treatment of Osa: The diagnosis of OSA requires the combined assessment of relevant
clinical features and the objective demonstration of abnormal breathing during sleep. Subjective and objective diagnostic aids are present which are useful in diagnosis of OSA. Subjective assessment includes stop bang questionnaire, Epworth’s sleep scale and Stanford sleepiness scale (SSS). Objective assessment include polysomnography, MSLT (multiple sleep latency test), cephalometry, anthropometry and demographic patterns.

Treatment Options: Weight reduction is expected to ameliorate some of the risk for co-morbid conditions like CAD, hypertension, metabolic syndrome. Both sedative medications and alcohol have a depressant effect on the pharyngeal dilator muscles and increase respiratory resistance, aggravating OSA.

A number of agents have been tried without success to ameliorate the excessive somnolence in OSA patients. The US FDA has approved the use of the wake promoting drug modafinil in improving alertness and subjective and objective sleepiness in patients with OSA.

Therapy with CPAP is the first-line treatment for OSA. Giles TL in 2006 stated that it delivers air at high flow (20-30 liters/min) through an interface to the upper airway, providing a constant mechanical splint (air at pressure) to prevent airway collapse during sleep, thus abrogating apnoeas and hypopnoeas. This reduces intermittent hypoxia, respiratory effort, sympathetic stimulation arousals and sleep fragmentation.

The CPAP provides similar inspiratory and expiratory pressures, however, in BiPAP the inspiratory positive pressure, (IPAP) is set to prevent upper airway closure and hypopnea due to partial closure. The expiratory positive airway pressure (EPAP) serves to stabilize the collapsible airway at end expiration such that the patient can comfortably trigger the delivery of an IPAP. It provides ventilatory assistance with improved patient compliance. It can be particularly helpful in patients with high CPAP pressures and underlying lung diseases compromising oxygen transfer or increasing the work of breathing.

The US FDA approves 16 devices for use in sleep apnoea. Oral appliances (OA) are now widely used as an alternative to CPAP therapy. They are designed to keep the upper airway open by either advancing the lower jaw forward or by keeping the mouth open during sleep. A recent meta-analysis found that OA should not be considered as the first-choice therapy for OSA, where symptoms and sleep disruption are severe. Although CPAP was clearly more effective at reducing the disruption to sleep, some people with OSA may prefer using OA if they are found to be tolerable and more convenient than CPAP. When an active OA compared with an inactive OA, there were improvements in daytime sleepiness and apnoea/hypopnoea severity. Also, OA may be more effective than corrective upper airway surgery.

Continuous positive airway pressure provides at best a control for OSA. It is surgery alone which can provide a “cure”. However, the role of surgery requires proper patient assessment and selection and is not for everyone. Uvulopalatopharyngoplasty (UPPP) is the most common surgery performed for snoring. It has been shown to decrease OSA severity, more so in patients with retro palatal obstruction. This surgical procedure has an approximately 52.3% rate of long-term reduction of respiratory disturbance index (RDI) or AHI of greater than 50% of patients with mild or moderate sleep apnoea. Site-specific surgery, including maxillomandibular advancement, has been shown to effective selected patients with certain anatomical abnormalities.

Oral appliance (OAS) were introduced as a treatment for OSA in the 1980s and continue to be used both as a primary therapy and for patients unable to tolerate PAP. They function by moving the mandible, tongue, and attached structures within the mouth and throat forward; thereby opening the airway space. The appliance function on the same principle as that used in the jaw thrust maneuver of cardiopulmonary resuscitation (CPR) to open the airway. Efforts to improve the efficacy of OA therapy have centered on varying how different appliances establish jaw protrusion. Most oral appliances for the treatment of obstructive sleep apnea are fabricated in a dental laboratory on custom stone models of the patient’s upper and lower teeth that are attached to a dental articulator; a machine that reproduces the spatial relations between the maxilla and mandible.

There are two groups of oral appliance treatments available; mandibular advancement devices (MAD), which are attached to the teeth and maintain the mandible in a protruded position, and the tongue retaining device which retains the tongue in anterior position and does not allow it to fall backwards which can obstruct airflow. MADs appliances are more commonly used than the other. Mandibular advancement appliances are of two types; they are the two-piece appliance and monoblock.
Both of these devices are designed to keep the mandible in a protruded and inferior position, consequently widening the pharynx in an anterior-posterior dimension, but even more so in the lateral dimension. The amount of mandibular protrusion depends on the anatomy of the individual and it may require a titration procedure, until the good results are achieved.

Thornton Adjustable Positioner (TAP-3) is an design approved by the Food and Drug Administrations for the treatment of OSA. It is essentially two custom fit mouth guards (one for the top teeth and one for the bottom) with an attachment and adjustment mechanism that connects along the anterior portion of each mouth guard. This adjustable mechanism is set to advance the lower jaw until the airway space behind the tongue is open enough to alleviate symptoms of OSA. The TAP-3 appliances contribute to patient comfort because, unlike many OA designs, it allows some freedom for lateral movement of the mandible.

Mandibular advancement device: In a review article, Lowe states that there are about 55 different oral appliances currently (2000) on the U.S. market, but only 14 have received market clearance by the FDA (Food and Drug Administration) for both snoring and OSAS. Although there are many different types of oral appliances, the mandibular advancement technique appears to be the most efficacious and is well tolerated. Different designs of these MAAs are available today: they include prefabricated and individually designed one-piece (monoblock) or two-piece appliances. However, the purpose of each of these appliances is the same. They should be inserted intraorally at night to displace the position of the mandible anteriorly with the aim of enlarging the retroglossal space. Moreover, this treatment mechanism thereby tenses the palatoglossal and palatopharyngeus muscles and thus reduces the degree of upper airway obstruction and pharyngeal collapse have shown that oral appliances change the volume of the upper airway; the augmentation of upper airway muscle activity and fewer nocturnal desaturations.

In a review article in 2001, Lindman and Bondemark found that the majority of the 30 reviewed studies still had few patients included and the follow-up time was short and without any control. In overall terms, the mean normalization rate (AHI<10) in these studies was 61%. It is important to note that these studies included patients with every degree of severity of OSAS. When distinguishing mild to moderate OSAS from severe, different normalisation rates are found. Patients with severe OSAS had less reduction in apneas (49%) than patients with mild to moderate OSAS (70%).

In recent years, some studies have been conducted with a randomized crossover design but only for short-term periods. These studies were conducted with either a randomized placebo-controlled crossover design or a randomized crossover design comparing dental appliances with CPAP

Clinical efficacy of MAD treatment: The American Sleep Disorders Association (ASDA) reviewed the available literature in 1995 and recommended that oral appliance should be used in patients with primary snoring or mild OSAS and in patients with moderate to severe OSAS who are intolerant of, or refuse treatment with, CPAP. One of the difficulties when is comes to comparing treatment results in different studies of MAA is the huge variety of designs of these appliances. However, since the overall aim is to advance the mandible, generalization maybe possible and it appears that, the greater the degree of advancement (achieved by gradual adjustment), the better the outcome. This fact may be related to a dose-dependent enlargement of the upper airway, the augmentation of upper airway muscle activity and fewer nocturnal desaturations.

OSAS had less reduction in apneas (49%) than patients with mild to moderate OSAS (70%).

In a randomized controlled trial, patients with mild to moderate OSAS found to be less effective than CPAP. However, the patients reported more side-effects with CPAP and generally expressed greater satisfaction with the oral appliance treatment. MAA appears to be an effective therapy for treating persistent apneas in patients who fail UPPP.

There is lack of reports about the patients who will benefit from MAA treatment. A number of cephalometric predictors have been used when treatment success is described; a retrognathic mandible together with a prognathic maxilla, high position of the hyoid bone,
relatively normal post-palatal and post-lingual airway and narrow tongue base\textsuperscript{23}.

Almost none of the studies evaluating the treatment effect of MMA have investigated the effect on the clinical symptoms related to OSAS. However, some studies reported fewer headaches and reduced day time sleepiness evaluated by the Epworth Sleepiness Scale and improvements in psycho-intellectual function\textsuperscript{6}.

**Patient Compliance:** After one year of treatments, 75-86\% of the patients continued to use their appliances\textsuperscript{14} In more extended follow-up studies, Yoshida noted 90\% compliance after a mean follow-up of about two years (range 6 to 59 months)\textsuperscript{24} and Menn et al. noted 70\% compliance after 3.4 years of use.

**Adverse Effects:** The most effective degrees of mandibular advancement for each individual patient is not well understood, although it has been reported that the maximum protrusion of the mandible produces the greatest airway enlargement\textsuperscript{23}. However, the maximum forward mandibular position is not appropriate as it cause temporomandibular joint pain, or masticatory muscle discomfort.

Minor side-effects and complications after treatment are reported by patients in several studies\textsuperscript{25} Increased salivation, dryness of the lips and throat and slight tenderness in the teeth and jaws after awakenings were the most commonly reported symptoms.

**Conclusion**

Mandibular advancement is one of the best treatment modality in cases of obstructive sleep apnea unless there is strong contraindication with respect to the treatment plan. Mandibular advancement device has been recommended for the treatment of mild to moderate sleep apnea in AASM guideline.

An Examining Approach to Exploring the Philosophy of Life
to the World Religion-Case Study

V. Nithyananthan¹, Christhu Raj M R², R. Vidhya³

¹Teaching Associate, ²Assistant Professor, Centre for Applied Research in Education, ³Assistant Professor,
Dept. of Computer Science and Engineering, SRM Institute of Science and Technology,
Kattankulathur, Tamil Nadu, India

ABSTRACT

Human lives in present scenario, all over the world faces lots of some problems, they are common in our
daily life. In Today’s world, Education has brought high distinction in various aspects of life. Every human
born with inherent physical power and mental ability in good order to understand and use them perfectly to
lead a life. The most important things for us to understand clearly and completely is about the philosophy
of life, Law of Nature, consciousness, its origin and end through the light of inner vision, realization of Self
and actualization of Truth blossom fully in the higher state of consciousness.

Keywords: Philosophy, Consciousness, Self-actualization, enmity, Morality, Charity

INTRODUCTION

Generally, Human beings is facing some sort of problems in day to life. It would be extremely accepted
by one and all. But it would be so readily subscribed to statement that there are solutions for all the problems we
are facing. Proper solution is easily and quickly available for clear-minded persons of deep thinking[1]. For others,
however, pains and miseries will flow from every problem. Unlike other living beings, man is a peculiar
phenomenon of dual might, with Nature and Will in constant combat, one striving to overcome the other.
With all other living beings, Will is subdued by Nature; and in their case, there is no conflict between Nature and
Will. Will functioning in harmony with Nature is known as instinct. Generally, a man Will is very powerful and
always tries to overcome Nature[2]. Will registers success and failure every now and then in its zeal and actions.
Until perfection is achieved by experience in accurately

assessing the relative strengths of Will and Nature, possibilities of failure would be there in every zeal or
action, in the perspective view of time, place and object of contact. In its effort to subdue Nature, Will creates
more problems in life by wrong approach. Even through there are solutions to all problems, the intervening period
between problem and solution will be one of trouble and disturbance to the body and the mind[3-4].

Philosophy of Life: The philosophy of life is takes to research about the relationship between an individual
and society. When a man protects himself from the natural pains for his survival and lives in harmony with
society, happiness blossoms. If one attains the realization of Divine, love and compassion multiply towards fellow
human being. One can see the whole world filled with peace and happiness.

Philosophy of life is a total perspective knowledge which includes all the universal secrets[5] This can be
easily understood by all and it would be used to all facts of life. This philosophy of life is defined by Saint Vethathiri
Maharishi says, “To lead a life with the knowledge of philosophy of life is like living in a well-lit house”. If
we try to climb a dark stair -case, we may put our leg not knowing where actually stepping in. We are likely to
stumble down. When there is light we can see the steps well and climb without any trouble. Leading one’s life

understanding the philosophy of life is similar to this. The philosophy of life is the very light of life [6].

The philosophy of life consists of twelve basic principles of life. It is sub-divided into four major groups and each group consists of three subgroups with explanations. These principles comprise three needs, three protections, three virtues and three stages in the development of knowledge.

For body - three needs
For life force - three protections
For society - three virtues
For nature - three stages in development of knowledge or Consciousness

Three Needs: There are three basic needs for all living beings. These are natural urges.

i. Needs to satisfy Hunger and thirst
   ii. Needs to make Adjustment to climatic variations
   iii. Needs to relieve Pressure of excretory forces

From the time of birth until death these three needs will important thing arise in man’s life. These are essential for man’s survival too. These urges must be balanced with proper commodities and facilities.

Three Protections: The three essential protections are:

   i. Protection from natural disasters
   ii. Protection from the enmity of other living beings
   iii. Protection from accidents

Protection From Natural Disasters: Earthquakes, eruption of volcanoes, cyclones, drought, flood and tsunami are some common disasters that the world experiences on now days. Man needs protection from them to lead a fear-free, peaceful life [11].

Protection From the Enmity of Other Living Beings: Enmity with another person is mostly related to food and protection. There may be some other reasons also like jealousy and social customs. Because of this enmity they mutually hate one another and inflict pain on others [12]. Everyone needs protection from the enmity of other living beings. Everyone needs protection from the enmity of other living beings.

Protection From Accidents: When we move from any place to the other, unfortunately we may face accidents unexpectedly due to unforeseen circumstances [13]. We need protection from these accidents. On one’s own planned activities there may be interference from other’s planned activities and accidents happen due to unforeseen circumstances. That will lead to affect one’s life. We need protection from these accidents created by circumstances. Wearing helmet protects one’s life during driving a Two-wheeler.

Three Virtues: Man has a habit of living in a group called society. He cannot change this and cannot think
of living alone like animals. One man’s effort or labour or intellect is not enough to produce all the articles and facilities required for his life [14]. He has to live in a society to get all his requirements. Therefore, man has some more responsibilities.

Three important virtues are:

i. Morality, ii. Duty, iii. Charity

**Morality:** One should restrict one’s thought, word and deed so that they may not result in pain to self or to others, to the body or to the mind, at present or in future[15]. This is morality.

Propriety of conduct leads to eminence; it should therefore be preserved more carefully than life.

**Duty:** Everyone lives in a society. He is given birth, reared, educated, granted position and protected only by the labour, intellect, love and care of the society. Society contributes for individuals to grow and individuals contribute for the society to grow [16]. At any point of time one cannot live alone. So, we are indebted to society. Every minute the dues are increasing. We have to repay these dues to the society in the form of good deeds. With a sense of gratitude and at the proper age, we should return these dues through our labour and love. Only then prosperity, harmony and peace will be maintained in society. This return of dues to society by way of labor and love is called duty:

**Charity:** When one, out of love that is beyond prejudice, unconditionally sacrifices all or a portion of one’s physical labour, intellectual talent or wealth, to help others, that is charity [17]. There is no expectation and no due but one has to do an act as sacrifice. Such a meaningful sacrifice is charity.

**Three Stages in Development of Knowledge:**

(i) Faith

(ii) Understanding

(iii) Realization (Perfection)

These are to be followed by all people according to their individual capacities.

**Faith:** Faith is the first stage in development of knowledge. Under this system those who are not capable of understanding the principles of life, either because of youth or because of underdeveloped intelligence, should lead their lives by faith [18]. They should obediently follow the teachings of wise men and elders with sufficient experience who are their guides or guardians. This is called ‘Bakthi Yoga’[19].

**Understanding:** Understanding is the second stage in development of knowledge. When one comes to the age of understanding and thinking faculty is developed, he understands the values of virtues. If one starts thinking on his own and analyzing, his intelligence is developed. He leads his life by understanding [20]. He follows the principles of life by learning from his own life experiences, by studying books, and by learning from lectures of experienced persons.

**Realization (Perfection):** Realization is the third and final stage in development of knowledge. This is called as actualization. All the understanding should be put into practical experience. One has to develop his knowledge to the fullest to make the life purposeful. When one understands clearly and completely the philosophy of life, philosophy (laws) of Nature, consciousness, its origin and end through the light of inner vision, realization of Self and actualization of Truth blossom fully in the higher state of consciousness [21].

**CONCLUSION**

For better living, the understanding of the above-explained twelve principles of life is imperative for all sections of people in the human society. These twelve principles of life are the essence of the Vedas and the core and goal of all the Religions in the world. The important of Science, Politics and Economics, are also having their roots only in these twelve principles of life. Knowingly or unknowingly, from time immemorial, only some people have understood and are following these twelve principles of life. The majority are not even aware of the existence of these principles. The result is that miseries and problems are increasing day by day in the human society all over the world. The time has come now for all people to understand these principles and follow them in their life. Leaders and publicists in all over the world are stressing the need to provide universal education. If these twelve principles are elaborated and taught properly to all the youngsters by methods suitable for the respective age-groups and levels of understanding, the purpose of education will be achieved. This itself will be real spiritual education. Philosophers, Scientists, Jurists, Educationists and Administrators should take
up unitedly the responsibility mankind through an international organization. All Governments, religious institutions and philanthropic people should cooperate and provide the required financial support. The Sciences have been developed to impressive proportions and material prosperity is more than enough. Only the spiritual development is required to the world people to attain peace in life with harmony. Further enhancement of research on the life of mankind and with all the responsibility and sincerity would be concentrated in all around the countries. It leads in giving fruitful and fulfilling all the basic needs and principles for a comfortable and peaceful life of mankind.

Abstract

Background and Objectives: Hajj is worship that has very complex implementation. Hajj pilgrims are required to have a good health condition or it usually called istithaah. Indonesian hajj pilgrims with high risk categories of 46-67% caused high morbidity and mortality of hajj pilgrims. If no effort is done in order to establish and improve the health status of hajj pilgrims during the preparation period at the Primary Health Care (Puskesmas). Research about the analysis of quality assurance of health development of hajj pilgrims at Primary Health Care in Bojonegoro District with a reference to Health Minister’s Regulation No. 15 of 2016 about Health Istithaah needs to be done to improve health services of hajj pilgrims in the Primary Health care before departure. Method: This study was conducted in March to April 2018. The data used in the study were primary data that collected by conducting an indepth interview with the officers of Hajj Medical Checkup Team (TPKH) at Primary Health Care in Bojonegoro District. The population in this research is the officers of TPKH in Primary Health Care that perform service at hajj pilgrims. The inclusion criteria of the study were TPKH officers serving high risk hajj pilgrims. The sample consisted of TPKH officers in 17 Primary Health Cares taken by simple random sampling method. This study used questionnaire instrument indepth interview guides. The questionnaire consisted of questions about the health development of hajj pilgrims conducted at the Primary Health Care. The questions are in line with the Technical Guidelines of Health Minister’s Regulation No. 15 of 2016 on Health Istithaah. Interpretation: The results of the study indicate that 100% of Primary Health Care in Bojonegoro District have not conducted a health development on waiting period for hajj pilgrims who will leave with a two-year estimate, 65% of Primary Health Care do not conduct hajj health care with home visits, and 71% Primary Health Care do not conduct hajj health education by disseminating information through printed media (leaflets, brochures, and posters). Efforts to improve the health development of Hajj pilgrims need to be done by Primary Health Care to run in accordance with the rules and provide maximum results in efforts to establish and improve health istithaah of hajj pilgrims.

Introduction

Hajj is the fifth pillar of Islam which is a lifetime obligation for every Moeislem who is able to fulfill it.

Corresponding author:
Mielka Ratna Kusuma Wardhani, SKM
Postgraduate Student at Magister of Health Administration and Policy of Public Health, Airlangga University, Kampus C Mulyorejo 60115 Surabaya, Indonesia, Email: mielkaratna@gmail.com

The fifth pillar of Islam has a special characteristic that is largely physical activity, for a long time (38-40 days), and is done in the month of Dhu al-Hijjah in Saudi Arabia. The implementation of the complex pilgrimage requires the prospective hajj pilgrims in a state of health that usually called istithaah.

Indonesia is the country with the largest number of hajj pilgrims in the world. In 2017 the number of Indonesian hajj pilgrims amounted to 221,000 people. Indonesian Hajj pilgrims is classified as having high
health risks. The percentage of high risk hajj pilgrims in Indonesia in the last five years ranged from 46-67%. The death of Indonesian hajj pilgrims is also relatively high at around 200-330 for each 100,000 hajj pilgrims. Embarkation of Surabaya is an embarkation with the highest number of hajj pilgrim deaths in 2017. Embarkation of Surabaya serves hajj pilgrims from East Java (96%), Bali (2%) and East Nusa Tenggara (2%).

Based on data collected from Siskohatkes (Information System and Computerized Hajj Integrated Health) it is known that Bojonegoro District is one of 38 District or city in East Java with the number of deaths of high risk hajj pilgrims above the general indicator standard since 2015 to 2017. The proportion of death of high risk hajj pilgrims in Bojonegoro District since 2015 to 2017 has the average 7‰ (general indicator of hajj health services is less than 2‰).

The fact that the high mortality rate of hajj pilgrims in Bojonegoro District is a matter that deserve further analysis. The risk of individuals to experience death during the pilgrimage can be influenced by many factors, one of which is the health care factor. Efforts or activities that can be done in order to establish and improve the istithaah health status of hajj pilgrims in health care facilities through health coaching. With reference to the problems above, the purpose of this study is to analyze the quality of health development hajj pilgrims in Primary Health Care Bojonegoro District with a reference to Health Minister’s Regulation No. 15 of 2016 about Health Istithaah.

### Material and Method

The research design used in this research is cross sectional with qualitative descriptive approach which describes the phenomenon that occurs by developing the concept and collecting facts. The study was conducted retrospectively by conducting an assessment of the examination activities and health development of hajj pilgrims in 2017. The study was conducted in March until April of 2018. Data used in the study were primary data. Primary data was collected by conducting an indepth interview with officer of Hajj Medical Checkup Team (TPKH) at Primary Health Care in Bojonegoro District. The population in this research is TPKH officer in Primary Health Care that performs service at hajj pilgrims. The inclusion criteria of the study were TPKH officers serving the high risk hajj pilgrims. The sample consisted of TPKH officers in 17 Primary Health Cares taken by simple random sampling method. This study used questionnaire instrument indepth interview guides. The questionnaire consisted of questions about the health development of hajj pilgrims conducted at the Primary Health Care. Questions are tailored to technical guidelines Health Minister’s Regulation No. 15 of 2016 about Health Istithaah.

### Findings

Istithaah Health Hajj pilgrim is defined as the ability of the hajj pilgrims from health aspects including measurable physical and mental with the examination and guidance that can be accounted, so the hajj pilgrims can perform their worship according to the guidance of Islam. The effort of examination and promotion of hajj health in order to achieve health istithaah is done through a series of activities to prepare the condition of the ability of the hajj pilgrims through standard mechanism on continuous standardized health service facilities. Stages of examination and health development hajj pilgrims in Bojonegoro is based on Health Minister’s Regulation No. 15 of 2016.

Based on the results of the first phase of medical checkup conducted at Primary Health care, it is known that 48.76% of pilgrims in Bojonegoro District in 2017 are included in the high risk category. The results of the second phase examination also illustrates that there are still 20.31% of hajj pilgrims who qualify health istithaah with assistance. The high number of high risk hajj pilgrims and istithaah with assistance should demand the service providers in Primary Health Care to provide esktra health development to the hajj pilgrims.

The health development given to the hajj pilgrims at the Bojonegoro District Health Center in 2017 can be seen in table 1.

Based on the result of the research, it is known that most (88%) of Primary Health Care in Bojonegoro District run health development with an integrated manner with other health program. Integrated Primary Health Care program such as mental health, sports health, infectious diseases, nutrition, and counseling. All (100%) Primary Health Care in Bojonegoro District have not run the waiting period in the hajj pilgrims who will depart in two years estimation.

Health development for Hajj pilgrim can be grouped into two kind. First is hajj health coaching and hajj health education according to Table 2.

Source: Primary data, 2018

The most common method of health development by Puskesmas in Bojonegoro District is by counseling and fitness exercise. Few puskesmas are running home-visit methods due to limited manpower.

### Discussion

The results illustrate that all Primary Health Care have not run health development waiting period in the hajj pilgrims who will depart in two years estimation. Primary Health Care generally conduct health development on waiting period about 3-8 months before departure. The implementation of such a short period of coaching is due to not yet the implementation of the first stage of health checks according to the rules.

The first phase of medical checkup was performed by the hajj pilgrims when they registered first time to obtain a portion number. The results of this first stage examination will be the basis of the implementation of health development that aims to fix and improve the health condition of hajj pilgrims. Therefore, the first phase medical checkup is a must for every hajj pilgrim to be done early (at least two years before the estimated departure).

Based on the results of indepth interviews with respondents, it is known that the obstacle such as first phase medical checkup and health development on waiting period has not been done according to the regulation. It can be caused by several things such as data provided by the Ministry of Religious Affairs is the estimated data of hajj pilgrims departing in the current
year. Every year there are always hajj pilgrims quota filler that has not been fulfilled and the reserve quota determined in very short time\textsuperscript{13}.

Use of appropriate health development methods should be considered as it will affect the outcome. The results shown that at the phase of hajj pilgrims counseling of 65\% Primary Health Care do not make home visits on hajj pilgrims. Periodic home visits serve to counsel hajj pilgrims including empowering their families. Home visits are also aimed to obtain more information about health risk factors on hajj pilgrims and indications of medical action that do not allow pilgrims to visit health facilities\textsuperscript{4}. Home visits are very important in later on Hajj with a high risk status and qualify with assistance to monitor the health condition.

Dissemination of information through printed media (leaflets, brochures, posters, etc.) is not implemented in 71\% of Primary Health Care in Bojonegoro District. Health education counseling can provide significant results in knowledge improvement. Nevertheless, counseling with printed media needs to pay attention to the benefits and effectiveness of its use to the target and extension workers, because printed media that less attractive will be less attention by the reader and also cost much in the production. Printed media will be effective if it has an attractive image with easily understood language by the target group\textsuperscript{3}.

**Conclusion**

Based on the results of this study, the following conclusions are obtained: 100\% of Primary Health Care in Bojonegoro District have not conducted a waiting period for the pilgrims who will leave with a two-year estimate, 65\% of Primary Health Care do not conduct hajj health care with home visits, and 71\% Primary Health Care do not conduct hajj health education by disseminating information through printed media (leaflets, brochures, and posters, etc).

Kampus C Unair, Surabaya, East Java, Indonesia

Abstract

High employee turnover rates are very problematic especially in private hospitals. Many studies on the quality of work life (QWL) relationship on nurses turnover intention (TOI) were found, but the study on all types of clinical personnel and from the perspective of holding hospital are limited. This study aimed to analyze the correlation between QWL of health workers with their turnover intention at P Group Hospital and determine whether there were differences of QWL and TOI in the three hospitals that applied the same policy in human resource management. This study was conducted cross sectionally involving 255 respondent, using standardized questionnaires. Sampling technique was stratified random sampling. Data were analyzed using descriptive statistics, Mann-Whitney, Kruskal-Wallis, and Spearman correlation test. The results showed a significant correlation between QWL and TOI, with negative direction (correlation coefficient -0.344), which means the higher the QWL, the lower the TOI. There were significant differences in QWL levels and TOI in the three hospitals, but the same thing was that all hospital employees least satisfied with growth and security dimension. The conclusions were that QWL was correlated with TOI, and even under the same policy of human resources management, employees’ QWL level and TOI at different hospital can varies each other.

Keywords: Quality of work life, Turnover intention

Introduction

Turnover is the process by which employees leave an organization and must be replaced.(1) High employee turnover rates are very problematic especially in private hospitals. No national data on hospital employee turnover figures in Indonesia, but some references indicate that hospital employee turnover rates in the period 2008 to 2015 were vary between 8.7%-20.3%.(2)(3)

High turnover among employees in health services and other services related to human services is a serious problem,(4) leading to company inefficiency,(5) affecting team instability, lack of knowledge and skills of the new employee, long-term job vacancy,(4) and for the remaining employees there will be an increase in workload, lower motivation,(5) lower job satisfaction, and increased stress.(6) All of these adversely affect the continuity and quality of service, patient safety and satisfaction.(4)(7) Overall, turnover provides negative implications for organizational performance and loss of human and social capital.(8)

Some of the causes of voluntary turnover are dissatisfaction in employment, salary and profit levels, supervision, geography, personal reasons, stress,(9) and career opportunities elsewhere.(1) A conducive working environment is very important to reduce the desire to quit work.(10) Various studies had shown that QWL, defined as employee satisfaction with working life,(11) was significantly related to TOI,(11)(12)(13) job satisfaction,(14) absenteism,(15) and productivity. (16) QWL development was intended to help balance work with the needs, interests and pressures faced by employees, so it can be useful for improving productivity and reducing turnover.

P Group Hospital is a holding hospital in Indonesia that consisted of 3 Hospitals with same human resource management policy. Its turnover rate in the period of 2016 to 2017 was high (13%), dominated by voluntary turnover of clinical personnel. According to Gillis (1994) employee turnover is said to be high if more than 10% per year. Analyzing the turnover level of the three hospitals is important to find appropriate correction action. The main purpose of this study was to analyze the correlation between QWL with TOI of health workers at P Group Hospital and determine whether there were differences in the level of QWL and TOI in the three hospital.

**Material and Method**

This study was a quantitative research, conducted cross sectionally in February 2018, at three hospital named PGH, GHH, and PGDH. The population were 470 clinical personnel with 225 sample. Inclusion criteria were doctors, nurses, and other health professional who were employees, and had been working there for at least 2 week at the time this study conducted. Specialist doctors, non-employee and employee who had worked less than two weeks were excluded.

QWL was measured using a standard questionnaire adapted from Walton’s QWL model that had been proven valid and very reliable (cronbach alpha 0.96), consisting of total 35 questions and 8 dimensions: adequate and fair compensation (4 item), safe and health environment (6 item), development of human capacities (5 item), growth and security (4 item), social integration (4 item), constitutionalism (4 item), the total life space (3 item), and social relevance (5 item). TOI was measured using a questionnaire consisting of a total of 10 questions with Cronbach’s Alpha value 0.94. All the scale was 4 points Likert scale (4 = strongly Agree, 1 = strongly disagree).

The data were analyzed using SPSS version 21.0 for windows. Descriptive analysis was used to show respondent characteristics, QWL’ level and TOI. For the overall QWL interpretation, the scores on each question were summed and then divided by number of question. The possible score was varied between 1 and 4. The total score ≤2.5 was included in the low QWL category, while the total score > 2.5 was high QWL. Each dimension of QWL was evaluated in the same way.

Mann-Whitney test and Kruskal-Wallis test were used to compare the TOI based on respondent characteristics. Comparison of QWL and TOI among three hospital were analyzed using Kruskal-Wallis test. Correlation between QWL and TOI was analyzed using Spearman correlation test. All significance values were set at p <0.05.

**Findings**

**Respondent Characteristics**

The majority of respondents were women (64.4%), young age between 20-30 years (72.9%), worked in shift (77.7%), had work of tenure between 4-10 years (38.2%), and income under regional minimum wage in this city (40.4%). Respondents consisted of nurses (56.9%), doctors (8.4%), and other health professional (34.7%). Permanent employees were almost in the same amount of contract employees (50.7%). It is shown in table 1 Hospital Employees’ TOI

**Table 1. Mean score of TOI based on respondent characteristics**

The comparison of TOI based on respondent characteristics were shown in table 2. The youngest age group of 20-30 years significantly had the highest average TOI compared to other age groups (p = 0.001). Employee with work tenure 1-3 years had the highest intention to leave, while new employee (less than one year) became the second. Contract workers significantly had higher TOI than permanent employees (p = 0.004). Meanwhile, there were no significant differences in sex variables, work rhythm, profession, and income.

The overall TOI was low (2.07). TOI in the three hospitals looked significantly different (p = 0.001). GHH employee had the highest TOI. This is shown in Table 2.

Correlation Between QWL with TOI

The correlation between QWL and TOI was analyzed using Spearman’s correlation test. The test result was shown in table 5. There was a significant correlation between QWL with TOI with p value of 0.001 (<0.05). The correlation direction is negative (correlation coefficient -0.344), which means the higher the QWL, the lower the TOI.

Discussion

Overall, hospital employees in this study reported high QWL score and low TOI. This finding contrary to several other study that reported low QWL and high TOI among healthcare employees.(20)(12)(21) Even though being categorized as high QWL and low TOI, the score was very close to dissatisfaction limit (score of 2.5). Looking at the high trend turnover rate during the period 2016-2017, which was dominated by clinical staff and voluntary turnover, it was still important to analyze and do action to reduce turnover without waiting until turnover rates become too severe. Overall, hospital employees in this study reported dissatisfied with growth and security dimension that consisted of 4 items related to the opportunity of professional growth, trainings given by company, situation and frequency of resignation occurred at the work, and incentive that had been given by company to employee to study.
Company should pay more attention on training programs and employee development, and make sure for creating equal opportunity to get training. Sometimes there is the assumption that if a company trains an employee, then that means the company will only train them for other employers. Developing employee skills will indeed make their market share increase, but will also increase retention. When employees are given training and development, job satisfaction will increase and increase the desire to remain. Creating job security, career development and promotion opportunity were several ways to improved internal labor market that able to make company more competitive and able to retain their staff. The Hospital can follow the regulation of the minister of health of the Republic of Indonesia number 129 year 2008 about the minimum hospital service standards which is stated that the number of employees who get training at least 20 hours per year should meet the standard ≥60%.

Situation and the frequency of employees who submitted the resignation can affect employees. Prior studies stated that turnover occurring to other nurses would lead to a decrease in manpower, which then morally affects, and causes stress from the remaining employees due to an increase in workload. If not well managed, long term high turnover can promote turnover culture among employees. Employees will tend to have TOI if the people around them have the same behavior changing jobs.

These three hospital were managed under the same human resource management policy, but QWL and TOI level were differ significantly. QWL dimensions were not only related to the central human resource management policy, but also with other dimensions in the work environment that differ each other.

There was a significant correlation between QWL with TOI (p = 0.001, coefficient correlation -0.344). The result was consistent with the Almalki study (2012) in primary health care in Saudi Arabia, and study in Iran by Mosadeghrad. Result showed that Youngest group respondents aged 20-30 years old had highest average TOI among others with significant value, consistent with prior studies showing that younger employees had a greater tendency to quit working than older.

Employee with work tenure 1-3 years had the highest intention to leave, while new employee (less than one year) became the second. It was contrary to other study that showed severe turnover among new hire employee. Majority the groups of employee with work tenure 1-3 years were still contract employees with less financial benefit, less clear career path (no guarantee about when a person will be appointed as a permanent employee). In this study, contract workers significantly had higher TOI than permanent employees (p = 0.004), consistent with other study.

Conclusions

QWL was significantly correlated with TOI in negative direction. The higher the QWL, the lower the TOI. Overall employee least satisfied with growth and security dimension. Even under the same policy of human resources management, employees’ QWL level and TOI at different hospital can varies each other. There were significant association between turnover intention with age, work tenure, and employment status.

Policy makers should give attention on increasing QWL as part of management to reduce turnover and increase productivity without having to wait for too high turnover rate, make a comprehensive treatment design by focusing not only on the holding hospital point of view, but also to each hospital, and should give more concern to improve retention of younger employees (age 20-30 years old), new employees until 3 years work tenur, and contract workers.

Development, Validity and Reliability for Motivation of Success to University Inventory

Mohammad Aziz Shah Mohamed Arip¹, Nurul Syahirah Husin², Harizah Izyan Samsudin², Norhusna Mohamed², Sarimah Arifin²

¹Associate Professor, ²Faculty of Human Development, Sultan Idris Education University, Tanjong Malim, Perak, Malaysia

Abstract

The study aims to build, acquire content validity and reliability of the Motivation of Success to University Inventory (MSUI). MSUI built on the combination of Motivation of Success to University Counseling Model (MSUCM) formulated by Mohammad Aziz Shah (2010) and the approach of Cognitive - Behavioral Therapy (CBT). MSUCM said there are seven strategies that need to be met in the hierarchy in building successful motivation to university; 1) Trigger Self-Awareness (TSA), 2) Build Motivation to Learn (BML), 3) Developing Self Potential (DSP), 4) Setting Life Goals (SLG), 5) Time and Learning Management (TLM), 6) Mastering Study Skills (MSS) and 7) Avoiding Social Problems (ASP). However, CBT explain approaches, concepts, techniques, activities and items in MSUI relationship based on thinking and behavior that affect mood. MSUI contains 70 positive items (10 items for each sub scale) represented by seven sub scale of sub scale 1: Trigger Self-Awareness (TSA), sub scale 2: Build Motivation to Learn (BML), sub scale 3: Developing Self Potential (DSP), sub scale 4: Setting Life Goals (SLG), sub scale 5: Time and Learning Management (TLM), sub scale 6: Mastering Study Skills (MSS) and sub scale 7: Avoiding Social Problems (ASP). Analysis of the content validity derived from nine experts panel from academics and practitioners in counseling psychology. The findings of the overall content validity of MSUI is high which is 88.6, while for the sub scale are TSA (90.1 %), BML (87.2 %), DSP (87.9 %), SLG (86.0 %), TLM (88.1 %), MSS (89.0 %) and ASP (92.2 %). Findings of reliability involving 40 students chosen at random. Data were analyzed using the Statistical Package for the Social Science (SPSS) and Cronbach’s Alpha test showed that all MSUI have the high reliability of .910. The value of each sub scale is also high, TSA (.807), BML (.809), DSP (.770), SLG (.754), TLM (.868), MSS (.750) and ASP (.821). Therefore, the research proves that MSUI validity and reliability. Therefore, this study successfully produced a prototype of the MSUI that can contribute to the development of the construction of psychological assessment instruments, counseling and measurement of motivation among students.

Keywords: Content Validity, Reliability, Motivation of Success to University Inventory

Introduction

Motivation is a topic that is quite popular and attracts the attention of many, especially in the field of education. Education is the most important agenda of the country and has always been a major concern and received a huge budget allocation from the government. This scenario occurs because education is a necessity for every individual. Through the education system, children and adolescents can advance themselves and this not only guarantees their future, but families and communities as well. As a result of these aspirations, many studies have been conducted and most findings show that the success of students to the University is due to the factors of existing self-awareness and motivation. Hence, various efforts and initiatives have been generated to increase
student motivation to achieve the goal of going to the University. Motivation of Success to University Inventory (MSUI) is a new questionnaire in psychology, counseling and education development developed to assess the level of motivation of success in achieving the goals of the University. This MSUI is developed based on a planned and systematic process driven by psychology and counseling in guiding the students to develop awareness, motivation and inculcate the values of excellence driven by the goal of success to University (Mohammad Aziz Shah, 2010). In this regard, the study was conducted to empirically test the validity and reliability of the Motivation of Success to University Inventory (MSUI) by using Cronbach Alpha’s reliability coefficient.

The validity and reliability of the instrument is very important in maintaining the accuracy of the instrument from being exposed to defects. The higher the value and the level of validity and reliability of the instrument, the more accurate the data will be obtained to produce good and quality research. According to Howard and Henry (1988), consistency means that when the same item is tested several times on the same subject at different intervals, the result score or the answer given is equal or nearly equal. It can be concluded that the reliability is sufficient for the determination of validity. Low reliability is considered to limit the degree of validity obtained, but high reliability does not guarantee that a high degree of validity is generated. In short, reliability only provides consistency that allows validity. Normally, the researcher refers to Cronbach Alpha’s reliability coefficient to measure the reliability of the items in each questionnaire. This reliability value is referred to in the commonly used measurement model based on True Score Test Theory (TSTT) or known as a classic model. The validity and reliability of items in a research instrument can also be determined by using the Rasch Measurement Model developed by Rasch (1980). Rasch Measurement Model is a measurement model that is formed because of consideration which take into account on the ability or capability of each candidate or respondent who answered the questionnaire, test or instrument and item difficulty for each test or item (Rasch 1980).

BACKGROUND OF THE DEVELOPMENT OF MSUI

The Motivation of Success to University Inventory (MSUI) is developed to measure the motivation of students to achieve successful aspirations of going to the University. This is a sequence of motivational problems among students. In addition, nowadays motivational aspect is also seen as the main factor that plays an important role in determining the achievement of students in public examinations such as PMR, SPM and STPM. According to Sternberg (2001), motivation means drive or need that leads to action. Motivation also involves a process that gives power and direction that moves one’s behaviour.

Singer (1980) states that motivation is a force that drives a person to achieve a goal and then strives to continue to achieve something more brilliant. Motivation can maintain a goal continuously in a person. However, a good motivation will be a drive and a strong pull for a person to advance. Motivation is also closely linked to the desire to achieve excellence in every effort undertaken (Mohamad Zaaba and Zuraida, 2004). According to them, if a student is encouraged to learn diligently to get excellent results then the student is a motivated student. Among the characteristics of a highly motivated student is that they always want to go early to school, want to go to library, love to read, love to learn and consider the exam as a challenge. Therefore, it is very important for all parties involved with education, especially the school to plan and implement various measures to increase students’ interest and motivation. The school should provide a positive school climate to motivate students to produce effective learning patterns. This is because the school climate is the most important factor in determining the quality of pupils’ learning at school, thus determining the effectiveness of a school.

Education excellence is an important agenda that is often discussed. This is because the future development and advancement of the country depends largely on the educational system and the shape of the student to be produced. In order to improve the quality of this education, more focus should be given to the motivation of the students. This is because students are the nation’s hope in the future. In fact, the teaching process, whether formal or informal, will not be optimum if the student does not have high motivation to pursue knowledge (Stephens and Crawley, 2002).

Therefore, no matter how consistent and solid the educational programs were planned and implemented, they will not achieve full results if the students are not interested and do not have a sense of learning. According to Mohamad Zaaba and Zuraida (2004), although the
attendance of students is quite satisfactory, physical presence does not guarantee mental involvement. Students are seen to fail to take full advantage of the teaching and learning process. This is because many students have no commitment to their studies. Individuals succeed in enhancing their inner motivation when they are aware of the level of motivation they have and are willing to understand and actively participate in motivational programs (McClelland, 1985). This statement proves that awareness of the level of self-motivation plays a big role in raising the level of individual's internal motivation. This motivational issue is very important because motivation will move someone forward in no matter what they do.

Hence, the development of MSUI is believed to be effective and practical to help students reassess their motivation, learning skills and develop goals to the University. Furthermore, students are increasingly challenged with low academic achievement issues, disciplinary problems, social problems and the pressures of meritocracy system.

Research Methodology

The design of this study is a descriptive study. Descriptive research is used to obtain the content validity and reliability value of the MSUI developed based on study literature. This study involved three phases of the study, i.e., Phase 1: MSUI Development, Phase 2: Obtaining Content Validity and Phase 3: Reliability Value Analysis.

Phase 1: Development of MSUI

MSUI is developed based on literature study and based on the combination of Motivation of Success to University Counseling Model and Cognitive-Behavioral Therapy approach. These two theories describe the approaches, concepts, techniques, activities and items in the MSUI based on the relationship of thought that affects feelings and behaviors.

Phase 2: Obtaining Content Validity

In this phase, after MSUI items are developed, MSUI were given to nine experts to review on its content accuracy. The expert is comprised of five academicians with two lecturers in the Department of Psychology and Counseling of Sultan Idris Educational University (UPSI), two secondary school teachers and a secondary school counselor and four others were practitioners of two education officers, a school clerk and a school laboratory assistant. The review by the expert panel is aimed at obtaining the content validity value for MSUI.

Phase 3: Analysis of Reliability

Next, the third phase is carried out to obtain the reliability value of MSUI. After MSUI has obtained the right validity value, it was administered to 40 secondary school students. A simple random sampling method was used for sample selection. The data findings were analysed using SPSS to get the Cronbach Alpha value to evaluate the reliability of MSUI.

The study subjects and study location

The study subjects were only involved in the second and third phase of the study. In the second phase of the study, the study subjects were nine experts panel of academicians in higher learning institutions and psychologist and counseling practitioners at schools and institutions of higher learning. In the third phase of the study, 40 students of Secondary School in Terengganu were selected to obtain reliability data of MSUI.

Research Findings

Phase 1 Findings: MSUI Scale and Sub-Scale Development.

MSUI development is based on literature review from books, articles and various journals nationally and internationally on the measurement of motivation. This literature review examines the definitions, concepts, factors and implications of motivation from various perspectives. Furthermore, the theoretical foundation for the development of the major scale and sub-scale of MSUI is based on two main theories, namely the combination of Motivation of Success to University Counseling Model and the Cognitive-Behavioral Therapy approach. Based on this, the developed MSUI contains 70 items and MSUCM clarifies that there are seven strategies that need to be fulfilled in the hierarchy in developing motivation of success to the University; sub-scale 1: Triggering Self-Awareness (TSA) (10 items), sub-scale 2: Build Motivation to Learn (BML) (10 items), sub-scale 3: Developing Self-Potential (DSP) (10 items), sub-scale 4: Setting Life Goals (SLG) (10 items), sub-scale 5: Time and Learning Management (TLM) (10 items), sub-scale 6: Mastering Study Skills (MSS) (10 items) and sub-scale 7: Avoiding Social Problems (ASP) (10 items).
The findings of Phase 2: Content Validity of MSUI

Based on the expert panel agreement, the MSUI value is as shown in Table 1.

Table 1: The MSUI overall validity value and sub-scale (n = 8)

</tbody>
</table>

Furthermore, the reliability analysis to test the quality level of the items being developed. For MSUI: Items 1-10 is sub-scale 1 i.e., Triggering Self-Awareness, Items 11-20 is sub-scale 2 i.e., Build Motivation to Learn, items 21-30 is sub-scale 3 i.e., Developing Self-Potential, items 31-40 is sub-scale 4 namely Setting the Life goals, items 41-50 is sub-scale 5 i.e., Time and Learning Management, items 51-60 is sub-scale 6 i.e., Mastering Study Skills and items 61-70 are sub-scale 7 i.e., Avoiding Social Problems. The built items quality is at a very good level and can be understood by respondents. This is in line with the opinion expressed by Mohd Majid\(^9\) (2005) who stated that the reliability coefficient of 0.60 or higher is acceptable.

Conclusion

Overall, this study has succeeded in establishing a Motivation of Success to University Inventory (MSUI) which has a high degree of content validity and reliability value. Therefore, MSUI is able to measure the level of motivation in achieving successful goals to the University which comprises of seven major sub-scales, namely Developing Self-Awareness (TSA), Building Learning Motivation (BML), Developing Self-Potentials (DSP), Setting Life Goals (SLG), Time and Learning Management (TLM), Mastering Learning Skills (MSS) and Avoiding Social Problems (ASP). The analysis of each item contained in this MSUI indicates that the quality of the items being developed is very good, satisfactory and understandable by the respondents. In conclusion, this study has shown that MSUI has high validity and reliability and produces a prototype that can contribute to the development of counseling and psychological assessment instruments to help students with motivation measurement.

Analysis of Internal and External Motivation Affecting the Adherence of Tuberculosis Patients Treatment in Public Health Center

Wiwik Rakhmawaty, Mielka Ratna Kusuma W, Anisa Binta J, Ratna Dwi W

1Postgraduate Student, Department of Health Policy and Administration, 2Lecturer, Department of Health Policy and Administration, Airlangga University, Surabaya, Indonesia

Abstract

The disease of pulmonary tuberculosis that occurs in adults mostly people who get a primary infection that is not handled properly. To achieve healing requires regularity or compliance treatment for every patient. Lack of adherence in the treatment of pulmonary tuberculosis either derived from the motivation or trust of the officers resulted in the treatment of pulmonary tuberculosis is not optimal.

This study aims to analyze the affecting of internal and external motivation toward adherence of pulmonary tuberculosis patients in the treatment of pulmonary tuberculosis in Public Health Center. This study was conducted in Bati-bati Public Health Center, Tanah Laut District, South Kalimantan Province from January to March 2015.

This research uses descriptive quantitative research design. The data used is the primary data obtained by interviewing the respondents by using questionnaires. Large Sample taken from the all of patients with pulmonary tuberculosis who are still undergoing treatment of pulmonary tuberculosis in Bati-bati Public Health as much 40 patients. Data were analyzed used Partial Least Square (PLS) with T-test.

The results of this research are the T-statistic score of internal motivation influence on adherence of pulmonary tuberculosis patients to treatment is 2,714, bigger than T-normal distribution table (1,96), meaning significant, hypothesis 1 accepted. The T-statistic score of external motivation influence on adherence of pulmonary tuberculosis patients to treatment is 3,742, bigger than T-normal distribution table (1,96), meaning significant, hypothesis 2 accepted. Internal and external motivation shows significant affecting to adherence of pulmonary tuberculosis patients in the treatment tuberculosis in Bati-bati Public Health Center, Tanah Laut District.

Keywords: Internal Motivation, External Motivation, Adherence, Pulmonary Tuberculosis

Introduction

Tuberculosis (TB) is a contagious disease that attacks the lungs caused by the germs of the Mycobacterium Tuberculosis. TB is a disease with high morbidity and is very easy to spread in the air through sputum (saliva) which is dumped on the streets by people with pulmonary tuberculosis. Therefore, TB should be handled promptly and carefully if it is found the case in a region.

Pulmonary TB is still one of the world’s health problems although control efforts with the DOTS strategy (Direct Observed Treatment, Shortcourse) have been applied in many countries since 1995[1].

Pulmonary tuberculosis is disease which almost one-third of the world’s population and in most countries in the world can not control TB disease due to the number
of patients who cannot be cured. The World Organization (WHO) in Annual Report on Global TB Control 2010 states that 22 countries are categorized as High Burden Countries (HBC)\[2\].

Indonesia is the country with the first rank among HBC in South East Asean region and is in the order of 5 countries with the highest Tuberculosis load in the world\[3\]. Epidemiologically, pulmonary tuberculosis disease in South Kalimantan since 2008 was in the 3rd position of 10 most diseases with positive TB disease rate of 113 per 100,000 population. In Tanah Laut District in 2010, 250 new patients found positive pulmonary TB (59.07 per 1000 population) with a conversion rate of 81.1% and cure rate of 79.5% and in Bati bati Public Health there were 40 people with pulmonary TB BTA positive where the cure rate is below 80% (79.1%)\[3\][4].

To achieve healing requires regularity or compliance treatment for every patient. Patient motivation is the drive to find a way (effort) to meet the health needs of patients. Or a condition that encourages or makes a person do the work consciously. Motivation is influenced by internal and external factors. Internal factors include: gender, physical character, attitude, experience, expectation, personality, intelligence, responsibility, while external factors include physical environment, family support, economy, culture and health education\[5][6][7][8].

Based on the above description, this research aims to analyze the affecting of internal and external motivation, on adherence of pulmonary tuberculosis patients in the treatment tuberculosis in the Public Health Center.

**Material And Method**

This research uses descriptive quantitative research design that analyzes the influence of internal and external motivation toward adherence of pulmonary tuberculosis patients in the treatment tuberculosis in Bati-bati Public Health Center, Tanah Laut District, South Kalimantan Province.

The data used are primary data obtained by interview with respondents by using questionnaire. It also used secondary data which is the data of pulmonary tuberculosis at Bati bati Public Health Center and Tanah Laut District Health Office 2015.

The population in this study were all residents in Bati-bati, Tanah Laut District who suffered from pulmonary TB and still undergoing pulmonary tuberculosis treatment. The sample or subject of the study in the case group is all of the patients with the results of sputum examination in the laboratory Public Health Center declared positive BTA (suffering from Pulmonary TB). Large Samples taken from the all of patients with pulmonary tuberculosis who are still undergoing pulmonary TB treatment at Bati-bati Public Health as much 40 patients and entirely used as a sample (total sampling).

Data analysis technique used is Partial Least Square (PLS) with T-test. But before the existing data were tested first the validity and reliability with the help of computer programs. PLS is a powerful analytical method because it is not based on many assumptions. PLS as data analysis techniques with smart PLS software version 2.0.M3\[9].

**Findings**

The characteristics of respondents based on Age could be described in Table 1:

**Table 1. The Distribution Frequency of Respondents Characteristics Based on Age**

<table>
<thead>
<tr>
<th>Age</th>
<th>Respondents</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>20-29 years</td>
<td>13</td>
<td>32.5</td>
</tr>
<tr>
<td>30-39 years</td>
<td>7</td>
<td>17.5</td>
</tr>
<tr>
<td>40 years</td>
<td>20</td>
<td>50</td>
</tr>
<tr>
<td>Total</td>
<td>40</td>
<td>100</td>
</tr>
</tbody>
</table>

Based on the table 1 can be seen that most of the respondents studied were patients aged > 40 years. The youngest respondent was 21 years old and the eldest was 70 years old. This is likely due to old age is very vulnerable to various diseases. Body resistance and organ function has began to decline so easily infected a disease especially infectious and degenerative diseases.

From the conceptual framework can be seen which includes Internal Motivation are Responsibility (X\(_{1.1}\)), Desire to heal (X\(_{1.2}\)) and Fear to contagion (X\(_{1.3}\)), while those included in External Motivation are Family support (X\(_{2.1}\)), Environment (X\(_{2.2}\)), Health education (X\(_{2.3}\)). And the factors that affecting the patient’s adherence to treatment pulmonary tuberculosis are Commitment.
(Y1.1), No dropped medicine (Y1.2), Cooperation with the health workers (Y1.3).

The characteristics of respondents by Gender can be seen in the following Table 2:

Table 2. The Distribution Frequency of Respondents Characteristics Based on Gender

<table>
<thead>
<tr>
<th>Gender</th>
<th>Respondents</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>14</td>
<td>35</td>
</tr>
<tr>
<td>Male</td>
<td>26</td>
<td>65</td>
</tr>
<tr>
<td>Total</td>
<td>40</td>
<td>100</td>
</tr>
</tbody>
</table>

Based on the above table it is known that some of the respondents who studied were male. This is probably due to the many men have risk factors such as smoking, lifestyle etc. which is a predisposing factor that can worsen the condition of pulmonary TB disease suffered.

Before the existing data were tested first the validity and reliability with the help of computer programs. PLS is a powerful analytical method because it is not based on many assumptions. PLS as data analysis techniques with smartPLS software version 2.0.M3. Test validity and reliability is the quality of data on the use of research instruments. Test each to know the consistency and accuracy of data collected from the instrument used. Indicators are judged on the correlation between the score items and the score constructs calculated by the PLS application. The reflective size is considered valid if it has a loading value above 0.50 and or T-Statistic above 1.96. The PLS output for convergent validity is shown in the following table 2:

Table 3. Test Results of Validity

<table>
<thead>
<tr>
<th>Internal Motivation</th>
<th>External Motivation</th>
<th>Adherence</th>
<th>Validity</th>
</tr>
</thead>
<tbody>
<tr>
<td>X1.1</td>
<td>0,896</td>
<td></td>
<td>Valid</td>
</tr>
<tr>
<td>X1.2</td>
<td>0,853</td>
<td></td>
<td>Valid</td>
</tr>
<tr>
<td>X1.3</td>
<td>0,873</td>
<td></td>
<td>Valid</td>
</tr>
<tr>
<td>X2.1</td>
<td>0,796</td>
<td></td>
<td>Valid</td>
</tr>
<tr>
<td>X2.2</td>
<td>0,702</td>
<td></td>
<td>Valid</td>
</tr>
</tbody>
</table>

From the table 2 can be seen that the value of loading all items > 0.50. Means it can be concluded all the items meet the good convergent validity. This validity test indicates that all factors influencing Internal Motivation as Responsibility (X1.1), Desire to heal (X1.2) and Fear to contagion (X1.3) are valid and External motivation are Family support (X2.1), Environment (X2.2), Health education (X2.3) also valid.

The next measurement model is composite reliability, a group of indicators that measure a variable has good composite reliability if it has a value greater than 0.70, although it is not an absolute standard.

Table 4. Composite Reliability on Test Reliability

<table>
<thead>
<tr>
<th></th>
<th>Composite Reliability</th>

<tr>
<td>Adherence</td>
<td>0,911</td>
<td>Reliabel</td>
</tr>
</tbody>
</table>

From the PLS output it is shown that all the variables have composite reliability value above 0.70 so it can be concluded that the construct has good reliability.

The basis used in hypothesis testing to accept and reject the hypothesis is from the output of PLS result for inner weights, shown in the following table 4:

The T-statistic score of internal motivation influences on adherence of pulmonary tuberculosis patients to treatment is 2.714, greater than normal T-distribution table (1.96), meaning significant, hypothesis 1 is accepted. The T-statistic score of external motivation influences on loyalty of pulmonary tuberculosis patients to treatment is 3.742, greater than normal T-distribution table (1.96), meaning significant, hypothesis 2 is accepted.

**Discussion**

From the PLS estimation result shows that the T-statistic value of the internal motivation influence the adherence of pulmonary tuberculosis patients in the treatment of pulmonary tuberculosis is 2.714, greater than the normal T-distribution table (1.96), meaning that there is a significant influence between internal motivation variable on affecting of pulmonary TB in treatment at Bati-bati Public Health Center, Tanah Laut District (hypothesis 1 accepted). In accordance with the allegations from the researchers that the internal motivation of self-pulmonary tuberculosis patients themselves can lead to adherence in the treatment of pulmonary tuberculosis because of the results of interviews with some respondents they are eager to recover and fear of contagious to their own families both husband, wife and biological children. Hope to heal is a possibility contagious to their own families both husband, wife and their children. Hope to heal is a possibility that is seen to meet the particular needs of an individual based on past experiences, both from one’s own experience and from others that give rise to a desire to recover from an illness.

The t-statistic value of the path of external motivation influence on the adherence of pulmonary tuberculosis patients in the treatment of pulmonary tuberculosis is 3.742, greater than the normal T-distribution table (1.96), meaning that there is a significant influence between external motivation variable on adherence of pulmonary tuberculosis in the treatment at Bati-bati Public Health, Tanah Laut District (hypothesis 2 accepted). In accordance with the allegations from the researchers that external motivation also affects adherence in the treatment of pulmonary TB. The most influential is the family factor. The family support is a very important social support seen by family members as being accessible to the family in the healing of an illness, but family members perceive that supportive people are always ready to provide help and assistance if needed which leads to motivation to recover from a disease.

Data from the results of the study that independent variables studied showed significant effect on adherence of pulmonary tuberculosis patients to the treatment of pulmonary tuberculosis is internal motivation and external motivation. From the above it can be seen clearly that which affects the adherence of patients with pulmonary tuberculosis in the treatment of pulmonary TB in Bati-bati Public Health Center, Tanah Laut District, South Kalimantan Province is an internal motivation either in the form of responsibility, the desire to heal and fear of contagion the disease to family members others, as well as external motivation in the form of family support, environment and health education who generate adherence in the treatment of pulmonary TB. With the results of this study is expected to the health workers who holds the pulmonary TB program more inculcate the character of motivation in pulmonary tuberculosis patients to recover and motivate the family of pulmonary TB patients to continue to support pulmonary TB treatment because long-term treatment.

**Conclusion**

Internal motivation (responsibility, desire to heal and fear of contagion) shows significant affecting to adherence of pulmonary tuberculosis patients in the treatment of pulmonary tuberculosis in Bati bati Public Health Center, Tanah Laut District.

External motivation (family support, environment and health education) showed significant affecting to adherence of pulmonary tuberculosis patient in pulmonary tuberculosis treatment at Bati bati Public Health Center, Tanah Laut District.

In relation of the results of this study is expected to the health workers, especially those who handle pulmonary TB programs at Public Health Center in order to improve the service better. For example with internal character motivation and motivate family of patient to continue to support patient especially in the case of adherence to treatment. In addition, health workers can also increase counseling from the way of taking medication and side effects from the drug that can cause patients not adherence again in taking pulmonary TB drugs.

Abstract

University students are prone to have an insufficient sleep and tend to feel sleepiness during daytime, in which may impact cognitive function; impair the psychological health and academic performance. This study aimed to compare the prevalence of daytime sleepiness between medical and non-medical students in Management & Science University (MSU)–Shah Alam campus and to investigate the relationship between daytime sleepiness among university students towards their academic performance. A cross-sectional study was carried using Epworth Sleepiness Scale (ESS) was to identify and evaluate the effect of daytime sleepiness on academic performance. A total of 152 undergraduate students ranging from the age of 19 to 27 years were participated and completed the questionnaires with a response rate of 76%. Statistical analysis was done using Pearson’s Chi-Square Test. There were 56.6% of participants showed an abnormal score of ESS (>9) in both groups. Medical students reported having a high prevalence of daytime sleepiness (52.3%) whereas non-medical students showed slightly less prevalence of daytime sleepiness (47.7%). The results obtained might be due to the medical students have exposure to the hectic and excessive academic load causing the need to study until late at night. Poor academic results were revealed among 84 (55.3%) university students. A statistically significant association was observed between daytime sleepiness and lower academic performance (p<0.001). Medical students have a higher prevalence of daytime sleepiness compared to non-medical students.

Keywords: Daytime sleepiness; Academic performance, Medical students, non-medical students.

Introduction

Inadequate sleep is highlighted to be a public health matter that has relation to medical effects. Sleep has been found to be neglected from the priority list of most individual especially students. The study on daytime somnolence has been defined that it is a sudden, uncontrollable compulsion to fall asleep during daytime causing weak of alertness and concentration, a decrease of motivation and a high level of stress (¹). College students are highlighted as a unique population with their cultural sleep-related disorders (²). Sleep deprivation is common among university students, which may result in the sleep disorder like excessive daytime sleepiness (³). Students sleep late at night to do their tasks which results
in inadequate sleep hygiene. Furthermore, students often use technology and substances that compromise sleep quality and quantity\(^3,\,4\). Untreated sleep disorder may develop numerous negative consequences\(^4\).

Circadian sleep rhythm disorder is a delayed sleep phase syndrome occurred among young adult\(^5\). Smoking at night to keep the person stays awake can be seen to be trending among students. This habit significantly contributes to inadequate of sleep hours and affects academic performances\(^6\). Reduction or alteration of sleep at night has been associated with excessive sleepiness and impaired academic performance\(^7\). Analysis of the role of sleep showed four long-term memory systems which include procedural memory, perceptual representation system, semantic and episodic memory\(^8\). It requires either non-rapid eye movement (NREM) or rapid eye movement (REM) sleep or needs both of the sleep stages to consolidate memories\(^7\). Sufficient sleep is pivotal to physical health and also mental development for learning and memorization ability. Adequate sleep may initiate the function of cognitive systems for the better aspects of life and performance\(^8\).

The tendency of committing errors, especially among medical students while assessing the patients may exist\(^9\). To the best of our knowledge, many researchers have done the study regarding sleep disorder and daytime sleepiness, but only focusing on a particular group, for example only medical students. With this study that has been conducted, it helps to compare the degree of daytime sleepiness among medical students and non-medical students with the academic performance.

**Materials and Method**

This study is a descriptive correlation study that investigated the relationships between the two variables of daytime sleepiness and academic performance. Apart from that, it has been designed to predict the relationship between daytime sleepiness and academic performance. It indicates the outcome within a specific range of sleep disorder that correlated with the scores of academic achievements.

This cross-sectional study was carried out between May to June 2016. The study population comprised of the students enrolled in the main campus of Management & Science University (MSU), Shah Alam, Selangor, Malaysia at this time. The inclusion criteria of this study involved the current MSU male and female students, students enrolled in bachelor program, mentally stable and cooperative. The study subject must be within 19 to 27 years of age. The exclusion criteria comprise MSU staffs and outsiders, and those who refuse to cooperate.

A quota sample of surveys has been administered to 152 students in which these participants consisted of male and female students ranging from 19 to 27 years; each group compromised 76 students of medical and 76 non-medical students.

Data were collected by using the structured questionnaires that comprised of questions covering all of the study variables on socio-demographic, lifestyle, sleep pattern characteristics of medical and non-medical students and their examination results. Academic performance was analyzed with the previous academic grade results. The first section was socio-demographic part with some of the response choices of yes or no, while other variables need to be marked based on its categories. Section 2 is the Epworth Sleepiness Scale (ESS). This questionnaire is primarily used to determine the daytime sleepiness among the respondents\(^3\). It is a well-validated eight-item questionnaire\(^{10,\,11}\).

**Results**

There were 152 students responded and completed this survey from the total population of 200 students with a response rate of 76%. Table 1 summarizes the demographic characteristics and other study variables.

Among the 152 participants, 86 were diagnosed as daytime sleepiness representing a prevalence of 56.6%. There were 66 (43.4%) of the respondents do not have daytime sleepiness. As being derived from overall 152 respondents, both of the group, which are medical and non-medical students were being divided into same quantity, 76 students in each group by using quota sampling method.

Medical students reported having a high prevalence of daytime sleepiness (52.3%) whereas non-medical students showed slightly less prevalence of daytime sleepiness (47.7%).

The findings in Table 2 revealed those who came with a good performance came with only 19.1% of daytime sleepiness while 80.9% do not have daytime sleepiness. It showed a weak academic achievement was greatly obtained from those who experienced daytime sleepiness (86.9%).

A statistically significant difference was found between high scoring of ESS (Daytime
Sleepiness) and poor academic performance with regards to excessive daytime sleepiness
(P<0.001) as shown on Table 3.

Discussion

Medical students sleep less than general populations. Their average nighttime sleeping hours are similar to those with insomnia (12). Also, daytime sleepiness, insomnia, and insufficient of sleep (less than seven hours per night) are associated with psychiatric disorders. In this study, daytime sleepiness was detected in 45 (52.3%) medical students compared to non-medical students with slightly less (47.7%) having daytime sleepiness.

The data of this study show a high percentage of daytime sleepiness (52.3%) among medical student responders compared with the result of the study conducted in International Medical University, Malaysia (35.5%) (13). Non-medical students have slightly less percentage of (47.7%) of daytime sleepiness. This variation could be due to the difference in the cut-off value of the Epworth Sleepiness Scale. In the current study, the standard means value is 9; while the cut-off value in the study by Zainilawati et al. was 11. The medical students have to be on their morning and
evening educational and clinical assignments. Also, they study the medical books until late at night (14, 15). Utilization of memory and brain causing the medical students to feel fatigue not only in physical part but also mental part, in which give implication towards the sleep-wake cycle. The syllabus learned by those non-medical students might be straightforward and light and the students were not under pressure to handle the situations as those in medical students who need to face weekly test and examinations. The medical students whowill be the medical staffs later, this sleeping disorder should be prevented to reduce the errors while handling the patients and during consultation or surgery (16).

The association between sleep disorder of daytime sleepiness and academic performance among medical and non-medical students has not been investigated thoroughly. Most of the studies only conducted for a particular group such as in the earlier study by Johns et al (10) that carried out the study among medical students. The findings earned in this study showed a significant association between academic performance and daytime sleepiness. It was supported by another study in which sleep disorder could give implication on the school result. Abdulghani reported a significant relationship between ESS scores and academic achievement (P=0.002) (17). The university students were likely to complain having a sleeping disorder in this study for around 56.6% of students evaluated of having daytime sleepiness.

Sleep can have a role in facilitating the learning and memory processes. Conversely, sleep deprivation and fragmentation usually impair these functions (18). The previous study expressed the association between education and ESS score. Stated that higher ESS score was gained from people with both low and high level of education, compared with those people of medium education level. A few studies have displayed a significant relationship between daytime sleepiness and academic result. In this study, it was found 56.6% of all the participants suffered from daytime sleepiness. Thus, the study revealed a clear correlation between academic performance and daytime sleepiness (P<0.001). In the current study, a statistically significant difference (P<0.001) was found between daytime sleepiness and poor academic performance; this result is in agreement with previous study (1), which concluded that 68.5% of 108 Sudanese medical students that were studied had daytime sleepiness. Sleeper students did not achieve excellence in the previous examination; therefore, the requirement to improve awareness among medical students and teaching staffs about sleep education and sleep hygiene in addition to implementing the best indicator in scheduling duty hour for the lecture. A highly statistically significant difference between the good students and the weak students was concluded with regards to the feeling of insufficient sleep (P<0.001) and sleeping less than five hours per night (19). This study concluded that sleep deprivation (less than five hours) became part of medical students’ exposure and is associated with poor work-related performance, mood and medical errors.

These findings provide health educators with good sleep as an additional positive reason to promote engagement in health behaviors (20). Practical applications of these data for health lecturer on university campuses can conduct. For instance, health experts could continue with the implementation of programs related to healthy habits with the correlation between sleep and academic performance benefits to document the importance and value of these programs. Also, these results should be relevant to educators, administrators, parents, and students. These understanding of the findings may contribute to another connection of health behaviors for better academic achievement. Disturbances of sleep-wake behavior can be affected by academic demands, depression during examination week, social schedule, and insufficient sleep education.

There is a great concern about the relationship between daytime sleepiness and academic achievement; therefore, screening for causes of sleep deprivation and daytime sleepiness among medical and non-medical students is highly recommended. Measures to improve living conditions, and educate about good sleep hygiene are needed.

**Conclusion**

A high prevalence of daytime sleepiness was reported in this study on medical students compared to non-medical students. The daytime sleepiness was measured using ESS comprising the score more than nine as abnormal. Daytime sleepiness significantly affects the academic performance among medical and non-medical students of MSU Shah Alam. Education and awareness on the importance of enough sleep hours and the quality of the sleep could aid in improving the academic achievement and along with the
psychological and physical health of an individual. As the recommendation, further research on a larger scope regarding daytime sleepiness with its relations towards academic achievements in both groups of students, medical and non-medical need to be carried out due to its lack of previous investigations. To conclude, this present study is conducted to be as the reference with the hope that awareness of daytime sleepiness among university students will arise.

Impact of Elevated Second Trimester Maternal Serum Alpha-Fetoprotein on Pregnancy Outcome – A Prospective Observational Study

Nivedhana Arthi P1, Jalakandan B2, Thiruselvakumar D3, Prabhakar Reddy E4

1Assistant Professor in OBG, 2Associate Professor in Anaesthesiology, 3Associate Professor in Community Medicine, 4Professor in Biochemistry & Central Lab Head, Sri Lakshmi Narayana Institute of Medical Sciences, Puducherry

Abstract

Introduction: The major goal behind prenatal screening is to identify and intervene in high risk pregnancy. Measurement of second trimester maternal serum alpha-fetoprotein (MSAFP) has been shown to be useful in screening both for Aneuploidies and neural tube defects. Additionally in Pregnancies with normal fetus, high levels of MSAFP is associated with increased risk of adverse pregnancy and fetal outcome. Aim: To determine the association between the second trimester MSAFP and adverse pregnancy outcome. Method: This Prospective observational study was conducted in 200 antenatal women of gestational age between 14-24 weeks, with singleton pregnancy. Determination of maternal serum AFP levels was carried out and were followed till delivery. Fetal outcome was reported in terms of live birth, still birth, neonatal death. Results: The mean age of study subjects with MSAFP≤2MoM was slightly higher compared to those with MSAFP>2 MoM and the difference was not statistically significant (P>0.05). The frequency of pregnancy outcomes were as following; 10(5%) Pre-eclampsia, 20(10%) Preterm labour, 7(3.5%) PROM, 18(9%) Oligohydramnios, 2(1%) Still birth. There were significant correlation between Preterm labour, Pre-eclampsia, Oligohydramnios and higher MSAFP levels and was statistically significant. But correlation between PROM, Still birth and MSAFP levels were not significant. Conclusion: Unexplained elevated second trimester MSAFP is associated with adverse pregnancy outcomes such as preeclampsia, oligohydramnios and preterm labour. So it would be worthwhile for screening pregnant women in second trimester for MSAFP, as it would help to identify high risk pregnancies.

Keywords: Alpha-fetoprotein, prenatal screening, preeclampsia, oligohydramnios, still birth, preterm labour

Introduction

Prenatal screening is now an established part of routine Antenatal care. The major goal behind it is to identify and intervene in high risk pregnancy. Maternal serum Alpha-fetoprotein(MSAFP) Screening is one of them. Alpha-feto protein (AFP) is a glycoprotein, which is synthesized early in gestation by the fetal yolk Sac and later by the fetal gastrointestinal tract and Liver. AFP is found in steadily increasing quantities in maternal serum after 12 weeks and reaches a peak between 28 and 32 weeks.

Increased maternal serum levels of AFP are the consequence of increased amniotic fluid concentration in association with fetal defects; increased transfer from fetal to maternal circulation as a consequence of Placental damage and increased production in the mother from germ cell tumour, hepatocellular carcinoma and metastatic cancer in Liver. In normal Pregnancy, serum AFP concentration is affected by gestational age and maternal characteristics, including maternal weight, racial origin and cigarette smoking. Therefore for the effective use
of serum AFP measurements in risk assessment, these variables need to be taken into account which can be achieved by standardizing the measured levels into multiples of the normal median values (MoM).

Measurement of MSAFP during the second trimester of pregnancy has been shown to be useful in screening both for Aneuploidies and neural tube defects\(^7\)-\(^8\). Additionally in Pregnancies with normal fetus, high levels of MSAFP is associated with increased risk of adverse pregnancy and fetal outcome, including fetal death, Pre-eclampsia, Preterm labor, low birth weight and fetal growth restriction\(^3\)-\(^10\)-\(^13\). Also a raised MSAFP during second trimester of pregnancy is one of the best biochemical Predictor of the risk of unexplained still birth\(^14\).

The aim of this study was to determine the association between the second trimester MSAFP and adverse pregnancy outcome.

**Materials and Method**

This Prospective observational study was conducted in 200 pregnant women attending Outpatient department in Obstetrics and Gynaecology, Sri Lakshmi Narayana Institute of Medical Sciences, Pondicherry. The antenatal woman of gestational age between 14-24 weeks, with singleton pregnancy were included in the study. Dating was based on the last menstrual period or an early sonogram. Patients with chronic hypertension, multiple pregnancy, molar pregnancy, chromosomally abnormal fetus, diabetes, chronic renal disease, autoimmune disorders, thrombophilias, family history of diabetes mellitus, hypertension, cardiovascular disease, and history of pre-eclampsia were excluded from the study. Determination of serum AFP levels in maternal serum was carried out. All these patients were followed till delivery and fetal outcome was reported in terms of live birth, still birth, neonatal death.

**Statistical Analysis**

The data were presented as Mean ± Standard Deviation. Statistical analysis were done by using Microsoft Excel and SPSS for windows version 11.5 (SPSS,Inc.,Chicago). P value<0.05 was considered statistically significant.

**Results**

In this study 200 pregnant woman with gestational age between 14-24 weeks were evaluated.

The mean age of study subjects with MSAFP≤2MoM (22.73 years) was slightly higher compared to those with MSAFP>2 MoM (22.28 years). However application of Chi-square test showed that this difference was not statistically significant (P>0.05).

The frequency of pregnancy outcomes were as following; 10(5%) Pre-eclampsia, 20(10%) Preterm labour, 7(3.5%) PROM, 18(9%) Oligohydramnios, 2(1%) Still birth.

There were significant correlation between Preterm labour, Pre-eclampsia, Oligohydramnios and higher MSAFP levels and was statistically significant.

But corelation between PROM, Still birth and MSAFP levels were not significant.

**Discussion**

There is a fundamental difference between screening and diagnostic tests. The aim of Prenatal screening is limited to the identification from among apparently healthy pregnancies to those at high enough risk of a given outcome to warrant the next step: an expensive or hazardous diagnosis; another secondary screening test; or preventative action. Markers are the building blocks of screening tests; the term itself implies the lack of a definitive result that characterizes screening in comparison to diagnosis. Maternal marker screening has advanced rapidly since AFP was first used to screen for fetal neural tube defects.

AFP is a glycoprotein, synthesized primarily by the fetal liver and yolk sac. It is also produced to a lesser extent by the fetal gastrointestinal tract. AFP synthesis by the proliferating fetal liver actually increases through the 20th week of gestation, after which it remains fairly constant until 32nd week. AFP is excreted in fetal urine and transported to maternal serum through the placenta or by the diffusion across fetal membranes.

In our study, unexplained high levels of MSAFP had been associated with preeclampsia, preterm labour, oligohydramnios. In a prospective study conducted by Konachuk et al, 35% of pregnancies with unexplained increased AFP level had at least one adverse perinatal outcome. Elevation of MSAFP was related to increased transition from fetomaternal circulation due to the placental feto maternal surface damage. Similarly, Wald et al reported that an increased incidence of low birth weight, Prematurity and perinatal death in pregnancies with AFP level above 3MOM. Bernstein et al and Kuo et al had also reported that woman with elevated MSAFP level had an increased incidence of Pre-eclampsia, Preterm labour, fetal growth retardation and fetal death.

In our study, the pregnancy that went on to develop Preeclampsia, the MSAFP levels were significantly raised. And the difference was statistically very significant. Waller et al, Williams et al, Bhattacharjee et al also had confirmed the association of unexplained MSAFP elevation with preeclampsia.

Similarly, there was significant association between elevated MSAFP levels and preterm labour in our study and was statistically significant. Neggers et al in their study on evaluation of relationship of MSAFP to preterm labour, had concluded that MSAFP levels greater than 90th percentile significantly increased the risk of preterm labour. Similar observations were also made by Rebecca Allen et al and Kuo et al.

Though MSAFP levels were raised in patients with PROM, the difference was not statistically significant. But Simpson et al had observed that women with PROM showed elevated MSAFP levels. Efficient antenatal care, early identification of patients at risk for PROM and subsequent management in our centre would have reduced the incidence of PROM even in patients with high MSAFP levels.
There was a very significant correlation between MSAFP levels and oligohydramnios and was statistically very very significant. This finding was consistent with the studies by Konachuk et al\textsuperscript{20} and Huerta – Enochian et al\textsuperscript{30}.

In our study, there was no significant association between the levels of MSAFP and stillbirth. But Waller et al\textsuperscript{31} and Cusick et al\textsuperscript{32} had found that women with high MSAFP levels had a very high risk of stillbirth. Probably the less number of cases (1%) of stillbirth in our study was not enough to evaluate the association.

**Conclusion**

Unexplained elevated second trimester MSAFP is associated with adverse pregnancy outcomes such as preeclampsia, oligohydramnios and preterm labour. So it would be worthwhile for screening pregnant women in second trimester for MSAFP, as it would help to identify high risk pregnancies.

But screening for MSAFP in second trimester seems to be of little value in predicting PROM and stillbirth. However further extensive studies are needed to validate our conclusion.

Menstrual Disorders: A Comprehensive Review

Haya Al-Fozan¹, Jipi Varghese², Aouhood Alharbi²

¹Vice President Female Affairs, ²Lecturer College of Nursing, King Saud bin Abdulaziz University for Health Sciences Riyadh, Kingdom of Saudi Arabia

Abstract

Menstrual disorders are the most common gynaecological issues encountered by women in their reproductive age and which can affect personal, familial and social life. The World Health Organization recently reported that 18 million women aged 18-23 years perceive their menstruation to be extreme.¹ The first menstruation or menarche occurs at around 11 to 15 years of age with an average of 13. Literature review from numerous studies indicates that starting from the third year after menarche, the interval between bleeding ranged from 21-34 days, with a blood flow lasting 3 to 7 days and a mean blood loss of 35 ml (range of 5-80 ml).²

The menstrual cycle is divided into two phases namely follicular and luteal phase. The first one follicular phase approximately 14-21 days commences with onset of menstruation and ends on the day before the luteinizing hormone (LH) surge. The second luteal phase begins on the day of LH and ends at the onset of the next menstruation 14 days.³

There are many types of menstrual disorders examples are amenorrhea, abnormal uterine bleeding, dysmenorrhea, and premenstrual syndrome are particularly common in adolescent girls.⁴, ⁵, ⁶ This article aimed at enhance the understanding of the common menstrual disorders like abnormal uterine bleeding, amenorrhea, dysmenorrhea, and premenstrual syndrome prevalence, causes, diagnosis, and management.

Keywords: Menstrual Disorders, Dysmenorrhoea, Amenorrhoea, Abnormal uterine bleeding, Premenstrual syndrome.

Introduction

Menstruation is a physiological phenomenon and this has a considerable effect on the health status and the quality of life of women. Deviation from normal menstruation is observed among young women.⁷ Menstrual disorders is described as a gynaecological morbidity during the reproductive age of women all around the world.⁸ Globally reproductive ill health constitutes 32% of total burden of disease among the reproductive age group women.⁹

The common abnormalities of menstruation includes dysmenorrhea, premenstrual syndrome, abnormal vaginal bleeding, amenorrhea etc.¹⁰ Premenstrual syndrome (PMS) and dysmenorrhoea were most prevalent among adolescent girls which accounted for almost 20-90% and the prevalence of PMS was found to be 47.8%.¹¹, ¹² Menstrual disorders are found to be associated with physical and psychological factors.¹³

Aetiology of Menstrual disorders

1. Physiologic: adolescence, perimenopause, lactation and pregnancy
2. Pathologic
   a. Hyperandrogenic
   b. Hypothalamic
   c. Thyroid disease
   d. Primary pituitary
   e. Premature ovarian failure
   f. Medications/herbal supplements

Introduction

AUB refers to the uterine bleeding of abnormal volume, duration, regularity or frequency.²⁰ AUB is reported to occur in 9 to 14% women between menarche and menopause²¹, ²² and may have a significant impact on their physical, social, emotional quality of life.²³
The commencement of conflicting terminology for AUB dates back to the late 1700s by William Cullen, Professor of Physic at the University of Edinburgh, Scotland. The term dysfunctional uterine bleeding was invented but certainly not clearly defined by Graves 1935. Menstrual Disorders Working Group within the International Federation of Gynecology and Obstetrics (FIGO) which was named as the Menstrual Disorders Committee who developed internationally supported recommendations on definitions and terminology for AUB. AUB have been conventionally articulated in terms like Menorrhagia, Metrorrhagia, Polymenorrhoea and Oligomenorrhoea presently the nomenclature to describe AUB has been classified and approved by the International Federation of Gynaecology and Obstetrics (FIGO) Executive Board as a FIGO classification system PALM-COEIN (2011).

Figure 1: PALM-COEIN

Acute AUB is defined as an occurrence of bleeding that is of sufficient quantity requiring immediate intervention to prevent further blood loss in a woman of reproductive age who is not pregnant. Chronic AUB is defined as bleeding from the uterine corpus which is abnormal in duration, volume, and/or frequency and has been present for the majority of the last 6 months. The most common cause of AUB are structural uterine pathology (eg, fibroids, endometrial polyps, adenomyosis), ovulatory dysfunction, disorders of hemostasis or neoplasia.

Diagnosis

- Obtain a thorough medical history focusing on age, details of bleeding episodes, past menstrual, obstetrical, gynaecological and medical history, bleeding disorders, sexual and reproductive history, overweight, obesity, hypothalamic or adrenal disorders, thyroid dysfunction, impact on quality of life and medication. History of obstetric or gynaecologic surgery and asking the women regarding the use of contraceptive methods.

- Physical examination includes focusing on signs of blood loss and estimating anaemia, BMI. Pelvic and speculum examination.

- Lab Investigation- Pregnancy test, complete blood count, blood type and cross match, Prolactin hormone, E2, FSH, TSH, Androgen levels, oestrogen levels sexually transmitted diseases and coagulation profile, thyroid disorders, liver disorders, sepsis, von willebrand factor antigen, and leukemia. Imaging studies includes MRI, trans-vaginal ultrasonography, hysteroscopy and endometrial biopsy.

Management

Management include pharmacological, surgical and radiological approaches.

Goals of management:-

- Regulations of menstrual cycles
• Reduce blood loss
• Improve the quality of life

The expert organizations The American College of Obstetricians and Gynaecologists (ACOG), 43-46 American Academy of Family Physicians (AAFP), 47 and National Institute for Clinical Excellence (NICE) 48 recommended to include oral contraceptives, progestins, NSAIDs, levonorgestrel IUD, and anti-fibrinolytics for management of irregular bleeding and AUB.

Pharmacological approach:-

The Pharmacological approach for AUB is based on the action of hormones and other inflammatory mediators on the endometrium, in addition to the hemostatic control of the bleeding.49-50 Pharmacologic therapies used for treatment of AUB are estrogens, progesterone, combination (estrogen and progesterone) hormonal formulations, non-steroidal anti-inflammatory drugs, antifibrinolytics, and gonadotropin releasing hormones. Medical interventions are generally considered first line treatment.51-52

Combined Oral Contraceptives 53-57

**Dosage**

**Acute bleeding**

Contraceptives with ethinyl estradiol 30 mcg or 35 mcg 1 tablet/day, every 8 hours, for 7 days, followed by 1 tablet/day for 3 weeks.

**Chronic bleeding**

Combined oral, combined transdermal contraceptives or combined vagina l ring - all according to the package insert.

**Oral progestogen 53-57**

**Dosage**

**Acute bleeding**

Medroxyprogesterone acetate 20 mg, every 8 hours, for 7 days.

**Chronic bleeding**

Oral medroxyprogesterone acetate (2.5-10 mg), or norethisterone acetate (2.5-5 mg), or megestrol acetate (40-320 mg) at the dose recommended in the package insert, or micronized progesterone (200-400 mg), dydrogesterone (10 mg).

**No ovulatory dysfunction:** 1 tablet/day from the 5th to 26th day of the cycle or continuously.

**With ovulatory dysfunction:** adjust dose/day, use for 2 weeks every 4 weeks.

**Levonorgestrel-releasing intrauterine system 53-57**

**Chronic bleeding**

Insert the levonorgestrel - releasing intrauterine system every 5 years, with release of 20 mcg/ day.

**Depot medroxyprogesterone acetate 53-57**

**Chronic bleeding**

150 mg intramuscularly injected every 12 weeks

**Gonadotropin-releasing hormone analog 53-57**

**Chronic bleeding**

Leuprolide acetate (3.75 mg monthly or 11.25 mg quarterly) intramuscularly, or goserelin (3.6 mg monthly or 10.8 mg quarterly), or sub dermal.

**Non-steroidal anti-inflammatory drugs 58**

**Dosage**

**Chronic bleeding**

Ibuprofen 600 to 800 mg, every 8 hours, or mefenamic acid 500 mg every 8 hours.

Contraindication: Pregnant, gastrointestinal bleeding, inflammatory bowel disease, severe asthma, use after CABG procedure, renal disease, CVD, CHF61

**Efficiency-** Moderate

**Tranexamic acid Anti-fibrinolytic agents 59,60**

**Dosage**

**Chronic bleeding**

US Food and Drug Administration (FDA): 1.3 g, 3 times a day, for up to 5 days, or 10 mg/ kg intravenously (at a maximum dose of 600 mg/dose, every 8 hours, for 5 days (in cases of bleeding without structural lesion).
Surgical approach

Surgical options are classified as first-generation (hysteroscopic) and second generation (non-hysteroscopic) endometrial ablation, myomectomy and hysterectomy, dilation and curettage (D&C), endometrial ablation, uterine artery embolization. Reports concluded that uterine artery embolization and endometrial ablation can successfully control acute AUB. Hysterectomy is only considered in case of uncontrolled heavy bleeding and for the patient who do not respond to medical management.

Comparison of Ultrasonographic and Doppler Mapping of the Intervillous Circulation in Normal and Abnormal Early Pregnancies

Ahmed Rifat Shakr¹, Suha AbdulJaleel Wadi¹, Farah Muayyed Gebriel¹
¹Senior Specialist in Obstetrics and Gynaecology, AL-Elwiya Maternity Teaching Hospital, Baghdad, Iraq

Abstract

Objectives: To assess the value of transvaginal ultrasonography and transvaginal colour Doppler imaging in characterizing the Intervillous circulation in normal and abnormal pregnancy.

Design: cross-sectional study. Setting: AL-Elwiya Maternity Teaching Hospital, Baghdad-Iraq. Main outcome measures: Comparison of detection the moving echoes in the Intervillous circulation with grey-scale and colour Doppler imaging in normal and abnormal early pregnancies.

Subject and Method: 162 pregnant women fulfilled the criteria for the inclusion in this study were evaluating for diagnosis and fate of pregnancy. All of the pregnant women were subjected to transvaginal ultrasound and transvaginal colour Doppler imaging examination only once time by using 5-MHz curve liner transvaginal probe, with pulsed colour and power Doppler facilities and real time grey-scale ultrasound were used to evaluate the placenta anatomy and to detect the moving echoes inside the Intervillous space at peripheral and central areas. 67 pregnant women has been subjected to both above examinations at 7-9 weeks, 53 of total 162 at 10-11 weeks and the rest 42 at 12-14 weeks of pregnancy.

Results: A significant different distribution of blood flow was found between normal and abnormal pregnancies at 7-9 weeks and 10-11 weeks but not at 12-14 weeks. There is no difference in the use of the transvaginal ultrasound and transvaginal colour Doppler imaging, regarding the efficiency of the equipment but it remain dependable on the efficiency of the sonographist.

Conclusion: Early prediction of pregnancy that ended with abortion during the first trimester for any reason (Genetic, Immunological, Infectious) can be studied by simple methods like transvaginal ultrasound (gray-scale) and transvaginal colour Doppler ultrasound and useful for the prediction of pregnancy fate.

Keywords: Intervillous circulation, transvaginal ultrasound (TVUS), transvaginal colour Doppler images (TVCDI), fate of the pregnancy.

Introduction

The early placental development create a low resistance arteriolar vascular system. The trophoblastic plugs are thought to act as valves and restrict the flow velocity of the spiral arteries in order not to damage the developing placental membrane, also develops in a hypoxic environment which stimulate trophoblast proliferation and inhibit trophoblast invasion. At about 10-12 weeks’ gestation, true Intervillous circulation is established and there is an increase in placental PO₂ Levels. After 11 weeks of pregnancy the primary chorionic villi develop and begin to branch to form secondary chorionic villi and the lined mesenchymal cells, which differentiate into arteriocapillary networks. During the first trimester of pregnancy, the growing embryo and its placenta are completely separated from the maternal circulation. After 12 weeks, the trophoblastic plugs in the spiral arteries, no longer obliterate the uteroplacental arteries and
real circulation is established \([1, 3, 7]\). Burton et al., examined the Boyd Collection, showed that there was significant blockage of the maternal spiral arterioles by trophoblasts at points of contact with the Intervillous space between 6 and 8 weeks and gradually eliminated between 8 and 12 weeks of gestation \([8]\), the first trimester low-flow concept has not been universally accepted \([9, 10, 11]\). Jauniaux et al. \([12]\) report a significant increase in placental Intervillous oxygen tension, and hence maternal perfusion of the placenta, between 8 and 12 weeks of gestation. Burton and colleagues \([8]\) had offered the presence of dilated endometrial glands below openings to the Intervillous spaces. It is well known that the endometrial glands of early pregnancy are characterized by hypersecretion \([13]\). Pijnenborg et al. proposed a two-wave hypothesis for trophoblast invasion an initial interstitial invasion in the first trimester followed by endovascular invasion in the second trimester. Physiological changes also seen in the region that the interstitial trophoblast were able to modify the maternal arteries indirectly, presumably via paracrine action, simply by surrounding these vessels \([14]\). Matijevic et al. \([15]\) using transabdominal colour flow and pulsed Doppler imaging, showed that these changes were complete at around 17 weeks of gestation and that impedance to blood flow is lowest in the uterine arteries in the central area of the placental bed. These findings were supported by Jaffe and Woods \([16]\), which studied 46 women from 6 to 12 weeks of pregnancy by using transvaginal colour Doppler ultrasonography. Some authors studied a group of normal pregnancies from 7 to 12 weeks’ Gestational age to evaluate the utility of colour Doppler sonography of the uteroplacental circulation in predicting the outcome of first trimester pregnancies. They described a higher incidence of abortions among pregnancies that showed a greater resistance index (RI) in the retro- trophoblastic region. They also detected blood flow in the Intervillous space between 7 and 12 weeks \([17]\).

**Materials and Method**

**Subjects:**

The study was conducted on pregnant women (162) attending the Obstetrics and Gynecology Department at Al-Elwiya maternity Teaching Hospital and from private clinic. The study was extended from 1/7/2014 to 1/7/2015.

The pregnant women evaluated for the following information:

* Diagnosis of pregnancy is based on the last menstrual period, pregnancy test and abdominal ultrasound in the outpatient clinic.

* Duration of pregnancy: The Gestational age was determined by the initial data of the last menstrual period, crown-rump length up to 14 weeks, biparietal diameter were used for evaluation the evolution of the pregnancy.

* Fate of pregnancy: the evolution of the pregnancy was assessed by clinical examination, abdominal ultrasound, TVUS and TVCDI to confirm the viability of the fetus or absence of embryo.

Criteria for exclusion from the study were as follow:-

*chronic maternal diseases [pneumopathies, hypertension, autoimmune diseases and diabetics Mellitus].

*Myometrial pathologies, uterine malformations.

*patients who had undergo surgical intervention through the present gestation.

*Echo graphic embryo malformation.

*Multiple gestation.

**Transvaginal ultrasound and transvaginal colour Doppler imaging examination:**

The examinations of the intraplacental circulation were performed to all pregnant women 162 for one time during their pregnancy in 67 pregnant women (7-9 week), 53 pregnant women (10-11 week), and 42 pregnant women (12-14 week), by using a 5-7.5 MHz Curvilinear transvaginal probe with pulsed colour and power Doppler facilities. In each Case, moving echoes inside the Intervillous space was detected, at the periphery and the central of the uteroplacental circulation. A minimum blood flow velocity detectable of 3.7 cm/s for color Doppler and 0.4 cm/s for power Doppler.

**Statistic**

The SPSS program (statistical package of social science) standard version, Version 9.1\(^{\text{th}}\), 2012 by SAS. Inst. Inc. Cary. N.C. USA, was used. It included application of the Chi Square test to assess the degree of significance between different variable P [0.05] it also included application of the frequency of the different variables and cross.
Results

The transvaginal ultra sound findings and the transvaginal colour Doppler findings:

The TVUS and TVCDI with \([P +ve, C-ve]\) 73 (45.1\%), \([P -ve, C+ve]\) 68 (41.9\%), \([P +, C+ve]\) 21 (13\%) and as shown in Figure (1).

Figure (1): The transvaginal Ultrasound finding, \(P=\) peripheral, \(C=\) Central.

The classification of the pregnant women according to the weeks of pregnancy:

Out of the 162 pregnant women, 67 (41.4\%) had the TVUS and TVCDI at 7-9 weeks of pregnancy, 53 (32.7\%) at 10-11 weeks of pregnancy, and the rest 42 (25.9\%) had the examinations at 12-14 weeks of pregnancy as shown in Figure (2).

Figure 2. The classification of the pregnant women according to the weeks of pregnancy.

The relation between the TVUS, TVCDI findings and fate of pregnancy according to weeks of pregnancy:

At 7-9 week:

Out of 162 pregnant women, 67 (41.4\%) pregnant women had TVUS, TVCDI: 39 (58.2\%) with \([P +ve, C-ve]\) all of them reached to full term, 28 (41.8\%) with \([P -ve, C+ve]\) all of them ended with abortion. No pregnant woman with both \([P+ve, C+ve]\) at this period of pregnancy. \([P = 0.001]\) as show in figure (3).

Figure (3): The \% of the pregnant women with TVUS and TVCDI findings at 7-9 weeks.

At 10-11 week:

Out of 162 pregnant women, 53 (32.7\%) pregnant women had TVUS and TVCDI: 29 (54.7\%) women were with \([P +ve, C-ve]\) all of them reached to full term. 23 (43.4 \%) were with \([P-ve, C+ve]\) all of the them ended with abortion. And only one 1.9\% with \([P+ve, C+ve]\) as the pregnant woman ended with abortion. \([P = 0.001]\) as show in figure (4).

Figure (4): The \% of the pregnant women with TVUS and TVCDI findings at 10-11 weeks.

At 12-14 week:

Out of 162 pregnant women, 42 (25.9\%) pregnant women had the TVUS, TVCDI: 5 (11.9\%) with \([P +ve and C –ve]\) and they reached to full term. 17 (40.5 \%) with \([P-ve and C+ve]\) and all of them ended with abortion. 20 (47.6\%) with \([P+ve, C +ve]\) and all of them reached to full term. \([P = 0.001]\) as show in figure (5).
Pregnant women with fate of the pregnancy:

Out of 162 pregnant women, 93 (57.4%) reach to full term pregnancy, and 69 (42.6%) end with abortion. 69 pregnant women end with abortion 34 (49.3%) with blighted ovum, 24 (34.8%) with missed abortion, and 11 (15.9%) with incomplete abortion, [P < 0.003] as shown in Figure (6).

Discussion

There is a significant association between TVUS, TVCDI findings and the fate of the pregnancy. According to figure (1) and (2) The fate in those women with these findings were, all The pregnant women with [P+ve, C-ve] reached to full term i.e. they had normal pregnancy, while with [P-ve, C+ve] ended with abortion i.e. they had abnormal pregnancy and with [P+ve, C+ve] 20 (95.2%) reached to full term and only one (4.8%) ended with abortion. These findings agreed with the findings of Hustin and Schaaps [5] who suggested that no real blood circulation in the Intervillous space was present in the early stages of pregnancy as well as they found that moving echoes could always be detected in the myometrial vessels in the normal pregnancies but these moving echoes could only be detected in the placenta in 6% of cases. by contrast, they found slow turbulent movements inside the placenta in 96% of cases of early pregnancy failure. These findings were further supported by Jauniaux et al. [18] who did not identify Intervillous flow before 12 weeks of gestation in normal pregnancy, although it was observed in women with abortions. He also suggested that in normal pregnancies, the Intervillous circulation starts in the periphery of the placenta (p), whereas in early pregnancy failures, it is more intense and diffuse throughout the placenta with central perfusion (C) [19], while moving echoes were mainly at the periphery of the uteroplacental circulation in the normal pregnancy, and at both the center and the periphery in abnormal pregnancy[20]. These results also seen in figures (3, 4), only one case ended with abortion with both perfusion central and peripheral start to appear at this period, which indicate that this finding must be abnormal at this period although the sample is small. While figure (5) shows the results of women with both central and peripheral perfusion and all of them reached to full term. these results indicate that the peripheral perfusion with or without central perfusion during this period 12-14 week indicate a normal pregnancy, while central perfusion without peripheral perfusion indicate abnormal pregnancy in this period, as same as 2 periods [7-9 weeks, and 10-11 weeks]. The explanation of these findings as Jauniaux found that during the first 10 weeks of normal pregnancy, the apical portions of the majority of the uteroplacental vessels are partial obliterated by plugs of invading trophoblast cells, he’s hypothesized that these plugs prevent continuous flow of maternal blood into the Intervillous space during this period and therefor the human placenta is not truly hemochorial until the end of the first trimester [21]. Norman and Lodwick [22] found that, in early pregnancy failure the trophoblastic shell is thinner and fragmented and the trophoblastic infiltration of both lumen and endometrial vessels and the decidua is reduced or absents. Figure (6), out of 162 pregnant women 69 (42.6%) ended with abortion. 68 (98.6%) of them were with [P-ve, C+ve] and only one (1.4%) was with [P+ve, C+ve] and this woman was at the 10-11 weeks of pregnancy period. The higher significant percent of type of abortion is with blighted ovum as they are non-embryonic pregnancy so there is no trophoblastic shell or plugs so there is continuous flow of maternal blood into the Intervillous space as an abnormal utero-placental circulation. Jauniaux [20] found that, Intervillous blood flow was significantly more frequently with in missed abortion, also suggest that the uteroplacental blood flow may be different in missed abortions and non-embryonic gestational sacs than in normal Pregnancies.
**Conclusions**

The beneficial use of the transvaginal ultrasound or transvaginal colour Doppler in estimation the conditions of the placenta in early pregnancy especially in the presence of abnormal pregnancy and the results of these examinations may give an idea to some extents about the fate of the pregnancy and indicate that there is no difference in the use of the transvaginal ultrasound and transvaginal colour Doppler imaging regarding the efficiency of the equipment but it remains dependable on the efficiency of the sonographist. Early prediction of pregnancy that ended with abortion during the first trimester for any reason (Genetic, Immunological, Infectious) still represent a big challenge to the clinicians and patients alike, and these two simple methods are useful for the prediction of the fate of the pregnancy that liable for abortion. Early normal color Doppler imaging can avoid unnecessary invasive techniques. The results of this study necessitate further studies to be carried out on the same field for further evaluation of these results.

Abstract

Background: Mammography is a tool for screening and diagnosis of breast cancer. Increasing density of the breast affects the accuracy of mammogram. Sociodemographic and reproductive factors play a role in varying density of the breast. Therefore, evaluation of the risk factors that may lead to increase density, will be an important key in the early detection of breast cancer.

Objectives: To comment on breast density in Iraq.

Method: A total of 400 patients were enrolled in the study. One hundred attendants were excluded due to insufficient data. The sociodemographic, reproductive data and mammographic views were acquired from record files.

Results: A peak density was type B (scattered fibro glandular). Age, parity, menstrual status, breast feeding and obesity were significantly affecting density of breast (p= 0.002, 0.003, 0.001, 0.001 and 0.007, respectively). Smoking, using contraception and family history of breast cancer were not affecting the mammographic density.

Conclusions: Higher breast density in younger age group, nulliparous, those were menstruating regularly or irregularly comparing with non-menstruating women, shorter duration of breast feeding with low BMI may increase the mammographic breast density. Dense breast might obscure the lesions and reduce the accuracy of mammography.

Keywords: breast density, risk factors, Iraq, mammography.

Introduction

Mammography is a tool for screening and recently become a diagnostic instrument.¹ Density of the breast affect negatively the accuracy of mammograph² which in turn, affects the early detection of breast cancers.³ High breast density on mammography is associated with an increased risk of breast cancer. It was estimated that the risk in women with highest breast density was 4.64 time than that in women with lowest breast density.⁴ Ductal tissue, where breast cancer arises, and the surrounding structurally supportive stromal collagen appear white, while fatty tissue appears dark on mammography.⁴ Literatures showed that density of the breast varied between regions ⁵ and affected by sociodemographic and reproductive factors.⁶,⁷

Breast density is a neglected subject of research in Iraq. Therefore, this study was carried out to comment on breast density in Iraq.
Materials and Method

A total of 400 attendants to woman health center in AL Elwiya Teaching hospital for maternity were enrolled to this study. They were recruited by including all attendants to woman health center for nine weeks. The period of 1st of October to 1st of December 2018. One hundred attendants were excluded because of insufficient data. The requested information was sociodemographic, weight, length, reproductive data and mammographic views acquired from file records. Thirty views were reviewed for second time by the same radiologist to confirm the accuracy of reports. The density was classified according to American college of Radiology including: (A) almost entirely fat (fibro glandular tissue <25%), (B) scattered fibro glandular densities (fibro glandular tissue 25- 50%), (C) heterogeneously dense (fibro glandular tissue 50-75%), and (D) extremely dense (fibro glandular tissue >75%). The BMI was measured (weight in kilogram divided on the squared length in meters). Data were dichotomized, density as (dense and non-dense), BMI as (non-obese and obese), contraception history as (negative and positive), smoking as (negative and positive). The age of attendants was grouped into <40, 40-59 and ≥ 60, feeding history was classified as (negative who never fed, those who fed for <2 years and those for ≥2 years). The menstrual status as (nomense, regular mense and irregular mense), family history of breast cancer as (negative, had 1st degree relative, 2nd degree relative and those had both).

The Chi-square test and Fisher’s exact test were used to examine the effect of studied factors (independent) on breast density (dependent). P value ≤0.05 was considered significant.

Results

Table 1 shows that 82 (27%) had extremely fatty breast (A), 138 (46%) had scattered fibro glandular breast tissue (B), 68 (23%) had heterogenous fibro glandular breast tissue (C) and 12 (4%) had extremely dense breast (D).

Table 2 shows, those aged <40 years, 17 (35%) had dense breast, of those aged 40 – 59 year, 61 (29%) had dense breast and those aged ≥ 60 years and 2 (5%) had dense breast. Density of breast was significantly declined with age ($\chi^2=12.2$, df= 2, p= 0.002).

Of nulliparous women, 10 (39%), of those with 1-4 parity, 44 (32%) and those with parity≥ 4, 26 (19%) had dense view. A significant association between density of breast and parity was noticed ($\chi^2= 7.4$, df= 2, p= 0.03).

Women with 1st, 2nd degree relative with history of breast cancer and both, had 6 (21%), 9 (25%) and 4 (25%) dense breast, respectively. No significant association between the breast density and the family history of breast cancer was observed ($\chi^2= 0.8$, df= 3, p= 0.9).

Of the total women with negative breast feeding history, 20 (36%) had dense mammographic view. Those breast fed <2 years, 41 (34%) and of those ≥2 years, 19 (15%) had dense view. A significant inverse association of the breast feeding and mammographic breast density was demonstrated ($\chi^2= 14.5$, df= 2, p= 0.001).

Seventy nine (27%) of those not using contraception, had dense view and of those used contraception, 1 (8%) had dense breast. No significant association between breast density and contraception use was demonstrated ($\chi^2= 2.1$, df= 1, p= 0.2).

Of those with regular or irregular mense, 48 (40%) and 19 (40%) had dense view, respectively. Of those with no mense, 13 (10%) had dense breast. No mense was significantly associated with dense breast ($\chi^2=34.8$, df=2, p= 0.001).

Four (3%) of obese and eight (6%) of non-obese women, had dense breast, respectively. Density of breast was significantly associated with non-obese women was noticed ($\chi^2=12.1$, df= 3, p= 0.007).

Discussion

The assessment of breast density is relatively easy on mammography and can be used as an important parameter for early intervention and prevention of breast cancer. Therefore, determination of the risk factors that may lead to increased density in mammography and evaluation of patients with these risk factors will be important key in the early detection of breast cancer.

This study showed that 27% of the women had dense breast. It is similar to that reported in Lebanon and Iraq being developing country, characterized by high fertility i.e. high parity which affect negatively the breast density.

Age was inversely related to density of breast. This finding is similar to that reported in Lebanon and Japan. The breast density decreases with increasing age. This seems logical because with aging, by the decreasing levels of ovarian hormone. The hormonal effect of ovary on breast tissue is reduced, which also results in the reduction of epithelial tissue of the breast tissue and its replacement with fatty tissue.

It was found that parity status was associated with breast density changes i.e. reduction in density of breast. This finding is consistent with that in Lebanon. Parity leads to changes in breast morphology, histology and biochemistry. This study showed that density of breast reduced dramatically when the parity is four and more. Other studies stated that parity was
positively associated with breast density.\textsuperscript{15,16} This difference might be explained by variations in methods of study, sampling and ethnic group.

No variation in mammographic density was noticed in family history of breast cancer.\textsuperscript{17} Some articles demonstrated that 1\textsuperscript{st} degree relative with breast cancer had significant association with breast density.\textsuperscript{18} It might be controversial, however, studies using BRCA1 and BRCA2 showed such association.\textsuperscript{19}

Longer duration of breast feeding was inversely significant associated with breast density. It is similar to that of other articles.\textsuperscript{20,21} This finding is inconsistent with that in Singapore, China and Korea.\textsuperscript{16,22,23} The difference might be attributed to the low fertility rates in regions of the studies. High fertility in Iraq might be responsible for such variation.

No significant relationship was observed between contraception usage and dense view. It is concordance with that in Iran.\textsuperscript{24}

No mense (natural menopause or by hysterectomy) was significantly associated with breast density. It is in agreement with that of Iranian study.\textsuperscript{24}

Smoking had no significant effect on breast density. It is in agreement with others.\textsuperscript{11,21} Evidence on the effect of smoking on mammographic density is controversial which might be due to timing of smoking (premenopausal or postmenopausal).\textsuperscript{25,26}

Body Mass Index (BMI) is significantly inversely associated with dense breasts. This is in agreement of that in other literatures.\textsuperscript{27} Obese women have a lower ratio of dense to fatty tissue in the breast. Direct correlation between BMI and the density was stated in other literatures.\textsuperscript{28}

\textbf{Conclusion}

Age, parity, breast feeding, menstrual status and BMI were related to breast density. Accurate interpretation of mentioned factors might increase the accuracy of mammography.

\textbf{Ethical Clearance:} Taken from Arab board of health specialization in Iraq/ executive office, Al Rusafa health directorate and administration of Al Elwiya Teaching Hospital were obtained.

Role of Inflammatory Cytokines and Immune Reactive Molecules in Pathogenesis of *Streptococcus Agalactiae* in Aborted Healthy Women

Ali A. Njum¹, Jabbar A. Alwan², Layla S. Abdul-Hassan³

¹AL-Furat AL-Awsat Technical University, Iraq, ²AL-Qadysia University, Iraq, ³AL-Furat AL-Awsat Technical University/College of Health and Medical Techniques, Kufa, Iraq

Abstract

*Streptococcus agalactiae* has been appearing as a vital human pathogen and a gradually important cause of aggressive infections in immunocompromised adults and older, the aim of the study was to find the effect of inflammatory cytokine (interleukin 8) and immune reactive molecules (CD79 and CD54 molecules) on pathogenesis of *S. agalactiae* that isolated from aborted women. A total of 100 aborted women aged between (18 - 42) years, were involved in this study. Placentas specimens were cultured to isolate the *Streptococcus agalactiae*, the level of cytokine in the serum was measured by commercial ELISA tests, while CD molecules was estimated by immunohistochemistery assay. Our results showed that there was streptococcal isolates from Placentas specimens, Specific isolation and identification were done for *S. agalactiae*. Significant difference could be found in serum levels of inflammatory cytokine (P≤ 0.05) between these two investigated groups (infected and uninfected with *S. agalactiae*) in addition to high expression for CD79 and CD54 in infected women as compare with non *S. agalactiae* infected women.

Keywords: CD Molecules, inflammatory cytokines, placentitis, *S. agalactiae*

Introduction

*Streptococcus agalactiae* is Gram-positive, oxidase- and catalase-negative. *Streptococcus agalactiae* has been divided serologically into 9 serotypes (Ia, Ib, and II-VIII) due to various in capsular polysaccharide *Streptococcus agalactiae* or group B streptococcus (GBS) is a commensal organism in humans, but can cause life threatening infection in susceptible hosts such as neonates, pregnant women and non-pregnant adults with chronic illnesses¹. The structure of the human vaginal flora is precious by some host factors, plus, phase, high parity, health care workers, high Body Mass Index, chronic diseases as diabetes, sensual action, gestation and the custom of contraceptives, antibiotics, as well as separate ways such as antiseptic-douching sterility².

Group B *Streptococcus* (GBS) has become the major cause of bacterial infections in the perinatal period, including bacteraemia, amnionitis, endometritis, and urinary tract infection in pregnant women as well as focal and systemic infections in newborns. It is a relatively rare cause of infection in older children and non-pregnant adults³.

Macrophage and monocytes in neonatal blood and in the urinary tract respond to GBS with a pro-inflammatory cytokine release, involving Interleukin (IL) IL-1α, tumour necrosis factor (TNF) and IL-6. Interleukin-8 secretion is elevated by oxidative stress, which in that way causes the enrolment of inflammatory cells, induces a higher in oxidative stress mediators, producing important parameter in localized inflammation⁴. If a pregnant woman has high levels of interleukin-8, there is an important risk of schizophrenia in her progeny. The preterm labor is related with the raised uterine construction of pro-inflammatory cytokines, IL-1β IL-6, IL-8 and TNF, where believed to excite uterine action, either straight or through a rise in prostaglandin construction, the pull of leukocytes, and tissue transformation⁵. Decreasing the inflammatory penetrate or preventing cytokines discharge in these cells might be energetic in the dealing of preterm labor.
In the matching way, these mediators can cause abortion.

The CD79 particle forms part of the membrane immunoglobulin complex on B lymphocytes. CD79 itself is required for signal transduction. CD79 is found on all mature B lymphocytes in the blood stream, and on B lymphocytes at all phases of development in the bone marrow. CD79 appearance is absent after distinction of B lymphocytes into plasma cells.

**Materials and Method Materials**

Mastastrep kit was provided by Merseyside/UK. API strep kit and Vitek 2 system kit were supplied by BioMerieux/France company.

**Method**

**Samples collection.** - Clinical signs of aborted women were recorded by physician to show pregnancy period, and clinical sings.

- Aborted Placentas:

Hundred placenta samples from aborted women have been obtained, at maternity and children hospital of Al- Samawa, after curtag operation (by gynecologists) placenta samples were cultured as described by Sainì et al., isolation and identification of *S. agalactiae* was performed by API strep kit and Vitek 2 system kit then determent groups of isolates by Mastastrep kit, where *S. agalactiae* positive for group B.

**cytokine assessments** (IL-8) in serum were performed by ELISA kit: Provided by Elabscience\ China.

**Immunohistochemistry** for placenta specimens was performed as described by (Abcam, UK). The expression of CD79 and CD54 were measured as the same scoring system used by Mao et al., The positivity of cells for expression of CD79 and CD54 were seen as brown staining. It was graded as four grad of the cells staining positive for CD79 and CD54.

</tbody>
</table>

**Statistical Analysis:** All data were analyzed using the statistical package for social science (SPSS) for Windows program on the computer. Chi-square was used to compare between the frequencies. Student t test was used to compare between means of groups. The significance was accepted as P value < 0.05.

**Results and Discussion**

**Clinical observation:**

Clinical signs in women included fever sweating, hypotension, pain, aches and bleeding most women infected with *S. agalactia* were aborted at first stage of pregnancy.

This result is in agreement with Young who found that *Brucella* transferred from mother through placenta to fetus during first stage of pregnancy and causes maternal bacteremia and spontaneous abortion.

-Bacterial isolation & identification:

Out of the 100 aborted women, 7(7%) were positive for culture after 2 days the *S. agalactia* culture recognized on the basis of colonial morphology on blood agar appeared as pinpoint , white to milky in color , Colonies of 1 to 2 mm in diameter and colonies showed β-hemolysis.

Isolates from blood and placenta samples were Gram-positive, cocci, arranged in short chain or small groups stained didn’t grow on macconkey agar and negative for catalase and oxidase

**Blood cytokine(IL-8) assessment:**

The results of this study showed a highly important increased (P<0.01) of IL-8 (93.88 ± 18.99) pg/ml in serum of aborted women infected with with *St. agalactiae*, compared with aborted women non infected with *St. agalactiae* (36.69±0. 95) pg/ml as shown in table(1). The result of current study same as reported by who discovered that highly significant increased (P<0.01) concentration of IL-8 (44.371± 8.772) pg/ml in serum of aborted patient at first month of gestation , control groups (non-pregnant women ) which were (7.423± 2.152) pg/ml , (6.908-+ 3.859) pg/ml respectively.

The inflammatory mediators, for instance IL-8, might show an important part in the contrivance of
protease-induced neurogenic irritation leading to effort or abortions by employing neutrophils and lymphocytes in the endometrium\(^{11}\).

While prior revision stated that female with natural abortions has significantly reduced plasma equal of IL-8, IL-6 and IL-11 compared to those with normal pregnancies\(^{12}\). The great equal of IL-8 in aborted female can be caused by the discharge of IL-8 from the endometrium\(^{13}\).

3. Immunohistochemical assay :

Histological section of placenta obtained from \(St . \ agalactiae\) infected women & non infected women revealed marked placentitis associated with \(St . \ agalactiae\) infection. chorionic villi showed necrotic changes of syncytial cells with extravascular accumulation of red blood cells in decidua and maternal blood spaces. there is infiltration of inflammatory cells (macrophages & neutrophils). Placentitis that occurred in placenta in the present study; necro-fibrinoid and necro-hemorrhagic type. in affected placenta, the trophoblastic epithelium lining the chorionic villi appeared necrotic with spreading of macrophage infiltration into mesenchyma of these villi. figure(1)

Fig( 1) Placenta of women infected with \(St . \ agalactiae\), showed fibrionoid deposits in the chorionic villi with degeneration and necrosis in the mesenchyma of these villi. Also there is scattered inflammatory cells (macrophage). H &E(100X).

Histopathological changes of placenta in aborted women positive for \(St . \ agalactiae\) infection showed conformity with clinical signs, cytokines and IHC assay results. where most of aborted placenta showed necrotic, hemorrhagic and had infiltration of macrophages this results was similar to that obtained by\(^{14}\) whom reported that Preterm delivery can occur when GBS has invaded the placental membranes decreasing the membranes tensile strength and elasticity causing it to rupture, it had also been suggested that GBS produces proteases that rupture plental tissue and similar mechanisms may promote membrane rupture causing miscarriage and preterm delivery. It has been shown that \(st . \ agalactiae\) may mostly attack the chorioamnion and amniotic fluid, improvement pass to the fetus, then start labor, lead to impulsive failure\(^{15}\).

GBS successfully impasses the extracellular matrix constituents fibronectin, fibrinogen and laminin, Strangely fine modified GBS fixes to restrained fibronectin to enable mucosal colonization, but not to soluble fibronectin that may aid as an opsonin for phagocyte respect\(^{16}\).

CD79 expression in placenta of aborted women infected & non infected with \(St . \ agalactiae\).

Result of immunohistochemical analysis demonstrated positive staining for CD79 in placenta of aborted woman as showed in (figure.2). It has been shown that aborted women positive for \(St . \ agalactiae\) infection showed high intensity for IHC staining of CD79 compared with that of negative for \(St . \ agalactiae\) infection which revealed low intensity for IHC staining of CD79 as show in (fig.2). Statical analysis with chi-square test, revealed that the total results of negative scores (1,2&3) in negative cases of \(St . \ agalactiae\) infection were pointedly developed (p≤0.01) than from negative cases. Mean while CD 79 intensity is significantly higher in positive cases. compared with that of negative cases. these score differences were also seen in (table 2).

Presence of CD54 molecules in placenta of aborted women infected & non infected with \(St . \ agalactiae\). According to study the CD 54 particles, stain was finished by anti-CD54 as seen in (fig.2). there is obvious rise for CD54 stain for placenta tissue through
St. agalactiae infection. as determined by staining of biopsies, the immune staining of CD54 were positive at high level in 85.71% (6 out of 7) in St. agalactiae infected patients, with highly statistical association (p≤ 0.05) between the infected & non infected groups (table 3). Result of our study showed significantly associated between ICAM-1 expression and cytokines, CD 79 and histopathological change.

Functional activation molecule (ICAM-1) is a cell adhesion molecule expressed on a cell and up-regulated by inflammatory mediators17. Several studies reported that ICAM-1 interaction not only is required for cell adhesion and migration, but also plays a key role in the immune response, in fact it involved in leukocyte function such as antigen-specific recognition by T lymphocytes, T lymphocytes activation, and Ig production through T-dependent immune response, thus higher expression of CD54 on T cells may reflect the activation state of lymphocytes18. We tried to determine the pathogenic importance of ICAM-1 through comparison of its expression in aborted women that infected & non infected with St. agalactiae. Our results made obvious that the strong up-regulation of both CD79 & CD54 give a strong evidence that lymphocytes in placental tissue were with in a state of immune dysregulation, that comes together with a study done by poriadia19 who showed that there is increased expression of activation induced antigens (CD54) on the peripheral blood lymphocytes from patients with various type of inflammatory disorders. Finally the high titer of cytokines (IL-8) and high expression of CD79 with profuse inflammatory cells in this study and other reports indicates that the St. agalactiae colonization in epithelial of placenta causing production of cytokines lead to tissue inflammation and damage by causing the recruitment of host immunity and activation of host leukocytes, macrophage & inflammatory cells. Progression along a Th1 & Th2 passageway in united up regulation for chemokines in tissue of placenta.

Figure 2. IHC staining results. A, B (expression of CD79) and C (expression of CD54): Women placenta positive for S. agalactia, specific staining of chorionic plate with DAB chromogen (brown) and counterstained with Hematoxylin (blue) (A:100x, B:400x). D: women placenta negative for S. agalactia; stained by DAB chromogen (brown) and counterstained with Hematoxylin (blue) notice, non IHC reaction for 3BHSD enzyme .100x.

Study The Effect of Healthy Biological Extracts Compared with Antibiotics on Some Bacteria Isolated from Infected Patients with Urinary Tract Infection

Aqeel H. Atallah, Sajaa R. Al-Saedi, Amaal M. Khudaier

1University of Al Zahra for Girls, Iraq, 2Department of Physiology/ College of Veterinary Medicine, University of Kerbala, Iraq, 3Department Pathological Analysis Techniques / College AL-Safwa University, Kerbala, Iraq

Abstract

Phytotherapy is a substitute for antibiotics therapy in these days since resistance to many antibiotics used in treatment are increasing along with extraordinary cost of some antibiotics and side effect on patients. The Citrus limon, Punica granatum and daucus carota juice have anti-microbial properties. This study propose that Citrus limon juice may be more effective than some antibiotics used in the treatment of some urinary tract pathogens (Escherichia coli, Staphylococcus aureus and Proteus spp.) and Punica granatum juice have operative on Staphylococcus aureus and daucus carota juice have operative on Proteus spp. This study is generally careful an effective approach in the discovery of new anti-bacterial agents from Citrus limon, Punica granatum and daucus carota juice.

Keywords: urinary tract infection, Citrus limon, Punica granatum and daucus carota juice.

Introduction

Urinary tract infection (UTI) is one of the important common infectious diseases and is defined as the presence of bacteria in urine together with symptoms. UTI is one of the most generally happening bacterial infections among men and women1,2.

According to The National Institute for Health and Clinical Excellence (NICE) guidelines 'urinary tract infection is well-defined by a combination of clinical features and the occurrence of bacteria in urine'. The Clinical symptoms of UTI usually include frequency, dysuria, pyuria, abdominal pain, back pain, fever or urgency6,7. But none of these symptoms alone is sufficient to establish UTI diagnosis in veral patient7.

Appreciative the predominance of Urinary Tract Infection in various populations will help guide to the suitable level of suspicion and the appropriate work-up for urinary tract infection8. It is difficult to assess the accurate incidence of UTI due to under reporting; this situation is complicated as the correct diagnosis of UTI depends on both the presence of symptoms and positively urine culture9. Throughout childhood the risk of UTI is 8% for girls and 2% for boys10.

Circumcision status in males, peri-urethral flora, micturition disorders, bowel disorders, local factors, and hygienic measures are important factors involve in the pathogenesis of UTI. The pathogenicity of bacteria in UTIs is influenced by both bacterial and host factors like bacterial adhesion and motility, in addition to hosts immune response and genetic factors11.

UTI is mostly cause by gram negative aerobic bacilli originate in the gastrointestinal tract well-known as Enterobacteriaceae, Included the Escherichia coli (70-95%), Klebsiella 1-2%, Proteus species 1-2%, Staphylococcus 5-10%, Enterococcus species, Enterobacter, Citrobacter, and Serratia species1,3. Furthermore physicians need to know local patterns of microbial susceptibility in UTIs for proper drug selection depending on culture and sensitivity but the degrees of exposures of a populations to specific antibiotic could play a role in this variations4.

Plants have continuous play a main role in the preservation of human health since ancient times like a sources of medicinals compounds. According to the World Health Organization plants extracts or their active components were used as folks treatment in traditions therapies of 80% of the world’s populations. Over 50% of all modern clinicals drugs are of natural products origins. Phytochemicals such as vitamins (A, C, E and K), caroteinoids, terpeinoids, flavionoids, polypheniols, alkailoids, taninins, sapionins, pigmients, enziymes and minerals that have anti-microbial and anti-oxidant activity.

Antimicrobiasl screenings of plants extracts and phyto-chemicals, then, represents a startings points for ant-imicrobial drugs discoverys. Phyto-chemical studies have attracteds the attentions of plants scientists due to the developments news and sophisticateeds methods. These methods playeds a significants roles in the searches for additionals resoiurces of raws maiterial for pharmiaceutical induistry.

**Materials & Method**

**Bacterial isolates:**

Differents clinicals microbials isoliates (Grams positives, Grams negatives bacterias) were isolateds and identified by using convsentional biochemicals tests and Api system and cultivatets in pures cultures, at microbiology laboratorys. These bacteria included: \( \text{(Escherachia colai, Staphylccoccus aureus, Priteus \text{spp.})} \)

**Antibiotic Sensitivity Test**

The anti-microbial susceptibility tests was performeded accordinces to Kirby-Bauer (disks diffusion) techniques using Muller-Hinton agar and different single anti-microbial disces provided commercially. Results are reads according to the National Committee for Clinical Laboratory Standards guidelines (NCCLS).

The diameters of inhibition zones for each individual anti-microbial agant was translated to terms of sensetive, intermedeate and resistant categoryes by referring to an interpretation chart of the National Committee for Clinical Laboratory Standards, subcommittee on anti-microbial susceptibility testing.

This study was carried out at the Department of pathological analysis / College Al Safwa University . The studies was conducteds durings the period from January 2016 untils February 2016.

**Source of plant extract**

The plants materiales useded in this studys consisted of \( \text{Citrus limon, Punica granatum and daucus carota.} \) These plants collected from a local market.

**Preparation of plant extract**

The fruit (\( \text{Citrus limon, Punica granatum and daucus carota} \)) was collected and washesd with steriles distilled water. Samples were crushed into partes and squeezed to remove the crude extract. The cruds extracts were filtered through filter peper and storid in sterile vials. The juice that used of \( \text{Citrus limon, Punica granatum and daucus carota} \) under study at concentretion (100%, 1:1, 1:2, 1:3).

**Determination of anti-bacterial activity**

The sensitivity studieis were conduicted using the Kirby and Bauer methods of sensitivity determinatios. Sterile Petri – dishes of Mueller Hinton agars were prepered according to manufaectures specification.

The wells diffusions method was used to scraen the anti-bacterial activity. In-vitro anti-bacterial assiay was screeaned by using Mueller Hinton Agar (MHA) obtained from Hi-Media, India. The MHA plates are prepered by pour 15ml of molten madia into hygienic Petri dishes. The Plates were allowed to solidify for 10 minutes and 0.1% inoculums suspension was swabbed uniformlyed and the inoculumis were allowed to dry
for 5 minutes. Wells (6 mm) were aseptical hit on the agar using a sterile corked borer letting at least 30 mm among adjacent wells. Fixed volumes of the plant extract were then introduced into the wells. The plates were then incubated at 37°C for 24 hours. The anti-bacterial action was evaluated by evaluating the diameter of the inhibition zone formed arounded the discs.

Results and Discussion

Antibiotic sensitivity

The results of the sensitivity test have shown that AK (30) was the most effective antibiotic on *Escherichia coli* (17 mm) and the other have less effective antibiotic on *Escherichia coli*, The CTX and SAM were the most effective on *Staphylococcus aureus* (27, 25 mm), and the CTX and TE were the most effective antibiotic on proteus spp. (35, 31 mm) respectively, SAM, GM and AK were have effectived on *proteus spp.* at (25 mm).

Antibacterial of biologecal extracts

Results shown in table (2) indicate that the *Citrus limons* have inhibition against *E. coli* in the concentration 100% and low inhibition in concentration (1:1) and the other concentration have no inhibition, in additions the *Punica granatum* and *daucus carota* juice have no inhibition too. According to NCCLs cheat [48], the results referred to sensitivity of Proteus and *E. coli* for carrot juice, and resistant to *Staph. aureus* and the *Citrus limon* have inhibition against *Staphylococcus aureus* in the concentration 100% and low inhibition in concentration (1:1), (1:2) and *Punica granatum* (100%), (1:1) and *Staphylococcus aureus* resistant to other concentration and *daucus carota* juice.

Results show that the *Citrus limon* juice have effective on *proteus spp* at concentration (100%), (1:1), (1-2) and the *daucus carota* (100%), (1:1), and the *proteus spp* are resistant *Punica granatum* juice at all concentration.
Tables (3-4) show *Citrus limon*, *Punica granatum* and *daucus carota* juice results (zone of inhibition in mm) against *E.coli*

The anti-microbial activity of pomegranate fruit is related to phytocompounds present, predominantly alkaloids and tannins, among which stands out the punicalagin compound, ellagitannin with proven anti-microbial activity\(^\text{19}\). This finding agreed with Hayes and Markovic (2002)\(^\text{20}\) who investigated this anti-microbial properties of lemon and foundly this lemon possesses significant anti-microbial action against *S. aureus*, *Klebsiella*, *Escherichia coli*, *P. aeruginosa* and other. Also Al-Ani et al (2009)\(^\text{21}\), mentionied that *C. limon* have virtuous bacterial inhibition against *S. aureus*, *P. aeruginosa* and *P. vulgaris*.

The result of the study presented that the *Citrus limon* and *daucus carota* juice produced zones of inhibition against *proteus spp*. This shows the presences of effective anti-bacterial activity, which confirns its use as anti-infective. Carrots have many important vitamins and minerals. They are rich in antioxidants Beta carotine, Alpha carotine, phyto-chemicals and glutathione, calcium and potassium, and vitamins A, B1, B2, B6, C, D and E, which are also considured anti-oxidants and immune system booster\(^\text{22}\).

**Conclusions**

The anti-bacterial activities of *Citrus limon*, *Punica granatum* and *daucus carota* juice againsts urinary tract causing organism is reported and it showeds the effectives of theirs juice that are importent to the local market. Further phyto-chemical elucidutions are required to determined the nature of compounds responsible for the anti-bacterial effeted. This study is generally considered an effectied approach in the discovery of new anti-bacterial agents from *Citrus*.
limon, Punica granatum and daucus carota juice.

Conflict of Interest: This research is a personal non-profit work and there is no conflict of interest.

Source of Funding: None.

Ethical Clearance: Ethical clearance was obtained from the Faculty Scientific Committee (University of Al Zahra for Girls, Iraq) to study the effect of healthy biological extracts compared with antibiotics on some bacteria isolated from infected patients with urinary tract infection.

Abstract

Background: Moringa leaves (Moringa oliefera L.) have many nutrients that contain bioactive components such as tannins, flavonoids, and saponins, as antimicrobials. The growth of Aggregatibacter actinomycetemcomitans and Porphyromonas gingivalis must be inhibited so that they do not become pathogens and cause periodontitis. Objective: The general purpose of this study was to determine the Minimum Inhibitory Concentration (MIC) and Minimal Bactericidal Concentration (MBC) and inhibitory power of moringa leaf extract (Moringa oliefera L.) against bacteria Aggregatibacter actinomycetemcomitans and Porphyromonas gingivalis. Method: The type of research used was laboratory experimental research. The design of this study is post test only control group design using the Kirby Bauer dilution method. With treatment extract concentration of 15%, 20%, 25%, 30%, 35% 100%, and positive control (Metronidazole). The measuring instrument in this study uses a caliper with millimeters (mm). Results: The results of the study of bacteria Porphyromonas gingivalis obtained from MIC by 20%, MBC 25% and bacteria Aggregatibacter actinomycetemcomitans obtained by MIC by 30% and MBC 35%. Kruskall Wallis test results showed that the value of p<0.05 so it can be concluded that there are significant differences in the inhibition zone of Aggregatibacter actinomycetemcomitans and Porphyromonas gingivalis. Conclusion: The extract of leaves of Moringa (Moringa oliefera L.) were able to inhibit bacterial growth Aggregatibacter actinomycetemcomitans and Porphyromonas gingivalis.

Keywords: Moringa leaves extract (Moringa oliefera L.), inhibitory power, bacteria Aggregatibacter actinomycetemcomitans and Porphyromonas gingivalis.

Introduction

Periodontal disease is one of the most common dental and oral health problems in the community. Based on Indonesia’s health profile in 2011, in 2010 there were 92,979 people who visited public hospitals belonging to the health ministry and local governments due to periodontal disease. Periodontal disease is an infection in the oral cavity that affects periodontal tissues. The main cause of this disease is microorganisms that colonize the surface of the tooth (bacterial plaque). Microorganism culture (bacteria) found in plaque shows the presence of certain gram negative bacteria in periodontitis.³

Periodontitis is an inflammation that affects the supporting tissues of a tooth, caused by microorganisms and can cause progressive damage to the periodontal ligament, alveolar bone and is accompanied by pocket formation.⁴ Periodontitis causes permanent tissue degeneration.
destruction characterized by chronic inflammation, migration of the fused epithelium to the apical, loss of connective tissue and loss of alveolar bone.6

The main causes of periodontal disease are the presence of microorganisms that colonize the dental plaque. Dental plaque is a structured, soft, yellow substance, which is attached to the tooth surface. The content of dental plaque is various types of microorganisms, especially the remaining bacteria are fungi, protozoa and viruses. Plaque containing pathogenic microorganisms plays an important role in causing and exacerbating periodontal infections.6

An increasing number of gram-negative organisms in subgingival plaques such as Porphyromonas gingivalis, Actinobacillus actinomycetemcomitans, Tannerella forsythia and Treponema denticola infect periodontal infection.7 Porphyromonas gingivalis is a gram-negative anaerobic bacteria involved in the pathogenesis of periodontitis and other inflammatory diseases that destroy dental support tissue. These bacteria can invade the periodontal tissues locally and survive the host defense mechanism by utilizing a panel of virulence factors that cause deregulation of innate immune and inflammatory responses.8 Aggregatibacter actinomycetemcomitans is a gram negative bacterium found in the oral cavity and one of the etiologies of aggressive periodontitis. This bacterium has the ability to produce leukotoxins which can cause damage to the periodontal tissues and one type of bacteria that is considered a periodontal pathogen.9 Inappropriate and excessive use of antibiotics can result in bacteria being Aggregatibacter actinomycetemcomitans and Porphyromonas gingivalis resistant to antibiotic drugs that have been given. The resistance of these bacteria to antibiotic drugs allows the use of herbal medicines from natural ingredients to be one of the other alternatives in the treatment of periodontitis. The use of herbal medicines from natural ingredients is generally considered safer than the use of modern medicine, because herbal medicines as traditional medicines have relatively fewer side effects than modern drugs.1

Natural ingredients used as herbal medicines one of which is Moringa leaves or known as the Latin name Moringa Oleifera. Moringa plants are efficacious as anti-cancer, anti-bacterial, hypotensive, inhibiting the activity of bacteria and fungi. This is related to the chemical content contained in it, which is rich in vitamin A and vitamin C, gluconic compounds and isothiocinates.10

Kelor leaves contain phytochemicals that make this plant capable of carrying out self-defense mechanisms. Phytochemicals contained include catechol tannins, galia tannins, steroids, triterpenoids, flavonoids, saponins, anthraquinones, alkaloids, and reducing sugars.11,12 The compound has the ability as a drug, its benefits are as antibiotics, skin care, anti-inflammatory, blood pressure, diabetes, and anemia.

Based on the description above, researchers are interested in conducting research to find out “The effect of Moringa leaf extract on bacterial growth, Aggregatibacter actinomycetemcomitans and Porphyromonas gingivalis cause periodontitis.”

Materials and Method

Type of research used in this study was a laboratory experimental study. The design of this study is post test only control group design using methods agar dilution and diffusion. This dilution method is used to determine the MIC (Minimum Inhibition Concentration) value, the lowest concentration that can inhibit the growth of test microbes. The diffusion method to be used to determine the activity of antimicrobial agents or often also called the inhibitory test. This method uses disk paper that has contained Moringa leaf extract and then put it into a culture medium.

The Kirby Bauer method was carried out in observing certain inhibitory zone diameters and producing a good batch-to-batch, resulting in satisfactory growth of the most pathogenic bacteria. The treatment was carried out 4 times with a concentration of 15%, 20%, 25%, 30%, 35% 100%. The positive control used is Metronidazole. The research tools used are petri dishes, round oases, autoclaves, bunsen, erlenmeyer flasks, suction pipettes, filter devices, rotary evaporators, filter paper, sterile cotton swabs, stationery.

The materials used in the research were (Moringa oleifera L.), test bacteria Aggregatibacter actinomycetemcomitans and Porphyromonas gingivalis. Obtained from the Laboratory of Hasanuddin University Faculty of Medicine, sterile distilled water, 96% ethanol, Metronidazole, Mueller Hinton Agar (MHA), label paper and aluminum foil.3 Samples of (Moringa oleifera L.) leaves were cleaned from the remaining dirt. After cleaning the moringa leaves are dried by air. After
drying, the sample is kept in a closed glass container. Oyster mushroom extract is obtained by maceration. The samples were in a closed container and then soaked with 96% ethanol solution and left for 5 days. After 5 days, the soaked sample is filtered using filter paper. The results of the filter are then evaporated using a rotary evaporator, so that a thick extract from the moringa leaf is obtained. The resulting thick extract is inserted into the vaporized container until all ethanol solvents evaporate.

Process of Testing Antimicrobial Effects of Diffusion Method

- 7 sterile test tubes were provided and Metranidazole. Dilution of the extract with sterile Aquadest was obtained to obtain concentrations of 15%, 20%, 25%, 30% and 35%, respectively as much as 5 mL.

- Each test tube is filled with the following conditions:
  
  Tube 1: 2.5 mL 15% extract + 2.5 mL suspension Porphyromonas gingivalis
  Tube 2: 2.5 mL 20% extract + 2.5 mL suspension Porphyromonas gingivalis
  Tube 3: 2.5 mL extract 25% + 2.5 mL suspension Porphyromonas gingivalis
  Tube 4: 2.5 mL 30% extract + 2.5 mL suspension Porphyromonas gingivalis
  Tube 5: 2.5 mL of 35% extract + 2.5 mL suspension Porphyromonas gingivalis
  Tube 6: 2.5 mL 100% extract + 2.5 mL suspension Porphyromonas gingivalis
  Tube 7: 500 mg Metronidazole + suspension Porphyromonas gingivalis (positive control)

- Each test tube is filled with the following conditions:
  
  Tube 1: 2.5 mL 15% extract + 2.5 mL suspension Aggregatibacter actinomycetemcomitans
  Tube 2: 2.5 mL of 20% extract + 2.5 mL suspension Aggregatibacter actinomycetemcomitans
  Tube 3: 2.5 mL of 25% extract + 2.5 mL suspension Aggregatibacter actinomycetemcomitans
  Tube 4: 2.5 mL 30% extract + 2.5 mL suspension Aggregatibacter actinomycetemcomitans
  Tube 5: 2.5 mL of 35% extract + 2.5 mL suspension Aggregatibacter actinomycetemcomitans
  Tube 6: 2.5 mL 100% extract + 2.5 mL suspension Aggregatibacter actinomycetemcomitans
  Tube 7: 500 mg Metronidazole + suspension Aggregatibacter actinomycetemcomitans (positive control)

Research Result

Minimum inhibitory effect of leaf extract Moringa (Moringa oleifera L.) against bacteria Porphyromonas gingivalis and Aggregatibacter actinomycetemcomitans.

The result of the tube dilution test is to see the turbidity level to determine the minimum inhibitory level. Tube dilution test results can be observed in Figures 1 and 2.
From the results of tube dilution test observations in Figure 1 the Minimum Inhibitory Level (MIC) can be determined in 30% tubes starting to look clear and Figure 2 Minimal Inhibitory Levels (MIC) can be determined on the tube 20% starts to look clear.

Minimal Bactericidal Concentration of leaf extract *Moringa oleifera* L. against *Porphyromonas gingivalis* and *Aggregatibacter actinomycetemcomitans*. From the results of the diffusion test observations in Figure 3, the Minimal Bactericidal Concentration (MBC) seen at a concentration of 35% shows that there is no growth of bacteria *Aggregatibacter actinomycetemcomitans* and in Figure 4 the Minimal Bactericidal Concentration (MBC) can be determined at a concentration of 25%.

**Conclusion**

The conclusions of this study are:

Extract (*Moringa oleifera* L.) can inhibit the bacteria *Porphyromonas gingivalis* and *Aggregatibacter actinomycetemcomitans*.

Minimal Inhibitory Concentration (MIC) of leaf extract (*Moringa oleifera* L.) *Moringa* which can inhibit bacteria *Porphyromonas gingivalis* is 20% with an average inhibition zone formed is 12.9 mm and for bacteria *Aggregatibacter actinomycetemcomitans* is 30% with an average zone inhibition of 10.2 mm.

The Minimal Bactericidal Concentration (MBC) of leaf extract killing (*Moringa oleifera* L.) which can inhibit bacteria *Porphyromonas gingivalis* is 25% with the average inhibition zone formed is 13.3 mm and for bacteria *Aggregatibacter actinomycetemcomitans* is 35% with zone average inhibition of 11.02 mm.

**Suggestions**

Need to be carried out further research on leaf extract (*Moringa oleifera* L.) with different methods to inhibit the growth of *Porphyromonas gingivalis* and *Aggregatibacter actinomycetemcomitans*.

**Conflict of Interest**: There is no conflict of interest in this study.

**Source of Funding**: Domestic government

**Ethical Clearance**: This study obtained a label of ethics escaped by the number: 0082/PL09/KEPKFKG - RSGMUNHAS/2018 and register number UH 17120068 on Oktober 9, 2018.

The Influence of Recitation “Murottal” Al-Qur’an to Anxiety Level Of Pre-Surgery Patients

Enny Virda Yuniarti1, Ima Rahmawati1, Asef Wildan Munfaldila1
1Bachelor of the Nursing Study Program, School of health Bina Sehat PPNI of Mojokerto, East Java Indonesia

Abstract

Surgery is a stressor that can cause physiological stress (neuroendocrine response) and psychological stress (anxiety and fear). One of the non-pharmacological measures that can be used to reduce the level of danger by using the recitation therapy of the holy verses of the Qur’an (Murottal Al-Qur’an). This research was to discuss recitation “Murottal” Al-Qur’an to anxiety level of patient in Hospital dr. Wahidin Sudiro Husodo Mojokerto. In this research use Pre-experimental design with one group pre-test-post-test approach. A sample of 27 people taken a consecutive sampling. The variable in this research was recitation Al-Qur’an and dependent variable is in the face of pre-surgery. Data collection using Kession Depression, Anxiety, Stress Scale (DASS-42). The Wilcoxon Signed Rank Test test shows that p (0.000) < α (0.05), recitation “murrotal” Al-Quran Status Punishment for the preoperative level of hospitalization at RSU. dr. Wahidin Sudiro Husodo Mojokerto. Recitation Qur’an as spiritual therapy, can provide peace, reduce fear and get closer to God and strengthen spiritual belief. Besides being of spiritual value, from the aspect of the sound has fulfilled the music as a relaxation therapy, where solid music will release the release of endorphins that will affect a person’s mood. Listening to al-Qur’an reading regularly will calm the heart and lower the level of anxiety.

Keywords: Anxiety, Recitation “Murottal” Al-Qur’an Pre-surgery

Introduction

Surgery is a stressor that can cause physiological stress (neuroendocrine response) and psychological stress (anxiety and fear) (1). According to Volicer & Volicer cited by Rosintan in 2003, clients will perform high-stress surgery actions with clients who are proven without the cost of surgery. One of the most improved factors for clients is to make the clients themselves arrive outside the operation (2).

Their anxiety is usually associated with all kinds of different procedures that the patient must undergo and also the threat to the patient’s life safety due to all kinds of surgical procedures and anesthesia (3).

The Anxiety and Depression Association of America wrote that anxiety disorders are the most common mental illness in the United States, affecting 40 million adults in the United States aged 18 and older, or 18% of the population (4). It is estimated that every year there are 230 million major operations performed worldwide, one for every 25 people alive. In Indonesia, the prevalence of anxiety disorders ranges from 6-7% of the general population (women more than male prevalence).

Recitation Qur’an (listening to the recitation of the holy verses of the Qur’an) affects the decrease of depression, sadness, preventing various diseases, and obtaining peace of mind. Al-Qhadi, president of the Islamic Medicine Institute for Education and Research in Florida, USA. At the XVII Annual Conference of the American Physicians Association, the US missile territory, Ahmad Al-Qadhi made a presentation of his research results with the theme of the influence of the Qur’an on humans in the perspective of physiology and psychology. The results show a positive result that listening to the holy verses of the Qur’an has a significant influence in decreasing nervous tension and capable of bringing tranquility up to 97% for those who listen to it (5).
According to Clinn Exell (6) if the anxiety experienced by a person is sustainable, it will enter in vulnerable maladaptive response panic. Individuals who experience panic are unable to do anything even with directions. Panic will also lead to increased motor activity, decreased the ability to connect with others, perverted perceptions, and loss of rational thought. This level of anxiety is not aligned with life; if it persists for long periods of time, there can be fatigue and death.

Method

The research design used in this research is Pre-Experimental Design with One-Group Pretest-Posttest Design approach. The population in this study were all preoperative patients at Dr. General Hospital Wahidin Sudiro Husodo Mojokerto. With an average population of about 115 - 120 patients per month. Sampling using Nonprobability sampling technique that is consecutive sampling. The number of samples is 27 respondents. This study was conducted on February 1, 2017, starting from preliminary studies to taking research data from May 1, 2017, to May 14, 2017. The measurement tool used the DASS-42 questionnaire (Depression, Anxiety, Stress Scale). Data analysis to know the influence of 2 variables that is the independent variable and the dependent variable, using test statistic Wilcoxon signed rank test with software program SPSS 20.0.

Result

Table 3 shows that before the recitation al-Qur’an treatment intervention, it was found that no respondents were not anxious and after the respondent treatment was not anxious to 3 people (11.1%), before recitation intervention, the respondents were light anxious 11 of respondents (40,7%) and after recitation treatment were 15 respondents (55,6%), before recitation intervention,
respondents were worried about 11 respondents (40.7%) and after recitation treatment were 9 respondents (33.3%), prior to recitation intervention, respondents who were worriedly weighted as much as 5 respondents (18.5%) and after recitation treatment no respondents who experienced severe anxiety.

Wilcoxon signed rank test statistic shows p-value (0.000) < α (0.05), the Z value of the table is (-1.645), and Z value count 3.873 turns out bigger than -1.645, meaning H0 is rejected, so there is Influence therapy recitation against preoperative patient anxiety level in Kertabumi Room Dr. Hospital. Wahidin Sudiro Husodo Mojokerto.

Discussion

The anxiety level of the preoperative patient before being given Recitation Al-Quran therapy in Kertabumi Room of Dr. General Hospital. Wahidin Sudiro Husodo Mojokerto

Table 1 shows that the respondent’s anxiety level before giving recitation al-Qur’an intervention from 27 respondents who experienced light anxiety as much as 11 respondents (40.7%), medium anxiety as many as 11 respondents (40.7%), and anxiously weight five respondents (18.5%).

The anxiety level of the preoperative patient after Recitation Al-Quran therapy in Kertabumi Room of Dr. General Hospital. Wahidin Sudiro Husodo Mojokerto

Table 2 above shows that after intervention recitation al-Qur’an there is a change in client anxiety level, that is respondent that is not anxious (normal) there are 3 people (11.1%), lightly anxious counted 15 people (55.6%), anxiety was 9 people (33.3%) and no respondents who experienced severe anxiety. Five respondents who experienced severe anxiety before therapy, after being given therapy all respondents are on moderate anxiety, and of all respondents due to the experience of the operation, that is first.

So it can be assumed that this recitation therapy can decrease the level of anxiety, due to sound elements and music contained in recitation including in relaxation therapy.

The influence of Recitation Al-Qur’an on preoperative patient’s anxiety level in Kertabumi Room of Dr. General Hospital. Wahidin Sudiro Husodo Mojokerto.

Results of research based on table 3 influence of recitation therapy to decrease anxiety level in facing pre-operation in Kertabumi Room RSU. Dr. Wahidin Sudiro Husodo Mojokerto obtained decreased anxiety. In Wilcoxon signed rank test, the result showed that Z value equal to -3.873 and show p-value (0.000) < α (0.05). Price Z table is (-1.645), and the price of Z arithmetic -3.873 turns out to be greater than -1.645, then H0 is rejected, and H1 is accepted which means there is the influence of recitation al-Qur’an therapy to preoperative patient’s anxiety level at Kertabumi Rumah DR. Wahidin Sudiro Husodo Mojokerto.

Based on psychoneuroimmunology, anxiety is a stressor that affects the limbic system as the emotional regulatory center that occurs through a series mediated by HPA-axis (Hypothalamus, Pituitary, and Adrenal). Stress will stimulate the hypothalamus to increase Corticotropin Realizing Hormone (CRF) production. This CRF will further stimulate the anterior pituitary gland to increase the production of Adrenocorticotropin Hormone (ACTH). This hormone will increase the secretion of cortisol and catecholamine action (epinephrine and norepinephrine). This will respond to stress.

In the autonomic nerves, sound stimulus in the form of music causes the parasympathetic nervous system to be above the sympathetic nervous system that stimulates alpha brainwaves that produce a relaxed state. Music also causes the release of endorphins by the pituitary gland, thus affecting a person’s mood. A calm psychological state will affect the limbic system and autonomic nerves that cause relaxation, safe, and fun to stimulate the release of gamma amino butyric acid, enkephalin and beta-endorphins that will eliminate neurotransmitters pain and anxiety that create calm and improve mood patients.

So researchers have the assumption that recitation therapy can reduce the level of anxiety in the face of pre-operation. This is evidenced by the results of research before and after given recitation therapy because recitation therapy has an aspect that is needed in overcoming anxiety. The spiritual aspect found in this recitation therapy can be a contemplation of the existence of God, so it is expected to form positive coping and hope in the patient. And also the sound and music elements that exist are part of the relaxation therapy.
Conclusion and Suggestion

Conclusion

In a study conducted on May 1 - May 14, 2017, in the Kertabumi Room Dr. Hospital. Wahidin Sudiro Husodo Mojokerto on 27 respondents got a result from Wilcoxon signed rank test obtained Z value equal to -3.873 and show p-value (0.000) <α (0.05). Price Z table is (-1.645), and the price of Z arithmetic -3.873 turns out to be greater than -1.645, so Hou is rejected, so there is the influence of Murotal Al-Qur’an Therapy on Anxiety Level of Pre-Operation Patient in Room Kertabumi Hospital Dr. Wahidin Sudiro Husodo Mojokerto. Recitation Qur’an as spiritual therapy, can provide peace, reduce fear and get closer to God and strengthen spiritual belief.

Suggestion

It is expected that this recitation therapy can be used as an alternative independent nursing action that nurses can use to reduce anxiety levels in preoperative patients. This therapy should not be done once to be able to get optimal results

Conflict of Interest: The author of this study was entirely supported by the college and there was no any financial concern between the researchers during research. there was no any kind of conflicts were existing among the researchers while writing, peer review, and editorial decision making.

Source of Funding: It was not a funded research study.

Ethical Clearance: Ethical clearance is not applicable for this study as it is a narrative review.

Molecular and Biochemical Study of Seven Pea (*Pisum sativum* L.) Cultivars through Using RAPDs, SSRs and Total Seed Protein by SDS-PAGE

Attyaf Jameel Thamir Al-Tamimi

Faculty of Science, University of Kufa, Department of Biology, Iraq

Abstract

**Background**: Cultivar identification is an essential step for crop improvement because it can direct plant breeders for suitable crossing to get heterosis, this study designed to use seed total protein, RAPDs and SSR to evaluate their ability in cultivar fingerprinting and identification.

**Materials and Method**: Seven pea genotypes with diverse origin were used. As biochemical marker, total seed protein extracted and profile established using SDS-PAGE. Genomic DNA extracted and used to examine ten of RAPDs primer and three SSRs were used as DNA markers and amplified by PCR followed by agarose gel electrophoresis, photographs and data analysis.

**Results**: Low genetic variation was observed using SDS-PAGE among studied genotypes. Primer OPA-04 successfully fingerprinted all genotypes. Primer PSMPA5 was the most efficient in all studied aspects among SSRs markers. No match observed between Phylogenetic analysis of RAPD and SSRs with genotypes origin.

**Conclusion**: Molecular markers proceed biochemical markers in fingerprinting and identification pea cultivars.

**Keywords**: Pea; SDS-PAGE; SSRs; RAPDs

Introduction

*Pisum sativum* L. is an annual herbaceous crop belongs to family Leguminosae refer to as garden pea, their seeds are consumed as dry or fresh vegetables in most countries and high in their sugar (12%), fiber, protein (about 19–27% in dry seeds) and vitamins with (2n=2x=14) chromosomes and genome size ~5000 Mbp, its next to soybean, groundnut and beans. Nowadays it’s become an alternative important source of protein to soybean in Europe, for its high nutritional value, the acceptance of pea proteins is increased. Pea beans contain biologically active components that may occupy therapeutic effects which are beneficial to health. Characterization of pea cultivars is achieved by several markers; biochemical (seed protein) and molecular RAPD, SSR, ISSR, SRAP etc. and morphological markers.

Generally studying genetic structure of germplasm by seed protein using (SDS-PAGE) is limited due to low polymorphism in most of the legumes in spite of its simplicity. Genetic variations at DNA level could evaluate degree of relationship among individuals without the influence of environmental factors. Randomly Amplified Polymorphic DNA (RAPD) technique is a PCR based DNA marker technology, its offer advantages include speed, technical simplicity, random coverage of genome and relatively higher level of polymorphism, their primers are simple arbitrary sequences of oligonucleotide with GC content of about 50%. marker systems is RAPD amplification. Application of SSRs markers in
plant has been accomplished for genetic variations, maize, tomato, soybean, Wheat and among pea genotypes, they were used for assessment genetic variation, an evolutionary studies, and to map loci responsible for the resistance to diseases or another important traits. Self-pollination in crops like pea lead to increase homozygosity in addition, that pea cultivars are possess narrow gene pool, genus *Pisum*, contains only four gene pools including *fulvum*, *abyssinicum*, *arvense* and *sativum* which increase the important of genotypes identification and genetic variation study for crop improvement.

**Materials and Method**

**Subjects:** Seven pea genotypes: 1-Sp12, 2-Vito, 3-GSN, 4-Onord, 5-P.V6-Nano, 7-Wp10 with diverse origin were used for biochemical and molecular study. Extraction of total seed protein was done by following procedure of. Preparation of sodium dodecyl sulfate-polyacryl amide gel was accomplished by method of at concentration of 12.5 percent, electrophoresis current was at voltage of 90 Volt, staining using coomaasie brilliant blue solution continue for about overnight while destaining continued till bands clearly visualized in white fluorescent light.

DNA extraction: Apical fresh leaves of seedling at age of four weeks were used for genomic DNA extraction using Genomic DNA Mini Kit (Geneaid Biotech. Ltd; Taiwan Company).

Ten operon primers A,B and C series were used. Amplification programmed as reported by for primers (OPA-01, OPA-02, OPA-03, OPA-04, OPA-10 and OPA-19) while primers (OPB-17, OPB-18, OPC-08 and OPC-09) as reported by later the amplified fragments were electrophorized at 70 V using agarose gel 1.2% for an 2-3 hours. **SSR markers:** Three simple sequence repeats were used. The PCR reaction initiated at 95°C for 10 min, later, 35 cycles started with 94°C for 30 s, 60°C for 30 s and 72°C for 30 s at. Final extension step was at 72°C for 5 min. PCR product was electrophorized at 70 V using agarose gels at concentration of 2.5% for an hour and half. Primers name and sequence illustrated in table(1).

Results

**Total seed protein:** Protein profile resulted in 13 bands ranging in their weight 17-75 KDa, out of them 12 were monomorphic, one unique and no polymorphic bands. Dendrogram grouped pea genotypes in two main groups, the first include only sp12 while the other included the rest genotypes as shown in figure (1).

**RAPD Markers:** Results showed that fragment molecular size in bp ranged 132-2326, high value for main bands (19) and seven unique bands produced by OPA-02, while OPA-04 gave high amplified bands (81). OPB-17 gave the highest value for polymorphic bands, polymorphism(%), primer efficiency and discriminatory value(%). Primer OPA-04 produced unique fingerprint for all studied genotypes while both OPC-01 and OPC-19 failed in giving any unique fingerprint for all studied genotypes. As shown in figures (2) and (3).

**Statistical analysis:** For RAPD markers Data scoring as presence of a product (1) and absence (0), then entered into PAST statistic vital program, version 62.1. While The resulting SSR markers data were analysed using Power Marker V.3 software (http://www.powermarker.net) to calculate the number of alleles, heterozygosity and polymorphic information content (PIC).
Phylogenetic analysis showed that all genotypes grouped together except Onord, clustering not concerned with their origin. Highest and lowest genetic distance were 0.43858 and 0.16427 respectively. SSR Markers: Results showed that marker PSMPA5 was the most efficient among used primers for most studied aspects. Molecular size of alleles produced by markers ranged between 142 bp-391bp. Figure (4) show the agarose gel electrophoresis of SSRs amplification product.

Phylogenetic analysis showed that studied genotypes divided between two main clusters, the first large one included P.V, Nano, Wp10 and Sp12 while the other small one included Vito, GSN and Onord neglecting their origin.

![Figure 4: Agarose gel electrophoresis of amplification product of primers PSMPA5, PSMSAA476 and X51594](image)

Discussion

High similarity with identical protein profile may resulted from the conservatization nature of seed protein. Despite high similarity (low polymorphism) in these patterns, they could be as general biochemical fingerprinting, especially changing in these profile in response to biotic and a biotic stresses. Establishment of relationship between cluster pattern and origin sometimes difficult, this might refers to that protein profiles data may related to agronomic traits. Variation among primer polymorphism concerned with number of polymorphic bands which is related to number of binding sites recognized by a primer because of loss or alteration (deletion or insertion) of nucleotide sequence changes (e.g. point mutation). Monomorphic bands refer to identical sequences are constant in genome or commonly refer to as sequence conservation. Unique fingerprint produced by some primers may related to variation in morphological traits which produce diverse RAPD patterns. The ability of primer PSMPA5 in producing high PIC value was recently reported by, while disagree for primers PSMSAA476 and X51594, this may belong to variance in characteristic of studied germplasm recognized by particular prime. SSR phylogram can be for building of breeding plans because the fact that crosses between closely related genotypes are less efficient to produce heterosis.

Conclusion

Molecular markers proceed biochemical markers in fingerprinting and identification pea cultivars especially primers OPA-04 and Primer PSMPA5.

Histological Study of Hypothyroidism Induced Effect by Methimazole on Heart and Blood Vessels of Healthy Female Rabbits

Batool A. Hussien, Shaima M. Yaser, Alaa M. Alsafy, Kaiser A. Mohameed

1Department of Biology, College of Education for pure Sciences, University of Kerbala, Iraq

Abstract

The study was designed to investigate the effect of hypothyroidism induced by methimazole drug on blood vessels and heart tissues histology of female rabbit. The experiment has included twenty adult female rabbit weighing 1500-2000 gm. They were divided into two groups (10 rabbit/group) as follows. Group one (G1) was a control group, ten female rabbits Water and regular food were given as a positive control group. Group two (G2) ten female rabbits were orally received only methimazole (0.02 mg/kg B.W). Histological sections revealed significant changes in the heart and blood vessels. Such changes include endothelium enlargement and thickening of lining of the vessel, hyperplasia, infiltration of inflammatory cells and fatty vacuoles in tissue cells.

Keywords: hypothyroidism, methimazole, heart, blood vessels, female rabbits.

Introduction

Thyroid gland is a butterfly shaped endocrine gland responsible for secretion Thyroxin (T4) and triiodothyronine (T3) hormones that have an important role in cell metabolism. The gland is representing the basis for energy generation by increasing the metabolic rate in the body. As a matter of fact, it controls the functions of the body as a whole, and regulate growth by increasing the rate of chemical reactions and stimulate metabolic activity in the body. Triiodothyronine (T3) and Thyroxin (T4) are the only amine containing hormones in vertebrates which contain iodine. They are the basic hormones considered to be important regulators of growth, differentiation, proliferation and metabolism of most tissues and organs. Clinical studies of hypothyroidism have shown a possible association between metabolic syndrome, obesity, and impaired lipid metabolism.

The hypothyroidism is a common disorder in the endocrine system, when the thyroid does not produce enough of its own hormones, or it might be an inactive gland which is unable to make enough hormones to maintain the activity of the body. Hypothyroidism causes inactivity and poor coordination of the motor function. It is often associated with low memory, especially in the elderly and loss of cognitive functions. Low thyroid function is a risk factor that increases the risk of atherosclerosis due to significant changes in fat metabolism, resulting in increased blood fat.

Methimazole as a drug inhibits thyroid peroxidase from conjugation in the stimulating reactions of Iodine tyrosine bindings but does not affect the process of converting iodine to oxidized form during the Iodination process, thereby limiting the production of thyroid hormones.

To investigate the harmful effect of hypothyroidism induced by Methimazole on some histological change in heart and blood vessel tissue.

Materials and Method

Animals and experimental design:

Twenty adult female rabbits, eight months old and mean body weight of 1.5-2 kg were used. The study was conducted at the animal house of Pharmacy college.
during summer of 2018. Ten rabbits were randomly designed to each of the 2 groups (G1, G2). Water and regular food were given for both groups. The rabbits of the control were maintained for the same water and food for the whole period of the experiment which lasts for four weeks. For group two (G2) as a treated group, the rabbits were given Methimazole drug (an Irish product produced by SAS). The drug was administered by gastric intubation with a dose of 0.02 mg/kg body weight for 4 weeks daily. The stock solution was prepared by dissolving one tablet (5 mg) of Methimazole to 250 ml of distilled water, as each 1 ml of solution contains a 0.02 mg concentration of the drug according to Amber et al. At the end of the experiment, the animals were euthanized and the samples were collected. The sample was initially saved after being removed from the animal in the formalin solution at a concentration of 10%. After four to five days it was extracted from formalin and washed several times with tap water and then preserved at ethyl alcohol at 70% concentration. It was then conducted a series of preparations.

**Histological sections**: were prepared according to the method described in (9)

**Results**

The heart sections of the control group showed normal histological structure to the epicardium and myocardium of ventricle with purkinje fibers(Figure 2).

The main microscopic findings in animals treated with 0.02 mg/kg of Methimazole are characterized by several vacuolation of muscle cells with dilation and Congestion of blood vessels in myocardium of ventricle (Figure 3). There is also Increase in volume of myocardium fibers (Figure 4). On the other hand, the histopathological examination of veins in treated group showed endothelium enlargement and thickening of blood vessel wall (Figure 5). there are fatty vacuoles can be observed(Figure 6). The results also showed hyperplasia in the blood vessel wall (Figure 7) beside wall thickening and infiltration of inflammatory cells (Figure 8). Also the sections revealed to the projection of endothelium inside the lumen of the vessel (Figure 9).
Figure (3) Histological change in heart of female rabbit in group treated with 0.02 mg/kg of Methimazole showed Increase in volume in myocardium fibers (H&E stain, 10X).

Figure (4) Histological change in treated with 0.02 mg/kg of Methimazole Showed Enlargement and thickening endothelium of blood vessels and Showed fatty vacuoles (H&E 40X).
Discussion

Thyroid hormones contribute to blood flow by increasing the rate of cardiac output by increasing the rate of heartbeat and the occurrence of hypothyroidism, which was created by a drug that is reflected in the body’s vital functions, including metabolism and regulation of the circulatory system. A drug is used to develop hypothyroidism in laboratory animals by inhibiting the work of an enzyme that binds iodine with the amino acid and then linked with the thyroid follicles, which is an important step for the production of thyroid hormones.

The oral dosage of a drug for one month led to changes in the tissue of the lining of the blood vessel such as hyperplasia and thickening in endothelia and infiltration of inflammatory cells.
as the appearance of fatty vacuoles and foamy cells, and the thickening and irregularity of the endothelium. This is consistent with the cause of damage to internal artery lining to the oxidative stress resulting from the rise in concentrations of many effective oxygen roots such as hydroxyl radicals, superoxide and hydrogen peroxide and in quantities exceeding the capacity of antioxidant tissue defenses to get rid of These roots cause damage and vandalism in the tissues as this drug has a role in causing oxidative stress and the generation of free radicals and damage in the tissues of the body accompanied by an increase in the stench of tissue leading to degradation Polyunsaturated fatty acids resulting in damage to the body’s various tissues. The mechanism of appearance of the tissue lesions represented by the oxidation of LDL-C fatty acids, ox-LDL-C molecules by phagocytic cells and the formation of foamy cells with adhesion and penetration of the monocytes of the vessel wall The formation of cytokines, the growth factors, the migration and proliferation of smooth vascular muscle cells, as well as the formation of vascular lesions accompanied by fibrosis and thrombosis.

The presence of thickening in the wall of the blood vessel is due to the proliferation of smooth muscle cells of the vascular stage of reproduction and then the emergence of fatty deposits due to the damage of the lining, which is followed by inflammatory infiltration to the vent under the lining to eat the molecules of low density lipoprotein oxidizing the formation of foamy cells and programmed death of these cells. To the formation of fatty threads.

The increase in blood cholesterol due to the oral dosage of a drug for a month lead to imbalance of the blood supply of the heart through the blood oxygenation, which leads to narrowing of the coronary arteries and closure and thus the occurrence of blood ischemia, which leads to the generation of free radicals that act on the oxidation of fat to the cell membrane and Membrane collapse and death of myocardial cells due to lack of oxygen.

**Conflict of Interest:** This research is a personal non-profit work and there is no conflict of interest.

**Source of Funding:** None.

**Ethical Clearance:** Ethical clearance was obtained from the Faculty Scientific Committee (College of Education for Pure Science, University of Kerbala, Iraq) to study of the histological hypothyroidism induced effect by methimazole on heart and blood vessels of healthy female rabbits.

Prevalence of Depression among Mothers of Children with Type 1 Diabetes Mellitus attending two Diabetes Centers

Dheyaa J. Kadhim¹, Sarah A. Kadhim¹, Fatima Z. Ali¹, Hayder A. Fawzi²

¹Department of clinical pharmacy, College of Pharmacy, University of Baghdad, Baghdad, Iraq,
²Department of Clinical Pharmacy, Baghdad Medical City hospital, Baghdad, Iraq

Abstract

Objective: This study aimed to measure the prevalence and to identify predictors of depression among mothers of children with type 1 diabetes mellitus.

Method: A cross-sectional study was carried out on 30 healthy control mothers and 100 mothers of type 1 diabetes mellitus children who met the inclusion criteria. The Arabic version of the 9–statement Patient Health Questionnaire used for screening of depressive symptoms.

Results: The prevalence of overall depression reported among the mothers of diabetic children was (95%). The mean 9–statement Patient Health Questionnaire score for depression was significantly higher in mothers of diabetic children (13.4 ± 5.0) compare to control group (7.57 ± 3.01). No depression and mild depression were more prevalent among control group when compared to case group; while, the moderate depression, moderately severe depression and severe depression were more prevalent among mothers of diabetic children compared to control group. Only education level appear as predictor of depression in mothers of diabetic children in which higher education levels had increased risk of depression.

Conclusions: The presence of diabetes as a chronic illness in children is a risk factor for developing depression by the child’s mother.

Keywords: depression, diabetic children, maternal depression, patient health questionnaire-9 (PHQ-9).

Introduction

Diabetes mellitus is a metabolic disorder characterized by hyperglycemia due to defects in insulin secretion and/or insulin action¹. The worldwide prevalence of diabetes in 2010 was about 280 million, predicted to increase by the year 2030 to about 440 million². Type 1 diabetes mellitus (T1DM) represents about 5 to 10% of the total cases worldwide³. T1DM resulted from immune-mediated pancreatic β-cells destruction⁴. Depression is a worldwide high prevalence condition; about 340 million people complaining of depression globally⁵. Depression is the leading cause of disability and the fourth leading cause of the global burden of disease on the World Health Organization (WHO)⁶. Diabetes mellitus, like other chronic diseases, can cause a serious inquietude in children as well as in their family⁷,⁸. The high diabetes-related stress are frequently associated with increased risk for depression and anxiety among mothers of children with diabetes⁹, with clinically significant symptoms reported in about 20–30% of mothers¹⁰,¹¹. Maternal depression was more commonly reported in the literature than the paternal depression¹². Knowing depressive status could aid health care professionals in helping parents address the feelings of frustration, burnout, and vulnerability¹². The aim of this study was to measure the prevalence and to identify predictors of depression among mothers of children with type 1 diabetes mellitus.

Subjects and method

Study design and participants

A cross-sectional study carried out from April 2017-to March 2018, on 30 healthy control mothers (age 32.6 ± 9.05 years) and 100 mothers of T1DM children (age 32.62 ± 8.06 years) who attended two diabetes centers in Baghdad/ Iraq (The National Center for Diabetes Treatment and Research, Al-Mustansiriyah University, and the Specialized Center for Endocrinology and Diabetes, Ministry of Health).

Inclusion criteria:

Any mother having a type 1 diabetic child (age ≤ 12 years) for more ≥ 1 year who will accept to participated in the study.

Exclusion criteria:

1-Any mother with diabetic child above 12 years or having the disease for less than 1 year.

2-Mothers who take antidepressant drugs, or being on treatment for any neurological or psychological diseases.

Data collection

The data were collected using a data collection sheet designed for the purpose of the study; the following information was recorded for each participant:

1-Demographic data related to mothers: age, residency, education, and number of children.

2-Demographic and disease characteristics of patients (T1DM children): age, duration of disease, number if insulin daily dose, and number of hospital admissions during the previous six months.

3-Questionnaire: The Arabic version of the 9–statement Patient Health Questionnaire (PHQ-9) was used for screening of depressive symptoms; The PHQ-9 is a multipurpose instrument for screening, monitoring and measuring the severity of depression; it is brief and useful in clinical practice. A score (ranging from 0 to 3) is given for each of the 9 statements; the sum of the total scores gives the provisional diagnosis for depression as shown in (table-1).

Statistical Analysis

Continuous data presented as mean ± standard deviation while categorical variables presented as mean and their percentage, independent t-test used to compare two continuous data while chi square test used for categorical variables. Binary logistic regression used to assess the relationship between different predictor in patients with depression, SPSS 22.0.0 (Chicago, IL) software package used to make the statistical analysis, p value considered when appropriate to be significant if less than 0.05.

Results

The personal characteristics of the participants enrolled in the study are shown in (table-2) where there were no significant differences between the mothers of diabetic children and the control group in age, education and residency.

Binary logistic regression
Discussion

Diabetes mellitus is a common metabolic disorder with medical and economic consequences. The Arab world will have the second highest increase in the percentage of people with DM in 2030 compared to other parts of the world\(^\text{4}\). Diabetes was an emerging epidemic in Iraq. There were 1,411,500 cases of diabetes in Iraq which represent 7.5% of total population in 2017\(^\text{7}\). This study intended to throw light on the important aspect of a common health problem in Iraq. The results have clearly shown that depression was significantly higher and more severe among mothers of diabetic children than in controls. The results of the current study showed that prevalence of (no depression) and mild depression were higher among control group compared to mothers of diabetic children. In contrast, moderate depression, moderately severe depression, and severe depression were more prevalent among mothers of diabetic children compared to control group. However, the mean PHQ-9-score of mothers of diabetic children was significantly higher than that of the control group. Surprisingly noticed, the high prevalence of mild depression (50.0 %) and moderate depression (33.3%) among the control group. Health Survey was carried out in 2006–2007 which studied the epidemiology of major depressive episode (MDE) in the adult Iraqi general population and found that MDE is a common mental disorder in Iraq, affecting around 475,000 Iraqi adults, of which 46% are severe or very severe cases\(^\text{16}\). Regarding the depression among the mothers of diabetic children, the results of the current study are consistent with that reported in other studies where a high incidence of psychiatric problems among the parents of diabetic children was observed in a Swedish study\(^\text{17}\). In a similar Scottish study, the mothers of diabetic children were found to be more depressed and anxious than mothers of the control group\(^\text{18}\). While fathers have an important role in caring children with diabetes\(^\text{19}\), mothers are usually the parents responsible for the most of treatment management\(^\text{12, 20}\). Accordingly, mothers may experience greater psychological stress than fathers when caring a child with diabetes\(^\text{12, 21, 22}\). Mothers also report constantly worrying about their hyper- or hypoglycemia, food management, insulin administration, blood glucose monitoring, and long-term complications\(^\text{22, 23}\). Maternal stress and depressive symptoms are linked with negative outcomes, including deteriorating glycemic control, poorer quality of life, and greater depressive symptoms\(^\text{24-26}\). The prevalence of overall depression reported among the mothers of diabetic children in the current study (95%) was higher than that (75.4%) reported by Maryam et al (2016) among Iranian parents of children newly diagnosed with T1DM\(^\text{27}\). Only education level appear as predictor of depression among mothers of diabetic children in which higher education levels had increased risk of depression (7.7 folds). This may be due to that educated mothers may have better knowledge about long-term complications of diabetes which may lead to higher depressive symptoms among them compared to lower educated mothers.

Study limitations

The study had some limitations. First, small sample size of the participants. Second it was conducted in only one city of Iraq (Baghdad), therefore, the findings and conclusions of the study should not be generalized to Iraq\(^\text{4}\).

Conclusion

In conclusion, the results of the current study clearly indicates that the presence of diabetes as a chronic illness is a risk factor for developing depression by the child’s mother. Such findings are important to the practicing health care workers, as such aspects of the disease are not well taken care of in the clinics.

Conflict of Interest : None

Ethical Clearance: Informed written consent was obtained from all the participants in the study, and the study and all its procedure were done in accordance with the Helsinki Declaration of 1975, as revised in 2000. The study was approved by college of pharmacy, Baghdad University.

Source of Funding: The workers was supported by authors only

Acknowledgment: The authors are grateful to the college of pharmacy university of Baghdad, college of pharmacy university of Al Mustansiriya, and the Specialized Center for Endocrinology and Diabetes medical staffs, for helping carrying out this work. Also we would extend our thanks to the parents and their children who participated in the study.

Effect of Leadership Style on Team Work, Patient Safety Performance, and Patient Safety Culture

Dike Widyakti Sawfina Maharani¹, Margono Setiawan², Dodi Wirawan Irawanto², Mintarti Rahayu²

¹Doctoral Program in Management Science, University of Brawijaya, ²Department of Management, Faculty of Economics and Business, University of Brawijaya

Abstract

This study was prepared to test and analyze the influence of patient safety culture factors, leadership style and teamwork on patient safety performance at Ulin Banjarmasin Hospital. A research concept framework that brings together four variables, namely leadership, teamwork, patient safety culture and safety performance. This study uses the positivist paradigm based on quantitative research. The results of the research obtained are leadership style that influences teamwork, leadership style influences patient safety performance, leadership style influences the patient safety culture.

Keywords: Leadership, Team Work, Safety Performance, Patient Safety Culture

Introduction

WHO in 2004 collected hospital research numbers in various countries, namely America, Britain, Denmark and Australia and found Unexpected Events with a range of 3.2% -16.6%. The data is a trigger in various countries to conduct research and development of patient safety systems.¹

In Indonesia, safety law has been made related to patient safety in 2009 which states that hospitals as health care agencies that deal directly with patients must prioritize safe, quality, anti-discriminatory and effective health services by prioritizing patient interests in accordance with standard home services.² Patient safety is a top priority in health services and is the first critical step to improve service quality and is related to the quality and image of hospitals.³

Improvements in patient safety outcomes, especially from organizations and individuals. In organizations there is a need for cultural change that focuses on the team and the Team Leader has the strong potential to bring patient safety management and better quality care. Teams must be tied to management in a way that enables their accountability to be recognized by everyone. A good team will be an open team learning from mistakes.⁴

Based on Minister of Health Regulation 1691 / MENKES / PER / VIII / 2011⁵ about Hospital Patient Safety that every hospital is required to carry out patient safety management. Ulin Banjarmasin Hospital is a hospital owned by the Provincial Government of South Kalimantan type A with complete classification according to the 2012 Hospital Accreditation Commission assessment Banjarmasin Ulin Hospital has a commitment to maintain and continue to improve service quality and patient safety so that it can provide excellent health services continuously and continuously for the community.

The culture of reporting an error is hampered because the formation of a blame culture is a frequent occurrence, so that solutions sometimes stop by pointing to someone’s mistakes. So that a system is needed where it can be seen how far the patient’s safety performance in the hospital can make continuous and continuous quality improvement efforts and to meet the needs and demands of the community and refer to the law on hospitals. This study aims to examine and analyze the influence of leadership styles on teamwork, patient safety performance, and patient safety culture.

Method

This study uses the positivist paradigm based on quantitative research. More specifically, this study aims to analyze the effect of exogenous variables on endogenous variables. Exogenous variables include: leadership style, teamwork. Endogenous variable is patient safety performance. In addition to exogenous and endogenous variables, in this study there are also mediating variables, namely the culture of patient safety.

The population in this study were all employees working in all installations at Ulin Banjarmasin Hospital. The need for the number of samples will be calculated using the Slovin formula by determining the number of members of the population that can be researched (N) of 1215 with a degree of inaccuracy (d) of 5%. Then the number of samples needed is:

\[ n = \frac{N}{1 + Nd} \]

= 300.9 rounded to 301

In variable measurement techniques, when viewed from the nature of their influence, the research variables can be classified into endogenous variables and exogenous variables. In this study, to be able to measure and study the hypothesized variables, it will use the second order CPA measurement model, where the dimensions reflect the first level latent variables while the hypothesized variables are called the second level latent variables. The measurement scale that will be used in this study on all variables is the ordinal scale in this case the Likert scale.

The data to be collected and analyzed in this study come from primary data and secondary data. Primary data is collected from research instruments, namely questionnaires, which are the main instruments in this study. The secondary data will be collected from Ulin Banjarmasin Hospital internal data. The secondary data is the hospital profile and patient safety program at Ulin Banjarmasin Hospital.

In the research instrument test consisted of validity and reliability tests. Data analysis methods used are descriptive statistical methods and inferential statistical methods. The purpose of the descriptive statistical method is to describe the demographic characteristics of respondents such as gender, age, profession, position, length of work as an employee at Ulin Hospital Banjarmasin. While the inferential statistical analysis method that is data analysis used in inferential statistical methods in this study is partial least square (PLS).7

The Leadership Style variable (ξ1) is second order reflective:

First order:

\[ \xi_{11} = \lambda_{11} \xi_{1} + \delta_{1} \]
\[ \xi_{12} = \lambda_{12} \xi_{1} + \delta_{2} \]

Second order:

Transactional Leadership Style (ξ11)

\[ X_{11} = \lambda_{11} \xi_{11} + \delta_{11} \]
\[ X_{12} = \lambda_{12} \xi_{11} + \delta_{12} \]
\[ X_{13} = \lambda_{13} \xi_{11} + \delta_{13} \]

Transformational Leadership Style (ξ12)

\[ X_{21} = \lambda_{21} \xi_{12} + \delta_{21} \]
\[ X_{22} = \lambda_{22} \xi_{12} + \delta_{22} \]
\[ X_{23} = \lambda_{23} \xi_{12} + \delta_{23} \]
\[ X_{24} = \lambda_{24} \xi_{12} + \delta_{24} \]

The Team Work Variable (η1) is reflective

\[ Y_{11} = \lambda_{31} \eta_{1} + \varepsilon_{11} \]
\[ Y_{12} = \lambda_{32} \eta_{1} + \varepsilon_{12} \]
\[ Y_{13} = \lambda_{33} \eta_{1} + \varepsilon_{13} \]

The variable Patient Safety Culture (η2) is reflective

\[ Y_{21} = \lambda_{41} \eta_{2} + \varepsilon_{21} \]
\[ Y_{22} = \lambda_{42} \eta_{2} + \varepsilon_{22} \]
\[ Y_{23} = \lambda_{43} \eta_{2} + \varepsilon_{23} \]
\[ Y_{24} = \lambda_{44} \eta_{2} + \varepsilon_{24} \]
\[ Y_{25} = \lambda_{45} \eta_{2} + \varepsilon_{25} \]
\[ Y_{26} = \lambda_{46} \eta_{2} + \varepsilon_{26} \]
\[ Y_{27} = \lambda_{47} \eta_{2} + \varepsilon_{27} \]
\[ Y_{28} = \lambda_{48} \eta_{2} + \varepsilon_{28} \]
\[ Y_{29} = \lambda_{49} \eta_{2} + \varepsilon_{29} \]
\[ Y_{210} = \lambda_{410} \eta_{2} + \varepsilon_{210} \]
The patient safety performance variable ($\eta_3$) is reflective

\[ \begin{align*}
Y_{31} &= \lambda_{31} \eta_3 + \epsilon_{31} \\
Y_{32} &= \lambda_{32} \eta_3 + \epsilon_{32} \\
Y_{33} &= \lambda_{33} \eta_3 + \epsilon_{33} \\
Y_{34} &= \lambda_{34} \eta_3 + \epsilon_{34} \\
Y_{35} &= \lambda_{35} \eta_3 + \epsilon_{35}
\end{align*} \]

Partial Least Square (PLS) analysis is done through two stages, namely evaluating the outer model and inner model. Outer model is a measurement model to assess construct validity and reliability. The second stage in PLS analysis is the evaluation of the inner model to determine the coefficient $R^2$ for the dependent construct and the $t$-statistic value to test the construct of significance in the structural model.\textsuperscript{7,8}

The characteristics of the respondents in this study consisted of age, gender and work period. Respondent characteristics in this study had a age of 31-40 years which was equal to 43.0%, then age 41-50 years which amounted to 26.7%, 25.2% were over 50 years old, and the remaining 4.7% were <30 years old. Based on gender, it was seen that the majority of respondents in this study were men. The proportion of the male group is 64.0%, while in the female group is 36.0%. And based on the working period, it was explained that the majority of respondents had a working period of 11-15 years of 25.6%, working period of 16-20 years was 23.3%, working period of 6-10 years was 20.9%, working period of more than 20 year 19.8% and work period of up to 5 years is 10.5%.

The patient safety performance variables of each item have an average value ranging from 2.66 to 4.79 which can give an idea that patient safety performance is good enough. The highest mean value of 4.79 is in identifying patients before administration of drugs, blood, or blood products. While the lowest 2.66 is in carrying out the provision of information that is timely, accurate, and relevant in the hospital environment. This study uses six indicators to describe the variables of patient safety performance, including indicators (safe) (KK1), (effective) (KK2), (patient-centered) (KK3) (KK4), (efficient) (KK5), and (equitable) (KK6).

Based on the results of the descriptive study that based on the average score of respondents’ answers to the leadership style variable is included in the good category, thus it can be said that actually all indicators are included in the criteria of good. Therefore, all of these indicators should be maintained or reused. This study uses 6 indicators to describe variable patient safety performance, including contingent reward indicators (KK1), active management by exception (KK2), passive management by exception (KK3), inspirational motivation (KK4), intellectual simulation (KK5), and individualized consideration (KK6), idealized influence (KK7).

The variable value of team work for each item has an average value ranging from 3.51 to 4.24 which can give an idea that the value of team work is good. The highest average value of 4.24 is in the team members committed to achieving common goals / missions, while the lowest 3.51 is in me giving to other team members in decision making. This study uses three indicators to describe
the variable value of team work, includes indicators of commitment to shared goals (TW1), decision making (TW2), and conflict management (TW3).

The variable patient safety culture of each item has an average value ranging from 2.26 to 4.31 which can give an illustration that the patient safety culture is quite good. The highest average score of 4.31 is in our mutual support for one another, while the lowest of 2.26 is unpleasant if working with other parts of the hospital. This study uses twelve indicators to describe the variable of patient safety culture, including perception indicators (BK1), frequency of reporting (BK2), supervision (BK3), organizational learning (BK4), intra-sub-departmental collaboration (BK5), openness of communication (BK6), reciprocal errors (BK7), error sanctions (BK8), staff/employees (BK9), management support for patient safety (BK10), collaboration between sections (BK11), and transfer and replacement (BK12).

Discriminant validity testing in research uses cross loading values and square root of average (AVE) with the aim of checking (testing) whether indicators are valid in explaining or reflecting latent variables.

The results show that the discriminant value of a variable’s validity is higher than the correlation value between variables. Thus it can be concluded that the outer model of this study has fulfilled discriminant validity. For example, the leadership style construct has an AVE value of 0.685, then the AVE root is 0.828. The large correlation coefficient construct leadership style with other constructs ranged from 0.473 to 0.574 so that this analysis concludes that there is a fairly discriminatory validity.

Reliability test results show that all constructs have a composite composite coefficient of more than 0.70. Thus, all measurement models used in this study already have high reliability. So that further analysis can be done by examining the goodness of fit model by evaluating the inner model.

Convergent validity measures the validity of an indicator as a measure of a construct, can be seen from the outer loading. Indicators are considered valid if the outer loading load 0.5 to 0.6 is considered sufficient, in the number of indicators per construct is not large, ranging from 3 to 7 indicators. In the PLS model, the loading factor for the reflexive indicator is outer loading, and for the formative indicator is the outer weight.

Model compatibility

Testing the structural model of Goodness of Fit on the inner model uses predictive-relevance (Q2) to measure how well the observation value is generated by the model. Q2 is based on the coefficient of determination of all dependent variables. The magnitude of Q2 has a range of values of $0 < Q2 < 1$, getting closer to 1 means the model is getting better. The suitability of the model can be assessed from several calculations such as the model coefficient of determination (Rm2) and the index of goodness of fit (GoF).

Hair et al. (2014) states that in general the coefficient of determination is low if it is worth 0.20 or less, while the results of this model are all worth more than 0.20. So based on these results the suitability of the model is quite good.9 The calculation results show the value of the inner model Rm2 is 0.800, which means that the research model has a high model match. The accuracy of the model is 80.0%, explaining that the contribution of the model to explain the structural relationship of the four variables studied is 80.0% and the rest is explained by other variables not involved in the model.

Structural Model Testing (Inner model)

The following are the results of measurements by testing the Inner model

Table 5. Path Coefficient Test Results in the Inner Model

<table>
<thead>
<tr>
<th>Relationship</th>
<th>Path coefficient</th>
<th>Standard Error</th>
<th>Statistic t</th>
<th>P</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variables with variables</td>
<td></td>
<td></td>

<tr>
<td>Leadership style -- Safety performance</td>
<td>0.188</td>
<td>0.066</td>
<td>2.861 *</td>
<td>0.002</td>
</tr>
</tbody>
</table>

The interpretation of the tables and images explains the relationships between variables as follows:

The leadership style of teamwork has a coefficient with a positive direction. The calculation results show that the path coefficient is 0.496 with a t-statistic of 8.632 ($p < 0.05$) giving a decision that the leadership style has a significant effect on teamwork.

The leadership style of the patient safety culture has a coefficient with a positive direction. The calculation results show that the path coefficient is 0.296 with a t-statistic of 5.689 ($p < 0.05$) giving a decision that the leadership style has a significant effect on the patient safety culture.

3. The leadership style of patient safety performance has a coefficient with a positive direction. The calculation results show that the path coefficient is 0.188 with a t-statistic of 2.861 ($p < 0.05$) giving a decision that the
leadership style has a significant effect on patient safety performance.

**Conclusion**

The leadership style has a significant direct effect on teamwork. The calculation results show that the path coefficient is 0.496 (p <0.05). The leadership style has a significant direct effect on patient safety performance. The calculation results show that the path coefficient is 0.188 (p <0.05). The leadership style has a significant direct effect on the patient safety culture. The calculation results show that the path coefficient is 0.296 (p <0.05).

The Effect of Karin’s Model on Positive and Negative Thinking and the Development of Some Offensive Composite Basketball Skills for Female Students

Doaa Muhbuldeen Ahmed¹, Manal Abbood Abdulmajeed¹, Liqaa Abdullah Ali¹
¹University of Baghdad/The college of Physical Education and Sport Sciences/Iraq

Abstract

The purpose of this study is to prepare and implement the modules in accordance with model Karin to develop some offensive skills basketball composite for students and identify the impact of gastric units with model Karin in positive and negative thinking and developing some offensive skills basketball composite for students either presumably there is research Statistically significant differences between the results of the tests of fingerprinting research experimental and control in the positive and negative thinking and developing some offensive skills basketball composite for female students and there is a statistically significant differences between the two sets of research officer and experimental results After tests in positive and negative thinking and developing some offensive skills basketball composite for students and researchers had used experimental method is experimental and one control totals tests on a sample of pre and post 45 freshman students phase in College Physical education and Sports Science/University of Baghdad and the positive and negative thinking was conducted on a sample of major experience as well as skill tests, then your approach has been applied to model Karen and then the researchers used statistical methods appropriate to extract the light results reached a number of conclusions from her stomach units with model Karin has a positive impact on the positive and negative thinking and experimental group than the control group in positive and negative thinking and superiority of the experimental group and control group was used to model Karen The approach used in the college in developing skills.

Keywords: Karin’s model, positive, negative thinking and composite skills.

Introduction

Education has an active role in the progress of nations and peoples and contribute to the achievement of hopes and aspirations, and this progress contributed to the creation of many methods and models of teaching, science has become doubly amazing and the student to be successful in reaching the goal required to receive a large amount of information is always renewable And know how to have the right information and useful at the same time to convert it to know “¹

In order to find more effective models that have an impact on the student, he must be able to acquire the information that helps them in confronting the new situations and to benefit from them in changing ideas and issuing judgments and generating new ideas in order to be able to achieve the objectives of the educational process. One of these models is the Karen model. This model is an integrated, multi-disciplined educational model based on cognitive theory. Its idea derives from the meaningful learning theory of Ozbel, which has made the learner the focus of the educational process, the exploitation of the previous knowledge, its activation and acquisition of new knowledge in an integrative, With the requirements of the educational situation in which the previous information is invested and the experience is recalled for the purpose of building knowledge “²

Positive and negative thinking is one of the most important types of thinking. Positive thinking is very important in human life because it leads people to solve their problems, overcome difficulties, achieve their goals and feel satisfied. Basketball is one of the most competitive and competitive games in the world. It has a number of complex offensive skills such as handling, plucking, handling, correcting, handling, stopping, and other complex skills that are important skills. Their mastery is an effective element in achieving the best results in matches. Hence the importance of research in the preparation of units model Karen, which may have an impact on the thinking of positive and negative and the development of some of the offensive skills compound basketball.

**Research aims:**

1. Preparation and implementation of units on the model Karen to develop some of the offensive skills compound basketball students.
2. Identify the units prepared according to the Karen model in the positive and negative thinking and develop some of the offensive skills compound basketball students.

**Research methodology and field procedures**

**Research Methodology:**

The researchers used the experimental approach and the design of experimental and control groups with both pre and posttests to suit the nature of the research problem.

**Community Research and sample:**

The research community of the second stage students in the College of Physical Education and Mathematical Sciences for Girls of Baghdad University for the academic year (2018-2019) of (102) students in the grades were chosen by the deliberate method. The researchers chose the random sample in the lottery method, B) The experimental group is 24 students and the second is the control group. The total number of students is (21) students to be the total number (45) students. The sample of the pilot experiment was chosen from outside the sample of (5) from class (D).

Methods used in research:

1. Arab and foreign sources and references.
2. The questionnaire.
3. Experts and specialists.
4. For objective tests.

**Tools and devices used:**

1. Basketball field and accessories.
2. A computer type Dell (1).
3. Camera photography.
4. Measuring tape to measure distances.
5. Adhesive tape
6. Hour manual stopwatch.
7. Whistle.
8. Paintings showing the drawings.
9. Pictures showing how the technical performance of the skills selected in the research.

Field research procedures:

**Field research:**

**Determination of measurements and tests:**

**Positive and Negative Thinking Scale:**

After studying the many sources and scientific references, studies and research for the purpose of finding a measure through which to identify the amount of positive and negative thinking of the sample of the search, they found only a measure prepared by Saba Duraid super-age (2016). The researchers obtained the original source of the scale of positive thinking The questionnaire was presented by a questionnaire to the group of experts and specialists in the field of tests, measurement, kinetic learning, and psychology to determine the suitability of the scales for the second stage students at the Faculty of Education for girls and measured to reflect on the positive and negative when the university students.

Correction Method for Positive and Negative Thinking Scale (Key Sealing): The researcher identified each alternative position (A, B) and corrected the respondent’s answers on the scales of the scale (58) position in weights (1, 2) The method of the answer by selecting the appropriate alternative to the student on the situation and in this way will calculate the total score of each respondent through the total number of grades on Scale sections.
Skills Identification:

The researchers relied on the basic skills set in the vocabulary of the second stage (first course) in the Faculty of Physical Education and Sports Science for Girls (2018-2019) and the skills are:

Composite offensive skills:

First test:  

The purpose of the test: is to measure the ability to receive and the high-end conversation.

Account Grade:

- Calculates the time since the player received the ball lab until the end of the attempt after the ball left the hand of the laboratory player.
- Time division on (60 Sec.).
- The score for each player is determined by a successful jump.
- The score for the player (zero) of the score for each case of a peaceful correction or performance is incorrect.
- Collect degrees (accuracy) of successful attempts.

Total: division of the output of precision over time.

Second test:  

The purpose of the test: measuring the ability to receive the finished by jumping - two points

Account Grade:

Calculates the time since the player received the ball lab until the end of the tenth attempt after the ball left the hand of the laboratory player.

Time division on (60 Sec.).

The player will score one score for each successful jump.

The score for the player (zero) of the grades for each case of a failed jump correction.

Collect degrees (accuracy) of successful attempts.

Total: division of the output of precision over time.

Pre Tests:

The researchers conducted the pretests for the sample of the (45) students on Tuesday (9/10/2018) before starting the main experiment with the control of all variables.

Implementation of the main study:

The researchers put the units of the Karen model of the experimental group and distributed to (8) units by one unit per week. The steps of the Karen model,

1. Review of previous information:
   A-At this stage, the information and skills that students learned in other lessons were reviewed.
   B-Preface: Started by the teacher in which the teacher provides applications with an introductory introduction includes the title and objectives of the lesson, and this stage aims to focus the attention of students in the subject of the lesson and then prepare for the integration of learning.

2. Overview: This procedure includes the development of a general organizational framework for the content of the lesson facilitates linking the content contained in the new information to be merged with the previous information of the learner and already exist in the construction of knowledge and the teacher can complete the stage of the overall view through the work of illustrations and maps concepts and the presentation of special videos. Skillfully, which in turn helps students to understand carefully the skill and help them to divide broad ideas into narrow and less comprehensive ideas.

3. The stage of strengthening the knowledge structure: This stage aims to install new information and establish it in the cognitive structure of the learner by making the student active in the research and survey and not be negative, but to do a number of internal and external activities

4. Registration: Students will record the results reached during the stage and these results are represented in the form of drawings and maps concepts, panels, lists, tables and reports.

5. Dialogue or discussion: As the students discuss the results recorded by students in the previous stages.

6. Knowledge supply: The teacher himself develops the ideas and conclusions reached by students in the previous stage (dialogue and discussion) and organizes and shows the relationship between them and then formulated and presented to students in the final

7. Application: Students practice alone or in cooperative groups skills that require dealing with them and employ their knowledge in new learning situations and requires when the implementation of this stage the passage of the learner in the stages of the previous model.

Posttests:

The researchers carried out posttests after completing the curriculum on (2-3 / 12/2018) on the two groups of control and experimental research of (45) students in the stadium and external theory hall in the Faculty of Physical Education and Sports Science.

Results and Discussions

Display the results of the pre and posttests of the experimental group in the investigated variables:

Table (2). Shows the mean, standard deviations and values calculated between the pre-test and the post-test of the experimental group in the variables investigated

<table>

The table value (1.741) was below the level of significance of 0.05 and the degree of freedom 23.
Table (2) shows the computational, standard deviations and calculated values of the differences between the arithmetic averages in the pre-test and the post-test. The results showed that the computed values of the receiving skill, the high discrete ending, the pacification and the positive, the positive and negative thinking were higher than the table values (1.714) below the level of significance of 0.05 and the degree of freedom 23, meaning that there are significant differences between the pre-test and the post-test of the variables investigated and for the post-test, meaning that Karen model positively affected the development of offensive skills and the effect of positive and negative thinking on the students in the research group. The researchers attribute this to the fact that teaching according to this Karen model makes the students the focus of the educational process and makes them positive, active, and active in their attention. Increase their effectiveness in participating in the lesson, stimulate their motivation, and help to organize ideas and develop better offensive composite skills.

Table (3). Shows the mean, standard deviations, and calculated values between the pre-test and the post-test of the control group in the investigated variables:

</tr>
</tbody>
</table>

The value of (t) Tabulated (1684) under the level of significance (0.05) and the degree of freedom (43).
Table (4) shows the arithmetic, standard deviations, and calculated values of the differences between the experimental and control groups in the post tests of the investigated variables. The results showed that the calculated values of the reception skill, 1.684) below the level of significance (0.05) and degree of freedom (43) This indicates the existence of significant differences between the experimental and control groups in all variables investigated and for the benefit of the experimental group and encourage the researchers to use a model that was He has an active role in demonstrating the abilities of female students through the use of complex offensive skills and increased their arousal and eagerness for skill. He emphasized Karen’s model of making students the center of the educational process and giving them the freedom to express their opinions without hesitation or fear. This reflected positively on their thinking and skills. The students’ involvement in the generation and discussion of ideas, which opened the way for their deep understanding, increased their skills and contributed to increasing the knowledge of female students in the cognitive structure.

Conclusions

1. Units prepared according to Karen model have a positive impact on positive thinking and negative.

2. Units designed according to Karen model effective approach to complex offensive skills.

3. The experimental group is superior to the control group in positive and negative thinking.

4. The experimental group that used the Karen model over the control group, which used the method used in the college in the development of skills under study.

Isolation, Identification And Sequencing Of Mycoplasma Galisepticum By Culture And PCR In Baghdad City, Iraq

Ebtesam J. Ali¹, Balqees Hassan Ali¹
¹College of Veterinary Medicine, University of Baghdad, Baghdad, Iraq

Abstract

This study is carried out to investigate the presence of Mycoplasma galisepticum in broiler and layer in farms infected with respiratory signs, a total of 200 samples were collected randomly from layer and broiler chickens with respiratory signs in Baghdad between January to May 2017. The results of culture revealed that the total rate of Mycoplasma species isolates (positive cultures) was 10%. The highest number of Mycoplasma species isolates was seen in trachea and lowest in conjuctivial swabs, oviduct and lung. There was no isolate from the choanal and nasal swabs, all positive cultures were staining with Diene’s stain. DNA was extracted from 20 positive culture isolates, all twenty isolates were positive for Mycoplasma genous by conventional PCR assay, and a product of 250 base pair was generated by amplification of 16S rRNA gene. Then twenty positive Mycoplasma spp isolates were subjected to MG and MS detection Kit, the result revealed 2/20 (10%) MG, 11/20 (55%) MS and 7/20 (35%) were positive for both MG and MS. The two MG isolates confirmation by subjected to amplification of the 16S RNA gene the results revealed that MG specific primers of the16S RNA gene the single band at 183bp the product of amplification of Mycoplasma galisepticum 16SrRNA gene was sent by MACROGEM (Korea) for sequencing. were submitted in Gene bank database and have accession number:ID: MG846120.1. Sequencing alignment showed that the 99% similarity of first isolate and second isolate of MG field isolates with standard reference Mycoplasma galisepticum strain ATCC, the phylogenetic analysis revealed that it was the Iraqi isolate was 100% similar to USA strain1NR104952, south Africa strain2MF196172, Iran strain7KC865737, VietNam H fatey strain 3AMO75207 and Egypt strain 6GO902040. Also which had 99% similar to Russia strain 8L36043.3, India strain 4KP685378.1 and Iran strain5AY705443.1.

Keywords: Isolation, identification and sequencing, Mycoplasma galisepticum.

Introduction

Mycoplasma disease is chiefly important in poultry as a cause of respiratory disease of chickens and turkey, it is related to the Class Mollicutes, Order Mycoplasmatales, family Mycoplasmataceae. Mycoplasma was characterized by small in their size, little genome, and loss of cell walls and bounded by a plasma membrane only. Avian mycoplasmosis was primarily described in turkeys in 1926, and in chickens in 1936. It is of world wide distributions and affects both the broiler grower and the layer birds. Mycoplasma gallisepticum, the most virulent and economically significant of the avian Mycoplasma, is the causative agent of chronic respiratory disease (CRD) in chickens and infectious sinusitis in turkeys. The disease can transmit both horizontally and vertically and remain in the flock constantly as subclinical form. Broilers and layer chicks in the age group of 4-8 weeks are affected mostly with suffering from respiratory sign. Isolation and identification of Mycoplasma galisepticum among poultry flocks improves prevention of pathogens spreading PCR method could be successfully used in the diagnosis of Mycoplasma infections besides the culture means. Genes 16S rRNA can use in many laboratories for diagnosis of Mycoplasma gallisepticum.

Mycoplasmas galisepticum in Iraq was first reported by were isolated by culture and serology tests. A
recent recorded by\textsuperscript{13,14} by using RTPCR and conventional pcr. The aim of this study is to detect the presence of \textit{Mycoplasma galisepticum} in the infected broiler and layer with respiratory sign in baghdad city of iraq using culture and molecular method.

**Materials and Method**

For obtaining \textit{Mycoplasma Galisepticum} different samples were collected during the period of 4 months. A total of 200 samples (organs and swabs) including Trachea, lung, air sac, oviduct, tracheal swab, conjunctivia swab, air sac swab and choanal cleft swab taken from layer and broiler poultry flocks in Baghdad were suffering from respiratory sign. were collected at necrobsy samples were transported to the laboratory labore in refrigerated container\textsuperscript{15}.

Small pieces of organ or swab were placed in 1–2 ml of PPLO broth with supplement growth and incubated aerobically at 37 C° for three days and then streaked on PPLO agar in an inverted position in candle jar or in anaerobic jar at 37 C° increased humidity and CO2 tension, these condition for 6 days all plates were examined for Mycoplasma growth at 3 days intervals under dissecting microscope\textsuperscript{16}. DNA extraction was performed on positive Mycoplasma colony suspected, that grow on pplo agar and stained with diense stain were sub culture overnight in pplo broth and used for DNA extraction according to\textsuperscript{19}. DNA was extracted according to manufacture of DNEasy blood and tissue extraction kit (QIAGEN, USA). Convetional PCR assay was used in this study for detection of Mycoplasma genus and spp so for detection of Mycoplasma genus was used primers based 16S ribosomal RNA gene were designed by\textsuperscript{20}, then the positive samples to Mycoplasma genus subjected to PCR for detection of \textit{Mycoplasma galisepticum} in this step were used \textit{Mycoplasma gallisepticum & Mycoplasma Synoviae} Detection Kit is direct detection of Avian mycoplasmosis (\textit{M. synoviae} and \textit{M. gallisepticum}) on the basis of a genetic data base. Interpretation Expected \textit{Mycoplasma synoviae} PCR product size: 557bp Expected Mycoplasma gallisepticum PCR product size: 224bp this Kit was performed according to the manufacturer instruction) also used the 16SrRNA gene for \textit{Mycoplasma galisepticum} confirmation, The primer sequence for the amplification gene 16SrRNA for \textit{Mycoplasma galisepticum} were designed by (15). The products of amplification MG strain obtained from conventional PCR was sent by Macrogen company to Korea. (NICEM) company for sequencing (sanger method), Nucleotides sets were used to obtain the identity score of our isolate strain with the other world references strains (six) by the Mega6+NCBI program according to\textsuperscript{21}.

**Results**

The results showed that a total of 200 samples were collected randomly from layer and broiler chickens with respiratory signs (60) from trachea, (30) Lung, (40) Air sac, (20) oviduct, (25) tracheal swab, (10) conjuctivial swab, (10) choanal swab, and (5) nasal swab. Percentage of positive samples revealed by primary culture was 10%. The highest number of Mycoplasma species isolates was seen in trachea (6) followed by Air sac (5), tracheal swabs (3), and lowest in conjunctival swabs (2), oviduct (2) and lung (2). There was no isolate from the choanal and nasal swabs as show in table (1). Positive samples revealed growth many forms of mycoplasma colonies on PPLO agar such as typical fried egg colonies with or without regular edge and colony with less center figure 1(a, b, c, d).

**Discussion**

In the present study, isolation of MG was used PPLO broth and agar medium with supplements which was found suitable for culture of Mycoplasma and this result agreement to the finding of\textsuperscript{11,12}. The suspected colonies were showed fried egg shaped on solid media\textsuperscript{22,23}. Also appear another form of colony with less center on solid media under stereomicroscope\textsuperscript{15}. In present study, the overall prevalence of Mycoplasma was 10% (20/200), this percentage lower than previous studies\textsuperscript{11,14} were isolated Mycoplasma at different localities from Baghdad with an incidence of (15.38)% and 14.43%) respectively also lower than other prevalence of Mycoplasma in other countries (Singapore, Pakistan and Egypt)by\textsuperscript{23,24,25}, with prevalence percentage of (49%, 14.4% and 27.6%) respectively, the reasons for low isolation rate in the present study, may be may be present antimycoplasmal substances, antiserum and different types of inhibitors decreased chances of isolation\textsuperscript{26}. The highest number of Mycoplasma isolate were from trachea 6/60 this result were substantiated by the finding of(23and27) might be attributed to a factor that trachea is the first organ of respiratory tract which is exposed to the infectious agent\textsuperscript{8}. In this study, similar result were obtained by\textsuperscript{28} were isolated Mycoplasma from chicken’s respiratory and reproductive samples this related to the air sacs and surface of the ovaries in close proximity to the abdominal air sacs or that MG organism can spread from via blood stream to the ovaries that indicated the tissue proclivity of MG\textsuperscript{29}. all the positive cultures isolate
were showed to be positive for genus Mycoplasma by subjected to PCR amplification created product of approximate molecular size 250 bp fragments of 16SrRNA gene (100%) . These results were in same line of the results obtained by 30,31 who were reported that 16SrRNA gene was able to identify all the examined avian Mycoplasma and routine PCR test in conjunction with conventional identification methods could be effective in providing a more accurate profile of the prevalence of Mycoplasma in poultry flocks. In present study was used kit of MG and MS detection (Conventional PCR ),the percentage of MG as pure culture was low may be due to fastidious nature of MG and a competition of other nonpathogenic mycoplasma to Mycoplasma gallisepticum32. The percentage of MG isolated in this study was lower than another studies were used conventional PCR23,25,33 who isolated M. gallisepticum with prevalence 73%,17.8 %,and21% respectively ,this differences in rate of isolation may be due to difference in sampling strategy, surveilance programme, and season of sample collection.

Conflict of Interest: This research is a personal non-profit work and there is no conflict of interest.

Source of Funding: None.

Ethical Clearance: Ethical clearance was obtained from the Faculty Scientific Committee (College of Veterinary Medicine, University of Baghdad, Iraq) to solate, identificate and sequencing of Mycoplasma galisepticum by culture and PCR in Baghdad city, Iraq.

Association between Platelet - Lymphocyte Ratio and Behçet’s Disease Activity: A Single Center Study

Faiq I. Gorial1, Zahraa Mustafa Kamel 2

1Rheumatology Unit, Department of Medicine, College of Medicine, University of Baghdad, Baghdad, Iraq,
2Rheumatology Unit, Baghdad Teaching Hospital, Baghdad, Iraq

Abstract

Objective. To evaluate the association between platelet-lymphocyte ratio (PLR) and disease activity of Behçet’s disease (BD). Patients and Method. A total of 66 Iraqi patients who were diagnosed with BD and 66 apparently healthy individuals matched in age and sex as controls were enrolled in the study. Demographic and Clinical data of the patients were assessed. Disease activity was measured using BD current activity form. PLR was calculated. Results. No significant difference between patients and controls in age and sex (p>0.05). Mean PLR was relatively higher but non significant in BD patients compared to controls (119.4 ± 58.7 vs 113.6 ± 20.6; P=0.45). No correlation between PLR and disease activity in BD (p>0.05)

Conclusion. PLR was relatively higher in BD patients compared to controls but statistically not significant. No significant correlation between PLR and disease activity in BD.

Keywords: Platelet-lymphocyte ratio, Behçet’s disease, Platelet, lymphocyte, White blood cells, inflammatory mediators.

Introduction

Behçet’s disease is a chronic, relapsing, and debilitating systemic vasculitis of unknown aetiology (1). The principal pathological process of the inflammatory vasculopathy is an obliterative and necrotizing vasculitis that affects both the arteries and the veins of all sizes in almost all organ systems(2), a process that occurs concurrently or consecutively. Mucocutaneous lesions are the hallmarks of the disease (3). It affects people mainly between the ages of 20 to 40 (4), and shows a male preponderance in Middle Eastern countries and the Mediterranean; however, women are more commonly affected in Japan and Korea (5) The estimated prevalence of 1.7 BD patients for 10,000 Iraqi population is more or less similar to the prevalence in other Mediterranean and Far East countries, excluding Turkey. The presence of recurrent mouth ulcers is a high predictor for developing BD among Iraqis compared to European individuals (6) Platelet Lymphocyte Ratio (PLR)) in peripheral blood is easy systemic inflammatory marker and calculated as the number of platelets divided by the lymphocyte count from the blood samples (7) It has recently emerged as a potential inflammatory marker,predictor and a prognostic biomarker (8) of diverse diseases such as cancer, cardiac, metabolic syndrome and inflammatory diseases (9) High PLR values indicate increased inflammation, and may be useful to estimate the disease activity in BD. Only in one study showed an association between PLR and disease activity in patients with BD, despite a few studies have investigated PLR in patients with BD (10-13). This study aimed to assess the relation between PLR in patients with BD activity among sample of Iraqi patients.

Patients and Methods

Study design. This case-control study was conducted at the Rheumatology Unit of Baghdad Teaching Hospital in Medical City from July 2017 to the end of February 2018.

Participants: Inclusion criteria included patients with Behçet’s disease diagnosed according to International Study Group criteria for Behçet’s disease

and compared with apparently healthy controls matched in age and sex. Patients were excluded from the study if they had other autoimmune diseases such as Systemic Lupus Erythematosus, Inflammatory Bowel Disease and psoriasis, skin diseases or allergy, inflammatory or infectious diseases, chronic diseases such as cardiovascular, hematological, liver, kidney, malignant diseases, diabetes mellitus and hypertension, received blood transfusion during the past 4 months, pregnancy or postpartum 6 months for female were also excluded from the analysis.

Data collection and entry: Data entry were done using paper clinical research form through interview and questionnaires. Patients age, gender, smoking status, body mass index (BMI) according the equation BMI=weight / height $^2$, BD duration All controls were asked for age, sex, smoking status, height and weight for BMI.

Methods and data monitoring: Blood samples were collected in both groups for measuring hemoglobin (Hb), red cell distribution width (RDW), mean platelet volume (MPV), white blood cells count (WBC count), neutrophils count, lymphocytes count, monocytes count, platelets count beside ESR and CRP were recorded. Blood PLR for each participant was calculated manually by dividing the platelets count on lymphocytes count after obtaining the results from laboratory. Disease activity was measured by using the Behçet’s Disease Current Activity Form (BDCAF).

Collection of blood samples: Blood samples were collected from each participant under aseptic venipuncture and 5 ml of venous blood were collected from each patient and control to calculate CBC, ESR,CRP.

Statistical analysis: continuous variables were presented as mean ± SD if normally distributed and median (interquartile range) if not normally distributed. Categorical variables were presented as numbers and percentiles. Students t test was used to compare between normally distributed continuous variables and Chi square test for categorical variables. P value <0.05 was considered statistically significant. Statistical software SPSS v24 was used for analysis.

Results

A total of 66 Behçet’s disease (BD) patients and 66 controls were enrolled in this study, the mean age of BD patients was $35.7 \pm 10.2$ years and $35.2 \pm 10.4$ for controls. Males were dominant in both studied groups; 63.6% among BD patients and 60.6% among controls. The mean body mass index (BMI) was almost equal in BD and controls groups, $27.9 \pm 5.2$ and $27.1 \pm 4.3$ kg/m$^2$, respectively. Smokers represented 36.4% and 33.3% among BDs and controls, respectively. No statistically significant differences had been found between both groups regarding their demographic characteristics, as shown in Table 1.

Table 2 shows that the median disease duration since diagnosis was 3 years (IQR: 0.78 – 5.0) median disease duration since onset of symptoms was 5.7 years (IQR: 2.6 – 10.3) and the median disease activity index was 3.0 (IQR: 1.0 – 5.0). Additionally, the same table shows the distribution of treatment received by BD patients during their disease duration; almost 60% of the patients used biologics, 50% used corticosteroids, 45.5% Colchicine, 37.9% Immunosuppressants and only 3% used Anticoagulants, it is worth mention that there was an overlapping in the treatment used where some patients used combinations of these treatment.

IQR, Inter Quartile Range; BD, Behçet’s Disease

The mean PLR was relatively higher in BD patients compared to controls; 119.4 ± 58.7 and 113.6 ± 20.6, respectively, however, the difference was statistically insignificant, (P>0.05), as shown in figure 1.

![Figure 1: Comparison of platelet lymphocyte ratio between Behçet's disease (BD) and controls.](image)

To assess the effect of baseline characteristics on PLR in BD patients, this analysis revealed that male gender was significantly associated with higher PLR, (Beta = 0.416, P. value = 0.01), and this was the only significant correlation, while no statistically significant correlation had been found with any of the other variables; age, BMI, smoking, disease duration disease activity or treatment, (P>0.05), as shown in the linear logistic regression analysis in Table 3.

Discussion

This study measured the level of blood PLR in BD patients in comparison with control group and evaluated different parameters to avoid the cofactors that may influence the results. It showed that there was statistically insignificant difference between patients and controls in PLR and the mean PLR was relatively higher in patients with BD compared to controls, however the difference was statistically not significant. We also study the correlation of ESR and CRP with activity of BD, and found there is no statistically significant correlation, after adjustment of the other demographic data, and this result was in agreement with El Menyawi M. et al study (16) which found that inclusion of (ESR) and (CRP) measurements would not add significantly measurement of disease activity, that where disease appeared to be clinically inactive with presence of raised ESR or CRP. Alan et al (17) found that PLR was significantly higher in patients with BD than in healthy controls. However, no association between the severity score of BD and PLR.
Jiang Y et al (13) demonstrated that severity score of BD correlated positively with PLR. In light of our findings, we assessed the disease activity by BD current activity forum (BDCAF) [15] and the median disease activity index was 3.0 (IQR: 1.0 – 5.0). This analysis revealed that male gender was significantly associated with higher PLR and this was the only significant correlation and this perhaps the males were dominant in both studied groups. An explanation for this discrepancy was the possibility that PLR alone was not an appropriate indicator of platelet activation in accordance with a conclusion stated by Beyan et al (18) that platelet indices should not be used alone as direct indicators of platelet activation, as they found no correlation between platelet aggregation responses and platelet indices. Additionally, 60% of the patients used biologics, 50% used corticosteroids, 45.5% Colchicine, 37.9% Immunosuppressants and only 3% used Anticoagulants. So medication used by the patient may alter PLR and/or LMR ratio. The difference of the current study from the previous two studies may be related to many limitations as the differences in the study design, small sample size, short duration, patients from a single tertiary center and were usually on treatment beside the geographical factors that by dehydration or overhydration can influence the result of the ratios which are difficult to control. However, this is the first study in Iraq that evaluated PLR as a parameter to assess disease activity of BD. This is a simple, rapid inexpensive, can be easily calculated as common component of the complete blood count (CBC) test that is nowadays widely distributed in nearly every health care facility and by an automated machine.

In conclusion, No statistical significant differences in PLR between patients and controls. No statistical significant correlation between BD activity with PLR. No statistically significant correlation had been found between BD activity with ESR and CRP. Male patients were significantly associated with higher PLR. These findings need larger sample size and longer duration study including other markers to further validate the findings of this study. PLR may not be dependent as a marker of activity of BD.

Clinical, Urodynamic and Ultrasound Study for the Evaluation of Urinary Incontinence Associated with Genital Prolapse

Farah Muayyed Gebriel¹, Suha Abduljaleel Wadi¹, Ahmed Rifat Shaker¹
¹Senior Specialist in Obstetrics and Gynaecology, Al-Elwiya Maternity Teaching Hospital, Baghdad, Iraq

Abstract

Setting: Gynaecologic outpatient Clinic, Al-Elwiya Maternity Teaching Hospital, Baghdad –Iraq. Patients and methods: The study was conducted on 69 women with urinary incontinence associated with genital prolapse. Detailed history and clinical examination including complete bimanual pelvic examination, stress test, Bonney test and Q-tip test, then ultrasound and urodynamics study were performed for them Results: nocturia and urgency were significantly more common in those with DI or mixed incontinence than those with GSI. Both Q-tip test and ultrasound were used to assess BNM and so can detect stress incontinence with sensitivity (81.8% versus 36.4%), specificity (50% versus 50%), positive predictive value (81.8% versus 66.7%), negative predictive value (50% versus 22.2%), and accuracy (73.3% versus 40%). From 30 women who underwent urodynamics study, 60% had GSI and 40% had detrusor instability or mixed incontinence. Conclusions: Q-tip test is a useful clinical test and more accurate than ultrasound in detecting bladder neck mobility. Urodynamics study is expensive and time consuming so limit its use to those with urinary incontinence, urgency and nocturia as they are more likely to have detrusor instability or mixed incontinence.

Key-words: Urinary incontinence, Genital prolapse, Ultrasound.

Introduction

UI is defined by the International Continence Society as the involuntary loss of urine which is objectively demonstrable and a social or hygienic problem. The prevalence of UI increases with age, parity, and obesity [1].

Types of Urinary Incontinence: Genuine stress incontinence (GSI): is defined as the involuntary loss of urine when the intraabdominal (and therefore intravesical) pressure exceeds the maximum urethral closure pressure in the absence of detrusor activity. [2]. This can result from hypermobility of the bladder neck (HBN) 75% or intrinsic sphincter deficiency (IDS) 25%. GSI is the commonest cause of UI in women. [3]

Detrusor Instability (urge incontinence) (DI): is defined as the presence of spontaneous or provoked detrusor contractions during the filling phase when the patient is attempting to inhibit micturition, that cause a sudden urge to urinate. It is the second commonest cause of UI in women [4]. Other types include Mixed, Retention with overflow incontinence, Congenital [4,5], Functional incontinence, Miscellaneous [6] and Fistulas [7].

Clinical Evaluation and Diagnosis of UI: The basic evaluation includes history, physical examination, local neurologic, gynaecologic examination, cough stress test, Bonney test, Q-tip test, urinalysis, 24 hr voiding diary, pad test, and estimation of post void residual urine [7]. Advanced evaluation: includes urodynamics, imaging, endoscopy and electromyography.

Patients and Method

This study includes 69 patients with urinary incontinence associated with female genital prolapse, who were selected from patients attending Al-Elwiya
Maternity Teaching Hospital. Those with neurologic diseases, pelvic cancer, pregnant patients or within 6 weeks postpartum and those with previous surgical treatment for UI, prolapse or hysterectomy were excluded. Detailed history and physical examination were performed looking for the risk factors and symptoms suggestive of urinary incontinence and genital prolapse which include (feeling of lump, backache, local discomfort, vaginal discharge, dyspareunia, frequency, urgency, nocturia, dysuria, leak of urine and wearing of pads for protection). Neurological status was evaluated including mobility and gait to rule out sensory or motor dysfunction that may affect the bladder, urethra and the pelvic muscles.

Informed consent was taken from the patient before starting the physical examination. The type of uterovaginal prolapse is assessed by examining the patient in dorsal position with a relatively full bladder on a gynecological couch using Sim’s speculum to retract the posterior then the anterior vaginal wall and ask the patient to strain. Complete bimanual pelvic examination was performed to exclude abdomino-pelvic masses, to assess irritation related to urinary leakage or from protection pads, and the vagina was observed for estrogen effect.

**Clinical assessment of UI:**

For all women urine was sent for microscopic examination, culture and sensitivity and UTI was treated if present. The patient was asked to cough vigorously while in the same position, if urine leakage was observed, an uplift of the urethrovesical junction was applied [2], when it control the leak, it was considered as positive Bonney test, while if no urine leaked in dorsal position, the test is repeated in standing position. Complete bimanual pelvic examination was performed to exclude abdomino-pelvic masses, to assess irritation related to urinary leakage or from protection pads, and the vagina was observed for estrogen effect.

**Ultrasound scan:** Used to assess bladder neck mobility (BNM) and post voiding urine volume in women who have clinical evidence of UI, as follows:

* **Bladder neck mobility:** The women lie in supine position with average 300 ml urine filling the bladder was examined using the perineal approach; the probe was put on a sagittal plane to identify bladder, urethra, bladder neck, the long axis of symphysis pubis and its lower border in the same image. The reference line was a straight line drawn perpendicular to symphysis axis. The distance between the bladder neck and this line is measured at rest and during straining. At rest the bladder neck is normally above or at the level of the reference line, ≥ 1 cm of bladder neck descent on maximum straining is considered a cutoff value that indicates hypermobility of bladder neck. If the bladder displaces but remains above the pubic symphysis, the amplitude of the displacement is the subtraction of these measurements, but if it displaces below the pubic symphysis, the result will be the addition of these measurements [3].

* **Postvoiding residual urine volume:** The patient was asked to empty her bladder; the residual urine volume was obtained by transabdominal ultrasound. The ultrasound bladder volume calculation using the three dimensions available as software embedded in the ultrasound scanner, taking > 50 ml as significant residual urine volume [6,8].

**Urodynamic evaluation:** Was advised for the sixty nine patients with UI as assessed clinically, only 30 did the test, after obtaining their informed consent. The woman was asked to empty her bladder and then examined in the supine position. A complete urodynamic evaluation was performed (subtraction cystometry and uroflowmetry).

* **Cystometry:** Double lumen urethral catheter 6 F was introduced using aseptic technique. Rectal catheter was also introduced and on each catheter a transducer is mounted. Sterile normal saline was infused at rate of 60 ml/min, zero reference for all pressure measurements is the level of the superior margin of the symphysis pubis.

The following measurements were done: Vesical pressure, abdominal pressure which is reflected through the rectal catheter, detrusor pressure calculated from the subtraction of abdominal pressure from the vesical pressure (significant detrusor pressure > 15 cm H₂O) [4,6,7].
Bladder capacity at 1st desire (N. 50-150 ml)

Bladder capacity at normal desire (N. 200-400 ml)

Bladder capacity at strong voiding desire (N. 400-600 ml) (1)

In addition to maximum bladder capacity (ml), compliance calculated from the formula = the change of bladder volume to the change in detrusor pressure. At 300 ml of saline infusion, these patients were asked to cough, when urine leaked, pressures were recorded.

* Uroflowmetry: Catheters were removed, the woman void in the sitting position, the following were measured. Flow time, voiding time, time to maximum flow, voided volume were measured then maximum flow rate (normally > 15 ml/s) (9) and average flow rate were calculated.

Statistical analysis: Results were presented as frequencies, mean and standard error of the mean (M ± SE) was calculated. Student t-test and Chi-square test were used as tests of significance taking p value ≤ 0.05 as a significant value. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy were calculated using 2 x 2 table.

Results

A total of sixty-nine women with UI associated with genital prolapse were included in this study. The mean age ± SE (year) was 41±0.79 (range 25-58) and BMI ± SE (kg/m²) was 32.6 ± 0.58 (range 23-51). It was found that 67.62% of the patients had cystocele, 64.17% had rectocele, 18.63% had uterine prolapse and 28.98% had enterocele. The mean PVR as assessed by ultrasound for the 69 women was 15.1 ml. The severity of UI was assessed by frequency of urine leak per week, the need to wear protection pads and when the leak is evident in the supine position. In our study, 34 out of 69 women (49%) had severe type of incontinence. From 69 women who were advised for urodynamics study, only 30 women underwent the test, 18 (60%) were found to have GSI, while the others (40%) had DI or mixed incontinence as shown in table 3.1. GSI was diagnosed when there was stress incontinence evident from symptoms and signs and/or leak during urodynamic study; provided that all the parameters of the subtracted cystometry and the uroflowmetry were normal. Also table 3.1 showed a significant relation between urgency and nocturia and type of UI as they are more in those with DI or mixed incontinence. Both Q-tip clinical test and ultrasound were used to assess BNM, it was found in table 3.2, that BNM as assessed by Q-tip test was present in 83% of those with GSI, and in 58% of those with DI or mixed incontinence, while BNM as assessed by ultrasound was present in 28% of those with GSI, and in 58% of those with DI or mixed incontinence. Q-tip test had a statistical significance in assessing BNM in those with GSI, more than ultrasound (p value 0.0025).

It was found from table 3.3 that sensitivity, specificity, PPV, NPV and efficiency of Q-tip were 81.8%, 50%, 81.8%, 50% and 73.3% respectively. Table 3.4 sensitivity, specificity, PPV, NPV and efficiency of ultrasound were 36.4%, 50%, 66.7%, 22.2% and 40% respectively.

Table 3.5 show that the Q-tip test had higher sensitivity, PPV, NPV, and efficiency than ultrasound.

Discussion

UI is a common problem, when it is associated with genital prolapse; it become a distressing condition which although rarely life threatening severely adversely affects all aspects of a woman’s quality of life. Ellerkmann et al, found in his study that 33% of the patients had anterior compartment prolapse, 19% had posterior prolapse (rectocele and enterocele) and 11% had uterine prolapse [10], while in our study 67.62% of the patients had cystocele, 64.17% rectocele, 28.98% enterocele and 18.63% had uterine prolapse. Cystocele and rectocele appear to coexist in our patients which probably reflect the same underlying aetiology that is in our society include high parity and the obstetrical malpractice by midwives and in rural area. Haylen et al, found that most urogynecology patients, have small residual urine volume and the mean residual for his patients was 14.8 ml and this comparable to our results where the mean residual was 15.1 ml [11].

Forty-nine percent of women with prolapse and UI in our study had severe type, while in a study conducted across four countries, showed that in 3.5-12.1% the incontinence was severe [13], this variation in the results may be due to that our sample of patients not reflect the general population and because of low number of patients and also may be due to the difference in the criteria chosen to determine the severity of UI. Urgency and nocturia in our study were found to be more common in those with DI or mixed incontinence than those with GSI and this is comparable to what is found in the medical literature, where the relative incidence of instability of the bladder increases with prominence of urgency and nocturia [9]. In our study, the incidence of GSI by urodynamics study was 60% and DI or mixed incontinence was 40% and these results are close to those described by Pinto et al, study where the incidence of GSI is 76.2% and that for DI or mixed incontinence is 23.8% [13]. Anatomically BNM has important aspect in the mechanism of UI, so widely accepted that preoperative evaluation of women with UI should include BNM which is assessed in our study by Q-tip test and ultrasound.

Q-tip test is abnormal in 95% of patients with GSI [14], while in our study, Q-tip test detect GSI in 83% of cases with a sensitivity, specificity, PPV, NPV, and accuracy of 81.8%, 50%, 81.8%, 50%, and 73.3% respectively. This is somewhat comparable to Joao et al. study that show that PPV and NPV of the clinical sign and test for the diagnosis of any type of UI were 97.1% and 26.7% respectively [15].

BNM assessed by ultrasound in our study was found to be abnormal in only 28% of those with GSI, its sensitivity was only 36.4%, specificity 50%, PPV
66.7% while in a study done by Pregazzi et al, the sensitivity, specificity and PPV were 87%, 68%, 55% respectively \[16\]. This variation in the validity of the test may be due to different sonographic scan machines used and different sonographers i.e. inter-observer bias. So when comparing the accuracy of Q-tip test with ultrasonographic assessment of BNM, Q-tip test is more accurate.

**Conclusions**

Urgency and nocturia are specific symptoms related to bladder dysfunction. Q-tip test is a useful clinical test and more accurate than ultrasound in detecting bladder neck mobility. Urodynamic study is expensive and time consuming, so limit its use to those with UI and urgency and nocturia as they are more likely to have bladder instability or mixed incontinence.

The Influence of the Use of a (Multi-Skills) Device according to the Various Exercises in the Development of the most Important Physical Abilities and Basic Skills of Futsal for Female Students

Hayder Jaber Mousa¹, Aqeel Kadhim Hadi², Wael Abbas Abdelhassen³, Thulfiqar Abdulameer Sulaiman⁴

¹Directorate General of Najaf Education/Iraq

Abstract

The research aims to identify the effect of the use of a (multi-skill) device according to various exercises in the development of the most physical abilities and basic skills of futsal. The research hypotheses show that there are significant differences in the basic physical abilities. The basic skills between the two research groups and for the benefit of female students, who used a (multi-skill) device. The research sample consisted of (24) students in the College of Physical Education and Sport Sciences in the 2017-2018 academic year. Many methods and tools were used to collect information. The researchers adopted the statistical means (SPSS). The researchers concluded that the multi-skill system has a positive effect on the development of the most important physical abilities and basic skills of futsal for female students. The most important recommendations were to emphasize the importance of using modern equipment including (multi-skills).

Keywords: Multi-Skills, Various Exercises and Futsal.

Introduction

Futsal Football, which is one of the collective games that requires male or female practitioners to be at a high level of performance in order to achieve some of the best achievements, especially when they have good physical abilities and in order to develop some physical abilities and scoring. It is necessary to study the possibilities in accordance with the requirements of the game of football futsal, the importance of research in the attempt to use a device (multi-skills) and study its impact in the development of the most important physical abilities and basic skills in futsal for female students.

The outputs of the Ministry of Education are inputs to the Ministry of Higher Education. Due to the lack of interest in physical education in schools and the lack of human and material resources, the level of some physical abilities did not rise to the level of performance of many skills for different games. Weakness in physical abilities and performance of football skills, so the problem of research is reflected in the researchers' attempt to use a (multi-skills) device and exercises aimed at improving the performance of skills in the base of football lounges.

Research aim:

The aim of the research is to identify the effect of the use of a device (multi-skills) according to the various exercises in the development of the most important physical abilities and skills of the basic futsal.

Hypothesis:

There are statistically significant differences between the pre and post testing of the experimental group and the control in the development of the most important physical abilities and basic skills of football lounges.

Research Areas:

Human Field: Students of the first stage in the Faculty of Physical Education and Sports Sciences - University of Kufa / for the academic year 2017-2018.

Time domain: Period from 1/10/2017 to 15/5/2018.

Spatial Field: Faculty of Physical Education and Sports Sciences - University of Kufa.
Search procedures:

The researchers used the experimental approach to suit the nature of the research.

Research’s Society and its Sample:

The research community was examined from the students of the first stage in the College of Physical Education and Sports Sciences / University of Kufa for the academic year 2017-2018, the number of (24) female students, the sample was chosen in a simple random way, the sample was (20) female student divided into two experimental groups and equal control.

Research tools and devices used:

1. Hall of Football Futsal is legal.
2. A (multi - skills) device.
3. Five balls five (10).
4. Mobile camera type (Galaxy) number (1).

Field Research Procedures:

Table (1). Shows homogeneity of the research sample for results.

Characterization of tests of the most important physical abilities used in research:

First Test (Vertical jump test of stability):²

- **Purpose of the test:** Measure the explosive force of the muscles legs.
- **Devices and tools:** Wall marking, Pair of aluminum profile and nails.
- **Performance Specification:** The lab raises its arm at full length to make a sign on the blackboard, then the student swings the arms and bend the knees to the vertical jump for the maximum distance you can reach to make another sign and the arm on the entire length.
- **The conditions:** Each laboratory has three attempts to record its best.
- **Registration method:** The distance between the first and the second marks the amount of the explosive force of the legs measured by the centimeter.

The second test (the test of the leg on the man for a distance of 10 meters and for both legs):³

- **Purpose of the test:** Measure the speed of the
muscles of the legs.

- **Tools**: The area of the test shall be determined by two lines, one for the beginning and the other at a distance of 10 meters for the end, in addition to seven persons to be placed along a distance of ten meters. The distance between one person and another shall be one meter except the starting line to the end line.

- **Test administrators**: Register person; Call the names firstly and record the test performance secondly. The timer number (2) gives the start and end signal with the timing and the observation of the validity of the performance.

- **Performance Specification**: The player is on one foot to stand behind the starting line, and when he hears the signal, he jumps between the characters to the finish line and both feet.

- **Attempts**: Each player is given two attempts to the right leg and two attempts to the left leg and record the best attempts.

- **Registration method**: Calculates time to nearest 1/100 seconds.

**Tests of the most Important Skills Basis in Research:**

**First test**, Test handling a small target at a distance of (10 m).

**The purpose of the test**: Measuring the accuracy of handling.

**Tools**:

- Balls for the halls number (3).
- Tape measure.
- A small target dimensions (75 x 100 cm).

**Performance description**: The tester stands with the ball 10 meters away from the target, and when the signal is heard, it handles the ball and is stationary towards the target.

**Performance conditions**: The test starts from the ball number (1) and ends with the ball number (3).

**Registration method**:

The tester is given 3 attempts.

) 2 steps) for a successful attempt.

(One degree) to try to touch the ball or the bar.

(Zero) of the grades for the failed attempt.

**Second Test, Test balls scoring**:5

**Objective of the test**: measuring the scoring accuracy.

**Method of performance**: distributed 7 balls in the penalty area, and the student starts running behind the person on the arc of the penalty towards the first ball, aim and return to the rotation around the person, and then go to the second ball, and the player freedom to choose any foot.

**Method of registration**: The score is calculated by the total scores obtained by the student from the scoring of the seven balls as follows:

3 marks if the ball entered the specified areas (1, 3).

One mark if the ball entered the area (2).

Zero if the ball came out of the goal.

**Pre Tests**:

The tests were carried out by the experimental tests on Sunday (4/2/2018) and the closed hall of the Department of Physical Education and Sports Sciences University of Kufa and the researchers to the extent possible to confirm the conditions related to post-tests.

**Curriculum**:

The researchers prepared an educational curriculum which lasted (8) weeks, and in order to achieve the objectives of the research. The curriculum was prepared on Tuesday, 6/2/2018 and until Sunday 8/4/2018 on the experimental group as shown:

The number of the educational units in per week (2) educational units and faculty (16 educational units).

The time of the unit is 90 minutes.

The educational curriculum to teach physical abilities (explosive power and speed characteristic) week for each skill, skills handling and scoring two weeks for each skill by 4 units of education.
Working mechanism (multi-skilled):

The experimental group applied the educational curriculum using multiple physical and skill trainees by using the multi-skill system under study prepared by the researchers for the students. The curriculum began to teach the explosive force skill in the first unit to a week. The second unit taught the skill at speed and the third and fourth instruction unit Teaching the skill of handling and the fifth and sixth educational unit Teaching the skill of scoring and the seventh and eighth teaching unit of the skill of putting down and applying the exercises to be taught and developed by the teacher The use of one or more students to apply the skill.

Length of the total machine 6 m divided into three parts each part (2 meters).

**Discussion**

**Discuss the results of pre and post-tests of the experimental group:**

Table (3) shows the appearance of the differences between the two in favor of posttests. This is an indicator of the effectiveness of the independent variable represented by the use of the multi-skill system which is one of the principles of learning and to explain the reasons for the effect of the exercises used in the educational units prepared by the researchers. In the educational units that lasted for eight weeks in which the students practiced the exercises in terms of applying the educational curriculum in a scientific and thoughtful in terms of providing tools and devices as this leads to an increase in the frequency of performance of students to the skill and prove the compatibility that the high levels of activity time are required and the level must not be less than (50%) of the total time of the physical education lesson.

As well as the implementation of these exercises, which rely on the basis of gradual learning from easy to difficult has led to the promotion of learning in the most basic physical abilities and basic skills, which Mahmoud Dawood pointed out that «methods of teaching can be used to teach different aspects of activity and follow these steps step by step in order The teaching depends largely on the age of the learner and the stage of education.»

In addition to the number of repetitions and taking into account the rest times that have an impact on the development of students of the experimental group in the most basic physical abilities and basic skills in the research as pointed out (Adel Fadel, 2000) that «the frequent repetitions practiced by the learner in the course of practical application helped to gain learning».

**Discussion of the results of the pre and post-tests of the control group:**

From table (4) the control group that used the traditional method of the teacher achieved a development in the post tests of the pretests. The researchers attributed this development to the teacher’s use of the curriculum followed by physical and professional exercises which increased the intensity of the competition in addition to the number of repetitions and taking rest time. And the basic skills under consideration, as well as the teacher’s focus on the repetition of the performance of skills because the uniqueness of the research sample from the beginner, as the repetition of continuous and intensive led to a kind of typification of these capabilities and skills, which reflected in the form of the performance of motor skills is closely related to physical attributes such as speed, strength, flexibility and agility, and that the good performance of motor skill cannot succeed if it does not depend to a large extent on the physical qualities required.

**Conclusions**

A multi-skill device has a positive effect in improving some of the motor skills and the most important skills base futsal for students.

The experimental group is superior to the control group in all post-tests.
Ethical Clearance - Taken from Directorate General of Najaf Education/Iraq committee

Mental Exercises to Intensive Method and Its Effect on Motor Prediction and Some Basic Skills in Soccer for Physical Education Students - University of Anbar

Hussein Habib Mosleh

University of Anbar / Faculty of Physical Education and Sports Sciences/Iraq.

Abstract

The purpose of this study is to develop mental exercises prepared according to extensive impact on motor prediction method in soccer, while hypotheses of research dealing with there is a positive impact of mental exercises to intensive method of kinetic projection and some basic skills in soccer, and use curriculum finder The pilot sample of second graders in College of physical education-University of Anbar, and (73). And it was found that exercise and positive impact method for students and increase kinetic projection and some basic skills in football game recommendations to develop mental exercises and confirms forecast special motor football with an emphasis on mental exercises to develop other skills in the game.

Keywords: Mental exercises, motor prediction and physical education.

Introduction

The interest in the process of training and skills in various games and especially in football game contributes to improved performance through the development of programmes and units seeking to develop, taking about mental training specialists deployed within educational and training curricula. And that mental exercises in physical education programmes of great importance because it contributes to the development of cognitive abilities and mental and physical skill, mental and functional access to motor performance.

Interest in the outcome and outputs for each stage in each course brought the attention of the researcher telling them the best scientific levels for students of the faculties of physical education and sports science, as care researcher with focus on implementation of the lesson and what exercises used during those methods and how correlation between them in achieving the best results and performance skills for learners, and tie them in expectation activist football game. Through this show that there is a shortage of mental exercises for students and its impact on the student’s abilities and motor skills to fit their abilities in learning good performance, as well as using the best method of learning. Mental side has been recruited by intensive method and its effect on motor prediction and some basic skills to students in an effort to achieve the correct performance after knowing the whole picture him mentally and physically and psychologically.

The diversity of teaching methods that contribute to the educational goals and get the highest level of access also to the performance required departments and results. And that certainly find better method contributes to enhancing access to sounder means too, and from here emerged the importance in providing educational or training methods and ways for learners from physical education students through attention to mental exercise intensive method scientifically to achieve best contemplating Motor and some basic skills for learners.

Research aim:

Identify the influence of mental exercises to intensive method of kinetic projection and some basic skills in football game of college students of physical education-University of Anbar.

Hypothesis:

There are statistically significant differences between the results of two tests of pre and posttest for two groups.
There are statistically significant differences between the results of two tests post and posttest for two groups.

**Field research approach and procedures:**

Research methodology:

Follow Finder to experimental method to design two powerful brokers (Control and experimental).

**Sample search:**

Sample intentional way research students phase in College of physical education, University of Anbar (72) students, and students were excluded repeaters and University team players and clubs, absent the implementation of tests and exercises (12) students, so the sample was divided into two groups for each group (30) students. Percentage of selected research estimated sample (38.33%) of the parent society and been parity between the two groups and experimental Brigade in expectation of a simple link which reached kinetic (0.87), is a moral link at freedom (58) and level indication (0.05) table value (0.256). That variable, measured out equal between the two groups to be a commencement of Labour, table (1) show the equal groups according to error rate obtained is less than (0.05).

Table (1). Show the mean and standard deviation calculated (t) value and error rate and the indications.

* Morality when the error rate is less or equal to the level of significance (0.05)

**Tools, devices and means of gathering information:**

1. Include scientific sources.
2. The Internet.
3. The observation.
4. The registration form.
5. The search equipment and tools included a football field.
6. A stopwatch.
7. A measuring tape.

**The pilot study:**

The pilot study was conducted on (10) second phase students on Wednesday (17/10/2018) at 10 am and they wished to ascertain the identification of the work team assistant and duties and determine the method of testing and avoid problems and errors in the test, and confirmation On the times and exercises of the program or method used.

**Tests used in the research:**

**Testers for the measurement of motion of the football:**

**Name of the first test:** Test the self-driving expectation of the place of the football

**Objective of the test:** Measure the motion of the football.

**Test tools used:** legal soccer stadium, (12) football, registration forms and pens.
**Performance:** A player stands in the middle of a final line area 18 yards for his pitch toward the goal of football is divided into (3 parts) to form a column and is blindfolded, hit the ball directly into the goal and ask him to anticipate where the ball entry and declares to expect registrants without being seen to target, and then mate also stand on its (18th) line similarly runs and expected the first place player’s ball for fellow

**How to register:** Register to the lab after hitting the ball was the fall ball into the target partition or areas outside the target or not, and calculates the degree of every sign is that six attempts, then leads fellow six strikes to be a total forecast when the twelve attempts to try a number that gets in it. The player’s highest score in the test.

**Notes:** Test has steadfastly 89% and 91.7% amounted to subjective sincerity honestly rate virtual expert and substantive agreement with my 100%.

**Skills tests:**

**Test Name:** Ability to control the ball:

**Objective of the test:** To measure the ability of the player to control the ball through absorption or mute.

**Tools:** balls number (3), tape measure

**Performance description:** Two concentric circles centered on the radius of the micro (1 meter) and the large diameter (2 meter) and at a distance of (10) m of the circle draws a line length (2 meter). The line of throwing the ball begins test that the laboratory stands in the middle of the lower circle and the coach stands on the line of throwing and the ball in his hand. When the signal is given, the trainer will throw the ball into the arc of the laboratory player within the circuit that is trying to control it in any part of the body. Each laboratory will be given three attempts.

If the player succeeds in controlling the ball within the lower circle he gets (30) score, but if the player succeeds in controlling the ball within the circle of the major gets (20) degree, either if the ball out of the two circles under control gets (zero). The final score is the total score of the three attempts.

**Test Name:** Intermediate Handling test:

**Objective of the test:** Measure the accuracy of the medium handling.

**The tool used:** (10) balls, measuring tape.

**Method of performance:** We draw four concentric circles, whose diagonals are respectively (4), (8), (12), (16) feet and given degrees respectively, (1, 2, 3, 4) where the center of the circle is the point of distance between the line Start or four circles, which are at a distance of (20) yards, but in the case of the ball outside the four circles, the attempt is unsuccessful as in the figure.

**Registration:** Each player is given two attempts, each attempt (10) consecutive balls and any of the feet in the air trying to drop in the small circle and the total score of the test is the total of what the player gets in the attempts.

**Field experience:**

**Pre Test:**

The pretest was conducted on the morning of Wednesday (22/10/2018) at ten o’clock on the sample of the two groups of control and experimental.

**Main experience:**

The application of mental exercises as an extension (2) on Monday, 29.10.2018 for a period of 8 weeks until on Monday 31/12/2018, has been carried out exercises mental neo-intensive experimental group of students from the second phase of the Division (b) in the main part of the units of education and by(25) minutes note that the total time of the part (40 minutes) and ensure that the main part of four exercises implementation of exercises from four weeks have been repeated to be number eight weeks as described below:

The first is the mental exercise intensive - to find the level of ideal excitement, and the second is the mental exercise intensive - to identify the sources of distractibility as well as the third is the mental exercise intensive linked to skillfully handling -Identify positive and negative perceptions of the fourth is also the mental exercise intensive associated with skill suppressions - learn how to pay attention and focus.

**Post-test:**

The post-test was conducted on Monday morning, January 7, 2018, at 10 am. The test was conducted under the same conditions as the pretest.
Results:

View and discuss the results of the control and experimental groups:

* Tabular value (2.018) to the degree of freedom (60-2 = 58) at the level (0.05).
Table (3) shows that there are significant differences in the post-test between the experimental and control groups and for the benefit of the experimental group in all variables under study because the error rate is less than the significance level (0.05).

**Discussions**

Table (2) shows that there is a significant difference between the results of the pre and posttests of the experimental group in the expected range. The difference was also significant in the control group, indicating that the mental exercises of both groups were carried out in different ways within the teaching methods of the students in improving the motor expectation of both groups. Only a slight improvement in the control group in the technical variables not to link fatty exercise skill as it was in the experimental group. The researcher also refers to this improvement in learning for the experimental group when it is ready to practice and practice with the explanation of Walt According to the scientific basis, the development of any skill, and that mental training leads to a significant positive transfer in the teaching of skill as a result of the perception of performance without being associated with a virtual act and that learning affects the other behavior of the individual and improve it to the best and be a cause of progress as well Motivational learning to change performance through the practice, inclination, experience and environmental factors in which the learner lives and that the adoption of intensive method confirmed the regularity of repetitions and rest in the application of skill according to compatibility with the work of muscular nervous system and this was confirmed by researchers that the process of time distribution to lead the learner to the skill and linked to exercise in time with the increase in frequency and lack of rest or lack thereof, which determines the size of performance and need To neuromuscular compatibility.

Table (3) indicates the effect of exercise on improving the motor expectation and basic skills of the experimental group students in the post-test between the two groups because intensive-style exercises have established a good dynamic expectation of the students of the College of Physical Education and Sports Sciences.

The research also attributes this result to the development of the diversity of exercises and its focus on the most important indicators of mental exercise and its variety and arrangement, which is confirmed by Wajih Mahjoub, because the skill of the order is affected by several factors, including training and readiness and scalability developed by explaining and clarifying the use of scientific means. Intensive exercise is one of the best ways to develop skills based on the size of performance with the compatibility of performance with appropriate frequency, far from the conditions of fatigue, despite the reduction of rest between As Schmid (1999) suggests that mental training affects the performance of motor skill and that it introduces into learning the cognitive elements of skill and how to learn skill as well as it helps the learner to think.

The development of the motor and skill prediction of the experimental group is more evident than that of the control group, which develops its motor and skill prediction in a simple way they are The result of exercise and practice, as well as the news gained in the implementation of the method followed, and depends on the dynamic expectation of the basic elements of the correct analysis of the movement as a result of the experience of the player as well as the flexibility of mobility and the extent of sense of distance and time with the prediction of the position of motor and that the dynamic prediction develops by several factors including concentration and movement, sequence of movements and exercises and linking it to skillful performance to improve the skill of the players.

The researcher believes that mental exercises contribute to the development of motor skills, including the motor and skill prediction of the association with the intensive method, which contributes to the promotion to achieve performance to the best levels when improving the performance of football players.

**Conclusions**

Intensive exercise in the intensive method used to have a positive impact on the expectations of movement and skill of football.

The approach adopted by the trainer has a positive impact on improving the motor expectation and a slight improvement in learning the skills studied.

Intensive exercises in the intensive method achieved a preference for the experimental group on the control group.

Abstract

Background and objectives: schizophrenia is a major public disease associated with a non-overt inflammation. Tumour necrosis factor alpha (TNFα) is an important pro-inflammatory marker involved in initiation and propagation of the immune response. Various studies carried out on schizophrenic patients showed an elevation of proinflammatory factors-like TNFα. Furthermore, it has been reported that these markers play a role in the aetiology of schizophrenia. In fact, recent studies indicated that antipsychotic drugs modulate the level of these markers. The present study aimed to describe the role of antipsychotic medications on the alteration of TNFα level.

Methods: serum levels of TNFα in schizophrenic patients were measured and compared with those of the apparently healthy control subjects. Two commonly prescribed antipsychotics; olanzapine and risperidone, were included in the study.

Results: the results showed that both drugs (olanzapine (p<0.05) and risperidone (p<0.001)) significantly reduced TNFα level compared to baseline and control levels, moreover, the onset of reduction was 4-weeks earlier with risperidone compared with olanzapine.

Interpretation and conclusions: the study concluded that the anti-inflammatory potency of risperidone is higher than olanzapine and the onset of anti-inflammatory action initiated earlier with the risperidone therapy compared to olanzapine; showing a priority of risperidone for an application in first-episode drug-naive schizophrenia and acute schizophrenic attacks.

Keywords: olanzapine, risperidone, TNFα, schizophrenia, antipsychotic.

Introduction

Schizophrenia is a chronic debilitating mental disease characterised by severe psychosocial dysfunction and the incidence is quite high in general population reaching up to 0.8%⁰.¹. The underlying mechanisms of schizophrenia are obscure. Recent studies indicated that the pathophysiology of the disease might be linked to immune system³.⁴. This assumption was supported by the improvement in neuroinflammation following anti-inflammatory prescription for schizophrenia⁵. Cytokines are signalling molecules between the immune system and central nervous system (CNS). They play an important role not only in the cell-cell communication but also in the function of the immunocytes in the central nervous system (CNS)⁶. Some of these cytokines (e.g. tumour necrosis factor alpha (TNFα), interleukin (IL)-1, IL-2, and IL-6) have been demonstrated to involve in immune-neuro-endocrine signalling and control of neuronal function in the CNS in healthy status and disease⁷.⁸.⁹.

TNFα is a pro-inflammatory cytokine which has an effect in most tissues and organs of our body including CNS. In CNS, TNFα is either produced by certain neuronal cell populations including microglial cells and astrocytes⁸,¹¹ or crossed the blood brain barrier during systemic inflammation¹². Various studies reported discrepant results regarding TNFα level in schizophrenic patients; unchanged, decreased, or increased¹².
It has been found that the total Positive and Negative Syndrome Scale (PANSS) scores were correlated to plasma TNFα levels suggesting that TNFα may have a role in the aetiology of schizophrenia\textsuperscript{13}. However, antipsychotic medications might be involved in the modulation of TNFα levels because almost all patients involved in these studies were on antipsychotic therapy. Therefore, the TNFα levels in schizophrenic patients need to be investigated in order to explore its effect on the disease status and subsequent prognosis. In the present study, we have aimed to determine the role of antipsychotic medications on modulation of TNFα levels, if any. To do so, two structurally different miscellaneous antipsychotic; olanzapine (thienobenzodiazepine) and risperidone (benzisoxazole), were included in the study, the two selected medications were characterised globally by high prescription rate.

**Subjects and Method**

**Subjects:**

A total of 60 newly diagnosed schizophrenic patients aged 18–55 years old participated in the present study. Samples were collected from the Psychiatry Unit of Al-Salam teaching hospital in Ninaveh Governorate, Iraq. Psychiatrists diagnosed the patients using a psychiatric semistructured clinical interview schedule which is approved in diagnosing schizophrenia. The medical history of the patients was evaluated to exclude any systemic disease that may impair the parameters to be diagnosed, including diabetes, liver disease, and renal disease; which are considered as an exclusion criterion. The patients were placed on continuous treatment of either olanzapine 10 mg/day (n=30) or risperidone 2 mg/day (n=30) as antipsychotics for schizophrenia. To ascertain that the patients were free from any acute phase reaction due to infection or inflammation, serum C-reactive protein (CRP) was diagnosed and found to be negative in all the samples tested (CRP < 6 mg/L).

Ethical approval was considered from the patients or their first-degree relatives. To achieve comparison of parameters, a total of 30 healthy subjects were randomly selected as the control group. Sex and age of these subjects were nearly comparable with that of the patients. These subjects were checked for any apparently health, emotional and physical problems. Serum CRP was also negative in the control group samples.

**Method**

The serum TNFα were estimated using an enzyme-linked immunosorbent assay (ELISA) supplied by RayBio®, USA. The serum CRP was measured using a semiquantitative agglutination kit supplied by Spinreact®, Spain. The serum and reagents were mixed, and agglutination occurred, and the result showed that the CRP ≥ 6 mg/L.

**Statistical Analysis**

The results of the normally distributed variables were expressed as (mean ± standard deviation). Mann–Whitney U test was used to compare the measured parameters between the patients (olanzapine-treated group versus risperidone-treated group) and the healthy control groups. The difference between the groups was statistically different when \( p < 0.05 \). All statistical analyses were performed using GraphPad Prism 6 (CA, USA). The figures were created using a Microsoft Office 2010 Excel program.

TNFα levels comparison between groups

The results of serum TNFα in schizophrenia, and control groups are presented in figure (1).

The result of analysis indicates that the level of TNFα in schizophrenia is significantly higher than control healthy subject. The antipsychotic drugs have significantly (olanzapine (p<0.05) and risperidone (p<0.001)) reduced the TNFα level after the course of therapy. Risperidone induced stronger reduction of TNFα level compared to olanzapine. Moreover, the reduction of TNFα induced by risperidone is earlier than that induced by olanzapine, since risperidone induced its significant reduction of TNFα with in first 4 weeks, this effect was achieved with olanzapine after 8 weeks of initiation of therapy.

![Figure 1. Olanzapine and risperidone reduced plasma TNFα concentration.](image-url)
(A and B) olanzapine and risperidone reduced TNFα level significantly as compared to control samples or baseline of patient samples. (C) risperidone induced the reduction in TNFα level within 4 weeks while olanzapine needed longer time to reduced TNFα level. Data expressed as mean±SD (n=30) #p<0.05 ##p<0.001 as compared to control group, *p<0.05 **p<0.001 as compared to baseline TNFα levels, OTG: olanzapine treated group, RTG: risperidone treated group, HCG: healthy control group, NS=non-significant.

**Discussion**

In the present study, we have investigated that TNFα level was elevated in psychotic patients compared to healthy control subjects and that their treatment with antipsychotic drugs were associated with the reduction in plasma level of TNFα (Figure 1A and B). However, the onset and intensity of reduction were far more prominent with risperidone compared to his counterpart; olanzapine (Figure 1C). Studies focused on the role of cytokines on schizophrenia has reported discrepant results. Some studies have shown elevated plasma TNFα and IL-6 levels and reduced IL-2 levels namely a decreased interleukin-2 (IL-2), however, others have reported no change in the cytokine levels. Inglof et al reported a correlation between interferon gamma (IFNγ) levels and aetiology of schizophrenia. Their results showed increased IFNγ in patients with positive symptoms and reduced IFNγ in patients with negative symptoms. Conversely, other researchers have found elevated serum/plasma IFNγ levels in schizophrenia. It has recently been confirmed that antipsychotic medications modulate cytokine production. The results of our study indicated that TNFα levels were upregulated in overall patients regardless of the predominance of positive or negative symptoms (Figure 1A and B).

It has been reported that antipsychotic have a different effect on cytokine levels. A meta-analysis study on schizophrenic patients on antipsychotic therapy, showed elevated sIL-2R and decreased IL-1B and IFNγ. Nevertheless, its uncertain whether these alterations in cytokine levels are solely linked to anti-schizophrenic medications, or whether they are linked to the improvements in the pathophysiology of the disease. Moreover, the heterogenous results is being reported despite of using single antipsychotic drug with variation between in vitro and in vivo studies, stages of the disease, and subtype of schizophrenia. In an in vitro study, it has been reported that some antipsychotics increase IL-17 levels, specifically risperidone has shown an immunosuppressive activity by inhibiting IL-12 production by Th1 cells and increasing IL-10 production by Th2 cells and pro-inflammatory cytokines (IL-6, IL-8, and TNFα). Additionally, risperidone showed a potent inhibitory activity on the production of TNFα, IL-6, and IL1B by IFN-γ-pretreated microglia. In laboratory animals, LPS-induced neuroinflammation model, risperidone has shown a clear suppression on TNFα and IL-6 and upregulation in IL-10. In the line with these studies, our results indicated that antipsychotics reduced TNFα in almost all patients (Figure 1A and B).

Inconsistent results have been reported regarding anti-inflammatory activity of risperidone. It has been shown that risperidone inhibit the production of IL-6 and TNFα, increase IL-10 anti-inflammatory cytokine while plasma IL-4 shown no change, and in IFN-γ-activated microglia risperidone induced beneficial immunomodulation effects. In this study, we have focused on 2 antipsychotics commonly prescribed in schizophrenia and TNFα was used as an anti-inflammatory marker, the results indicated that both drugs reduced TNFα level, moreover, risperidone shown stronger and earlier action than olanzapine (Figure 1C).

Risperidone suppressed TNFα and IL-6 production and increased IL-10 production in in vitro LPS-induced neuroinflammation model using laboratory animals. Moreover, risperidone suppressed LPS-induced expression of proinflammatory markers and restored anti-inflammatory pathways suppressed by LPS. Recently, it has been reported that atypical antipsychotics may elevate IFNγ and decrease IL-4, IL-6, and IL-27 levels in schizophrenic patients. The data of the present study demonstrate significant stimulation of immune responses in schizophrenic patient despite of the absence of any other inflammatory disorder. Therefore, schizophrenia can be regarded as inflammatory disorder, and the use of immunomodulatory drugs as adjuvant treatments is under investigation for more applications.

**Conclusion**

In summary, our data showed that TNFα level was elevated in schizophrenic patients. The elevated TNFα might be linked to the pathology and/or the progression of the disease. The increased TNFα might be associated with positive or negative symptoms or both; further
studies required to confirm such correlation. The antipsychotic therapy reduced TNFα level in the schizophrenic patients and there is a clear difference between the 2 antipsychotic drugs regarding their effects on TNFα levels demonstrated by stronger and earlier effect of risperidone compared to olanzapine therapy. Further clinical studies are recommended to confirm the relation between the TNFα levels, and treatment with the antipsychotic in relation to the progression of the disease. However, this study gives an evidence that there is an immune change that may be linked to the progression of the disease? The study also suggests that immunomodulating therapy may become a new approach of therapy for schizophrenic patients.

Effect of Adding Local Minerals Clay (Meqdadia) in the Female Japanese quail Diets upon Production Performance, Egg Quality and Carcass Traits

Ismail Younis Hasan Al-Hadeedy1, Mohammed Ibrahim Al-Nuaimi1, Abbas Rashid Ali2

1 Animal Production Department, Collage of Agriculture, University of Kirkuk, Iraq
2 Applied geology department, Collage of Science, University of Kirkuk, Iraq

Abstract

One hundred and twenty of adaptable females Japanese quail aged 24 weeks were affected to five dietary treatments and six replicate (4 bird/replicate) per dietary treatments. T1 (control treatment) without clay, T2, T3, T4 and T5 were add local mineral clay (Meqdadia) with 0.5%, 1%, 1.5%, and 2% of diet respectively. Adding 2% of local mineral clay (Meqdadia) to the diet is significantly (p≤0.05) increased egg production, while the egg mass of the control treatment significantly decreased comparing to the diets contained 0.5%, 1%, 1.5% and 2% of local mineral clay (Meqdadia). The bird of fifth treatment significantly (p≤0.05) consumed higher diet and energy comparing with the birds of control treatment. No significant difference in the feed, energy and protein conversion ratio among the bird of all treatments. Egg shell thickness (mm) and shell weight (%) were significantly (p≤0.05) higher by adding local mineral clay (Meqdadia). On other hand the difference in the percentage weight of the carcass parts were no significant among all treatments.

Keywords: Clay, performance, egg quality, quail.

Introduction

Any major reduction or decrease in the cost of feed will extensively reduce the overall cost of production and increase the profile margin of the farm1. Recent studies including supplementation minerals clays (muds) as feed additive (natural additive) have direct beneficial effects (positive effects) upon poultry performance2. The clay is a natural product that can be economically used to achieve healthy digestive tract and optimize poultry performance3. Clays are also recommended for their nutritional properties and healthy digestive tract and for their antitoxic capacity to many undesirable substances in the gut and have positive effect on the digestive efficiency and dropping moisture3. Therefore the aim of this study was to evaluate over egg production period of 60 days, the effect of 0%, 0.5%, 1%, 1.5% and 2% of local mineral clay (Meqdadia) on the egg production, egg quality and carcass traits of females Japanese quail.

Materials and Method

One hundred twenty female local Japanese quail 24 weeks of age were used. The birds were housed in battery (cages measuring 40*30*20 cm Length, width and height respectively) in an environmentally controlled room. Five dietary treatments were then randomly distributed to the 30 experimental units (30 cages). Therefore each treatment was replicated six times (6cages). Birds were fed on the experimental diets for ten days pretest period for adaptation to the experimental diets, followed by a 60 days test period. Feed and water were available ad libitum and the birds received 17 h of light daily. Meqdadia clay which described as (LMCM) obtained from Meqdadia, Iraq. The chemical compounds of LMCM is shown in table 2. The level of the LMCM were 0.0 %, 0.50%, 1.50% and 2.0 % in the experimental diets (table 1). Birds were weighted at beginning and at the end on the experiment. Egg were collected daily and egg production were expressed on a hen hay basis. All egg laid, egg weight, feed intake and feed conversion ratio recorded by 20 days. To determine the egg internal, shell quality traits and egg shape index,
egg laid collected randomly from each treatments (2 eggs from each replicate) each 20 days.

1 LMCM: local mineral clay meqadia

### Statistical Analysis

All data were analyzed using the GLM procedure of SAS software for analysis of variance as completely randomized design (CRD). Significant difference among treatments means were tested by applying Duncan’s multiple range test.

### Results and Discussion

Table 3 shown the effect of adding LMCM in the diets of female Japanese quail upon production performance. A significant difference (p ≤ 0.05) were found in the egg production (H.D.%) and egg mass (gm egg/bird/day) for the birds of T5 (78.53 and 7.48) by compared that with the birds of T1 (64.40 and 5.19). On the other hand the birds of the fifth treatment (2% LMCM) consumed feed significantly (p ≤ 0.05) higher than the birds of the control treatments (T1), while the difference between the T1 (control) and T5 were no significant for the feed conversion ratio, energy conversion ratio and intake and conversion ratio of protein, while the energy intake of the birds of the T5 were significantly higher than the bird of the control group (T1). The improvement in the egg production (H.D.%) and egg mass (gm egg/bird/day) by supplementation 2% of LMCM in the diet might be explained that LMCM usage may increase improved energy efficiency and slowed down feed passage. The digest retention time and therefore the endogenous enzyme activity might be more effective in the digestion of the protein, fat and carbohydrate and improve their absorption to promote healthy digestive tract and to enhance performance.

### Table 3. Effect of adding LMCM in the diets of female Japanese quail upon production performance (mean ± SE)

1 LMCM : local mineral clay meqdadia

T1 : control, T2, T3, T4 and T5: adding 0.5%, 1%, 1.5% and 2% of LMCM respectively

Table 4 shown the effect of adding LMCM in the diets of female Japanese quail upon egg quality traits, Dietary LMCM 2% (T5) supplementation significantly improvement the shape index, egg specific gravity, egg shell thickness and shell weight comparing with control dietary group (T1). Improving shell quality above might be explained that the 2% LMCM may increase calcium utilization. On other hand dietary treatments (levels of MC in the diets) did not significantly affect to egg surface area, yolk index, yolk weight percentage, albumin index, haugh unit and albumin weight percentage. However15,16 reported that egg shape index, breaking strength, shell thickness and haugh unit were not affected by the usage of Sepiolite, while11 reported the dietary treatments 0.5% or 1 % Sepiolite did not significantly effect on egg shape index, egg albumin higher, egg albumin index, egg yolk index and high unit for layer hens egg.

Detection of Risk Factors of Human and Birds that Related to Influenza Type A (H1N1) pdm09 Infection

Jalal Y. Mustafa1; Hasan A. Hammadi2; Azhar A. Neamah3; Jenan N. Sadeq3, and Khetam Q. Al-Hamdawee4
1Department of Public Health, College of Veterinary Medicine, Al-Basra University, Basra, Iraq. 2Department of Pathology and Poultry Diseases. 3Department of Microbiology, 4Zoonotic Diseases Unit, College of Veterinary Medicine, Al-Qadisiyah University, Al-Qadisiyah, Iraq

Abstract

Background: Influenza is a worldwide zoonotic disease caused by Orthomyxoviridae virus. The appearance in humans of the A (H1N1) pdm09 influenza virus, a complex reclassified virus of swine origin, highlighted the importance of worldwide influenza virus surveillance in birds. To date, wide-control surveillance studies have been reported for Asia and North America, but such deep data have not yet been described in Iraq.

Material and Method: One hundred forty-five (145), human samples used in the study were collected from General Teaching Hospital and Specialized Hospital Maternity and Children Teaching Hospital and Center Pulmonology and Respiratory Specialist in Al-Diwaniyah city following the WHO (15) influenza-like illness case definitions. A total of 145 clinical samples (throat swabs and nasopharyngeal swabs [73], bronchial lavage [72]) collected in December 2015 to January 2016 (2 Months period) and evaluated for the presence of influenza A (H1N1). Chicken tracheal swabs were (113) Sample) from different broiler flocks in Al-Diwaniya. All samples tested directly by using taq man Real Time- PCR technique.

Results: showed that the infection incidence with influenza A(H1N1) pdm09 in humans (18%) and in broiler (65.48%), the study proved that there was a significant difference at the site of infection in the respiratory tract (URT& LRT) for humans, as well as in terms of age groups.

Conclusions: Influenza is a highly potential zoonotic circulating disease between peoples in Al-Diwaniyah city and clearly defined risk groups: people with respiratory infection, heart and vascular disease, immunosuppressed patients and distributed in chicken in broiler flocks that have respiratory disorder. Real Time –PCR is a potential tool in diagnosis of A(H1N1) pdm09 virus between human and chicken

Keyword: A(H1N1) pdm09, human, broiler, Taman real time-PCR, respiratory diseases, & Iraq.

Introduction

Newly emerged swine origin A H1N1 pandemic consider the cause of a populations worldwide issue started in early 2009 and identified between humans in Mexico, United States (US), with a significant impact on public health reached annually to 15-20% in the world population1. Of belief it has been derivative from the 1918 influenza pandemic3.

Globally, influenza A(H1N1) virus distribution was appreciated to be higher than that of seasonal influenza viruses3. Out of the three types of influenza viruses (A, B, and C), Influenza A virus is a zoonotic and infection has been recorded in a variety of mammalian and avian species. Mainly waterfowl such as ducks and geese are considered the natural reservoir of many influenza A viruses4,5. Genetically, fourfold re-assortment of an influenza A virus include two swine strains, one human strain, and one avian strain, which could be remixed through pigs as an intermediate host of mammalian. About one half of the genetic component is originated from swine, somewhat less than one fifth arises from human, and one third is of avian origin6.
Influenza is a well-known cause of acute respiratory disease in different hosts and spreads by aerosol transport but also can spread via fomites. In human symptoms include bronchiolitis, pneumonia, febrile disease, cough, sore throat, headache, myalgias, chills, and fatigue; gastrointestinal symptoms have also recorded. While most influenza viruses cause in poultry high pathogenic forms or asymptomatic mild infection, however almost reported isolates are of low pathogenicity in chickens and turkeys birds vary based on molecular characteristics of the virus and the ability of the virus to cause disease and mortality in chickens in a laboratory setting.

In Iraq, June 2009 the first infection confirmation with pandemic influenza has been announced by Iraqi health ministration, precisely, in Erbil province northern Iraq H5N1 was found, in Sulymanyia the infection confirmed by fatal human case, highly pathogenic H5N1 in poultry were recorded too. While H1N1 caused epidemic during 2009 and 2013. During 2013 outbreak appeared between peoples in eleven central and south Iraq governorates (Baghdad, Babylon, Diyala, Wasit and Anbar (Najaf, Qadisiyah, Maysan, Muthanna, Dhi Qar and Basrah) and in another survey (13%) of children under 5 years old were infected with influenza virus type A.

Materials and method

The study was collected from General Teaching Hospital and Specialized Hospital Maternity and Children Teaching Hospital and Center Pulmonology and Respiratory Specialist in Al-Diwaniyah city following the WHO influenza- like illness case definitions. A total of 145 clinical samples (throat swabs and nasopharyngeal swabs) collected in December 2015 to January 2016 (2 Months period) and evaluated for the presence of influenza A (H1N1). Most patients have been showed (sore throat, cough, rhinorrhea, wheezing chest, fever between 3-7 days while temperature of 38-39°C, chills, runny or stuffy nose, bronchial breathing, muscle or body aches, headache, fatigue, sometimes associated with vomiting and diarrhea. The cases were defined with physical examination by the consultant physicians, chest X ray and signed. Dacron throat swab specimens were collected under proper sterile precaution, submerged in 3.0 ml viral transport media, and immediately transported to Laboratory Biogenic techniques in an iced carrier box. As per the laboratory criteria for diagnosis the samples, use of appropriate biosafety measures and personal protection equipment (PPE) in dealing with samples. The swabs freeze at -70 °C, until used for viral genomic RNA extraction. 113 samples were collected from different infected broiler flocks most of them were expressed severe respiratory signs (ocular and nasal discharge, gasping, grossly there were severe congestion of trachea, cast plug in the bifurcation of the trachea, affected swollen pale kidneys), with moderate mortality rate. Tracheal swabs were collected from 5 chickens per flocks by using sterile cotton swab for rapid detection of influenza virus. Tissue samples of trachea, lung, kidney and cecal tonsils were collected in sterile plastic test tubes and stored in deep freeze at (-42°C) in Dewanyia veterinary hospital until used for qRT-PCR.

Viral RNA extraction: The extraction of viral RNA from nasopharyngeal secretions specimens by using (AccuZolTM RNA extraction kit Bioneer. Korea). A 250µl nasopharyngeal sample was placed in 1.5ml microcentrifuge tube, and then 1m trizol reagent was added and mixed well by vortex for one minute. After that, 200µl chloroform was added and mixed vigorously for 15 seconds, and then the mixture incubated on ice for 5 minutes. The tubes placed in cold centrifuge 4°C at 12000 rpm for 15 minutes. The supernatant was transferred to a new microcentrifuge tube, and 500µl isopropanol was added and the mixture mixed by inverting the tube 4-5 times and incubated at 4°C for 10 minutes. The tubes back to centrifuge at 12000 rpm for 10 minutes, and then supernatant was discarded. The RNA pellet was washed by added 1ml 80% Ethanol with DEPC and mixed again, then placed in centrifuge at 12000 rpm for 5 minutes. After that, the supernatant was discarded and the RNA pellet left to air dry. Finally 50µl DEPC water added to elution of RNA pellet, and then the extracted RNA sample was checked by Nanodrop spectrophotometer and store in -20°C freezer until used in RT-PCR assay. Reverser Transcription Real-Time PCR : RT-qPCR technique was performed for rapid detection of Influenza A virus H1N1 virus according to method described by (11). Real-Time PCR primers and probe were designed in this study by using conserved region in hemagglutinin (HA) gene in influenza virus A /Florida/62/2014(H1N1) lineage A(H1N1)pdm09 (NCBI-GenBank Code: KT836512.1) with an amplicon size of 102bp. These primers and probe were provided by Bioneer Company. Korea HA primer (H1N1) F AAAGGTGTAACGCGCAGCATG,
R TGGGTAGATCGTGGTATG / HA probe (H1N1) FAM-CCTCACGCTGGGGCAAAAGC-BHQ1. The Reveres Transcription Real-Time PCR amplification reaction was done by using one step reaction kit (AccuPower™ Dual star RT-qPCR master mix kit, Bioneer, Korea) and the qPCR master mix were prepared for each sample according to company instruction 5μL of RNA template, 1μL of NA Forward primer (10pmol), 1μL of NA Reverse primer (10pmol), and 12.5μL DEPC water to reach total volume 20μL. These qPCR master mix reaction components that mentioned previously were added into standard RT-qPCR premix tube which contain (RocketScript reverse transcriptase enzyme, DNA polymerase, dNTPs, and 10X buffer). sterile white RT-qPCR strip tubes and transferred into Exispin vortex centrifuge for 3minutes, and placed in MiniOpticon Real-Time PCR system and applied the following thermocycler conditions: RT step 50 °C for 1hour 1cycle, Initial Denaturation 95 °C for 3min 1cycle, [ Denaturation 95 °C for 10 sec, Annealing\ Extension 56.7 °C 30 sec, Detection(scan)] 45 repeated cycles.

**Result & Discussion**

This study deals with an important theme & clearly illustrates of some significant epidemiological features of influenza A H1N1 in infected patients and poultry. From all 145 patients suspected cases, 18(12.16%) were positive to H1N1 virus while, out of 113 poultry tested swabs there were 74(65.48%) highly positive incidence (table 1), the assay results confirmed the specify for subtype A (H1N1), while the sensitivity reached 100 copies/reaction, it is top of the convential RT-PCR (figure 1, 2). Most patients suffered from dyspnea, bone pain, fever, myalgia, and sore throat. This clinical symptoms of Influenza, came in agreement with the records of13,14 whereas predominantly infected broiler-breeder chicken with LP influenza virus showed mild respiratory signs gasping, dyspnea, coughing, nasal discharge, our finding is consistent with18,19 which experimentally existence of A (H1N1)pdm09 infection between chickens, turkey breeder flocks and ducks in the United Kingdom.

Risk Assessment in the Laboratory of Epidemiology

Jemmi Wahyu Santoso¹, Dani Nasirul H.¹, Putri Ayuni Alayyannur¹, Mulyono¹, Yenni Rohma Wijaya¹

¹Department of Occupational Safety and Health, Faculty of Public Health Universitas Airlangga, Surabaya 60115, East, Java, Indonesia

Abstract

Background and Objectives: Risk management is an endeavor in managing risks in the field of Occupational Safety and Health to halt the occurrence of unwanted occupational accidents comprehensively, planned, and structured in a well-managed system. The incidence of occupational accidents are likely to be found in many workplaces, and one of those is in a laboratory. The Laboratory of Epidemiology in the Faculty of Public Health, Universitas Airlangga is a site for students to conduct numerous activities, such as experiments, research, and tests and/or calibration. Those activities are supposed to be containing potential hazards, namely fingers injuries caused by laboratory equipment, eye fatigue, and Musculoskeletal Disorders (MSDs). Method: This research aims to identify the hazards and attempts to perform risk assessments by implementing HIRADC method in a laboratory in the Faculty of Public Health Universitas Airlangga to prevent the occurrence of occupational accidents and occupational illnesses suffered by the laboratory users. This research is descriptive research. The data are collected by conducting a direct observation and interviews with the laboratory workers. The variables in this research are hazard identification, risk assessment, and risk control. Results: By implementing the HIRADC method, the results show that there are 12 risks discovered, namely 10 low-risk level of hazards and 2 moderate-risk levels of hazards. Amongst the proposed risk controls are the use of standardized Personal Protective Equipment (PPE), the music playback to reduce stress levels, and the addition of seat cushions to minimize the complaints of MSDs. Therefore, the mentioned controls and recommendations are expected to facilitate the attempt to reduce the risk level occurrences in the Laboratory of Epidemiology in the Faculty of Public Health, Universitas Airlangga.

Keywords: HIRADC, occupational safety and health, laboratories, risks

Introduction

Referring to the Government Regulation Number 50 of 2012, Occupational Safety and Health is any action to ensure and protect the safety and health of the manpower by preventing occupational accidents and occupational illnesses.⁴ According to Widodo (2015), Occupational Safety and Health is a field that is related to health, safety, and welfare of those who work in an institution or a site project.⁵ The prevention of occupational accidents in Indonesia can be done by implementing the Occupational Safety and Health Management System.

Risk management is an endeavor to manage risks in the field of occupational safety and health to prevent the happening of unwanted occupational accidents comprehensively, planned, and structured in a well-managed system (Ramli, 2010). In accordance with OHSAS 18001, a risk can be described into a combination between the possibility of danger or exposure and the severity of injuries or health problems as a result of the exposure. Meanwhile, risk management itself is outlined as a process to manage risks that are likely to exist in every activity (Ramli, 2010).

Risk management is an endeavor to manage risks in the field of occupational safety and health to prevent the happening of unwanted occupational accidents comprehensively, planned, and structured in a well-managed system (Ramli, 2010). In facilitating the implementation of risk management, several methods
are fundamental to be carried out, and one of those is HIRADC. HIRADC, which stands for Hazard Identification, Risk Assessment, and Determinant Control, is a sequence of the process to identify potentially occurring hazards in every routine and non-routine activity. Then, the risk assessment is formulated based on the hazard identification before the assessor developing a hazard control program with the intention to minimize the risk level to prevent any possible accident.

During the operation of HIRADC, there are three steps to be completed, starting from determining the type of work, identifying hazard sources, to obtaining the risks. After that, the risk assessment and risk control to decrease hazard exposures contained in every occupation are to be reported. The assessment of the identified potential hazards through analysis and evaluation is carried out to determine the level of risks by considering every possibility and the consequences it may cause. Then, from the results of the analysis, the risk assessment can be categorized from low-risk level until high-risk level. The results of risk analysis are then evaluated and compared to the specified criteria or to the applied standards and norms to resolve the risk level, which later can be prevented in order to minimize the risks of occupational accidents.

Occupational accidents are likely to be discovered in any workplace, and one of those is in a laboratory. A laboratory is a site to conduct any activity, for example, experiments, research, and tests and/or calibrations. Inasmuch as many people are involved in every activity conducted in a laboratory, the risks of occupational hazards may also involve a quite big number of people. Thus, every person who performs activities in a laboratory must have familiarity with occupational safety and health in a laboratory. The issues of occupational safety and health in a laboratory are given quite an attention that is in accordance with the practice of education, research, and analysis. Due to that reason, the presentation of clear, detailed, and thorough information regarding the hazards in a laboratory as well as the attempt to provide occupational safety in a laboratory are indeed indispensable.

**Material and Method**

This research applied the descriptive method. According to Nurbuko (2005), the descriptive method is a method that can portray clear pictures of an issue and a condition based on the factual data that it is merely the obtained fact and data elaboration. As for the data collection, the method used was field observation and document analysis by implementing HIRADC method. The data analysis was carried out by identifying hazards and assessing risks along with the controls, followed by risk level analysis to figure out the risk level of each discovered hazard.

**Findings**

The data analysis was completed by enforcing the HIRADC method that consists of hazard identification, risk assessment, and risk control.

**Hazard Identification**

The hazard identification process is the following process of activity identification. In the hazard identification process, the risks of every identified activity are elaborated. As for the activities performed in the laboratory are the experiment process and laboratory equipment and computer preparation and resolution. During the experiment activity, the most-occurred incidence arises from the treatment to the laboratory equipment. Such incidence usually occurs due to the lack of human attention during the experiment. Other than that, the lack of familiarity of the standard operational procedures resulting in work negligence. The hazard identification process in the laboratory is obtained by conducting a field observation as well as a consultation with the laboratory workers.

**Risk Assessment**

The identified potential hazard assessment consists of analyzing and evaluating hazard risks to determine the consequences followed is carried out by considering any possibility and the effect of the occurrences. The mentioned risk assessment includes risk analysis and risk evaluation. The variables used in the risk assessment are Likelihood and Severity. Likelihood is the probability of occupational accidents occurrence, while Severity refers to the severity level of occupational accidents. Likelihood variable is used to determine the number of activities that cause occupational accidents. On the other hand, Severity portrays the severity level of an occupational accident. The elucidations of the risk assessment are drawn in the table below.
From the results of the risk assessment, it can be noticed that there are 12 discovered hazard risks in the laboratory. The risk assessment is aspired to arrange the priority handling of the identified hazards. Conferring to the data that have been presented beforehand, there are only two hazards which get the priority handling, namely the hazard of fingers injuries when preparing and resolution laboratory equipment as well as the hazard of electric shock when turning on the computer. Thus, for that reason, the control performed must be initiated from the ones with the highest risk level to the lowest ones.

**Risk Control**

The risk control is objectified to minimize the risk level by handling the existing hazards. The table below shows the risk control of the hazards discovered in the laboratory.

The attempts to decrease the risk levels are as follow as for the electric shock hazards, when turning on the computer, the control can be done by wearing Personal Protective Equipment, such as leather gloves. This is in accordance with the Law Number 1 of 1970 article 13 on the Occupational Safety, namely the obligations when entering workplaces, and the Minister of Labor Regulation 03/MEN/1998 on the Procedures for Reporting and Checking Accidents as well as the regulation-standard installation of the electricity. As mentioned in the Minister of Labor Regulation 75/MEN/2002 on the Enactment of Indonesian National Standards number 04-0225-2000 on the General Regulation of the Installation of Electricity 2000 (PUIL 2000) and formulating installation instructions or any installation in workplaces.

As for the fire hazards, the risk control can be performed by the procurement of fire extinguishers. This is in correspondence with the Law Number 1 of 1970 on the Occupational Safety, the Minister of Labor Regulation Number 04/MEN/1980 on the Provision of Installing and Maintaining fire extinguishers, and Government Decision 186/MEN/1999 on the Fire Prevention Unit in workplaces.

As for the psychological hazard, for instance, stress, the control is operated by the music playback during working hours to create a more convenient working environment. As for the irritation hazards caused by the dust and the radiation from the computer screen as well as the irritation as a result from the heat, the control is carried out by wearing Personal Protective Equipment, for example, gloves and goggles. This refers to the Law Number 1 of 1970 article 13 on Occupational Safety, namely the obligations when entering workplaces.

As for the injury hazards resulting from the scratch and broken laboratory equipment, the control is to be enforced by wearing Personal Protective Equipment, such as gloves and goggles as well as by putting on
coverall and safety shoes to protect the feet. This control is pointed out from the Minister of Labor Regulation Number 187/MEN/1999 on the Diagnosis and the Reports of Occupational Illnesses.10

As for the MSDs hazards due to the non-cushioned seats, the control can be executed by adding several cushions to the seats. As for the diseases transmitting hazards generated from the experiment in the laboratory, the control is to be done by wearing Personal Protective Equipment, for instance, masks, gloves, and goggles.

Conclusions

Based on the results obtained from the research conducted by implementing HIRADC method, it can be inferred that there are 12 hazards that consist of 10 low-risk level hazards and 2 moderate-risk level hazards.

Amongst the proposed risk controls are the wearing of standardized Personal Protective Equipment, the music playback during working hours to reduce the stress level, and the procurement of seat cushions to minimize the complaints of MSDs. Therefore, the suggested controls and recommendations are highly expected to support the endeavor in reducing the risk levels that are likely to be discovered in the laboratory.

Effectiveness of An In-Service Education Program on Knowledge and Practices Regarding Biomedical Waste Management among Staff Nurses

Jobby George¹, Jipi Varghese², B.A Yathi Kumara Swamy Gowda³
¹Assistant Professor, College of Applied Medical Sciences, ²College of Nursing, King Saud bin Abdulaziz University of Health Sciences, Riyadh, Kingdom of Saudi Arabia, ³Professor, Principal, Moodbidri -Alva’s College of Nursing Dakshina Kannada District Karnataka, India

Abstract

“Biomedical waste” is defined as any type of waste, produced during the diagnosis, management or vaccination of human beings, animals or during research which is related to or in the production or testing of livings¹. The purpose of this study was to assess the effectiveness of in-service education programme on knowledge and practice regarding biomedical waste management among staff nurses. A quasi experimental approach with pretest posttest design was implemented among 30 staff nurses using a simple random sampling technique. At pretest a structured practice checklist was used to assess the existing practices of handling, collection, segregation and storage as well as disposal of biomedical waste and a structured knowledge questionnaire was administered to the staff nurses respectively to assess the knowledge in the areas of handling, collection, segregation and storage as well as disposal of biomedical waste was assessed. The posttest findings of an in-service education program on biomedical waste management among staff nurses indicate that it highly served to improve the knowledge and practices.

Keywords: In Service Education, Biomedical Waste Management, Staff nurses

Introduction

Hospital related wastes are infectious as well as hazardous. It causes serious risk and health impact on the environment and it necessities the need of safe disposal methods². Due to mushrooming of hospitals, nursing homes, clinics and diagnostic laboratories a mounting amount of waste is generated³. Appropriate waste management systems have been developed and installed globally to handle both hazardous and non-hazardous biomedical waste⁴.

The government of India responded to global concern and enforced the biomedical waste management and handling rules in 1998, which is applicable to hospitals, nursing homes, veterinary institutions and animal shelters that generate biomedical waste. The Ministry of Environment and Forest had published the, “Biomedical waste management and handling rules 1998/ 2000 under the Environment protection act, 1986 that compel all hospitals, clinics, nursing homes, slaughter houses and laboratories to ensure a safe and environmentally sound management of waste produced to protect the environment and community health⁵.

Bio medical waste management rules, 2016 classifies biomedical waste into four categories based on their separation and color code. The color coding follows the mandated categories 1. Yellow, 2. Red, 3. White and 4. Blue. The yellow biomedical waste disposal containers have been further subcategorized from “a” to “h”. All the yellow category waste are finally incinerated or deeply buried. The Red category stores contaminated waste which is recyclable. The Blue category stores glassware and metallic body implants whereas the white

category is used to segregate waste which are sharp objects including metals\(^1\).

It is required to provide a safe working environment for all health care providers which include nurses\(^5\). Thus this study aims to evaluate the relationship between knowledge and practice of biomedical waste among nurses.

**Aims of the study**

The aims of the study were divided into two phases. Phase -1, evaluated the existing practice regarding biomedical waste management among staff nurses using a structured practice checklist, and followed by assessment of knowledge of staff nurses on biomedical waste management utilizing a questionnaire. Phase -2, evaluated the effectiveness of an in-service education programme on biomedical waste management among staff nurses.

**Material and Method**

A quasi experimental approach was employed for the study. 30 staff nurses who met the inclusion criteria (Staff nurses willing to participate in the study and present in the hospital during data collection, Staff nurses with full time employment status, Staff nurses with total years of clinical experience of not less than 2 years) was chosen using simple random sampling technique. Every participant signed a written informed consent as agreement to participate and to maintain confidentiality of identity. A structured practice checklist was prepared for assessing the existing practices of handling, collection, storage and segregation as well as disposal. The tool was found to be reliable with reliability co-efficient \((r = 0.93)\). Structured knowledge questionnaire was administered to the staff nurse with maximum score was 26. Section A, had 6 items regarding handling. Section B, consisted of 7 items regarding collection. Section C, had 6 items regarding storage and segregation. Section D, had 7 items regarding disposal. Descriptive and inferential statistics was used for data analysis.

**Findings**

Majority of the sample (56.7\%) belonged to the age group 25-35 years, and 33\% had working experience of 10-15 years. The existing level of practice showed that more than 55\% of the staff nurses were in the fair practice category. Post-test scores on practice were significantly higher than pre-test practices scores which had majority of the nurses under good and very good category as illustrated in (Fig. 1). An assessment of pre-test knowledge showed that (56.7\%) nurses had average knowledge and (43.3\%) had poor knowledge regarding biomedical waste management. Post-test assessment showed that majority of the staff nurses (53.3\%) had acquired good knowledge and (36.7\%) had acquired very good knowledge as depicted in (Fig. 2). The mean of the post-test (20.63) knowledge scores was higher than the mean of pre-test (11.30) knowledge scores as demonstrated in (Table.2). Data revealed statistically significant difference between pre-test and post-test knowledge scores \((t_{(29)}=13.68, p<0.05)\). The maximum percentage gain after in service education occurred in the area of handling, followed by collection, then in the area of storage and segregation of waste and the lowest percentage gain was recorded in the area of disposal as shown in (Figure 3).

Conclusions

This study findings show that an in-service education program on biomedical waste management among staff nurses is very effective in improving the knowledge and practices.

Regular and ongoing training program on biomedical waste management its regulation and hospital policy regarding disposal should be insisted giving special consideration for the newly joined staff. The Central pollution Control Board, the Ministry of Environment & Forests has recommended that there should be a course on biomedical waste management in under graduate nursing curriculum.

The study is limited to small number of participants. The following recommendations are made based on the present study for future study; similar study may be conducted on a larger sample.

To fulfill the Biomedical Waste Management and handling Rules and to safeguard health of health team professional they should be equipped with proper education of safe handling, collection, segregation approaches storage, treatment and disposal of biomedical waste. This study was found to be effective in improving knowledge and practices in nursing staff.

Conflict of Interests: The authors declare that they have no conflict of interests with any organization regarding the materials discussed in this manuscript.

Source of Funding: The study received no grant from any funding agency in the private or public sectors.

Acknowledgment: The authors would like to extend their thanks and appreciations to all staff nurses who spent their valuable time and provided to consent to participate in the study.

Ethical Clearance: Ethical clearance was obtained from the Research Ethical committee Alva’s college of nursing Moodbidri.

The Impact of Qualitative Exercises in the Development of Some Aspects of Attention to the Boxers National Center for the Care of Sports Talent

Khalil Ibrahim Al-Hadithi, Anmar Fawzi Jasim Albufahad

Abstract

That there are differences in the performance of some players compared to the standard within the Center’s plan, which led the researcher to study this problem and develop the right solutions to reach the performance of skilled through the design of specific exercises aimed at the capabilities of players and their impact in the development of some aspects of attention. In developing some aspects of attention to the National Center for the Advancement of Sports Athletics in Boxing.

The sample of the research consisted of (24) males representing (80%) after excluding the remaining boxers who participated in the pilot experiment (6) boxers distributed according to weights except heavy weight, as each weight included two boxers or four boxers distributed by lottery. After collecting the data, the data were analyzed statistically and obtained the results through which the most important conclusions were reached, including: The specific exercises have a positive effect on the development of some aspects of attention to the people of the National Center for Sports Boxing.

Keywords: Qualitative exercises, attention and boxers.

Introduction

The importance of research in the selection of educational experiences (specific exercises) and formulation in dynamic sentences that fit with the special requirements of the performance of skills and the potential of the boxer at the age of (14-15) years are the independent variables that we expect positive change in the variables dependent (focus attention). As a result of the boxer’s passing of these experiences and his interaction in performing these specific exercises. Thus, the boxer can be capable of self-defense and attack because he needs skill alongside punches and intelligence in attack and defense, so it is a sport where art triumphs over power.

One of the most important aspects of attention is the concentration of attention and means the readiness of the athlete to direct mental activity towards a specific goal and the extent of response is an important means to raise the level of the player and ability to observe things clearly and high accuracy of concentration and enables the player to distract distraction and focus on the main points in the performance universe. The focus is good performance. “If attention is a general concept, the focus is a core,” and Yahya Kazem (1990) sees it as “narrowing attention to a certain emotion or keeping an eye on a particular emotion.”

But it is an integrated sport that builds the character of the individual and returns to the endurance, self-reliance, speed of knowingness, behavior, courage and courage, as well as gaining high physical fitness and self-confidence. Boxing cannot be used outside the competition for aggression against people, the boxer does not infringe on anyone and does not hurt anyone with his art and skills.

Research aim:

Identify the impact of specific exercises in developing some aspects of attention to the people of the National Center for Sports Boxing.

Research methodology and field procedures:
Research Methodology

The researcher used the experimental method to suit the nature of the research problem with the design of the two parallel groups with pre and post-test.

Search community and sample:

The research community was identified as the founding members of the National Center for the Advancement of Athletics in Boxing (30), which represents the society of origin for the year 2018-2019. The research sample consisted of (24) males representing (80%) after excluding the remaining boxers participating in the experiment (6) boxers distributed according to weights except heavy weight as each weight included two boxers or four boxers distributed by lottery to two groups.

Specify search variables:

Exercises designed (quality):

In the light of the researcher’s knowledge of Arab and foreign sources as well as the training of the National Center for the care of sports talent for young people, the exercises were prepared on the basis of scientific aims to identify the weaknesses of the large and identified through the video analysis, which the researcher photographed and presented to specialized experts, Exercise and after the presentation to the experts have been deleted and modified some exercises to become (27) exercise. Examples of exercises that have been modified is a matching exercise that was a wheel frame diameter of 60 cm from the inside and put the two boxers front feet (leader) within the framework and performance skills Offensive and defensive To become a drawing after the adjustment ring on the ground that the fact that the colored or tape players from the emerging category and height is not sufficient and that the height of the frame approximately (25 cm). This is opposed to the movement of their feet while performing the exercise.

Specification of the tests used in the search:

First: the test of measuring the attention of the boxers:

Purpose of the test: Measure the attention of boxers

Tools used: Boxing gloves, electrical connections, registration form the machine consists of a board made of wood measuring (60 × 60) cm coated with sponge thickness (5) cm and the outside is encased in a piece of white leather, as there are inside the board electric lamps number (7) in different colors (yellow - red - blue - Green) are distributed in four directions. These lamps are connected to a (5 meter) long cable connected to an electronic base and its room. Recording the results by electronic display, control of lamps, instructions and timing. It contains 30 different programs for running lamps so that the laboratory cannot keep the test. The test has the duration of the test (convert now (40) second is divided into four colors for each color (10) seconds, and the duration of the light is half a second.

Performance: The boxer stands in front of the light pad in the standby mode. The test begins with a signal from the device (three consecutive flashes). At the start, the laboratory will only perform a yellow color punch for 10 seconds. After that, the switch will be red for 10 seconds. The lab is converted to blue for 10 seconds. At the end of the test, the laboratory turns green until the end of the test and the conversion is according to the instructions issued by the device. It is an electronic siren connected to the device.

Method of recording: The number of lamps extinguished by the laboratory is recorded for 40 seconds (total four color timing).

Second: Measuring the attention of boxers:

Purpose of the test: To measure the concentration of attention among boxers.

Tools used: gloves, electrical connections, registration form.

Specification of the device: The machine consists of a board made of wood (60 × 60) cm and thickness (30) cm sponge coated with thickness (5) and outside (7) in different colors (yellow, red, blue, green) distributed on four directions where they relate (30) different program to restart the lamps so that the laboratory cannot keep the test and the duration of the concentration test is (15) Second, the lamp’s life time is half a second.

Method of performance: The laboratory stands in the standby mode and, when hearing the electronic instructions issued by the apparatus, the laboratory performs the tests as quickly as possible the red color the
player will focus on. It is among the other colors where the other colors are not counted if extinguished by the laboratory.

**Recording method:** The registrar records the number of white lights that have been turned off by the recording screen.

**Pilot study:**

The pilot study was conducted for the specific exercises prepared by the researcher on Sunday (14/10/2018) at 4:00 pm. The purpose of conducting the experimental experiment for the exercises is to determine and evaluate the exercises within the scientific bases.

**Equal search groups:**

In order to return the differences to the experimental factor that affects the experimental research group, the researcher conducted the parity between the experimental and control groups in some aspects of attention using the t-test of the unattached samples of the same number and to find out the difference between the two sets of dependent search variables. The calculated (t) values of the control and experimental groups in the search variables are smaller than the tabular value (2.07) in front of the freedom score (12 + 12-2 = 22) and the significance level (0.05). Therefore, the difference is statistically significant.

**Field research procedures:**

**Pretests:**

Pre tests were conducted on the experimental and control groups of the research variables, which include some aspects of attention (focus attention and divert attention) on Sunday (21/10/2018) at 4:00 pm.

**The main research experience:**

The main research experiment was carried out on Wednesday, 24/10/2018, by applying the specific exercises designed for all members of the experimental group for a period of 6 weeks and five units per week. “The changes resulting from repetition, repetition and training are usually within (6-8) weeks,” he said, citing Euroconnell.

The researcher’s share in the application of his exercises is (25) minutes taken from the application section in the main part of each educational unit to be the total time for the application of the curriculum as shown:

(25) Minutes Exercise (30) Educational units = (750) minutes Total time of application of the curriculum.

(27) Different exercises were designed according to the size of errors that appeared in the analysis of video and distributed scientifically on the number of units and the share of each unit (3-4) exercise and the proportion of exercises in the development of capacity.

**Posttests:**

Post-tests were carried out on the experimental and control groups of the variables (focus attention and divert attention) on Wednesday (5/12/2018) at (5:30 pm).

**Results**

**Presenting the results of some aspects of pre and post attention to the control and experimental research groups and analyzing them:**

Table (1). Shows the computational circles, the standard deviations of the differences, the calculated value (t) and the significance between the pre and posttests of the control and experimental groups in the search variables

The value of (t) the tabular (2.20) and the degree of freedom (12-1 = 11).
From table (1), the value of (t) calculated by focusing attention and diverting attention to the control group was (5.18, 4.65) for variables (concentration of attention, attention shift). The values (11.75, 11.36) for the experimental group and for the same variables, and to detect the significance of these differences, it was found that the value of (t) calculated greater than the value of (2.20) in front of the freedom degree (11 = 1-12) and the level of significance (0.05). And for the results of the tests of posttest and the value of the mean of the calculation of the tests.

Presenting the results of the post tests for some aspects of attention to the control and experimental research groups and their analysis:

Tabular value (2.07) and degree of freedom (12 + 12-2 = 22)

Table (2) shows the results of the tests on the differences between the distance tests in the variables (attention concentration, attention shift) of the experimental and control groups and that the calculated values (t) were respectively (4.48 and 3.18). To detect the significance of these differences, (2) and (0.05). Therefore, the differences are statistically significant for the benefit of the experimental group and the values of their computational values.

**Discussions**

**Discussing the results of pre and posttests of some aspects of attention, special motor abilities and the skillful performance of the control and experimental research groups and their analysis:**

From table (1) the researcher attributes this to the effective exercises used by the trainer in the implementation of educational units and to the diversity of means of learning Skills, which include different skills that led to learning in the variables in question and in varying degrees, as well as to the repetition of the movements that had a prominent role in learning the skills studied. This is confirmed by Kurt Minell (1987), is being clear and objective direction and to improve motor mobility.  

The repetition and variation of the sample level, as well as the repetition and gradation, were easy and difficult during the execution of the units. The enhanced repetition of the exercise helped the player to master the sub-movements which represent the required skill and to achieve compatibility between these movements, and appropriate weight.  

The researcher believes that the main goal sought by educational programs through performance, menses and repetition is to improve the motor programs of the individual and improve the level of motor performance is the basis of the learning process as it works to provide the learner a range of physical and skill capabilities and increase the number of motor programs that are stored in the brain, In achieving the best levels and skills to be improved and progress in the performance during the different play situations.

**Discussing the results of posttests for some aspects of attention, special motor abilities and the skillful performance of the control and experimental research groups and their analysis:**

From the table (2) the researcher attributed this and in terms of attention to the attention-focused exercises and diverting the attention used for the experimental group, which reflected a clear image of the players as they contributed to the development of their abilities, which improved through commitment to educational units and repetition in the exercises used by the researcher, which was intended to develop attention. Other exercises contain a contribution to the mental abilities, which is to divert attention and concentration of attention and exceeded the cases of tension and frequency of some
situations that accompany the performance of skill after the player from the state of perception and memory and investment memory “The higher the focus on the players, the better the exercise will be. When there is no good focus on what is happening to you, the performance or reaction is not achieved optimally”. An important thing to consider is to help the player control the voluntary movements when performing the skill movements as the mental processes are in turn, to create the image needed for optimal performance and to choose the appropriate plan to carry out the required assignment “.11

The researcher attributes this to the components of the exercises that adopted the process of concentration of attention and turn it into a complementary stage, as well as the ability of motor compatibility and control of the performance of skills as the boxer needs high consensual performance and adaptability and the time of education and the most important focus and divert attention,12 which plays an important role in all characteristics of motor kinetics Early implementation of motor performance in accordance with a decree to implement the motor duty gives the player the opportunity to choose the quick and correct response during performance.13 This is what has been given through quality exercises to focus and transform attention. An athlete when he has a deep focus and is able to possess the special motor compatibility “,14 and this is what was achieved in the experimental group by the specific exercises that reflected the effect of positive and in the best results.15

Conclusions

Specific exercises have a positive effect on the development of some aspects of attention to the people of the National Center for Sports Boxing.

There is a difference in the results of the posttests between the experimental control groups and for the experimental group in the variables in question.

Functional Gastrointestinal Disorders in Pediatrics

Khudhair Khalaf Shallal
High Diploma in Pediatrics, Directorate of Health of Anbar, Iraq

Abstract

Characterization over infancy then adolescent practical gastrointestinal disorders (FGIDs) has advanced in the course of the longer rome manner nowadays culminate among another rome. The generation regarding diagnose the Fgid only then organic sickness has been excluding is wan, now we bear proof in conformity with supporting symptom based diagnosis. The child adolescent rome five, we lengthen thinking means of putting off the word up to expectation in that place was “no proof because natural disease” in all the definition and replace that along “after fabulous clinical evaluation the signs and symptoms can’t lie attributed after any other scientific conditions.” This changing allows clinician in conformity with perform selective and not checking out in imitation of the guide a high-quality analysis about the FGID. The additionally point so much FGID can be coexist together with sordid medicine stipulations so much them selves end results between GI symptom (exciting bowel diseases). In Rome five, purposeful nausea and functionally vomiting currently describe. Rome third “abdominal punishment related practical gastrointestinal disorders” has been modified to “functionally stomach castigation disorder” and we have derived a modern terms, useful belly pain not in any other case specified, in conformity withdraw youth whosoever function now not suit a unique disorder, such namely cross bowel, purposeful dyspepsia, then belly migraine. Rome five FGID definition beautify clarities because of each clinician then researcher.

Keywords: Children, Adolescent, Abdominal, Nausea, Vomiting, Functionally Disorder

Introduction

Behavioral research on psychological and social effects to understand the bulge of the digestive system. The actual behavior of visceral hyperplasia and hypersensitivity detected among a huge subset of those suffering from IBS and FD is still unclear. Thinking about “visceral hypersensitivity” such as pain thresholds is much less experienced during sensorial sensory examination as it is, reporting punishment in less pressure or volumes all through frequent inflating the GI balloon catheterization (1). However, as much we bear outlined, such is becoming an increasing number of clear that psychological procedures yet psychosocial elements may affect visceral perceptual sensitivity. There are various research endorses so a multiplied psychological aptitude according to record pain, as can stand pushed by hypervigilance, underlies the diminished punishment thresholds among IBS patients, rather than improved neurosensory sensitivity. Studies of the consequences about stressors about appreciation concerning colorectal distention into healthy topics and IBS sufferers hold best particularly inconsistent findings, fit in conformity with variants amongst the stressors ancient then potent confounders, such as distraction (2). However, an instruction as controlled because distraction proved as IBS patient, not healthful subject, rated rectal distensions extra intense and unpleasant throughout dichotomously ear strength compare together with relaxations (3).

Throughout the recorded history, the decade of entertainment at home has had intimate connotations that the pace of the amount goes beyond its real function. It is usually considered personal or ambiguous. Their dysfunction is related to embarrassment, emotion, shame or strong bowel performance as required by general well-being. In addition, we understand intestinal function after dysfunction, so the animals are closely linked with strength and emotion: I find them strong in swallowing, I cannot drop that much longer, and then I
have the butterflies in my stomach. On the contrary, or perhaps as it evolves for health benefit, the substance and feces are unhealthy according to the senses; the scene or odor, or after contact with it, executes the administration according to the pathological responses, nausea, or vomiting. Each person has a scary law so that it is then combined derived next to an equal anlage, the original neural crest. This facility in the intestines also explains what is the element of tension or psychologically compounded components after the intestinal properties and dysfunction of the function, Gastrointestinal symptoms, disease, and bitter. The understanding of how these factors are pronounced in the tradition of some other factors, along with changing norms, trust systems, or prototyping, has evolved in a timely manner, the similar section traces cultural influences in terms of research, capacity for symptoms, gastrointestinal symptoms, Thus leading to the identification and classification of beneficial GI disorders.

**Environmental Influence**

Childhood environmental factor: parental belief and behavior. There is a familial total regarding morning FGID. Children about grown-up irritable bowel symptom (IBS) sufferers accomplish more fitness greatness visits than the young people on non-IBS parents. This pattern is no longer confined in conformity with gastrointestinal (GI) signs and symptoms and holds because of maternal yet paternal symptoms. Although even is permanent research within a genetic clarification because of these familial patterns, where teenagers analyze out of parents do reduct a too greater performance according to the hazard because of increasing an FGID than genetics. The primary learning principle over fantastic reinforcement or reward, described as a match following partial behavior that will increase the likelihood about so much behavior occurring among the future, is a likely contributor according to what that be able to occur. Children whose mothers enhance sickness conduct ride extra extreme stomachaches yet extra school absences than vilen children. In addition, when parents had been requested in imitation of show effective and feeling responses in imitation of their children’s punishment in a laboratory, the frequency regarding pain complaints was once higher than parents are recommended in imitation of pass by them. Finally, a great randomized scientific analysis regarding teens with useful belly punishment found as cognitive-behavioral cure (CBT) targeting coping strategies, as well as like parents’ then children’s beliefs about, or responses to, children’s discipline complaints, brought about increased baseline in accordance with follow-up decreases in discipline and GI signs compared together with an educational intervention controlling for time yet attention, yet up to expectation it impact was mediated by way of changes within parents’ cognitions as regards their child’s pain.

**Function Gastrointestinal Disorder**

Regurgitation. Reflux refers within consequence including retrograde involuntary motion concerning gastric issue within then overseas of the stomach after is often referred to as gastroesophageal reflux. When the reflux is immoderate ample afterward maintain visualized certain is called regurgitation. Regurgitation atop stomach contents among the esophagus, mouth, and/or nose is widely used among kiddies afterward is inside the predicted quantity about behaviors amongst sound infants. Infant regurgitation is the most common FGID within the advanced yr concerning life. Recognition over infant regurgitation avoids useless scientific medical doctor visits then bold investigations yet remedy because about gastroesophageal reflux sickness (GERD). Infant regurgitation is super out of vomiting and is described by using an internal frightened system exposure involving both autonomic and skeletal muscle agencies concerning who gastric factor are forcefully expelled thru the trencherman due to the fact over coordinated actions upstairs the youthful bowel, stomach, esophagus, and diaphragm. Regurgitation is moreover excellent out of ruminating, inside who till at present swallowed food is returned in accordance in imitation of the pharynx or mouth. When the regurgitation about gastric issue reasons troubles or contributes of accordance concerning adroitness injury and irritation (eg, esophagitis, obstructive apnea, wonder full airway disease, pulmonary aspiration, maintenance, and all difficulties, afterward failing into pursuance including thriving), such is referred in accordance with as like GERD.

The cause because of acceptance regarding diagnostic entities. Based regarding medical experience, especially about youngsters alongside anxiousness then depression, practical nausea but realistic vomiting are at existing blanket ed of Rome IV. Some sufferers maintain nausea alone, partial bear vomiting alone, but scrappy have nausea then vomiting. We agree with so much the absence over concomitant discipline between
that troubles suggests he ought to now not continue to be sure namely portion regarding beneficial dyspepsia. Pathophysiologic considerations. Clinical evaluation. We preserve set up realistic nausea and beneficial vomiting as detach entities, but sufferers together with chronic nausea dense times file mild vomiting including more than a few frequencies. The attendance of extreme vomiting amongst culling in pursuance with nausea affords a one-of-a-kind state of affairs among as like middle anxious governance disease, GI anatomic abnormalities (eg, malrotation), gastroparesis, or inner pseudo-obstruction hold excluded. Biochemical trying out may also also encompass pardon regarding serum electrolytes, calcium, cortisol, or thyroid hormone levels. Intestinal bunker but dynamism troubles (eg, gastroparesis, inner pseudo-obstruction) labor in conformity with posture considered then cut far away from the appearance regarding recurrent vomiting. Kin about useful nausea or vomiting after sluggish gastric emptying in teens is no longer in reality established. We did no longer consider an everyday pinnacle GI endoscopy a makes use of because of forecast on practical nausea besides vomiting. Psychological evaluation is imperative in younger people inclusive of practical nausea afterward practical vomiting (11).

Clinical evaluations

Effortless repetitive regurgitation, swallowing, and/or spitting inside minutes in regard to beginning a feast outline rumination. Other ordinary complaints correspond concerning stomach pain, bloating, nausea, heartburn, then a number of somatic symptoms, absolute namely headaches, dizziness, yet sleeping difficulties. Differential foreboding includes gastroesophageal reflux, gastroparesis, achalasia, bulimia nervosa, and ignoble purposeful then bodily gastric yet tiny inside diseases, but within none regarding what entities does the regurgitation bust location directly away later on eating. One instruction suggested to that amount high-resolution esophageal manometry execute discover subgroups including surprising mechanisms touching disease to up to expectation total reply to precise management techniques stability (12).

Treatments

An uncompromising understanding of cogitation omen yet a colorful inspiration according to conquer that are fundamental among achieving successful treatment. Due to concept syndrome does posture conceptualized into phrases regarding a discovered habit, remedy hourly has historical techniques profitable in the administration upstairs dependancy disorders. A worthwhile current inpatient interdisciplinary strategy so worried pediatric psychology, pediatric gastroenterology, scientific nutrition, toddler life, remedy recreation, afterward rubdown therapy has been mentioned between younger people along with so condition (13).

Morbidities

Morbidity associated with FGIDs is among overall psychosocial. Pain interferes collectively together with day-to-day college appearance afterward performance, mate relationships but distribution in household yet non-public activities. One outdoors concerning x teens together with practical belly punishment attends college into deep situations whilst extra than 28% in relation to sufferers have absenteeism larger than secure day concerning people Data beyond adults undergo tested according to that amount victims whosoever suffer beyond FGIDs may also additionally undergo cough difficulties, headaches, dizziness yet fatigue. Similar studies, however, are lacking in pediatrics. Furthermore, psychological issues definitive specifically anxiety and fail are common. Children alongside FAP bear a leaning into conformity on maintaining a lower attribute concerning entity than wholesome teenagers but the comparable multiplication on existence specifically sufferers along with demonstrable herbal gastrointestinal disease. There are additionally pointers, therefore, siblings concerning teens inclusive of FGIDs journey extra emotional/ behavioral signs and symptoms than their peers however their symptoms are not quite virtually identified by way of their mother and father (14). Children which include persistent belly discipline preserve immoderate utilization about the fitness outweigh system namely as they, along collectively along with their parents, pray solutions due to the fact the unexplained stomach pain. They hold a couple of visits between consequences with healthcare vendors and may also also even petition 2nd but third opinions. They document the challenge about lowlife a widespread background upon to desire is neglected through road about their provider. As a result, pediatricians may also additionally experience compelled then concern victims in imitation of a doublet about tests, which includes pick tests, radiological lookup afterward endoscopies according to preserve outside from missing a big illness.
Figure 2. Functionality gastrointestinal disorder dominant diagnosis in Norwegian children with abdominal pain. FAP=functional abdominal pain. IBS=irritable bowel syndrome. (10)

Functional Dyspepsia

The prevalence involving dyspepsia varies in 3.5% and 27% relying related to affect us on a respecting the origin. The recurrent abstention afterward discipline situated into the higher abdomens as much is not relieved with the aid of defecation, not related collectively along with an exchange among stool pattern than no longer defined with the aid regarding a natural disease. The penalty needs to recur at least as soon as a hebedomad for at least two months due to the fact on foreboding afterward remain made. Dyspepsia is typically polysymptomatic. Ninety-nine percentage above big sufferers bring extra than associate symptoms, more than 80% file larger than signs a lot less than 0.1% record partial symptom. The castigation or castigation may additionally posture related in conformity with vomiting, nausea, stomach fullness, bloating but rapidly satiety. The referred in imitation of and 26% over 127 pediatric subjects had ulcer-like symptoms even as 15% manifested dysmotility like signs (16).

Prognosis

Every baby is pronounced in regard to the natural history of FGID. In adults, the occurrence over Ibs and Fd is regular upstairs time, alternatively collectively including a big turnover inside multiplication status. Patients who have diagnosed along with realistic stomach judgment no longer fast end on abject a natural disease as regards approximate follow-ups. after his colleagues pronounced to that amount volume 30% - 45% on their sufferers together with continual stomach judgment persisted between accordance together with journey discipline then two years touching a follow-up but it have an impact on concerning the kid’s behavior, social functioning afterward usage regarding fitness greatness decreased. The proven above according to desire on to 70% on young adults alongside dyspepsia had been asymptomatic yet an awful bunch elevated intestinal 2 years over the diagnosis. Other studies, however, observed so 30%-50% on formative years which includes continual purposeful stomach castigation seasoned frugality as many adults via the discipline restricted everyday activity inside totally 30%. Moreover, victims are more into the whole likelihood than controls afterward trip anxiety, somatization, hypochondriasis, yet associative dysfunction as like adults. Studies endure proven then extreme symptoms at the gratuity namely accurate as much an as improvement within signs and signs at three months bear been related alongside with greater prognosis, whilst psychological elements but judgment tolerance hold been terrible prognostic warning signs (17).

Conclusion

Chronic belly castigation of infancy remain very difficult clinic essence according the average pediatrician as properly as specialist. The differential analysis enormous then no confirmatory laboratory marker. However, including beyond Rome criteria, white records then absolute bodily examination in mixture with restricted laboratory then imaging research now indicated need to conduct in accordance to the diagnosis. FGIDs the purpose concerning giant anxiety, immanency, and illness into young people so nicely namely adults. As our perception about this stipulations improves, our medicine interventions pleasure growth too, no longer solely try after take them, however additionally in conformity with interfering promptly into the disorder direction hence namely according to the rule in long term. Pediatrician have to keep aware of doubtlessly modifiable morning chance factor then must provide this young person and their households a therapeutic option so takes within a score the physiological properly as the psychological factors about the diseases.

The impact of Api toxin (Bee venom) on promastigote on both Leishmania tropica and Leishmania Donovani in Vitro

Montaha A. Al-Safar¹, Salwa. S. Muhsin¹, Sarah A. Mahmood¹
Department of Community Health, Medical Technical Institute, Baghdad Middle Technical University, Iraq

Abstract

Leishmaniasis is a type of serious diseases which is triggered by a protozoan parasite of the species Leishmania. It has been known for many hundreds of years. This disease is transmitted by a sand fly’s bite which is known as subfamily Phlebotominae. Limited drugs are available for the treatment of Leishmaniasis, and general drugs have many side effects on patients. These necessitate the need for urgent active treatment of leishmaniasis. The aim of the study is to develop a new type of antileishmanial agent instead of the classical drug by investigating the effectiveness of Api toxin (Bee venom) on the phase promastigote of both Leishmania tropica and Leishmania donovani in vitro.

The cytotoxic effect of Bee venom was evaluated by exposing L.tropica, and L.donovani promastigote phase was exposed to six diverse concentrations (1, 2, 3,4,5,6 and 5µg/ml) and determined by colorimetric assay (MTT) after 4hr. The outcomes of the study showed high effectiveness on parasites numbers in the same concentrations reached to inhibitory growth (the viability percentage of promastigote). The cytotoxic effect (MTT) was decreased by increasing the concentrations with the same amount of time, which reached to (22.83± 1.67) and (72.46 ± 1.49) after 4hr in 5µg/ml of a cytotoxic solution of Bee venom for Leishmania tropica and Leishmania donovani successively. The IC₅₀ was also calculated depending on the results of the MTT assay to determine the most effective concentration of Bee venom on the viability of Leishmania tropica promastigotes. The result was 1.3 µg/ml. The conclusion of the study is that the Bee venom – based treatment has a very important role in overcoming cutaneous leishmaniasis as results showed the high inhibitory effects on L.tropica at low concentration in vitro.

Keywords: Leishmania tropica, Leishmania donovani, Phlebotominae

Introduction

In tropical regions, leishmaniasis stands second after malaria in having a high morbidity and mortality burden leading to economic loss. An obligate intramacrophage protozoan of the class Leishmania is the cause of Leishmaniasis. Protozoan parasitic diseases are considered as a serious threat for public health. The types which are widely known are cutaneous leishmaniasis (CL), mucocutaneous and visceral leishmaniasis (VL), or kala-azar. In the Indian subcontinent and Africa, Leishmania donovani causes is the causal organism of VL in these places, whereas in Mediterranean basin VL is caused by Leishmania infantum. Flagellated Promastigotes are the major morphological forms in the life cycle of Leishmania. They reproduced and grow in the vector’s midgut (sand fly). Then they are curved amastigotes, which bread within the vertebrate host’s macrophages. The infection happens through the inoculation by the insect bite of metacyclic promastigotes into the vertebrate host. In the wound area, the parasites meet different cell types such as neutrophils, and dendritic cells, keratinocytes Langerhans and tissue macrophages, all help as the

Corresponding author

E-Mail: dr.montahabio@yahoo.com
primary contact host cell. Lanier (2000) suggested that the innate immune response against Leishmania includes phagocytes, Natural Killer (NK) cells, and cytokines. However, believe that Phagocytosis and anti-leishmanial activity of macrophage are major factors in the elimination of Leishmania parasites. One route to estimate the infectivity of Leishmania and anti-parasite immune response is to assess the germicidal activity of macrophages via the generation of reactive oxygen and nitrogen intermediates, particularly nitric oxide. The responsive nitrogen species (RNS) and responsive oxygen species (ROS) within the host cell are the cellular main arms against Leishmania. At the process of the change of L- arginine to L- coralline NO is produced by nitric oxide mixtures (NOS). The membrane – bound NADPH-dependent oxidases (NOX) generate O2- and other reactive oxygen species (ROS). These ROS contribute to the formation of others as nitrogen trioxide NO2 and ONOO- . Antimonial compounds are the first-line drugs cure for leishmaniasis (e.g., meglumine antimoniate and sodium stibogluconate). Second – line drug is Amphotericin B is exhibiting teratogenic effects and nephrotoxicity. Miltefosine is an oral treatment to treat leishmaniasis. The scientific researchers are motivated to develop more effective drugs due to the fact that treatment failure rates are tremendously high. these therapeutic protocols are usually expensive and cannot be used efficiently by poor countries. Moreover, these drugs are associated with increasing parasite resistance, severe toxicity, hard to administer and poor efficiency in widespread countries. Son et al., (2007) advised that Api-toxin is produced and secreted by a gland which exists in the abdominal cavity of the Bee and consists of a complex mixture of several biologically active peptides including Mellitin (MEL), enzymes, bioactive amines, and non-peptide components that has different medicinal features. Previous research explained that the biological MEL effects of as antifungal, antiviral, antibacterial, anti-parasitic, and anti-tumor and proposed the origin of MEL action as a non-selective cytolysis’ peptide which disrupts all prokaryotic and eukaryotic cell membranes physically and chemically. Different methods are used to monitor the responses and health of cells after treatment with various stimuli such as assays to measure proliferation, viability, and cytotoxicity. One of the important factors in experiments is to know the number of viable cells are remaining when the experiment finishes such as: ATP detection, reassuring reduction, tetrazolium reduction (MTT assay) and protease markers. The MTT (3-(4,5-dimethylthiazol-2-Yi)-2-5-diphenyltetrazolium bromide) tetrazolium reduction assay is a quantitative, sensitive, and dependable colorimetric assay for measuring cell metabolic activity, proliferation, viability and activation of cells. Died Cells cannot convert MTT into formazan, when viable cells with active metabolism convert MTT into a purple colored formazan product with an absorbance maximum near 620 nm, thus color formation serves as a useful and convenient marker of only the viable cells. To conclude the aim of this study is to evaluate the antileishmanial activity of Api toxin (Bee venom) on metabolic activity (viability) and proliferation percentage of Leishmania tropica and Leishmania donovani parasites in promastigote stage in vitro condition.

Materials and Method

1. Venom collection:
Venom is collected from Apis mellifera which are Africanized honeyBees (AHBs) which their ages ranges (30-40) days. Venom goes through processes such as extraction which occur through simulation electrically two times a week, isolation and distillation of melittin by process of phase liquid chromatography (RP-HPLC) (University of Baghdad Faculty of agriculture apiaries).

2. Leishmania Tropica and Leishmania donovani Parasites isolate: -
It was obtained from parasitology lab postgraduate students in the College of science, University of Baghdad. These parasites were maintained and subcultured in Novy- MacNeal-Nicolle (NNN) every 1-2 weeks until started using them.

3. Testing the possibility of the parasites: -
Assays used are: Cytotoxicity MTT (3-4,5-dimethylthiazol-2-Yi)-2-5-diphenyltetrazolium bromide).

Firstly, A cell-based assays are used: in order to screen groups of compounds and to decide if the molecules have an effect on cell proliferation or in order to show if direct cytotoxic effect leads to the death of cells.

Secondly: cell-based assays are also generally used to assess receptor binding and a variety of signal transduction events that could be involved in monitoring
organelle function or in the expression of genetic reporters or transferring of cellular components.

MTT is a salt tetrazolium which is soluble in water yielding a yellowish solution. Cleavage of tetrazolium ring by dehydrogenating enzymes is used to change dissolved MTT to an insoluble purple formazan. Verma and Dey (2004) suggested that Dimethyl Sulfoxide (DMSO) is used to change this water-insoluble formazan into solubilized. There is a way to measure the dissolved material by Spectro photometrically yielding absorbance as a purpose of the concentration of converted dye in the following formula:

\[
\text{Viable cells (\%) = } \frac{(AT- AB)}{(AC- AB)} \times 100
\]

Where

\begin{itemize}
  \item AT: is the absorbance of the treated samples
  \item AC: is the absorbance of the untreated samples
  \item AB: is the absorbance of the blank
\end{itemize}

- The promastigotes of both Leishmania tropica and Leishmania donovani at a concentration of 1x10^4 parasite/ml and test compound (Api toxic Bee venom) were prepared and dispensed in a good microtiter plate of flat-bottom 96-, containing a final volume of 100µl / well.

  \- The temperature of incubating the microtiter is 26°C for 24hr.

  \- To add ten µl of MTT solution per well to get a final concentration of 0.5 mg/ml

  \- The duration of incubating the microtiter plate is 4hr at 26°C.

  \- In order to solubilize the formazan crystals, the media was removed, and 100µl of DMSO solution was added.

  \- Stirring gently the micro titer plate gently left for ten minutes

  \- The reading of absorbance was at 620 nm using ELISA reader.

In order to detect different factors in this study, the statistical analysis system- SAS (2012) Program was used.

- The Least significant difference-LSD test was used to find out the right comparison between means in the study.

- Excel program to calculate the values of IC50 is used to determine the right concentration so the parasite can inhibit by 50% (IC50).

**Results and Discussion**

This research presented the effect of different concentration (1, 2, 3, 4, 5, 6 and 5µg/ml) of Api toxic Bee venom on *L. tropica* and *L. donovani* promastigotes number. The parasites treated with all concentration of Api toxic Bee venom showed significant (p<0.05) differences there was a decrease in the number of the parasites in the comparison between *L. tropica* and *L. donovani*.

Log (concentration ) µg/ml
Figure (1) the IC50 of Api toxic Bee venom against *L.tropica* promastigotes number after 4hr

The number of promastigotes treated with Bee venom with a high concentration (6 and 5 μg/ml) after 4hr was 22.83 ± 1.67 and 72.46 ± 1.49 x 10^4 cell/ml of *L.tropica* and *L.donovani* respectively as shown in the table (1),fig (1). The results in this research showed that there are substantial differences (p< 0.05) between different concentrations of the Bee venom toxin. *L.donovani* promastigotes treated with Bee venom showed high viability compared to those treated with *L.tropica* in all concentrations, and these results indicated the positive effects of Bee venom toxin on the proliferation of promastigotes form of *L.tropica*. The data used showed that the most effective venom was melittin which is about 3-fold more effectiveness against *Leishmania Tropica* promastigotes than the whole venoms. Diaz-Achirica *et al.*, (1998) has research about the activity of melittin against *Leishmania donovani* promastigotes which showed that an IC50 value of 0.87 μg/ml, which causes damage to the parasite’s plasma membrane. Whereas in this study, as the report above shows that *Leishmania donovani* promastigotes were about 32-fold more resistant than *L. tropica*. 16, 17.

Melittin is a type of Bee venom protein which is introduced as a potential adjuvant. Although Bee venom is a traditional oriental medicine which has been used widely, yet no detailed effects on Th1 and Th2 immune response are outlined. Moreover, it is not useful to increase the number of Bee stings. Mahmoud (2012) suggested that scientifically proved that to measure the exact amount of melittin to standardize and regulate Bee venom doses to be used as a treatment. Medical properties were tested in vitro on *Leishmania* spp.

El-Haj *et al.*, (2009) showed in his study that honey Bee venom has lethal effects on both types of *Leishmania: Leishmania major* and *Leishmania donovani* which depends on its concentration. The results showed that the maximum effect was achieved when a higher concentration of honey bee was used. (1 mg of venom) giving an initial 100% mortality.

**Conclusion**

The conclusion of the study is that the Bee venom – based treatment has a very important role in overcoming cutaneous leishmaniasis as results showed the high inhibitory effects on *L.tropica* at low concentration in vitro.

Hematological and Biochemical Profile of Iraqi Breed Pekin Ducks

Nadia Abdul Hadee Abdul Ameer¹, Saleh Abed Al Wahed Mahdi², Bahaa Abd Alhussain Musa²

¹ Animal Production Department, Technical Institute- kufa, University of Al-Furat Al-Awsat Technical, Iraq, ² Animal Production Department, College of Agriculture, University of Karbala, Iraq

Abstract

Fifty white male one week old Iraqi Pekin ducks were used to investigate their hematological biochemical values. The birds used were purchased from the commercial breed of poultry farming halls of Animal Production Department in Kufa Technical Institute; bred for 8 weeks, then, 5 ml of blood per bird was collected via brachial vein and send to lab to be analyzed. Some of important results were measured as (mean ± standard deviation) as follows: red blood cell (RBC) 4.650 ± 0.761 x 10⁶/ cubic millimeter (c mm), hemoglobin (HB) 13.293 ± 1.6467 g/dl, packed cell volume (PCV) 39.103 ± 2.6397%, white blood cell (WBC) 8.243 ± 2.3372 x 10³ / cmm, Lymphocyte 19.433 ± 5.6466 x 10³ /cmm, Cholesterol 144.447 ± 28.3941 mg/dl, Glucose 261.007 ± 66.7837 g/dl, total serum protein 4.405 ± 1.6086 g/l, sodium 155.543 ± 12.0153 m mol/ l potassium 3.740 ± 1.7138 g /l and calcium 9.610 ± 2.5395 mg/dl.

Keywords: Iraqi Pekin, RBC, WBC, cholesterol and serum protein.

Introduction

Domestic ducks have served from ancient times as a source of food in many parts of the world, mallard ducks (Anas platy rhynchos) were domesticated of over 4000 years which led to the development of the Pekin ducks (commercial breed)¹, ducks’ production is a rapid growing industry worldwide with six fold rate of consumption greater than 1960³. Ducks had the ability to subsist and grow on a relatively simple diet based on locally available feed stuff⁴. Approximately 90% of their adult weight at 7 weeks of age were much better than common ducks even under less optimum conditions and for their ability to tolerate hot weather¹⁵. Hematological and serum biochemical profiles will provides reliable information of animals’ health status⁶ and reflect a responsiveness to their internal and external environment⁷. Hematological analysis can be useful for the diagnosis of birds’ diseases⁸. There is a limited research on the hematological and biochemical profiles in Pekin ducks which were bred in Iraq recently; so this may be the first study that reported the normal hematological profile and some of the biochemical values. These information may form important reference data for the routine diagnosis and management of diseases and nutritional problem.

Materials and Method

Animals:

Fifty white male one week old Pekin ducks were used for this study, purchased from the commercial breed of poultry farming halls of Animal Production Department in Kufa Technical Institute. The birds were bred for 8 weeks from February the first to the 31st of March 2016, in an environmentally controlled room. They were fed commercially prepared feed contains 22% protein for the first four weeks and 17% protein for the remaining period in addition to vitamins, minerals and green food. Water was provided for ad libitum consumption over the entire study period (8 weeks), approximately 8 kg per duck weekly⁹. At the age of 8 weeks, the duck’s weight

Corresponding author:
Nadia Abdul Hadee Abdul Ameer
E-mail: Nadia.alneame70@gmail.com, Bahaa
ranged between 3 to 3.5 kg and then blood collection started. The ducks have not been treated against disease and parasites, but were inspected daily for any health problem.

Sample collection:

Approximately 5 ml of blood per bird was collected via brachial vein in heparinized tubes, all blood samples were collected at 8-9 a.m and refrigerated immediately before being sent to be analyzed in the laboratories of the Pathological Analysis Department in Kufa Technical Institute for hematological and biochemical assay. Red blood cell (RBC) and white blood cells (WBC) were counted using hemocytometer. Packed cell volume (PCV) was determined using microhematocrite method, while hemoglobin concentration was measured by HB meter. The glucose level was measured using enzymatic method (glucose oxidase method), where serum protein total is calculated by the Biuret method and the total cholesterol is measured enzymatically. The data was calculated as the mean value ± standard deviation (STD)

Results and Discussion

The mean of values of RBC, PCV and HB in table 1 and WBC in table 2 were higher than the values reported by10 for local Muscovy ducks of southern Nigeria and in dabbling ducks11. Also PCV values in the study were higher than those of southern Nigeria adult Pekin ducks, Indian native ducks, Diving and Dabbling ducks11, which may be related to the differences in local environment or nutrition systems8, and this trait could be behind the heat tolerance in local duck breeds12. The values of HB and PCV in the study (table 1) agree with the work on mallard13 and were less than those reported for mallard and laboratory ducks14, but higher than values reported for a group of six weeks old Pekin duckling15, this could be because of seasonal changes or might only reflect species or age differences15 or due to the differences in nutrition as mentioned in16. The results of PCV and HB in this study are close to another study on the mallard reared under the traditional extensive management system in Funtua a north central region of Nigeria17, who reported the averages of PCV and HB for the birds of different ages while the birds in this study were maintained under intensive care and were at 8 weeks age at the time of (sample collection), it’s possible that the values reflect the effect of better nutrition. Species and sex were reported to have strong effect on avian hematological parameters18.

</table>

The results of WBC which were counted in table 2 showed less than those data presented by\textsuperscript{19} on laboratory ducks and on the Cairina Moschata ducks\textsuperscript{9}, while the lymphocyte count is slightly higher than another studies on Pekin ducks in other countries\textsuperscript{9,20}, neutrophil count in this study was similar to those in\textsuperscript{21} and more less than those of\textsuperscript{22}. These changes may be due to controlled environment since the ducks used in this study were not exposed to stress which cause WBC’s count to be high or because of species differences. The WBC’s values was also higher than the values in Nigerian ducks\textsuperscript{10,23}, nevertheless the WBC’s value in the this study was lower than those reported in the black duck\textsuperscript{22} and wood duck\textsuperscript{24}, the observed of lower WBC’s count in this study disagreed with reports\textsuperscript{9,11}. Total leukocyte, lymphocyte and Neutrophils, have been reported to be higher during dry than wet season\textsuperscript{25,26}. There wasn’t any significant effect of season observe\textsuperscript{27} on total lymphocyte count (TLC), but\textsuperscript{28} observed that the highest RBC’s, HB’s, PCV and WBC’s values showed increasing pattern from anestrus to proestrus, the higher level of WBC in our study may be due to the infertility of our commercial breed\textsuperscript{29,30} demonstrated significant cyclic changes in TLC, blood PH and total protein but not in RBC and its indices in sows.

Table (3): Biochemical values in Pekin ducks

<td>1.6086</td>
</tr>
</tbody>
</table>

The values of cholesterol (table 3) in this study were higher than other studies\textsuperscript{31,32} but similar to the value given by\textsuperscript{33}. Sumiati and Wiryawan\textsuperscript{34} illustrated that breed age and management may influence some serum biochemical constituents in duck\textsuperscript{31}. The values of total protein in table 3 agreed with results of control group of Pekin ducks in other study\textsuperscript{31}. The total serum protein levels perhaps are reflection of greater protein intake this explain was described by\textsuperscript{34,35} as well. Moreover increase protein intake in poultry may enhance resistance to infection\textsuperscript{31,36}.

<td>9.610</td>
<td>2.5395</td>
</tr>
</tbody>
</table>

The mean sodium concentration in the Iraqi Pekin ducks was (155.543) (table 4) which was similar to the values reported by10 in the Nigerian duck while the values of potassium (3.740) is clearly lower than that, the mean calcium values (9.610) was similar to the value reported by11 for adult Diving and Mallard ducks, but higher than the levels reported in guinea fowls8. The differences in nutrition may be responsible for this disparity or it may be because the differences between species12,16.

Conclusion

As a conclusion Iraqi Pekin ducks breed had adapted to Iraqi arid and semi-arid environment successfully and had their specific hematological and biochemical parameters which may deviate from other breed in main species. In general RBC, PCV, HB and WBC values were higher than those in other foreign breeds except those of 19. Lymphocyte and neutrophils’ count were slightly higher and similar to other breed respectively. The biochemical traits were similar with other in general except the cholesterol level which be higher than some other breed like those of31,32. The concentrations of sodium equaled with Nigerian duck while the values of potassium is clearly lower than that. The mean of calcium values was similar to the value for adult Diving and Mallard ducks, but higher than the levels reported in guinea fowls.

The Influence of Learning with Mobile Application in Improving Knowledge about Basic Life Support

Nadia Oktiffany Putri¹, Wisnu Barlianto², Setyoadi³
¹Student in Master of Nursing Program, ²Lecturer in Department of Child Health, ³Lecturer in Department of Nursing, Faculty of Medicine, Universitas Brawijaya, Indonesia

Abstract

Introduction: Basic Life Support (BLS) knowledge and abilities are important for all people to help the survival life of someone who experiences life-threatening conditions, such as cardiac arrest. Nursing students are one of the bystander components to provide assistance in emergency situation.

Aim: The aim of the study was to determine the influence of providing BLS learning with mobile application in knowledge improvement.

Method: The study used a pre-test and post-test of true-experimental design with two comparison groups. The groups were control group and experiment group. The research location was at STIKes Kendedes School of nursing, Malang, Indonesia. Forty eight students were recruited using simple random sampling. Each group consisted of 24 students. The paired t-test and independent t-test was used for data analysis.

Findings: The findings showed that there was a significant difference of BLS knowledge between mobile application group and traditional method group (p = 0.016 < 0.05).

Conclusions: In conclusion, the findings highlight that mobile application has more significant influence on BLS learning in nursing students by improving their knowledge. The use of mobile application provides opportunities to make learning process more accessible and flexible.

Keywords: Basic Life Support (BLS), mobile application, traditional method

Introduction

Prevalence of cardiac arrest in the world tends to be high. In United States, cardiac arrest events reach more than 166000 incidents in a year, and 60% of them are handled well, but only 6.4% can survive until they are discharged from hospital⁴. In Indonesia, prevalence of cardiac arrest is approximately 10000 incidents in a year, or 30 incidents in a day⁵. Data from Harapan Kita National Heart Center Hospital in Indonesia show that 26.9% of patients who came to the Emergency Department were diagnosed with Acute Coronary Syndrome (ACS). This condition has the potential to cause cardiac arrest⁶. Therefore, BLS action on cardiac arrest victims needs to be given immediately for reducing victims’ morbidity and mortality.

Knowledge and abilities of Basic Life Support (BLS) are important for all people to help the survival life of someone who experiences life-threatening conditions. The incidence of cardiac arrest, choking, and other life-threatening conditions require appropriate and immediate treatment by anyone. Anyone who finds the victim and gives first aid is called a bystander. The victim’s survival life can be achieved depends on bystander’s readiness and ability to carry out BLS action⁷. Nursing students are one of the bystander components who are authorized to provide BLS in emergency situations.

Important things need to be taken by introducing early basic actions to save lives, such as BLS learning.
BLS learning has been provided with different methods. The standard curriculum in BLS learning process nowadays is using traditional methods, such as lectures and demonstrations. However, several previous studies stated that traditional methods have not been effective in improving student knowledge. One study stated that the combination of two traditional methods (lecture and discussion) did not provide a significant impact in BLS knowledge\(^5\).

Along with advances in technology system, BLS learning methods are also developing. Non-traditional learning methods using technology have more effectiveness than traditional method. One of the learning methods using technology is through mobile application. The concept that distinguishes between mobile application and other is focusing on student mobility, so they can learn in a more flexible way\(^6\). Learning with a mobile application can help students learn anytime and anywhere, so the opportunities for learning will be more various.

Knowledge increases through various approaches in a learning process, including knowledge about BLS. The results of previous study regarding the use of technology as a method of learning BLS theory with educational video games in high school students showed that there was a significant impact in the knowledge aspect\(^7\). Based on the literature review above, researchers want to develop technology-based learning methods with mobile application. Finally, this study aimed to find out changes in nursing students’ BLS knowledge through mobile application learning.

### METHOD

The type of research was true-experimental study with a pre-test and post-test control group design. The study was conducted at STIKes Kendedes School of nursing, Malang, Indonesia. The total respondents were 48 nursing students who were divided into two groups, the control group and the experiment group. Each group consisted of 24 respondents. Respondents were obtained using simple random sampling technique.

The data was taken twice, before and after BLS learning. The control group received BLS learning with traditional methods (lectures and demonstrations) and the experimental group received BLS learning using mobile application. BLS knowledge questionnaire was developed by researchers based on the concept and guidance of American Heart Association (AHA) in 2015. The score on the questionnaire in each question is 0 if the answer is wrong and 10 if the answer is correct. Validity and reliability tests were carried out on 15 respondents. In 30 questions, 20 questions were declared valid and reliable.

The mobile application in this study was named “Life Saving: Learning and Guideline”. The characteristics of this mobile application include text, images, and audio recordings. While, the features offered are BLS concept menus, BLS stages, exam menus, location maps, and audio recording of the chest compressions frequency. The paired t-test and independent t-test was used for data analysis. This study was stated ethically feasible by the Health Research Ethics Commission in Faculty of Medicine, Universitas Brawijaya with number series 20 / EC / KEPK – S2 / 01 / 2019.

</tbody>
</table>
Findings

Table 1 showed if the average age of the respondents at most is in the category of late adolescence with a range of 15-19 years old, with total of 28 respondents (58.3%). Most respondents were female with total of 45 respondents (93.8%). The current education level at the most is diploma with 32 respondents (66.7%).

The results showed that before receiving BLS learning, respondents had poor BLS knowledge with 46.67 ± 20.18 mean score in the control group and 45.63 ± 9.59 in the experiment group. Before receiving BLS learning, the majority of respondents gave incorrect answers in questions about handling cardiac arrest cases. Lack of knowledge about BLS, especially on the topic of handling cardiac arrest can be caused since all respondents have never known about BLS.

The results of data analysis showed that the knowledge of respondents in each group has improved. However, an improvement of higher knowledge was shown in the experiment group with 79.38 ± 9.01 mean score. The analysis results between groups showed p-value = 0.016 (p-value < 0.05) which means that there was a significant difference in the knowledge improvement between groups. The results also provide evidence if learning by using mobile application has a significant influence on the respondents’ knowledge.

Knowledge improvement can occur because the mobile application used in this study provides BLS concept menus that can be learned by students anywhere and anytime. The results of this study were similar with another study conducted in Korea regarding the use of interactive mobile application as one of the learning methods for nursing students. The results of that study showed if significant improvement occurred in the concept of clinical practice knowledge by learning with interactive mobile applications. The significant improvement of clinical practice knowledge in that study was because the interactive mobile application feature provided a 3-dimensional simulations to facilitate education process of nursing clinical practice\(^8\).

Another study discussed the training of Cardiopulmonary Resuscitation (CPR) using mobile application and showed results if the respondents’ knowledge as CPR-bystander had a significant difference in improvement when compared to simulation method. This improvement occurred because the “be a bystander” application in that study provided concept and practical guidelines for implementing CPR\(^9\). The previously mentioned study has similar results with this study that is the presence of significant improvement of BLS knowledge in the mobile application group. In this study, besides providing concept and guideline for implementing BLS, it is also completed with exam menus. In the exam menus, students could find out their learning outcomes directly to evaluate how much knowledge they have.
Knowledge can improve through various approaches in a learning process. This study choose a technology approach based on multimedia support that is mobile application. Cognitive theory in multimedia-based learning stated that someone can learn more when information is presented through more than one media, for example a combination of words and images. It was because information processing was received through various ways such as auditory and visual, so learning with more than one media could make the learning process more profound and the information absorbed could be long stored in memory. The use of more than one media could also ease the processing of information to be received by brain\(^{(10)}\).

Learning through electronic devices such as mobile application are a trend in digital learning field today. Digital learning is one of the most significant developments in education field. Learning with mobile application offers several advantages and benefits. The flexibility provided through mobile application learning is one of its advantages and benefits. The flexibility means that students can learn anytime as they want and can be accessed unlimitedly each day\(^{(11)}\).

The use of mobile application also provides an opportunity to make learning process more accessible\(^{(12)}\). This method is more interesting and makes learning process more enjoyable compared to traditional methods that are routinely carried out in the classroom with the lecturer or speaker as the center of attention. Learning method with mobile application can be carried wherever students go and can be done by students in their leisure or desired times\(^{(13)}\).

Learning with mobile application is not focused on the technology aspects, but focused on students. Students with various activities and keep moving around are the center of the learning process, and technology as the support that will enable students to learn in any context, anywhere, and anytime. Another advantage is students do not need to carry heavy burdens such as books or laptops to start learning\(^{(14)}\).

“Life saving: Learning and Guideline” is an android-based mobile application that is used as a BLS learning method in this study. This mobile application has characteristics that are not much different from previous studies that also used technology as learning method. The characteristics of this application include text, images, and sounds. The exam menus and location map are the additional and novelty things offered in this mobile application. The exam menus will support students to evaluate their own learning outcome so they can measure independently their knowledge improvement. The location map menu is provided to help students or users to access the nearest Emergency Medical Service (EMS) to the location of the victim with emergency conditions discovered. The features presented in this mobile application can ease students to learn about BLS in accordance to the advantages and benefits offered through learning by using mobile application. It also can produce good stimulus and ultimately able to improve the knowledge and cognitive abilities of students.

BLS learning or training is an effort that has the potential to provide additional insight to anyone who in certain situations will act as a bystander, one of them are nursing students. Bystanders must have awareness regarding the importance of having knowledge and skills in implementing BLS to be able to maintain one’s life. BLS knowledge and abilities will be able to reduce morbidity and mortality due to life threatening conditions such as cardiac arrest and choking. The use of technology as BLS learning or training offers greater effectiveness and flexibility than traditional methods. Mobile application with its advantages is one of the good learning methods in an effort to improve the knowledge of bystander regarding BLS.

**Conclusions**

BLS learning to nursing students by using mobile application can give significant influence in improving knowledge. The use of mobile application as BLS learning method provides greater flexibility and effectiveness compared to traditional learning method.

**Conflict of Interest:** There is no conflict of interest in this study.

**Source of Funding:** Funding in this study as a whole is accounted on the researcher independently. There are no other funding sources.

ITGB2 (CD18) mRNA Expression in Hirschsprung-Associated Enterocolitis (HAEC)

Nita Mariana¹, Andi Asadul Islam², Muhammad Nasrum Massi³, Warsinggih², Mochammad Hatta³, Ilhamjaya Patellongi³

¹Division of Pediatric Surgery, Departement of Surgery, Faculty of Medicine, Hasanuddin University, ²Departement of Surgery, Faculty of Medicine, Hasanuddin University, ³Post Graduate of Medical Science, Faculty of Medicine, University of Hasanuddin, Makassar, Indonesia

Abstract

Background: HAEC is a condition of inflammatory bowel which has clinical characteristics such as fever, abdominal distension, diarrhea, foul-smelling stools and sepsis. At Hirschsprung Disease autopsy that has HAEC, crypt abscesses, mucous ulcerations, and transmural necrosis are seen. In the pathogenesis of inflammatory bowel disease, intestinal flora may also play a key role in the pathogenesis and development of HAEC. CD18 leukocyte disorders and T cell regulation can be associated with genetic predisposition (ITGB2) for HAEC.

Aim: The aim of this study was to investigated the ITGB2 (CD18) mRNA expression in a cohort of patients with Hirschsprung-associated enterocolitis (HAEC)

Method: Screening for ITGB2 (CD18) mRNA expression was performed on DNA extracted from colonic tissue samples of 30 HAEC patients from the Makassar, South Sulawesi, Indonesia population. Polymerase chain reaction amplification was performed, followed by heteroduplex single-strand conformation primer analysis and bidirectional semiautomated DNA sequencing analysis.

Results: From 30 HAEC patients; 25 (83.3%) male patients, 5 (16.7%) female patients. 13 (43.3%), aged ≤ 1 year, 3 (10.0%) aged 4-5 years. The value (p-value <α) or (0.038<0.05) can be concluded that there is a relationship between ITGB2 mRNA expression (CD18) and Genesis HAEC, it can be concluded that the lower the ITGB2 mRNA expression (CD18) then the HAEC event will be increase.

Conclusions: There is a relationship between ITGB2(CD18) mRNA expression and the occurrence of HAEC, the lower of ITGB2(CD18) mRNA expression, the higher histopathological severity degree of HAEC.

Keywords: Hirschsprung’s-associated enterocolitis (HAEC), mRNAITGB2(CD18), Hirschsprung’s disease.

Introduction

Hirschsprung-Associated Enterocolitis (HAEC) was first known at the end of the 19th century by Harald Hirschsprung who also described congenital megacolon. HAEC is a condition of inflammatory bowel which has clinical characteristics such as fever, abdominal distension, diarrhea, foul-smelling stools and sepsis. At Hirschsprung Disease autopsy that has HAEC, crypt abscesses, mucous ulcerations, and transmural necrosis are seen.

Although couples of aetiologies have emerged, the biological mechanisms underlying HAEC are still poorly understood. HAEC is the cause of morbidity and mortality of Hirschsprung sufferers. The incidence of HAEC around the world ranges from 6% to 58%. While the mortality rate at HAEC is still quite high from 6% to 30%. The non-specific clinical manifestations of HAEC cause frequent diagnosis of gastroenteritis, so the diagnosis of HAEC is missed or late.
At present, the pathogenesis of HAEC is still unclear. Recent studies have shown that injuries to the intestinal mucosal barrier, abnormal immune responses in the intestinal tract and infections due to certain pathogens may play an important role in the pathogenesis of HAEC. Enteric pathogens can attack the bloodstream through damaged intestinal mucosal barrier and then induce an inflammatory response such as a waterfall. In addition, histology and immunological studies show that persistent inflammation and decreased immune function in the intestinal tract of the baby causes repeated HAEC. In the pathogenesis of inflammatory bowel disease, intestinal flora may also play a key role in the pathogenesis and development of HAEC.

Zhi Cheng reports that from a HAEC trial in mice, it shows genetic deficiency of endothelin B receptor images, abnormal immunophenotypes characterized by small lymph size, lymphopenia in B and T cells, and abnormal images from colon histopathology occur.

Sam reports that CD18 leukocyte disorders and T cell regulation can be associated with genetic predisposition (ITGB2) for HAEC. This allows a genetic link for the selection of HAEC patients, by identifying the potential molecular targets.

Research Objectives

This study aims to determine the relationship of ITGB2 (CD18) mRNA expression to the occurrence of HAEC in Hirschsprung patients.

Research Methods

The design of this study was a cross sectional study with simple random sampling in patients of Hirschsprung Disease to determine the relationship of ITGB2 (CD18) mRNA expression to the occurrence of HAEC. Colon preparations of Hirschsprung Disease patients were assessed histopathologically according to HAEC severity that is based on the classification of Teitelbeum. RNA extraction uses the Boom method. The quality test of mRNA was using fluorometer, and quantification of the ITGB2 (CD18) gene mRNA was using RT-PCR.

Data Analysis

Statistical analysis of the data was using the Spearman Rank test, the conclusion for the statistical analysis test based on the significance value of \( p \), if the value of \( p < 0.05 \) then the research hypothesis is accepted.

The researcher used the SPSS version 23 computer program for Windows.

Discussion

From this study, the data obtained showed that there were more male than female, that is 25 (83.3%) compared to 5 (16.7%). Similar to the study of Philip et al. (2018) who also reported in his study that of 116 HAEC sufferers, 99 (85.34%) of them were male and the remaining 17 (14.66%) were female. Likewise the research conducted by Joseph et al. out of 110 sufferers, the ratio of male to female was 3.6:1.

From the description of the age of HAEC sufferers found in this study, most were under 1 year old of age (13 children or 43.3%) and only 4 or 13.3% who were over 5 years old.

Philip K et al. reported that failure to recognize Hirschsprung Disease in the initial prenatal period could place children at greater risk for HAEC, they get 18% - 50% experiencing HAEC in the pre-operative period. Surana et al also reported that the incidence of HAEC in infants was higher in the first week of life (24% were diagnosed with Hirschsprung Disease) compared to those diagnosed more than the first week (11% were diagnosed). In addition, the delay of meconium also affects the occurrence of HAEC (53 hours : 44 hours). Delayed diagnosis of Hirschsprung Disease also affects the occurrence of HAEC in children (16.6 : 4.6 days).

The results of this study found that the highest degree of HAEC was histopathology II and IV (cryptitis or abscesses of two crypts and fibrinopulent debris and mucosal ulceration) each constituted 7 patients or 23.3%. While the fewest were patients with histopathological degrees 0 and V (there were no abnormalities and transluminal or perforated necrosis), which were 2 patients or 6.7% each. The high pathological score of HAEC from all three segments increases the risk of enterocolitis. The high pathological degree in the
transitional segment is significant for postoperative HAEC events.\textsuperscript{9}

Teitelbaum et al. reported that 88% of patients with HAEC III degree and above, and 83% without HAEC with II grade and lower. They use the degree of enterocolitis in patients with Hirschsprung Disease to predict the development of HAEC after definitive pull-through surgery for III degree and above.

Clinical assessment of the degree of enterocolitis may prove to be a useful method for early detection of infants at risk of HAEC. There was a significant change in intestinal mucin with an increase in neutral mucin and a decrease in sulfomucin acids identified in HAEC tissue specimens. The organisms attached to enterocytes are seen in 39% of HAEC tissue specimens.\textsuperscript{10}

The results of this study found that the mean of ITGB2 (CD18) mRNA in HAEC patients was 11,037 and SD was 1,229. The description of HAEC sufferers based on ITGB2(CD18) mRNA expression, as many as 18 children or (60.0%) were patients with low ITGB2(CD18) mRNA expressions and the remaining 12 children (40.0%) were patients with high ITGB2(CD18) mRNA expression. From the correlation coefficient, the value obtained was (p-value <\textalpha) or (0.038 <0.05) so it can be concluded that there is a relationship between ITGB2(CD18) mRNA expression and the incidence of HAEC, the lower the ITGB2(CD18) mRNA expression, the higher number of HAEC occurrence. The lower the ITGB2(CD18) mRNA expression, the higher the degree of histopathology in HAEC patients.

Proinflammatory cytokines also trigger the production of local chemokines which will deliver leukocytes from the circulation to the location where PAMPs or DAMPs are located, to carry out its effector function. The leukocyte effector function is to kill pathogens and to clean tissue from dead cells. The entry of many neutrophils into the tissues is a sign of acute inflammation. Whereas chronic inflammation that may appear later is dominated by the deposition of monocytes and lymphocytes into the inflammatory area.\textsuperscript{11}

After leukocytes meet with inflammatory agents and the remains of dead tissue, the neutrophils and macrophages will actively eliminate them by phagocytosis. To carry out this function, on the surface of phagocytes there are a number of receptors and other molecules used to carry out their functions. Cytokine and chemokine receptors in menbran phagocytes are triggered by cytokines for the production of ROS, NO and lysozyme and inflammatory mediators (metabolism of arahidonic acid and cytokines) for amplification of the immune response.

The presence of leukocyte-1 adhesion deficiency will occur in the leukocyte system, the recruitment of granulocytes which is not effective in responding to bacterial invasion, which ultimately results in recurrent bacterial infections. This is what causes the increased incidence of HAEC and the severity of HAEC in patients with Hirschsprung Disease.

Chronic inflammation can arise from acute inflammation that does not heal or indeed a chronic inflammation from the beginning (not preceded by acute inflammation), for example chronic inflammation that occurs in fat tissue. Acute inflammation that does not heal is usually caused by: failure of neutrophils to eliminate pathogens, the presence of foreign elements, autoimmune diseases and unclear causes.

The same was reported by Moore et al. that variations in ITGB2(CD18) gene immunomodulatory (CD18) were found in 66% of patients with Hirschsprung Disease, and 59% of these patients suffered HAEC. More than one variation of the ITGB2(CD18) gene is associated with more severe HAEC. Further research on genetic variation in HAEC may explain its pathogenesis.\textsuperscript{12}

Chronic inflammation mediated by immune diseases (eg. Rheumatoid arthritis (RA)), psoriasis, multiple sclerosis, and inflammatory bowel disease (IBD) are characterized by the recruitment of unregulated leukocytes. Neutrophils, which are short-lived outside the circulation, migrate to the site of inflammation and undergo apoptosis, while monocytes remain in inflamed tissue for several days, where other monocytes become permanent occupants. The leukocytes migrate to the site of inflammation throughout the walls of post-capillary venules by involving specific molecules expressed on special endothelial cells. Endothelial molecules function as mechanical anchors and to provide network specificity for the recruitment process.\textsuperscript{13}

The type of \textbeta subunit which is present in each heterodimer defines a discrete integrin subtype, which displays a unique pattern of structure, network specificity, and function. The integrin families \textbeta2, \textalpha 4 and \textbeta 7 play the most prominent roles during immunological and
inflammatory conditions, because they are leukocyte-specific. The β2/CD18 integrins combine with different α chain ligands to produce four β2-heterodimers. Their cellular distribution varies between different heterodimers and several such as CD11c which is now generally seen as a monocyte lineage cell marker. Essential information for the functional importance of β2 integrins is obtained from clinical and immunological phenotypic studies of mice or humans that contain mutations of each gene. In particular, lymphocytes and neutrophils mainly express CD11a/CD18 (LFA-1). LFA-1 binds to ICAM-1 and ICAM-2 which is expressed in endothelial cells and mediates migration, antigen presentation, and cell proliferation.

Recent genetic studies explain the important role of CD18 integrins in innate immunity. Where, 26 human and 21 rats, carry zero or hypomorphic mutations in the ITGB2 (CD18) gene (which encodes the β2 (CD18) integrin subunit) resulting in genetic abnormalities of leukocyte-1 (LAD-1) adhesion deficiency. This condition is characterized by recurrent bacterial infections. The pathophysiological disorder underlying the clinical phenotype is the recruitment of granulocytes that are ineffective in responding to bacterial invasion.

Intestinal-related lymphoid tissue, gut-associated lymphoid tissue (GALT) is the largest lymphoid organ in the body and is responsible for protecting against various antigens that may enter the body, including food particles, pathogenic bacteria and their toxins. Peyer’s patches (PP) are the main inductive for intestinal mucosal immunity. PP is a collection of immune cells, follicles that are similar to lymph nodes and are located along the intestinal anti-mesenteric surface. In circulation, T-naive lymphocytes and B-lymphocytes, α4β7 integrins and L-selectin, migrate from PP through binding of MADCAM-1 (mucous cell 1 cell addressin adhesion molecules), which is expressed in high endothelial venules in PP. Above the PP mucosa contains M cells, a special epithelium for transporting antigens from the intestinal lumen to PP, which is presented for naive lymphocytes, such as dendritic cells (DC). Activated lymphocytes then enter efferent lymphatic channels to travel to “mesenteric lymph nodes” (MLN). From MLN, activated lymphocytes travel through the thoracic duct into the systemic circulation. The travel of activated lymphocytes to the lamina propria (LP), through the main effectors of mucosal immunity, occurs through coordinated action of a number of cellular adhesion molecules, cytokines and chemokines. After being in LP, T lymphocytes produce Th-2 cytokines pro-inflammatory interleukin-4 (IL-4) and pro-inflammatory IL-10 to stimulate the production of immunoglobulin A (IgA) with terminal differentiated B lymphocytes, called plasma cells. IgA, the most widely immunoglobulin isotype produced in the body, is then actively transported to the mucosal surface in the form of dimers by polymer immunoglobulin receptor (pIgR).

In addition, they also observed a decrease in marginal zone B lymphocytes, suggesting impaired development of B lymphocytes. Both groups showed changes in lymphocyte population, similar to those experiencing stress (such as HAEC). In an effort to describe the contribution of the EdnrB -/- genotype to the HAEC phenotype, Frykman, et al. performed bone marrow transplantation from EdnrB -/- animals to Rag2 recipients -/- and, separately, induced intestinal obstruction in experimental animals. They concluded that stress due to obstruction produced lymphocyte changes seen in the HAEC model. In addition, in the EdnrB -/- model, animals undergoing surgery and continuous intestinal blockages will have a 40% risk of HAEC.

Conclusion

There is a relationship between ITGB2(CD18) mRNA expression and the occurrence of HAEC, the lower of ITGB2(CD18) mRNA expression, the higher histopathological severity degree of HAEC.

Urinary α-Amylase Level in Patients with Hypertension

Omar D. Salman
Al-Bayan University / College of pharmacy, Baghdad –Iraq

Abstract

Background: Amylase is a digestive enzyme which is secreted from salivary gland and pancreas; it cleaves cooked starch in the mouth, cooked and uncooked starch in the upper part of intestine mainly in jejunum. The final product of digestion is three glucose units then to glucose monosaccharide.

There are 3 types of amylase enzymes which are: (α, β & γ) Amylase.

The renal clearance of amylase enzyme ranges from 1 to 3 mL/min.

Hypertension is an increase in the force which the blood places on blood vessels as it moves through the body. Hypertension in most of cases is clinically asymptomatic but it is one of the risk factors for cardiovascular disease and causes progressive damage to kidney in a long term process which leads to excessive excretion of low molecular weight compounds like albumin and amylase in urine.

Objectives: Assay of alpha urinary amylase level and using it as a better reliable indicator for glomerular damage.

Patients and Method: Our study is based on measuring the absorbance for samples by using spectrophotometer device; we collect 92 urine samples from different hypertensive patients, and then calculate the concentration of amylase level by using fixed rate colorimetric method:

\[
\Delta E = A_2 - A_1
\]

Alpha amylase (U/L) = \(\Delta E \times 765\)

Results: approximately all samples show an increase in amylase enzyme level above 450U/L.

Conclusion: Amylase can serve as a better indicator of glomerular damage.

Keywords: Amylase, starch, renal clearance, Hypertension, glomerular function.

Introduction

Amylase Enzyme

Amylase is a digestive enzyme that normally acts extracellularly to cleave starch into smaller carbohydrate groups and, finally, into monosaccharides, by hydrolysis of internal alpha-(1→4) glycoside bonds, which results in the production of maltose, dextrine and oligosaccharides. Among healthy individuals, the pancreas and the salivary glands account for almost all serum amylase, 40-45% from the pancreas and 55-60% from the salivary glands.\(^1\)

Types of Amylase:

1. α
2. β
3. γ
The renal clearance of amylase has been shown to range from 1 to 3 mL/min and is constant over a wide range of urine flow. Increased blood levels of amylase are followed by increased excretion into the urine. It has been shown that this increase in excretion in pancreatitis is further enhanced by an increased renal clearance rate of amylase. Determination of the enzyme activity is done by measuring the reducing sugars released as a result of the action of α-Amylase on starch.

Another method is to measure the extent of hydrolysis by reading absorbance of 2-chloro-4-nitrophenol (CNP).

The reference range of amylase is as follow: 3

- Serum test: Normal is 40-140 U/L
- Urine Test: Normal is 24-400 U/L

Hypertension:

Blood pressure is the force of blood pushing against blood vessel walls as the heart pumps out blood, and high blood pressure, also called hypertension, is an increase in the amount of force that blood places on blood vessels as it moves through the body. Factors that can increase this force include higher blood volume due to extra fluid in the blood and blood vessels that are narrow, stiff, or clogged. Hypertension in most cases is clinically asymptomatic but it is one of the risk factors for cardiovascular disease and causes progressive damage to kidney in a long term process. Hypertension impairs glomerular function and also leads to subclinical atherogenesis, there is an excretion of low molecular weight compounds like albumin and amylase in urine.

Renal hypertension can cause chronic kidney disease. This is a slow decline in kidney function. Until the condition is well advanced, chronic kidney disease also causes no symptoms. Because there are usually no symptoms, a doctor may suspect renal hypertension when someone has uncontrolled high blood pressure despite multiple medications or has unexplained chronic kidney disease.

Macroamylasaemia:

In some patients, high plasma amylase activity is due to low renal excretion of a macroenzyme form, despite normal glomerular function. The condition is symptomless and it is thought that the enzyme is bound to IgA, giving a complex of molecular weight about 270 kDa. If amylase and creatinine are assayed in simultaneous plasma and urine samples, an amylase clearance to creatinine clearance ratio can be calculated. If the result is multiplied by 100, a ratio of less than 0.02 is suggestive of macroamylasaemia.

Electrophoretic techniques can also be used to determine the presence of macroamylasaemia.

This study was conducted to analyze the changes in amylase levels in hypertension.

Materials and Method

The device we used for measuring absorbance is spectrophotometry

- Working equipment includes:
- Laboratory water bath
- Cuvette
- Micropipette
- Test tubes
- Urine test containers
- Gloves
- Alpha Amylase kit.

The study was conducted from Baghdad Teaching Hospital. Ninety two urine samples was collected from 92 patients with hypertension, samples are collected under certain conditions, including stocked and stored in refrigerators under a temperature between 4 to 8°C and duration of storage does not exceed 24 hours.

Method: (fixed rate colorimetric method)

Procedure:

- Wave length = 405 nm
- Light path = 1 cm
- Temperature = 37°C
- Reagent Blank = Against distilled water
- Reaction = Fixed rate

Allow reagents to reach working temperature before use.
1. Take (25 µL) of each sample and mix well with (1000 µL) of reagent.

2. Incubate for 1 minute at 37°C then read the absorbance A1.

3. After exactly 4 minutes later read the absorbance A2. [7, 8, 9]

Calculation:

\[ \Delta E = A2 - A1 \]

Alpha amylase (U/L) = \( \Delta E \times 765 \)

Discussion and Conclusion

Hypertension has been shown to accelerate atherogenesis in animals, and because of this damaging impact of subclinical atherogenesis, glomeruli becomes dysfunctional and there is excretion of low molecular weight compound like albumin in urine. Amylase another low molecular weight substance is cleared through kidney. Our study shows significant increase in urinary amylase levels in patients with uncontrolled diabetes which are in parallel to other studies.

Amylase has a molecular weight of 55,000 k dalton which is less than the molecular weight of albumin (74,000 k dalton). Mostly the filtered amylase and albumin are re-absorbed by the tubular cells. In the case of amylase only about 45% of the filtered molecules are reabsorbed, whereas more than 90% of the filtered amount of albumin is reabsorbed by the tubular cells. Serum Albumin can therefore not serve as a reliable marker of glomerular damage. On the other hand amylase because of less variability in serum by common disorders plus less efficient reabsorption of filtered amylase by tubules can serve as a better indicator of glomerular damage.

The change in amylase was much significant (p value 0.01 ). Some authors have proposed that hypertension may increase capillary pressure, and acute elevation in systemic perfusion pressure may accelerate hyperfiltration, and these events lead to damage to kidney. The damage to the kidney is reflected in the increased excretion of low molecular weight substances like albumin and amylase.

Serum Levels of IL-12 Family in Hepatitis Patients with HBV and HCV Infections

Osama B. Al-Saffar¹, Jwan Sabah Bajlan²

¹Department of Biology, Madenat Al-elem University College, Baghdad-Iraq,
²Ministry of Science and Technology, Baghdad-Iraq

Abstract

Hepatitis is inflammation of the liver, with hepatitis, the liver not working well. Viruses one of the most causes of hepatitis in the world. Cytokines are small proteins produced by cells have a specific interaction effect on the connection between the component of the immune system. Therefore, the present study aimed to investigate the serum level of the interleukin-12 family is a unique cytokines in comprising the heterodimeric, includes (interleukin-12, interleukin-23, interleukin-27, and interleukin-35). All investigated cytokines (IL-12, IL-23, IL-27, and IL-35) showed significant variations. Serum level of interleukin-12 and interleukin-23 showed a significant difference in viral hepatitis patients compared to controls according to age group. Distribution patients and controls into males and females revealed some significant differences in the serum level of the interleukin-12, interleukin-27, and interleukin-35.

Keyword: serum level, IL-12 family, HBV, HCV, Iraqi Patients

Introduction

Hepatitis is liver inflammation. Viral hepatitis has emerged as a major problem of health throughout the world, affecting many millions of people. Also, considerable morbidity and mortality in the population, and one of the most common causes of hepatitis in the worldwide.

Five main viral hepatitis referred to as types A, B, C, D, and E. These type’s hepatitis B virus (HBV) and hepatitis C virus (HCV) together, are the most common cause of liver illness, cirrhosis, and cancer.

IL-12 is mainly produced by dendritic cells (DC) and B lymphoblastic cells stimulated by antigen and macrophages, and cytotoxic effects of NK cells by inducing interferon gamma (IFN-γ) expression, and it is an essential mediator of resistance to bacterial and viral infections, treatment of malignant tumors and occurrence some of the infectious diseases. IL-23 is secreted mainly by activating macrophage cells and dendritic cells (DC). The similarity between IL-12 and IL-23 can also stimulate IFN-γ and T-lymphocyte cell proliferation.

IL-27 is mainly produced by antigen-presenting cells (APCs), such as activated dendritic cells (DC), monocytes and their receptors, and expressed in the lymphocytes, thymus and spleen especially on surfaces of CD4+ T cells and NK cells.

IL-35 is a negative regulated immune factor playing a critical role in inhibiting proliferation of effector T-lymphocyte cells and Th17 cell differentiation.

IL-12 and IL-23 act mainly as pro-inflammatory. In contrast, both IL-27 and IL-35 act primarily as anti-inflammatory cytokines. IL-39 is stimulates neutrophil differentiation thereby is involved in promoting inflammation. There is some identical and non-identical function among IL-12 family members which make them a novel bridge between immune system branch (innate and adaptive).

The balance between viral infection and host defense defines as the course of infection and pathogenesis, with persistent viruses such as HBV and HCV, are generally

Corresponding author:
Osama B. Al-Saffar
E-mail: Osamaalsaffar@gmail.com

not directly cytopathic effect and have developed immune mechanisms of evasion to survive without damaging the host \(^{(12)}\). The goal of hosts is prevented, eliminate, or at least control viral infection while limiting undue collateral destroy \(^{(13)}\). Therefore, this study was planned to estimation the role of IL-12 family in the etiopathogenesis of HBV and HCV in terms of serum level.

**Material and Method**

**Subjects**

This study was extended from June 2017 to May 2018. The present case-control study was conducted at the GHTH in Baghdad after obtaining the approval of the Ethics Committee at the Iraqi Ministry of Health. The consultant medical staff was diagnosed subjects, which was based on clinical, and serology test by ELISA, in addition, was confirmed by molecular method real-time PCR. 10 ml were drawn and distributed into 2 plain tubes. The serum tested by ELISA method to detect anti-viral (HBV and HCV) antibodies (Biomerieux HBs Ag HBV kit; France), and if it was positive, the diagnosis was confirmed further by real-time PCR analysis to detect the viral genetic material (COBAS® AmpliPrep/COBAS® TaqMan® HBV and COBAS® AmpliPrep/COBAS® TaqMan® HCV kits; USA), in addition all patients were firstly diagnosed and none of them was under treatment, in addition, the chronic patients were excluded. Two hundred subjects, 154 of them were suffering from acute viral hepatitis and were classified into two groups: **The group I:** 76 patients with acute HBV, mean ± SD: (43.37 ± 10.67) years. **The group II:** 76 patients with acute HCV, mean ± SD: (33.63 ± 15.35) years. **The group III:** 48 controls mean ± SD: (39.20 ± 11.32) years. The controls were blood donors and their laboratory profile in the CBB (Central Blood Bank-Baghdad) revealed that they were negative for Hepatitis B and C viral infections.

**Assessment of IL-12 family Serum Levels**

Acute hepatitis sera of patients and controls were assessed for level of IL-12, IL-23, IL-27, and IL-35 using commercially available kits (PeproTech; UK) by means of ELISA that was based on similar principles.

**Statistical Analysis**

Serum level of these interleukins was given as mean ± SD, and significant differences between means were assessed ANONA (Analysis of Variance) followed by either Duncan or LSD (Least Significant Test) using the software SPSS version 13.

**Results and Discussions**

**Total serum Level of the IL-12 family**

Acute hepatitis patients (HBV, HCV) showed a significantly increased level of all interleukins compared to control table (1).

**Patients Distributed by Age and Gender**

Out of the Four investigated interleukins (IL-12, IL-23, IL-27, and IL-35), all of these showed significant variations. Serum level of IL-12 was significantly increased in HBV and HCV patients with controls according to age group (35.22 ± 10.44; 32.46 ± 11.40 vs. 18.16 ± 12.8 pg/mL) respectively. IL-23 serum level was also significantly increased in (HBV) and (HCV) patients compared controls (41.32 ± 11.69; 39.47 ± 14.45 vs. 24.38 ± 11.28 pg/mL) and (39.13 ± 18.17; 35.24 ± 10.71 vs. 30.33 ± 10.42 pg/mL) in the age groups (< 40 and ≥ 40 years) respectively, while IL-27 level showed no significant among patients compared to controls in the age groups (< 40) years, while showed significantly increased in age groups (≥ 40) years. Finally, IL-35 serum level showed significant differences in (HBV) and (HCV) patients in both age groups (< 40 and ≥ 40 years), compared to controls (30.33 ± 11.19; 48.41 ± 8.09 vs. 28.16 ± 10.98 pg/mL) and (39.23 ± 12.38; 33.31 ± 11.71 vs. 18.31 ± 8.22 pg/mL) as shown in the table (1,2,3,4).

Distribution patients and controls into males and females revealed some significant differences in the serum level of the IL-12, IL-27, and IL-35. Females hepatitis patients HBV, HCV showed no significant differences compared with controls in the level of IL-23 (42.73 ± 16.35; 39.33 ± 15.23 vs. 37.22 ± 12.02 pg/mL) (table 1,2,3,4).

These findings came to be consistent with the pro-inflammatory role of IL-12 in host defense mechanism against intracellular pathogens; including HBV and HCV \(^{(14,15)}\). Such cytokine has been demonstrated to suppress the replication of HBV and promotes its eradication via the pathway of stimulating HBV-specific cytotoxic T-cell response, and role of these interleukins in viral clearance is produced in response to viral infection \(^{(16,17,18)}\).

Such results may have suggested that the age
is not critical factor that affects the serum level of the investigated cytokine; however, caution must be considered in explaining these results because the specimen size in patients and controls may not permit a firm conclusion. In addition, age can be considered an affected factor when we have subjects at age more than 60 years, because it is often that a dysregulation in the immune functions, and a health decline and increased sensitivity to different diseases are associated with age people, for this reason, cytokines act a central immunologic communication, age-associated changes in cytokine production may contribute to these changes \(^{(19)}\). However, in agreement with present findings, Kim et al. (2011) showed that serum levels of IL-2, IL-12, IFN-γ, and TNF-α showed no significant differences between two age groups of healthy subjects (< 40 and ≤ 65 years) \(^{(20)}\). In addition, Kleiner et al. (2013) found that some interleukins show differences between young children and adults \(^{(21)}\). Finally, Goetzl et al. (2010) reported that the production of IFN-γ and IL-17 by eliciting T-lymphocyte cells were higher or minimally varied for healthy older female as compared with young females \(^{(22)}\).

Some studies have shown a correlation between cytokine serum levels and gender, and this may have been influenced by various factors, and among them is the hormonal status \(^{(23)}\). In this regard, immune defense capacity has shown differences between human males and females. In addition, males are found to be more prone to infections, while females are at greater risk to develop autoimmune diseases. These findings were correlated with humoral responses to the foreign antigenic challenge, and the suggestion was that sex hormones may affect immune functions \(^{(24)}\). With respect to cytokines, Elahe et al. (2006) reported that inflammatory cytokines were variable regulated in response to hepatic infection in male and female mice \(^{(25)}\). Finally, Klingstrom et al. (2008) revealed that the cytokine responses not similar in females and males during viral infection; implying that the subsequent activation and function of immune responses might differ between them upon infection. These findings may explain part of the showed sex differences in infections susceptibility to diseases and in mortality after viral infections \(^{(26)}\).

**Conclusion**

Based on the findings, it is possible to reach the following conclusions: the serum profile of IL-12 family was upregulated in hepatitis B and C patients, and the infections were associated with an increased level of these cytokines.

Analytical Study of Strategic Watch at Paralympic Committee Members in Iraq

Rawaa Abdul Ameer Abbas¹, Najlaa Abas Nasif¹, Nihad Mohammed Alwan¹
¹University of Baghdad/The college of Physical Education and Sport Sciences/Iraq

Abstract

Research is important in highlighting the concept of strategic vigilance as a modern administrative methods for development and change that can make a quantum leap in performance sports institutions and cadres. Search problem was the instability of the political, economic and social conditions for many years, affecting development capabilities and administrative institutions and particularly strategic decisions, and that reflects on the future of the organization. Which made the Paralympic Committee urgently need to adapt to those changes, to address shortcomings in financial possibilities and raise levels of enterprise performance and achieving adequate progress and achievement athlete who seeks to achieve in international forums, and that only by adopting the methods and modalities diverse management as strategic vigilance system which carries with it change and innovation in the area of administrative work.

Goal of research to analyze the reality of strategic Watch Committee members addressed the Iraqi Paralympic by identifying strengths and weaknesses in strategic watch and its dimensions have Paralympic Committee members in Iraq.

Use a descriptive analytical survey method on the Iraqi National Paralympic Committee members of b (the Executive Office, sports associations, committees in the provinces) and (132) and distributed measurements of strategic watch a sample search, and after collecting Results and addressed the following conclusions reached by researchers:

The strategic vigilance of axes (internal vigilance, technological, competitive vigilance, alertness) got high agreement rates by Paralympic Committee members, an indication of the ability of its members to understand the organizational and technological and competitive environment, environmental Access to success.

Technological Paralympic Committee members help to improve the efficiency of their performance through the use of modern technologies and evolution in the field of sports.

Keywords: Analytical study, strategic and Paralympic Committee.

Introduction

Sports institutions have faced numerous threats because of various changes and technological developments, which made those institutions seeking to keep abreast of these developments and rapid and complex changes and method adaptation. Forcing managers to find new management systems and non-traditional methods are consistent with these variables and environmental developments and handled in a great way. And strategic Watch system which is one of the most effective computer systems what sets high capacity to provide administrative needs of futuristic and realistic information to control and monitor and track workflow and adjust its relationship with the environment that activates and selects the competitors’ strengths and weaknesses And their goals and aspirations and attitudes and their policy and strategy, and in return it knowing what goes into the external environment through her skull, and analysis of opportunities and threats and collect their information processing and delivery in time to make the right choice to succeed and Excel in their performance.
The instability of the political, economic and social conditions for many years until this day impact on the development of capabilities and administrative institutions and particularly strategic decisions, which reflected negatively on the Organization’s future. Which made the Paralympic Committee need administrative departments able to adapt to those changes, to address shortcomings in financial possibilities and raise levels of adequacy of performance and achievement of success helps them achieve progress and achievement athlete who seeks to achieve in the forums International, and it is only by adopting various methods and management methods as strategic vigilance system which carries with it change and innovation in the area of administrative work. So the researchers sought to analyze the reality of strategic Watch Committee members have Paralympic Games.

Here lies the importance of research to highlight the concept of strategic vigilance as a modern administrative methods for development and change that can make a quantum leap in performance level administrators in sports organizations. So the strategic vigilance concept achieves many benefits to members of management in sports organizations to improve decision making, respond quickly to changes in the environment, and improve the efficiency of performance, which prompted the adoption of the concept of strategic watch one of the most important pillars To build future plans and visioning that might improve the adequacy and performance of the enterprise (Paralympic Committee in Iraq) and maintain its competitive position.

**Research aim:**

Analysis of strategic vigilance by identifying strengths and weaknesses in strategic watch and its dimensions have Paralympic Committee members in Iraq.

**Research methodology and field procedures:**

**Research methodology:**

Use a descriptive analytical survey method of research problem to fit it.

**The research community and samples:**

Select search intentional way society of Iraqi National Paralympic Committee members of b (the Executive Office, sports associations, provincial subcommittees) except for the Kurdistan region. And (150 members), as shown in table. (1)

Table (2) shows that the sample reflects the strategic vigilance and research themes that computational community values for vigilance and greater themes of hypothesis and community values that indicates the Paralympic Committee members possess a level of alertness and application strategy in their work and sports management, as Strategic watch an indispensable strategy process because it provides them with information that qualifies them to face better competition that this information affect many aspects in the environment of opportunities and threats. As the world and its many changes in the field of sports, made them realize the importance of technological development and technical success of action sports it thoroughly to facilitate their administrative procedures, which ask them to follow the new scientific and technical developments, as well as required Providing individuals who possess competencies and skills for optimal use in order to make action sports to reach high achievements.

Paralympic Committee members enjoy competitive level of vigilance in their work and sports management by monitoring their competitors strengths and weaknesses and their readiness to own proactive information about competitors and the possibility of opening new specialties in the field of sports. The competitor analysis is a fundamental step in the process of analyzing the competitive environment of the institution by examining and understanding their performance and predict future actions also allows detection of strengths that provide the opportunity for sports organization if done well.4

Strategic vigilance makes members of the Paralympic Games follow and monitor various risks that could threaten the future of Paralympic Committee, as well as take advantage of various opportunities to exploit, permanent and strict analysis environment variables for accurate information and necessary to take Comprehensive and accurate decisions. Since environmental vigilance is interested in providing all the information concerning the environmental components Paralympic and it must be dealt with carefully selected information in terms of analysis and processing for making the right decision. 5

The researchers believed that members observe the Paralympic responsibility and authority through a clear organizational structure and chart them and building on strong foundations and sober, and that this may contribute to the implementation of plans and strategies through having experience and competencies, “to achieve sporting events should be on top Degrees of regulation, proper organization on the activation of these activities that enable them to achieve a high level of efficiency and effectiveness and accomplishment. 6

This was confirmed by Ahmed “must be given the responsibility and authority of Department members work as part of their tasks and duties, as this Department must assume all responsibility for implementing all cadres formulates plans and programmes and does not mean a lack of coordination and consultation on all aspects of institutional work.

The researchers felt that the attention of the members of the Committee of the technological information sources as one of the most important technological developments in the external environment and the particular technology used by competitors in sports activities or developed to meet their needs to create competitive Compared to its competitors it allows them to shorten the route and speed the adoption of appropriate technologies and best its rivals, there must be awareness of the Paralympic Games, members of the importance of technological which aims to contribute to achieving comprehensive and integrated information system, which meets all Requirements for administrative work in Committee through speed and accuracy in performing

operations and that fully reflected the work of the Committee. The availability of technology, effective information systems, which are activated, to the extent necessary for coping and adapting new technological changes, increases the degree of benefit from continuing the enterprise successfully.  

Competitive vigilance appears as a main factor in the success of enterprise performance continuity, so when collecting information on the performance of current and new competitors by knowing their plans and their methods and knowledge of strengths and weaknesses members analyze and manipulate their environment in order to turn them into meaningful information and then directed by its users to be taken into account in strategic decisions and strategies and have followed all movements and changes in the external environment and thereby contributed to the effective performance efficiency by comparing its findings with members of Arabic Paralympic Committees and regional, that this procedure helps to know his standing among other Paralympic Committees which in turn helps to correct mistakes and be discovered as a result.

Environmental vigilance also allows members of the Paralympic Games to identify and monitor political, social and legal aspects associated with their performance and provide an appropriate environment for administrative work contributes to consolidate all Paralympic Committee members to achieve goals and make good exchanges between them and the ease of processing Internal problems, which tracks all activities that relate to the surrounding environment which greatly affect performance.

Ethical Clearance - Taken from University of Baghdad committee

Source of Funding - Self

Conflict of Interest - None

Conclusions

The researchers reached the following conclusions:

The members of the Paralympic Committee gave explicit attention to the requirement of vigilance strategy in all its dimensions.

The strategic vigilance of axes (internal vigilance, technological, competitive vigilance, alertness) got high agreement rates by Paralympic Committee members, an indication of the ability of its members to understand the organizational and technological and competitive environment, environmental access to success.

Technological help Paralympic Committee members to improve the efficiency of their performance through the use of modern technologies and evolution in the field of sports.

Competitive vigilance role in supporting the sample discussed in improving the efficiency of their performance by controlling the current and new competitors, and identify strengths and weaknesses to ensure an active presence in competitions and Paralympic distinguish competitors.

For environmental vigilance has a positive impact on the evolution of events in Paralympic Committee adequacy, as its members are watching and the sequence of events through situational scopes of environmental information and assess the risks and face them consciously.

Effects of Iraqi Medicinal Plants on the Growth of 
Trichomonas vaginalis in Vitro: A Narrative Review

Rawwaa Ghanim Mohammed¹, Jassim Fatehi Ali²

¹Department of Clinical and Laboratory Science, College of Pharmacy, University of Misan, Iraq, ²Department of Basic Medical Science, College of Dentistry, University of Misan, Iraq

Abstract

Objectives: Regarding with improving the therapy of Trichomoniasis, natural products could be a provenance of new drugs with low toxicity and high effectiveness. Considering the side effects of metronidazole in the treatment of T. vaginalis infection, and to evaluate substitutional drugs, the effect of different Iraqi plants extracts on T. vaginalis in vitro was reviewed in this study.

Method: A computerized search for published articles was conducted over Iraqi Academic Scientific Journals, PubMed, Google Scholar, Scopus, and EBSCO databases. Exemplary investigation strategies have used for each databases. After incipient search and screening 5 papers were included in the study.

Results: The effect of different Iraqi medicinal plants extracts on T. vaginalis in vitro have reviewed. Just Five articles have included in vitro experiments. Eight types of Iraqi medicinal plants were investigated against T. vaginalis. Reviewed medicinal plants appeared uncommonly effective on T. vaginalis.

Conclusions: The present narrative review provides inclusive and useful information about searched medicinal plants with anti-T. vaginalis activity, which would be tested in the future experimental and clinical trials, and medicinal plant natural products combination therapy.

Keywords: Trichomonas vaginalis, Iraqi medicinal plants, Artemisia herba-alba, Myrtus commanis, Punica granatum.

Introduction

Trichomonas vaginalis is a unicellular protozoan flagellate parasite, that has only the trophozoites stage. Infection usually involves the urogenital tract, affecting both female and male of the reproductive age. Symptoms occur after a period of incubation of 4–28 days. In women, the usual presenting complaint is vaginal. This parasite can also lead to serious consequences, such as infertility, premature shredding of placental membranes, precocious delivery, low-birth-weight infants, and neonatal death. It is spread via unprotected sexual intercourse with an infected partner but may also be spread out of the fingers after masturbation. Trichomoniasis affects approximately 57–180 million people with the majority living in developing countries. Several epidemiological studies carried out in Iraq on this protozoan reported different ranges of prevalence. High rates of 20.11% were reported by. Some reported as low as 2.4%

Metronidazole drug commonly used for trichomoniasis treatment belongs to the 5-nitroimidazole drug family and it is notified to have about a 95% cure rate for trichomoniasis, is relatively cheap and is well tolerated but resistant strain exist. In some cases few reverse reactions have been noticed to standard doses of metronidazole, and they are usually a consequence of an allergic reaction to nitroimidazoles.

In the last decade, attentiveness has been paid to the looking for alternatives to chemotherapy for the treatment of diseases, and people now more aware and percipient in alternative therapies, specially using plants for the treatment of diseases that natural products could be a source of new drugs with low toxicity and high activity.
Considering the side effects of metronidazole in the treatment of trichomoniasis, and to evaluate alternate drugs, the effect of different Iraqi plant extracts on *Trichomas vaginalis* in vitro was reviewed in this study.

**Materials and Method**

This review includes all information about local medicinal plants in Iraq that searched as potential anti *T. vaginalis*, published in local and international journals from 2001 to 2018 using various databases including Iraqi Academic Scientific Journals, PubMed, Google Scholar, Scopus, and EBSCO databases. A computerized search for published articles was conducted, and after incipient search and screening 5 papers were included in the study.

**Results**

**Effect of Iraqi medicinal plants extracts on *T. Vaginalis* in culture medium**

Table 1. summarizes the overall effects of Iraqi studied plant as anti-*Trichomas vaginalis*.

1- *Artemisia herba-alba* *Artemisia* belongs to the family Asteraceae, is a widespread genus which comprises more than 400 species. Distributed in western and north of Iraq. Phytochemical studies on this plant evidenced the existence of many beneficial compounds such as herbalbin, cis-chrysanthenyl acetate, flavonoids (hispidulin and cirsinoleol). Some reported that plant have various biological activities including, antibacterial, anti-malarial, widely used in ancient times and is still used in the dismissal of Ascaris worms and *Aspergillus niger, Candida albicans*. The extract of alcohol used in the treatment of diseases caused by several parasitic worms.

An investigation in vitro to evaluate effects of some alcoholic and aqueous extracts of plant on growing, number, and activity of *T. vaginalis* in CPLM medium manifested that 0.50% concentration of alcoholic plant extract showed complete cessation of parasitic activity at 24 hours while the 0.25% showed complete cessation after 48 hours, while water extract at 1% concentration had total inhibition through 24 hours.

2- *Myrtus commanis* Common myrtle belongs to the *Myrtaceae* family, which comprises approximately 145 genera and over 5500 species. *M. communis*, known as true myrtle, is one of the important aromatic and medicinal species from this family. Myrtle is useful in home use for urinary tract infections and for bladder infections, infections of the urethra, antiseptic (urinary, pulmonary). The liquid plant extracts of *M. communis* in Iraq tested at different concentrations with *T. vaginalis*, 10⁶ organisms/ml. caused death of organism at pH 4.65, but no such effect was observed at pH 6.00.

3- *Capparis spinosa* A plant belongs to Capparidaceae family. grows spontaneously in cracks, crevices of rocks and stone wall sand naturally in very dry and semi-arid places in Iraq. All parts of plant used in medicine as well as root. Extracts of *Capparis spinosa* can affect *T. vaginalis* activity and it’s growth on CPLM media because it contains glycosides which have antiseptic effect.

4- *Eucalyptus camaldulensis* Member of the family Myrtaceae. The species grows in all regions of Iraq. It is a large perennial woody tree grows to 20 m tall, occasionally reaching 50 m, Leaves grey-blue, alternate, drooping, 8-22 cm long, 1-2 cm wide, often curved or sickle shaped, tapering, short pointed at base. The medicinal part of the plant is aromatic leaves which have many benefits especially in the medical field as well as oil extract from these papers, and the most important compounds effective which is a pilot oil containing a ketone group. Aqueous extract of *E. camaldulensis* (50 mg / 0.1 mL medium) at (pH 5.35) caused death of *T. vaginalis* after 24 hours in vitro.

5- *Trigonella foenum-graecum* Belongs to family Leguminosae, commonly known as fenugreek and locally as “Hulbah”. It is planted in various countries. In Iraq it grows in different regions (Ghurraf District, Southern Desert District, Central Alluvial District). The plant radiates a spicy odors which persists on the hands after touching. Wild and cultivated varieties exist. Medicinal uses (anti-diabetic, lowering blood sugar and cholesterol level, anti-cancer, anti-microbial, etc.). It is widely cultivated as a drug plant. The mucilaginous seeds are reputed to have many medicinal virtues, as a tonic, emollient, carminative, demulcent, diuretic, astringent emmenagogue, expectorant, restorative, aphrodisiac and vermifugal properties.
Aqueous extract of the plant completely inhibited the growth of *T. vaginalis* at 48 hours but mixing it with extracts of some other plants produced best effects, Mixed extracts of *T. foenum-graecum* with *Matricaria chamomilla* can completely inhibit the growth of *T. vaginalis* at 24 hours flowed by *Thymus vulgaris* at 72 h. and with *Cyperus rotundus* at 96 h.

### 6- *Viola odorata*
Member of Violaceae family. It is popularly known as sweet violet, English violet, and common Violet. It is an evergreen perennial herb growing about 10 cm tall. *V. odorata* spreads with stolons. It flowers in late winter. It distributes in many countries because it grows in most types of soils, It is cultivated in gardens and in the tree beds.

It possesses active compounds, such as alkaloids, flavonoids, refined oils and soap, with medical importance as a laxative, a vomiting and a sedative. It is also used in the treatment of burns, hypothermia, blood pressure, asthma, treatment Respiratory diseases, and against many infections caused by bacteria Its drug is also anti-inflammatory.

### 7- *Ruta graveolens*
Odoriferous herb belonging to the family Rutaceae. It is a small evergreen sub-shrub or semi woody perennial 0.6 to 0.9 m tall and almost as wide. The stems become woody near the base, but stay herbaceous nearby the tips The sea green foliage has a strong, pungent, rather unpleasant scent when bruised. Combination of two aqueous extracts of medicinal plants with concentrations of 0.15625, 0.3125, 10-20 mg/ml namely the violet, *Viola odorata*, and the rue, *Ruta graveolens*, on growth of *T. vaginalis* cultured in (CM161) medium during periods of 24, 48, 72, and 96 hours studies by Complete inhibitory effect after combination was noticed at concentration of 20 mg/ml within 24 hours and at concentration of 10 mg/ml during 48 hours.

### 8- *Punica granatum*
Pomegranate (Punica granatum) belongs to family Punicaceae, is an edible fruit cultivated in many countries and consumed around the world. It is a small tree or shrub which is native for Asia. The exfoliate and pulps of pomegranate do not consume by human because they are unpalatable, but they comprise more antioxidants power than many sources such as green tea and red wine and they are a rich sources of bioactive compounds such as poly phenols, anthocyanidins, Flavinoids and minerals mainly potassium, calcium and sodium. Pomegranate and their constituents have safety been consumed for centuries without adverse effects. However, modern research suggests that pomegranates might be useful in treating such serious conditions as prostate cancer, skin cancer, osteoarthritis, and diabetes.

Treatment with hot water extract of *Punica granatum* peel showed the best results to treat the infection of rats with trichomoniasis, where 90% of animal treated after 6 days post treatment at concentration 40%, while treatment with cold water extract appeared that 50% of rats was treated after the same time and concentration. The alcoholic peel extract treatment appear the lowest efficiency and lead to vaginal inflammation and the concentration 20% was applied only.

Discussion

Trichomoniasis is the most predominant non-viral sexual disease with an incidence of almost 170 million new cases worldwide. This disease is correlating with divers complications. The usual medication for trichomoniasis is metronidazole, but some resistant strains to this treatment have been notified.

In this paper we have reviewed the effectiveness of eight Iraqi medicinal plants on *T. vaginalis* in vitro in our searching for an alternate drug for the treatment of trichomoniasis. Because a single method was not utilized in the various studies on the impact of medicinal plants on *T. vaginalis* in vitro, it is difficult to compare them in order to elect the plants with the best trichomonocidal activities.

The hydro-alcoholic extract of numbers of these plants have exhibited anti trichomonas activity, which was as efficacious as metronidazole in some cases.

Thus, there are enough plants with vigorous antitrichomonas activity that could be more investigated in clinical trials. Fortunately it has been noticed that some of these plants have anti-bacterial and anti-fungal affects. Thus, future investigations could be considered for the evolution of these drugs for the treatment of vaginal infections. Moreover, the combination of several plants may be recommended for future studies, as well as there are huge number of Iraqi medicinal plant their effects have not yet been studied and there is a need for further investigation in this field.

Conclusions

On the basis of this narrative review article it can be concluded that there are only few studies done in Iraq considering the effect of medicinal plants against *T. vaginalis* and more studies are needed in to cover this area. However some of these eight studied Iraqi medicinal plants showed effective capacity and could be appropriate candidates for developing new antitrichomonas drugs.

Moreover, anti-bacterial and anti-fungal effects of number these plants have been shown and so this plant can be considered as an appropriate drug for the treatment of vaginal infections. Therefore, a recommendation for developing a convenient formulation for this plant can be made for analysis in a clinical trial to evaluate its Trichomonocidal activity in vivo. studies are needed to achieve the desired results in the use of plants in trichomoniasis treatment.

Conflict of Interest: The authors assure that this review article content has no conflicts of interest.

Abstract

The purpose of the study was to find out the effect of mobility training and combination of strength and mobility training on selected physiological variables namely explosive power in terms of vertical distance (vertical jump), explosive power in terms of horizontal distance (standing horizontal jump). To achieve this purpose of the study, forty-five school (boys) cricket players studying in the schools at Thiruvallur District were randomly selected as subjects. The age of the subjects were ranged between 15 to 17 years. The selected subjects were divided in to three equal groups of fifteen subjects each. Group I underwent mobility training, Group II underwent combination of strength and mobility training and Group III acted as control who did not undergo any special training programme. The obtained data from the experimental and control group initial and final readings underwent statistical analysis along with analysis of covariance (ANCOVA) with the application of Scheffe’s post hoc test to examine the groups’ difference and testing condition. The level of confidence had a fixation of 0.05 confidence level. The group that acted as the experimental group had improved significantly on the chosen variables in comparison with control group.

Keywords: Physiological variables, Explosive power, Vertical distance, Horizontal distance, Cricket players

Introduction

Training is a systematic process of repetitive progressive exercise of work involving learning and acclimatization. Training is the total addition of adaptations stimulation through regular exercise. Students on the exercises with reference to fitness state that it enables to tolerate more effectively, subsequently stresses of similar nature. The method of creating force on the sportsman and his capability to adapt to this stress is called sports training that leads to the enhancement of sports performance. Strength training refers to an interest in physical fitness or importance of strong weight of the body to develop specific areas of the body. Generally, it is used to develop muscular strength and power. It also develops muscular endurance elasticity and co-ordination. Strength training is the use of systematic exercises with weight and it is used merely as a mean to increase resistance of the muscle contraction. The main aim is not in learning to lift as much of possible weight but to enhance strength and power for the purpose of some other sports. Strength training refers to an interest in physical fitness or importance of strong that range of motion. There should be a period of time either before/after training or even on a separate day that is dedicated to improving mobility. Something as little as 5-10 minutes daily can be enough to see progress. One of the most common reasons you feel non athletic is because you aren’t able to get into the positions and postures that you want. It is easy to perform little mobility work as a routine for preserving it and have to perform to get it again 5 minutes a day takes a long way.

Strength training is use of resistance other than weight of the body to develop specific areas of the body. Generally, it is used to develop muscular strength and power. It also develops muscular endurance elasticity and co-ordination. Strength training is the use of systematic exercises with weight and it is used merely as a mean to increase resistance of the muscle contraction. The main aim is not in learning to lift as much of possible weight but to enhance strength and power for the purpose of some other sports. Strength training refers to an interest in physical fitness or importance of strong

in a particular sport. It is not usually an end in itself but as a means to an end. The subject of Strength training is a controversial one. Many physical educationist believe it makes participants “muscle bound” but muscles in a permanent state of partial, limits reduces speed, causes the learning of sports skills. The necessity of strength training with regularity and the application of slow progress in training intensity with the rules of over loading maintained with proper nutrition and sufficient rest not similar to endurance training, weight training that does not require many calories. As it has a limited role in reducing the body weight, also the weight due resulting from muscle hypertrophy strength training will not result in the loss of flexibility or turn to be muscle bound. Studies on olympic athletes have shown only the gymnasts have better flexibility than the weight lifters. Strength training does not slow down muscular movement. It has also been established that increase in muscular speed (Explosive power) accompanies an increase in muscular strength.

Statement of the problem

The research aims to assess the the effect of mobility training and combination of strength and mobility training on selected physiological variables namely explosive power in terms of vertical distance, explosive power in terms of horizontal distance.

Methodology

During the training period, Group I and Group II underwent mobility training and combination of mobility training with strength training respectively for three days per week for twelve weeks of the training programme. In every day training session, the work out lasted approximately between 45 minutes and an hour, which included warming up and limbering down. Group III acted as control that did not participate in any special training programme or strenuous physical exercises apart from their regular activities as per the curriculum. The experimental groups underwent their respective training programmes under the supervision of the researcher. The subjects were carefully monitored and questioned about their health status throughout the training programme. None of the subjects have reported any injury. The obtained data from the experimental and control group initial and final readings underwent statistical analysis with ANCOVA and Scheffe’s post hoc test to examine the groups difference and testing condition. The confidence level is fixed at 0.05. The statistical analysis computed with IBM-SPSS – v21 software.

* Significant at .05 level of confidence.
The table values required for significance at .05 level of confidence for 2 and 27 and 2 and 26 are 3.37 and 3.35 respectively.

The table I shows that the pre-test mean values on explosive power in terms of vertical distance of mobility training group, combination of strength and mobility training group and control group are 92.70, 92.50 and 92.60 respectively. The obtained “F” ratio of 0.04 for pre-test scores is less than the table value of 3.37 for df 2 and 27 required for significance at .05 level of confidence on explosive power in terms of vertical distance. The post-test mean values on explosive power in terms of vertical distance of mobility training group, combination of strength and mobility training group and control group are 92.70, 92.50 and 92.60 respectively. The obtained “F” ratio of 0.04 for post-test scores is less than the table value of 3.37 for df 2 and 27 required for significance at .05 level of confidence on explosive power in terms of vertical distance. The adjusted post-test mean values on explosive power in terms of vertical distance of mobility training group, combination of strength and mobility training group and control group are 92.70, 92.50 and 92.60 respectively. The obtained “F” ratio of 0.04 for adjusted post-test means is more than the table value of 3.35 for df 2 and 26 required for significance at .05 level of confidence on explosive power in terms of vertical distance. The results of the study indicated that there was a significant difference among the adjusted post-test means of mobility training group, combination of strength and mobility training group and control group on explosive power in terms of vertical distance.

Since, three groups were compared, whenever the obtained ‘F’ ratio for adjusted post test was found to be significant, the Scheffe’s test to find out the paired mean differences and it was presented in Table II.

Table II: The Scheffe’s test for the differences between paired means on explosive power in terms of vertical distance

2Graduate Student of Dental Health Science, Faculty of Dental Medicine, Universitas Airlangga

Abstract

Background: Tambakrejo Health Center is one of the public health services in Surabaya that provides integrated dental and oral health services. As many as 69% of the community in health center working area were exposed to periodontal problems, and around 18% suffered from diabetes mellitus.

Objective: This study aimed to identify the factors that play a role in compliance with drug consumption in patients with diabetes mellitus associated with periodontal tissue in the working area of Tambakrejo health center in Surabaya.

Methods: This was an observational analytic study with cross sectional method. The study sample was 60 people with diabetes mellitus selected with a random sampling technique. Respondents filled out questionnaires to measure patients’ perceptions, knowledge, attitudes, and actions about drugs, diabetes mellitus, periodontal health, and the level of compliance with drug consumption. The sample oral hygiene status was determined using the Russell Index.

Results: The data obtained showed that as many as 67% of the samples had low level of compliance. Whereas, 20% of the sample had moderate level of compliance. Only 13% of the sample had high level of adherence.

Conclusion: There was a significant correlation between the level of compliance of patients taking antidiabetic drugs and the periodontal health.

Keywords: Diabetes mellitus, patient compliance, Patient medication knowledge, periodontitis

Introduction

The prevalence of diabetes globally affected around 9% of adults aged 18 years and over in 2014. The World Health Organization (WHO) projects that diabetes will be one of the main causes of death because the number has increased. Indonesia is the 4th largest country with a growth of 152% of diabetics or from 8,426,000 people in 2000 to 21,257,000 in 2030.1

According to Trekas (1984) in Tombokan et al (2005), the ability of DM patients to control their lives can affect the level of adherence. A person who is health-oriented tends to adopt all habits that can improve and restore his/her health. Non-compliance will be an obstacle to achieving treatment goals. This non-compliance can be overcome by providing counseling to people with Diabetes Mellitus and their families.2 According to Ajzen (2005), several factors that can influence medication compliance is the intention of the sufferer, which includes the attitude of the patient, support from the husband and the patient’s belief in treatment.3

According to Herlena and Widiyaningsih (2013), an attitude will not necessarily be realized in the form of an action. The realization of a positive attitude requires supporting factors or a possible condition. If all positive behaviors have been implemented, DM patient can be included in the group of DM patients with high compliance. An impact of compliance, one of which, is control of diabetes. The attitude of respondents which is not good is indicated by the attitude of respondents who do not support the treatment of DM.

In the previous study on “Diabetes mellitus as a risk factor for periodontal problems in people aged >20 years in the working area of Tambakrejo Health Center in Surabaya 2017”, one of the highest risk factors was found. The relationship between the level of compliance with drug consumption in people with diabetes mellitus and health status periodontal showed the prevalence of patients who do not routinely consume drugs by 48%. The regularity of treatment can be supported by family support, education, patients’ knowledge about the disease and the medication they consume (Laoh et al., 2013).

Based on what has been described above, researchers are interested in conducting research to find out what factors influence compliance with drug consumption in patients with diabetes mellitus associated with periodontal tissue in the working area of Tambakrejo Health Center, Surabaya.

Subjects and Method

This was an observational analytic study with cross sectional method. This study was carried out in Tambakrejo Health Center working area, Surabaya. The population in this study were 60 people age 45-60 years old with diabetes mellitus who were in the Tambakrejo Health Center working area as samples obtained through random sampling techniques.

The independent variable in this study was compliance to drug consumption in people with diabetes mellitus. The dependent variable in this study was periodontal tissue. Data collected by questionnaire and intra oral examination for checking the periodontal health with Russell Index. Data were analyzed by Correlation Test and significance with 95% confidence intervals. To identify risk factors, Prevalence Ratio, Relative risk, a significance were calculated, and correlation with linear regression test was carried out so that the level of possible risk of each variable studied on the level of compliance taking medication could be estimated.

Findings:

Table 1. Analysis of periodontal health data with the Russell index

<table>
<thead>
<tr>
<th>Variable</th>
<th>n</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clinically normal</td>
<td>1</td>
<td>1.7</td>
</tr>
<tr>
<td>Simple gingivitis</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Beginning destructive periodontal disease</td>
<td>1</td>
<td>1.7</td>
</tr>
<tr>
<td>Established destructive periodontal disease</td>
<td>37</td>
<td>61.6</td>
</tr>
<tr>
<td>Terminal disease</td>
<td>21</td>
<td>35</td>
</tr>
<tr>
<td>Total</td>
<td>60</td>
<td>100</td>
</tr>
</tbody>
</table>

Based on Table 1, the highest percentage is found in respondents who have the Russell index in the form of Established Destructive Periodontal Disease, which is 61.7%. Then, it was followed by Terminal Disease, which was equal to 35%. The third were Clinically normal and the Beginning Destructive Periodontal Disease, which were 1.7% respectively, and the last was Simple Gingivitis with a percentage of 0%.

Table 2. Correlation and significance of risk factor variables with the level of respondents’ compliance to antidiabetic treatment

<table>
<thead>

<th>Compliance of patients in taking medication</th>
<th>Russell Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spearman’s rho</td>
<td>0.265</td>
<td>0.041</td>
</tr>
</tbody>
</table>

Based on Table 2, there is a correlation between the level of adherence of patients taking antidiabetic drugs and the periodontal health level as measured by the Russel Index with α of 0.041 <0.05 and the correlation index of 0.265.

The results of the study on patients’ knowledge of diabetes drugs were obtained with a low category of 30%, moderate of 46.7% and high of 28.3% of respondents. Drug knowledge of these patients was influenced by several factors, especially the level of education of patients, explanations and how the explanations received by patients and how the role of health care workers in explaining to these patients. This is in accordance with research by Dunning and Manias (2005) in patients.
with diabetes mellitus in Australia in which there is a close relationship between the level of education and “training” received by patients on how patients act in dealing with diabetes and the reasons patients sometimes only take medication if told to do so.⁶

Based on the results of the study with the risk factors for knowledge of patients with diabetes mellitus, the highest percentage was found in respondents who had high or good knowledge of diabetes mellitus by 55%, then 35% of respondents had moderate level of knowledge of diabetes mellitus, and 10% of respondents had low level of knowledge. This is not in accordance with studies that stated that patients with better knowledge of diabetes mellitus have a good level of compliance to taking drugs. This can happen because the level of adherence to taking antidiabetic drugs is not only influenced by knowledge about antidiabetic drugs, but also by other factors, such as communication with the family and health care workers.⁷

From the results of the research on the patients’ knowledge regarding the role of health services, the results showed that the knowledge of the general practitioners and their suggestion to refer to patients with diabetes mellitus to the dentist had an effect on the level of compliance to taking patient medication.⁸

Patient attitudes towards antidiabetic drugs found 85% of respondent’s were high or good attitudes towards anti-diabetic drugs, 15% of patients were on anti-diabetic drugs and no respondents had low or bad attitude towards anti-diabetic drugs. Most patients wanted to get well soon from their diabetes and thought that anti-diabetic drugs were important for consumption, but it was not comparable to the actions they took on antidiabetic drugs and diabetic control, which was consistent with research in the third world where most population have low knowledge but have high attitude to recover, but it is not supported by adequate facilities.⁹

From the results of the study, 93.3% of respondents had good attitude towards diabetes. No respondent had poor attitude in dealing with diabetes. This showed that even though the patients’ attitude was good towards diabetes mellitus, it did not affect the level of awareness of patients in taking anti-diabetic drugs. This is the same as expressed by the study that even patients have good attitude, if it is not supported by adequate knowledge, the output of the patients’ actions remains poor.⁹

From the results of this study, most respondents (80%) had moderate/normal attitude towards periodontal health. There is a difference between attitudes and knowledge of diabetes and periodontal disease. This is different from research in developed countries. The average patients have knowledge and good attitudes towards the health of the body, including the oral cavity and good correlation due to good health service factors, the government that cares about the community, and affordable and even free health services because they are covered by insurance.⁶

From the results of the research respondents’ perceptions of antidiabetic drugs, it was found high/good perception rate of patients on anti-diabetic drugs by 81.7%, and no patients had a low/poor perception of anti-diabetic drugs. This is because the price of diabetic medicine is relatively cheap and even free and can be obtained easily by patients both at the nearest pharmacy and at the health centre. Patients also feel that the consumption of drugs does not disturb their diet. The dosage is also sufficient for patients, it is not difficult for respondents to drink.⁶

From the results of research with risk factors for patient perceptions of health services, it was found that the highest percentage was in respondents with moderate perceptions of health services (51.7%), followed by high perceptions of health services (30%), and low perception of health services (18.3%). Good interpersonal relationships will make patients feel a good appreciation too, which ultimately makes them happy, even satisfied with the service received. The satisfaction that remains within them will shape the perception that health services have certain quality.¹⁰

From the results of the study of patient perceptions of the duration of therapy, data obtained showed that 53% of patients answered yes to the question “Tired of having taken too long medicine”, in which it was negative. Furthermore, 47% of patients answered no to the statement in which it was positive. This was due to many factors, such as the data distribution which was not good or because there were not many samples. Respondents tended to be bored because the use of drugs that lasted long and continuously. This research was in line with the research results.²

Data from the research on the patients’ actions on antidiabetic drugs found high or good level of patient...
action on antidiabetic drugs as much as 61.67%. Whereas, 28.3% of respondents had low or poor levels of action against antidiabetic drugs, and 10% of respondents had moderate level of action on antidiabetic drugs. This illustrates that the patients’ actions on antidiabetic drugs affected compliance to taking anti-diabetic drugs. The patients’ actions are included in understanding the doses, complications, and side effects of the drug. If the patients have good understanding and action, they will tend to be more responsible in the routine of taking medicine. 

Data from research on the actions of patients on diabetes mellitus showed the level of action of patients which was high or good for diabetes mellitus by 71.67%, the level of patient action was low for diabetes mellitus by 18.3%, and the level of action of patients which was moderate on diabetes mellitus by 10%. This illustrates the relationship between actions against diabetes mellitus with compliance to taking diabetes mellitus medication. With good actions from patients, such as routinely doing blood sugar checks and control in the doctor, patients will tend to be more obedient in taking antidiabetic drugs.

The results of the study also discussed the actions of patients on periodontal disease and found that respondents had moderate actions on periodontal health (71.7%), respondents had high actions on periodontal health (16.6%), and respondents had low actions on periodontal health (11.7%). Patients who had low knowledge and poor attitude towards their periodic health also had poor or inadequate actions to keep their periodic health, such as never visiting a dentist, not regularly toothbrushing, doing toothbrushing in wrong way, and never using dental floss.

The results of statistical tests showed high and significant correlation between the Russell index which describes the periodontal condition and the Patient Compliance Level for consumption of antidiabetic drugs. There was correlation between the level of compliance of patients taking antidiabetic drugs and the periodontal health measured by the Russell Index with α of 0.041<0.05 and correlation index of 0.265.

**Conclusion**

There was close relationship between the level of compliance of respondents to the treatment of diabetes with the level of periodontal health (Russell Index).

Design and Implementation of Maximum Airflow Meter

Safa L. Kailan1, Sadiq J. Abbas2, Abbas F. Al-Hashim3
1Asst. Lecturer, 2Asst. Prof. Department of Biomedical Engineering, College of Engineering, Al-Nahrain University, Baghdad- Iraq, 3Asst. Prof. Department of Physiology, College of Medicine, Al-Nahrain University, Baghdad- Iraq

Abstract

Many physiological changes occur during pregnancy, especially changes in pulmonary which occur in the fourth week of pregnancy due to an elevation of the diaphragm and thoracic wall. The aim of this study was: (1) developed and implementation of Maximum Airflow Meter for measuring the airflow parameter during expiration to detect various types of diseases and obstruction in the respiratory airway and (2) used of Statistical package for social sciences (SPSS) which is a statistical analysis software run t-test to make a comparison between the airflow parameter of pregnant and non-pregnant women. The research was carried out on twenty-three women who perform Maximum Airflow Meter to obtain their airflow parameter. The results showed the change in airflow between the pregnant and non-pregnant and the results of the SPSS displayed a significant difference ($P<0.004$) between these pregnant and non-pregnant women.

Keywords: airflow, p-value, Arduino, SPSS.

Introduction

The main function of the respiratory system is a gas exchange. Oxygen (which cells need to function) is transferred from the external environment into the bloodstream while carbon dioxide (Which is a waste product of cellular function) must rid of into the outside air. Many of tissue cells in the body located too far from the inhaled air where gas exchange takes place directly, and instead, blood carried the oxygen to the cells, this occurs during breathing where oxygen enters the mouth or nose during inhalation. After entering the nose, the air passes through the larynx and then to the trachea which in turn splits into two bronchi. Each one of the bronchi (bronchus) bifurcates into two smaller branches forming bronchial tubes. The bronchial tubes form a great number of pathways inside the lung and terminating at the end to small sacs called alveoli. The gas exchange takes place at the alveoli, where oxygen diffuses into the lung capillaries and exchange with carbon dioxide. After the gas exchange occurs, exhalation begins and the air containing CO$_2$ return through the bronchial pathways and expelled to the external environment through the mouth or nose $^{1,2,3,4}$.

Airflow resistance in the airways of the respiratory system is a concept that used to describes the resistance to air flow beginning from its breathing point to alveoli, which caused by forces of friction $^{5,6}$.

The airflow resistance has the unit (cm H$_2$O s/L), and it describes the relationship between the rate of airflow and the driving pressure: $^{6,7,8}$

The resistance is proportion inversely to the fourth power of the radius; therefore, airway resistance decreases as lung volume increases $^{5}$.

In turbulent flow, the resistance is comparatively large because of large driving pressure is necessary to yield the same airflow rate in contrast with a laminar flow. The high resistance which causes problems in the function of respiration may be an indication of obstructed pulmonary diseases as asthma $^{5,6}$.
\[ R = \frac{\Delta P}{\bar{V}} \]  

(1)

Where
\( \bar{V} \): the volume flow rate, ml/s,
\( \Delta P \): the pressure drop, cm H\(_2\)O, and
\( R \): is the resistance of airflow, cm H\(_2\)O s/L.

For a laminar flow, the flow rate can be calculated using Poiseuille’s law by: 5, 6, 7, 9

\[ \bar{V} = \frac{\Delta P \pi r^4}{8 \eta l} \]  

(2)

Where
\( \eta \): is the viscosity of the gas, poises,
\( l \): is the airway length, cm, and
\( r \): is the radius of the tube, cm.

**Cases Classification**

Twenty-three women were selected in this study, these women perform airflow test by using Maximum Airflow Meter and they are classified as follows:

**Maximum Airflow Meter:**

**Control group**, 15 cases of healthy normal non-pregnant women.

**Experimental group**, 8 Cases of healthy normal pregnant women. All cases of pregnant women in this group are in their third trimester.

The height of these women are range from 147 to 171 cm, their weight are range from 43 to 117 kg, and their age are range from 20 to 40 years, therefor this study is carried only for the women in these limitations.

**Developed of Maximum Airflow Meter**

The following components, as shown in Figure.1 were used to developed and implementation of Maximum Airflow Meter:

**Airflow Sensor**

The airflow sensor (airflow sensor, china) is high sensitive, low offset pressure, high resolution, and accurate airflow reading, as shown in Figure.2. It does not suffer from noise produced by long cables. This sensor has measurement range of up to 1000 L/m. It is used in a wide range of applications. In this research, the airflow sensor is used in respiratory system application to measure the flow of air coming from the lungs and mouth during expiration. The output of this sensor is number and has unit of (liter per minute) which is very important to detect and identify disease or any obstruction in the airways. It is not used only for measuring the airflow of pregnant and non-pregnant women as in this research but it also can be used to measure the airflow of patients and identify diseases such as asthma. The airflow sensor has two ports, the top port is “active” (measures the pressure of air from open at the front of pitot tube) and the bottom port is “static” (measures ambient air pressure).

![Figure 1: Components of Maximum Airflow Meter.](image1)

![Figure 2: Airflow sensor with pitot and rubber tubes.](image2)
B. Pitot tube

Pitot tube has two pipes, one angled pipe for static port and other straight pipe for active port of the sensor, as shown in Figure.2.

C. Rubber Tubes

Rubber tubes are used to connect the airflow tube to the airflow pin, as shown in Figure.2.

D. 4 pin cable

The 4 pin cable is used to connect the airflow sensor to the Arduino, as shown in Figure.2.

E. Arduino Uno and PC with IDE software

Arduino Uno (Arduino Uno, China) is an open-source physical board used for building a wide variety of electronics projects. It can control and interact with different types of sensors. The main advantages of this type of Arduino are:

- Simply use for many purposes
- Simply connect to the computer by USB cable
- 32 KB of flash memory for storing code
- Powered it with battery, and
- Inexpensive.

Arduino Uno consists of the microcontroller which is a physical programmable circuit board, as shown in Figure.1, and a part of the software, or IDE (Integrated Development Environment) that can be run on a computer to write and upload code to the physical board. The Arduino IDE uses an easy version of C++ to simplify learning to program. The voltage needed for most types of Arduino models is between 6 and 12 Volts. The Arduino has numerous pins (6 analog pins and 13 digital pins); each pin is labeled on the physical board and allow connect the external hardware to Arduino to use it for a specific function.

F. Standard A-B USB cable

USB cable (USB 2.0 A-Male to B-Male cable) is used to plugin Arduino board into computer, the USB connection has high speed to load code on the Arduino board, the USB cable is shown in Figure.1. It is multi-shielded cables to minimize interference.

G. Liquid Crystal Display (LCD)

LCD is a flat display (16 X 2 segments) essential to display the output data of the measurements to the users, as shown in Figure.1. It can control the display of data by the microcontroller by connected the LCD to specific pins in the Arduino.

H. Wires

Wires were used to make connection between LCD display and Arduino.

I. Breathing tube with a mouthpiece

The Breathing tube and mouthpiece contains the rubber tube and airflow sensor within the core of the tube and mouthpiece to prevent the influence and interference of external environments on the measurements of the sensor, as shown in Figure.4.

J. Batteries

Two batteries (3.7 V) were used to power up an Arduino which is long lived battery, as shown in Figure.1.

Implementation of Maximum Airflow Meter

1. The IDE software was installed in PC and open to prepare for programming.

2. The Arduino was connected to PC by USB cable and it was connected to batteries by wires, as shown in Figure.1 and Figure.3.

3. The LCD was connected to Arduino by wires, as shown in Figure.3.

4. The airflow sensor was connected by 4 pin cables to Arduino, as shown in Figure.3.

5. The pitot tube was connected to the airflow sensor by rubber tubes, the straight pipe connected to active port and the angled pipe connected to static port, as shown in Figure.2.

6. The specific codes used to power and programming Arduino, LCD, and airflow sensor were written in IDE software.

7. Battery was connected to Arduino and used to power up it instead of PC (after run and save program with codes in Arduino), as shown in Figure.3, this enable airflow measurement device to perform test and to display the reading without PC.
8. A switch was connected to battery and used to turn on and off the airflow measurement device.

9. The breathing tube and mouthpiece was enclosed the rubber tubes and air airflow tube, as shown in Figure.4.

10. A box was designed and manufactured to houses all components to protect them from damage and/or cutting in wires, as shown in Figure.4.

11. Finally, the pregnant and non-pregnant women were closed their nose by using nose clip and breathed out through the mouthpiece as forcibly as possible to obtain airflow parameter to make comparison between them.

In this study, an independent sample test is used to make a comparison between the expiration of non-pregnant and pregnant women in the third trimester depending on their airflow test. The one-way analysis of variance (ANOVA) is used to obtain whether there are any statistically significant differences between the averages (means) of two or more independent groups. In this research, it is used to obtain the means airflow parameter of pregnant and non-pregnant women and then draw the mean to facilitate the comparison between these groups.

**Results of Maximum Airflow Meter**

The result of Maximum Airflow Meter is the airflow parameter which is the amount of air that is flowing out of the lungs through the respiratory system during expiration.

In this research observed that there are differences between the values of airflow between the pregnant and non-pregnant women. Results showed that airflow for non-pregnant women are range from 305 to 585 (L/m) and airflow for pregnant women are range from 304 to 388 (L/m). The airflow parameter for non-pregnant women is shown in Table.1 and the airflow parameter for pregnant women is shown in Table.2.

**Statistical Analysis**

SPSS is a software program used for statistical analysis of the results obtained in the research; it is used to run the t-test and one-way ANOVA. The t-test is used to make a comparison between the means or an average of two different groups and explain if these differences are significant or occur by chance.

Conclusion

- This research confirmed that there was a significant difference in airflow parameter ($P<0.004$) between pregnant and non-pregnant women.

- In this research observed that there are decreases in the values of airflow parameter in the third trimester of pregnancy this decreases in airflow value is due to a reduction in the compliance of the lungs because of enlarges the chest wall circumference during pregnancy and causes limited expansion of the lungs.

Effect of An Educational Program about Polycystic Ovarian Syndrome on Knowledge of Adolescent Female Students

Salwa H Almukhtar
Department of Clinical Nursing Sciences, College of Nursing, University of Mosul, Mosul, Iraq

Abstract

Background: Polycystic Ovarian Syndrome (PCOS) is a problematical disorder with various presentations. The disorder, however, can be treated carefully and efficiently to aid the female student patients to increase their fertility and lead healthy lives.

Objective: The objective of this article is to evaluate the impact of an educational program on the knowledge of adolescent female students about PCOS.

Methodology: A quasi-experimental design was conducted at the College of Nursing University of Mosul for the period 16th to (19th) February 2018 on sixty female students who were divided randomly into two groups (study=30 and control=30). Before implementation of the EP, both groups were exposed to pretest. Only the study group was enrolled in the EP. After one week both groups were exposed to the post-test.

Results: Before implementing the EP both groups show low levels of knowledge regarding POCS. After one week of the implementation of the teaching program the study group shows improvement in their knowledge scores about all knowledge categories related to POCS. Statistically significant difference was found between students’ age and family factor with their knowledge at pretest.

Conclusions: The EP had a positive impact on students’ knowledge concerning POCS. The study recommends that further education programs regarding POCS should be implemented in multi-setting on different target populations in order to generalize the outcomes.

Key Words: Adolescent Female, Educational program, polycystic ovarian syndrome POCS.

Introduction

Adolescence is one of the most dangerous stages in which a human passes through his various stages characterized by constant renewal and progress in the ascension towards human perfection. The vulnerability at this stage that moves women from childhood to adulthood is the changes in the various manifestations of growth (physical, physiological, mental, social, emotional, religious and moral), and the human being is subjected to multiple conflicts, both internal and external [1-4]. Polycystic ovarian syndrome (PCOS) is a very common endocrine disorder affecting about 5-10% of women of the real causes of the syndrome does not have childbearing age. Carefully identified, presentation symptoms vary greatly from case to case, making it challenging for doctors to diagnose them [5-8]. Primary signs and the syndrome of POCS are irregular or absent menstrual cycles, increased secretion of androgen, male hair growth, and abnormal morphine. It is challenging to diagnose PCOS because women do not always show all symptoms. It is associated with varying degrees of abdominal obesity, insulin resistance, and other risk factors for chronic diseases including dyslipidemia, hypertension, and increasing levels of pro-inflammatory signs [9-10]. The causes of PCOS are still unknown. However, it is concluded that PCOS is a large-scale
metabolic disorder that extends beyond patients to excess fertility and androgen [11-14]. Recently, it was observed that there is an increased prevalence rate of PCOS and it has short- and long-term effects on physical and mental health, as well as costs on the health-care system. However, these rapid changes are having a serious effect on women’s health, one may ask why there is a lack of awareness about the syndrome Polycystic Ovaries [15-21]. Education is one of the overall strategies to promote public health. It is therefore more important to establish an awareness program on adolescent polycystic ovary syndrome to identify early signs of PCOS. The researcher was motivated to conduct an educational program to increase the knowledge of adolescent girls about PCOS. The main goal of the current study was to determine the effect of an educational program upon the nursing student knowledge regarding PCOS.

Methodology

Research Design

A pretest post-test quasi-experimental design was carried out in the current study for the period of 16th to 20th of April, 2018.

Study Setting

The study was conducted in the College of Nursing/University of Mosul at Mosul City, Iraq.

Population and Sampling Strategy

The initial sample consisted of Sixty (60) students. All of the participants were aged between 18 and 19 at the beginning of the study. The students were divided into two equal groups (study group = 30 and control = 30 participants) using the simple random sampling technique.

Inclusion and Exclusion Criteria

Data Collection Procedures

The interview sheet was constructed by the researcher to gather information interrelated to the sample’s socio-demographic characteristics like age in years, level of parent’s education, menarche history, menstrual regularity family history, and source of information. Forty questions were adopted to examine students’ knowledge regarding PCOS and covered general concepts—etiology-risk factors, signs and symptoms, and types of disease. Participant responses to the knowledge questionnaire were scored and the correct responses were given (one) and wrong answers were given (zero). For each category of knowledge, a mean score was calculated. The structured educational program includes introduction of polycystic ovarian syndrome, causes and risk factors, diagnosis, and complication and management of polycystic ovarian syndrome. The study instruments and EP were tested for validity and reliability.

Data Analysis

Data were entered into a PC file; using Statistical Package for the Social Science (SPSS, version 22) in statistical analysis. Two approaches were applied, Descriptive Data Analysis, an approach that is employed through calculation of Frequency, Distribution, Percentage, Mean of Score and Standard Deviation and Inferential Data Analysis, calculation of the Independent Samples test (t).

Ethical Clearance: Prior to commencing the study, an ethical clearance was sought from the relevant authorities. The participants were informed of the importance and purpose of the study and their verbal and written consent were taken before conducting the data collection.

Results

The differences between pretest and post-test are highlighted in Table 1. Paired t-test was performed to assess the effectiveness of the EP on PCOS knowledge. For the study group the observed value (15.1) was higher than the tabulated value (df 29 = 1.8) at (p< 0.05). The mean post-test knowledge score was (52.1±3.1) significantly higher than the mean pretest knowledge score (17.2±2.7). For the control group the “t” observed value (1.2) was lower than tabulated value (df 29 = 1.8), which means that the EP was impactful in enhancing the knowledge of adolescent females regarding PCOS for the study group. Table 3 shows the differences between pretest and post-test knowledge scores of adolescent about Polycystic Ovarian syndrome. The “t” test was calculated to this purpose. Further statistical tests revealed that scores in post-test in all categories were significantly increased as compared to pretest knowledge scores.

Discussion

PCOS is a common condition affecting 20% of females of childbearing age. The percentage is increasing continuously and significantly, however, these rapid changes are having a serious effect on women’s health which requires finding solutions and efforts to this problem. The students’ knowledge on PCOS was estimated at pretest, the study showed that highest of the students had low level of knowledge and only 7.3% of students had respectable knowledge. This deficiency of knowledge concerning PCOS may be due to students not obtaining sufficient facts related to PCOS. The results presented in table demonstrated that the education program effectively upgraded and promoted the knowledge of teenage females concerning PCOS. These results also confirmed in the study conducted by Mohammed A which showed that the mean post-test scores after the educational program were significantly higher compared to mean scores in pretest. The findings of the current study are consistent with those of Tamilarashi B, Vathana V which indicates increase an in knowledge score after implementing a structured teaching program. These findings further support the article of Patel K who stated that strategic intervention sessions enhanced the knowledge of adolescent females. This also accords with an earlier observation, which revealed that post-test scores were higher than pretest scores. Therefore, it was verified that the structured teaching program did improve the knowledge of adolescent females. The findings observed in this study mirror those of the previous study that have examined the effect of educational intervention on female Sciences student knowledge about PCOS. The students (82.9%) who had the largest deficit in their knowledge about PCOS were enrolled in an educational program and after that all of them were knowledgeable about PCOS. Finally, the present findings seem to be consistent with other research which found highly statistically significant improvement in nurses’ knowledge immediately after program implementation, as significant differences were found between the mean pretest and post-test knowledge score.
Conclusions and Recommendations

The study concluded that the EP had a positive impact on students’ knowledge concerning POCS. Based on the findings of the current study, the researcher recommends the importance of adopting educational programs that help teenage females acquire adequate information about PCOS. The researcher also believes that the study should be reapplied to a variety of female groups of society to generalize the study outcome.

Improving Treatment Compliance with Hypertension Patients Involving Family Role

Semuel Tambuwun¹, Lucia Moningka¹, Yourisna Pasambo¹, Onlyta Nelvi Rompas¹

Health Polytechnic Ministry of Health Manado, Indonesia

Abstract

The role of the family is very important in every aspect of the health of family members, in the process of monitoring, maintaining and preventing complications of hypertension. This study aims to determine the relationship of the role of the family with treatment compliance with hypertensive patients. The results showed that treatment compliance of hypertensive patients increased with increasing family role (p <0.05). It is expected that the health center can make a program to improve the role of the family in the treatment of hypertensive patients so that it can improve treatment compliance for hypertensive patients.

Keywords: family role, medication adherence, hypertension patients.

Introduction

According to the World Health Organization (WHO) Hypertension or high blood pressure is an increase in per system pressure in the arteries, where systolic blood pressure is above 140 mmHg and diastolic pressure above 90 mmHg. Hypertension contributes to almost 9.4 million deaths from cardiovascular disease every year ¹⁴. The national hypertension prevalence based on 2013 risk is equal to 25.8%, the highest in the Bangka Belitung Islands (30.9), while the lowest in Papua is (16.8). Based on these data, from 25.8% of people with hypertension only 1/3 were diagnosed, the remaining 2/3 were undiagnosed. Data shows only 0.7% of people diagnosed with high blood pressure do not take hypertension medication. This shows that most hypertensive sufferers are not aware of suffering from hypertension or getting treatment.

One indicator of the health status of a family in the implementation of the Healthy Indonesia program is that hypertension sufferers take medication regularly. The healthy Indonesia program through a family approach emphasizes the importance of the role of the family in health development. According to the data of the Ministry of Health (Kemenkes) of the Republic of Indonesia, there are 75% of families suffering from hypertension but not taking medication ²⁰.

Based on preliminary data obtained at Kawangkoan Health Center, North Kawangkoan Subdistrict, Minahasa Regency, from January to October 2017 there were 104 hypertensive patients, 64 of whom did not come to control and discontinued medication, but previously diagnosed, 40 other patients came obediently to the puskesmas. The survey results on November 8, 2017 during interviews with 10 hypertensive patients who came to the Kawangkoan Health Center from interviews with 3 patients delivered by their families and routinely treated the puskesmas once a week, 4 patients had a low level of adherence and rarely controlled treatment on the grounds that they stated not feeling any complaints back / feeling healthy, 3 other patients forgot to remember the time of treatment control because they were busy with their activities or work.

The role of the family is very important in every health aspect of his family members, in the process of monitoring, maintaining and preventing the occurrence of complications of hypertension. In addition, the role of the family is able to improve the compliance of hypertensive patients in undergoing treatment⁷.
The formulation of the problem in this study is whether the family plays a role in improving compliance with treatment for hypertensive patients at the Kawangkoan Public Health Center, North Kawangkoan District, Minahasa Regency?

Material and Method

This study aims to determine the role of families in improving adherence to treatment for hypertensive patients at the Kawangkoan Public Health Center.

The type of research used is analytical survey with method cross sectional. The study was conducted in September 2017 until July 2018 at Kawangkoan Health Center, North Kawangkoan Sub-District, Minahasa Regency.

The independent variable is the role of the family and the dependent variable is compliance with treatment for hypertensive patients. The family role is measured using a questionnaire consisting of 12 questions, with good role categories (≥ 80 - 100%) and poor roles (<79%). Medication compliance for hypertensive patients was measured using a questionnaire consisting of 22 questions, with obedient categories (≥ 75 - 100%) and non-compliance (<75%).

The population in this study are families that have family members who suffer from hypertension in January-October 2017, amounting to 104 patients. The sampling technique used was purposive sampling, ie samples taken intentionally or planned by researchers. Obtained a sample of 50 people.

Data collection was carried out after obtaining permission from the head of Kawangkoan Health Center. Researchers waited for hypertension patients to come to visit the health center, then the researcher explained the purpose of the study and gave informed consent. After obtaining approval from the respondent, blood pressure measurements were taken and questionnaires were distributed to respondents to be filled. Data obtained through the next questionnaire were obtained using univariate analysis and bivariate analysis. Statistical analysis using software namely SPSS for windows and using the chi-square statistical formula with a degree of significance (α) <0.05, and a significant level of > 95%.

Finding

Distribution of Hypertension Disease

Based on the frequency of hypertensive patients, it was found that from 52 samples of hypertension patients found the highest with 23 people (53.8%) at moderate hypertension, while the lowest with 10 people (21.2%) at the level of hypertension light.

The Role of the Family on Medication Compliance with Hypertensive Patients

From the analysis of the relationship of the role of the family with medication treatment for hypertensive patients above it was found that some of the roles of the family were poor and categorized as noncompliant with 14 respondents (70.0%), for which the role of the family is poor and obedient in treatment there are 6 respondents.
(30.0%), while the role of the family is good and non-compliant, there are 8 respondents (25.0%) and the role of the family is good and obedient to treatment 24 (75.0)

**Conclusions and Recommendations**

Based on the results of the study showing that 52 families were found that some of the roles of the family were not good and categorized as non-compliant, there were 14 respondents (70.0%), whose family roles were not good and were there were 6 respondents (30.0%), while the family role was good and non-adherent, there were 8 respondents (25.0%) and the family’s role was good and obedient to treatment 24 (75.0%). From the results of statistical tests using the chi-square test, the p-value = 0.001 means that p-value <0.05, so Ho is rejected and Ha is accepted. This shows that there is a significant relationship between the role of the family and compliance with treatment for hypertensive patients at the Kawangkoan Health Center, Kawangkoan sub-district, north of Minahasa district. So it can be concluded that if the family role is good then compliance will be higher.

**Discussion**

This study is in line with previous research conducted by Agnes, et al. (2015). It was found that most of the family roles were poor and categorized as non-adherent treatment with 19 respondents (29.7%), whose family role was poor and obedient to treatment with 4 respondents (6.2%), while there are 6 respondents (9.4%) who have good and disobedient family care, and those who have a good family role and adhere to treatment there are 35 respondents (54.7%) from the results of statistical analysis using the test The chi-square value obtained \( p = 0.000 \), which means that the p value is smaller than \( \alpha \) (0.05). There is a relationship between the role of the family and adherence to treatment for hypertensive patients at the Kawangkoan Health Center, Kawangkoan sub-district, north of Minahasa district.

The results of this study are supported by the theory of Young and Busgeeth, (2010) illustrating that the role of families in providing care at home can reduce morbidity and mortality in patients. It was also explained that the role of the family is able to improve patient compliance. Family support can improve patient adherence to treatment 14.

According to researchers, families can be a determinant of the success or failure of treatment carried out by someone in undergoing a treatment because the family can be very influential in determining the beliefs and health values of individuals and can also determine about the health programs they can receive.

The results showed that family members who gave good support and showed caring attitudes to family members suffering from hypertension had an important role in adherence to treatment. According to researchers, the attention of family members ranging from delivering to health services, helping with medical treatment, reminding them to take medication, proved to be more obedient to undergoing treatment compared to hypertensive patients who received less attention from family members.

The results of this study are supported by previous research conducted by Triyani, et al. (2013) stating that there is a significant relationship between family support and adherence to treatment of hypertensive patients in Ngaliyan Semarang Public Health Center, compliance with treatment for hypertensive patients in Ngaliyan Semarang Public Health Center is 37 patients (52.9%).

The results of this study are also supported by the theory of Palmer & William, (2007) that treatment adherence to hypertensive patients is important because hypertension is an incurable disease but must be controlled or controlled so that complications do not result in death10.

**Conclusion**

The results of this study are expected to contribute positively to improving treatment compliance for hypertensive patients. It is expected that the health center can create a program that can increase the family’s understanding of the importance of support and what forms of support can be given to families to improve treatment compliance for hypertensive patients.

**Conflict-of-Interest Statement**

In this study between researchers and research, subjects have no conflict of interest, because they do not have personal relationships or informal relationships with researchers.

**Source of Funding:** The source of funds in this study is independent funding from the research team.
**Ethical Clearance:** Ethics of this research were obtained from the Ethics Polytechnic Commission of the Ministry of Health of Manado, Manado, Indonesia.

The Role of Inflammatory Markers in the Development of the Osteoporosis in Women after Menopausal

Rusul Ali Al-Masaoodi¹, Alaaualdeen S.M. Al-Sallami², Hamadallah AL-Baseesee³

¹Physiology and Endocrinology, Collage of Medical Techniques, The Islamic University, Iraq,
²Faculty of Science, University of Kufa, Iraq, ³Faculty of Medicine, University of Kufa, Iraq

Abstract

Background: Osteoporosis is a porous bone. It is common disease of bones, and causes insufficient bone formation or loss of bone mineral density(BMD), making the bones more susceptible to fractures. The aim of the current study is to determine the role of inflammatory makers in women with osteoporosis after menopausal ,this biomarkers include the ; Interleukin-1β(IL -1β)and Resistin.

Patient and Method: According to case-control study. This study was conducted at DEXA (dual-energy x-ray absorptiometry) Unit in Radiology Department in Al-Sader teaching hospital in AL-Najaf province / Iraq from to know the prevalence of osteoporosis in Iraqi menopausal women. A total number of the study include (88) women involved in this studyp. IL -1β , Resistin and estrogen were measurement by using a solid phase enzyme-linked immunosorbent assay (ELISA).

Result: In current study showed a significant decrease (p< 0.05) in level of serum estrogen, calcium and phosphorus in menopausal women with osteoporosis compared with healthy group. The biomarker show a significant increase (p< 0.05) in the concentration of IL-1β and Resistin in menopausal women with osteoporosis compared with healthy group.

Conclusion: In this study found the role of immunity after menopausal and relation to osteoporosis through measured the level of IL-1β and Rsisten which increase after menopausal and activation of the bone resorption.

Keyword: resistin, Menopausal, estrogen (E2) , IL-1β, BMD.

Introduction

Osteoporosis (OP) is a osteometabolic chronic, progressive disease characterized by a deterioration of bone microarchitecture and reduction in bone mineral density(BMD), which leading to mechanical fragility and ready to spontaneous and traumatic fractures¹. The causes of osteoporosis is increase breakdown of bone structure, decrease in bone formation, or an imbalance between the activity of bone cells responsible for bone remodeling, which excessive the number or activity of osteoclasts and reduction in number or activity of osteoblasts². Postmenopausal women considered most cases of osteoporosis due to estrogen deficiency. Fractures of osteoporosis occurs in spine and hip therefore considered high morbidity and mortality¹. Fractures in osteoporosis affect the muscle and the skeletal systems, cause loss of functional capacity, chronic pain, and compromise quality of life¹. Menopause is an irreversible and universal process, that result from loss of ovarian sensitivity to gonadotropin stimulation , this part of the overall aging process⁵.

The immune system has a strong association with bone metabolism⁶. For example, interleukin (IL)-6 promotes osteoclast differentiation and activation⁷. IL-1 is another potent stimulator of bone resorption⁸. The IL-1 family of ligands includes 11 members and among them IL-1β emerged as the primary therapeutic target for an expanding number of inflammatory conditions. The inactive IL-1β precursor is cleaved by caspase-1 via a protein complex called inflammasome into an active cytokine, IL-1β binds type I (IL-1RI) and type II (IL-1RII) specific receptors⁹. IL-1β is a strong stimulator of
in vitro and in vivo bone resorption. IL-1β upregulates the production of RANKL enhancing its activity and stimulating osteoclastogenesis. IL-1β also regulates the production of osteoprotegerin (OPG), a natural inhibitor of RANKL. OPG inhibits osteoclast differentiation by binding RANKL. IL-1β increases prostaglandin synthesis in bone.

Human resistin is a 12.5 kDa cysteine rich peptide with a mature sequence composed of 108 amino acid. The site of resistin gene found on chromosome 19, Human resistin plays important role in the regulatory of inflammatory response, during which macrophages, peripheral blood mononuclear cells (PBMC), and vascular cells are the primary targets of resistin. Resistin regulation of expression of pro-inflammatory cytokines such as TNF-α, IL-6, IL-12, and monocyte chemoattractant protein (MCP)-1 in PBMCs, macrophages, and hepatic stellate cells via the nuclear factor-κB (NF-κB) pathway. Resistin expression has also been identified in the non-adipocyte fibrotic livers and atherosclerotic lesions. Moreover, circulating resistin concentration are associated with inflammatory and fibrinolytic markers such as C-reactive protein (CRP).

Material and Method

This study was conducted in the research from Al-Sader teaching hospital in AL-Najaf province from DEXA unit in the Radiology Department, Fractures and Joints Department and in laboratories of Biology Department/ Faculty of Sciences/ University of Kufa, during the period from. The samples tested were 88 samples which divided to control group were 20 samples, 68 samples from menopausal women patients.

Biochemical Parameters

Specific kit for measuring human Calcium and phosphate concentrations in serum by spectrophotometer was supplied by Biolabo SA, France. Another specific kits were using to measuring Interleukin-1β level and Resistin level by ELISA technic supplied by Elabscience Biotechnology, while serum estradiol level supplied by CALBIOTECH, China.

Statistical Analysis:

The well-known statistical system (Graph Pad prism ver. 5) was adopted, and the analysis of variance table one – way anova (by Tukey’s multiple comparisons test) was used for the comparison among subdivided groups in the measured parameters. The results were expressed as (Mean ± Stander Error). The comparison between subgroups was analysed by t-test.

Results

The results in figure 1 and 2 reveal statistically significant differences of menopausal women with osteoporosis compared with Healthy group, there was significant decreased (p<0.05) in BMD and t-scores in (MO) compared with Healthy group in menopausal women.

![Figure 1: BMD and T-scores in spin between menopausal women with osteoporosis group and healthy group.](image)

![Figure 2: BMD and T-scores in right femur between menopausal women with osteoporosis group and healthy group.](image)

Table 1 revealed significant differences in minerals and hormonal between MO and healthy groups, that show significant decrease in the E2, Ca and Pi. The significant was found (the mean values ± the standard errors) in the serum. The results in figures 3 and 4 exhibit significant increase (p<0.05) in serum levels of RETN and IL-1β in POM group compared with in HT group.

Discussion

The results of the study revealed that the bone density data from a DEXA scan are reported as decrease in BMD and T-scores in menopausal women with osteoporosis when compared to healthy women. In this study shown an age-dependent decrease in BMD was seen in women in age groups and most in postmenopausal age were found to have low BMD of osteoporotic range; This result is similar to20,21. The study of 22 showed the major determinant of bone strength was bone mass and, after reaching peak values in the third decade of life, bone mass and density begins to decline until age 60-6522.

The age 56–60 and 46–50 years which notice in women a quick reduced in BMD, with a maximum bone reduction occurring at 51–55 years, and a decelerated reduced in BMD after 56–60 years23. This study noticed that the DEXA, which gives criteria for the diagnosis of osteoporosis and the related with risks fractures24. In this study show the DXAE most common test to diagnosis of the osteoporosis but not show the reason of the osteoporosis, therefore; suggest using the biochemical test. The results of this study have revealed a significant decrease (P<0.05) in serum estrogen in menopausal women with osteoporosis more than healthy women. This result agree with 25, 26,27.
In the menopause, estrogen concentration rapidly decreases, therefore women have a hypo-estrogenic state\textsuperscript{28} consequently, the exposure to estrogen during these key periods may dramatically affect a woman’s bone health\textsuperscript{29}. The estrogens are able to block bone resorption through two mechanisms: both by direct interaction with osteocytes and osteoclast and by regulation of T-cell and osteoblast formation and activity\textsuperscript{30,31}. The common effects of estrogen deprivation lead to an obvious induced of bone resorption and a period of quick bone loss that is major for the beginning of osteoporosis in postmenopausal\textsuperscript{32}. Combined effects of estrogen deprivation cause a marked stimulation\textsuperscript{33}. The results of this study have revealed a significant increase (P<0.05) in serum IL-1β. Pro-inflammatory cytokines (IL-1β and IL-6) were significantly elevated in patients than controls, consistent with other studies that induct the association between osteoporosis and inflammation\textsuperscript{34}. Inflammatory cytokines produce from the Innate and adaptive immunity cells which not only perpetuate inflammation but also may activate bone degradation and inhibit bone formation and causes diseases in women before menopause\textsuperscript{41}, the degree of the inflammation correlates with the extent of local and systemic bone loss\textsuperscript{35}. Pro-inflammatory cytokines may participate to bone loss by osteoclasts which activated by receptor activator of nuclear factor κB ligand (RANKL) leading to osteoporosis\textsuperscript{36}. Target cell for IL 1β is the osteoclast that provides an important stimulus the formation and activity of osteoclasts, resulting to elevated bone resorption, found of osteoblast and stromal cells was critical in the formation of osteoclasts by IL-1β\textsuperscript{37}. IL-1β may also act in the formation of osteoclasts by nuclear factor kappa-light-chain-enhancer of activated B cells and prevents its apoptosis\textsuperscript{38}. Resistin play a role in bone remodeling\textsuperscript{39}. The study have observed moderate correlations between resistin and a marker of increased osteoclast activity\textsuperscript{40}. Resistin have important role in bone metabolism by stimulating osteoblast and osteoclast differentiation, possibly through the nuclear factor kappa B (NF-kB) pathway\textsuperscript{41}.

The loss of ovarian function lead to deficiency estrogen in postmenopausal women which promote signaling and gene expression cascade of major pro-inflammatory cytokines that directly induce early osteoclast precursor formation\textsuperscript{42}.

Significance Statements

In this study found the role of immunity after menopausal and relation to osteoporosis through measured the level of IL-1β and Rsisten which increase after menopausal and activation of the bone resorption. This study is the first clinical study in Iraq.

Conflict of Interest: There was no any conflict of interest in this study.

Funding: There was no fund in this study.

Ethical: There was no conflict of interest in this study.

The Relation Between Serum Concentration of High Mobility Group Box-1 Protein with Some Criteria in Metabolic Syndrome Patients

Shumoos H - Alwaid¹, Arshad Noori Al-dujaili²

¹Medical Laboratory Department, Collage of Medical Technology, The Islamic University, Iraq,
²Biology Department, Collage of Science, University of Kufa, Iraq

Abstract

Metabolic syndrome (MetS) is a worldwide distributed public health problem and its incident in increase. (MetS) is characterized by clustering of several metabolic abnormalities, including central (intra-abdominal) obesity, dyslipidemia, hyperglycemia, and hypertension. The ultimate importance of this cluster is to identify individuals at high risk of both type 2 diabetes and cardiovascular disease. High-mobility group box-1 protein (HMGB1) plays an important role in alarming of inflammation and immunity response processes. The aim of the current study is to evaluate the serum level of high mobility group box-1 protein (HMGB1) biomarker levels in MetS patients regarding to MetS risk factors, age, gender and BMI.

Method: This study was conducted at Diabetes and Endocrinology Unit in Al-Sader Teaching Hospital in AL-Najaf province /Iraq from January2018 to July 2018 to know the prevalence of metabolic syndrome patients who attended the hospital for monthly checkup. A total of the (130) participant involved in this study, blood samples had been taken from the (90) metabolic syndrome patients (50 female and 40 male), and from (40) individual who were apparently healthy as a control group. The age, gender, WC and BMI of patients and control is taken during physical exam lipid profile and blood glucose also estimated for all groups. HMGB-1 protein biomarker in serum was measured by using a solid phase enzyme-linked immunosorbent assay (ELISA).

Result: The result of the current study have revealed a significant increase in concentration of serum HMGB-1 in MetS compared to healthy group. There was significant increase in the serum concentration of The HMGB-1 in Mets female group compared to in Mets male group. In regard to BMI, the results indicated a significant difference (p>0.05) in serum HMGB-1 concentration at different BMI (over and obese weight) between female and male Mets patients respectively in same the BMI. Regarding waist circumference, significant increase has been found in serum level of HMGB-1 in Mets patients.

Keyword: Metabolic syndrome (MetS), high mobility group box-1 protein (HMGB1), age , gender , BMI, waist circumference and lipid profile

Introduction

The metabolic syndrome (MetS) is a collection of several metabolic abnormalities, including central obesity, dyslipidemia and hypertension. The individuals with three of these abnormalities are at high risk of both type 2 diabetes and cardiovascular disease (CVD) (¹). MetS is also a state of chronic low-grade inflammation as a consequence of complex interplay between genetic and environmental factors (²). Since obesity is associated with a chronic low-grade inflammation and inflammatory pathways could be critical in the mechanisms underlying obesity-related metabolic diseases (³). In addition to adipocytes, other cells located in adipose tissue such as endothelial cells, fibroblasts, and immune cells may

Corresponding author:
Arshad Noori Al-dujaili
E-mail: arshad.aldujaili@uokufa.edu.iq
secrete inflammatory peptides and chemokines. In particular, high-mobility group box-1 protein (HMGB1), a 30 kDa nuclear and cytosolic ubiquitous protein, is actively secreted by innate immune cells and it has been shown to stimulate necrosis-induced inflammation (4). The proinflammatory cytokines promote inflammation and insulin resistance acting in autocrine, paracrine, and endocrine manners in adipose and other target tissues (5).

Previously, it has been shown that HMGB1 interacts with toll-like receptor 2 (TLR2), TLR4, and the receptor for advanced glycation end products, (RAGE) inducing immunostimulatory and chemotactic responses and triggering receptor expressed on myeloid cells (TREM)-1 (a cell surface receptor) is recognized as a potent amplifier of acute and chronic inflammation plays an important role in the pathogenesis of chronic inflammation (6). It has been recently proposed that HMGB1 may represent a diagnostic marker for obesity-related complications in children. Moreover, obesity is associated with an increased expression of HMGB1 in subcutaneous adipose tissue (4). Elevated HMGB-1 levels in serum have been found in acute inflammatory conditions. HMGB1 is found to be released from cell to act as a damage associated molecular pattern (DAMP) (7).

Since TLRs and RAGE belong to a family of pattern recognition receptors (PRRs) which recognize (DAMPs), that is strongly involved in insulin resistance and (T2DM) (8). Chronic inflammation in obesity may lead to insulin resistance and TREM-1 may play a potential role in inducing obesity IR (9). MetS also resulting from chronic exposure to elevated levels of free fatty acids and lipopolysaccharides which stimulates TREM1-induced activation of TLRs receptor cascade in lipid rafts lead to more HMGB1 associated with TREM-1, TLRs and RAGE (10). Hyperlipidemia and dyslipidemia may involved directly in the inflammation process and mediator in atherosclerotic coronary artery diseases (11). In the current study we aimed to do further investigation about the relation between high level of HMGB-1 protein and MetS risk factor hyperlipidemia, dyslipidemia, obesity and hyperglycemia in regarding to age and gender of Iraqi metabolic syndrome patients.

Material and Method

Patient and control groups

A total of 130 participants were enrolled in this study. In particular, 90 patients subjects 50 women divided according to age to (13 mean age 40-49 year), (25 mean age 50-59 years) and (12 mean age 60-69 year) and 40 men who also divided according to age to (10 mean age 49-59), (20 mean age 50-59 year) and (10 mean age 60-69 year) who had been previously diagnosed with metabolic syndrome by physicians at the Endocrinology and Diabetes Unit at Al-Sader Teaching Hospital in AL-Najaf province / Iraq and they were attended the center regularly for monthly check up, during the period from January 2018 to July 2018. According to BMI patients subject divided to over, morbid and obese and according to W.C subject divided to three group; (100-119 cm), (120-139 cm) and (140-160 cm). Exclusion criteria included: endocrine diseases (other than diabetes or impaired glucose tolerance (IGT)); syndromic obesity; hepatic, infectious; craniopharyngioma. Anti-inflammation drug consuming patient. Forty healthy (20 male and 20 female) were enrolled as controls (control group). Subjects had to be normal weight. Apart from obesity, inclusion/exclusion criteria were identical to those used for the obese group. The study protocol was approved by the Hospital’s Ethics Committee. Written informed consent was obtained from the patients and control.

Blood samples collection

Five ml of venous blood was acquired by antecubital venipuncture utilizing needle drained from Mets and control subjects between 8:30-10 AM following 12 hours fasting. The blood was permitted to clot in plain test tube at room temperature. The serum was suctioned after centrifugation at 3000rpm for 10 min, divided into aliquots in epindroff tubes and stored at -20°C for measurements of levels of glucose, lipid profile and HMGB-1 protein.

Biochemical analyses

Total cholesterol measured use (Biolabo SA, France), (HDL) (Biolabo SA, France), TG concentrations (Biolabo SA, France). Calculation of (LDL) was calculated by this formula: LDL(mg/ml)=TC(mg/dl) − HDL(mg/dl). Calculation of blood glucose by (Biolabo SA, France). Determination of serum High mobility group protein B1 level. Specifickit for measuring human HMGB1 concentrations in serum was supplied by (Biomatik, Ontario, Canada. Catalogue No: EKF57253)
Results

Characteristics of the population

The results in table (1) revealed significant differences in lipid profile between Mets group and healthy group, significantly increased (p<0.05) in serum cholesterol, TG-C and LDL-C compared with healthy group, while a significant decrease (P<0.05) in serum HDL-C concentration of Mets compared with HG. The results of same table revealed significant differences in lipid profile between Mets female group and Mets male group, significantly increased (p<0.05) in serum TGand LDL-C in female Mets group compared with male Mets group, while a significant decrease (P<0.05) in serum HDL-C concentration of female compared with male Mets group.

Statistical analyses

Statistical analysis was performed with IBM SPSS version 23 software by use of the t test. and ANOVA ,P<0.05 was regarded as indicative of statistical significance.

Comparison of HMGB1 level between patients and control

HMGB1 levels were statistically higher in Mets patients than in the control group. The result in figures (1) exhibit significant increase (p<0.05) in serum levels of Hmgb1 in Mets patients groups in compared with in control groups (healthy persons) respectively.

HMGB-1 levels in MetS female patients and MetS male patients groups

The result in figures (2) revealed a significant increase (p<0.05) in serum HMGB-1, concentration in Mets female group and in compared with in Mets male group respectively.

Comparison of HMGB1 among different age groups of Mets patients.

The results of figure (3) reveal there is significant increase in serum Hmgb1 level in Mets female patients when compared with Mets male group at same age group.
in (40-49y) and (60-69y), and there is no significant difference (p<0.05) in serum Hmgb1 in Mets female patients when compared with Mets male group at same age group in (50.59y). Also, the same figure showed there is no significant difference in serum Hmgb1 level Mets when compare among different ages (40-49y) (50-59y) (60-69y) in female group and male group.

Comparison of HMGB-1 among different body mass index (BMI) groups of Mets patients.

The results of figure (4) indicate there is a significant difference (p>0.05) in serum HMGB-1 concentration at different BMI (over and obese weight) as compared between female and male Mets patients in same BMI while there is no significant difference between the female and male patient groups in morbid weight of BMI. The same figure showed there is a significant difference (p>0.05) in serum HMGB1 concentration as compared between different BMI (over and obese weight) of female patients groups.

Comparison of HMGB-1 level among different waist circumference groups of Mets patients.

The results of figure (5) reveal there is significant increase in serum, Hmgb1 level in Mets female patients with WC between (140-160 cm) as compared with the male patient in the same WC. The same figure also showed significant deference in Hmgb1 level Mets male with WC between (100-119 cm) as compared with Mets male group with WC between (120-139 cm).

Discussion

The present study indicates an elevation of HMGB1 serum level of Mets patients in comparison with healthy group. According to study by Jilal et al (13); HMGB1 significantly increased in MetS patients in compared with control which secreting from adipose tissue for Mets patients and these engage to the TRLs found in these tissues and other tissue that contributing to the pro-inflammatory state and insulin resistant state. Another previous study has been shown that adipocytes of obese individual undergo regular necrosis upon stressful damage, leading to releasing of cellular contents like HMGB-1 more HMGB1, leading to recruitment of additional immune cells, and induces adipocyte death. HMGB-1 play important role in the maintenance of long-term inflammatory state in adipose tissue (14). The present study revealed a significant increase in serum HMGB1 among female MetS patients in comparison with Mets male patients with in the same age group in (40-49y) and (60-69y), A cording to study by Vitseva et al; (15) demonstrate that TLRs are inducible in adipose tissue of obese women with high BMI and associated central obesity with high waist circumference in age group (40-50y) and that why HMGB1 level is higher in women at this age groups.

The results of this study also indicate there is a significant difference (p>0.05) in serum HMGB1 level at different BMI (over and obese weight) as compared between female and male Mets patients in same BMI. And between female patient groups there’s a significant
different also indicate. HMGB-1 was found to be dependently correlated with BMI which in turn correlated with age and gender\(^{(4)}\). This study showed there is an elevation in serum, HMGB1 level in Mets female patients with WC between (100-119cm) and (120-139 cm) as compared with the male patient in the same WC while a significant deference in HMGB1 level of Mets male with WC between (100-119cm) as compared with Mets male group with WC between (120-139 cm). According to Wang et al Plasma HMGB1 levels were higher in obese subjects than those subjects with normal weight and were positively correlated with waist hip ratio(WHR) and waist circumcises\(^{(16,17,18)}\).

**Conclusion**

The present study provides that HMGB1 biomarker is strongly correlated with some of MetS risk factors like; (BMI, WC, Lipid profile, Glucose level) in regarding to age and gender and also demonstrated that women population is more effected with MetS risk factors than men population in our community. HMGB1 may be considered as good biomarker for diagnosis and detect early symptom of metabolic syndrome and also can-do further research for consider HMGB1 as pharmaticular target for limitation of MetS risk factors threatening on public health.

Abstract

Background: This study aims to analyze the impact of pollution of batik wastewater on dug well water in the center of the batik industry in Pekalongan City. The significant result of the coloring process with synthetic/chemical dyes containing heavy metals. One of the dominant heavy metals in batik waste is lead (Pb). Puddles of waste on residential settlements have the potential to pollute the environment in the event of infiltration and enter into community wells.

Methodology: This research is descriptive analytic with quantitative methods with cross-sectional approach. This study explored the source of Pb heavy metals from the start of waste, wastewater, well water. The waste samples were taken from the beginning of the batik industry site along with the pool of waste around 67 waste samples.

Results: The level of pollution of batik wastewater to the dug well water was quite high, as much as 60.5% of dug well water contained Pb exceeding the maximum permissible limit. It is recommended to prioritize the handling and management of batik industry waste starting from the source of batik producers.

Conclusion: There is a total of 29.9% of the pool of wastewater in open channels of residential settlements has a Pb content exceeding the specified wastewater quality standard.

Keywords: lead waste, batik, well water, heavy metal

Introduction

One type of industry that has the potential to pollute the environment is the batik industry. The batik process in the batik industry includes the stages of painting, night closure, coloring, breakdown, washing, and drying using raw materials of gray cloth, synthetic dyes, wax/night, energy and water. Each household batik industry on an average per year uses 10,950 kg of batik wax, gray cloth 182,880 meters, H₂O₂ 1600 Liter, boarding 2000 Kg, Teepol 200 Kg. The batik production process for household scale requires an average of 15,000 liters of water, 10 liters of kerosene. Whereas for a year the wax is wasted 12.5%, the product fails 9,144 meters, H₂O₂ is scattered 200 Liters, Kostik is scattered 24 Kg, wastewater 80% of the water used, Teepol is scattered 10 Kg, coloring agent 50, 4 Kg. Still, very little industry batik which uses natural dyes that do not pollute the environment.

According to data from the Jenggot Village, there were 905 households (82.95%) out of 1,091 homes that used dig well as a source of clean water. The researcher has carried out preliminary research by taking 15 water samples from dug wells located in residential locations that are located near five inundation points of wastewater in the sewers in the settlement. From several parameters that are directly related to health, namely Cd, Total Cr, and Pb, only Lead content (Pb) exceeds the quality standard for both wastewater and clean water. The Pb level in the wastewater in the ditch inundation

DOI Number: 10.5958/0976-5506.2019.02040.0
reaches > 0.7 mg / L and the Pb level in the well water reaches 0.04 mg / L from the standard quality set at 0.01 mg / L. This shows the real existence of environmental pollution in the area of Jenggot Village, mainly related to heavy metal Lead (Pb). Whereas as a source of drinking water, the quality of groundwater in these shallow wells must meet drinking water quality standards based on Regulation of the Minister of Health No. 492 of 2010.

Based on the results of the preliminary study, it is necessary to study the effect of batik wastewater that is directly discharged to the environment on decreasing groundwater quality due to Pb heavy metals in dug wells located in the center of Jenggot Village batik industry, Pekalongan Selatan District.

**Method**

The study was carried out at the Jenggot Batik Industrial Center in Pekalongan City, Central Java Province. The study was conducted in 7 (seven) months from October 2017 to April 2018.

This research is a type of descriptive research analytic with a quantitative approach. The quantitative approach is carried out by using the Cross-Sectional survey method in the form of research in the field to obtain the value of several variables in the form of facts from existing symptoms and to find factual information in the Batik Jenggot Industrial Center. Sampling is done using the Purposive sampling method. The sampling technique chosen in this study based on consideration consists of types of industries. For all types of batik industry to be represented, a sample of 67 batik industries were selected as research samples.

**Results**

Out of the 67 batik industries that have the most are Printing batik industry of 20 sectors (29.9%) in addition to printing and screen printing with the same amount of 12 (17.9%) respectively. The variety of types of products from the existing batik industry also results in differences in the use of production materials, especially the coloring materials used. Most of them used synthetic or chemical dyes. Besides, some use a trademark, and some use more than two types of brands. Based on preliminary table research, it shows that almost the entire batik industry in Jenggot (95.53%) of producers dispose of their waste directly into residential settlements without being processed first.

Table 1. Wastewater category based on Pb content

Table 2 above shows that as many as 25.4% of wastewater is discharged directly into settlement channels by the batik industry exceeding the specified wastewater quality standards. Based on the table according to the Decree of the Minister of Environment Number 115 of 2003, it shows that the wastewater falls into the category of heavily polluted because of the number > 10. This result shows that the wastewater does not meet as a water source for the category I to IV water classes.

The existence of puddles of batik wastewater on residential settlement channels indicates contamination in water sources, especially dug well water which is around the pool of wastewater. This is due to the process of infiltration of contaminants into the soil. For this reason, a sample of dug well water is taken around the pool of waste from the closest distance to the furthest. Each inundation point is taken at least three samples.

</table>

From table 3 shows that as much as 60.5% of dug well water has Pb exceeding the maximum permissible limit. The average Pb level in well water of 0.0316 mg / L indicates that the content exceeds 300% of the permissible level.

The measurement results of the Pollution Index on the content of the digging well water Pb get the number 7.47, indicating that the pool of wastewater falls into the medium polluted category because the number is in the range of 5-10.

Discussion

The batik industry is a very potential industry to produce waste dangerous with heavy metal content which is quite high and causes pollution of the water environment (1). The batik industry wastewater in the Batik Jenggot Industrial Center can be categorized into three, namely stamp batik, writing, and printing or screen printing. The resulting batik waste is known to be very dangerous and contains heavy metals because it uses chemical dyes. The chemical coloring agent is synthetic and will produce liquid waste containing oil and inorganic dyes that are very difficult to decompose (2).

Dyes synthetic material that is commonly used in the batik industry in Jenggot village contains several heavy metals so that wastewater, water puddles on the surface and groundwater polluted by heavy metals, among others: Lead (Pb), cadmium (Cd) and Chromium (Cr). As a result, batik industrial wastewater becomes rich in heavy metal content. Direct disposal of huge waste without treatment in the area around the batik industry location results in soil and groundwater around waste disposal contaminated by heavy metals such as Pb, Cd, and Cr (3).

Lead Content (Pb) in Wastewater Outlet

The results of the analysis of 67 samples of wastewater discharged at outlets in the Jenggot batik industry center showed the results of 25.4% of samples containing lead (Pb) of more than 0.03 mg / L with a pollution index of 13.93. Lead (Pb) is a chemical element that is inorganic in the form of inorganic salts that are insoluble in water, and are toxic (4). Pb ranks first in grouping compounds with significant and toxic effects on human health by the US Agency for Toxic Substances and Disease Registry.

The presence of Pb in a liquid waste can be a severe problem of the human body because Pb is also a systemic poison. Pb poisoning will cause symptoms of metallic taste in the mouth, black lines on the gums, anorexia, vomiting, clicks, encephalitis, wrist drop, irritability, personality changes, paralysis, blindness, and in acute poisoning, will occur meningitis cerebral, followed by stupor, coma, and death. Some previous studies stated that Pb is a type of high priority pollutant found in batik industrial waste (5).

Lead Content (Pb) in Channel Inundation Open.

Based on the results of observations on open channels in residential areas, liquid waste disposed of by the batik industry does not flow well during the dry season resulting in a pool of liquid waste. During the rainy season, the inundation conditions do not cause many problems because wastewater also decomposes in the flow of rainwater. The results of the water quality test in the inundation in the residential settlement channel showed an average Pb content of 0.04 or twice the average Pb content in the outlet, with 29.9% of the waterlogged sample exceeding the specified water quality standard criteria and including in the category of moderate contamination with contamination rates of 7.55. The Pb content in stagnant wastewater in residential channels is higher than that of outlets suspected to be due to continuous accumulation of liquid waste.

The types of industries whose wastes most often pollute groundwater with heavy metals include the metal industry, textile, leather tanning, paint and coloring materials, and the electricity industry. The accumulation of heavy metals in the soil will change the physical and chemical characteristics of the land. One of the heavy metals used as the primary study object in this study was lead (Pb) (6).
The content of Lead (Pb) in Well Water.

Residents around the center of the Jenggot batik industry are known to use dug well water as a source of clean water supply for their daily lives. Therefore the dug wells should meet physical specifications following government standards so that the quality of groundwater in dug wells is not polluted and safe for consumption. Based on observations on 210 samples of drilled wells in residential areas around the Jenggot batik industry center, the location of 61.9% of dug wells was more than 10 m from pollutant sources. Digging wells could be said to be safe from pollution if they were more than 10 m away from pollutant sources.

In addition to the superiority of its physicochemical properties, Pb utilization continues, plus its properties which cannot be decomposed biologically cause its content in the environment to accumulate with increasing danger potential (7). Groundwater can also be contaminated by heavy metals because of the effects of continuous leaching. Contamination of groundwater by heavy metals is a serious threat to human health and the environment (8),(9),(10).

The results of the analysis of Pb content in groundwater in 210 dug wells belonging to residents around the center of the Jenggot batik industry indicate that, as many as 127 (60.5%) dug wells on average contain Pb as much as 0.316 mg / L with a pollution index of Pb content of 7.47. Based on these results, 60.5% of dug wells cannot be used in daily life because the Pb content exceeds 300%. The maximum limit of Pb levels allowed according to the Regulation of the Minister of Health of the Republic of Indonesia groundwater in 60.5% of the dug wells was included in the medium polluted category because the numbers were in the range of 5 - 10.

In comparison, the well water was dug in the Soko Duwet village area which was not an industrial center of batik and had no soil porosity different from the center of the Jenggot batik industry, after being analyzed the average contains Pb of 0.005 with a pollution index of Pb content of 0.87. Based on these results, 60.5% of dug wells cannot be used in daily life because the Pb content exceeds 300%. The maximum limit of Pb levels allowed according to the Regulation of the Minister of Health of the Republic of Indonesia groundwater in 60.5% of the dug wells was included in the medium polluted category because the numbers were in the range of 5 - 10.

The observation results showed that there were differences in Pb levels in well water dug in the rainy and dry seasons. In the rainy season, the Pb level in the dug well groundwater is 0.01 mg / L which means lower than in the dry season of 0.04 mg / L. This is following the previous research that, concluded the water quality of wells dug differently in the rainy and dry seasons. During the rainy season, there is an increase in the volume of permeate groundwater which has reduced the concentration of existing pollutants, whereas in the dry season the amount of wastewater will be more dominant compared to rainwater, causing water quality to be weak and an increase in heavy metal content in water.

Conclusion

The average Pb content in batik wastewater taken from batik industry outlets is 0.0216 mg / L, and 25.4% of wastewater from outlets that are disposed of directly to settlements by the batik industry exceeds the specified wastewater quality standard. There is a total of 29.9% of the pool of wastewater in open channels of living arrangements has a Pb content exceeding the defined wastewater quality standard. The average Pb level in dug well water is 0.0316 mg / L. The lowest Pb level is 0.0023 mg / L and the highest is 0.1461 mg / L. As much as 60.5% of the dug well water contains Pb exceeding the maximum permissible limit of 0.01 mg / L.

Ethical Clearance: Ethical clearance was obtained from the University of Diponegoro Semarang. We also wish to thank all the participants who contributed to this study.

The Relation between Serum Concentration of Paraoxonase-1 Enzyme with Some Criteria in Metabolic Syndrome Patients

Shumoos H Alwaid¹, Arshad Noori Al-dujaili²

¹Medical Laboratory Department, Collage of Medical Technology, The Islamic University, Iraq,
²Biology department, College of science, University of Kufa, Iraq.

Abstract

Metabolic syndrome (MetS) is a worldwide distributed public health problem and its incidence in increase. (MetS) is characterized by clustering of several metabolic abnormalities, including central (intra-abdominal) obesity, dyslipidemia, hyperglycemia, and hypertension. The ultimate importance of this cluster is to identify individuals at high risk of both type 2 diabetes and cardiovascular disease (CVD). PON1 an antioxidant enzyme carried by HDL, it can hydrolyze lipid peroxide in lipoproteins as a result of its lipolactonase activity thereby decreasing oxidative stress in serum lipoproteins, macrophages, and atherosclerotic lesions. The aim of the current study is to evaluate the serum level of paraoxonase -1 biomarker levels in MetS patients regarding to MetS risk factors, age and gender.

Method: This study was conducted at Diabetes and Endocrinology Unit in Al-Sader Teaching Hospital in AL-Najaf province /Iraq from January2018 to July 2018 to know the prevalence of metabolic syndrome patients who attended the hospital for monthly checkup. A total of the (130) participant involved in this study, blood samples had been taken from the (90) metabolic syndrome patients (50 female and 40 male), and from (40) individual who were apparently healthy as a control group. The age, gender, WC and BMI of patients and control is taken during physical exam lipid profile and blood glucose also estimated for all groups. PON-1 enzyme biomarker in serum was measured by using a solid phase enzyme-linked immunosorbent assay (ELISA).

Result: The result of the current study showed a significant decrease in concentration of serum PON-1 in metabolic syndrome patients in compared with healthy group. The PON-1 biomarker revealed a significant increase in the serum concentration in Mets female group in compared with in Mets male group respectively on the other hand the study show there is a significant difference in serum PON-1 level in Mets females patients when compared with Mets male group at same age group in (40-49y). Significantly increase in PON1 of Mets female patients with WC group in (140-160cm) as compared with the male patient in the same WC while, no significant increase in serum PON-1 level among other study groups.

Keyword: Metabolic syndrome (MetS), Paraoxonase-1, age, gender, BMI, waist circumference and lipid profile

Introduction

The metabolic syndrome (MetS) is a collection of several metabolic abnormalities, including central obesity, dyslipidemia, hyperglycemia, and hypertension¹. The individuals with three of these abnormalities are at high risk of both type 2 diabetes and cardiovascular disease (CVD). Reactive oxygen species (ROS) are oxygen-containing molecules that produced during normal metabolism (free radical). When the production of damaging (ROS) exceeds the capacity of the body’s antioxidant defenses to detoxify them, a condition known as oxidative stress occurs which can cause tissue damage, particularly in the endothelial tissue². Lipids are a major target of free radical attack, which induces lipid peroxidation. Free radical induced
peroxidation of cellular membrane damage. Because it leads to alterations in the biophysical properties of the membrane. Therefore, measurement of products of lipid peroxidation has been commonly used to assess oxidative stress (3). Blood high-density lipoprotein (HDL) levels are inversely correlated with oxidative stress with this beneficial effect of HDL being partly attributed to its antioxidant properties mediated by paraoxonase -1 (PON1) (4). PON1 an antioxidant enzyme carried by HDL it can hydrolyze lipid peroxide in lipoproteins as a result of its lipo lactonase activity thereby decreasing oxidative stress in serum lipoproteins, macrophages, and atherosclerotic lesions. The early atherosclerotic lesion is characterized by macrophage foam cells, filled with cholesterol, oxysterols and oxidized lipids (6). Therefore, PON-1 protects lipoproteins and arterial cells against oxidation, probably by hydrolyzing lipid peroxides and preventing the formation of foam cells accumulation (7). PON1 was found to use efficiently not only lipoprotein-associated peroxides (including cholesteryl linoleate hydroperoxides), but also hydrogen peroxide (H2O2). PON1 inhibits the accumulation of peroxynitrite-generated oxidized phospholipids by its ability to hydrolyze phosphatidylcholine (PC) core aldehydes and PC isoprostanes to yield lysophosphatidylcholine (8). Because of reducing hydroxide and cholesteryl linoleate hydperoxide in LDL, it is considered that PON1 has an activity like peroxidase. Thus HDL-PON may play an important role in the prevention of atherosclerosis (9). In the current study we aimed to do further investigation about the relation between low level of paraoxonase-1 enzyme and MetS risk factors hyperlipidemia, dyslipidemia, obesity and hyperglycemia in regarding to age and gender of Iraqi metabolic syndrome patients

Material and Method

Patient and control groups

A total of 130 participant were enrolled in the study. In particular, 90 patients subjects 50 women divided according to age to (13 mean age 40-49year),(25 mean age 50-59 years) and (12 mean age 60-69 year) and 40 men who also divided according to age to (10 mean age 49-59), (20 mean age 50-59year) and (10 mean age 60-69year) who had been previously diagnosed with metabolic syndrome by physicians at the Endocrinology and Diabetes Unit at Al-Sader Teaching Hospital in AL-Najaf province / Iraq and they were attended the center regularly for monthly check up , during the period from January 2018 to July 2018. According to BMI patients subject divided to over, morbid and obese and according to waist circumference subject divided to three group; (100-119cm), (120-139cm) and (140-160). Exclusion criteria included: endocrine diseases (other than diabetes or impaired glucose tolerance (IGT)); syndromic obesity; hepatic, infectious; craniopharyngioma. Anti-inflammation drug consuming patient. Forty healthy (20 male and 20 female) were enrolled as controls (control group). Subjects had to be normal weight. Apart from obesity, inclusion/exclusion criteria were identical to those used for the obese group. The study protocol was approved by the Hospital’s Ethics Committee. Written informed consent was obtained from the patients and control.

Blood samples collection

Five ml of venous blood was acquired by antecubital venipuncture utilizing needle drained from Mets and control subjects between 8:30-10 AM following 12 hours fasting. The blood was permitted to clot in plain test tube at room temperature. The serum was suctioned after centrifugation at 3000 rpm for 10 min, divided into aliquots in epindroff tubes and stored at-20°c. for measurements of levels of glucose, lipid profile and PON-enzyme.

Biochemical analyses

Total cholesterol (TC) measured use (Biolabo SA, France), high density lipoprotein (HDL) (Biolabo SA, France), TG concentrations (Biolabo SA, France). Calculation of low density lipoprotein (LDL). Low density lipoprotein was calculated by this formula: LDL (mg/ml)=TC(mg/dl) ─ HDL(mg/dl). Calculation of blood glucose by (Biolabo SA, France). Determination of serum High mobility group protein B1 level. specific kit for measuring human PON-1 concentrations in serum was supplied by (Biomatik, Ontario, Canada. Catalogue No: EKE61260

Statistical analyses

Statistical analysis was performed with IBM SPSS version 23 software by use of the t test and ANOVA P <0.05 was regarded as indicative of statistical significance

Results

Characteristics of the population The main Clinical characteristic of Mets patient according to gender group
are summarized in Table 1. The results showed a significant (P<0.05) increase in BMI between male Mets patients (36.51±5.7) kg/m² when compared with female Mets patient group (31±5) kg/m², both groups are subdivided according BMI into overweight, obese weight and morbid weight. Also, the results reveal statistically significant differences of female compared with male, there was a significant increased (p<0.05) in W.C of female compared with male patient with metabolic syndrome and there is a significant increase (p<0.05) in fasting blood glucose level of Mets females as compared with Mets males group at same age group.

The results in Table 2 revealed significant differences in lipid profile between Mets group and healthy group, significantly increased (p<0.05) in serum cholesterol, triglycerides, TG-C and LDL-C compared with healthy group, while a significant decrease (P<0.05) in serum HDL-C concentration of Mets compared with healthy group. The results of same table revealed significant differences in lipid profile between Mets female group and Mets male group, significantly increased (p<0.05) in serum triglycerides and LDL-C female Mets group compared with male Mets group, while a significant decrease (P<0.05) in serum HDL-C.

Figure (2): Comparison of serum PON1 level between males and females of Mets patients

**Comparison of PON1 between Mets patient and control in both male and female.**

The result in figure (1) exhibit significant decrees (p<0.05) in serum levels of PON1 group compared with control groups.

Comparison of PON-1 between Mets males and females patients figure (2) revealed a significant increase (p<0.05) in serum PON1 concentration in Mets female group and in compared with in Mets male group respectively.

Comparison of biomarkers among different age groups of Mets patients

Figure (3) show a significantly increase (p<0.05) in serum concentrations of PON1 of Mets females patients when compared with Mets males group at the same age group in (40-49y), while there are no significant differences in serum concentrations of PON1 between females and males groups in the same age (50-59 y) and (60-69 y). The same figure indicated there is no significant differences in serum concentrations of PON1 when compared among different ages (40-49y) (50-59 y) (60-69 y) in females group and male group.

**Comparison of PON1 among different waist circumference groups of Mets patients.**

Figure (4) show a significantly increase (p<0.05) in serum concentrations of PON1 of Mets females patients with WC group in (140-160cm) as compared with the males patients in the same WC while, no significant increase in serum PON1level among other study group.
Discussion

The results of this study exhibit a significant decrease (p<0.05) in serum levels of paraoxonase-1 (PON1) in MetS patients group compared with control groups. PON1 is a HDL-associated, pleiotropic enzyme and may play a role in several different pathways: from the protection against oxidative damage and lipid peroxidation to the contribution to innate immunity processes and from the detoxification of reactive molecules (10). More specifically, PON1 is capable of protecting lipoproteins from lipid peroxidation by degrading specific oxidized cholesteryl esters and phospholipids, and antioxidant properties of HDL have been attributed, at least partially, to PON1 (11). The decrease level of PON1 may play important role in metabolic peroxidation of LDL-C several studies have been found several mechanism to discussed the decreased in PON-1 level connected with increased LDL-C lead to inactivation of Pon-1 level by interaction with free sulfhydryl group and oxidized LDL also a high level of (CD/LD) lipid peroxidation were increased with decrease Pon-1 (12,13). Several studies has been suggested that imbalance between oxidant and anti-oxidant was impaired as a severity of metabolic syndrome so the increase oxidation stress and low antioxidant were detected in patient with metabolic syndrome (14). A recent study has been investigated the hydrolytic activity of PON-1 towards lactones (cycle esters) is considered an active also cytokines and oxidized phospholipid reduced both PON-1 expression and activity (15). Martinelli et al.,(2011) observed a progressive decrease of paraoxonase activity by increasing the number of MS disturbances . Concomitantly, a progressive increase of lipid peroxides concentration was observed, and a greater degree of severity of MetS is associated with an increased oxidative stress which inactivates PON1 function (16).

The current study also revealed a significant increase (p<0.05) in serum P1 concentration in Mets female group in compared with Mets male group respectively. Males have been more likely to have atherosclerosis and decrease in the PON1 activity than females (16). Also, the results of this study indicate that the PON1 concentration in serum independent on age of male and female in all study groups. The result of current study indicate no significant difference in serum level PON1 at different BMI (over, obese, morbid weight) groups of Mets patients while show a significantly increase (p<0.05) in serum concentrations of PON1of Mets female patients with WC (140-160cm) as compared with the male patient in the same WC while, no significant increase in serum PON1 level among other study groups. (17,18)

Conclusion

The present study provides that paraoxonase-1 enzyme is correlated with some of MetS risk factors like; (WC, Lipid profile) in regarding to age and gender and also demonstrated that women population is more effected with MetS risk factors than men population in our community. PON-1 may be considered as good biomarker for diagnosis and detect early symptoms of metabolic syndrome and also can-do further research for consider PON1as pharmaticular target for limitation of MetS risk factors threatening on public health. The study protocol was approved by the Hospital’s Ethics Committee. Written informed consent was obtained from the patients and control.

Abstract

Objective: This research had the objectives of studying the prevalence and relationship between game playing behavior and stress of lower secondary school students using the sample group of 242 students of the lower secondary school students of the Chiang Mai University Demonstration School.

Method: The research tools consisted of a questionnaire for demographic characteristics, Game Addiction Screening Test (GAST) for children and adolescents, the Suanprung Stress Test as well as statistical analysis involving frequency, percentile, standard deviation, and the Pearson’s Product Moment Correlation Coefficient.

Results: The results showed correlation coefficient as follows: (1) Preoccupation with the game and stress had no relationship. (2) Loss of control in game playing and stress had very little relationship, whereas the correlation coefficient was 0.15 and statistical significance was 0.05 (3) Function impairment and stress also had little relationship whereas the correlation coefficient was 0.221 and the statistical significance was 0.01 and (4) Game playing behavior and stress had very little relationship as well whereas the correlation coefficient was 0.159 and the statistical significance was 0.05.

Keywords: Game Addiction, Game Playing Behavior, Stress, Adolescents, Thailand

Introduction

Nowadays, technology has inevitably played a great role in our lives whether in our daily life, work or even in entertainment. Game addiction (GA) has become a serious mental health condition in many countries 1-3. We are able to make good use of it. But at the same time, it has also created some negative impacts on the users that like online game 4-9. One of them is game addiction when man is unable to control himself and this affects people’s relationships and life conduct. It is a legitimate leisure activity worldwide 10. Game playing is evidently very popular and interesting as it is a dream world with beautiful desirable imagination. High technology has been employed to create all sorts of games, to create virtual reality. This results in children being addicted to games more and more. Some of them might want to escape from the world of reality due to family problems, stress, friends making them want to exclude themselves from society and it can affect their responsibility as well 11. Some had problems with concentration on their study, skipping school to play games, alienating themselves from society or such inappropriate behavior as telling lies, stealing and violence. However, some studies showed some advantages to game playing such as reduction stress and loneliness, providing fun and keeping people from drugs or sex obsession so they could spend their time righteously 12.

From the statistics on Thai teenagers becoming addicted to online games 7. Some children (10-15% of the students in Thailand) were so addicted to it that they...
could not stop playing it. A survey remarkably showed that Thai children played online games via mobile phones and the Internet as long as 3.1 hours a day, number one in Asia. They spent over 60.7 minutes per day playing games. It was also found that 54% of them had mental health problems, stress and degraded learning, 27.2% engaged in gambling, 19% were in debt and unable to quit, 14% had family problems, 9% suffered social and family relationship problems and 4%-5% committed suicide due to game playing during their teens, the stage between childhood and adulthood in particular which is a transition period from being children to adults, a very sensitive period for all kinds of problems to easily emerge when all kinds of development changes occur very quickly. A more recent study also revealed some impacts of social online sites on a person’s identity development as reflected in some game playing. As such, this researcher became interested in studying the relationship between game playing behavior and stress of the lower secondary school students of Chiang Mai University Demonstration School with the expectation of obtaining the results that would provide guidance to promote and prevent game playing and stress including appropriate spending of time on game playing as well as building suitable readiness for their development and their age.

Materials and Method

Study Design: A cross sectional study design was used.

Population and Sample: Sample 242 high school students from 626 population of Chiang Mai University Demonstration School in Chiang Mai, Thailand based on the table by Krejcie RV, & Morgan, D.W.

Instruments

Game Addiction Screening Test: GAST: developed by Ratchanakarin Institute of Child and Adolescent Mental Health and the Child and Adolescent Psychiatry Department, Faculty of Medicine Siriraj Hospital.

Suanprung Stress Test-20, SPST–20: developed by Suanprung Hospital, Department of Mental Health.

Analysis Methods: Descriptive statistics and inferential statistical analysis involved Pearson’s Product Moment Correlation Coefficient.

Ethical Clearance: The research ethics committee of the Faculty of Associated Medical Sciences of Chiang Mai University for project number AMSEC-60EX-070.

**Discussion and Conclusion**

Game playing behavior show data. (see Table 1-3) The game playing behavior can be categorized into 3 levels of game addiction. It was found that 5.8% were in likely addicted, 14.4% in obsession and 79.8% in normal, \(= 13.78, \text{S.D.} = 7.72\). Stress level found that 29.3% were in severe stress, 49.2% high stress, 20.2% moderate stress and 1.2% little stress, \(= 53.55, \text{S.D.} = 14.39\). (see Table 4)

The relationship between game playing behavior and stress was at a very low level of positivity with the correlation coefficient as follows: (3.1) Preoccupation with the game and stress had no relationship, (3.2) Loss of control in game playing and stress had very little relationship, whereas the correlation coefficient was 0.15 and statistical significance was 0.05 (3.3) Function impairment and stress also had little relationship whereas the correlation coefficient was 0.221 and the statistical significance was 0.01 and (3.4) Game playing behavior and stress had very little relationship as well whereas the correlation coefficient was 0.159 and the statistical significance was 0.05 (see Table 5) and discussed as follows:

1) The game playing behavior of the sample group could be said to be at an addiction level, 14 students or 5.8%. However, the tests showed that most of the sample group had a grade range at a normal level. Since they stayed with their parents, it was likely that they were monitored in terms of controlling the time for game playing. Most of the students played games every day but for only 1-2 hours each time. They also could spend time on other social online activities such as Facebook besides playing games.\[1-3, 13, 19-22\].
2) The study showed no relationship between preoccupation with game playing and stress. It was likely that game playing could affect the study and responsibility such as low grade, lack of concentration on the work and relationship with family members in particular, which could result in depression, anxiety and stress. However, the students seemed to spend some time in social activities online instead.

3) The study also found that the loss of control in game playing and stress had very little positive relationship, meaning that if the control on game playing was higher, the level of stress would also increase and vice versa, which means they wouldn’t be able to control themselves to play within the allotted time only or continue playing for seven hours or more. This would cause more impacts and finally result in stress. This went along with Kimberly Young’s saying that technology was both beneficial and also created negative impacts and that game players could be preoccupied with game playing and neglect their responsibilities, causing a low grade, inability to concentrate on their work, as well as lacking relationship with others, especially family members, which could cause depression, anxiety and stress.

4) Function impairment and stress were found to be of a little positive relationship and this could be affected by loss of control on game playing as well, which corresponds to Mun-Oun who said that game playing could make a child separate himself from society and affect his responsibility also. For example, it could make him neglect his study, skip class to play games, stay away from others or have other unsuitable behavior like telling lies, or stealing or worse. This corresponds to Pornnopadol C. et al. explaining that game playing affected students’ responsibilities in paying attention to their study and homework, causing them to sneak out from school or home to play games, a drop in grades, caring less for socialization and family activities, which could bring about several negative impacts and stress. There are support by Apisitwasana, N., et al. who report the program based on self-regulation and school and family participation is effective for preventing gaming addiction in students in Bangkok, Thailand.

5) As for the relationship between game playing behavior and stress among the students in the lower secondary school, it was found that the behavior had very little positive relationship with stress whereas the correlation coefficient was 0.15 and the statistical significance was 0.05. This means that the game playing behavior had a certain level of relationship with stress which could be due to several factors in terms of the students themselves, then family, friends that caused them to stay away from socialization, and then to the game playing for relaxation and better feelings as pointed out by Kannika N. et al. who said that stress was a major factor that led young people to become addicted to online games, and found that children with high stress tended to become addicted to games more, which agreed with them the causes for game playing among the youth were for relaxation and socialization. The activity programs should be developed to enhance the immunity to prevent students from becoming addicted to games by focusing on making students to be aware of the situation and to be able to manage the stress appropriately and efficiently in terms of time management from game playing and leisure activities, life skills enhancement for youth for concrete prevention and solutions.

The Effect of Mixture of Citrus Dates Juice Extract (*Phoenix dactylifera* L) on Blood Profile Changes for Post-Partum Mother

Sri Rahayu¹, Sri Wahyuni¹, Ngadiyono¹

¹The Ministry of Health Polytechnic Semarang, Indonesia

**Abstract**

**Background:** Iron is essential for maintaining the health of the body and the system for producing red blood cells. Alternative iron fulfillment for postpartum mothers is to consume vegetables or herbs that contain high iron in the food menu. This study was to determine the effect of citrus-dates juice extract (*Phoenix dactylifera* L) on changes in the blood profile of postpartum mothers.

**Method:** This study used randomized Control Group Design With pretest and post-test. The population of all postpartum mothers in the Semarang City Regional Health Center numbered 17 treatment groups and 17 control groups, taken by random cluster sampling. The independent t-test was applied to analyze the data.

**Results:** The characteristics of the respondents of the two groups were mostly reproductive, parity was almost the same between primipara and multipara. The nutritional status had a body mass index in normal conditions, and the diet was mostly good. Descriptive analysis of respondents’ blood profiles before treatment was an average hemoglobin level of 10.8 mg/dl, hematocrit value of 31.9%, mean erythrocytes of 3.70 million / mm³, platelets 227 cells / mm³. Bivariate analysis showed that there were differences in hemoglobin, hematocrit levels erythrocyte, platelets in the group given citrus date juice compared to the control group.

**Conclusion:** Citrus-dates juice extract is better in stabilizing and improving hemoglobin, hematocrit, erythrocytes, and platelets, so the need for socialization at that citrus-dates juice extract for postpartum mothers as an alternative to raise the profile of the blood.

**Keywords:** Citrus date juice, blood profile, postpartum mother, iron

**Introduction**

High morbidity and mortality in postpartum mothers are mostly caused by postpartum hemorrhage (¹). The postpartum mother needs substances needed by the body for metabolic purposes. Nutritional requirements for the post-partum is increased by 25%, which is useful for the recovery process after childbirth and to produce enough milk to nourish the baby (²).

Giving iron tablets to postpartum mothers is recommended for up to 40 days after delivery, but not all mothers consumed iron tablets given (³). This period is quite essential for health workers always monitor postpartum mothers because the implementation of a less than optimal can cause mothers to experience various problems which can even lead to complications during the post-partum, such as puerperal sepsis. Different types of foods that contain iron are critical to be consumed regularly. Iron acts as activity body that is very important, especially for maintaining the health of the body and the system of red blood cell production.

One alternative in fulfilling iron requirements in postpartum mothers is to consume vegetables or herbs that contain high iron in the food menu. Previous research reported that administration of date fruit extract amount 60-120 mg adjusted to bodyweight could increase iron levels in normal mice (⁴). Besides, other studies stated that ethanol extract from dates could increase platelet counts.
in mice. Preclinical studies have shown that dates have free radicals, antioxidants, antimutagenic, antimicrobial, anti-inflammatory, gastroprotective, hepatoprotective, nephroprotective, anticancer, and immune stimulatory activities (5).

To increase absorption of iron in the body requires an acidic atmosphere and the presence of reducing agents. For example, vitamin C contains amino acids that are useful for binding iron in the body so that iron absorption is more effective (6). To speed up the metabolic process in the absorption of iron in dates can be helped by using natural vitamin C, one of which is the content of sweet citrus fruit (Citrus Aurantium). The purpose of this study was to determine the effect of giving a combination of dates citrus juice (Phoenix dactylifera L.) to postpartum mothers to changes in hemoglobin, hematocrit, erythrocyte, and platelet levels.

Method

This type of research was experimental with a randomized control group design with pretest and posttest. The population of all postpartum mothers in the Semarang City Regional Health Center numbered 17 treatment groups and 17 control groups, taken by random cluster sampling. Data was collected by providing postpartum mothers 250 mg of dates extract and sweet citrus juice (Citrus Aurantium) 100 ml of which had been made concentrated on the first day until day 14. On the first and 14th day, an assessment of the maternal blood profile will be carried out, while the control group will be given iron tablets according to the standard. Data were analyzed by the Independent t-test, while the confounding variables were analyzed with MANCOVA.

The respondents in the study are given the juice of the citrus dates of the two groups in reproductive age, most parity gave birth to second children. Further, education was mostly secondary or high school education with the average nutritional status was BMI 23, and dietary patterns were 58.8% in the category of good.

*= independent t-test and Mann Whitney
Table 3. shows there are differences in the value of hemoglobin, hematocrit, erythrocytes, and platelets between groups given juice of citrus dates with the control group, which p-value <0.05. This means that the postpartum given the juice of dates + citrus will contribute effectively to increase the value of hemoglobin, hematocrit, erythrocytes, and platelets.

**Discussion**

Hemoglobin is a protein in erythrocytes that functions as a carrier of oxygen from the lungs throughout the body. Hemoglobin also transports carbon dioxide back to the lungs to be removed from the body. Hemoglobin as a red pigmented protein contained in red blood cells functions to carry oxygen from the lungs to be carried throughout the body (7). Dates contain various nutrients that are important and beneficial for health. From previous studies mentioned dates contain high carbohydrates (total sugar, 44/88%), fat (0.2 / 0.5%), 15 salts and minerals, protein (2.3 / 5.6%), vitamins and high percentage of dietary fiber (6.4 / 11.5%) (8). Postpartum mothers need twice as much nutrition as preparation for breastfeeding and the recovery process in the puerperium (9). Previous research also stated that consuming dates Halawi versus Medjool for 100 grams/day for four weeks did not increase fasting and triacylglycerol serum glucose levels and even significantly lower serum triacylglycerol levels, so consuming dates has beneficial effects and is considered an anti-atherogenic nutrient (10).

Post-partum mother given juice of citrus dates has a hemoglobin level better than the control group because the dates contain flavonoids, vitamin and dietary fiber 6.4-11.5% (10). Flavonoids are one component that helps in the formation of hemoglobin which affects the absorption and release of iron from transferrin into body tissues. The role of flavonoids in the process of dates can inhibit the enzymatic activity of hyaluronidase in the process of decomposing hyaluronic acid, which is the primary ingredient of the bone marrow. The previous study showed that there was an influence on changes in hemoglobin levels in the 16-18 age group year who received dates (11). Some previous research also states there is an effect of giving palm juice to hemoglobin in second-trimester pregnant women (12).

In this study also obtained a better hematocrit value in the group given citrus juice extract. Decreased volume and increase in blood cells in pregnancy are associated with an increase in hematocrit and hemoglobin on day 3-7 postpartum and will be standard in 4-5 weeks postpartum.

On the first day post-partum, the levels of fibrinogen and plasma will decrease slightly, but the blood thickens with an increase in viscosity which increases blood clotting factors. Leukocytosis increased where the number of white blood cells can reach 15000 mL during labor will remain high in the first few days of postpartum. The amount of hemoglobin, hematocrit, and erythrocytes will vary significantly at the beginning of the postpartum period as a result of blood volume, placental volume and varying levels of blood volume. All these levels will be influenced by the nutritional status and hydration of the woman (13).

The value of erythrocytes in this study also showed a significant difference in postpartum mothers given citrus date juice. Red blood cells (erythrosine) are round sprawl, both surfaces are concave (biconcave), and non-nucleated, in women about 4 million / mm3. Red blood cells contain hemoglobin (red dye in the blood) which functions to bind O2, including iron (Fe), maintaining the immune system. Following previous research that giving date fruit extract can improve the system immune modulatory namely increasing the number of IFN-γ cells, CD49b, and IL-12 (14).

Mothers given citrus date juice have better platelet levels than the group control. Freezing blood cells (platelets) in the form of freezing blood platelets are not fixed. Its function for blood clotting, in the amount of about 200,000-400,000 / mm3, is made in the bone marrow (15). If a person is injured, the pieces of blood flow with the wound blood, when touching the surface of the wound it will break, and thrombokinase is formed, with the help of calcium ions it will convert prothrombin (in blood plasma) to thrombin. The formed thrombin will convert fibrinogen to fibrin (fine threads) which will close the wound so that the bleeding stops (16). In postpartum women who are given juice of citrus dates will be a faster recovery process of the puerperium because citrus dates juice can increase blood platelet levels (17). In another study, Ajwa date palm fruit extract contained active antioxidants such as polyphenols, flavonoids, and flavones with positive effects on protecting various tissues and warding off free radicals with antioxidants (18). To improve the recovery process of postpartum maternal tissue, substances that can help improve maternal health.
status are needed so that dates can be one of the best alternatives for postpartum mothers.

Date palm fruit combined with baby java citrus contributes well in stabilizing the blood profile of postpartum mothers, especially hemoglobin, hematocrit, erythrocytes, and platelets, because of the components of flavonoids in dates. All types of flavonoids are metabolized in the same way, which is transformed into aglycone compounds and hydrolysis processes, which occur in the stomach and most importantly occur in the proximal colon by regular flora-flora activity and produce beta-glucosidase (19). To sum up, this method can become an alternative instead of massaging which is commonly applied among Indonesian women (20), (21).

**Conclusion**

The characteristics of the two study groups were mostly reproductive age, and their education was secondary, parity mostly gave birth to the second, while nutritional status had a healthy BMI and adequate diet. There are differences in hemoglobin, hematocrit, erythrocyte, and platelet levels in postpartum mothers given citrus date juice with a control group. Citrus date juice contributes better in stabilizing and increasing levels of hemoglobin, hematocrit, erythrocyte and thrombocyte in postpartum mothers so that there is a need for socialization to postpartum mothers, about the utilization of citrus date juice as an alternative to increasing maternal blood profile besides midwives as one of the health workers can provide information to the public.

Abstract

Introduction: Iron is one of human micronutrients which is the most abundant micro mineral in the body. Iron deficiency can affect the human immune system because this mineral is essential for cell differentiation and growth. In addition, white blood cells that function to destroy bacteria becomes unable to work effectively and will result in changes in oral microorganisms which can increase intensity of oral mucosa inflammation including recurrent aphthous stomatitis (RAS). This study aimed to determine the association between blood iron levels and recurrent aphthous stomatitis in traffic police officers at Surabaya Police Department.

Materials and Method: This research was an analytical observational with cross sectional approach. The respondents of this research were 98 traffic police officers at Surabaya Police Department, they were selected by simple random sampling method by fulfilling several criteria. Researchers then performed intra oral examination and anamnesis to know the history of ulceration in the mouth of the respondents.

Results: Respondents who had abnormal iron levels experienced RAS more than respondents with normal iron levels. The correlation test between iron blood level of and RAS with chi-square test resulted in P-value of 0.034. Because the p-value (0.034) is less than significance level (0.05), the null hypothesis is rejected. Thus, this means that there is a relationship between blood iron levels and RAS.

Conclusion: There is relationship between blood iron levels and Recurrent aphthous stomatitis in traffic police officers at Surabaya Police Department.

Keywords: Stomatitis Aphthous, Fe blood level, police, lead poisoning

Introduction

Iron is one of the essential human micronutrients which is the most abundant micro mineral in the body. It is essential for survival. The ability to obtain, store and use iron is a universal requirement for all organisms¹.

Iron is absorbed through the duodenal mucosa. Iron levels in the body are affected by iron absorption rate. Factors affecting iron absorption rate are, amount and form of iron, ascorbic acid, phytic acid, tannin, gastric pH level, iron requirement level and intrinsic factors such as body iron requirement level². In addition, Pb or lead in high amount and frequency can also affect the iron absorption process. Lead is a direct competitor of iron on the bonding site at the duodenal receptors. Therefore, people who experience lead poisoning will be accompanied by iron deficiency. Consistent with this, iron deficiency can exacerbate lead poisoning in the body³.

Chronic or continuous iron absorption disorder will lead to a state of iron deficiency in the body⁴. Iron
deficiency can affect the immune system of the individual because iron is essential for cell differentiation and growth. In addition, in the state of iron deficiency, white blood cells that function to destroy bacteria becomes unable to work effectively. Reduced bactericidal substances produced by the body result in changes in oral microorganisms. This change causes increasing intensity of oral mucosa inflammation including recurrent aphthous stomatitis (RAS).

Traffic police officers are the implementing element of traffic regulation. Traffic is a major factor supporting productivity in modern society to improve the quality of life of the community. In order to support these tasks, nutritional adequacy is needed to achieve excellent health. The oral cavity with a variety of normal flora inside is very sensitive to changes in the immune response. Oral infections can serve as a marker for subclinical malnutrition. Based on the above background, this study aimed to determine the association between blood iron levels and recurrent aphthous stomatitis (RAS) in traffic police officers at Surabaya Police Department.

**Subjects and Method**

This research was an analytical observational with cross sectional approach. The respondents of this research were 98 traffic police officers at Surabaya Police Department, they were selected by simple random sampling method by fulfilling criteria of physical and mental health, not taking drugs, willing to do blood examination to obtain blood levels of iron and willing to be interviewed about meal and Recurrent Aphthous Stomatitis frequency. Participants first filled the informed concern then proceeded to the blood sampling. Blood sample was obtained as much as 3 ml in the cubital vein using EDTA as anticoagulant. Then it was inserted into the tube and stored in cold storage with temperature maintained about 4°C. The levels of iron and pb in blood were measured using atomic absorption spectrophotometer (SSA) method with μ/l unit. Respondents were asked about the frequency of consumption of iron, vitamin C sources consumption, tannin sources consumption, and general data through interviews using questionnaire. Researchers then performed intra oral examination and anamnesis to know the history of ulceration in the mouth of the respondents.

**Findings**

This research was conducted on traffic police officers at Surabaya Police Department with 98 respondents. The average age of respondents was 37.3 years with an average working life of 15.5 years. RAS-affected respondents accounted for 14.28% of total respondents with average blood Fe and blood Pb 938.61 μ / l and 146.71 respectively. Characteristics of respondents are described in table 1.

Cross tabulation between Fe blood levels is divided into abnormal and normal categories with RAS in respondent is categorized as positive and negative described intable 2. The results of cross-tabulation were found that from 16 people who had abnormal iron levels, 31.3% experienced RAS and from 82 people who had normal iron levels, only 11.0% was affected by RAS. Respondents who had abnormal iron levels experienced more RAS than respondents with normal iron levels. The correlation test between blood iron level and RAS with chi-square test resulted in P-value of 0.034. Because the p-value (0.034) is less than significance level (0.05), the null hypothesis is rejected. Thus, this means that there is a relationship between iron blood levels and RAS.

In the correlation test between the blood iron level and RAS in respondents who rarely consume Fe, chi-square test showed value of 0.396, while the relationship between blood levels of iron and RAS in respondents who often consume Fe have chi-square test value of 0.004. Because the p-value is (0.004) less than (0.05), the null hypothesis is rejected which means that there is a correlation between blood iron levels and RAS in respondents who frequently consume Fe.

In the correlation test between iron blood levels and RAS in respondents who frequently consume Vitamin C, chi-square test showed value of 0.005. Because the p-value is (0.005) < (0.05), then the null hypothesis is rejected which means that there is a correlation between blood iron levels and RAS in respondents who frequently consume Vitamin C.

In the correlation test between iron blood levels and RAS in respondents who frequently consume tannin chisquare showed test value of 0.027. Because the p-value of (0.027) < (0.05), the null hypothesis is rejected which means that there is a correlation between blood iron levels and RAS in respondents who frequently consume tannin. Risk estimation test showed value of 1.09 which means that frequent tannin-consuming traffic police officers are 1.09 times more susceptible to the incidence of RAS than those who rarely consume.
The correlation test was tested on lead in the blood and the factors of lead entry in the blood that could affect blood iron levels as described in table 4.

Table 4. Cross-tabulation between Fe in blood and RAS based on the variables of lead blood levels and the factors of lead entry in the blood.

Form the table, we can see that respondents who had normal iron levels and did not experience RAS were more likely occurred in normal blood Pb. In the correlation test between the correlation between blood iron levels and RAS on the respondents who had abnormal blood levels of Pb, chi-square test showed value of 0.07. Because the p-value of (0.07) ≥ (0.05), then the null hypothesis is accepted which means that there is no correlation between iron blood levels and RAS in the respondents who are abnormal blood Pb.

The result of cross tabulation between blood glucose level and RAS based on work period, respondents who had normal iron levels and did not experience RAS were more likely occurred in long working period. In the correlation test between blood iron levels and RAS on short or new working period, chi-square test value is 0.060. Because the p-value is (0.060) ≥ (0.05), the null hypothesis is accepted which means that there is no correlation between blood iron levels and RAS in the respondents whose working period is short.

The result of cross tabulation between blood levels of iron with RAS differentiated by type of position in traffic police officers found that respondents who had abnormal levels of iron and experienced RAS more likely occurred in field officers. In correlation test between blood iron levels and RAS on field officers, chi-square test showed
value of 0.000. The null hypothesis is rejected, and there is a correlation between blood iron levels and RAS in respondents whose position as field officers.

Traffic police officers assumed to have iron deficiency due to high lead exposure turned out to only 16.3% of respondents who have blood levels below normal blood levels. In fact, they are officers with lead blood value above the normal value of 58.2%. This is due to the fact that iron deficiency in the body is a terminal symptom caused by various factors such as blood loss, increased need for iron such as during growth and pregnancy condition, low iron intake from foods, iron absorption disorders and iron metabolic disorders.

In this study, respondents who had abnormal levels of iron and experienced RAS more likely in rare iron intake. This is in accordance with the literature where the main cause of iron deficiency in the blood is due to a lack of iron intake and low absorption\(^9\). The absorption of iron in the blood is influenced by other factors such as tannin and vitamin c intake. In this study the frequency of consumption of vitamin C and tannins was studied and used as a moderate variable equivalent to blood lead levels as a factor affecting iron absorption.

Respondents who had abnormal levels of iron and experienced RAS more likely occurred in respondents who often consumed Vitamin C. This is not in accordance with the literature stating that vitamin C intake from food will provide an acidic atmosphere to facilitate the reduction of ferric iron into ferro to make it easier to be absorbed in small intestine. Iron absorption in the form of nonheme increases fourfold with vitamin C presence\(^9\). In addition to helping in the iron absorption, vitamin C also plays a role in maintaining endurance if consumed adequately. This is caused by the function of vitamin C involves various aspects of metabolism such as electron transport. Administration of vitamin C meant for supportive care through tissue regeneration, thereby shorten healing time.

Another factor that affects iron absorption is tannin consumption. Tannin has polyphenolic compounds such as tannins in the tea and coffee. Tea can reduce absorption by up to 80% as a result of the formation of iron-tannate complex. Coffee also contains polyphenols but, in less amount, compared to tea\(^11\). In this study, iron inhibition due to high tannin consumption will lead to a decrease in the body’s immune system to infections that cause an increase in RAS incidence by 1.09 times higher than low tannin consumption cases.

Respondents who had normal iron levels and did not experience RAS were more likely to occur in respondents with normal Pb blood level. This is in accordance with the literature which mentioned that iron deficiency and lead poisoning should be interconnected and will occur together\(^12\). Exposure to lead can interfere with erythropoiesis which will ultimately interfere with iron absorption. Almost 50% of erythropoiesis activity is inhibited at Pb blood levels of 15 μg / dl\(^13\). In normal Pb blood level, there is no decrease in immunity that can increase the incidence of RAS. Pb blood level that affect Fe blood levels can be affected by the working period and job position of respondents. Based on the results of this study, it is found that the working period does not affect the emergence of RAS, while the position affects the occurrence of RAS. This is not in accordance with previous experiments in which both work and occupation could affect blood levels of iron. The longer the work period and duration will affect the level of lead in the blood. This is in accordance with previous research which states that long working periods will lead to longer lead exposure, therefore increasing lead levels in the blood\(^13,14,15\). Differences with previous experiments may be caused by that members of administrative officers who have long working period but possibly have lower lead exposure.s

**Conclusion**

From this study, we can conclude that there is a significant relationship between blood iron levels and Recurrent aphthous stomatitis in traffic police officers at Surabaya Police Department.

Abstract

High Motility Group Box 1 (HMGB1) is a protein that is expressed constitutively in almost all types of cells. In response to microbial infections, HMGB1 is secreted from immune cells activated to regulate inflammation. Here we review the different mechanisms by which several herbal components inhibit the action or secretion of HMGB1 such as by modulating inflammatory activation, autophagic degradation, or endocytic uptake.

High Motility Group Box 1 (HMGB1) was initially identified as a DN-binding protein binding to proteins that participate in DNA replication, repair and regulation of transcription of gene expression. Although the role of HMGB1 is not well understood, recent studies characterize the emergence of extracellular HMGB1 roles as prototypical danger signals that regulate inflammatory and repair responses. In conditions of sterile infection, injury and inflammation, HMGB1 can occur passively released from damaged or active cells secreted from the immune-activated cell. Inflammasome, a caspase-1-activating large protein complex, has recently been shown to play an important role in mediating extracellular release of HMGB1 from activated and infected immune cells. High Motility Group Box 1 (HMGB1, also known as amphoterin) has been identified initially as a non histone DNA binding factor revealed by almost all eukaryotic cell nucleations.

Keyword: HMGB1, DNA, Gene, inflammation

Introduction

HMGB1 (High Motility Group Box 1), evolutionarily using a 30 kDa DNA binding protein, is then expressed in almost all cell types. Sequence (NLS), HMGB1 is transported into the nucleus by a nuclear import complex, which then retains it in the preformed protein ¹.². The HHG box allows HMGB1 to bind to chromosomal DNA and fulfill nuclear functions in stabilizing nucleosome structures and regulating gene expression. Test local HMGB expression ¹ makes animals susceptible to infection. Strengthens the role of beneficial intracellular HMGB1 in immunity to infection and injury ³. In response to infections and injuries, however, HMGB1 is secreted from immune cells that are activated or released passively from injured cells ³,⁴

Result and Discussion

Settings of HMGB1 secretion

In response to microbial products (for example,
ds-RNA, CpG-DNA, and endotoxin), macrophages / monocytes are secreted HMGB1 into the extracellular environment in a delayed manner. Because it does not have a leader peptide sequence, HMGB1 cannot be actively secreted through the classic endoplasmic reticulum - the Golgiocytocytic pathway.

Nucleus-to-cytoplasmic transcription is governed by post-rational modification (e.g., acetylation or phosphorylation) of NLS, which causes absorption from HMGB1 into cytoplasmic vesicles. The result of a protein complex, called “inflammasome”, is responsible for splitting procaspase-1 to produce caspase-1, which triggers activation inflammation and pyroptosis. Reduces inflammatory activation, pyroptosis, and HMGB1 secretion.

Structurally, HMGB1 is a 30 kDa protein consisting of two homologous DNA binding motives (called Boxes ‘A’ and ‘B’) followed by a negatively charged tail of acid at the carboxyl end. The importance of HMGB1 in regulating nuclear processes is emphasized by the phenotype of HMGB1-deficient mice, which die shortly after birth due to severe energy deficits and hypoglycemia, possibly due to impaired glucocorticoid signaling. HMGB1 induces recruitment of cell inflammation, contributing to dendritic cell maturation and for the proliferation of activated T cells.

Inflammasomes activate signaling pathways that contribute to immune responses and host defense mechanisms when they (directly or indirectly) sense the presence of certain pathogenic microbes and DAMPs in the cytosol host or in intracellular compartments. Interestingly, NLRP3 inflammasome activation has recently been shown to be important not only for the secretion of IL-1β, but also for the release of HMGB1 from LPS-primed macrophages treated with ATP or exposed to nigericin. Caspase-1 itself requires activation by large protein complexes called ‘inflammasomes’ which are assembled in NOD-like receptors (NLR) and HIN-200 protein scaffolds. NLR contains centrally located NACHT domains.

Similarly, extracellular release of HMGB1 from macrophages infected with S. typhimurium relies on activation of caspase-1 by NLRC4 inflammasome. Unlike IL-1β and IL-18, HMGB1 does not undergo caspase-1-mediated processing. HMGB1 release takes place continuously in macrophages which are less known caspase-1-substrate (IL-1β, IL-18 and caspase-7) show that caspase-1 can induce noncanonical HMGB1 and other secretions of proteins through proteolytic activation of unknown secretion devices.
HMGB1 mediated immune response

DAMPs such as HMGB1 in shedded microbes, secretory lysosomes or exosomes. In addition to mediating the non-conventional pro-inflammatory secretion of cytokines, HMGB1 has been identified as a critical hazard signal that contributes to necrotic-related inflammation.

This is illustrated by necrotic observations that cell debris from HMGB1-deficient cells significantly decreases in inducing pro-inflammatory cytokines. HMGB1 and S100 proteins. In conclusion, inflammasomes may release HMGB1 circulating through unconventional protein secretion, or as a consequence of cell lysis during pyroptosis. Depending on the pathological context, the secretion of proteins can be frankly the inflammatory masmas-mediated subtleties release signals of danger and inflammation of cytokines.

The mechanism of HMGB1 to TLR2 and TLR4 in inflammation, Autophagy and modification of DNA

HMGB1-induced immune receptor activation may involve assembling immunostimulatory complexes with endogenous or microbial co-factors. Besides RAGE, HMGB1 is recommended to induce secretion of pro-inflammatory cytokines and chemokines by inducing NF-kB signaling downstream of toll-like receptors (TLR) 2 and TLR4 activation.

Thus, extracellular HMGB1 can bind microbial components or endogenous substances released from injured tissue to induce or increase the production of inflammatory mediators during infection and in response to (sterile) trauma. An interesting question he has is how HMGB1 moves from the nucleus to reaching the extracellular environment considering that it has no classical secretion signal.

Such a signal peptide is usually needed to transport secretory proteins through the lumen of the endoplasmic reticulum (ER) to the extracellular space in the Golgi secretory vesicles. HMGB1 has been shown to be released from active LPS monocytes and cell line macrophages are consistent with its role as prototypical alarmin. Other proteins think to undergo unconventional.

5. Extracellular HMGB1 as a DAMP Molecule

After release, extracellular HMGB1 functions as a DAMP to signal, record, and activate immune cells. For example, HMGB1 binds to various PAMPs (eg, CpG DNA or LPS), thus facilitating their recognition by each receptor, and consequently increases the
inflammatory response induced by PAMPs. HMGB1 interacts with the family of cell surface receptors and binds to proteins including RAGE, TLR4, TLR9, differentiation groups 24 (CD24) / Siglec-10, Mac-1, thrombomodulin, and single transmembrane protein domains (eg, syndromes). HMGB1 contains three cysteine residues in a very sustainable position: 23, 45 and 106. Recently a consensus conference proposed an isoform nomenclature, called “HMGB1”.

HMGB1 is secreted through pyroptosis also hyperacetylated on the NLS Site. This is consistent with the understanding that HMGB1 treated with inflammation Discharge is a very regulated process. Furthermore, various types of inflammasome activation induce different HMGB1 post-translational modifications. For example, NLRP3 inflammatory stimuli, such as ATP, monosodium uric acid, and adjuvant aluminum, induce HMGB1 “disulfide” secretion; whereas activation of NLRC4 inflammasome produces very reduced HMGB1 secretion.

One possible explanation is activation of inflammation of NLRP3, but not NLRC4 inflammasome, associated with the production of mitochondrial ROS, which promotes HMGB1 oxidation and formation of C23-C45 disulfide bonds. HMGB1 redox status allow for appropriate immune response to different pathogens. HMGB1 release, which facilitates leukocyte recruitment to eliminate invading bacteria contributing to sequential leukocyte recruitment, activation, and ultimately inflammation.

**Conclusion**

High Motility Group Box 1 (HMGB1) is a protein that is expressed constitutively in almost all types of cells. In response to microbial infections, HMGB1 is secreted from immune cells activated to regulate inflammation. DAMPs such as HMGB1 in shedded microbes, secretory lysosomes or exosomes. In addition to mediating the non-conventional pro-inflammatory secretions of cytokines, DAMPs and growth factors, inflammatory activation in immune cell activation triggers the induction of a special caspase-1-mediated cell death program called pyroptosis. After being fully oxidized, HMGB1 has no chemokine or cytokine activity.

Analysis of the Implementation of School Partnership Programs as Evaluation to Improve Education Quality

Wining Widiharti¹, Burhanuddin Tola², Wardani Rahayu², Yetti Supriyati²

¹Doctoral Student of Research and Education Evaluation Study Program, State University of Jakarta, East Jakarta, Indonesia, ²Research and Education Evaluation Study Program, State University of Jakarta, East Jakarta, Indonesia

Abstract

This study was prepared to evaluate and analyze the results of the implementation of the 2013 curriculum (K13). The aim is to provide evaluations to existing schools to make improvements in the form of solutions that can improve the ability of schools to manage. In addition, in this study, it is also expected to provide encouragement to teachers in providing optimal teaching. So that later on education that applies the 2013 curriculum can develop. This study uses a qualitative approach to evaluation research methods, applying a mixed-model model, namely Kirkpatrick and Countenance Stake. The main instruments of this study are the researchers themselves and supporting instruments in the form of interview guides, questionnaires, observation guidelines and document analysis guidelines. In general, the principal’s partnership program has a real impact on the quality development in the impact schools in the form of improving the quality of education through the exchange of knowledge and experience between partner school principals.

Keywords: Curriculum, School Principal, Evaluation.

Introduction

Leadership in all organizations including schools as a formal institution has a strategic position. In education, the principal has the authority to make plans and programs that are relevant to the school’s development needs. The success of the school is very dependent on the ability or creativity of the principal in identifying challenges and problems faced by the school and then formulating the right solution by optimizing the resources available in the education unit he leads.¹

Evaluation was a process of activities aimed at making decisions, in contrast to evaluative research designed to answer questions, test and prove hypotheses. However, both have many similarities. Among them are both of them can study the same focus or problem; use design with the same methods and techniques of measurement or data collection; can use samples with the same location or scope; using the same data analysis techniques and interpretation of results.²

Sukmadinata further explained that evaluation has two main activities, namely: (1) measurement or data collection, and (2) comparing the results of measurement and data collection with the standard used. Similarly, Dun, as quoted by Hadi and Mutrofin² says that the term evaluation has a related meaning and each refers to the application of several scale values to the results of policies and programs.

On Job Learning (OJL) is an activity to identify and analyze the implementation of the plan to improve the leadership quality of the principal. Through the mentoring mechanism, the Facilitator and Principal Partner will conduct assistance in the impacted schools that implement it for several days to collaborate as well as assist and assist the affected school principals in implementing the change agenda that has been formulated in the On the Job Learning plan. In general, the substance of the principal’s partnership program is

curriculum management.3

**Literature Review**

**School Principal’s Partnership**

The partnership program that began in 2015 was carried out through the mechanism of exchanging partner principals with the impacted school principals and was named the Principal Leadership Comparative Study Program. The activity was attended by 1500 school principals, namely 750 school principals in affected schools and 750 school principals in partner/affecting schools. In 2016, the continuation of the program will be carried out in the form of mentoring by the Facilitator and the Principal Partner of the School Principal. The 2016 program will generally continue planning changes that have been designed at 2015 In-Service Learning-1 and On the Job Learning Workshop while identifying and analyzing the implementation of plans to improve the leadership quality of principals after the In-Service Learning-1 Workshop. Through the mentoring mechanism, the Facilitator and Principal Partner will conduct assistance in the impacted schools that implement it for several days to collaborate as well as assist and assist the affected school principals in implementing the change agenda that has been formulated in the On the Job Learning plan.4

The principal goal of the principal’s partnership is not only in the aspect of academic substance but also targeting the contextual things such as the spirit to change, the mindset of change and the spirit of togetherness that is expected to be permanently built between the partner principal and the affected headmaster. In general, the substance of the principal’s partnership program includes curriculum management, supervision of learning and strengthening the school ecosystem. Management of curriculum and supervision is basically inherent in the principal task of a school principal.5

Management of the school ecosystem includes the internal and external environment of the school or as part of the school system itself. Internally, environmental management, both physical and non-physical, is a necessity for schools, especially for school principals, in optimizing the educational outcomes targeted by schools. In addition, in the external environment of the school, the involvement of stakeholders, in this case, the community at large should be a serious concern from the principal.6,7

The impact generated by the intimate relationship between the school and the community through the effectiveness of the principal’s leadership appearance, are: (1) increasing active participation of the community in educational activities; (2) improve communication between the school and the community; (3) schools can improve school education programs whose results are really needed by the community (link and match); and (4) the possibility of increased support from the community in the form of: funding, information and political support.4

**Method**

This study used a qualitative approach with evaluation research methods that implemented a mixed-model model namely Kirkpatrick and Countenance Stake. This research was carried out in the Directorate of Education Personnel Development by selecting 100 principals as the main respondents. In addition, researchers also collected data on in-depth interviews with 20 teachers, 10 supervisors and 2 managers of the principal’s partnership program. The research process is generally described as follows:

Pre-study carried out from January-March 2016. This study is intended as an initial process to understand the problems of implementing the partnership program that began in 2015. The study was also intended to get a picture of the potential changes in the principal’s post-I leadership stage 2015.

Follow-up research conducted from July to August 2016. This continued research is at the core of implementing partnership program evaluation research. This process is a further and in-depth search of the object of research accompanied by the collection and analysis of all data related to each component of the program in accordance with the procedures, methods, and techniques that have been planned.

The main instrument of this research is the researchers themselves. However, for more effective data retrieval processes related to the focus of research, this study uses supporting instruments in the form of interview guidelines, questionnaires, observation guidelines and document analysis guidelines. For this purpose, an instrument grid and theoretical validation are arranged. Data analysis was performed using the Miles and Huberman Model, namely a qualitative analysis model through three activities or processes, namely: data
reduction, data display, and verification.

**Result**

The following are the results of research conducted on 100 principals as the main respondents. In addition, the researchers also collected data on in-depth interviews with 20 teachers, 10 supervisors and 2 managers of the principal’s partnership program as follows.

**Teacher’s Perception**

Teacher’s perception of the implementation of the 2013 curriculum since the 2 (two) years partnership program was carried out seen from 5 (five) aspects, namely: 1) Teacher’s confidence in implementing K13, 2) Enthusiasm or response of students with K13-based learning, 3) Teacher readiness to implement K13, 4) Supporting Facilities for K13-based learning, and 5) School environment support.

**School Principal’s Perception**

The impact of school principals’ perceptions is related to the implementation of K13 in their schools after 2 (two) years of partnership between principals seen from 1) teacher enthusiasm, 2) teacher readiness, 3) teacher’s efforts to continue learning, 4) school committee support.

The principal’s perception of the implementation of K13, in particular, the criteria related to teachers is quite positive even the achievement index is quite high at 0.91 and 0.95 respectively. This means that principals are quite optimistic about the application of K13, especially related to teacher factors. Even though the principal considered that the teacher did not yet have adequate readiness to implement K13 but at the same time the principal considered positively that the teacher showed enthusiasm and effort and continued to learn to implement K13 better.

In general, principals find it difficult to facilitate the implementation of the 2013 curriculum due to free school policies from local governments that do not allow schools to charge fees from the parents/community. While for the ideal, support for facilities, tools, and certain materials/media is needed for the implementation of the 2013 curriculum.

**RPP Development**

In the aspect of RPP development, it can be seen that the criteria are met and those that are not met are 3 criteria. This means that in descriptive only half of the criteria are met so that the achievement of this aspect as a whole is still far from the standard. In addition to the descriptive analysis shown in the figure above, the results of the document analysis found several problems related to the development of the RPP outlined below.

There are still indicators and learning objectives that are not right. Indicator formulation in both KI and KD is too broad and not adjusted to the subject matter. There is a formula for learning objectives that are not right, because what is described is only the process and there is no description of the results to be achieved. Learning resources seem to be written formally in the lesson plan: in general, the RPP made by the teacher includes several learning resources, but in fact only one source is available, the book. There were several RPPs that write learning resources from the internet and print media but the sources are not clearly written. The formulation of learning experiences has not yet described the real “scientific” process: most of the RPPs made by the teacher have not yet described the essence of developing creativity through the scientific approach. Some of these RPPs do not show specific learning experiences

**Study Plan Document**

Some components of teacher RPP meet the criteria and the picture above shows that there are 3 criteria that are fulfilled, namely: clearly loading the media and learning resources used, as well as the description of the material in accordance with the formulation of learning competencies to be achieved. Problems encountered through document review are the inconsistencies between written in RPP documents and supporting physical evidence, for example about learning resources that are listed as not in accordance with reality.

**Rating**

Assessment aspects are the weakest part of implementing K13 in impact schools. Although there are 2 criteria that meet the standard but the other 4 criteria are quite low. Even the teacher’s ability to make assessment rubrics related to indicators of student learning outcomes shows very low achievements. In addition, the results of the document analysis show that almost all teachers do not have a question bank. There is a collection of questions taken from various sources and not yet analyzed.
There still needs to be sufficient reinforcement for teachers’ understanding of the assessment of learning processes and outcomes. In general, teachers do not have a good understanding of the concept of authentic assessment, especially non-test assessment, and attitude assessment. The assessment instruments used by the teacher including the assessment rubric and scoring are generally less “applicable” or difficult to apply in classical judgments. There needs to be a choice of instruments that are easier to use especially in assessing aspects of attitudes and skills (not always relying on complicated rubrics).

The learning plan is not equipped with concise material. Almost all RPPs include portfolio assessments even though the results of interviews and document validation, in general, have not yet developed a portfolio and teacher assessment as a whole yet have a full and correct understanding of portfolio assessment.

Apperception of Learning

The teacher’s performance in initiating the learning process or what we know by the term apperception is generally illustrated in the following graph. The teaching and learning process including the apperception section should not be a problem for the teacher because generally, the respondents who were subject to PBM evaluation were those who already had a service period of more than 5 years. In addition, these teachers have also received support from partner school principals during in the job learning assistance.

From the results of interviews with teachers, it turns out they face difficulties when they have to put in contextual examples or elaborate examples in apperception activities and relate them consistently with the basic competencies being taught. In addition, there are still teachers who consider apperception activities not too important and they focus more on the material to be taught. Even though apperception activities are not only about how to link the past material with the material that is sedan will be taught but also how to build a classroom atmosphere. The classroom atmosphere here is related to students’ learning readiness, how to build their learning motivation, how to get their attention. Apperception can even determine the next learning process. When the teacher succeeds in challenging students’ interests and learning motivation by presenting an interesting learning context, the opportunity to manage classes and learning effectively is more open. The following table describes the conditions of the teaching and learning process in the apperception section. Apperception has not been well developed. Apperception has not been used as an entrance to develop a pleasant classroom atmosphere and learning atmosphere and inspire/motivate students to learn. Some teachers seem to be in a hurry to directly enter the learning material so that some important parts in the apperception are abandoned. Some teachers managed to display interesting shows on the apperception section but did not elaborate coherently to enter into core activities (not sequential / interrupted by core activities). The use of ICT in apperception is still very lacking (how to use the advantages of ICT with visual and sound effects that can arouse student learning interest.

Core Activities

Teacher’s ability to carry out a learning process with a scientific approach has not shown the optimal achievement. Some learning criteria have reached the standard but with relatively good results. But more than half of the criteria that have achieved are low and do not reach the standard. The following table describes the general problems faced by teachers in using the scientific approach.

Group discussions have not been well developed. Group assignments have not been formulated and activity scenarios are made so it is not clear how the process and what will be produced by the group, what will be assessed both in groups and individuals. In general, groups are not provided with clear instructions (teachers should be able to prepare instructions, scenarios, and assessments through impressions / ICT). Groups should be facilitated with shows (available on a lot of internet / Youtube). This means that teachers have not been optimal in utilizing ICT in the learning process (only limited to PPT). Teachers still need to encourage students and them to be proactive in discussing and convincing them not to fear to be wrong, most importantly how they are trained to express ideas and be critical in seeing problems. Scientific nuances are not yet strong. Some learning activities have begun to show a scientific approach but the rather weak parts are the “questioning” and “reasoning” processes that are most often missed by the teacher’s emphasis. The inquiry process tends to be weak because the teacher sometimes rushes to conclude on his own so students
lose the moment to find and conclude the results of their observations and analysis. The limitations of teacher understanding regarding learning methods and models have an impact on learning processes and outcomes that are not optimal. Teachers tend to be very attached to examples of methods and models of learning obtained in training. The interview method, for example, is very suitable for certain KDs and subjects, but the teacher does not have the understanding and experience in developing the method.

**Conclusion**

In addition to relating to learning, especially the implementation of K13, which has been detailed in detail above, the context of curricular management has also shown quite good progress. Of the 10 impacted schools that were the target of deepening partnership data in the context of the program evaluation, it was found that all of the schools in question had already formed a Curriculum Development Team which previously (before the partnership program) did not yet exist. Likewise, it relates to the curriculum itself, where all impacted schools that are participants in the partnership generally still use KTSP (Curriculum 2006) before participating in the partnership, but since 2016 gradually the schools have started to implement the 2013 curriculum.

Factors Associated with Behavior Usage of Respiratory Protective Equipment among Sugarcane Factory Workers in Northeast of Thailand

Wipada Panakobkit¹, Pornpun Sakunkoo²

¹Student of Doctoral Program of Public Health, Faculty of Public Health, Khon Kaen University, Khon Kaen, Thailand, ²Department of Environmental Health Occupational Health and safety, Faculty of Public Health, Khon Kaen University, Khon Kaen, Thailand

Abstract

Several sugar industries in Thailand are highly effected to environmental health, including a safety at work, mainly the areas surrounded of bagasse.

This research aimed to study on factors associated with behavior usage of Respiratory Protective Equipment (RPE) among sugarcane factory workers. A cross-sectional study was conducted among 588 workers at 4 sugarcane factories in Northeast of Thailand, between December 2017 to April 2018. Workers were selected by multi-stage random sampling to completed structure questionnaires. The multivariable analysis was used by multiple logistic regressions.

The majority were males (71.94%). Their mean age was 38.28 (±10.56) years old. Financial status was poor (65.65%). Department were juice extraction machine (67.52%). The majority types of RPE usage were cotton masks (94.56%) and their behaviors usage of RPE had good level (64.80%, 95%CI: 60.92-68.67). Additionally, factors associated with good behavior usage of RPE were included age (AOR= 1.65, 95%CI: 1.14 to 2.38; p=0.007), financial status (AOR= 1.57, 95%CI: 1.07 to 2.29; p=0.021) and department of work (AOR= 0.66, 95%CI: 0.31 to 1.40; p=0.017).

Almost two-third of sugarcane factory workers had good behavior usage of RPE. Work safety awareness is important to prevent and promote among sugarcane factory workers to the adaptation their working environment.

Keywords: Behavior, Bagasse, Respiratory Protective Equipment (RPE), Work-Safety.

Introduction

In Thailand, 16.8% workers are involved in manufacturing industry, normally the labor in the system preferred to work in factory and machinery operators (12). It’s impact has increased due to lack of public awareness, and exposure of workers to inferior air quality at the workplace leads to ill health(7). Personal Protective Equipment (PPE) is worn by workers(15). Nevertheless, Respiratory Protective Equipment (RPE) is not always used, even in situations with high exposure risk(13).

Therefore, The occupational health problems in the sugarcane industry had existed in more than 40 countries in the world(9). In 2016 Sugarcane on average accounts for about 80% of global sugarcane production. Production has become increasingly concentrated. The trend of top ten countries of sugarcane producing in 1980 accounted for 56%, whereas in 2016 accounted for 76% respectively. More interestingly, Thailand was third ranked after Brazil and India among top ten of sugarcane producing in the world(6). Harvesting occurs in dry season between mid-December and the end of April(8). Sugarcane industry constitutes one of the big industries,
there are 55 plants in Thailand and 20 plants in Northeast of Thailand\(^{(2)}\).

The working conditions of the sugarcane industry workers are extremely poor. The occupational health and safety issues in the workplace are significant due to the diversity of occupational safety factors. That the workers are exposed to high concentration of excessive heat, high intensity noise, high intensity of dust in cane yard section, bagasse dust in mill and bagasse baling section are the main causes of respiratory problems among these workers\(^{(10)}\). We found out that the workers at sugarcane factory have faced with health and sanitation problems because there are variety issues which do harm to their health, especially the concentration of bagasse. Inhalation of bagasse dust causes a respiratory disease called Bagassosis\(^{(11)}\).

If the workers who work in the environment which are insufficient oxygen or dusty area, the RPE is necessary indeed. It is also reducing any loss and risk to the workers because it is harmful to their health and might cause of lung cancer and respiratory deceases\(^{(4)}\). Wearing RPE could prevent respiratory deceases which be able to reduce the bagasse dust. It is an important preventive measure to their career. Anyway, it is totally safe their health if they do wear them correctly and the equipment have been in good maintenance constantly. However, the strictly usage of the RPE by workers or company or workers themselves are still the main majority issue\(^{(4)}\).

Therefore, this study aimed to investigate the factors which relate to behaviors of usage the RPE of workers in sugarcane factory. A sample group was collected from workers within Northeast of Thailand.

**Material and Method**

**Study Design and Sampling**

A cross-sectional study was conducted in 4 factories in Northeast of Thailand. Data was collected from December 2017 to April 2018. The sample size was calculated following formula\(^{(5)}\)

\[
np = \frac{n_i}{1 - \rho^{2,1,2,3,\ldots,r}}
\]

The approximate sample size was 327 which were further adjusted to control the over-fitting using the rho (\(\rho\)) of 0.50 and variance inflation factor (VIF) equal to 2.00. Therefore, the total number of the sample was 588. Data sampling processes: Firstly 4 factories in Northeast of Thailand were randomly selected. Then 3 departments facing with dusts at the working area were drawn. There were 7,965 sugarcane factory workers registered at the department of industrial work. Finally, all participants who met the inclusion criteria were randomly selected proportionally to size of the samples added to the total of 588 samples. (Figure 1).

![Figure 1. Flowchart of study design and sampling of sugar factory workers](image)

Proportionally to size of the samples added to the total of 588 samples. (Figure 1)
Questionnaires

The questionnaire was modified from reviewed literatures based on research questions. The questionnaire contained 3 parts which were: 1) Demographic Characteristics, 2) Attitude to the usage of the RPE, and 3) The behaviors of usage the RPE. The questionnaire was validated by 3 experts and tested for reliability.

Data Analysis

Descriptive and analytical statistical data were analyzed with STATA® (version.13; college Station, TX, USA: Stata Corp) was used to analyze the data. Demographic characteristics of the participants were described as frequency and percentage for categorical data; mean and standard deviation for continuous data. Inferential statistics, a simple logistic regression, was used for bivariate analysis to identify individual factors associated with good behaviors for usage of RPE. The factors that had $p$-value $<0.25$ were processed into the multivariable analysis using multiple logistic regression and reported the adjusted odds ratio (AOR) and their 95% confidence interval (95% CI) and $p$-value$<0.05$ was considered as statistically significant.

Result

Demographic Characteristics

The total 588 sugarcane factory workers in Northeast of Thailand, the majority were males in 71.94% and average age was 38.28 years with a range of 19-69, level of education was primary school, and marital status was marriage, average income each month 10,146 THB. Financial statuses were poor 65.65%. Majority it’s in juice extraction department is 67.52%, worked less than 5 years were 42.69%. Most of them get the information how to use the RPE from safety officer were 77.89%. Principally they wear cotton masks while working at factory is 94.56% (Table 1)

Factors associated with behaviors of usage RPE: Multiple logistic regression analysis

Multiple logistic regression analysis by Backward elimination indicated that sugarcane factory workers who have group of age over or equal 40 years old was 1.65 times of having good behavior using RPE when compared with those who aged less than 40 years old (AOR= 1.65, 95%CI: 1.14 to 2.38)

Those who have good financial status were much better 1.57 times of good behavior using RPE when compared with those having poor financial status (AOR= 1.57, 95%CI: 1.07 to 2.29)

Those who worked in the departments of steam-boilers and bagasse yard were 0.59 times and 0.66 times of having good behavior using RPE when compared with those who worked in department of juice extraction (AOR= 0.59, 95%CI: 0.40 to 0.83) and (AOR= 0.66, 95%CI: 0.31 to 1.40) respectively. (Table 5)

Discussion

This study revealed that the good behaviors usage of RPE among sugarcane factory workers were 64.8%. And the associated factors with good behavior of usage RPE among sugarcane factory workers were found 3 factors including: age, financial status and department of work.

The association between age and good behaviors usage of the RPE was consistent with study in Nepalese industrial workers which revealed that increasing of age of workers had associated with good behaviors usage of the RPE(1).

Financial status had associated with PPE(1) where the RPE was one of subset PPE. To the current study, monthly income of workers were about 10,146THB equal to US dollar about (320$), had received the information how to use the RPE from safety officer were 77.89% that encouraged them using cotton masks of 94.56%.

The department of working, we found that group of worker in steam-boilers department is more likely better behavior usage of RPE than department of Juice extraction 0.59 times. However, sampling group in bagasse yard, they wear the RPE much better than the steam-boilers department at 0.66 times. The reason of did not use RPE maybe from difficulty in breathing, pain in the ear, small size of the face(3).

Conclusion

Behavior usage of RPE can improve occupational health and safety at workplace among factory workers. Besides, it emphasizes them to practice appropriate behavior of health preventive in workplace. This research has been collected the data from only three departments; juice extraction machine, steam-boilers and bagasse
yard. Therefore, we suggest next research should collect the data to cover all work-functions in the factory because they also are risky to inhale the dust while working. The current study of cross-sectional design was first a snap of associated factors with outcome being evident. Then the next study will be conducted on evidence-based recommendations promoting to change behavior in the actual workplace situation.

Research Ethics approval for this study was obtained from the Khon Kaen University Ethics Committee for human Research (HE602331).

The Impact of an Educational Curriculum Using Technical Learning and Ginseng Accompanied in Development of Response Speed and Learning the Front and Back Dropped for Badminton Players

Wissam Salah Abdul Hussein1, Ebtighaa Mohammed Qasim1, Abeer Ali Hussein1

1University of Kerbala /The College of Physical Education and Sports Sciences/ Iraq

Abstract

The researchers noted through his presence in the field of badminton, that most players with ages of (13-15) years suffer from weakness in the response and reaction, and this affects the impact on the basic strikes of the badminton plane, because the process of identifying stimuli and awareness helps to create dynamic programs in the brain, making the response quick. This is where the research problem is concentrated. The aim of the research is to develop an educational curriculum using technical learning and ginseng in the development of response speed and learning the projected front and rear projection of the players of the plane. And to identify the impact of the educational method using technical learning and ginseng in the development of response speed and learn the strike of front and back dropped for badminton players.

The researchers used the experimental approach with the design of the two sets of pre-and post-test tests to suit the nature of the problem and achieve the research objectives. The study sample represented the entire research community and they are the players of the training center in the district of Mahaweel - Babil province for the season 2019 and the number of (6) players and ages (13-15) years and this means the researcher used the method of comprehensive inventory of all members of the community.

The most important conclusion is that the curriculum using technical learning and ginseng has a significant role in the development of response speed and the projected impact of the front and rear of the players of the badminton. The experimental group is superior to the post tests, which means that the educational curriculum using the technical learning and ginseng was active and effective.

Keywords: educational curriculum, technical learning, front and back dropped.

Introduction

Many of the educational methods used in learning mathematical skill varied proportions used with success in the skill and cognitive performance and emotional so experts and researchers sought to find methods of serving sporting events and skills all in line with the learner, the style technical is one of these modern methods in the learning process, which means the arrival of the learner to the point of workmanship and installation mechanism in the development of learning outcomes (skill, cognitive, emotional) and access to their degree and then move perfection to learn another skill.

The speed of the motor response is one of the motor abilities that have an important role in the technical performance of offensive and defensive skills and together with other factors is an important basis in resolving the situation, as the striker in the badminton must be characterized by shortened the time of his motor response to reach the badminton. And through the readings of researchers in many references and scientific research to improve or increase the capabilities of the athlete and the positive performance of referees and
players observed the use of medicinal plants in the field of sports and widely, for many reasons, including the absence of chemicals that may harm health, as well as non-food. As well as to avoid side effects caused by the use of chemical drugs.²

The majority of players aged (13) to (15) years suffer from weak response and reaction, which affects the basic plane crash, because the process of identifying stimuli and recognizing them Helps to create dynamic programs in the brain, making the response quick. Hence, the problem of research was determined. Therefore, the researchers decided to prepare a learning curriculum using technical learning, which aims at mastering the skill, controlling its kinetic pathway and using food supplement in developing the response speed and learning the projected front and rear projection of the players with the badminton.³

The variety of badminton tournaments (singles, doubles and mixed doubles) for men and women has made most countries adopt the principle of specialization in the game, because badminton skills are characterized by a high degree of accuracy and difficulty because of the high speed of the badminton and the multiple paths of movement at one point, which requires the player to recognize on all stimuli and kinetic variables in order to be able to respond in the least possible time, and hence the importance of research in the preparation of an educational curriculum using technical learning and the use of food supplement Ginseng in the development of response speed and learning the projected blow front and back of badminton players.

Research aims:

Preparation of a curriculum using technical learning and Ginseng in the development of response speed and learn the strick of front and back dropped for players of the badminton.

Research Methodology and Field Procedures:

Research Methodology:

The researchers used the experimental approach to design a single group with pre and post testing, in order to suit the nature of the problem and achieve the research objectives.

Search community and sample:

The study sample represented the entire research community and they are the players of the training center in the district of Mahaweel - Babil province for the season 2019 and the number of (6) players and ages (13-15) years and this means the researcher used the method of comprehensive inventory of all members of the community.

Search tools and devices:

1 - Integrated badminton courts type (Yonex) number (2)
2- Yonex badminton rackets (12)
3- Yonex badminton balls (10)
6 - Magic colored pens number (5) 7 - colored adhesive tapes number (10) Role
8 - Linen measuring tape 20 m length 9 - Chinese stopwatch number (2)
10 - Tests 11 - Questionnaire 12 - Data dump form
13 - Large rubber balls (4) 14 - Rubber ropes 5 - 15 - rope for jumping (5) 16 - A ground ladder made of linen length (10 m).

Technical tests and response speed:

Front and back dropped test:

Purpose of the test: measuring the skill of the front projection shot.

Required tools: feather rackets, feathers, striped playground with test design as shown in figure (1).

Description of performance: After the test is explained to the labs, each laboratory (5) will be given experimental attempts to warm up and then the player will stand at the specified location (X) and (5m) from
the net, he is holding his racket with a forward catch to receive the badminton sent to him from the opposite field ( ). Drop it in the top-rated area (3, 2, 1).

**Performance Calendar:** The player performs (12) attempts and calculates his best (10) attempts.

The degree is given according to the place of fall of the feather.

Badminton located on a line between two regions given the highest degree.

The highest points the player can get are (30) points.

![Diagram of badminton court](image)

**Figure (1). Explain the layout of the badminton court to test the front and back dropped**

**Nelson Test for Kinetic Response:**

**Purpose of the test:** Measurement of the ability to respond and move quickly and accurately according to the choice of stimulant

**Tools:** A flat area free of obstacles (20m), width (2m), stopwatch and tape measure.

**Procedures:** The layout of the test area with three lines between each line is 6.40 m and the length of the line is 1 m.

**Test Instructions:**

Each laboratory is given a number of attempts outside measurement on the same basic conditions in order to identify the testing procedures.

The referee must train on the start signal, so that he can give this signal by the arm and run the clock at the same time.

The referee before the test to the laboratory to withdraw the previous ten cards in a random way and recorded in the order of withdrawal in a special card and put it in one of his hands to guide in the sequence of signal trends and record time for each laboratory separate from the other and this is used to prevent the laboratory from expecting to try next.

The laboratory must not know that it is required to perform ten attempts distributed equally in both directions, but it is possible that the number of attempts to direction is greater than the other and that the order of performance of attempts is random and varies from laboratory to laboratory.

The test should begin with the referee giving the following signal: Prepare - once, in all attempts the time interval between (reset-start) should be between (0.5-2) seconds.

The laboratory should do some light exercise for the purpose of warm-up, preferably wearing light shoes and the test area must be free of any contraindications.

**Registration:**

The time of each attempt is calculated for the nearest second.

Laboratory degree is: average ten attempts.

**Pre Tests:**

The researchers applied the pretests on 2/2/2019 in the closed hall in the district of Mahaweel - Babil province at 10 am, where the technical tests, testing and response speed were conducted.

**Exercises used in research:**

The researchers designed an educational curriculum according to the method of technical learning by giving repetitions to the learner to achieve one skill to master the real and adjust the motor path and then move to the other skill, in addition to the dietary supplement was taken ginseng, where the doses of US ginseng were determined:

Effective doses of adults aged 25-35 years should be between 50-75 g and 2 to 8 g for a period of 8-12 weeks maximum. So half of this quantity has been adopted to match the sample search

Ginseng should be taken every 12 hours or twice a day.

It is recommended to take the American ginseng before eating to increase the speed of absorption of food and to benefit more.
The use of US ginseng more than 3 months because it leads to vitamin B6 deficiency in the body, leading to feelings of indigestion and depression.

The good product of American ginseng is that contains Ginsenoside by between 4 to 7 percent.

The main experiment was applied in 4-2, 5-3-2019, where the educational curriculum was implemented at two units per week and 90 minutes per unit.

Post tests:

The post-tests for the technical tests and the response speed were applied to the two groups on 7/3/2019 and in conditions similar to the pretests.

</table>

From the table (1) show that use of educational exercises and their suitability to the level of learners and to give appropriate repetitions with the type of exercise and the ability of the learner during the main section of the unit and stated that “the repetition of motor performance is a requirement that people need to reach a high level of learning locomotive”. There is also a clear impact on the educational method used to take into account the difficult skill segmentation and takes into account the individual differences in the learning process and the promotion of feedback.

This is characterized by the technique of education, “which is an educational plan that provides each student with the time needed to reach the level of ability as individuals learn at different rates “[8]. The researcher believes that the method of learning proficiency through attempts to master the successful performance of skills contributes to the educated sense of self-esteem and self-confidence and control their emotions when they identify and diagnose themselves negative and positive aspects, trying to correct them feedback, which increases the confidence and ability to achieve the achievement of the duty of motor.[9]

The use of the experimental group to the American ginseng, which led to this, as the American ginseng with the most important medicinal plants because it contains ginsocides, which in turn increase the focus and works to stimulate the individual physically and psychologically, especially contain the element (f11) Blood circulation. And gives the individual the ability to endurance and fatigue resistance US ginseng is a natural tonic that increases the stamina and helps increase energy levels, helps athletes use oxygen more effectively, regulates metabolism, and increases recovery.[10] The player needs to adapt and fast switch and control the badminton and what the opponent does and this depends on the speed
of the player because the speed of the shuttle is large and needs a quick response, the shorter the speed of the response speed of the motor player was able to act proper and timely especially the deception games performed by the opponent.

Conclusions

The curriculum using technical learning and Ginseng has a significant role and effective in the development of response speed and the front, back dropped impact of the front and rear of the badminton players.

The experimental group is superior in the tests of the dimension, which means that the educational curriculum using technical learning and Ginseng was active and effective.

The Relationship between Overlapping Wave Strategy and Healthcare Performance Improvement

Yousef Hichaim Sultan¹, Karar Saleh Suhail²

¹Prof. Dr. University of Kufa / College of Administration and Economics, Iraq, ²Assist. Lect. Al-Rafidain University College / Business Management Department, PhD Candidate, University of Kufa, Iraq

Abstract

Healthcare performance is important factors in all health systems worldwide. Many studies tried to assess the factors that improving healthcare performance. Hence, this paper aimed to explore the relationship between overlapping wave strategy and performance improvement in Iraqi healthcare institutions. According to the literatures conceptual framework were proposed and tested using structural equation modeling and regression, the results confirmed that overlapping wave strategy and its dimensions positively affected healthcare performance.

Keywords: Iraqi Healthcare, Healthcare performance, Strategic Navigation, Genius Leadership, Future Managing, Knowledge Leadership.

Introduction

Iraq has gone through decades of war and substantial sanctions from the United Nations. For example, as a result of the Gulf War in the 1990s and a decade of sanctions were among the side effects on hospitals¹. Before these conditions, Iraq had a very high standard of healthcare when compared to other countries in the Arab region. Healthcare in the country was free by then, administered centrally through the ministry of health and well equipped with necessary equipment and appropriate number of personnel². Basic medicines have often been unavailable in various hospitals in the country, As a result, the mortality rate, more also the infant mortality rate has more than doubled up³. Unless some drastic measures are undertaken to improve the situation in the country, Iraqi’s health care sector is likely to worsen even further. More focus should be placed on how to provide essential facilities like basic sanitation, essential drugs and immunization services⁴.

Accordingly, Iraqi health institutions need to employ successful strategies to improve performance. in this area we find many success stories about the concept of overlapping wave strategy, and they have proved positive results in many areas. The philosophy of research was initiated by the ideas of Siegler (1996)⁴ which presented overlapping wave strategy, and have proved positive results in many areas.

Accordingly, this paper aims to explore the relation between overlapping wave strategy and healthcare performance improvement.

Literature Review

Overlapping Waves Strategy

The theory of overlapping wave strategy is a modern perspective. Here, the strategists use a number of strategies to do their work, so many different strategies will appear to address all the old and new information and data, and there will be a simultaneous process in strategy development⁵. Showing the process of competing in individual ideas to reach a more useful idea⁶. Thus, Siegler presents the theory of overlapping wave strategy based on three assumptions:

1. At any time, personnel or employees think in a variety of ways about most administrative problems.

2. These different ways of thinking compete with each other.

Corresponding author:
Karar Saleh Suhail
E-mail: Islamll@yahoo.com
3. The development of strategic knowledge results in gradual changes in the frequency of these ways of thinking.

Figure 1 shows the diagram of these assumptions, which indicates that any vertical segment in the figure indicates that multiple methods are used simultaneously. The use of the curve for any strategy indicates that strategies will continue to be used for long periods of time. Looking horizontally across the figure indicates that the relative frequencies of all strategies gradually change over time, with sometimes new strategies being added and sometimes old strategies ceasing to be used. Thus, the diagram focuses on several key issues: the set of approaches used by individuals in a particular situation, the factors that influence their choices among these methods, the mechanisms that change the use frequencies of existing approaches, and the mechanisms that lead to the discovery of new approaches.

![Figure 1: Overlapping waves strategy](image)

**Luxury leadership**

Luxury leadership is a leadership style based on creative knowledge. This type of leadership requires organizations to be prepared to change by starting shifts from the current reality and encouraging change. Perfectionist customers may see that there is additional value. Luxury leadership is a management, strategy and performance that teaches everyone how to develop, experience products and services, and long-term loyalty.

**Strategic navigation in leadership**

Navigation leadership is the case when leaders influence their followers to increase their moral standards, views, beliefs, alliances, and motivations. Inspirational leadership involves the link between the leader and followers. It is inspirational, giving subordinates the ability to test current assumptions seriously and encourage them to think across broader dimensions. Thus, they have the ability to influence their followers behavior, resulting in positive outcomes.

**Genius leadership**

Intelligence and genius are closely related to each other and the Genius leadership is determined by the energy emitted from the inner side of individuals and their own abilities. Genius is a very important tool for leadership where leaders can acquire and use knowledge to solve problems within the organization. Genius leadership is a recognition of the best principle of trust to be able to stand in the place of personal power and intelligence.

**Future Managing**

Researchers noted that management thinking has moved to an understanding of human actions as a sense-making process. The future of an organization is determined by sense-making relationships of its employees rather than the decisions of a few influential individuals. Future managing is described as the practice of managing goals and performance targets of the organization. Management of any organization requires great agility, capacity to rapidly and positively respond to change. Future managing explores innovative talent management, emerging leadership concepts and managerial response and techniques for addressing future organization needs.

**Knowledge leadership**

Knowledge is an important and necessary tool for leadership. It enables them to identify creative solutions and make the right decisions. Knowledge leadership is defined as the process of supporting individuals in the learning process required to achieve group goals or organizational needs. The leadership of any successful institution lies in the knowledge that creates the demand for individuals and teams to exchange and transfer knowledge within the organization.

**Healthcare Performance Improvement**

Health care includes all services performed by the medical team to the community. Healthcare Performance Improvement provides proven methods for building and sustaining a culture of safety. The quality
of the health service is defined as a set of procedures to ensure the achievement of high levels of quality health service provided to customers. It represents the range of characteristics that the health service has and the way in which they provide and which affect the satisfaction of the needs of customers. The World Health Organization pointed out that the quality of the health service must be of the same standards and trends in a safe and cost-appropriate and contribute to the impact of positive situations that contributes to providing opportunities to improve care and solve problems. Which represents a scientific method to provide and improve the health service.

**Material and Method**

**Instrument**

The current survey is an applied research and in terms of data collection, it is considered a survey. The population of this study are physicians. because this group of people directly related to the study subject; therefore, their views can be relied upon. Second, the issue of changing healthcare quality seems to need a valid scientific opinion. So the researchers decided to select a group of physicians as a statistical population, in the case of search variables, in order to mention their ideas and opinions. The sampling method in this study is random. The questionnaires used in this study were distributed from a total of 130 and 102 questionnaires were considered acceptable.

**Research Model and Hypotheses**

The research work was qualitative and in its development a linear analytical sequence was followed. In addition, it has relied on the constructivist paradigm and two research methods: one for the construction of the theoretical model and another for empirical validation structural equation modeling. Due to the importance of both methods. The study methodology consist of several stages like literatures, data collection structural equation modeling and regression analysis, the literature and related studies help to discover the conceptual theory that related to overlapping wave strategy (OWS) and healthcare performance improvement (HPI) and using the methods of analysis. And the conceptual model consists of the OWS as independent variable and HPI as dependent variable as it shown in figure 2. Hence, the following hypothesis is proposed:

- **H1**: Luxury leadership positively affects HPI.
- **H2**: Strategic navigation positively affects HPI.
- **H3**: Genius leadership positively affects HPI.
- **H4**: Future managing positively affects HPI.
- **H5**: Knowledge leadership positively affects HPI.

![Figure 2: Research Conceptual Model](image)

**Measuring Variables**

The study’s questionnaires were adopted from relevant literature review. Accordingly, 20 questions in the field of establishment rate of overlapping wave strategy (OWS) with five dimensions (luxury leadership (LL), strategic navigation in leadership (SN), genius leadership (GE), future managing (FM), knowledge leadership (KL)) were offered that has been used in the present research and 8 questions about the healthcare performance improvement (HPI).

Questions asked in the questionnaire, by a number of professors who have conducted researches in this area were reviewed and were approved by them. Therefore, it can be concluded that face and content validity of questionnaire is acceptable. The reliability of the questionnaire was assessed by Cronbach’s alpha and it was acceptable with an overall reliability coefficient for 28 questions of the questionnaire of 0.967 , for 20 questions of overlapping wave strategy was 0.978 and for the 8 questions of Healthcare Performance of 0.963

**Characteristics of Statistical Sample**

In order to provide clear picture from collected statistical samples, three demographic variables were
included in the questionnaire. Descriptive statistics for these variables are shown in Table 1. It is clear that the majority of sample is male (59.8%) and (40.2%) female, the age refer to (46.08%) less than 30 years, (28.43%) between (30-40) and (14.71%) between (41-50) and the other (10.78%) are more than 50 years, and regarding to the education it been the majority of respondents are BSC (60.78%), the (20.59%) MSC and (18.63%) PhD.

Thus, after conducting this study analysis, strength relationship between dependent variable and independent variable can be obtained by the structural modeling to get the multiple relation. Table 3 shows the results of the estimates of the multiple relationships between the five factors of OWS and their impact on HPI. Estimates of multiple linear regression were obtained by SEM. The results showed that there was no statistically significant effect of the factor (LL) because the degree of significance was not within the acceptable range (P>0.05), and there was a significant effect of factor (SN). A regression coefficient (0.40) (P<0.05) was recorded. As for factor (GE), it was found that there was a statistically significant effect. A regression coefficient (0.27)(P<0.05). The results also indicate that there is a significant effect for the factor (FM). A regression coefficient

Results

In the study, the relationship between variables was examined with the use of person’s correlation coefficient. Table 2 results indicate a positive relationship between factors of OWS and HPI. Where the relationship between LL and HPI (r=0.796, p<0.001). At the same time, the SN and HPI are positively related (r=0.859, p<0.001). Also the relationship between GE and HPI (r=0.837, p<0.001). At the same time, the FM and HPI are positively related (r=0.726, p<0.001). Finally the relationship between KL and HPI (r=0.726, p<0.001).

Regarding to the regression analysis table 2 shows how HPI affected by factors of OWS, LL has a positive effect on HPI (B0=0.014,B1=0.908, R2=0.634, p<0.001), The hypothesis 1 outcomes are thus supported. And the HPI is affected positively and significantly to SN (B0=0.187,B1=0.894, R2=0.738, p<0.001), this result support hypothesis 2. Moreover, HPI is positively and significantly affected by GE (B0=0.196,B1=0.872, R2=0.701, p<0.001),The hypothesis 3 outcomes are thus supported. HPI is positively and significantly affected by FM (B0=0.147,B1=0.828, R2=0.527, p<0.001),this result support hypothesis 4. Finally HPI is positively and significantly affected by KL (B0=0.144,B1=0.931, R2=0.755, p<0.001),this result support hypothesis 5.
(0.13),(P< 0.05). And significant effect for the factor (KL) with regression coefficient of (0.72),(P< 0.05).

**Discussion**

Organizations select and implement success strategies in favor of improve performance and the achievement of competitive advantages. The justification for implementation, maintenance and improvement of the strategy represents a challenge for the professional of the quality of performance. The healthcare organizations can adopt strategies such as overlapping wave strategy to improve its performance.

The present investigation gives an account of the impact of the overlapping wave strategy with dimensions of (Luxury leadership, strategic navigation in leadership, genius leadership, future managing, knowledge leadership) to improve performance in Iraqi healthcare organizations. The impact of luxury leadership has been positively reflected in healthcare performance. This is in line with studies that proved the positive relationship among leadership commitment, organizational performance. Strategic navigation in leadership has proven its positive impact in performance, strategic navigation improve the performance. Also the study proved the effect of genius leadership in improving the performance. This result is in line with literatures which refer to the genius as an exceptional ability in thinking and creative work that produces unexpected results, which would greatly improve performance. As for future managing it has positive impact on performance, the studies indicated future management and strategic planning will improve performance well, because it gives a clear picture of the future and how to manage it.

**Conclusion**

The knowledge leadership important for performance, where knowledge contributes to giving the leader the right picture and help him make the right decisions at the right times. Accordingly, healthcare organizations have to have overlapping wave strategy in order to improve their performance.

E-learning Readiness from Perspectives of Medical Students: A Case Study of University of Fallujah

Yousra Abdulaziz Mohammed
Lecturer at College of Medicine, University of Fallujah, Iraq

Abstract

Until this time, the classical face-to-face learning with minimal e-communication is the method used in the medical school of the University of Fallujah in Iraq. The main goal of this study is to explore medical student’s readiness for E-Learning in the University of Fallujah in Iraq and to build a model for assessing its predictors.

This study was conducted using descriptive statistics, Spearman’s correlation, multiple regressions, and ANOVA. The results obtained indicate that students are not ready to move to E-Learning, as indicated by their technological, cultural, attitude and content readiness. The study concluded that Information and communications technology (ICT) is not sufficient to support the use of E-Learning.

Keywords: E-Learning, Readiness, University of Fallujah, Medical Students.

Introduction

The traditional learning was with face to face interaction between teachers and learners in classrooms. However, the spread of the Internet and electronic devices over the years in the world causes a great change in the way learning at different levels of educational institutions is carried out. At first, this change started in the developed countries, but has broadened as expected, to cover the developing regions such as Arabian countries, where Iraq belongs. One of the most advantages of E-Learning is expanding learning, which allows different paces to learn however, Zhang et al. mentioned that there are some disadvantages like “being uncomfortable for some users”. Teaching medical education and health has been proved to be more effective using E-Learning in the developed countries. At first, it was widely believed that E-Learning was the same as distant education where learning was only web-based; As time goes by this concept expanded. E-Learning is defined as a means of combining all arrangements for E-Learning, or one can say E-Learning is a means of learning and teaching using ICTs, inside the classroom and outside it.

Medical training in Iraq, lasts six years from 1st year to 6th year. At present, it is necessary that educational institutions broaden and develop their learning strategies to include E-Learning. This has been observed in medical education in developing countries. In order to achieve this on the ground, E-Learning readiness assessment is important because one of the basic elements in designing E-Learning programs is self-directed learning which signals that the availability of enabling E-Learning ambience and readiness of participants in E-Learning are both essential to get successful E-Learning programs. In the studied university, teaching medical students are mostly done by the traditional classroom method and by physical attendance in clinics with very little e-communication. Hence, this study was to decide the E-Learning readiness, E-Learning readiness predictors and to set a model for medical students E-Learning readiness in the studied university.

Background

E-Learning

According to the Organization for Economic Co-operation and Development (OECD, 2005) E-learning is “the use of information and communications technology (ICT) to foster and/or support learning in university education”. Rosenberg defined E-Learning as “the use of internet technologies to deliver a broad array of solutions that enhance knowledge and performance”. Negash & Wilcox classified E-Learning into six types:
1. E-Learning with physical presence or face-to-face and without e-communication
2. E-Learning without e-communication and without presence
3. (Asynchronous) E-Learning with e-communication and without presence
4. (Synchronous) E-Learning with e-communication and with virtual presence
5. (Blended/hybrid-asynchronous is a mix of asynchronous E-Learning and face-to-face E-Learning).
6. (Blended/hybrid-synchronous) which is E-Learning with e-communication and with presence.

**E-Learning Readiness**

E-Learning readiness was defined by Borotis & Poulymenakou as “the mental or physical preparedness of an organization for some E-Learning experience or action”[8]. The readiness assessment enables institutions to design systems and appropriate measures to succeed. Readiness assessment of E-Learning users is becoming vital in developing countries where e-Maturity is low, because it is gaining popularity.

The assessment should consider the factors that are pivotal, and from reviewing the existing research, it could be seen that there are some common factors e.g. technical readiness, content readiness, financial readiness and human resources readiness. Furthermore, there are important factors in E-Learning which are demographic factors like education level, gender and, age[11]. Furthermore, it is necessary to bear in mind that readiness is not a one-time phenomenon but it must be a persistent process of assessment.

**Conceptual Model For E-Learning Readiness Assessment**

Scholars have proposed different notions to assess E-Learning readiness. A model with 3 broad component was proposed by Psycharis[12] which were education, resources and environment in addition to 2-3 sub-components for each of the main components. A 4-broad component model was proposed by Oketch, Njihia, & Wausi[13] for developing countries with these components: demographic factors, content readiness, culture readiness, and technological readiness.

Nevertheless, Rogers[14] indicated that every organization can be effective in spreading innovation in its system and has its own standards. According to this perspective, it is clear that these models may not work for institutions of other countries. Recently, it was shown that higher education organizations in developing countries have made advancement in using ICT. This leads to the fact that most of the strategies and implementation conditions that are widely used in developed world have not yet been adopted.

According to the review of E-Learning readiness models, the model shown in Figure 1. was developed to direct the study. Taking in consideration that different communities differ in their response and acceptance of learning initiatives, that’s why, the conceptual scope of this study has been modified from reviewing similar literature conducted in other developing countries[13,15]. Concentration, in this study will be on these five parameters that have been reported to affect E-Learning readiness which are; psychological readiness, technological readiness[11,16], content readiness[8,12,16], culture readiness[8,15] and demographics [11]. Technical readiness has two sub-factors which will be considered while the assessment period. The model shown in Figure 1. is a result of Integrating these ideas.

![Figure 1. E-Learning Readiness Assessment Model](image)

**Technological Readiness**

According to Rogers[14], one of the parameters that can be used effectively “to adapt a technological innovation in an organization is technology”. It is very hard, if not impossible to use any E-Learning without appropriate equipment and easy access[17]. Using the E-Learning system, requires that users to posses technical skills. In this study, the technological readiness has two sub-factors; technical skills, and access to resources. They will be used to assess the availability of
computers and internet to the students and the students
ability to use them.

**Culture Readiness**

If institutions are willing to have a successful
E-Learning, they should be environmentally and
culturally prepared\(^{[18]}\). Therefore, this factor will
examine the students perception in terms of two sides;
perceived ease of use and perceived usefulness.

Ease of use, is essential for predicting and explaining
actual aim and the way of usage, while perceived
usefulness determine how an individual sees that using a
particular system could influence performance of job\(^ {19}\).

**Content Readiness**

The driving engine for any system is content. For
education, content readiness measurement is used to
determine E-Learning readiness. The model developed
in this study will examine the availability of E-Learning
content to the students and their satisfaction with the
content.

For E-Learning readiness, training is necessary
and it should be accounted in the implementation of
E-Learning\(^{[20]}\). Therefore, the model will assess if
the development of E-Learning materials need more
training.

**E-learning**

The demographic factors such as, gender, age
and the respondents level of education\(^{[11]}\) are collected
in this parameter. They handle all human resources
characteristics of an institution and individuals who have
a higher education level and are expected to adopt an
innovation more than others\(^{[14]}\). Therefore this parameter
will help define the effect of demographic factors on the
e-Learning readiness.

**Psychological readiness**

Psychological readiness reflects an individual’s
state of mind in terms of being ready for E-Learning.
A student’s mental preparedness is among the most
important factors that could affect the success of
E-Learning. This type of readiness is regarded as being
among the most significant aspects that could affect the
implementation process.

**Research Design and Method**

This study is a cross-sectional descriptive study of
medical students in university of Fallujah from second
to sixth year. The study excluded students in first year
because they have not started school at the time of data
collection.

Krejcie & Morgan table\(^{[21]}\) was used to determine the
sample size and 123 students were sampled. Participants
were stratified firstly according to study level and then
by proportionate sampling. For each level the proportion
of students was selected by simple random sampling.

A semi-structured self-administered questionnaire
was used in the study. It was an adaptation developed
by the researchers from the E-Learning readiness
model suggested by\(^{[13]}\) and other literature\(^{[8,15]}\). The
dependant variable was personal E-Learning readiness
while attitude toward E-Learning (psychological
readiness), technological readiness, culture readiness,
content readiness, and demographic variables were the
independent variables.

The mean value of the level of readiness was
considered in this study as 3.4 as was suggested by
Aydain & Tasci\(^{[11]}\) and has been adopted by Oketch et al.\(^{[13]}\). Analysis was done using SPSS version 19.

ANOVA and Spearman’s correlation tests were
conducted to determine association. In order to specify
the predictors of E-Learning readiness one step multiple
regression was applied, and an assessment model of
E-Learning was developed from the multiple regressions
result.

**Results**

A total of 110 questionnaires were returned which
gives a response rate of 89% which was quiet enough
for analysis. The value of Cronbach’s alpha was 0.913.

The results in Table 1 show that most of the participants were aged 21-24 years. Mean±(SD) age at first use of a computer was 12.75(±3.91) years with a range of 4-20 years.

The descriptive statistics indicate that total mean of attitude toward E-Learning was lower than the mean of expected readiness level, and that the total mean of content readiness was lower than the mean of expected readiness level whereas the required basic ICT skills for E-Learning mean was lower than the mean of expected readiness level.

Also it was shown that the overall technological readiness mean was lower than the mean of expected readiness level. Furthermore, the results show that the university does not have enough professional staff for E-Learning trainings (M=3.18).

The results in Table 2 show that demographic variables are not significantly associated with E-Learning readiness. Students in 6th year were significantly less ready than students in other levels for E-learning. Also the results in Table 2 show that the correlations ranged from 0.304 (psychological readiness) to 0.638 (culture readiness).

In the multiple regression analysis Table 3, attitude toward E-Learning, technological readiness and culture readiness, are statistically significantly predicted E-Learning readiness P<0.05 except content readiness. F(4,105)=28.141 and it is higher than its tabular value (F(4,105)tab=2.46 for α=.05), P=0.000, R²=0.517. On the other hand all demographic variables, did not statistically significantly added to the prediction. Hence, the model explains only 51.7% of readiness in this population.

Discussion

The descriptive analysis showed that the level of E-Learning readiness recorded in this work among students in a sixth stage of study was low (M=3.0714±1.050), this clashes with the proposition by Rogers[14] that higher educational levels has more influence on E-Learning readiness. Chapnic have got the same findings[16], the explanation for this might be that at sixth stage of study in medical school, students are preoccupied with clinical training than the traditional classroom approach.

The model developed in this study explained 51.7% of E-Learning readiness of the students which means that there are other parameters that affect E-Learning readiness among these medical students that were not taken into consideration in the study.

Conclusions

The medical students in this environment are not ready for E-Learning. Not ready yet to step forward beyond the traditional face-to-face method, however they believe that E-Learning is more powerful and can enhance the quality of their learning. They do not have basic ICT skills. They need further training on E-Learning content because it is necessary to attract users. They believe that their university does not have enough professionals to train students for E-Learning, nor sufficient IT infrastructure.

Indicators of E-Learning readiness in this study are attitude, technological readiness, culture readiness, and content readiness.

Recommendation

If the university is to implement E-Learning, it should condense training sessions for both faculty and student, in order to improve ability for E-Learning content. Access to ICT resources for medical students should be improved, while medical curriculum reviews should comprise, using interactions of E-Learning to enhance content and culture and enhance learning. Additional studies should include qualitative methodology for devising other factors that may affect E-Learning readiness in this community. Blended learning which describes, according to Rogers[14], “learning activities that involve a systematic combination of co-present (face-to-face) interactions and technologically mediated
interactions between students, teachers and learning resources”, is advised to be applied as a first step before turning totally to E-Learning.

**Limitations**

This study was applied on medical students in just one university in Iraq and hence, the findings may not be generalized to all Iraqi medical students.

**Ethical Clearance:** Was taken from the Scientific Committee in College of Medicine University of Fallujah.

Study of Parathyroid Hormone, Calcium and Phosphorus in Patients with Type 2 Diabetes Mellitus and Non-Diabetic Control in Salahaddin General Hospital

Zaidan Jayed Zaidan

Prof. ass. Department of Internal Medicine, College of Medicine, Tikrit University, Tikrit – Iraq

Abstract

Background: Diabetes Mellitus is a metabolic disorder characterized by the presence of chronic hyperglycemia accompanied by greater or lesser impairment in the metabolism of carbohydrates, lipids and proteins. Both primary and secondary hyperparathyroidism are involved in abnormal glucose metabolism. Diabetic patients frequently develop electrolyte disorders and phosphorus is included.

Aim of the study: To measure serum parathyroid hormone, calcium and phosphorus in patients with type 2 diabetes mellitus and compare them with non-diabetic control, and to see if there is any relationship with HbA1c and duration of diabetes mellitus in diabetic group.

Patients and Method: This study is a descriptive case control study conducted in Consultancy Clinics of Salahaldin General hospital in Tikrit city. The duration of study was through the period from 1st of January, 2018 to 28th September, 2018. The study group enrolled (95) patients with type 2 diabetes mellitus and the control group enrolled (95) apparently healthy volunteers. Data collected from study and control groups including blood samples to measure HbA1c, S. PTH, S. calcium and S. phosphorus.

Results: the study and control groups was comparable in regard to gender, age and BMI without significant difference. The mean of HbA1c (8.18%), S. phosphorus (3.83 mg/dl) and S. PTH (49.08 pg/ml) in diabetic group was significantly more than that in control group (4.45%, 3.53 mg/dl, and 42.58 pg/ml respectively). While mean of S. calcium (7.97 mg/dl) in diabetic group was significantly less than that in control group (9.19 mg/dl). There were no significant difference in serum level of S.PTH, S. phosphorus and S. calcium in relation to duration of DM or the control of DM represented by HbA1c level in diabetic group. There was significant negative association between S. calcium and S. phosphorus in diabetic group. While there was weak negative association of PTH (but not significant) with HbA1c and weak positive association with duration of DM, while there was no significant association between serum phosphorus and calcium with HbA1c and duration of diabetes mellitus.

Conclusion: Diabetic group had significant higher level of serum PTH and phosphorus and significant lower level of serum calcium in comparison to non-diabetic group. In diabetic group, there was significant negative association between serum phosphorus and serum calcium, weak positive association between serum PTH and duration of diabetes mellitus and weak negative association between serum PTH and HbA1c.

Keywords: Type 2 diabetes mellitus (T2DM), parathyroid hormone (PTH), S. calcium, S. phosphorus.

Introduction

Diabetes Mellitus (DM) is a metabolic disorder characterized by the presence of chronic hyperglycemia accompanied by greater or lesser impairment in the
metabolism of carbohydrates, lipids and proteins\textsuperscript{1}. The origin and etiology of DM can vary greatly but always include defects in either insulin secretion or response or in both at some point in the course of disease. Mostly patients with diabetes mellitus have either type 1 diabetes (which is immune-mediated or idiopathic) or Type 2 DM (formerly known as non-insulin dependent DM) is the most common form of DM characterized by hyperglycemia, insulin resistance, and relative insulin deficiency\textsuperscript{2}. Type 2 DM affect more than 400 million people all over the world and it is expected to affect more than 640 million people in 2040\textsuperscript{3}. Parathyroid hormone (PTH) is a polypeptide containing 84 amino acid\textsuperscript{4} and it is maintaining the serum calcium in its narrow normal range\textsuperscript{5}. Both primary and secondary hyperparathyroidism are involved in abnormal glucose metabolism\textsuperscript{6}. Insulin secretion is a calcium dependent process. Calcium is important for insulin mediated intracellular processes in insulin responsive tissues such as adipose tissue and skeletal muscle with a very narrow range necessary for optimal insulin action. Further calcium is necessary for insulin receptor phosphorylation and proper signal transduction\textsuperscript{7}. Patients with resistance to 1, 25-OHD were found to have abnormal insulin secretion only if they were hypocalcaemia\textsuperscript{8}. Diabetic patients frequently develop electrolyte disorders and phosphorus is included\textsuperscript{9}.

**Aim of the Study**

Measure serum parathyroid hormone, calcium and phosphorus in patients with diabetes patients and compare them with non-diabetes, and to see if there is any relationship with HbA1c and duration of diabetes mellitus in diabetic group.

**Patients and methods**

**Patients:**

**Design, Settings & Sampling:**

This study is a descriptive case control study conducted in Consultancy Clinics of Salahaldin General hospital in Tikrit city. The duration of study was through the period from 1\textsuperscript{st} of January, 2018 to 28\textsuperscript{th} September, 2018. All type 2 diabetic patients presented to Consultancy Clinics of Salahaldin General hospital were the study population.

**Inclusion criteria:**

1. Adults (age ≥27 years).
2. Type 2 diabetes.

**Exclusion criteria:**

1. Type 1 diabetes mellitus
2. Type 2 diabetic patients on insulin therapy.
4. Stroke patients.
5. Thyroid and parathyroid dysfunction.
6. Chronic kidney diseases.
7. Patients refused participation in the study.

A convenient sample 100 type 2 diabetic patients were selected after eligibility to inclusion and exclusion criteria( 5 patients were excluded because of hemolysis of blood sample), age range was (27-80 years). A convenient sample of 100 apparently healthy controls was selected from volunteered relatives of patients presented to Consultancy Clinic of Salahaldin General hospital ( 5 patients were excluded due to hemolysis of blood sample), age range was (40-60 years).

**Methods:**

**Data collection:**

The data collection was carried out for each studied patient in a questionnaire sheet. The information was taken mostly from patients directly.

**Assessment of patients:**

The body weight and height of the patients and controls were measured using Seca scale instrument; then body mass index was calculated according to equation:

\[
\text{BMI}=\frac{\text{weight}}{\text{(square of height in meters)}}
\]

A sample of 5 ml of venous blood was collected by non-tourniquet method from diabetics and controls, and then 1 ml of blood was taken for EDTA tube for HbA1c. Four ml of blood was centrifuged for 10 minutes and serum used for measurement of calcium, phosphorus and parathyroid hormone. The calcium and phosphorus kits used were
Bio Lab kits processed by BTS-350 Biosystem while parathyroid hormone kit was Roche processed by Cobas e411. The kits used for HbA1c test were Stan Bio kits (USA).

Normal limits of investigation:

1. Serum calcium (8.5-10.5 mg/dl)
2. Serum phosphorus (adult: 2.48-4.34 mg/dl)
3. Serum parathyroid hormone (16-75 pg/ml)
4. BMI according to Asian population (17.5-23 is normal, 23-28 is overweight, >28 is obese). The laboratory investigation were done in Ibn-alhaithum private lab.

Statistical Analysis:

The data of type 2 diabetics were analyzed by application of Microsoft excel analysis were arranged in scales variables (means ± standard deviation) and in categorical variables. Chi-square test was used for comparison between categorical data (Fishers exact test applied when expected variable was less than 20% of total). Independent sample t-test was used to compare between two means. Pearson correlation test was used to assess expected relationships between different variables. The level of significance (p value) was set as ≤ 0.05.

Results

The present study included 95 patients with type 2 DM, 36 (37.9%) of them were males and 59 (62.1%) were females, and 95 apparently healthy volunteered, 48 (50.5%) of them were males and 47 (49.5%) were females. The BMI of diabetic and control groups was comparable with statistically insignificant difference, table (1).

Discussion

In this study there was no significant difference in age, sex distribution and body mass index between diabetic group and control group, that mean there will be no effect of these variables on the differences occur in both groups. The present study revealed very high significant increment of HbA1c in diabetic group. HbA1c is a glycated hemoglobin that percent is effected by the level of blood glucose and it is logical to be higher in the diabetic group, beside that, HbA1c is recommended as an essential indicator for the monitoring of blood[12].

The present study revealed significant increment of serum PTH in diabetic group in comparison to control group. Previous studies indicated that the combination of hypo-vitamins is D and increased PTH seems to independently predict β-cell dysfunction, insulin resistance and hyperglycemia in diabetic and prediabetic patients[13,14,15]. Other studies suggest that level of PTH can cause β-cell dysfunction irrespective of level of vitamin D in diabetic and prediabetic patients[16,17].

The present study also revealed that serum calcium was significantly lower in diabetic group than control. In Iraq there were three studies, the first had similar results[18], the second[19] stated that there was no difference in calcium level between diabetic and control, while the third one[20] stated that calcium was higher in diabetic patients than in control. However the second study done on patients with short duration of diabetes mellitus while the sample size of the third study was small (30 diabetic and 20 control) in comparison to the present study. Many authors stated that hypomagnesaemia caused by renal failure or volume depletion are the main causes of low calcium level among diabetic patients in addition to effect of vitamin D deficiency and parathyroid hormone[21,22,23]. Other studies suggested that supplementation of population with vitamin D and calcium reduces the risk of type 2 diabetes mellitus development as insulin sensitivity increased after calcium and vitamin D intake[9,24]. Furthermore serum calcium level is involved directly with all components of metabolic syndrome and specifically affects hyperglycemia[25].

The present study revealed also significant increment of serum phosphorus in diabetic group in comparison to control. Disturbances in divalent-cation and phosphorus homeostasis are related to hyperglycemia and are thus common in patients with diabetes[26]. Also increase in serum level of phosphate may induces hypocalcaemia by interfering with phosphorus excretion in the malfunctioning kidney[27]. In addition, phosphate binds ionized calcium and removes calcium from the bloodstream. Advanced chronic renal insufficiency may be associated with hypocalcaemia due to increased phosphate level or low levels of blood vitamin D[21].

Limitation of this study: Serum vitamin D had not assessed due to limitation of resources because this study was done by the researcher own fund with no sponsors.

Conclusion

Diabetic group had significant higher level of serum PTH and phosphorus and significant lower level of serum calcium in comparison to on-diabetic group. In diabetic group, there was significant negative association between serum phosphorus and serum calcium, weak positive association between serum PTH and duration of diabetes mellitus and weak negative association between serum PTH and HbA1c, while there was no significant association between serum phosphorus and calcium with HbA1c and duration of diabetes mellitus.

The Effect of Compound Exercises in the Lactic Ability in the Futsal for Female Players

Zainab Abdulhassen Hadab¹, Nada Abdulsalam¹, Lamia Abdulsattar¹

¹University of Baghdad/The college of physical education and sport sciences/Iraq

Abstract

The importance of the research lies in the importance of the physiological side and the role it plays in assessing the training and functional status of the five penthouse football players and what the trainer can do to train the training to develop the athletic ability of five-legged football players to continue the skillful performance for the longest period without feeling tired.

The problem of research in the low level of physical performance and weakness of the ability to maintain the same level as they started in the competition and this decline in the level of physical reflected clearly on the performance of the team in the skill and weakness in the speed of the implementation of the various skills required by the nature of the game during the game, the case drew the attention of the researchers and its interest to know the hidden reasons behind it in order to diagnose and try to develop solutions and appropriate treatments through a training curriculum to develop the athletic ability of the players of the five-footed football halls. The aim of the study was to identify the effect of the use of compound exercises in the athletic ability of five-legged football players.

The researchers used the experimental method in the controlled control method, experimental group, pre-test and control group for its suitability and the nature of solving the research problem. The entire community of Basrah, Al-Basrah players was selected by five football lounges as a sample and randomly divided into two groups (experimental group and control group), with five players in each group. And then make them homogeneity and equivalence for the purpose of starting from the point looked one. The researchers prepared five physical exercises in futsal, within the period of special preparation of the team to compete with 36 training units over a period of three months with (12) weeks and exercise time 30 minutes from the main section of (60) minutes.

The results were statistically significant. The researchers concluded that the Compound physical and functional exercises at (30) second and over three months resulted in an improvement in the lactic ability of the functional organs better than the traditional exercises. Therefore, the researcher recommends the need to apply and implement the Compound exercises and its time is relatively long to develop the physiological indicators of lactic ability.

Keywords: Compound exercises, lactic ability and Futsal.

Introduction

The game of Futsal of sports that require exercise. The player has some physiological qualities that enable them to continue hard training with the performance of motor skills with high efficiency, high level of accuracy, and good harmony between contraction and expansion, and the evolution and change. In the level of skill and physical is the natural result of the development of the readiness of the internal organs of the body to do the normal function, in terms of the adequacy of the circulatory system and breathing and the speed of energy processing of muscle tissue and the speed of recovery.

The high sports levels require the athlete to use their physical, skill, planning and psychological skills in an integrated manner. The aim of the sports training is to increase the physiological efficiency. The physiological
Continuous training is the only solution for the development of the level of female players in the game of five football halls that require the development of all special abilities due to the rapid development of physiological, anatomical and mental and the exploitation of physiological characteristics.\(^2\)

The maintenance of the efficiency of physical and skill performance over the period of the game is of great importance and the main bases upon which to achieve the required results as the retention of the level of skill and physical ability despite exposure to effort match or training is a clear indication of the physiological competence of the team that has this attribute in addition to the basic skills of the game, as the province of the player in the performance is one of the important steps to win the game.

The researcher noticed through the follow-up training for players of the girl of Basra and the presence of some of the competitions feeling tired and low level of physical performance and their ability to maintain the same level that started in the competition and this decline in the level of physical reflected clearly on the performance of the team in the skill and weakness in the speed of implementation skills. The different game required by the nature of the game during the two stages of the game, this situation drew the attention of the researcher and its interest to know the reasons behind the hidden for the sake of diagnosis and try to develop solutions and treatments appropriate to them through a training curriculum to develop the ability of lactic for female players in the futsal.\(^3\)

The importance of the research in the importance of the physiological side and the role of the assessment of the training and functional status of the five-player futsal, and what the coach can do to regulate the training to develop the athletic ability of the futsal to continue the performance of the skill for the longest period without feeling tired.

**Research aim:**
To identify the effect of the use of exercises in the non-athletic ability of female football players.

**Hypothesis:**
The use of Compound exercises has a positive effect on the athletic ability of female football futsal.

**Research methodology and field procedures:**

**Research Methodology:**
The researcher used the experimental method in the controlled control method, experimental group, pre-test and control group for its suitability and the nature of solving the research problem.

**Search community and sample:**
The society of the research was identified by the players of the Basra football club for the five football lounges. The total number of female footballers was 10, aged 20-22 years, and the whole society was randomly assigned to two groups (experimental group and control group) and five players in each group. And then make them homogeneity and equivalence for the purpose of starting from the point looked one.

**Means, tools and devices used in research:**
Arab and foreign sources and references.
International Internet Information Network.
Observation and experimentation.
Futsal stadium and (10) balls.
Metric measuring tape.
Colored and sticky tapes.
Wooden terraces, ropes and hoops.
Whistle.
Electronic stopwatch.
Laptop.
Video Camera.
Medical balance with ruler to measure height and weight.
Box height (40) cm.

**Test of lactic ability:**
The objective of the test is to measure the anaerobic ability for (30) second.

**Performance specifications:** The player stands against the side of the box, one of the feet is placed on the box (the man preferred by the player) while the other man is free on the ground, and when indicating the start of the timing begins the player raise the free man
and put it next to the man above the box and repeat this
performance rhythm of two times Two (one top - two
down) and the player must perform the largest number
of steps during (30) second. The step cannot be counted
if the player stumbles forward or flexes the free man.

The player counts the number of steps he
performs during (30) second which is the performance
time, and the anaerobic ability is calculated by the
following equation:

\[ \text{Ability} = \text{body weight (mass)} \times (40 \text{ cm} \times \text{number of}
\text{steps in 30 second}) \times 1.33 \]

Unit of measurement = kg. M / min.

To calculate the anaerobic capacitance ability in
real power units by watt, the output is divided into 6.12
kg. M / min, as (one watt equals 6.12 kg / m / min)

Unit of measurement (kW).

The pilot study:

The researchers conducted two exploratory
experiments on a random sample of the girls’ club
players, one for the tests to determine the time taken for
the tests and their implementation on 2-9-2018. And
the second for the Compound exercises to learn how to
implement the sections of the unit and the duration of
each exercise in the unit on 3-9-2018.

Procedures of the main experiment:

Pre Test:

The pre-test of the lactic ability of the two
research samples was conducted on 7/9-2018 with the
stabilization of all temporal and spatial conditions for
the purpose of standardization with the post-test. The
researchers extracted the homogeneity and equivalence
of the research sample through the pretests as shown in
table (1).

Table (1). Shows homogeneity and equivalence of the research sample in lactic ability.

Compound exercises:

The researchers prepared physical exercises in
futsal, within the period of preparation of the preparation
of the team for competitions and the reality of (36)
training units over a period of three months and a (12)
week has included each week on (3) training modules.
The researcher identified the main part and duration (60)
d invested from 30 minutes to carry out the Compound
exercises from the beginning of each training module.
The duration of the training unit (90 d) was divided into
a preparatory part of (25) d and a final part of (5) d. The
warm-up and the final section of the training unit for both
experimental and control groups were implemented. The
experimental group is separated from the control in the
main part when the composite exercise begins.

The experimental group carries out the Compound
exercises. The control group implements the curriculum
prepared by the trainer. After the time the two groups
merge to complete the remaining components of the
training modules. In order to carry out the training,
the researcher followed the method of high frequency
high frequency training, no more than (30th) for each
frequency and frequency of (4-5) for each group and the
number of groups (2-3) according to the team level and
training condition. Approximately 120 beats per minute
before starting the next repeat.

Post-test:

The post-test of the lactic ability of the two research
samples was conducted on 15-12-2018 with the
stabilization of all temporal and spatial conditions in the
pretest.
Results and Discussions

From table (2) that the two types of research have evolved to have the ability to carry out athletic performance. The researcher attributed this to the repetition, repetition, regularity and continuous training in the skills of the game of five football lounges during a period of three months. The continuation of training and regularity develops the physiological abilities of the trainees the training in times of 25 to 30 seconds is designed to develop endurance and anaerobic ability, a sign of loading formation training that develops anaerobic ability.

Table (3) shows that the experimental group is superior to the control group in measuring the lactic ability, and the researcher attributed this to the use of Compound exercises and at (30) second. Continuing training over relatively long periods of time is developing physiological abilities, especially lactic ability. Compound and similar exercises of skill performance, combining physical and skill training in one performance, similar to the competition and within the performance times close to the actual performance time during attack and defense in the five futsal football, improves the efficiency of the internal functional organs of the individual. This is consistent with the results of the present study and the realization of its hypothesis.

That the exact cause of delayed muscular pain is still unknown, most research indicates that there is actual damage in muscle cells, and a rising release of various metabolic compounds in tissues surrounding the muscle cells. These reactions result in hard exercise into a corrective response accompanied by inflammation, resulting in swelling and pain that peaks after a day or two of hard work and fades after a few days, depending on the severity of the damage. In fact, this type of muscle contraction seems to be a major factor in late muscular pain. When you stretch a muscle to carry a heavy weight - imagine that your arms are trying to hold a very heavy weight - called contraction of the muscle then contraction concentric.

In other words, the muscle is actively retracted in an attempt to shorten its length. However, this process fails. These decentralized contractions have been shown to result in damage to the muscle cells rather than with concentric contractions, in which the muscle is successfully shortened during Contractions against
pregnancy, and therefore exercises that involve a lot of decentralized contractions - such as jogging on the slopes - will result in more severe muscle pain, even if there was no noticeable sensation of burning in the muscles during the exercise.\textsuperscript{10}

Because delayed muscular pain, which is the result of hard work, is very common, physical physiologists are looking at the potential role of anti-inflammatory drugs and other supplements to prevent and treat these muscular pains, but there are no definitive recommendations at the moment. Although anti-inflammatory drugs seem to relieve muscle pain - this is good - it can limit the muscle’s ability to treat damage, which can have adverse effects on muscle function in the weeks following hard work.\textsuperscript{11}

\textbf{Conclusions}

Continuing regular and structured training is an evolution in the non-functional ability of functional devices.

Compound exercise (physical and skill) at (30) second and over three months there is a development in the ability of lactic functional organs better than traditional exercises.

Molecular Diagnosis of CD14 and MnSOD Genes and their Effect on Asthma in Holy Karbala, Iraq

Zainab Nizar Jawad

Department of Biology, College of Education for Pure Sciences, University of Kerbala, Karbala, Iraq

Abstract

Asthma is a chronic respiratory disease that affects the lungs, impairing air from reaching the lungs, leading to shortness of breath and severe cough. This disease is caused by environmental and genetic factors including change in CD14, MnSOD genes and others. CD14 is a high-affinity receptor for various bacterial products as lipopolysaccharides (LPS) and acts as a vector of inflammation. Blood samples were collected from 80 patients with asthma after being diagnosed by the specialist at Imam Hussein Medical Teaching Hospital, holy Karbala, Iraq, and compared with 50 apparently healthy individuals as a control group. DNA was extracted from blood samples for all study samples. Molecular detection of single nucleotide polymorphisms (SNPs) was performed in genetic sites using PCR and PCR-RFLP techniques. CD14 gene levels showed significant differences between the patients and control groups in the CC model, while no significant differences were found in CT and TT genotypes. The study showed no significant differences between the genotypes (Ala-Ala, Val-Ala, Val-Val) in patients and healthy group. The study examined the effect of certain factors such as age, sex, place of residence, smoking, family history on the rates of asthma to determine their relation to the polymorphism of the studied genes.

Keywords: PCR, PCR-RFLP, CD14, MnSOD, ROS, Asthma.

Introduction

Asthma is a complex bronchial disease caused by various environmental and genetic factors which include exposure to allergens\(^1\), viral and bacterial infections\(^2\), or airway irritants such as cigarette smoke\(^3\) and other environmental pollutants\(^4\). Genetic factors such as genes CD14, MnSOD play an important role in the incidence of asthma where CD14 is a receptor for various bacterial products, such as (LPS), and is also a mediator of inflammation\(^5\) by modulating Plasma IgE levels and may have effects on asthma related phenotypes \(^6\). This gene also has several genetic variants that may be inherited or due to exposure to environmental factors\(^7\). Humans have a large number of polymorphisms in different parts of the gene\(^8\), (MnSOD) is an ROS scavenger, which is found in the mitochondria, where it is produced naturally from metabolic processes and in an environment where antioxidants are abundant and the ability to repair. This gene breaks down DNA, lipid peroxidation, protein modulation, membrane rupture and mitochondrial damage in the case of a lack of defense mechanisms in the body, exposure to toxic agents and oxidative stress\(^9\). Other functions of this gene it catalyzes the dismutation of superoxide radicals, thereby producing hydrogen peroxide and oxygen, hydrogen peroxide may react with ferrous iron to form more cytotoxic hydroxyl radicals\(^10\). Genetic models (TT/CT) genotypes were found to be associated as compared to non-atopic children carrying the CC genotype\(^11\). The MnSOD gene contains polymorphisms (Val-Ala / Ala-Ala, Val-Val) associated with asthma, where atopic children with MnSOD (Val-Ala/Ala-Ala) genotypes linked to the risk of asthma than did non-atopic children with the MnSOD (Val-Val) genotype\(^12\).

This study aimed to test the diagnosis of individual polymorphism SNPs in the genes studied (CD14, MnSOD) as one of the main causes of asthma.

Materials and Methods

All peripheral blood lymphocytes samples were collected from Imam Hussain Teaching Hospital in holy Karbala province, Iraq. The samples included 80 samples of asthma patients and were compared with 50 apparently healthy individuals as a control group, samples were collected from the period November 1, 2017 to April 30, 2018. The DNA was extracted using the DNA extraction unit (Bioneer, Korea). Polymerase chain reaction (PCR) were adopted for amplification of target region in the genes. Primers used for the amplification of the CD14 gene were (F: 5’- GTG CCA ACA GAT GAG GTT CAC - 3’ and (R: 5’- GCC TCT GAC AGT TTA TGT AAT C- 3’). The cycling conditions were as the following: one cycle at 94°C for 5 min, 35 cycles at 94°C for 30 s, 64°C for 30 s, 72°C for 1 min, and one final extension cycle at 72°C for 10 min. The PCR product is digested by using (AvaII). Homozygous CC had a product fragment of 497 bp, while 353-bp and 144 bp bands represented homozygous TT, and heterozygous CT has all three bands. The Primers used for the amplification of the MnSOD gene were (F: 5’- ACC AGC AGG CAG CTG GCG CCG G- 3’) and (R: 5’- GCG TTG ATG TGA GGT TCC AG- 3’). The PCR reaction had an initial melting temperature of 95°C (5 min) followed by 35 cycles of melting (95°C 1 min), annealing (61°C; 1 min), and extension (72°C; 2 min). An extension period of 7 min at 72°C followed the final cycle. PCR products in MnSOD gene were digested by the use (NgoMIV) enzyme. The Homozygous Val-Val appeared as 107 bp, bands 89bp and 18 bp referred to the homozygous Ala-Ala, and heterozygous Val-Ala had all bands.

Statistical Analysis

The results were statistically analyzed using the Special Packages of Social Since (SPSS) V.22 using the means (±) standard error value, where the significance of P≥ 0.01 and P≤ 0.05.

Results

Molecular detection of all study samples was performed using the PCR for two of the genes are CD14, MnSOD. Fig. 1. shows the electrophoresis of the CD14 gene after amplification by PCR. Where the last column represents the size marker (100-2000bp), while the rest of the bands refer to the gene CD14 of 497bp. All the products of this gene were visualized on a 2% agarose at 70 V for two hours.

The results of the molecular diagnosis were shown in Fig. 2. showing the electrophoresis of PCR products of the MnSOD gene on a 2% agarose at 70 V for two hours, while The last lane represents the size marker (100-2000bp), and the rest of the bands represent MnSOD of (107bp).
Figure 1: PCR amplification of the CD14 gene

The results of the molecular diagnosis were shown in Fig. 2, showing the electrophoresis of PCR products of the MnSOD gene on a 2% agarose gel at 70 V for two hours, while the last lane represents the size marker (25-2000bp), and the rest of the bands represent MnSOD of 107 bp.

Figure 2: PCR amplification of the MnSOD gene

Figure 3 shows the electrophoresis of the CD14 polymorphisms on agarose gel at 3% at 70 V for 2 hours, using the enzyme (AvaII) to digest the PCR product in this gene. Columns (1, 2) refer to the homozygous (CC) (497 bp), while the columns (3, 4) represent homozygous TT (353, 144 bp). The columns (5, 6 and 7) were represented heterozygous CT (497, 353, 144 bp), Column 8 was size marker (100-2000bp).

Fig. 3: PCR products of CD14 polymorphism

The results showed the distribution of samples (80 patients and 50 control group) according to risk factors in Table 1. Females had the highest incidence rate 64 (80%) and males 16 (20%) in asthma patients. Compared with the control group, males at a higher rate 28 (56%) than females 22 (44%), there was no significant difference in the sex factor between both group. 72 (90%) of those patients with no hereditary history were higher than those with a hereditary history of the disease 8 (10%). In the control group, the proportion of individuals with a hereditary history was 12 (24%) compared to 48 (96%) individuals without a genetic history. The patients residing in the city are the highest proportion 68 (85%) and for the rural patients 12 (15%), while in the control group was 40 (80%) of individuals living in the city higher than individuals living in the rural regions 10 (20%). The results also showed that the proportion of 33 (66%) smokers patients...
was higher than those who non-smokers patients 17(34%), compared with the control group in which the proportion of 63(78.75%) smokers was higher than the proportion of non-smokers 17(21.25%) the differences were highly significant among smokers and nonsmokers in patients and control group, The results also show that the highest percentage 50(62.5%) of asthma cases in the age group (20-30 years), while the age groups (40-50 years) and (50-60 years) revealed the lowest proportion 1(1.25%), while the ratios 8(10%) in the age groups (10-20 years) and 20(25%) in the age groups (30-40 years). In the control group, the lowest percentages (0%) in the age groups (10-20 years) and (50-60 years), the highest rate 29(58%) was recorded in the age group (30-40 years) followed by the percentage 18(36%) in the age group (20-30 years), While the percentage 3(6%) was recorded in the age group (40-50 years), while significant differences were observed for age groups between patients and control group.

Discussion

Asthma is a chronic disease in adults and children caused by genetic changes in many genes, such as genes CD14 and MnSOD, Where the genetic changes in those genes are the most important risk factors and molecular diagnosis. CD14 plays an important role in the development of asthma and allergy among patients in the results of the current study, which is identical to the results of the study. the study show that MnSOD plays an important role in asthma and allergies but has a lower incidence of CD14 gene,. This was not consistent with the results of a study.

By collecting data for 80 patients and 50 healthy groups, the effect of some important factors on asthma rates such as sex, where the study. The results of our study showed that there is a relationship between the family history of asthma in the incidence rates among patients and control group these results agree with the results of,, where he noted that asthma is doubled when there is a family history. When examining the smoking factor was studied as an important factor in determining the effect of asthma on the incidence of asthma in the studied samples. the results of the study showed that smokers are the highest and significantly affected by asthma and bronchial reactivity than non-smokers in USA, This is consistent with the results of the current study. The results of the current study on the place of residence and its impact on the rate of asthma, the highest rate of infection was in the patients of the city and the lowest proportion in rural patients, This is due to the presence of dangerous environmental factors such as lifestyle, air pollution, household smoking, high household humidity, indoor mold growth, and water pollution. The study of age is one of the important risk factors in asthma. It is clear from the results of the present study that young people in the age group (20-30 years) are the highest proportion of the rest of the other ages due to the housing in the city and smoking and the presence of pollution and lifestyle factors, A study showed that that boys aged four to fourteen are the most affected by asthma among girls, but after puberty girls become more severe and suffer from asthma. In his study, he noted that the patients of the aged >15 years
old females who visit the hospital are three added, while the incidence is twice that of males who are age <15 years old. A study\(^2^3\) showed that patients with T-alleles are the most common in patients of the healthy in the case of nonatopic asthma, A study\(^2^4\) showed that the genotype is associated with an increased incidence of asthma and increases its genetic expression. While the results of the current study indicate that the genotype (CC) is associated morally with asthma, while the two models (CT,TT) did not show any significant effect or correlation with the disease. This difference may be due to the distribution of genotypes due to the environment\(^2^5\). The results of the present study showed that there were no significant differences between patients and Control group in the three genotypes(Val-Val, Val-Ala, Ala-Ala) in MnSOD gene.

**Conflict of Interest:** This research is a personal non-profit work and there is no conflict of interest.

**Source of Funding:** None.

**Ethical Clearance:** Ethical clearance was obtained from the Faculty Scientific Committee (College of Education for Pure Science, University of Kerbala, Iraq) to Study the effect of Lycium barbarum Polysaccharide on bone and thyroid gland in hyperlipidemic healthy male albino rats.

Abstract

In the current study silver nanoparticles were synthesized the use of the chemical method. Current research job has been discontinued into accordance over seem at anticancer recreation regarding seen SNPs of opposition in imitation of endemic just cancers mobile phone lines. Silver nanoparticle (AgNP) bear been aged within medicine and dentistry fit in imitation of its antimicrobial properties. AgNPs hold integrated within biomaterial between kilter in conformity with forestall and decrease biofilm formation. Due in conformity with greater surface in accordance with a total ratio or tiny particle size, it annexes lovesome antimicrobial employment except affect the mechanical property over the materials. This unique properties regarding AgNPs make these substances namely filler on choice in one-of-a-kind biomaterials whereby those circulate an integral position among enhancing the properties. This comment targets to talk about the have an effect on concerning summation over AgNPs in imitation of various biomaterials back within distinct dental applications. The evaluation of the vigorous electron microscope suggests namely the spherical silver nanoparticles are spherical along sizes ranging in the company of 11 according to after 33 nm relying on pH condition. The outcomes of X-ray alteration analysis exhibit the manifestation regarding silver nanoparticles below their understandable nature. The consequences over such lesson embellish pilot proof and SC-mixed SNPs be capable target as like as an anticancer deputations then are pregnant to conquer the boundaries regarding ordinary most cancers chemotherapy.

Keywords: Chemical way; Metal Nanoparticle; Antibacterial activity; XRD

Introduction

Nanotechnology is a greater hopeful place due to the fact regarding producing on the spot purposes within biotechnology or nanoscience (¹). Silver nanoparticles (AgNPs) are a detour in greater and extra typical hence antibiotic retailers concerning textiles, bandages, scientific units and household appliances, such as fridges and washing machines (²). Among the deep nanoscale products, the close standard nanoparticle merchandise is nanosilver. AgNPs hold been ancient due to the fact antimonials, antioxidants, antioxidants, afterward anti-inflammatory consequences (³). Nanotechnology is death with calf discipline due to the fact concerning producing recent kinds above nanomaterials for biomedical capabilities (⁴). It is defined as like the amplify concerning cells and kinky tissues in accordance with up to expectation aggregate are subdivided asleep yet have the dynamic afterward infiltrate or ruin the body’s natural tissues. Cancer suggests a larger mortality content than coronary bravery ailment and strokes (⁵). Global epidemiological shifts continue after epidemiological side-by-side in line with the booming prosperity of nearby cancers on the upper floor of the long-term visit (⁶). Leave the injured man or woman affected functionally after psychologically completed impending isolation between

Email: physics1984@yahoo.com
neighbors. In chemotherapy caused by the fact of cancer, multiple drug arrests (MDR) have grown in the tradition of maintaining an important risk among follow-up on the care of a person’s fitness by negatively affecting the dimensions of prosperity in relation to treatment. MDR is resistant to out-of-the-box treatment of dangerous chemotherapy drugs, as is properly the case with many cross-resistance replicas including anti-cancer capsules after quantitative maintenance of unique structures after mechanisms (7). Because of detailed cancer eradication mechanisms, limits of organic activity, and then the toxicity of MDR anxieties, modern-day chemists have failed to meet the ideal requirements because of the fact that most cancers are treated (8). Thus, in the tradition of rhythm, it is a hassle so far battle including life-threatening diseases where large deaths are thrown around the world, in this area is an urgent pleasure after raising the approach of instant or non-invasive drugs since the deal along cancer patients exhausted (9).

The absolute nanometer with respect to the superior biotechnology branches below has a distinct characteristic among most types of ruler cancers along with superlative requirements but physical methods (10). Recently, nanoparticles mainly nanoparticles (SNPs/SNP) have been widely continual due to the fact their medical services among almost cancers remedy fit to the truth related to their specific physical, physical or chemical properties, pleasure concerning installation, characterization or ground modification on the nanoscale (11). Moreover, silver has gained a giant act in relation to pastime among the scientific disciplines due to the fact regarding a widespread length upon homes secure specifically antifungal, antibacterial, antimicrobial, or antiviral (12).

Nanoparticles are constructed using a number techniques such as much chemical method, hot decomposition, the electrochemical method, microwave irradiation, laser etching (13). Although the chemical method is the easiest route between conformity together with synthesizing silver nanoparticles so is recognized between imitations together with producing a full-size range concerning hazardous by-products afterward between the end regimens in accordance with environmental incompatibility (14). These defects of the chemical method, renown because of an on the spot yet environmentally delightful path according to after synthesizing nanoparticles (15).

Fig. 1: Schematic representation of green synthesis, characterization, and biocompatibility of SC mediated biosynthesis of SNP and their potential anticancer activity 11.
Ag-NPs received a technical preference mostly used between surgical instruments, contraceptives, wear wounds, and orthopedic prostheses (16). On the lousy hand, silver has been old so a brawny antimicrobial agent because of many years. The floor plasmon resonance or antibacterial endeavor of Ag-NPs had been good according to mean natural yet inorganic chromosomes (17). Many researchers stated as Ag-NPs had been synthesized by using one of a kind methods because of potential features as biological parameters because of singular molecule detection, bactericidal labor (18). Cytoprotection about HIV-1 infected cells then experiences concerning adventurous materials (19). After interplay together with bacteria, AG-NPs synthesize the column protein precursors, the plasma membrane with the aid of its characteristic yet minimize the tiers over adenosine intracellular that carried to telephone demise (bactericidal action) (20). The permanency over nanoparticles is generally mentioned into phrases of pair standard classes on static, still yet still stabilization. Electrical permanency is executed by using the harmony about anionic species, certain as like halides, carboxylates yet polysaccharides, between metallic particles. This consequences in the formation on a duplicate electric powered seam (in fact, a diffuse electrified layer), who reasons the Colombian opposition of the nanoparticles. Static permanency is achieved by means of the emergency concerning large-scale natural materials, as repeatedly avert nanoparticles from fall fit in imitation of their mass. Polymers or substantial cations certain namely alkylammonium are examples over fixed stabilizers. The choice of the installer also lets in because of the willpower regarding rot regarding nanoparticles (21).

Material and Method

In recent years, the bio-synthesis concerning metallic nanoparticles, especially nanoparticles of silver then gold, using drive into extracts namely nano plants, has emerged as an essential issue over research among the discipline about nanotechnology (22). In vitro research on rat bosom cells have shown in conformity with bear oxidative power then impaired mitochondrial function. Exposure in imitation of AgNPs has been related along art damage in particular of the liver. No Observable Adverse Effect Level (NOAEL) above 30 mg/kg afterwards insignificant external Adverse Effect Level (LOAEL) concerning a hundred twenty-five mg/kg has been executed because regarding Ag NPs of rats. Alternate research additionally resulted from oxidative injury above AgNPs by technology about reactive oxygen kind by way of mitochondrial respiratory chain, duty in conformity with the governance after trespass within ATP generation. Such interference government in accordance after apoptotic mobile injury since DNA destruction or in the end occupy the mobile survival. Contrarily, advertisement on nasal AgNPs because over ninety days does no longer production, anybody, genetic toxicity neutral on 6 touching the driver animals. Along impaired mitochondrial characteristic with the aid of AgNPs, that nanocarriers are recognised according in accordance with motive leakage regarding the cell membranes yet trespass together with its ionic permeability, therefore pass together including the job potential. Recent lookup maintain executed its potent according in conformity with on the spot oxidative damage, immune-toxicity, cytotoxicity, yet apoptosis by means of interference on caspase exercise (23).

Evaluation about antibacterial recreation on the synthesized silver nanoparticles

The ring attachment approach ancient to stay historical amongst the manners due to the fact of the evaluation on the antibacterial interest of the synthesized silver nanoparticles. The antibacterial task over C. anguria silver nanoparticles was once as soon as evaluated among emulation according to each Gram-positive (Staphylococcus aureus) yet Gram-negative (Escherichia coli) pathogenic microorganisms. In brief, Mueller Hinton (MH) agar deteriorative plates had been prepared using unproductive 90 mm Petri dishes. MH agar used to be as soon as inoculated which includes MH juice subculture about every bacterial form or poured over the degenerated plates within consequence concerning shape a homogenous layer. Filter shipping note discs (5 mm within diameters) had been sterilized and the bad consignment over exchange discs bear been dipped among silver nanoparticle answer (10 μg/ml); imperfect had been located within silver nitrate solution then some meager discs have been dipped between C. anguria letter extract. These discs had been due to the fact breeze dried below fruitless conditions. The useless bad discs had been positioned in accordance with the seeded pinnacle tier above the MH agar plates yet hold been left because 30 min at chamber heat because committed diffusion. Kanamycin was historical hence advantageous control. Plates hold been incubated because concerning
24 h at 37°C and the zones involving ban were first rate then recorded into millimeters (24).

![Figure 2: spherical AgNPs with difference size in solution](image)

**Result and Discussion**

**Ultra violet-visible analysis**

Bio-synthesis concerning silver nanoparticle has once monitor the use of a GENESYS 10S UV spectrometer at the wave over 200 to 800 nm at one-of-a-kind instances regarding installation (1, 12, 24 then 48 hours). The land survey was repeated using silver nanoparticles installed about distinct pH (4, 7, 9, 10) or nanoparticles created at distinctive letter concentrations (1, 2, 3 ml). Distilled water was old between an empty images.

![Figure 3: The UV-Vis Spectra of (AgNPs)](image)

**Antibacterial Activity AgNPs**

Antibacterial recreation over the synthesis silver nanoparticle was well-read in opposition to bacterial strains, E. coli. The taboo zones around the silver nanoparticles, silver nitrate and letter banish disks regarding both bacterial traces was noted and reasonable afterward 20 H regarding at 37°C. The synthesised AgNPs sure in imitation of seizing enhanced antibacterial activity towards E. coli, as truly.

![Figure 4: Antibacterial activities of (1) AgNPs, (2) AgNPs 3, (3) Plant extract and (4) kanamycin against. Aureus. Illustrate by the clear zone of inhibitions produce in figures 4 and 5.](image)

X-ray Diffraction Analysis

XRD consequences are shown over Figure 6 along primary peak at 38.126, 44.142, 64.511 then 77.426° like to the 111, 200, 220 and 311 plane, respectively. The sample was once prepared by way of grinding nanoparticle particles within high-quality dust then positioned over a sample holder. The check used to be observed the usage of a 40-kV X’PERT-Goniometer including a present day over forty mA with Cu kα radiation. The scanning paint ancient was once non-stop together with the survey measure 2 beyond as regards four tiers in imitation of in relation to 89 degrees. The present images had been in contrast including the Joint Commission of the Library concerning Powder Buffer Standards in conformity with reckon the clear structure.
Fig. 6: X-ray diffraction shows the intensity of the peaks as a function of the diffraction angles.

Conclusion

AgNPs show special biological houses unlike sordid biomaterials robotically back between dentistry then execute worship as like a new software in the restorative dentistry, prosthetic dentistry, endodontics, implantology, oral cancers and periodontology. AgNPs hold comprehensive potent fit in conformity with theirs antimicrobial, antiviral, antifungal actions. This awkward chemistry approach has evolved in conformity along the science concerning SNPs together with particle elevation properties and required stability. The biocompatible behavior upstairs gauche SNPs is synthesized fabulous into pursuance about the lack above cell toxicity between competition in conformity with ethnical fibroblasts yet erythrocytes into the blood. The phytochemicals present within the drive within fabric at last not solely result on the wonderful reduction respecting silver nitrate of pursuance along the SNPs then again also work namely like a financial institution thing building the make-up biocompatible in accordance in imitation of the nanoparticles. The between vitro anti-cancer assay concerning SNPs established a dose-dependent anti-cancer effect between the cognizance measure above 2-78 μg / ml towards ethnic cancer cellular phone lines, for this reason confirming its intensive anti-cancer activity.

Correlation between the Levels of Coxsackie Virus B IgG Antibody with the Glutamic Acid Decarboxylase Auto Antibodies and with Pro-inflammatory Cytokines in Type 1 Diabetes Mellitus Patients

Mohammed Abdulkadhim Sayah¹, Musa Nima Mezher¹

¹Biology Department, University of Kufa, Iraq

Abstract

Background: Coxsackievirus B (CVB) which belong to enterovirus, has been widely implicated into triggering of Type 1 Diabetes Mellitus disease through many suggested mechanisms. This study was designed to investigating and understanding the relationship between CVB infection and inducing Type 1 Diabetes disease via estimation of many parameters within patients’ serum like Anti-Glutamic acid decarboxylase autoantibody and proinflammatory cytokines (TNF- and IL-6) that induced upon CVB infection.

Patients and Method: A case-control study included 58 of diabetes mellitus type 1 patients and 30 normal control. All patients were diagnosed according to clinical history and the patients and control subjected to estimation of (Anti-CVB IgG, Anti-Gad, TNF- α and IL-6) within serum via ELISA assay.

Results: The frequencies of (Anti-Gad, TNF- α and IL-6) showed higher levels among T1D patients in comparison to control and these parameters revealed significant association with high level of Anti-CVB IgG among patients.

Conclusion: The high level of (Anti-Gad) and (TNF- α and IL-6) within CVB-T1D patients may indicated the possible role CVB viruses in the inducing autoimmunity disorder of T1D.

Keyword: Coxsackievirus B; β-cells; Glutamic acid decarboxylase autoantibody; Type 1 Diabetes Mellitus; TNF- α; IL-6

Introduction

Type 1 diabetes, called insulin dependent diabetes mellitus (IDDM) is caused by lack of insulin secretion by beta cells of the pancreas¹. T1D results from the destruction of insulin-producing β-cells by a specific autoimmune process². The destruction of β-cells attributed to a variety of environmental and genetic risk factors³.

Type 1 diabetes accounts for about 5-10% of all patients with diabetes. It is estimated that 1,106,500 people ages 0 to 19 years have type 1 diabetes worldwide, with 132,600 newly diagnosed cases each year⁴. Worldwide, the incidence of type 1 diabetes is increasing by 3% every year, although the reasons for this are unclear⁵,⁶.

The etiology is multifactorial, however, the specific roles for genetic susceptibility, environmental factors and immune system in the pathogenic processes underlying type 1 diabetes remain unidentified⁷. In susceptible individuals, environmental factors like viruses may trigger the immune-mediated destruction of pancreatic β-cells⁸.

Enteroviruses, especially CVB, are among the viruses was more likely to be involved in the pathogenesis of the T1D disease⁹,¹⁰.

CVB non-enveloped viruses containing a positive, ss RNA genome of ~7.5 kb that encodes a single open reading frame flanked by 5’ and 3’ un translated regions
The genome is packaged into a viral capsid of ~30 nm in size. There are many possible mechanisms of β-cells destruction have been proposed upon CVB infection like cytolytic activity, bystander activation damage, prolonged inflammation due to persistent infection and molecular mimicry due to partial homology. Immune response to GAD in type I diabetic patients suggests that anti-GAD antibody may be considered as an autoimmune marker. Antibodies directed against the enzyme glutamic acid decarboxylase (GAD) are believed to be the main cause of destruction of pancreatic β cells in type I diabetes mellitus. The production of inflammatory cytokines upon CVB infection has been also suggested to be contributed with the autoimmune reactions associated with β cell damage that leads to development of T1DM.

Material and Method

Patients and methods

Fifty-eight serum samples were obtained from T1DM with clinical history who attended to diabetic center in Al-sadder hospital, aldwiwyah hospital and some private laboratories, patients, (34 males, 24 female), with an age range of (7-25) years. The healthy control group included 30 serum samples, (18 males, 12 female) and they were age matched with the study group. Serum sample stored at (-20 c) until assayed.

1- Sandwich enzyme-linked immunosorbent one-step (Elisa)

Human Anti-Coxsackie virus antibody (IgG) ELISA Kit (Qayee-Bio, CVB-IgG, china) used to assay the level of the anti-covxsackie virus IgG in samples. The instructions of the manufacture were followed for the procedure.

2- Solid phase ELISA for human anti-Gad auto antibodies detection

The anti-Gad autoantibody were assed using ELISA kit assay (Qayee-Bio, anti-gad, china) which provides a quantitative assessment for human auto-antibodies against GAD in serum. The instructions of the manufacture were followed for the procedure.

3- Sandwich enzyme-linked immunosorbent assay

Human tumor necrosis factor alpha Elisa kit (ELABSCINCE, TNF-α, China) used to detect level of TNF-α within samples. The instructions of the manufacture were followed for the procedure.

4-Sandwich enzyme-linked immunosorbent assay

Human interleukin 6 Elisa kit (ELABSCINCE, IL-6, China) Used to detect level of IL-6 within samples. The instructions of the manufacture were followed for the procedure.

Statistical Analysis

Data were analyzed by using the (Graph pad prism statistics 8). One-way analysis of variance (ANOVA) was used to test differences between the means of different variables and T- test was used to evaluate the differences between two groups.

Values of p < 0.05 were considered to be statistically significant and results were expressed as means ± standard deviation (SD). Correlations between IgG, IL-6, anti-gad and TNF-α were determined using the Pearson correlation coefficients.

Result

The Elisa assay revealed the high increase of (anti CVB-IgG, Anti-Gad, TNF-α and IL-6) levels within T1D patient’s serum in compare to healthy groups, with significant difference at p<0.05 as shown in tables (1,2,3,4) respectively.

Discussion

The study revealed IgG and anti-GAD auto-antibodies showed a significant increase in serum level within T1D-CVB patients, in comparison to the control group as shown in tables (1,2) respectively.

These result agreed with result of Bason et al; Frisk and Tuvemo who referred to observable increased of autoantibody (anti-Gad) in seropositive CVB in T1D patients.

While the result disagreed with Heino et al which revealed there was no differences between autoantibody in diabetic patients who infected with CVB and control.

The positive correlation between CVB infection and high level of Anti-gad that shown in figure (5) may due to partial similarity between P2-C protein sequence of CVB with human GAD. This molecular mimicry suggested to induce cross reactivity response representing by anti-gad autoantibody and auto reactive T-cells activated upon CVB infection, which might act as strong enhancers that may accelerate or aggravate the ongoing autoimmune response against β-cells leading to T1D progression.

The result also revealed that proinflammatory cytokines (TNF-α & -IL-6) showed significant increase within serum of T1D-CVB infected patients compared to the control group as shown in tables (3,4) respectively.

These result agreed with results of van der Werf et al and Ghazarian et al who referred to observable increased production of TNF-α and IL-6 upon CVB.
infection in T1D diabetic patients.

But it disagreed with result of Abdel-Latif et al\textsuperscript{23} who revealed there was no change in induction of IL-6 between CVB related diabetic and another form of diabetic person.

However, result showed Significant Positive correlation between proinflammatory cytokines and IgG and between them as shown in table(5).

The high levels of proinflammatory cytokines that associated with seropositive CVB-T1D patients was suggested to play an important role in the pathogenesis of insulin development diabetes mellitus. It is well documented that TNF-α can be cytotoxic, cytostatic since it inhibits insulin synthesis and secretion. Additionally, TNF-α and IL-6 mediated damage to micro-and macro vascular tissues\textsuperscript{24}.

Beside that CVB could induce dysregulated cytokine secretion which might result in inflammatory and autoimmune diseases like T1D\textsuperscript{25}.

High concentration of IL-6 would damage β-cells and promote apoptosis. The cytotoxicity of high IL-6 concentrations could up regulate the expression of cleaved caspase-3 and ultimately leads to cell destruction\textsuperscript{26}.

TNF-α has been proposed as a central player in inflammatory cell activation and recruitment and is thought to play a critical role in the development of many chronic inflammation and tissue destruction disorder especially involvement with T1D pathogenesis and it has been suggested that TNF-α induces β cell apoptosis\textsuperscript{27}.

**Conclusion**

The high levels of CBV– IgG antibodies in serum of T1D patients and their correlation to the high levels of anti-gad auto antibodies, and high levels of proinflammatory cytokines may refer to the potential role of these viruses in triggering multiple mechanisms that induce pathogenesis of T1D ultimately.

Application of Gallic Acid Enhances Alveolar Socket Healing

Abdul Karim A Al-Mahammadawy1; Emad H Abdulla2; Imad K Abbas Al-Rifae3; Athraa Y Al-Hijazi3

1College of Dentistry, Mustansirya University, Baghdad, Iraq, 2College of Dentistry, IbnSina University of Medical Pharmaceutical Sciences, Baghdad, Iraq, 3Al-Mustaqbal University College/Dentistry Department, Babel, Iraq

Abstract

Background: Alveolar bone regeneration can be guided by the application of a Gallic acid following tooth extraction.

Aim of the study: The present study was designed to evaluate the histological and immunohistochemical aspects of socket healing in extraction site received Gallic acid, compared with control site that healed spontaneously.

Materials and Method: Twelfth Sprague-Dawley male rats were subjected for a surgical tooth extraction of upper central teeth of both sides. The right side be the control one as the socket healed spontaneously. while left side treated with 3μL of Gallic acid. The rats were scarificated at 14 and 28 days post extraction. Socket healing was examined histologically and evaluate immuno-expression of osteocalcin.

Results: Experimental site illustrates trabecular bones formation between the peripheral and central regions of the sockets at 14 day and increment of bone formation was observed, filled most of socket at 28 days. Results show intense positive expression of osteocalcin by bone cell in experimental group in comparison to control. The results confirmed by statistic analysis of the data, which revealed a high significant difference in the mean of positive cells specifically at day 14 postoperative.

Conclusion: The present study, highlighted on osseo-inductive and angiogenesis effect of the local application of gallic acid in socket healing.

Keywords: alveolar bone, bone regeneration, socket healing, Gallic acid, osteocalcin, tooth extraction

Introduction

Tooth extractions cause tissue injuries by mechanical damage in bony socket walls and laceration of soft tissue with a wound left exposed to the oral cavity. Gallic acid is a natural phytochemical found in gallnuts, sumac, witch hazel, tea leaves, oak bark, and other plants and have a variety of cellular functions with have protective effects against chronic diseases, such as cancer and metabolic syndrome. The beneficial effects of gallic acid illustrate on human skin, anti-inflammatory, anti-oxidant, anticancer, and anti-aging. Furthermore, several clinical trials and biomedical researches have evaluated the effectiveness and the powerful health benefits of gallic acid.

Osteocalcin is the seventh most abundant protein in human bone, and the most abundant non-collagenous bone protein, accounting for 10–20% of them.

Osteocalcin is a small protein synthesized by mature osteoblasts, odontoblasts, and hypertrophic chondrocytes. And is generally regarded as a sensitive and specific marker of osteoblastic activity, thus reflects the rate of bone formation. In the present study, the effect of gallic acid on tooth-extraction wound healing is investigated histologically with identification of immuno-expression of osteocalcin.

DOI Number: 10.5958/0976-5506.2019.02055.2
Materials and Method

Animals

Twelfth Sprague-Dawley male rats aged (10–13-week) and weight (260–300 g) were kept in the animal department of (National Center of Drug Control and Research /Iraq) at a constant humidity and temperature of 23°C according to the National Council’s guide for the care of laboratory animals. The rats were subjected for a surgical tooth extraction of upper central incisors (right side was considered as control site, that tooth socket healed spontaneously, while left side (experimental site) received 3μL of gallic acid.

Materials

Gallic acid (3,4,5-trihydroxybenzoic acid) (ab142880) soluble in water to 50mM.

Anti-Osteocalcin antibody [OC4-30][ab13418].

Methods

Surgical procedure

After anesthetizing the animal by general anesthesia the upper left and right central incisors extracted by simple extraction without trauma. The left socket treated with a 3μL of gallic acid as experimental site, while the right one left without treatment (control). The two sockets were sutured with black silk suture. Rats were sacrificed at 14 and 28 days post-extraction for the analysis of the extraction sites. (n=6 in each group at different sacrificed time point).

Histological Examination and Assessment

The premaxilla were resected cutting till the end of dental canal, fixed in 10% buffered formalin, decalcified in 10% formic acid, dehydrated and embedding in paraffin wax then serial cut 5μm cross section and stained with Hematoxylin and Eosin (H&E) for histological study. Other similar sections were taken for immunohistochemical analysis to assess the expression of osteocalcin.

Histomorphometry was used to assess the amount of new bone formation, by estimation of trabecular separation (Tb.Sp, in microns) in different portions of socket healing (coronal, middle and apical), each section was evaluated by 2 independent examiners at 10x.

Immunohistochemical scoring of osteocalcin

Quantification method of Immuno-reactivity was estimated for positive cell that expressed osteocalcin. It was assessed by identifying and scoring 100 cells in five fields (X40) along examined area of different sections, the scoring is: (Score 0, none; score 1, <10%; score 2, 10-50%; score 3, 51-80%; score 4, >80%).

Statistic Analysis

The data were analyzed using one-way ANOVA test with multiple comparisons by (LSD Method).

Results

Histological findings revealed an absence of inflammatory cells in all studied sites, whereas bone formation varied in the experimental compared to control and according to different periods.

At 14 day post extraction period, histological feature for control site shows few, sparse bone trabeculae at apical portion of socket. At 28 day a thin bone trabeculae found in apical and few in middle portion of the socket.

At 14 day post extraction period, histological view illustrates trabecular bone formation with active angiogenesis. At 28 day a new bone filled and coalesce with socket bone.

Statistic analysis show less record for trabecular separation measurement in experimental site in comparism to control. And in the apical portion for both studied sites in comparism to other portions. Moreover, trabecular separation measurement decreased as the period proceed in both control and experimental sites with a high significant value.

Immunohistochemical findings revealed a positive expression of osteocalcin by bone mesenchymal stem cell, bone cells (include osteoblast, osteocyte) in both study groups but in different scoring and in different periods.

Results show intense positive expression of osteocalcin by newly bone tissue in experimental group with a high significant difference in the mean of positive cells specifically at day 14 postoperative in comparism to control.

### Discussion

Healing of extracted wound is a complex physiological process involving a coordinated interaction of hematopoietic cells, immune cells that involved in clot plug, with development of new blood vessels and bone cell precursors. Multiple factors share the regulation of socket healing at molecular events, which affects different stages in the development of osteoblast, endothelial, epithelial lineages during multiple processes such as migration, proliferation, chemotaxis, differentiation and protein synthesis[11,12].

In present findings the experimental site illustrates trabecular bones formation in the peripheral and central regions of the sockets and bone formation was observed, filled most of socket at 28 days, these results may explained on the base of the followings:

Gallic acid exhibit antioxidant property and anti inflammatory, antimicrobial action[5] promote a regenerative response by its effectiveness for acceleration of osteoblasts growth[3].

its potential role in preserving osteogenic mesenchymal stem cells, by its ability to enhance angiogenesis. As gallic acid may play an important role in angiogenesis and granulation tissue formation specifically at early healing stage after tooth extraction to initiate alveolar bone repair.

In present study, mesenchymal stem cells seem to differentiate directly into osteoblasts, which secrete an osteoid matrix to form bone[13,14], this process illustrates obviously in 14 days duration of socket healing. Furthermore, application of gallic acid has been associated with some of biological activities such as angiogenesis that enhance vascularization and promote bone formation, therefore, statistic analysis records less trabecular separation measurement in experimental site in comparisum to control.
Higher expression of osteocalcin is observed in the experimental group by newly formed bone at 14 days post operative period by enhancing osteoblast activity\(^ {15}\). Thus, osteocalcin protein is a specific product of the osteoblast and indicates that application of gallic acid may accepted as a marker of osteoblastic activity\(^ {16,17}\) and resulted in enhancement of new bone formation more rapid than a self-limiting process in control and may be useful in clinical medicine.

**Conclusion**

Our results demonstrate that gallic acid might be a viable for socket healing agent and a potential intervention to bone formation.

¹Poltekkes Kemenkes Palu, City of Palu, Indonesia, ²Faculty of Agriculture, Tadulako University, City of Palu, Indonesia, ³Biology Education, Faculty of Teacher Training and Education, Tadulako University, City of Palu, Indonesia

Abstract

The use of pesticides that do not conform to recommendations have a negative impact on health and the environment. The purpose of this study was to determine the relationship between age, duration of spraying, dosage, position of spraying and the use of personal protective equipment with pesticide poisoning on farmers in Tolai Village. This study was an observational study with cross sectional design. A sample of 96 people was obtained by purposive sampling technique. Independent variables include age, duration of spraying, dosage, spraying action, use of personal protective equipment, while the dependent variable is pesticide poisoning. The results showed that 20.8% of respondents were poisoned with <75% cholinesterase levels. Knowledge and behavior of farmers about the use of pesticides was still low such as the length of pesticide spraying > 3 hours (20.8%), dosage dosage > 0.5/10 liters of water (34.4%), the position of spraying is not in the direction of the wind (33.3%) and use of incomplete personal protective equipment (86.5%). Factors associated with pesticide poisoning were the length of spraying (p= 0.000), dose (p= 0.003), spraying position (p= 0.041), but not related to age (p = 0.683) and use of personal protective equipment (p= 0.461). Conclusion, there was a relationship between the length of spraying, dosage and position of spraying with pesticide poisoning on farmers in Tolai Village.

Keywords: Risk Factors, Pesticide Poisoning, Farmers.

Introduction

The use of pesticides that do not conform to recommendations can have a negative impact on health and the environment. Pesticide poisoning can be recognized by the cholinesterase test¹. Cholinesterases are the target enzymes of numerous pesticides and chemical warfare agents and have been used for over two decades in the detection of these compounds². The prevalence of abnormal cholinesterase levels varies between regions, farmers who experience pesticide poisoning in Central Benin amount to 60.61%³. In migrant farm workers from Cambodia after workplace exposure on fruit plantations in eastern Thailand only 4.4% had normal levels of cholinesterase activity, 20.5% had slightly reduced levels, 58.5% had markedly reduced levels and were “at risk,” and 16.6% who had highest levels of cholinesterase inhibition were deemed to be in an “unsafe” range⁴. We examined the effects of pesticides in migrant farm workers from Cambodia after workplace exposure on fruit plantations in eastern Thailand. Methods: We studied 891 migrant farm workers employed on pineapple, durian, and rambutan plantations in Thailand. Data were collected via a detailed questionnaire survey and measurements of serum cholinesterase level (SChE). In Thailand abnormal acetyl cholinesterase erythrocytes amount to 12.5%⁵. Results: A total of 6,222

DOI Number: 10.5958/0976-5506.2019.02056.4
to pesticides causes sustained oxidative stress. In addition, workers (41 men and 9 women) and oxidative stress. Blood samples from 50 rural various pesticides and the presence of DNA damage observed. The objective of this study is to investigate and mutagenic capacity of these substances can be non-pesticide users. Pesticides cause DNA damage and oxidative stress. The effects of exposure to pesticides cause DNA damage and oxidative stress 16including different types of cancer, since the genotoxic and mutagenic capacity of these substances can be observed. The objective of this study is to investigate the relation between the occupational exposure to various pesticides and the presence of DNA damage and oxidative stress. Blood samples from 50 rural workers (41 men and 9 women) 17. Long-term exposure to pesticides causes sustained oxidative stress 18and oxidative stress is often claimed as one of the underlying mechanisms. In fact, different pesticides have been reported to induce oxidative stress due to the generation of free radicals and/or alteration in antioxidant defense enzymes. The present study examined greenhouse workers regularly exposed to diverse pesticides under integrated production system, and a group of controls of the same geographic area without any chemical exposure. Two different periods of the same crop season were assessed, one of high exposure (with greater use of pesticides).

The pesticide residue exceeds the maximum residual limit at 4% eggplant, 44% tomato, and 19% chilli 19. Chlorpyrifos methyl and pirimiphos methyl are the most commonly detected residues 20. Highly dangerous and prohibited pesticides are still used in Tegal Regency with a high level 21.2. Spraying farmers are one of the populations at risk of experiencing pesticide poisoning due to agricultural activities that are very close to pesticides. Various factors related to the risk of pesticide poisoning to farmers are due to the length of work 22, knowledge of pesticides and smoking when spraying pesticides 23, working time of farmers, frequency of spraying, level of knowledge of farmers 10, the direction of the spray against the wind direction and the mixing of the types of pesticides. The absence of publications on the prevalence of pesticide poisoning and the factors that influence the basis of this research are carried out.

The purpose of this study was to determine the relationship of risk factors for age, duration of spraying, dosage, spraying position and use of personal protective equipment against pesticide poisoning in farmers in Tolai Village.

Material and Method

This study was an observational study with cross sectional design. It was held in Tolai Village, Torue District on September - November, 2018. The population in this study were all farmers in Torue Village with 2,539 people. A sample of 96 people was obtained by purposive sampling technique. Independent variables include age, duration of spraying, dosage, spraying action, use of personal protective equipment, while the dependent variable includes pesticide poisoning (Table 1). Data collection used a questionnaire and tintometer kit. Cholinesterase levels are measured by a tintometer kit 24,25,26.
Data Analysis

Univariate analysis to describe the variable age, duration of spraying, dosage, spraying action, use of personal protective equipment and pesticide poisoning. Bivariate analysis of Chi Square Test (p < 0.05)

Results

Based on table 2, respondents were more than 38 years old as many as 61.5%. In general, spraying pesticides is good <3 hours a day (79.2%). More than half of the respondents (65.6%) have mixed pesticides with the appropriate dosage. The position of spraying pesticides is mostly done well (66.7%). However, in general do not use complete personal protective equipment when spraying (86.5%). Blood cholinesterase enzyme examination level <75% was found in 20 respondents (20.8%). This means that there are 20.8% of farmers who experience pesticide poisoning in Tolai Village.

Table 3 shows that there was no relationship between age and pesticide poisoning on (p= 0.683). There was a relationship between the duration of spraying with pesticide poisoning on farmers (p= 0,000). Based on the results of the chi-square test obtained a value of p = 0.003 so that it can be seen that there is a relationship between the dose with pesticide poisoning on farmers (p= 0.041).

Discussions

The results of statistical analysis in the study revealed that several risk factors showed a relationship with pesticide poisoning with a value of p <0.05, among others: duration of spraying, dosage, spraying position, while age and the use of personal protective equipment were known to have no relationship with p> 0.05.

Age is one of the demographic factors that influence one’s perception and health condition. This indicates that spraying pesticides can be done by respondents aged young to old. Based on the test results obtained p value = 0.683 (p> 0.05) so that it can be seen there was no relationship between age and pesticide poisoning on farmers. Zakaria (2007) who stated that there was no relationship between age and pesticide poisoning (p= 0.209) in pest spraying farmers in Pedeslohor Village. Likewise, Rahmawati & Martiana’s (2014) study showed no influence between age and cholinesterase levels (p= 0.194) on rice farmers in Sumberejo Village. This is in line with Bahadur’s research on tea farmers in West Bengal India who stated that age does not affect the activity of the cholinesterase enzyme.

The duration of pesticide exposure to organophosphate pesticide poisoning, sometimes cholinesterase blockade still occurs for 2-6 weeks. Continuous exposure is more dangerous than intermittent exposure at the same time. In this study the duration of spraying was related to pesticide poisoning on farmers (p= 0,000). Similarly, according to Zulmi, which states that the duration of spraying (p= 0,000) is related to cholinesterase activity, the duration of spraying has the strongest relationship with the incidence of poisoning of pesticides which is characterized by a decrease in cholinesterase. Yuniastuti & Istianah’s (2017) who stated a significant correlation between length of work (p= 0.044) and pesticide poisoning in farmers in Brebes Regency. The duration of spraying was related to pesticide poisoning on farmers (p= 0.000). Similarly, according to Zulmi, which states that the duration of spraying (p= 0.000) is related to cholinesterase activity, the duration of spraying has the strongest relationship with the incidence of poisoning of pesticides which is characterized by a decrease in cholinesterase. Yuniastuti & Istianah’s (2017) who stated a significant correlation between length of work (p= 0.044) and pesticide poisoning in farmers in Brebes Regency. The duration of spraying was related to pesticide poisoning on farmers (p= 0.000). Similarly, according to Zulmi, which states that the duration of spraying (p= 0.000) is related to cholinesterase activity, the duration of spraying has the strongest relationship with the incidence of poisoning of pesticides which is characterized by a decrease in cholinesterase. Yuniastuti & Istianah’s (2017) who stated a significant correlation between length of work (p= 0.044) and pesticide poisoning in farmers in Brebes Regency.

Based on the results that there was a relationship between the dose and pesticide poisoning on farmers. Suparti et al. (2016) who stated that the pesticide dose (p= 0.002) was proven to be a risk factor for organophosphate poisoning. The habits of farmers by increasing the dosage of pesticides used is the farmers’ effort to eradicate pests and diseases that damage crops or if they threaten crop yields. In Tolai Village, some farmers mix pesticides not according to the recommended dosage because if the pesticide cannot kill the pest, the farmer will increase the dose, then if the pest cannot yet be handled, the farmer will mix one pesticide with the
The use of Personal Protective Equipment (PPE) when spraying can affect the number of pesticide particles entering the sprayer body. Personal protective equipment that must be used when spraying includes masks, long sleeves, and gloves. The more complete the PPE used when spraying, the more likely the abnormal cholinesterase level will be smaller\(^2\). There was no relationship between the use of personal protective equipment and pesticide poisoning on farmers. Zuraida (2012) who stated that there was no association of PPE with pesticide poisoning \((p=0.680)\) on farmers. The farmers in this area used incomplete PPE, they only used an average of 3 PPE in the form of long sleeves, masks and hats\(^3\). Farmers generally assume that using personal protection when handling pesticides is impractical and is considered troublesome. If the tool is not used, then this pesticide will enter through the skin, and respiratory tract. Pesticides are generally contact poisons, therefore the use of personal protective equipment for farmers when spraying is very important to avoid direct contact with pesticides.

Conclusion

Blood cholinesterase examination showed that as many as 20 farmers (20.8%) experienced pesticide poisoning in Tolai Village. Knowledge and behavior of farmers about the use of pesticides was still low such as the length of pesticide spraying > 3 hours (20.8%), dosage measurement > 0.5 / 10 liters of water (34.4%), the position of spraying was not in the direction of the wind (33.3%) and use of incomplete personal protective equipment (86.5%). There was a relationship between the length of spraying, dosage and position of spraying with pesticide poisoning on farmers in Tolai Village, Parigi Moutong Regency.

Compliance in Maintaining Hand Cleaning on Health Care Workers in Neonatology Unit in Tertiary Referral Hospital Indonesia: The Usage of CCTV for Supervision

Amalia Marjan Taryana¹, Mahendra Tri Arif Sampurna¹, Gadis Meinar Sari¹

¹Faculty of Medicine, Universitas Airlangga, Indonesia

Abstract

Background: Hand hygiene is an effort to overcome Healthcare-associated Infections especially in the neonatology unit but the implementation in various hospitals is still not in accordance with the standards.

Aim: The study is aimed to determine the health care workers compliance in maintaining hand cleaning monitored through CCTV as a media of supervision.

Method: An observational descriptive study was conducted with a cross sectional approach in the highest referral hospital in East Java Indonesia. All health care workers in the Neonatology Unit, who was on duty and recorded by CCTV, was involved in the research during the observation, both nurses, doctors, college students, health care workers, and cleaning services. Hand hygiene compliance was assessed using the WHO observation sheet.

Result: The study revealed that hand hygiene compliance on health care workers in the Neonatology Unit as a whole was 74.5%. Based on five moments for hand hygiene, 83.3% were obtained before contact with patients, 100% before taking aseptic action, 90% after risk of exposure to body fluids, 74.5% after contact with patients, and 42.2% after contact with the environment patient. Of the five indicators, one indicator did not meet the hospital’s target. Based on the profession category, the hand hygiene compliance was found 78.4% in nurses, 30% in doctors, 78% in college students, and 22.2% in others.

Conclusion: Hand hygiene compliance on health care workers are found to vary based on five moments for hand hygiene and professional categories of health care workers.

Keywords: Hand hygiene, health care workers, neonatology units, CCTV, referral hospital

Introduction

Nosocomial infection or currently referred to as Healthcare-Associated Infections (HAIs) is still a health problem in various countries in the world, including Indonesia. Hundreds of people around the world die from infections acquired when receiving health services. The neonatology unit is a place with a high risk of HAIs which is one of the main causes of death in neonates.

Prevention of the transmission of harmful germs needs to be done to reduce the incidence of HAIs. Hand hygiene is a simple action that can save many people if done at the right time and in the right way through five moments for hand hygiene. Hand hygiene is one of the efforts that must be applied in all health service facilities and carried out by all health care workers, as a sign of competence, professionalism and responsibility. Therefore, compliance with hand hygiene becomes a crucial part of health services in hospitals.

Strict hand hygiene compliance can reduce the risk of cross infection. The policy in developing countries regarding compliance monitoring is urgently needed for the application of basic infection prevention practices.
in health care arrangements.\textsuperscript{[5]} Periodic environmental supervision including health care workers who provide services can give advantage at avoiding irrational antibiotics usage.\textsuperscript{[6]} Long-term hand hygiene compliance can be done by direct monitoring and feedback on the results of monitoring.\textsuperscript{[7]}

Direct observation is still the “gold standard method” for assessing hand hygiene compliance.\textsuperscript{[8]} In India for example, in which technology for monitoring compliance may not be available, direct observation remains the main standard.\textsuperscript{[9]} However, camera-based systems or Continued Circuit Television (CCTV) can be used to monitor the health care workers hand hygiene compliance in accordance with five moments of hand hygiene. The process of observation is direct and continuous in order to avoid the occurrence of the Hawthorne effect, which is a person’s behavior that is different from usual, caused by feelings being observed in a study.\textsuperscript{[10]} CCTV monitoring is the most appropriate, reliable, and neutral method for observing hand hygiene compliance because observation is carried out directly and closed so as to hinder bias from the results of the study.\textsuperscript{[11]}

The hospital chosen is the highest referral hospital in East Java Indonesia with the Joint Commission International (JCI) accreditation standard which establishes hand hygiene compliance as one indicator of the health services quality.\textsuperscript{[12]} The Neonatology Unit has CCTV monitoring facilities that can be used to monitor health care workers hand hygiene compliance adequately. This study is henceforth aimed to examine the health care workers hand hygiene compliance monitored through CCTV as a media of supervision in The Neonatology Unit.

**Material and Method**

The present observational descriptive study with a cross sectional approach was carried out at the first level referral hospital in East Java Indonesia (Dr. Soetomo Hospital) for 5 months in 2017-2018. All health care workers working in the Neonatology Unit of Dr. Soetomo Hospital, namely the profession category of nurses, doctors, college students, health care workers, and cleaning services represented by officers who were on duty and recorded in CCTV videos when observations were made. The sampling technique used was accidental sampling.

Health care workers hand hygiene compliance was measured through 5 WHO moments, namely before touching patient, before aseptic procedures, after body fluid exposure/risk, after touching a patient and after touching patient surroundings. Data collection was carried out by observing hand hygiene using the WHO observation sheet through 3 (three) CCTVs installed. Observations were carried out in a closed manner by looking at CCTV videos in a one-hour special room so that a total duration of 7 hours was reached for 1 week. The research variables were the amount of hand hygiene opportunities considered as hand hygiene moments compared to hand hygiene attitude in accordance with the moments performed. The researcher was assisted by the research team in the observation to obtain objective data so that it was done repeatedly until the results of both observations had similarities. The obtained data was described descriptively.

**Result**

In the research location, the location of the sink and soap dish was quite strategic to do hand hygiene using handwash techniques also alcohol handrub was available on each storage cabinet next to the incubator and open baby box. The clerk had 660 hand hygiene opportunities during the observation. Nearly half of the opportunities for hand hygiene of 258 opportunities (39.1%) occurred in the moments before contact with patients, and a small percentage of opportunities were 11 opportunities (1.7%) occurred in the moments before taking aseptic action. Every profession had different opportunities and opportunities depending on work procedures and care that was done. Most opportunities with a total of 388 opportunities (58.8%) occurred in the nurse profession category, and a small percentage of opportunities were 9 opportunities (1.4%) occurred in other professions categories.

Health care workers hand hygiene compliance was described according to five moments and the type of profession presented in table 1. In table 1 it was noted before carrying out aseptic actions, the hand hygiene compliance was 100% while after contact with the patient’s environment as many as 42.2% compliance was obtained. According to the profession category, nurse compliance was considered as the largest percentage with the total amount of 78.4% while other professions such as cleaning services, and other health care workers had the lowest compliance of around 22.2%

Table 2 described the hand hygiene compliance by profession based on on five moments. The result of the greatest hand hygiene compliance before contact with patients was found in college students with the numbers that were not far from nurses while doctors did handwashing more than half the chance (53.8%). Hand hygiene compliance before contact with patients had the greatest number of opportunities. The biggest percentage of adherence to hand washing before aseptic action was 100% for both college students and nurses.

**Discussion**

The number of opportunities obtained was sufficient to obtain adequate results. Assessment of hand hygiene compliance, needed a minimum of 200 hygiene opportunities occurred during the assessment period. In this study, the hand hygiene compliance in the neonatology unit is good category. There was one moment with results that had not reached the standard at the time after contact with the patient’s environment. The results obtained were not in accordance with the results of the research conducted in the short term given to the research obtained from the results of no more than 40% [1] Hand hygiene compliance was good if the percentage of hand hygiene reached ≥50%, while it was considered poor if the percentage hand hygiene <50%. [13] Whereas other sources of reference mentioned that the average compliance level in accordance with the recommended hand hygiene technique among healthcare workers was 78%, which was below the 90% benchmark for critical care fields. [9] Target for hand hygiene compliance in the health care institution was set to > 90%, in which regarded as a very high value, unachievable and unrealistic. [14] The decision of hand hygiene compliance target must be realistic and could be agreed upon, because it needed to be done long-term in improving hand hygiene itself. [3] There was no fixed target agreed internationally for ideal hand hygiene compliance, so that it was necessary to determine the target of each institution carried out as part of the assistance to improve the quality of the care unit. [15]

The factors that most caused healthcare workers to be disobedient in carrying out hand hygiene were limited time, large number of jobs must be done, lack of knowledge, skepticism about hand hygiene as a method of prevention, not strategic placement of sinks and soaps, and lack of motivation in improving hand hygiene compliance. [16] Other studies suggested that easy and adequate access, pre-survey orientation programs and training were not ensuring adequate compliance. Continuous training, performance feedback and verbal reminders would be needed to maintain compliance with hand hygiene. [9]

The ease of facilities was seen at the time of observation so as to support the achievement of good hand hygiene compliance. Most hand hygiene opportunities occurred on moments before contact with patients and after contact with patients. These two moments often occurred simultaneously, for example when a health worker completed an action from one patient, then took action on another patient. Hand hygiene opportunities at moment 1, 4, and 5 were the most likely to occur, which was about 80% of all opportunities for hand hygiene by healthcare workers. [17]

The compliance rate was based on five moments and the type of profession varies. Previous research found the different things. Some found that nurses dominated hand hygiene opportunities but there were also those who found professions and other health workers. [18] This happened because each hospital had different procedures and division of labor. In general, nurses had an important role in caring for patients in research. The variation in compliance with hand hygiene in each occupation was likely to be caused by constant nurse contact with patients so that the opportunity for hand hygiene that occurred to nurses was higher than other professions. [19] Healthcare workers who made a lot of contact with patients needed to have high hand hygiene compliance. [20]

Various policies needed to be developed related to hand hygiene compliance monitoring. Accuracy of
monitoring procedures and hand hygiene compliance was essential in order to protect patients and health care workers from infections related to health care. Training on the quality of observations and patient involvement in improving hand hygiene compliance monitoring needed to be considered.\footnote{21} In addition to general compliance indicators, procedures such as monitoring and recording compliance periodically, providing feedback to personnel regarding staff performance, and monitoring the volume of alcohol-based swabs (or detergents) used for hand washing or hand antisepsis) used per 1,000 patient-days. In addition, when an outbreak of infection occurred, it was necessary to assess the adequacy of hygiene of health care workers hands.\footnote{22} Installation of CCTV could be considered as an additional medium to monitor the implementation of hand hygiene.

The limitation in this study is that it can only assess hand hygiene compliance based on five moments of hand hygiene recommended by WHO, unable to assess hand hygiene techniques through CCTV, the use of video recordings from three different cameras, the need for several people in observation and repetition, and limited time research. So the future research may study hand hygiene techniques, and conduct the same research in the long term.

**Conclusion**

Hand hygiene compliance of healthcare workers was found to vary based on five moments of hand hygiene and professional categories of healthcare workers. Of the five moments, one moment does not meet the target, namely healthcare workers’ hand hygiene compliance after contact with the patient’s environment.

Study the Role of Green Silver Nanoparticle Against Aspergillus Niger in Adult Albino Male Rats

Layla Abd-Al-Sattar Sadiq Laylani
Community Health Department. Institute Kirkuk Technical, Northern Technical University, Iraq

Abstract

The current study was designed to show the role of green silver nanoparticle against toxicity Aspergillus niger. The study used 20 adult albino male rats that distributed randomly to four groups (each group consists 5 rats); control group administrated ad libidium, rats group A. niger, rats group administrated A. niger and treated with 50ug/kg AgNPs, rats group administrated A. niger and treated with 100ug/kg AgNPs. The results levels show significant of MDA high (P < 0.05) (malondialdehyde) and low significant in levels of glutathione (GSH), total antioxidant capacity and catalase compared with the control group. Histological, the sections that prepared from lungs of this group show hemorrhage, thickening walls of alveoli with fibrosis. While, after used rats group administrated A. niger and treated with 50mg/kg AgNPs with A. niger, the results showed non-significant changes (P < 0.05) in MDA, GSH, total antioxidant capacity, and catalase compared with the control group. It was concluded that AgNPs has been potential role against toxicity of Aspergillus niger in adult male albino rats.

Keywords: Green silver nanoparticle; Aspergillus niger; MDA (malondialdehyde); glutathione (GSH); catalase.

Introduction

The silver nanoparticle was used in various utilization in industry, medicines due to its characterized essentially antifungal, antibacterial, larvicidal and anti-parasitic(1). Chemically, physically, and biologically techics have been developed to synthesis nanoparticles but chemically, physically methods are included in the production of toxic byproducts which are risky in addition the methods are very expensive (2-3). The physical methods require a large amount of energy to maintain high pressure and heat needed for the reaction (4). Thus the chemical and physical methods have their own limitations; these are thought about expensive and unsuitable for continuous ecosystem (5). The exceptional characteristics of Aspergillus niger have made them applicable in various fields like drug delivery biomedical, agricultural water treatment (6,7,8,9). Aspergillus niger is applied in inks, electronic devises, adhesives, pastes due to high force (10). So, the purpose of this study is to show the function of green silver nanoparticle against toxicity Aspergillus niger.

Materials & Method

Animal model

Twenty adult male rats were used in the present study, (wt 200-250 mg with age3-5 month) obtained from Technical college/ North Technical University, and kept on standard pellet diet and water.

Prepared of A. niger suspension

Spore concentration of different spore suspensions was adjusted by using hemocytometer, according to the classical procedure. Fungal pellets were resuspended in saline solution and were adjusted to 10^5 - 10^7 spores/ml using hemocytometer to prepare working solution from microorganism spores (11).

Green tea (Camellia sinensis) extract

The leaf powder (25 gm) were extracted, by mixed with 250 ml pure water, using the soxhlet material and H_2O bath source of heating (70°C). The extract was then

Corresponding author:
Layla Abd-Al-Sattar Sadiq Laylani
E-mail: doctor.layla@ntu.edu.iq
evaporated at 70°C using a rotary evaporating, then crude extra of Gt was storage until use (12).

**Silver nanoparticles synthesis**

18 ml of silver nitrate (2mM) solution was prepared. 2 ml of green tea extract was added to the silver nitrate solution. AgNO3 ions bioreduction happen within 5h. green tea extract is the yellow color which converted to the brown color that means the formation of AgNPs (13).

**Experimental design**

20 albino male rats are used and distributed randomly as follow (each group consists of five rats):

- Control group received standard pellet diet for two weeks and then killed.
- Rats group were injected (intraperitoneal) with $10^5$ A. niger spores and killed after infection.
- Rats group were injected (intraperitoneal) with $10^5$ A. niger spores and treated with 50ug/kg AgNPs for two weeks
- Rats group were injected (intraperitoneal) with $10^5$ A. niger spores and treated with 100ug/kg AgNPs for two weeks

**Prepare of blood solution**

Blood samples collecting by cardiac puncher, under anesthesia, then put in test tubes. Then, tubes were centrifugation for 10 min to obtain serum that stored by deep freezing until used.

**Serological tests**

MDA (malondialdehyde) was measured, according to colorimetric reaction with thiobarbituric, acid (TBA) using, spectrophotometer (14). GSH level estimated by mixed 2.3 ml buffer with 0.2ml of the sample, and then added 0.5ml of DTNB. The mixture was analyzed by spectrophotometer (15).

**Histological study**

At the finishing of the experiment, rats were anesthetized with ketamine/xylocaine, the lungs were excised then fixed by using formalin 10% for 48 hours. After that, the lungs were dehydrated in ascending series of ethanol (50, 60, 70, 80, 90, 100, 100), cleared in xylene and embedded in paraffin wax, sections (5 µm) were taken by a rotary microtome. These sections were dye by using Harris hematoxylin and eosin (Luna,1968). Part of the lungs was homogenized to serological tests (16).

**Statistical study**

The Data were analyzed using a statistical Minitab program. A statistical difference between the means of the experimental groups was test using one-way analysis of variance (ANOVA).

**Results**

**Serological tests**

The levels of MDA (2.82 ± 0.28), GSH (0.329 ± 0.052), catalase (0.64 ± 0.07) and TAC (0.552 ± 0.039) in rats injected with A. niger spores show high significant increased (P < 0.05) compared with control rats (1.63 ± 0.07; 0.529 ± 0.052; 1.1 ± 0.04 and 0.732 ± 0.052 respectively). The levels of MDA (2.15 ± 0.17), GSH (0.453 ± 0.032), catalase (0.92 ± 0.03) and TAC (0.611 ± 0.081) in rats injected A. niger spores and treated with 50ug/kg AgNPs show significant increased (P < 0.05) compared with control group rats. While, the levels of MDA (1.69 ± 0.04), GSH (0.541 ± 0.064), catalase (1.03 ± 0.01) and TAC (0.728 ± 0.06) in rats injected A. niger spores and treated with 100ug/kg AgNPs show significant increased (P < 0.05) compared with control group rats as shown in chart (1).

**Histological study**

The sections that prepared from lungs of normal rats show the normal structure of alveolar sacs and alveoli (fig 1). Where, in rats that injected with A. niger spores show a thickening wall of blood vessels and alveoli with congestion and infiltration of lymphocytes with fibrosis (fig 2). After treatment, the sections prepared from lungs of 50ug/kg (fig 3) and 100ug/kg (fig 4) AgNPs closed to a normal structure.

Figure (1): lungs of control group show normal structure of alveolar sacs (AS) and alveoli (AL) H&E 400X.
Figure (2): lungs of infected group show thickening wall (TW) of blood vessels and alveoli with congestion (CON), lymphocytes infiltration (IL) and fibrosis (F) H&E 400X.

Figure (4): lungs of infected and 50μg/kg AgNPs group show of alveolar sacs (AS) and alveoli (AL) H&E 400X.
Discussion

The results show that *A. niger* lead to increase in the levels of MDA and decrease GSH, CAT and TAC levels with different lesions in sections of lungs, this findings similar to Shafiq and Akbal (2010) who reported various histological changes found in tissues of lung included necrosis in alveoli with abuses, formation and inflammatory cells infiltration in adding hemorrhage with thickness in lung alveolar sac wall and brancheolis (17). The results of the present study show the antimicrobial activity of AgNPs. Where, The antimicrobial, effect of metal nanoparticles was referred to their mini size and high surface to volume rate, that permits them to relate closely with microbial (bacteria, fungi) membranes and is not merely as a result of the release of metal ions, in solving (18). Mahmood (2012) referred that the silver nanoparticles possess antimicrobial, activity. where, suggest that The method of inhibiting the activity of silver ions on, microorganism, shows that upon Ag+ treatment, DNA loses, its replication ability and expression, of ribosomal subunit proteins, as well as other cellular proteins and enzymes essential to Adenosine TriPhosphate production, becomes inactivated (19). In another study, The biosynthesized silver, nanoparticles showed excellent antimicrobial, activity. The antimicrobial activity concluded that the synthesized, nanoparticle more, effective for gram-positive bacteria. The results of synthesized nanoparticle lead towards clinical use as an antimicrobial agent (20).

Effects of Artificial Aging on Some Properties of Room-Temperature-Vulcanized Maxillofacial Silicone Elastomer Modified by Yttrium Oxide Nanoparticles

Yasir N. Al-Mohammad¹, Faiza M. Abdul-Ameer²
¹MSc. Student, ²Assistant Professor, Dept. of Prosthodontics, College of Dentistry, University of Baghdad, Baghdad-Babulmoadam, Iraq

Abstract

Background: The daily usage of maxillofacial prostheses causes them to mechanically deteriorate with time. This study was aimed to evaluate the reinforcement of VST50F maxillofacial silicone by using yttrium oxide (Y₂O₃) nanoparticles (NPs) to resist aging and mechanical deterioration.

Materials and Method: Y₂O₃ NPs (30–45nm) were loaded into VST50F maxillofacial silicone in two weight percentages (1 and 1.5 wt%), which were predetermined in a pilot study as the best rates for improving tear strength with minimum increase in hardness values. A total of 120 specimens were prepared and divided into the control and experimental groups (with 1 and 1.5 wt% Y₂O₃ addition). Each group included 40 specimens, 10 specimens for each parameter tested (i.e., tear strength, surface roughness, hardness, tensile strength and elongation percentage). Specimens were artificially aged in a weathering chamber for 150 h and then tested. Data were analyzed by ANOVA and Tukey’s honestly significant difference (HSD). Statistical significance was set to \( P \leq 0.05 \). Scanning electron microscopy (SEM) and Fourier transform infrared (FTIR) spectroscopy were also conducted.

Results and Discussion: SEM results showed that Y₂O₃ NPs were distributed well within the silicon matrix. FTIR results indicated that the NPs were physically dispersed within VST50F silicone without chemical interaction. After 150 h of accelerated artificial aging, adding Y₂O₃ NPs significantly increased the tear strength, hardness, surface roughness, and elongation percentage. Tensile strength increased non significantly.

Conclusion: Adding Y₂O₃ NPs as fillers improved the mechanical properties of artificially aged maxillofacial silicone elastomer.

Keywords: maxillofacial silicone, Y₂O₃, nanoparticles, fillers, artificial aging.

Introduction

Construction of a maxillofacial prosthesis to replace missing facial parts caused by injuries, tumors, or congenital anomalies may be rendered necessary to restore esthetics and function (¹). Surgical rehabilitation may have to be excluded because of the size, site, or cost of surgery (²). Silicone elastomers had become the most widely used replacement material because of their biocompatibility, esthetic outcome, easy pigmentation, and easy application (³). Replacement materials should possess adequate mechanical properties, such as high tear and tensile strengths and hardness close to that of the replacement site, and maintain these properties for the adequate lifetime of prosthesis service (⁴). Silicone elastomer prostheses have short service life because of aging and deterioration of mechanical properties (²). Multiple studies have been conducted to improve silicone

properties and protect resulting materials against aging such as nanofiller addition. The mechanical properties of A-2186 maxillofacial silicone were improved by adding silanated nano-SiO$_2$ (6).

Different nanoparticles (NPs; e.g., titanium dioxide, fumed silica, and silanated silica) have been added to A-2000 and A-2006 silicones and improved certain properties (6). Wang et al. (2014) proved the antiaging effect of TiO$_2$ on MDX4-4210 silicone tensile strength against thermal and UV aging (7).

**Materials and Method**

VST50F room-temperature-vulcanized maxillofacial silicone elastomer (Factor II, Inc., Lakeside, AZ, USA) was incorporated with Y$_2$O$_3$ nanopowder (US Research Nanomaterials, Inc., USA) and placed in a weathering chamber of an accelerated weathering tester (Model QUV/spray, Q-Lab corp. USA) for 150 h. Silicone with and without Y$_2$O$_3$ NPs addition were mechanically tested and compared.

**Pilot study:** Y$_2$O$_3$ nanopowder was added in two weight percentages, namely 1 and 1.5 wt%, to improve the tear strength with minimal effect on the hardness of the silicone elastomer.

**Study grouping:** A total of 120 specimens were prepared and divided into the control group (Group A; 0% nano-Y$_2$O$_3$ addition) and experimental groups (Group B, 1% Y$_2$O$_3$ addition; and Group C, 1.5% Y$_2$O$_3$ addition). Each group included four subgroups according to the parameters to be tested, namely, tear strength, surface roughness, shore A hardness, tensile strength and elongation percentage. All specimens were artificially aged for 150 h in the accelerated weathering chamber.

**Mold making:** AutoCAD was used to design the dimensions of specimens. A computer numerical control machine (JL-1612, Jinan Link Manufacture and Trading Co., Ltd., China) was used to form the mold matrix for material pouring (8).

**Mixing base, catalyst, and Y$_2$O$_3$ NPs:** A digital electronic balance with 0.000 accuracy (China) was used for measurement. The silicone base was measured initially and then added with the accelerator at 10:1 ratio (according to the manufacturer’s instructions). The materials were mixed with a vacuum mixer (Multivac 3, Degussa, Germany) at 360 rpm for 5 min under −10 bar vacuum pressure (9). In case of NP addition, Y$_2$O$_3$ nanopowder was measured first followed by the silicone base (9). The two materials were mixed for 10 min to form the modified base, in which the first 3 min was without vacuum suction to preserve the nanopowder. Vacuum pressure of −10 bar was applied in the following 7 min to obtain a properly mixed, bubble-free mixture (10). The catalyst was added at 10:1 ratio (modified base to catalyst) and mixed for 5 min with vacuum suction of −10 bar. All mixing steps were performed at a relative humidity (RH) of 50% ± 10% and temperature of 23 °C ± 2 °C (11).

**Pouring the material into the mold:** The mixture was poured in the matrix portion of the mold, and the cover was applied and locked with four screws, four nuts, and four G-clamps with 1 kg of load until complete curing (9). Mixture was poured under standard conditions (RH of 50% ± 10% and temperature of 23 °C ± 2 °C) (12,13).

**Specimen storage, retrieval, and finishing:** A storage box was used to preserve the temperature and humidity at standard levels (20 °C–25 °C, 50%–60% RH) and provide light protection (14). After polymerization and complete vulcanization, the specimens were cleaned from flashes and checked to be free from bubbles. Defects with defined borders were discarded (5).

**Accelerated artificial aging of specimens:** The specimens were artificially aged for 150 h in a Weather-Ometer device (QUV) according to ASTM G-154/7(15) with each aging cycle at 12 h. The light cycle of 8 h was 340 nm, irradiance of 1.55 W/m$^2$ at 60 °C ± 3 °C. The following dark cycle of 4 h was at 340 nm, irradiance of 1.55 W/m$^2$, and water spray for 15 min for thermal shock induction, followed by 3.45 h for condensation at 50 °C ± 3 °C. Each 150 h of artificial aging was equal to approximately 4.7 months of clinical use (real-life aging) (16,17).

**Mechanical testing procedures:**

A) **Tear strength:** Type C specimens according to ASTM D624 (13) were used and tested by a universal testing machine (Laryee Technology Co., Ltd., China). The specimens were stretched at 500 mm/min until the apex completely ruptured. Tear strength was calculated as follows: Tear strength = $f/d$, where $f$ is the highest recorded force for complete rupturing (kN), and $d$ is the specimen average thickness (m).
B) Hardness: Specimens with dimensions of 25 mm (length) × 25 mm (width) × 6 mm (thickness) were used according to ISO 7619-1 (2010) and tested with a Shore A hardness digital tester (HT-6510A, China) characterized by1.25 mm diameter dull indenter. Hardness is the mean of five different measurements at points separated by 6 mm distance.

C) Surface roughness: Specimens similar to those used to test hardness were tested by a digital surface roughness tester (SRT-6200S, China). The diamond probe moved on the specimen surface and recorded the roughness value at micrometer scale.

D) Tensile strength and elongation percentage: Type 2 specimens according to ISO 37 (dumbbell shaped specimens) were prepared and tested by a universal testing machine at 500 mm/min until the complete rupturing at the thin portion. Tensile strength was calculated as follows: Tensile strength = \( F/A \), where \( F \) is the highest recorded force to rupture the specimen at the thin portion (N), and \( A \) is the specimen cross-sectional area (width × thickness) (mm\(^2\)). Elongation percentage was calculated using the specimen length before and after rupturing. This parameter was calculated as follows: Elongation percentage = \( (L_o - L_f)/L_o \times 100 \), where \( L_o \) is the original length, and \( L_f \) is the length after rupturing.

**Additional tests:** A scanning electron microscope (SEM) (Inspect S50, FEI Company, Netherland) and Fourier transform infrared (FTIR) spectroscope (Tensor 27, Bruker, Germany) were used to check the dispersion of the NPs and whether the NPs reacted chemically with the silicone elastomer.

**Statistical analysis:** bar charts were plotted and ANOVA and post-hoc Tukey’s HSD tests were performed using the SPSS software with significance level set to \( P \leq 0.05 \).

**Findings**

**SEM and FTIR examinations:** SEM images indicated that the Y\(_2\)O\(_3\) NPs were distributed well within the silicon matrix before and after aging with no sign of reagglomeration caused by aging (Figures 1A and 1B). The FTIR spectra of VST50F maxillofacial silicone modified with Y\(_2\)O\(_3\) nanopowder before and after aging indicated the absence of degradation or chemical change caused by aging.

![Figure 1: Scanning electron microscope images show the good dispersion of fillers with no reagglomeration caused by aging. (A) Before aging (10 µm magnification). (B) After aging (10 µm magnification).](image)

**Tear strength:** Groups B and C showed significantly increased mean values of tear strength compared with group A \( (P < 0.05) \) with non significant difference between them \( (P > 0.05; \text{ Table 1}) \).
Table 1: Descriptive statistics, one-way ANOVA and Tukey’s HSD of tear strength.

**Discussion**

Maxillofacial prostheses require replacement every 6–12 months\(^{22}\) because of impairment and deterioration in properties. In this study, maxillofacial silicone reinforced with \(Y_2O_3\) NPs was artificially aged for 150 h to evaluate the antiaging effect of such reinforcement. Incorporating \(Y_2O_3\) NPs significantly increased the tear strength probably due to the entrapment of the NPs within the polymer matrix. Thus, 3D physical networks were formed and obstructed the movements of the polymer segment, thereby increasing the overall density and strength\(^{23}\). The hardness was significantly increased after filler incorporation probably because of the increased rigidity resulting from the enhanced overall stiffness as the filler occupied the spaces between polymeric chains\(^{24}\). This increase was proportional to the increase in filler weight percentage as observed in the significant difference between groups B and C. The acceptable clinical range of hardness is 25–35\(^{7}\), and this value was not surpassed by filler addition nor aging for 150 h. Filler incorporation significantly increased surface roughness, which can be related to the aging-induced changes on the material surface, such as microcracks or fissures associated with the NPs random dispersion on the material surface causing increased surface roughness\(^{25,26}\). Tensile strength was not significantly increased after NPs addition, which may be attributed to the presence of the NPs that acted as obstacles preventing the sliding of polymer chains over each other. Thus, higher tensile forces were required\(^{27}\). The elongation percentage was significantly increased after NP incorporation probably because of the cross-linking action of the NPs. This action formed powerful bonds between the hydroxyl groups and polydimethylsiloxane chains by hydrogen bonds to protect these chains from breaking under higher tension\(^{9,28}\).

Silicone elastomers modified with NPs dispersed in their matrix are characterized by network structures and increased cross-sectional area. Thus, these materials are more resistant to the effect of aging processes, such as photo-oxidation or free radical formations\(^{29}\).

**Conclusion:** After 150 h of artificial aging, adding \(Y_2O_3\) NPs to VST50F maxillofacial silicone significantly increased the hardness (within the acceptable range), surface roughness, and elongation percentage and slightly increased the tensile strength.

Hyperlipidaemia in Hypertensive Patients in Kirkuk City

Bilal Jamal Kamal

Lecturer in Kirkuk university college of medicine, (Internal Medicine), Iraq-Kirkuk-Al-Shorja-College of Medicine-Department of Internal Medicine

Abstract

Hyperlipidemia and hypertension are important risk factors for atherosclerosis and specially ischemic heart disease, so this study is conducted to assay the association of hyperlipidemia in hypertensive patients in Kirkuk city in Iraq by collecting 150 hypertensive patients and 100 control participants, from Azadi teaching hospital in Kirkuk city in the period between: 01/01/2016 to 01/01/2018, lipid profile is done for all the participants, BMI and waist circumference are calculated also for all the participants and the findings have revealed significant association between hyperlipidemia and hypertension.

Keywords: hyperlidaemia, hypertension, BMI, WC

Introduction

Blood pressure normally rises with age, but when it become higher than the normal average for a matched age and sex diagnosis of hypertension ensues. This level is about 140/90 for those less than 80 years old and 150/90 for 80 years old and older. Hypertension is mostly asymptomatic problem and it is diagnosed by clinical exam. Most of cases are due to unknown causes, which is called essential hypertension (90-95%), with a 5-10% of cases having underlying causes, like Conn’s syndrome. Cushing disease, glomerulonephritis, in these conditions it is called secondary hypertension. (1)

Early diagnosis and proper treatment of hypertension is so important as far as is can cause serious complications in multiple systems as cardiovascular, central nervous system and it is a common cause of chronic kidney disease. So the aim of the treatment of hypertension is normalize the blood pressure level (<120/80) and prevent the different complications. (2)

Hyperlipidemia, which means both high LDL and TG and altered ratio of total cholesterol level to HDL, is usually seen in patients with increased blood pressure (BP) levels, and it is considered to be the leading cause of the atherosclerosis which affect the different parts of the cardiovascular system. (1,2,3)

Lipids are normally present in the serum in different forms, as: cholesterol, triglyceride & lipoprotein. These different forms of the serum lipids are important for normal physiology and it is involved in the cell wall synthesis, but any abnormality especially in serum cholesterol can cause serious complications in the cardiovascular system. (3)

Serum cholesterol is independent risk factor for cardiovascular diseases as it is the leading cause for atherosclerosis which affects the arteries, it is presented in three different separate cholesterol fractions with different prognostic significance: low-density lipoprotein (LDL), very-low-density lipoprotein (VLDL) and high-density lipoprotein cholesterol (HDL). LDL is atherogenic and high levels can predispose for atherosclerosis, while HDL is protective against atherosclerosis and low serum HDL is independent risk factor for cardiovascular diseases. (4)

Total cholesterol-to-HDL ratio best measure for predicting cardiovascular risk as it can cause atherosclerosis, which leads to thickening and narrowing of the arteries and in turn this cause predispose to ischemic heart diseases specially when there is other risk factors, like: hypertension, diabetes mellitus and smoking. (4)

Hyperlipidemia together with the above risk factors can lead to the well known cause of morbidity and mortality, atherosclerosis, which can affect any artery, but specially the coronary arteries, and causes the ischemic heart diseases in different forms. (5)
Obesity is a major world epidemic now and it is well known risk factor for high triglyceride, LDL, impaired glucose tolerance and hypertension, in which in turn can lead to atherosclerosis and serious cardiovascular complications. BMI is used to assess the degree of obesity and waist circumference (WC) to assess central obesity.(6)

**Material and Method**

This is a cross sectional study in which 250 participants are involved, the hypertensive patients were 250 and 100 participants were control with normal blood pressure, all of them are collected from Azadi teaching hospital at Kirkuk city for routine check in the period between: 01/01/2016 to 01/01/2018. All the participants are resident at Kirkuk city, aged: 30-70 years old, selected randomly from the outpatient clinic. All the patients included in the study were taking lipid lowering drugs nor taking anti-hypertensive drugs and were not complaining from renal, cardiac or hepatic complications.

After taking written informed consent, face-to-face interviews was used for data collection, anthropometric measurements, clinical examinations, and blood sample for serum lipid profile by trained research assistants.

Body mass index (BMI) is an important parameter so it is calculated for all the participants by measuring weight in kilograms, divided by height in meters squared (kg/m²), also waist circumference (WC) is used as a parameter in this study and it is measured from midway between the lowest rib and the iliac crest using a Gullick II tape with the participants in the standing position and at the end of expiration.

Blood pressure was measured for the participants using mercury sphygmomanometer by a physician two measurements are taken for the participants with 5 minutes interval in between after the patient had rest for 10 minutes. Hypertension was defined as an average SBP ≥140 mmHg and DBP ≥90 mmHg without antihypertensive medication.

5 mL of venous blood is taken from all the participants after an overnight fasting and the serum is used for assessment of the lipid profile (Total cholesterol TC, low density lipoprotein LDL, high density lipoprotein HDL, triglyceride TG & very low density lipoprotein VLDL) at the Azady hospital laboratory. Hyperlipidemia is assessed as following: Cholesterol in Adults (Adult Treatment Panel III): Total cholesterol (mg/dl) <200= desirable, 200–239= borderline high, ≥240= very high; LDL cholesterol (mg/dl) <100= optimal, 100–129= near optimal/above optimal, 130–159=borderline high, 160–189= high, ≥190= very high; triglyceride (mg/dl) <150= normal (goal), 150–199= borderline high, 200–499= high, ≥500=very high; HDL cholesterol (mg/dl) <40=low, ≥60= high.

**Statistics and data analysis:**

Descriptive statistics was used to present the demographic characteristics of the study participants. Continuous variables were presented as mean ± standard deviation (SD) and were compared using independent group Student’s t-tests. Analysing the relationship between hypertensive patients and the the normal control is done by using binary logistic regression analysis after adjusting for, BMI,age, sex, and BP. A P-value <0.05 was considered statistically significant.

**Results**

Data from 250 participants in this study is analyzed, and the result as showed in table 1 was: mean age ± SD 43.23 ± 4.1, mean WC ± SD : 90.21± 4.3 and it was higher in female than male, BMI ± SD: 26.87 ± 3.90, higher in female than male, SBP and DBP (mmHg) ± SD: 147.94± 8.66 and 95.64± 7.64 respectively, Total cholesterol ± SD: 245.31±4.78, Triglyceride ± SD: 202.83±7.22, LDL: 137.1± 6.96, HDL ±SD: 35.92± 3.17. BMI and WC were high in female than male, while total cholesterol, LDL and HDL were higher in male than female, all findings were statistically significant (P<0.05).

Table 2 showed that the mean age of the hypertensive and normotensive participants was 45.12±5.1 and 38.4±3.7 respectively. WC was higher in hypertensive than normotensive: 93.31± 6.96 and 90.18±4.89. BMI was higher in hypertensive than normotensive: 27.1±4.54 and 25.22±3.88.

Mean SBP of the hypertensive and normotensive participants was: 150.64±7.87 and 117.21±8.53 mmHg respectively and DBP was 99.91±7.65 and 78.32±6.14.

Total serum cholesterol was higher in hypertensive than normotensive participants: 254.66±4.42 and 192.81±7.49, LDL: 162.1±8.21 and 102.41±7.76,
Triglyceride: 212.54±6.77 and 148±9.97 respectively. HDL was lower in hypertensive than the normotensive participants: 36.29±3.88 and 40.33±4.76. All these findings in table 2 was statistically significant with p value < 0.05.

**Discussion**

Hypertension is one of the commonest diseases globally and important risk factor for serious disabling medical conditions like: ischemic heart diseases (IHD), stroke and chronic kidney disease. Many studies showed relationship between hypertensive patients had other co-morbid conditions like: obesity and hyperlipidemia, in which can exacerbate the risk of IHD and stroke. This study has analyzed the relationship between hypertension and BMI, WC, and hyperlipidemia. The study showed that the mean BMI, WC, serum: TC, TG and LDL were higher in hypertensive compared to normotensive. HDL was lower in hypertensive participants compared normotensive. These relationships were statistically significant.\(^{(5,6)}\)

Scale study in Mexico revealed that TC, LDL and TG are higher in hypertensive participants and HDL is lower in hypertensive participants compared to normotensive. European study conducted to assess LDL, triglyceride, HDL and obesity showed significant relationship among hypertensive patients, as the TC, LDL and TG was significantly higher and HDL was lower in hypertensive patients.\(^{(7,8,9,10,11)}\)

In Bangladesh two studies conducted to assess the lipid profile, BMI and WC, and these studies showed that LDL, triglyceride, BMI and WC were higher and HDL was lower in hypertensive compared to normotensive participants.\(^{(12,13)}\)

Other studies conducted in India and Nigeria had found the relationship of high LDL, TG, TC and BMI in hypertensive patients and low HDL with high BMI and WC in hypertensive patients.\(^{(14,15)}\)

**Conclusion**

This study has revealed significant relationship between high serum TC, LDL, TG in hypertensive patient and low HDL, in which can lead to serious cardiovascular complications. BMI and WC were higher in hypertensive participants.

**Recommendations:**

We strongly recommend the hypertensive patients to have optimal BMI and WC and to check their lipid profile and treat any abnormality.

Abstract

Background: In recent years, an increased approach has appeared in the use of autologous blood products to assist tissue and organ healing. Application of PRP has emerged as a potential solution for infertile women with poor ovarian reserve in reproductive specialty.

Objective: To estimate the efficacy of trans-vaginal ovarian injection with PRP in rejuvenation of ovaries in women with poor ovarian reserve.

Methods: A stratified, non-randomized, Before-After comparison clinical trial. It was performed in the High Institute for Infertility Diagnosis, and Baghdad fertility center from August 2018 to May 2019. 50 Infertile women of different age group with poor ovarian reserve were included.

For each patient, autologous PRP preparation was done and it was injected to both ovaries under ultrasound (US) guidance.

Outcome measures: hormones tests was measured before and after four weeks of intervention to monitor ovarian reserve tests. Before and after Follicle-stimulating hormone (FSH), anti-Müllerian hormone (AMH), antral follicles count (AFC), and mean ovarian volume (MOV) in different categories for variables.

Results: Infertile women showed a significant improvement of instead of ovarian reserve tests after PRP injection. A reduction in FSH level, an increase in AMH level, with an increase in AFC, and mean ovarian volume, were observed.

Conclusions: 4 weeks after PRP injection for ovarian rejuvenation had favorable effects in women with poor ovarian reserve, opening an opportunity window in management of infertility.

Keywords: PRP, ovarian rejuvenation, women infertility

Introduction

In recent years, an increased approach in the use of autologous blood products to assist healing in a variety of medical care interventions (¹). Of these products, PRP, prepared by centrifugation of peripheral blood, is obtained when the volume of plasma fraction of autologous blood having a platelet concentration more than 200,000 platelets/ul, with growth factors concentration 5 times greater than plasma, researches have revealed the application of PRP stimulates recovery and healing not only in affected tissues, but to overall organ function as well (²).

The identified causes of premature ovarian failure can be categorized into genetic and environmental, ovarian failure may end with infertility due to a lack of follicle growth and ovulation that leads to poor ovarian reserve (OR). Many studies stated that the introduction

Corresponding author:
Sallama Hamid Abbas
E mail: asiraq2005@yahoo.com
of platelets bearing growth factor directly into the ovaries might trigger recovery in oocyte production (3).

Treatment with PRP is labeled as ovarian rejuvenation; in this procedure, PRP is injected into the ovary under the guidance of ultrasound, similar to ovum pick up in in vitro fertilization (IVF) (4). This treatment modality is still being examined in many clinical trials all over the world as a promising method in order to regenerate the ovarian tissue and so they can have more possibilities for a successful pregnancy (5).

Ovarian reserve test (ORT) provides an indirect estimate of a woman’s remaining OR. It includes, in addition to ultrasound AFC, biochemical testing which includes FSH, AMH, and many other tests (6).

This study aimed to estimate the efficacy of transvaginal PRP injection to rejuvenate ovaries in woman with poor ovarian reserve, and to assess any association of some women variables (age, menstrual status, parity, BMI) as predicting factors in success of ovarian injection with PRP.

**Methods**

**Ethical Consideration:** The study protocol was approved by the authority of High Institute for Infertility Diagnosis & assisted reproductive Technology and the Arab Board of Health Specializations in Iraq. Written informed consent was obtained from each patient after detailed explanations for the purpose of the study, administration, possible benefits or not of the intervention.

**Trial Registration:** clinicaltrials.gov Identifier: NCT03946813

**Study Design & Setting:** This is a stratified, non-randomized, Before-After comparison clinical trial. It was performed at The High Institute for Infertility Diagnosis and Baghdad Specialized Fertility Center, during the period from August 2018 to May 2019.

The study included: Menopause or peri-menopause under the age of 50, Premature ovarian insufficiency or ovarian failure before the age of 40 or woman with primary ovarian failure of any cause, these women with high FSH level (more than 15 IU/l), low level of AMH (less than 0.9 ng/mL), and low AFC (3 or less follicles) on second day of menstrual cycle. Data collection from each patient about age, BMI, parity, pre (baseline) and post intervention level of AMH, FSH, AFC, and right & left ovarian volume.

The time of intervention for amenorrheic women was at any time, while in menstruating women, the procedure was performed early in the cycle during the menstrual period, or shortly after cycle prior to the development of an egg follicle. Patients were instructed to come in fasting status (for 8 hours prior to the procedure), since it will be done under anesthesia.

From each participant, about 18 ml of blood was taken and mixed with 2 ml anticoagulant to form 20 ml. This mixture was injected into a special kit tube and centrifuged.

The PRP rich top layer (rich with growth factors) was obtained. Immediately after mixing with calcium chloride activator, this extract was injected inside ovaries. The 20 ml blood sample gives 2.5 ml PRP, 1.25 ml would be injected in each ovary. The PRP preparation takes about 10-15 minutes.

**Outcomes measure:** In the next visit (after 4 weeks), AMH, FSH are measured together with measuring AFC and ovarian volume by ultrasound to assess the benefit of PRP. If AMH raised and AFC increased, or FSH decreased, then an objective evidence of ovarian rejuvenation was considered.

**Statistics:** Statistical analyses were performed using SPSS Statistics for Windows software (version 21.0; IBM Corp.). Descriptive statistics were demonstrated as number, frequency, percentage and table. Inferential statistics were obtained by using paired t test to estimate the significances of pre and post intervention. P value less than 0.05 considered statistically significant.

**Results**

The age of infertile women in this study sample (N=50) was ranged from 20 to 49 years, with mean (±SD) of 39.74 (7.03) years. The obesity and overweight constituted 60% of them with mean (±SD) of BMI of 26.49 (4.16). Based on the age, three groups were obtained: Group A from 20-29 years, Group B from 30-39 years, and Group C from 40-49 years. The BMI (Mean ±SD), infertility years (Mean ±SD), parity (No & %), and menstrual cycle status (No & %) of each age category are shown in table 1.

**FSH response to PRP**

Statistically significant reduction in FSH levels before and after PRP injection in the total women sample. The before FSH mean level (IU/l) was reduced from 31.85 (±12.03) to 25.24 (±11.63) after four week (p=0.004). But, after categorization of the women, only women with: age group 40-49, obesity, infertility more than 5 years, primary infertility, and irregular menstrual cycle or amenorrhea showed a non-significant reduction in FSH levels as shown in table 2.

Table 2: FSH levels (mean ±SD) before and after PRP injection according to age, BMI, Infertility duration, infertility type, menstrual cycle status and total sample.

AMH response to PRP

AMH levels showed a highly statistically significant increase in comparison of before and after PRP injection in the total women sample. The before AMH mean level (ng/mL) was increased from 0.125 (0.057) to 0.532 (0.087) after 4 week (p=0.001). But in category analysis, these significant increases were not shown only in women with: age group 20-29 years, and obesity (Tables 3).

Table 3: AMH levels (mean ±SD) before and after PRP injection according to age, BMI, Infertility duration, infertility type, menstrual cycle status and total sample.

AFC response to PRP

Statistically significant difference between before- after intervention means. The mean (±SD) had been raised from 0.86 (0.508) before to 2.29 (1.067) after PRP injection. This significant increased were also showed in all categories of study variables except in 20-29 year age group, obese women, and women with irregular cycle or amenorrhea as shown in table 4.

Mean ovarian volume (OV) in cm³ response to PRP

The before-after intervention measurement of mean OV (both ovaries) also showed a statistically significant difference. The mean (±SD) elevated from 3.98 (1.761) to 5.21 (2.352) in the total study sample. But, in category-analysis, there were no such significant differences in; age groups 20-29, and 40-49 years, obese women, women with more than 5 years history of infertility, primary infertility women, and amenorrheic women as shown in table 5.
Discussion

One of the biggest challenges in the management of infertile women is the loss of ovarian reserve which might occurs at any age and for different reasons. This study examined PRP application to ovarian tissue with a view to document its effect on ovarian reserve among women attending for infertility treatment. To the best of our knowledge, this is the first study estimating this effect in Iraq and one of few in the region.

Before that, many centers in Europe and Middle East have reported success in women with Premature Ovarian Failure (POF), Diminished Ovarian Reserve, peri menopause and menopause through intra-ovarian injection with their own PRP and may result in successful pregnancies for patients that previously had no hope. The same was applied to endometrial PRP injection to improve implantation rate (7).

Promising results were found in this study, as the indicators for ovarian reserve volume (reduction in FSH level, increase in AMH level, with an increase in AFC, and mean ovarian volume) were change for positive findings. The exact mechanisms of PRP in this improvement are not exactly clear, but previous experimental studies have shown that the increased concentration of growth factors in PRP can potentially speed up the healing process. Growth factors promote wound healing by initiation of the following stages: Resolution, Chemo taxis, Cell regeneration, Cell proliferation and migration, Extracellular matrix synthesis, Remodeling, Angiogenesis, and Epithelialization (4).

A recent report on three live births in women with poor ovarian response following intra-ovarian injection of PRP was released in April 2019 (8). This study appeared to be the first report on the effects of intra-ovarian PRP injection not only on the increase of ovarian responses, but even on the spontaneous conceptions of women with poor ovarian response. These patients underwent ovarian stimulation, and the mean numbers of oocytes increased from 0.64 before PRP injection to 2.1 after rejuvenation. Two patients experienced spontaneous conceptions. The third case achieved clinical pregnancy and delivered a healthy baby in June 2018. Of course, this is a case report and further evidence of the application of PRP is hopped to achieve in the future, confirmed by the anticipated large clinical trials, to extrapolate that it could become an option for prematurely menopausal women aiming to achieve a pregnancy.

In conclusion, this study found that PRP is effective in ovarian rejuvenation in women with poor ovarian reserve as it improved clinical hormone levels of FSH, AMH toward normal ranges after 4 weeks. Moreover, it might increases the AFC and ovarian volume making more chance for ovulation and may be later for fertilization.

The Effect of Prenatal Yoga in Reducing Pregnancy Complaints

Anna Veronica Pont1, Ni Made Rosiyana2, Vira Pratiwi2, Enggar2, Nurfatimah1, Kadar Ramadhan1

1Health Polytechnic of Palu, City of Palu, Indonesia, 2Cenderawasih Nursing Academy, City of Palu, Indonesia

Abstract

There are physical and psychological changes during pregnancy which could lead to discomfort, especially during third trimester of pregnancy. Prenatal yoga is one of pregnant treatments with benefits to reduce signs and symptoms commonly experienced by pregnant women. The aim of this study is to find the effectiveness of prenatal yoga in reducing maternal discomfort at third trimester of pregnancy. We used quasi-experiment design with one group pretest – posttest design. This study was performed from July to October 2017 in four different primary healthcare units (Public Health Center) in Palu: Talise, Sangurara, Mabelopura, and Mamboro. Samples were obtained from pregnant women at third trimester of pregnancy, fit with our criteria in these Public Health Centers, amounted to 34 respondents in total. We collected the information by performing interview, observation and prenatal yoga as direct intervention. The data were then analyzed using Wilcoxon test. We found that the average complaints experienced by pregnant women during pretest were 7.21 with deviation standard (SD) of 3.4. Post-test data showed a mean of 3.06 with SD 1.7. Our statistical analysis of those comparison was p=0.000. There was significant difference of complains before and after prenatal yoga. Prenatal yoga could reduce pregnancy complains during third trimester of pregnancy.

Keyword: Prenatal Yoga, Pregnancy Complaints, third trimester of pregnancy.

Introduction

Anatomical, physiological, and biochemical adaptation will occur during pregnancy. Most of these changes begin shortly after fertilization occurs, and will continue to happen throughout the gestation period1. Dramatic weight gain makes pregnant women easily feel tired, have difficulties to fall asleep, breath shortness, foot and hand edema2. In line with fetal growth, there are changes in the shape and size of chest cavity due to fetal growth, causing pregnant women to experience breath shortness1,2.

Increased height of the uterine fundus accompanied by enlarged abdomen makes the body weight fall in the front. It happens so as an effort of adjusting to excessive body weight to push the spine backwards, creating lordosis posture. It causes the mother to feel sore waist, varicose veins and cramps in the legs. Muscle spasm is caused by traction of a number of nerves and muscles and is associated with lordosis posture in pregnancy1,2.

Changes in uterine size and body metabolism cause pregnant women to experience frequent urination, feeling hot flashes/ feverish heat, varicose veins in the limbs, hemorrhoids and constipation1,3,4.

Pregnant women are advised to do light exercise during pregnancy to keep their bladder healthy and reduce the problems normally appear during pregnancy5–7. Yoga is one of the mild exercise choices that can be done by pregnant women8,9.

Prenatal yoga focuses attention on the breath rhythm, prioritizes comfort and safety in training, thus providing many benefits10. Yoga is similar to body, mind and mental exercise that is highly helpful for pregnant women to flex joints and calm the mind, especially in the third trimester. Prenatal yoga has five ways, for instance yoga physical exercise, breathing (pranayama), position

DOI Number: 10.5958/0976-5506.2019.02061.8
(mudra), meditation and deep relaxation that can be used to get benefits during pregnancy. It can also help smooth, natural, and healthy pregnancy and childbirth.

The objective of this research was to determine the effectiveness of yoga in reducing complaints of pregnant women in the third trimester of pregnancy in the Public Health Center of Palu.

**Material and Method**

**Research design**

The present research was quasi-experimental design research with the design of one group pretest-posttest design, as it measured changes in the level of complaints of mothers in the third trimester after performing a certain treatment, namely yoga. The research conducted observation before treatment (pretest) and after yoga intervention (post-test).

**Samples**

The respondents as samples of this research was 34 in total, using purposive sampling, namely the sampling taken from the entire pregnant women population in the work area of Mamboro, Sangurara, Mabelopura and Talise public health centers in August 2017, according to the inclusion criteria. The inclusion criteria for this research: willingness to be put under study, no pregnancy complications, and no preterm labor in previous pregnancies, the growth and development of the fetus according to gestational age, and no mental disorder.

**Data collection**

The research was carried out by examining the complaints of pregnant women in the third trimester before (pre-test) and after (post-test) prenatal yoga. After conducting interview for pre-test, Yoga was held for 8 times: twice every week for a month. Yoga were held in the morning and evening, according to the joint time contract between the researcher and the respondents. Yoga was conducted with duration of 30-60 minutes, including whole movement and relaxation/meditation. Each movement was done for 10 seconds, and 3 minutes for relaxation, meditation for breathing, respectively. The movements used in this research covered Mudhasana (child posture), Utkasana (seat posture), pelvic rocking, squatting posture, Baddha Konasana (butterfly posture), Sufi twirl, and meditation.

**Data analysis**

To analyze the data collected, the technique used was univariate analysis, with frequency distribution of respondent characteristics, independent variables and dependent variables. Bivariate analysis was to see the difference in the level of complaint of the experimental group before intervention. After the final treatment, Wilcoxon test was used with a significance value of 0.05 using a confidence interval of 95%.

**Results**

Based on the level of education and employment (Table 1), it appears that the majority of pregnant women earned higher education (82.4%); and most of them are housewives. Based on age, it was known that the average age of pregnant women was 27.08 years old mean age of 28 years old, and SD 4.8, the youngest was 19, while the oldest was 37.

</tbody>
</table>

From 34 respondents, interviews were conducted to 16 complaints mostly felt by pregnant women. As shown in Table 2, frequent urination was the most common complaint during pre-test (91.1%), while the least perceived complaint was hemorrhoids (9%). After Yoga, post-test interviews were conducted with the results showing that all respondents no longer felt muscle spasms (0%). Even so, lower abdominal pain and frequent urination were felt by half (50%) of the total respondents.

This bivariate analysis used paired T test for the hypothesis to see the difference on reduced complaints perceived by pregnant women in the third trimester, before and after prenatal yoga. Therefore, the normality test result of Shapiro-Wilk test produced a probability value (p) <α (0.05), which meant that the data were not normally distributed. Therefore, the hypothesis test used was Wilcoxon test. The results of the statistical analysis (Table 3) show that the mean score of pre-test and post-test complaints is 4.7. Wilcoxon test obtains significance p value of = 0.000, therefore the p value is = 0.000 <α = 0.05. It can be concluded that prenatal yoga is effective in reducing complaints in third trimester of pregnancy.

Discussions

There are sixteen pregnancy complaints as a measurement of the effectiveness of prenatal Yoga in this research: fatigue, difficulty to fall asleep, breath shortness, edema, low back pain, muscle spasm, anxiety, lower abdominal pain, feverish heat and hot flashes, frequent urination, feet cramps, fake contractions, varicose vein, hemorrhoids, stretch marks, and constipation.

Data analysis, in general, shows a significance value of p = 0.000 (p <0.05), indicating that prenatal exercise has real and significant potential in reducing pregnancy complaints. A number of movements performed in Yoga
have an impact on various organ systems that each plays a role in causing complaints in the third trimester of pregnancy.

Systemic inflammatory response and increased CRP level occur during pregnancy. Lack of physical activity, coupled with psychological factors can turn pregnant women vulnerable to inflammation and other disorders associated with inflammation and hormonal fluctuations

Hot flashes are generally felt by women who have reached menopause health, or lifestyle factors.

METHODS We followed 3198 women enrolled in the Study of Women’s Health Across the Nation during 1996 through 2002. We analyzed frequency of vasomotor symptom reporting using longitudinal multiple logistic regressions. RESULTS Rates of vasomotor symptom reporting were highest among African Americans (adjusted odds ratio [OR]=1.63; 95% confidence interval [CI]=1.21, 2.20. However, these symptoms can also occur in pregnant women due to hormonal fluctuations. Physical activity can help improve changing body’s metabolism during pregnancy, thus reducing complaints of hot flashes. However, frequent and regular physical activity is needed to completely eliminate the complaints.

Frequent complaints of frequent urination are caused by the influence of progesterone hormone. Increased glomerular filtration is sometimes exacerbated by the occurrence of pyelonephritis as another effect of anatomical changes in the ureter, causing this complaint to be quite common. Yoga, besides playing a role in helping control hormonal fluctuations, can also help reduce symptoms of anatomical and physiological changes during pregnancy.

Disorders of the circulatory system and respiration see a decrease after doing Yoga. It is evident from the reduced complaints of fatigue and breath shortness. Anatomical changes due to pressure from pregnancy on the diaphragm which narrowed chest cavity could be handled through exercise. Mechanical adaptation to the respiratory system, including increased resting inspiration capacity and bronchodilator, leads to increased VT expansion when pregnant women are engaged in physical activity. Through regular activities, therefore, fatigue and breath shortness complaints can be resolved properly.

Musculoskeletal complaints, i.e. low back pain, muscle spasm, stretch marks, and foot cramps are also proven to have been reduced through Yoga. Practicing yoga on regular basis can improve muscle health, blood circulation, balance and range of motion. Relaxation that appears through Yoga can also help muscle relaxation which results in reduced musculoskeletal complaints.

The scientific explanation of the physiological effects of each movement in prenatal Yoga makes these sixteen movements in this research usable as basic Yoga movement. The results of this research also illustrate the significance of changes in complaints, before and after the research. These movements, therefore, can be recommended for use in Public Health Centers and other institutions that wish to include prenatal yoga as one of their programs.

The present research is not conducted throughout the third trimester, but only for 1 month. Further research, especially conducted throughout the third trimester, is needed to determine the effects of this exercise within lengthy period of time. Also, items of physiological pregnancy disorders that may change during pregnancy can be added in the third trimester as effectiveness indicators of prenatal yoga.

Conclusion

Yoga has considerably good effectiveness in controlling and reducing complaints during the pregnancy.

Effectiveness of Clindamycin in Treatment of Periodontitis

Irene Edith Rieuwpassa¹, Harun Achmad², Rahmasari³

¹Lecturer, Oral Biology Dentistry Department, ²Lecturer, Pediatric Dentistry Department,
³Clinical Student, Faculty of Dentistry, Hasanuddin University, Makassar, South Sulawesi, Indonesia

Abstract

Clindamycin is a systemically administered antibiotic to support periodontal treatment. Each antibiotic has specifications in destroying microorganisms.

Giving prescription drugs for handling a bacterial infectious disease must consider the effectiveness of these antibiotics, therefore to see the level of bacterial sensitivity to certain antibiotics a bacterial sensitivity test is carried out in vitro. It is important to do research to see whether clindamycin is still effectively used for the treatment of periodontitis in patients at RSGM Kandea Makassar.

Identification of bacteria from patient samples was diagnosed with periodontitis to obtain Porphyromonas gingivalis (P. gingivalis) and Aggregatibacter actinomycetemcomitans (A. actinomycetemcomitans) bacteria in the Microbiology laboratory of the Faculty of Medicine, Hasanuddin University. From 20 samples, A. actinomycetemcomitans were identified in 13 samples and P. gingivalis bacteria in 4 samples. From the disc diffusion test, 8 samples (61.5%) of A. actinomycetemcomitans and 3 samples (75%) of P. gingivalis were still sensitive to Clindamycin.

From these results it can be concluded that clindamicyn antibiotics are still quite effective in killing bacteria that cause periodontitis. Clindamicyn is still an alternative medicine for bacterial infections of the oral cavity.

Keywords: Clindamycin, Treatment Periodontitis

Introduction

Antibiotics are needed to remove bacteria from periodontal tissue. The most common antibiotics used in periodontal treatment are penicillin, metronidazole, tetracycline and clindamycin. Irrational use of antibiotics can cause resistance. Resistance is the ability of bacteria to neutralize and weaken the working power of antibiotics.

In Southeast Asia the problem of antibiotic resistance is also quite serious. WHO Southeast Asia region sets out several strategies, among others by rationalizing antibiotic use, reducing selection preassure, changing the behavior of antibiotic prescribers and making the issue of antibiotic resistance a national problem in every country in Southeast Asia. Mechanism of antibiotic resistance involving various biochemical mechanisms in bacterial cells can be explained by the existence of mutations in genes that encode one of the components involved in biochemical interactions between antibiotics and bacteria. Phenotypic changes in bacteria can result in bacterial resistance to antibiotics.

Clindamycin is a systemically administered antibiotic to support periodontal treatment which has shown good results. Each antibiotic has specifications in destroying microorganisms.

Antibiotics can be classified based on the mechanism of action into six major groups, namely:

Inhibits cell wall synthesis, including: penicillins, cephalosporins, vancomycin, inhibits betalactamase, carbapenems, aztreonam, polymyxin and bacitracin;

Inhibits protein synthesis, including: aminoglycosides (gentamicin), tetracyclines, macrolides, chloramphenicol, clindamycin, linezolid and streptogramins;

Inhibits DN synthesis, including: fluoroquinolones and metronidazole;
Inhibits RNA synthesis, including: rifampicin;
Inhibits the synthesis of mycolic acid, including: isoniazid;
Inhibits folic acid synthesis, including: sulfonamides and trimethoprim.

**Clindamycin**

Clindamycin is a semisynthetic derivative of lincomycin, a natural antibiotic produced by actinobacterium Streptomyces lincolnensis. Lincosamide (eg lincomycin, clindamycin) is a class of drugs that bind the 23S part of the bacterial 50S subunit and inhibits the initial elongation of the peptide chain by inhibiting the transpeptidase reaction. In this sense, they have similar actions towards macrolides.\textsuperscript{6,7}

Clindamycin has a bacteriostatic effect. It is used primarily to treat infections caused by anaerobic bacteria.\textsuperscript{5,8} Clindamycin can also be used in combination with chloroquine and quinine to treat malaria caused by Plasmodium falciparum. This is commonly used as a topical treatment for acne, and can be useful in some methicillin-resistant Staphylococcus aureus infections (MRSA).\textsuperscript{5}

Clindamycin is used in the treatment of recurrent periodontal diseases, especially if mechanical treatment or other antibiotic treatments (penicillin and tetracycline) do not show success.\textsuperscript{9}

The mechanism of resistance in bacteria includes mutations, inhibition of enzymatic antibiotic activity, protein changes which are targets of antibiotics, changes in metabolic pathways, antibiotic efflux, changes in the channel and changes in membrane permeability.\textsuperscript{10,11}

Gram negative bacteria such as Aggregatibacter actinomycetemcomitans, Fusobacterium nucleatum, Porphyromonas gingivalis, Prevotella intermedia and Eikella corrodent types of dental plaque bacteria in healthy periodontal tissues.\textsuperscript{12} Systemic antibiotic therapy for periodontal treatment is usually monotherapy including amoxicillin, metronidazole, tetracyclines (tetracycline, doxycycline, minocycline), clindamycin and ciprofloxacin.\textsuperscript{13}

**Method**

The type of research that will be conducted is descriptive. The sample used in this study were patients diagnosed as periodontitis in the Dental and Oral Hospital of the Faculty of Dentistry, Hasanuddin University, Makassar. The number of samples were 20, the sampling method used in this study was purposive sampling.

23. Calipers

B. Materials

1. Specimen of subgingival bacteria
2. Medium transport: BHIB
3. Bacterial Culture Medium: Nutrient Agar (NA), Mac Conkey Agar (Me)

**Procedures**

Samples that met the criteria were taken for bacterial specimens in the subgingival area using swabs. Swabs containing bacterial specimens were put
into the transport medium and then tightly closed and taken to the Microbiology Laboratory of the Faculty of Medicine for further examination. Bacterial culture was carried out into Sodium Agar (NA) and MacConkey (Me) media in petri dishes, then incubated for 24 hours at 37°C. After incubation then carried out gram staining and looked at the colony (microscopic), biochemical test (not done). An interpretation of the type of bacteria present in the sample was carried out. Bacterial culture which was included in the criteria into the medium NA slant. Bacteria originating from medium NA slant were suspended (MHA bacterial suspension into sterile 0.9 NaCl, mac fallen standard turbidity 0.5).

Bacterial culture into the MHA medium for sensitivity testing. Test the sensitivity of the test by inserting an antibiotic paper disc, and then incubation for 24 hours at 37°C. Measuring the inhibitory zone using calipers to see the results of the bacterial sensitivity test.

**Results**

Identification of Bacteria

Based on the research carried out, bacteria were identified in periodontitis patients at the Dental and Oral Hospital (RSGM) in Kandea Makassar (table 1).

Based on biochemical and physiological tests, 10 types of microbes have been identified, namely *Bacteria A. actinomycetemcomitans* amounting to 13 (65%), *P. gingivalis* as many as 4 (20%), Propionibacterium as many as 3 (15%), Klebsiella as many as 2 (10%), Enterobacter agglomerous as many as 2 (10%), *S. Pneumoniae* as many as 1 (5%), Fusobacterium as many as 1 (5%), Staphylococcus as many as 1 (5%), and E. coli as many as 1 (5%) and Candida sp. as many as 5 (25%).

**Bacterial Resistance Levels**

The bacteria found in people with periodontitis were not all bacteria that may cause periodontitis. Based on the formulation of the problem that we have determined, we will test antibiotic resistance in pathogenic bacteria that cause periodontitis. Bacteria that causes periodontitis in this case are bacteria *Porphyromonas gingivalis* (*P. gingivalis*) and *Agregatibacter actinomycetemcomitans* (*A. actinomycetemcomitans*). Of the 20 samples we took were identified *A. actinomycetemcomitans* in 13
samples and P. gingivalis bacteria in 4 samples. The results of the resistance test for A. actinomycetemcomitans and P. gingivalis bacteria can be seen in Table 2 below.

### Table 2. Bacterial resistance test results

Of the 13 samples A. actinomycetemcomitans the number of samples that are still sensitive is 8 samples (61.5%) and for P. gingivalis samples, there are 3 (75%) samples that are still sensitive to clindamycin.

#### Discussion

**Identification of Bacteria**

In this study, bacteria were identified in periodontitis patients and carried out bacterial resistance testing for periodontitis with clindamycin antibiotics. The main bacteria causing periodontitis tested in this study were the bacteria Aggregatibacter actinomycetemcomitans (Aa) and Porphyromonas gingivalis (Pg). Aggregatibacter actinomycetemcomitans is an anaerobic Gram-negative bacterium in the form of a coccus measuring around 0.4x1.0 μm while Porphyromonas gingivalis is a melanogenic, non-monolytic, and part of anaerobic negative Black-pigmented Gram colonies.

In this study 10 types of microbes were identified, namely Aa Bacteria of 13 (65%), Pg of 4 (20%), Propionibacterium of 3 (15%), Klebsiella of 2 (10%), Enterobacter agglomerus of 2 (10%), S. pneumoniae of 1 (5%), Fusobacterium of 1 (5%), Staphylococcus of 1 (5%), and E. coli and Candida sp. of 5 (25%).

In this study the most common bacteria were Aa bacteria, which is as much as 65%, which is in line with research conducted in Finland, namely 50% of adult periodontitis containing the bacterium Aggregatibacter actinomycetemcomitans.14

The lack of the type of bacteria obtained in each sample is also likely to be caused by bacteria found in periodontitis are anaerobic bacteria while the culture process is not carried out anaerobically.

#### 5.2 Levels of resistance of bacteria Aa and Ph to clindamycin antibiotics

According to Krismariono A., systemic antibiotics help with mechanical treatment. Each antibiotic has certain specifications, so it is important to test the main bacterial sensitivity for the cause of periodontitis with antibiotics to be given. As in this case the clindamycin antibiotic which is a bacteriostatic antibiotic that works to inhibit bacterial protein synthesis, is very effective against anaerobic bacteria that produce enzymes β-lactamase.3

Systemic use of clindamycin antibiotics can reduce the rate of tooth loss due to periodontal disease.14 In addition to systemic, topical administration of clindamycin in concentrations below 1% is also effective in aiding the treatment of periodontal disease.15

In other studies, it is recommended to reduce the use of clindamycin antibiotics in patients with caries or periodontal disease. This is because the bacteria isolated from dental plaque found a resistance level of 83%.16

The results of our research, from 13 samples of A. actinomycetemcomitans, the number of samples that were still sensitive was 8 samples (61.5%) and for samples of P. gingivalis, there were 3 (75%) samples that were still sensitive to clindamycin.

From these results it can be seen that clindamycin antibiotics are still quite effective in killing bacteria that cause periodontitis. this is in line with the results of a study conducted by Gunawan S. et al. who conducted a study of differences in the antibacterial power of zinc oxide-based root canal medicaments in combination with 5% clindamycin hydrochloride and calcium hydroxide against enterococcus faecalis bacteria. In this study the zinc oxide combination of clindamycin hydrochloride...
was 5% more effective than other medicaments. This proves that clindamicyn is still an alternative drug for bacterial infections of the oral cavity.

The relationship between drug consumption patterns and resistance levels

Definite resistance begins with antibiotic exposure, and although only one or two bacteria can survive, they have the opportunity to create a new strain that is resistant. This new resistant strain can spread from one person to another, increasing its potential in epidemic proportions. This spread is facilitated by weak infection control and extensive use of antibiotics. Resistance is defined as the inhibition of bacterial growth by giving systemic antibiotics with normal doses that should or minimum inhibitory levels. Whereas multiple drugs resistance is defined as resistance to two or more drugs and drug classification. While cross resistance is the resistance of a drug followed by other drugs that have never been exposed Resistance occurs when bacteria change in one way or another that causes a decrease or loss of effectiveness of drugs, chemical compounds or other ingredients used to prevent or treat infections.

Conclusion

In this study 10 types of microbes were identified in subgingival specimens of periodontitis patients. The bacteria that caused periodontitis, Aggregatibacter actinomycetemcomitans (A. actinomycetemcomitans), are found in 13 samples (65%) and Porphyromonas gingivalis (P. gingivalis) in 4 samples (20%). Resistance tests were carried out on two types of bacteria. Obtained the results of A. actinomycetemcomitans bacterial resistance to clindamicyn reaches 38.5% while the level of resistance of P.gingivalis bacteria to Clindamicyn is 25.0%

A Comparison Between Luteal Phase Treatment with Estradiol and GnRH Antagonist for Ovarian Follicular Synchronization in ICSI Cycle

Nassrin Malik Aubead1, Basima Sh. AL.Ghazali2, Muayad Sraibet Abbood3
1M.B.Ch.B, DOG, CABOG, FIBMS OG, College of Medicine /University of Babylon, Hilla – Iraq, 2Professor and Consultant Obstetrician and Gynecologist, Obstetrics and gynecology Department, , College of Medicine /Kufa University, Kufa- Iraq, 3Assistant Professor in Department Of Applied Embryology, High Institute of Infertility Diagnosis and ART/AL Nahain University, Baghdad-Iraq

Abstract

The Objective of this study is to compare the results of luteal phase treatment by estradiol versus GnRH antagonist on antral follicular size coordination and hormonal levels before ICSI cycles, assessment of follicular growth synchronization during controlled ovarian stimulation and evaluate ICSI outcome. This a prospective randomized clinical trial included 60 infertile women evaluated in second day of menstrual cycle for antral count and their sizes, FSH, LH, estradiol, and progesterone, then assigned randomly according to luteal treatment to 3 groups; with 20 patients in each treated with estradiol, or cetrorelix acetate or no treatment. All then enrolled in ICSI with flexible antagonist protocol. Findings revealed significantly reduction of antral follicles sizes, and improve their growth symmetry in early follicular phase after treatment, reduction in second day FSH, LH and progesterone. Reduction in follicular growth discrepancies at day 8. At trigger day the antagonist group had a significant more numbers of the follicles size ≥17 mm. larger number of retrieved–oocytes, (MII) than other groups, (P<0.05). No significant difference in biochemical and clinical pregnancy rates between groups. In conclusions premenstrual estradiol or GnRH antagonist treatment decrease size discrepancies of antral follicles, and improve synchronization of their growth.

Keywords : ICSI, synchronization, GnRH antagonist, estradiol.

Introduction

Through the initial follicular portion of the menstrual cycle, the size of the antral follicle is usually heterogeneous. These differences in follicle size are due to the early exposure of F.S.H. -sensitive follicles to F.S.H. gradient-concentrations through-out the luteal phase1,2. This event, may potentially impact the outcomes of controlled ovarian stimulation (COS), because of the pre-existing asynchronous follicle size may disturb coordinated follicular growth during COS3. In addition, at COS, asynchronous follicular growth can be intensified by the administration of exogenous FSH and as the exogenous FSH begins in the early follicular phase, a period in which endogenous FSH levels dropped to lower than the threshold for the already existed antral follicles. This results in the growth of some of the antral follicles to preovulatory stage and this more likely lead to further discrepancies in the sizes of the growing follicles throughout the COS, this more likely to intensify the differences in the sizes of the grown follicles during COS, which results in a decrease in the maturity of the oocytes and the rate of fertilization, which inversely affects the number of transferable embryos and the probability of conception4,5.

Many approaches can be used in ART to ascertain the good synchronization of the antral follicle, one of these approaches is suppression of the natural increase in the level of FSH during luteofollicular transition by medications6,7. The pre-treatment of estradiol lead to reduced premature gradual exposure of the follicles to

FSH in the late luteal phase by inhibiting the secretion of GnRH and during the succeeding early follicular phase in the next cycle, a significant condensation of the mean follicular size with improved homogeneity in the overall follicles size through the follicular phase. It also induces the formation of FSH-receptor in the resistant-follicles and leads to further coordinated gonadotropin responses.\textsuperscript{8,9}

The GnRH antagonist when administered in the mid-luteal phase, results in premature decease of the corpus leuteum which leads to a new group of healthy follicles by discontinuing the inhibitory effect of the progesterone on the growth of the antral follicles, furthermore, it results in optimal synchronization of the sizes of antral follicles via prevention of the elevation of the levels of premature FSH throughout the luteo-follicular conversion. during luteo-follicular transition, and after the acutely induced luteolysis, there is FSH flare-up that positively could influence follicular growth and estrogen concentrations in serum.\textsuperscript{10,11}

Patients and Method

This was a prospective randomized clinical trial conducted at the Fertility center- AL Sadder Medical city, AL-Najaf, Iraq between November 2018 to the May 2019.

It included 60 women who attend for ICSI cycle having either primary or secondary infertility.

**Inclusion criteria:** Age 20-35 years, BMI 18-25Kg/m\(^2\), regular cycle(25-35days), the 2 ovaries seen with normal uterus, no previous hormonal treatment within the last three months.

**Exclusion criteria:** Single ovary, ovarian cyst or had ovarian cystectomy, endometriosis, pelvic inflammatory diseases, history of autoimmune, endocrine or metabolic disorders, severe male factor or azoospermia, and hypogonadotrophic hypogonadism.

Participant women were assigned randomly into 3 groups with 20 women in each:

- **Estradiol group** received oral estradiol 4 mg/ day from day 20 of the menstrual cycle, until first day of next cycle.

- **GnRH Antagonist group** received cetrorelix acetate as daily subcutaneous injections of 0.25 mg for 3 consecutive days before the first day of suspected next cycle.

**Control group** started with ICSI cycle of flexible antagonist protocol immediately without luteal phase treatment.

Patients in Estradiol and GnRH antagonist groups were reevaluated in the second day of the second menstrual cycle (immediately after luteal phase treatment) for FSH, LH, estradiol, and progesterone, then enrolled in a flexible antagonist protocol.

In all groups the stimulation was initiated on day 2 of the cycle. Recombinant FSH in form of follitropin alpha was administered subcutaneously, starting dose ≥ 150IU were adjusted to each individual according to AMH, FSH, age, BMI, and previous IVF cycles response, the starting dose constantly maintained for five days, then subsequently set according to the ovarian response. The follicular growth was monitored by transvaginal ultrasonography performed on day 6 and 8 of stimulation, then continue every two days until day of trigger. When the leading follicles diameter reached 12-14 mm, cetrorelix acetate 0.25 mg was given as daily subcutaneously up to the time of HCG intake. In all groups when at least three follicles ≥ 18 mm were obtained, serum estradiol and progesterone levels were detected, and an i.m. injection of hCG (5000-10,000 IU) were given at 11:00 pm.

Transvaginal oocyte retrieval(OR) achieved 35-36 hours later. ICSI was done, and embryos transfer was performed two days later.

Data analysis performed by SPSS version 25. Appropriate statistical tests were applied at level of significance of 0.05.

Results

Findings revealed a significant increment in the recruited antral follicles, significant reduction of their sizes, and improve their growth symmetry in the early follicular phase in both treatment groups, (Table 1). At day 2, a significant reduction in the levels of serum-LH and FSH after treatment with E2 or antagonist was reported, (P.value<0.05). Estradiol-levels were elevated significantly in estradiol group, while they reduced in antagonist group, (P.value< 0.05). There was a significant reduction in progesterone levels after
estradiol and antagonist treatment (P<0.05). Antagonist reduced the FSH, and progesterone more significantly than estradiol. (Table 2)

A significant increment in number of follicles that measured 15-16mm in antagonist group (p =0.001), and good reduction in follicular growth discrepancies at day 8. At day of trigger the antagonist group had lower number of follicles of 11-14 mm, 15-16 mm, and higher number of follicles ≥17 mm, (P<0.05), than other 2 groups, progesterone was more elevated in the estradiol group. Higher number of retrieved oocytes and MII in antagonist group (P<0.05), and higher number of embryos transferred in estradiol and antagonist groups than controls (P<0.05). (Table 3)

The HCG positive rate in estradiol group (20%), in GnRH antagonist group (35%), and in control it was (30%) (Figure 1). The clinical pregnancy rates of the studied groups were (20%) , (30%), and (25%), respectively, (Figure 2). The clinical pregnancy rates of the studied groups out of HCG positive cases were 100%, 86% and 83%, among the three groups, respectively, (Figure 3).

Discussion

The present study showed that suppression of FSH by luteal phase treatment by either oral estradiol and GnRH antagonist lead to significant increment in the recruited antral follicles, and significant reduction in their sizes and improve their growth symmetry in the early follicular phase. The extent of follicular size reduction was statistically significant more in antagonist than in estradiol group specially for antral follicles that measure 6-10 mm (P < 0.001). These findings agreed that reported by Fanchin et al, there was attenuation in the antral follicle size heterogeneity after administration of cetorexil or estradiol during the luteal phase, but there were no significant change in total no. of antral follicles after treatment with E2 or antagonist. Batool et al found significant reduction in the early antral follicles sizes after using estradiol or antagonist in luteal phase.

In the present study a significant reduction of day 2 serum FSH, LH, and progesterone levels after treatment, and the antagonist reduced FSH and progesterone more significantly than estradiol. Estradiol levels were significantly elevated within estradiol group, while in antagonist group there was significant reduction. Batool et al, also found significant reduction of FSH in early follicular phase in both estradiol and antagonist group but no difference found when compared the 2 groups. A significant elevation of E2 levels in estradiol group ,and it was insignificantly reduced in antagonist group. Similar findings reported by Blockeel et al.

In the current study, no significant difference among the three groups, regarding the gonadotrophin dose or length of stimulation period. Hong Ye et al and Cédrin-et al had same findings.

In the present study a significant increment in number of follicles that measured 15-16mm in antagonist group with good reduction in follicular growth discrepancies at day 8. At day of trigger the antagonist group had lower number of 11-14 mm, and 15-16mm follicles, and higher number of follicles ≥17 mm, when compared with other 2 groups. Fanchin et al stated that luteal FSH reduction by either estradiol or GnRH antagonist treatment improves the homogeneity of early antral follicles during the early follicular phase, an effect that persists during ovarian stimulation.

While Cédrin et al observed a significant lower number of medium-size follicles on day 6 of ovarian stimulation and a lower ratio of cycles had follicles more than 15 mm in women treated with E2 proposed a retarded in the initiation of follicular development.

In our study there no significant differences in estradiol levels at day of trigger between 3 groups, but there was significant elevated progesterone levels in group treated with estradiol. Also Hong Ye et al reported similar findings.

In the present study, antagonist group had significant higher number of oocytes retrieved and high number of mature oocytes. More, embryos transferred in estradiol
and antagonist than control, but the results between E2 group and antagonist group were not significant. It is worth mentioning that some patients in all groups had no embryo transfer due to different factors. The biochemical and clinical pregnancy rates were insignificantly different among the 3 groups. The HCG positive rates in estradiol group was 4/20 (20%), in GnRH antagonist group 7/20 (35%) and in control was 6/20 (30%). The clinical pregnancy rates were 4/20 (20%) in estradiol group, 6/20 (30%) in GnRH antagonist group, and 5/20 (25%) in controls. Cunha et al found no significant differences in the number of oocytes retrieved between group received luteal phase estradiol combined with GnRH antagonist, and control group. Nigel et al found no significant differences in the total and MII oocytes retrieved, or in the rates of biochemical and clinical pregnancy, between the group treated with E2 and that had COCP in luteal phase.

Conclusion

Premenstrual estradiol or GnRH antagonist treatment decrease size discrepancies of antral follicles, and improve synchronization of their growth. GnRH antagonist achieved that more significantly than estradiol. Higher total oocytes and MII retrieved in antagonist group, significant embryo transferred in both treatment groups.

Diagnostic Study on Intestinal Parasites Isolated from Raw Consumed Vegetables in Misan City/ Iraq

Rawwaa Ghanim Mohammed¹, Heba Abdul Hussein Kadhim², Jassim Fatehi Ali²

¹Department of Clinical and Laboratory Science, College of Pharmacy, University of Misan, Iraq, ²Department of Basic Medical Science, College of Dentistry, University of Misan, Iraq.

Abstract

Objectives: It is well known that raw vegetables have an important role in human nutrition. And considered as an agent for transmission of intestinal parasites Therefore, the present study is designed to detect the parasite contamination in Misan city.

Method: A total of 45 fresh vegetables were randomly collected. All samples were examined according to standard methods for detection of protozoan cysts, oocysts, helminth eggs as well as larva.

Results: Intestinal parasites were detected in 23/45 (51.1%). The highest contaminated vegetable were celery (66.7%) followed by cress (46.7%) and lettuces (40%). Giardia lamblia cysts were the most prevalent (43.5%) followed by Fasciola hepatica eggs (34.7%), Entamoeba spp. cysts (26.1%), Hymenolepis nana eggs (17.4%), Cryptosporidium spp. oocysts (13.1%), Toxoplasma gondii oocysts (8.7%), Enterobius vermicularis eggs (8.7%) and Emeria spp.oocysts (3.4%).

Conclusions: These findings provide evidence for the high risk of acquiring parasitic infection from the consumption of raw vegetables in Misan city.

Keywords: Vegetables, Intestinal parasites, Celery, Cress, Lettuces, Misan.

Introduction

Leafy vegetables regarded as an important part of the healthy diet. In many countries such leafy plants are eaten raw and this practice may also favor the likelihood of foodborne parasitic infections ¹. In recent years, there has been an increase in the number of report cases of food-borne illnesses linked to consuming fresh vegetables. Parasitic diseases can be considered among the most common diseases on earth, transmitted to humans through water, soil, and foodstuffs ². Vegetables, especially salads, are an important route of transmission of intestinal source of food borne outbreaks in developing countries ³,⁴. In Iraq there are many epidemiological studies of the intestinal parasitic infections. In Naienawa province show the total percentage of the intestinal parasites was (70%) where including (19.5%) Entamoeba coli (3.11%) Entamoeba histolytica (11.9%) Giardia lamblia (19.5%) Hymenolepis nana (11.8%) Enterobius vermicularis (2.95%) Ascaris lumbricoides and (0.6%) Ancylostoma duodenale ⁴, in field study for intestinal parasites infection among Deiala city 6645 stool specimens were tested and revealed that total infection was 29.1% and many intestinal parasites were recorded such as E. histolytica (13.6%) , E coli (1%), G. lamblia (11.1%), H. nana (0.6%), E. vermicularis (1.9%) and A. lumbricoides (0.2%) ⁶.

Many studies had been conducted to evaluate the role of raw vegetables in the transmission of intestinal parasites, for example, in Iraq, Alexandria, Egypt; Tripoli, Libya; Riyadh, Saudi Arabia, Tehran and Qazvin Province, Iran; and the Philippines. All have stressed the importance of fruits and vegetables, particularly which are consumed raw and unwashed in the transmission of medically important parasites ⁵.

The aim of the present study was to know the prevalence of intestinal parasitic contamination in raw vegetables in Misan city and to explore the types of intestinal parasites in these vegetables.
Material and Method

Sample collection

Three types of green vegetables were selected in this study lettuce (*Lactuca sativa*), Celery (*Aplum graveolens*) and Cress (*Lepidium sativum*). A total of 45 samples (15 samples from each type of green vegetables) were purchased at the smallest retail size available. Samples were collected monthly and picked randomly from, supermarkets and street vendors in Misan city during October 2017–April 2018. 200 grams were being prepared from the edible part of each vegetable sample.

Procedure for sample preparation and washing

Fresh samples were collected randomly from Misan city. Each vegetable sample was placed in a separate nylon bag and labeled with a unique number and date of collection. Approximately 200 gm. of each vegetable was soaked (for fifteen minutes) in one liter of physiological saline, Vegetable sample was removed and the remaining wash solution was left for 12 hours for sedimentation. The top layer was discarded and the remaining wash solution was filtered through a sieve (425 um pore size) to remove large debris and then centrifuged at 2000 rpm for 15 min. The supernatant was decanted into another tube to be examined by flotation, and a few drops of the sediment were placed on glass slides and examined for parasites. The sediment was mixed and examined with (Simple smear, Iodine smear staining and Modified Zeihl–Neelsen stain).

Data Analysis

Statistical analyses were carried out using the chi-square. Differences among samples were considered to be statistically significant if p<0.05.

Results

The examination of vegetables collected from Misan city showed contamination of these vegetables with many types of parasites (eggs and cysts). The parasites were determined in 23/45 (51.1%) samples. The highest contaminated one was celery (66.7%) followed by cress (46.7%) , and lettuces ( 40%). Statistical analysis showed that there was no significant differences among the three studied types of vegetables.

The rate of contamination with mixed parasites (65.2%) was higher than the rate of contamination with single parasites (34.8%) (Table 1). There was no significant difference between single and mixed contamination (P>0.05).

*Giardia lamblia* cysts were the most prevalent (43.5%) followed by *Fasciola hepatica* eggs (34.7%), *Entamoeba* spp. cysts (26.1%), *Hymenolepis nana* eggs (17.4%), *Cryptosporidium* spp. oocysts (13.1%), *Toxoplasma gondii* oocysts (8.7%), *Enterobius vermicularis* eggs (8.7%) and *Emerica* spp.oocytes (3.4%).

Discussion

Intestinal parasitic diseases are still a public health problem in the developing countries, more than two billion people are infected with intestinal parasites. It was clear from the results obtained from this study that percentage of contamination of vegetables with different intestinal parasites was (51.1%)(23) positive out of 45 samples were examined. This percentage considered close to results obtained by study 9 in Mosul which showed that 52% of vegetables were found contaminated with parasitic stages but less than what reported in retail markets in Tripoli, Libya (58%) 10 and higher than those in study 11 done in Saudi Arabia that appeared 76 out of 470 samples (%16.2) contained parasite stages. Results of study 12 have reported that the rate of parasitic contamination of vegetables was (31.7%) in Alexandria, Egypt.

These differences can be explained by the influence of environmental conditions, difference of the used techniques of investigations, the soil’s type, type of water used for irrigation, climatic conditions, geographical locations and sanitary habits 13.

In present study we found celery vegetables were highly contaminated with the parasitic stages than others, these results were similar to the findings of 14 that showed that the contamination with the parasitic agents was higher in celery, rocket and parsley, while was lower in leek, dill and cressa in Erbil and disagreement with 15. The highest percentage of contamination was detected in...
lettuce samples and Said in Egypt.

The rate of contamination by mixed parasites (65.2%) was higher than the rate of contamination by single parasites (34.8%) with significant differences between single and mixed contamination (P>0.05) and this agree nearly with that reported that among all examined fresh vegetable samples none of them had single parasitic contamination.

According to the results of this study we would like to aware the people in Misan city for the presence of many causatives of parasitic disease in vegetables in markets, and to avoid infection with these parasites, we would like to suggest the appropriate washing of vegetables with tap water for many times to remove all parasitic agents from the vegetables. Contamination of vegetables may occur in a variety of ways, such as from contact with soil, and from contact pre- and postharvest. In most cases, contamination is associated with the water used for irrigation.

Our study has isolated different types of parasitic stages from the vegetables. *Giardia lamblia* cyst was the most common parasite detected in the examined vegetables (43.5%) followed by *Fasciola hepatica* egg (34.7%), *Entamoeba* spp. cysts (26.1) *Hymenolepis nana* eggs (17.4%), *Cryptosporidium* spp. oocysts (13.1%), *Toxoplasma gondii* oocysts (8.7%), *Enterobius vermicularis* eggs (8.7%) and *Emeria* spp. Oocysts (3.4%). This is in agreement with several studies carried out in different parts in the world which detected different parasitic stages in vegetables, the study showed that *Entamoeba* spp. was the most common parasite detected in the examined vegetables 41(%25.30) followed by *Ascaris lumbricoides* 33 (%20.37), *Giardia lamblia* 28 (%17.28), *Fasciola hepatica* 26 (%16.04), *Trichuris trichiura* (%5.55), *Toxocara* spp. 7 (%4.32), *Taenia* spp. 7 (%4.32), *Hymenolepis nana* 6 (%3.70) and *Stronglyloides stercoralis* (%3.08) in Al-Nassiriyah city. in Kenya the intestinal parasites found on the vegetable samples include protozoa: *Entamoeba histolytica, Giardia lamblia* and *Balantidium coli* and helminthes: *Ascaris lumbricoides, Trichuris trichiura* and hook worms, while in Iran the parasites’ stages detected in the vegetables were *Giardia lamblia* cysts (7%), *Dicrocoelium* eggs (6%), *Fasciola* eggs (5%) and *Ascaris* eggs (2%).

Some studies indicated that agricultural use of untreated wastewater was the major cause of the increase in intestinal parasites. The use of sewage water plays also an important role in the epidemiology of transmission of parasitic diseases to human through consuming such vegetables.

### Conclusions

These findings provide evidence for the high risk of acquiring parasitic infection from the consumption of raw vegetables in Misan city, Iraq.

Factors Affecting the Smoking Behavior of 17-25 Year-Old Teenagers in Urban Areas

Yoas Yosia Kristianto1, Abu Bakar1, Deni Yasmana1
1Faculty of Nursing, Universitas Airlangga Surabaya, Indonesia, Jl. Mulyorejo, Surabaya City, Jawa Timur

Introduction. Indonesia is one of low-income countries with smoking as its primary health problem. This problem also appears among women living in urban environments. Although Indonesian culture previously held smoking to be a taboo for Indonesian women, with the passing time, the number of female teen smokers has been growing.

Objective: The aim of this research was to analyze factors influencing the smoking behavior of urban females of 17–25 years of age. Method. This quantitative research employed a cross-sectional design. The population of this research includes urban females aged 17 to 25 years old. The sample used consisted of 35 respondents who were selected by the consecutive sampling technique. The independent variables of this research were environment (peer and family support), location, and psychological factor (stress). The dependent variable was smoking behavior. The whole data were analyzed using Spearman’s statistical test. Results. The research results show that the smoking behavior of females in their late adolescence was influenced by peer support (p = 0.026), family support (p = 0.038), and location (p = 0.003). The psychological factor, stress, did not affect the smoking behavior of females in their late adolescence (p = 0.133). Conclusion. Location was the dominant factor that influenced female adolescents’ smoking behavior (correlation coefficient = 0.482). It is expected that this research provides recommendations for preventing the increase in the number of female smokers, especially those living in urban environments.

Keywords: smoking behavior, female in late adolescence, peer, family, location, stress

Introduction

Tobacco consumption has caused the world’s smoking-induced mortality to increase significantly1. By 2030, 8 million people are predicted to die from smoking, with those in low- and medium-income countries accounting for the majority of the number2. Although being a developing country with smoking behavior as its main health problem—which has claimed over 200,000 lives every year—Indonesia becomes the only country within the Asia-Pacific region that has yet to sign the WHO Framework Convention on Tobacco Control3. Developing countries consume tobacco at a rate of 2.7% per year, while the tobacco consumption rate of developed countries has decreased to 1.8% per year4.

Some 90% of smokers are 18 years of age, and 99% of all cigarette addicts are about 265. A previous study estimated that every day, 3,000 to 5,000 teens try smoking for the first time in their lives6. Both female and male smokers engage in this high-risk behavior7 low leisure-time physical activity, low fruits/vegetables intake, and high alcohol consumption, with 250 million females worldwide having been smoking, most of whom being citizens of low-income countries8. Consequently, 1.5 million females die from smoking tobacco annually9.

Traditionally, Indonesian women do not smoke. However, there is a rising trend of smoking among women in cities as a consequence of cigarette ads, promotion, and sponsorship as well as influence from peers to smoke10. A fair number of women in urban environments have a tendency of smoking as a way of relieving stress and relaxation11.

The effect of smoking on health in women is stronger than in men. Female smokers’ lungs are more...
susceptible to COPD (chronic obstructive pulmonary disease) than male smokers\textsuperscript{12,13}. Not only are they prone to such general health problems as heart disease, cancer, hypertension, and diabetes mellitus, women are also at a high risk of problems men are unaffected by such as pregnancy issue and certain cancers like cervix cancer\textsuperscript{14}.

Smoking behavior in youths today has become a common phenomenon we can encounter at any time. Not only men, we can now readily find smoking young women in public areas such as cafés, malls or department stores, recreational places, to name but few. Previously, smoking in women was considered to be a deviance\textsuperscript{15}. Earlier findings also indicate that women who smoked in the past experienced stigma from society\textsuperscript{16}. This research aimed to analyze the factors influencing the smoking behavior of female adolescents in urban environments.

Method

2.1 Research Design and Sample

This research is quantitative research with a cross-sectional design\textsuperscript{17,18}. Because this research used a small sample size (less than 100), the sample was selected by a convenience sampling technique. The research sample of 35 respondents, consisted of females in the age range of 17 to 25 years who lived in the City of Surabaya, Indonesia.

2.2 Research Variables and Instruments

The independent variables in this research included peers, family, psychological factor, and age. The dependent variable was the smoking behavior in females who were in their late adolescence. Data were collected using research instruments in the form of questionnaires which previously were subjected to validity and reliability testing. The questionnaires were intended to figure out the factors causing smoking behavior, including, peer support, family support, location, and psychological factor (stress), as well as the smoking behavior itself.

2.3 Data Processing

After all the needed data were collected, data processing was conducted. The data processing began with editing, in which all questions were rechecked for completion, followed by scoring, in which every answer was scored. The data were encoded for the ease of the data processing that was aided by the SPSS program for Windows through the final stage. The data were analyzed using univariate and bivariate analyses. These analyses were followed by Spearman’s rho calculation.

RESULTS

There were 35 respondents representing a population of urban young woman smokers in this research. The characteristics of the respondents are presented in detail in the following table.

Table 1. Frequency and percentage distribution of socio-demographic characteristics of the participants (n = 35)

</tr>
</tbody>
</table>

In the occupation category, 60% of the respondents were students, 20% private employees, 2.9% entrepreneurs, 8.6% part-timers, and the rest unemployed. These respondents were later re-categorized into two: 65.7% were graduates of senior high schools, and 34.3% graduates of higher education institutions. Out of all respondents, 48.6% knew cigarette since the ages of 17–25 years (late adolescence), 34.3% since the ages of 12–16 years (early adolescence), and the remaining 6% since the ages of 5–11 (childhood). An analysis of the factors influencing the smoking behavior of females in late adolescence was then conducted based on those characteristics.

Correlation coefficient = 0.377; p = 0.026

According to Table 2, all moderate and heavy smokers stated that the smoking behavior of their peers had an effect on their own. Three respondents (8.6%) who stated that the smoking behavior of their peers did not affect their own smoking behavior were all engaged in light smoking behavior.

Out of the 32 respondents who stated that their peers supported their smoking behavior, a majority revealed that they had smoking friends and were once offered cigarette. The Spearman’s test yielded a p value of 0.026 (p < 0.05), meaning that peer support had a significant effect on smoking behavior. The correlation coefficient was 0.377, which was below 0.40. This value indicates that peer support and smoking behavior of females in late adolescence was related at a low level of correlation. The positive mark of the correlation coefficient shows that there was a positive relationship between peer support and smoking behavior.

</tbody>
</table>

Correlation coefficient = 0.353; p = 0.038

Table 3 indicates that the number of severe smokers who received influence from their families was higher than that of severe smokers without the influence of their families. The Spearman’s statistical test yielded a p value of 0.038, meaning that there was a significant relationship. The correlation coefficient obtained was 0.353, suggesting that the relationship was positive. A correlation coefficient that was below 0.40 indicates that the correlation between family support and the smoking behavior of females in late behavior was low.
Table 4. Relationship between location and the smoking behavior of females aged 17–25 years in urban environments

| Location       | Smoking Behavior |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          | Total     |

| Private        | 5 (14.3%)        | 0        | 0        |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |
| Heterogeneous  | 6 (17.1%)        | 16 (45.7%)| 5 (14.3%)|          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |
| Homogeneous    | 1 (2.9%)         | 0        | 2 (5.7%) |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |
| Total          | 12 (34.3%)       | 16 (45.7%)| 7 (20.0%)|          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |

Correlation coefficient = 0.482; p = 0.003

Table 4 shows that 16 moderate smokers preferred smoking in heterogeneous places. Only 3 respondents (8.6%) did in homogeneous places such as smoking areas. This is due to the society’s lack of awareness of the effect that can be inflicted on passive smokers. The society tended to be ignorant of the surrounding. As many as 7 heavy smokers smoked in heterogeneous or homogeneous places. These results show that location had a significant effect on smoking behavior at a p value of less than 0.05 (p = 0.03). It was found that there was indeed a relationship between the two variables, location and the smoking behavior of females in late adolescence. The correlation coefficient of more than 0.40 indicates that the correlation between location and the smoking behavior of females in late adolescence was moderate.

Table 5. Relationship between stress and the smoking behavior of females aged 17–25 in urban environments

| Stress   | Smoking Behavior |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          | Total     |
|----------|------------------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|
|          | Light            | Moderate | Heavy    |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |
| Mild     | 8 (22.9%)        | 2 (5.7%) | 0        |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          | 10 (28.6%)|

Correlation coefficient = 0.273; p = 0.113

Table 5 indicates a p value of 0.113 (p > 0.05), meaning that psychological factor (stress) did not significantly influence the respondents’ smoking behavior. Eight respondents (22.8) were under a severe stress condition, yet such psychological condition did not drive them to be heavy smokers. This shows that stress level is not always directly proportional to the level of cigarette consumption.

**Discussion**

Through interactions, adolescents can share their feelings, problems, and thoughts with their peers. They have higher confidence in their peers than in their family. Behaviors and attitudes in adolescents and young adults are strongly influenced by peers and family, either directly or indirectly and attitude may influence young people to initiate smoking. The aims of this study were to 1. This behavior is assumed to be the function of the belief, while the belief determines the presence or absence of factors that facilitate or hinder performance, hence the formation of the behavior.
On average, female adolescents started smoking around the age of 20\textsuperscript{11}. The desire is stronger in more popular female adolescents than the lesser ones\textsuperscript{22}. Everyone in a popular female adolescents group is expected to be on par with the rest of the group. Consequently, one will befriend another who shares smoking behavior with them. This is the very reason why teens are selective when choosing friends\textsuperscript{1994-1996} (46.6% female, mean age at outset=15.4 years).

This study also shows that peer support and family support improved the smoking behavior of females in their late adolescence. The two factors were also responsible for the increase in the severity of cigarette addiction of females in late adolescence as was revealed by several earlier studies\textsuperscript{24,25}. This study reveals that those who engage in smoking behavior had latest education at senior high school level. Females of higher education, in this case those with Bachelor’s degree or above, preferred not to smoke out of their take that smoking is a negative behavior\textsuperscript{26}.

Family support was measured based on the smoking actions of family members (parents or siblings) that might support the respondents’ decision to smoke. Most respondents in this study had smoking family members (father or siblings). This caused the family members to be unable to prohibit the respondents from smoking. Smoking parents mostly would increase the possibility of their teen children to smoke\textsuperscript{27}.

Location was also related to peer influence on smoking behavior. This research’s results are in line with those of previous research, which states that community or location is one of the factors causing the development of smoking behavior\textsuperscript{28}. To smoking females, private or quiet places such as toilets are highly preferable for smoking\textsuperscript{29}. This is related also to females’ hangout and favorite spots.

**Conclusion**

Many factors might influence the smoking behavior of females aged 17–25 in urban environments. Support from parents and peers had an effect on the smoking behavior of females in late adolescence. Yet location was the dominant factor that influenced their smoking behavior. Meanwhile, stress as a psychological factor did not have any influence on their smoking behavior.

Effectiveness of the Otaria’s Postpartum Gymnastic Model and Caregiver Assistance on Decreasing of Uterine Fundal Height in Postpartum Mothers

Emy Rianti¹, Elina¹, Mugiati², Yudhia Fratidhina³, Suparman⁴, Agus Triwinarto⁵

¹Department of Midwifery, Health Polytechnic of Jakarta I, Indonesia, ²Department of Midwifery, Health Polytechnic of Tanjung Karang, Indonesia, ³Department of Midwifery, Health Polytechnic of Jakarta III, Indonesia, ⁴Department of Nutrition, Health Polytechnic of Bandung, Indonesia, ⁵Center for Research and Development of Public Health Efforts, Indonesia

Abstract

Postpartum gymnastic is one of the efforts to restore the postpartum mother’s womb, therefore the development of postpartum gymnastic to get an effective gymnastic model is still needed. The purpose of this study was to assess the effectiveness of the Otaria postpartum gymnastic model and caregiver assistance to reduce of postpartum maternal uterine fundal height, using matching pretest-posttest with control group, involved 160 postpartum maternal. The final results based on the General Linear Model-Repeated Measures (GLM-RM) for the difference (Δ) between of uterine height in the intervention group and the control group showed that a very significant difference occurred on the 6th day to the 7th day postpartum with a difference of 1.65 cm (p<0.05). Conclusion, that by implementing Otaria’s postpartum gymnastic model and caregiver assistance, the uterine height will return to its normal form on the 7th day postpartum.

Keywords: Postpartum, Gymnastic, Caregiver, Uterine Fundal Height

Introduction

The maternal mortality rate has decreased since 2002 at 307 per 100,000 live births, and in 2008 it was 228 per 100,000 live births, but the MMR increased again in 2012 to 359 per 100,000 live births. Based on the evaluation of the Millennium Development Goals (MDGs) in 2015, cases of maternal deaths in Indonesia are still 305 per 100,000 live births, even though the target set by the United Nations is 102 per 100,000 live births, the program has not been implemented properly so that the program is currently being continued through Sustainable Developments Goals (SDGs) with the target is to reduce maternal mortality to below 70 per 100,000 live births by 2030.¹ The cause of maternal death in Indonesia is still dominated by bleeding, namely 32%, hypertension 25%, followed by 5% infection, 5% prolonged labor and 1% abortion. One of the causes of the bleeding is uterine atony.²

Uterine involution is the process of the uterus returning to the condition before pregnancy. Uterine involution in postpartum mothers must return well, so that there is no uterine sub involution or delayed uterine return to normal size which caused bleeding, and occurs diastasis recti abdominis or separation of the right and left side of the rectus abdominis.³ To restore reproductive organs, postpartum mothers need effective postpartum care, including early mobilization and exercise. Contraction of the abdominal muscles will help the process of uterine involution, with ambulation as soon as possible and frequency is often very necessary in the process of uterine involution,⁴ (there was relationship between early mobilization and involution). The results of similar the study in Lampung showed that the factors associated with a decreased in uterine fundal height in postpartum mothers were early mobilization.⁵

The cause of diastasis recti is the softening of the ligament due to hormones resulting in very
rapid stretching of the abdominal wall due to uterine enlargement.\(^6\) The results of the study on the application of transversus abdominis muscle strengthening exercises in postpartum mothers have a significant relationship with a high decrease in uterine.\(^7\)

South Jakarta Health Center has the highest number in performing postpartum services by health workers, which is 35,588/year. South Jakarta is ranked the second highest in capital city of Jakarta, which is 38,832.\(^8\) Whereas in Lampung Province there are 115 Public Health Center units inpatient care and 85 units (73.9%) there are basic essential obstetric neonatal health service center.\(^9\)

The purpose of this study is assessing the effectiveness of the Otaria postpartum gymnastic model and caregiver assistance to decrease in the height of the uterine fundal in postpartum mothers.

**Method**

The study design was matching pretest-posttest with control group. The population was all postpartum mothers who gave birth in health centers of South Jakarta and Bandar Lampung. The intervention group were 80 postpartum mothers who gave birth at Pasar Minggu Health Center, South Jakarta and Kota Karang Health Center, Bandar Lampung. They were treated with the Otaria’s postpartum gymnastic model from 1\(^{st}\) day to 10\(^{th}\) day. The control group were 80 postpartum mothers who gave birth at Jagakarsa Health Center, South Jakarta and Kemiling Health Center, Bandar Lampung. They were treated with early mobilization. Sample restriction: the age of the mother during childbirth 20-35 years. Matching samples: multiparous mothers 2 and or 3, normal BMI values (18.5-22.9), normal Hb (11-12 gr/dL). Inclusion criteria: postpartum mothers who gave birth normally, did not experience labor complications, gestational age \(\geq\) 37 weeks, were born alive, by informed consent. A sample size of 160 people, calculated using the sample size formula with 95% of CI, 80% of power,\(^10\) selected by accidental sampling. Data was collected in May to October 2018, then analyzed by GLM-RM.

**Results**

Table 1 shows that based on measurements in centimeters unit the average value of uterine fundal height in the intervention group was lower than the control group and it’s began to occur on day 3 to day 7 and it was not palpable on the 8\(^{th}\) day. Whereas in the control group until the 10\(^{th}\) day the average of uterine fundal height was still as high as 1.01 cm.

**Discussion**

Based on centimeter unit measurements, the average of fundal height reduction of intervention group is faster than control group. This is in line with the opinion of Kenneth, that the process of decreasing uterine fundal height was fast if on the 3rd day the uterine fundal height was >3 fingers below the center. On the third to fourth day uterine fundal height was 2 cm below umbilicus, on the fifth to the seventh day uterine fundal height was half the symphysis, and on the tenth day the uterine fundal
height was not palpable. Immediately, after removal of the placenta the fundal drops 1-2 cm every 24 hours and after 6 days the fundal will be between the symphysis pubis and the umbilicus.\(^{(11)}\)

Based on measurements in the fingers unit it appears that the intervention fundal height was lower than the control group began to occur on the 5\(^{th}\), 6\(^{th}\), 7\(^{th}\), and on the 8\(^{th}\) day all were not palpable. Whereas in the uterine fundal height control group on the 9\(^{th}\) and 10\(^{th}\) day some were still half finger high.

The results of research in Kupang, measurement of day 2 uterine height there were 38 respondents (86%) experienced a decrease of 3 fingers below the center in mothers with primiparous age <35 years, there was a relationship between mobilization early with a decreased in uterine height where mothers who did early mobilization did not experience sub involution or failure in uterine involution.\(^{(12)}\)

Based on delta analysis, the average decreased in uterine height based on centimeter showed that the average decreased in uterine height in the intervention group was greater than that of the control group, starting at the 3\(^{rd}\) to 10\(^{th}\) day. The biggest difference in the decrease in uterine height in the intervention group compared to the control group occurred at the time period of the 7\(^{th}\) day postpartum with a difference of 4 cm.

After labor, the abdominal wall is loose because it is stretched for so long, but usually recovers within 6 weeks. Exercises carried out on certain muscles will give effect to increased muscle blood flow so that the transport of oxygen and other nutrients to the muscles also increases, this will give maximum strength to the muscles.\(^{(13)}\)

Otaria puerperal exercise carried out from the first 2 hours, 6 hours and 24 hours postpartum as initial mobilization and continued until 7 days postpartum. With early mobilization the mother will be more active in moving so that it will accelerate the process of involution of uterine devices, expedite the release of lockhea, and increase the smooth circulation of blood.\(^{(14)}\) A study found that there was a difference in the decrease in uterine fundus height between groups who performed a combination of abdominal and pelvic muscle exercises with a group that only performed pelvic floor muscle exercises.\(^{(15)}\) A Quasi-Experimental revealed that there were significant differences between pre-intervention and post-interventional scores of uterine involution in the experimental group and controls among postnatal mothers with p-value<0.05.\(^{(16)}\)

Strengthening the transversus abdominis muscle is an exercise by providing a stimulus to the part by contracting so that it can increase intra-abdominal pressure. The benefit of strengthening the transversus abdominis muscle is to tighten the uterine wall, accelerate uterine involution and facilitate the removal of lockhea.

**Conclusion**

The results of this study concluded that by implementing Otaria’s postpartum gymnastic model and caregiver assistance, the uterine involution process and/or High Uterine returned to its original form as before pregnancy occurred on the seventh day postpartum.

Problem-Based Learning Strategy based on Cognitive Style to Improve the Learning Outcomes of Nursing Students

Juliati Koesrini1, I Nyoman Sudana Degeng2, Punaji Setyosari2, Atti Yudiernawati3

1Postgraduate Student, Department of Learning Technology, Malang State University / Health Polytechnic of RS dr. Soepraen of Malang, 2Department of Learning Technology, Malang State University, 3Department of Nursing, Health Polytechnic of Malang

Abstract

Problem-based learning (PBL) are very effective in nursing schools, because nursing students will face problems when they provide nursing care. Important problems that often occur in learning activities are learning outcomes. One of the characteristics of students that is important to understand and think about by lecturers is cognitive style. This study discusses PBL learning strategy and cognitive styles on learning outcomes in the nursing diploma III program, using a quasi-experimental design. The results: (1) there were significant differences in the learning outcomes of understanding basic nursing concepts between PBL group and DI group, (2) there were significant differences in understanding concepts between FI group and FD group, (3) there was an interaction between PBL learning strategies and strategies for learning with cognitive styles FI and FD. Thus PBL has advantages over DI in achieving learning outcomes understanding concepts depends on cognitive style. Educational institutions are expected to make policy policies to improve the quality of learning, especially in developing student-centered learning strategies.

Keywords: Problem based learning, Cognitive style, Learning outcomes.

Introduction

The progress of management of health personnel education in various levels and types will greatly determine the quality of health workers who are graduated. Therefore, the belief in the importance of advancing the process of education of health personnel must be truly considered important by the managers of educational institutions. Learning strategies are basic in efforts to help students in learning activities to achieve learning. Thus, teachers can use teaching materials as learning media. Learning strategies are a series of materials and learning procedures that are used together to obtain student learning outcomes.

The use of learning strategies that are lacking or inappropriate, which does not involve students playing an active role will influence student learning outcomes. The low student learning outcomes will have an impact on the decline in the quality of students in mastering the competencies of the subjects that must be mastered. This situation will lead to the low quality of graduates produced by these universities. Important problems and often faced in learning activities are the resulting incompatibility of learning outcomes as stated in the learning objectives. Understanding the character of the content of the subject matter, the character of students, and also the learning process is a determinant of success in learning. Bloom (1976) describes the relationship between student characteristics and the quality of learning and learning outcomes. Increasing the quality of learning and the ability of students to learn science in an effective and efficient way is influenced by the use of appropriate learning strategies.

PBL is a learning process that starts from real problems in life, based on a problem students are stimulated to learn problems based on the knowledge and experience previously possessed by students. This will make them have new knowledge and experience. PBL
learning strategies are very effective to use in nursing schools, because nursing students will be faced with problems when they provide nursing care and students are then required to solve the problem.

Comparison of PBL strategies in this study is used direct instruction strategy (direct learning). This learning strategy is a learning strategy that is actually teacher centered. This strategy according to the researcher is a strategy that can be used because it is in accordance with basic declarative nursing learning and procedural knowledge.

The purpose of this study is to test and analyze: 1) the presence or absence of differences in the learning outcomes of understanding basic nursing concepts between groups of students who learn to use PBL learning strategies with DI. 2) there is a difference in the learning outcomes of conceptual understanding between groups of students who have a cognitive style FI with FD. 3) whether there is an interaction between PBL and DI learning strategies with cognitive styles FI and FD on the learning outcomes of understanding the basic concepts of nursing of students.

### Materials and Method

This quasi-experimental research involved 129 nursing students who divided into experiment and control group, selected by cluster sampling technique. To determine the treatment class differently, random assignment was done. The design used in this study was factorial design (2x2). The experimental class studied using PBL learning strategy, and the control class using the DI learning strategy. The moderator variable was cognitive style, namely: field dependence and field independence. The dependent variable was learning outcomes (understanding and application of concepts). The variables that need to be controlled were the ability of lecturers, learning facilities and learning time. The research instrument were: GEFT cognitive style test and learning outcomes test. The data was analyzed by MANOVA (Multivariate Analysis of Variance).

### Findings

The understanding the concept obtained by the price of F=70.829 with a significance value of 0.000 (there was significant differences in understanding basic nursing concepts between groups of students who learn to use PBL strategy and DI strategy.

R-Squared=0.512 (Adjusted R-Squared=0.501)

This can also be shown in terms of the estimated marginal means of understanding the concepts in both learning strategies (PBL and DI) as follows.

The mean-score of conceptual understanding of PBL group was higher than DI group. The F score for understanding basic nursing concepts based on cognitive style was 74.344 with p-value of 0.003 (there was a significant difference in understanding the concept between groups of students who have cognitive style FI and cognitive style FD.

This can also be shown in the form of an estimated marginal means of understanding the concepts based on cognitive style (FD and FI) as follows.

Figure 1. The estimated marginal means of understanding concepts in both learning strategies (PBL and DI)
It can be seen that the average value of the conceptual understanding of the student group had a relatively higher cognitive style FI than the average value of the student group that had the cognitive style of FD.

The results of calculating data to test hypotheses regarding the interaction between learning strategies and cognitive styles of students towards the ability to understand basic nursing concepts can be seen by looking at the calculated F scores and significance scores on the source learning strategy and cognitive style. Based on the table it is known that $F = 10.009$, with $p$-value $= 0.002$ (there was significant effect on the interaction between PBL learning strategies and DI learning strategies with the cognitive style of FI and FD).

This can also be shown in terms of the estimated marginal means of understanding basic student nursing concepts based on the interaction of learning strategies (PBL and DI) and cognitive styles (FI and FD).

By using PBL learning strategies, students are stimulated to learn so that conceptual understanding of the material is well achieved. The difference in learning outcomes between classes / groups of students learning using PBL learning strategies with DI shows that learning outcomes are influenced by learning strategies, even though students are given learning material and questions and the same facilities.

This is in line with Yudierawati’s research (2015) which states that there are differences in the learning achievement of nursing nursing clinical learning applications between learning and PBL strategies with direct learning strategies.

Some studies that show the effectiveness of PBL strategies in improving learning outcomes one of them is Oliveira et al (2016) which states that:

“The teaching strategies used and tested in the RCT with the aim of developing CT in undergraduate nursing students included PBL, the concept map, simulation, reflective writing, Role Modeling and Animated Pedagogical Agents. Furthermore, based on the meta-analysis of the studies included, the effectiveness of PBL was demonstrated in the increased overall CT scores"
from homogeneous studies. This result confirmed our hypothesis that the teaching strategies that show better efficacy in RCT are those that involve the use of active methodologies.

The results show that there are significant differences in the learning outcomes of conceptual understanding between groups of students who have cognitive styles and students who have cognitive style of FD. This shows that the ability to understand the concept of students who have a FI cognitive style is better than students who have a cognitive style of FD.

Woolfolk (1993) describes the definition of cognitive styles. Cognitive styles are about individuals to receive and organize information from the surrounding environment. Based on these opinions, it can be interpreted that what is meant by cognitive styles is the way a person processes, stores, or uses information to examine a task or interpret various types of environmental situations.

The results of this study are in line with the results of research from Udiyono, U. Research results from Hikmawati et al. (2013) also support that there is an influence of cognitive style on students’ mathematics learning outcomes. While the marginal mean of mathematics learning outcomes of students who have the FI cognitive style is better than the mathematics learning outcomes of students who have the FD cognitive style.

The success in the group of students who have the cognitive style FI, shows that students who have the cognitive style FI are strong analytical power (in response to the stimulus have a tendency to use their own perceptions and more analytical), more autonomous in concluding a conclusion, independent in working duty and confidence in his abilities because he has a high level of intellectuality and feels efficient when the task is done alone. A student with a cognitive style FD, finds difficulties in processing, but easily perceives when information is manipulated according to the context. He will be able to separate stimuli from the context.

The results of the calculation of data in order to test the hypothesis obtained the results that there is an interaction between PBL learning strategies and strategies of learning with the cognitive style FI and FD in understanding the concept of basic nursing students. The results of data calculations to test hypotheses about the interaction between learning strategies and cognitive styles of students towards the ability to understand basic nursing concepts can be known by looking at the calculated F scores and significance scores on the source learning strategy and cognitive style. Based on table 3, it is known that $F = 10.009$, with p-value of 0.002 (there was a significant effect on the interaction between PBL and DI strategy with the cognitive style of FI and FD).

The results of research that supports the results of this study are Shi, Changju (2011) which states that the results of the study show that cognitive style has a significant influence on the choice of learning strategies for students. Similarly, Suliani (2014) conducted a study on the effect of learning and cognitive style on students’ critical thinking skills in learning history. The results of the study obtained results that there is an influence of the interaction between learning strategies and cognitive styles on students’ critical thinking skills in learning history.

**Conclusion**

Based on the results of research and discussion, the conclusion of PBL learning strategies has advantages over DI learning strategies in achieving learning outcomes understanding concepts depends on the cognitive style possessed by students.

Educational institutions are expected to make policies to improve the quality of learning, especially in the development of learning strategies that are more student-oriented or better known as student centered learning. Lecturers are advised to use PBL learning strategies in managing nursing learning to improve student learning outcomes. PBL is a learning approach that is used to stimulate high-level thinking of students in situations that are oriented to real-world problems, including learning how to learn.

Abstract

The increase of terrorism cases recently has become the world’s interest and Indonesian government’s as well. One of the cases occurred in Surabaya on May 13 and 14, 2018 that targeted three churches and one police station. There is a major change in terrorism act in which it now involves the bomber’s family members as the attacker. If in the previous cases women are considered as the influencers, in the present case they become the perpetrators who also involve their children to be a part of the attack. Thus, this present study aims to elaborate the psychological condition of the suicide bombers’ family.

Keywords: Health, Psychology, Family, Suicide bomber

Introduction

Terrorist refers to the person who uses violence by creating extreme fear in order to achieve his/her goals, for instance political goals(1). Terrorism is “planned, political-oriented violence performed by splinter groups or underground agents and aimed for unarmed targets in order to provoke public”(2).

Ancient Greek history Xenophon (430-349 SM) stated that psychological warfare had been used as an attempt to defeat enemy. In the early of French revolution (1793–1794), terrorism became a belief of coercion that is used to express opinion by doing something illegal that leads to violence, brutality and even murder(3).

Terrorism is chosen by certain group of people or organizations to force their will. Those people collectively choose terrorism as the primary action to achieve the goals without considering other alternatives(4).

A suicide bombing case occurred in several church in Surabaya on May 14, 2018. The bombers are Dita Aprianto and his whole family members that also have been killed during the bombing. They are Puji Kuswati, Dita’s wife; his daughters Fadilah Sari [12] and Pamela Riskika [9]; and his sons Yusuf Fadil [18] and Firman Halim [16].

There is a major change in terrorism act in which it now involves the bomber’s family members as the attacker. If in the previous cases women are considered as the triggers, in the present case they become the perpetrators who also involve their children to be a part of the attack.

Chief of the Indonesian National Police, Tito Karnavian explains that it is the first bombing case that involves children. This statement is also supported by Heru Susetyo, a critic from University of Indonesia. He explains that recently, there is a change in terrorism attack pattern. Formerly, terrorists are mostly young man with poor education background. Lately, terrorism attack also involves women and children in the action(5).

Post (1984)(6) in his study revealed that there is no psychopathological indication in the terrorists. Similar study is also conducted by Crenshaw(7) concerning the characteristics of terrorist organization called National Liberation Front (NLF) in Algeria. Crenshaw described that usually, terrorists are considered as common people

Corresponding Author:

E-mail: ariefbudiono@umpo.ac.id
or civilians with high intelligence.

Heskin (1984)\(^6\) who conducted study on terrorism case of the members of Irish Republican Army (IRA) in North Ireland. The result of the study indicates that terrorists are considered having emotional disorder. From the results of those studies, it can be inferred that generally, most terrorists or bomb attackers have psychopathological disorder. In regard to their social background, Clark, in his study of terrorism of Euzkadi Ta Askatasuna (ETA) in Spain, stated that most terrorists come from marginal families that experienced harassments in many aspects of life\(^8\).

Sociologically, multicultural issues often cause racial centrism that vulnerable to conflict as it closely related to ideology believed by those social groups. Thus, the result of several studies complied by Reich\(^9\) assert that ideology-related terrorism is not a sui generis concern–unidentified uniqueness–nor unexplained, random attack on humanity.

Reich\(^9\) from his experience in Weatherman organization explained that there are three phases of withdrawal process that underlying the formation of terrorism; (a) trust crisis phase, (b) legitimacy conflict and (c) legitimacy crisis. Each phase shows certain collective political stance identities that want to be achieved by certain groups are ideologically motivated.

Oppenheim\(^10\) undertook a study on radical ideology, terrorism and barbarian war of a group of adolescence and young adults. The result of the study showed that actually there is no certain sociological or psychopathological characteristic identified in those adolescences. However, there is a tendency of having triggers of weaknesses in regard with narcissism and identity.

The phenomenon of bombing case in Surabaya as what has been explained before shows that radicalism is getting worse since the perpetrator no longer execute his action individually but also involve the whole family member as the attacker\(^11\). This concern is crucial and is of significant to be analyzed. Therefore, this present article aims to discuss the psychological condition of the suicide bombers family in Surabaya.

Based on the previous explanation, this article will discuss how the psychological condition of the suicide bombers is and what kind of motivation the family had to do the suicide bomb.

**Research Methods**

This present study is a sociological research. It employs descriptive qualitative approach\(^12\).

**Results and Discussion**

Process that Triggers the Family to be the Suicide Bombers

To understand the process that may change common people into a terrorist, the researchers apply the theory of Staircases to terrorism from Moghaddam (2005)\(^13\). Staircases to terrorism refers to the processes someone may go through in becoming a terrorist. The aforementioned staircases include:

Ground floor that refers to search for meaning. In this stage, there is a disappointment and deprivation towards other groups’ condition that is perceived better than one’s own condition. Such condition is commonly known as identity crisis that may lead to a judgmental injustice perception of own group towards other groups.

First floor that refers to presenting the ideology. In this stage, there is a tendency to search for enemy or party to blame that is perceived being injustice or unfair to their groups. Thus, they start questioning how to defeat that injustice.

Second floor or known as cultivation stage. In this stage, the psychology and mental processes that triggers certain group to defeat injustice groups occur. The basis is displacement aggression; activities of torturing or cursing the other parties that are perceived causing injustice.

Third floor or the moral engagement. This stage involves moral doctrines to influence the perpetrators’ psychology. The purpose is to make them believe that what they do is not wrongdoing. Thus, they are mentally convinced and steady to spread the terror.

Ahmad Faiz Zainuddin [40], one of Dita’s colleagues, explains that he has close relationship to some people in Dita’s circle including the mentor or indoctrinator. Faiz further says that during his schooldays as senior high school student, Dita often conveyed his ideology in which he believed that the country should apply Islamic law. However, he never turned his ideology into an action, even violence\(^14\).
The founder of Indonesian de-radicalization organization Ali Fauzi assumes that Dita has believed the doctrine of radicalism and then pass it through his wife and children for a long time(15).

This statement is in line with the statement of Suratno, suicide bomber researcher. In this case, he states that indoctrination or brainwashing through psychological influence, family relationship and marriage is the easiest brainwashing activities to do.

Family relationship and marriage is considered effective to form networking since there is a strong psychological effect that bond one to each other. The affective aspect appears due to the close relationship as family while the cognitive aspect is involved since such close relationship is utilized in an extreme way(16).

The director of Institute for Policy Analyst of Conflict (IPAC) Sidney Jones (2018) states that such doctrines that convincing one’s thought psychologically is the same doctrine technique used by ISIS. Chief of the Indonesian National Police Tito Karnavian confirms that the bomb attacks in Surabaya that involve family members indicate a correlation between the attacker and ISIS. Even though the families never come to Syria before, those families have the same ideology and are still connected to other families that have been in Syria before yet currently stay in Indonesia(17).

In accordance with two previous statements, Inspector General of Indonesia National Police Machfud Arifin asserts that the bomb attacker Dita Aprianto engaged his family members in the doctrine processes through recitations or religious studies. In such studies, many videos showing how terrorists execute their bomb attack from which the prospective attackers and their family got brainwashed to be suicide bombers(18).

According to preceeding description, it can be seen that the whole family members of Dita Aprianto have been following the psychological doctrines as what has been explained by Fathali Maghadam in the Staircases theory(19). Actually Dita had been through the first and the second floor during his school life as senior high school student.

The third floor had been through once Dita graduated from senior high school. then he has been radicalized and radicalized his family. Dita believed in the doctrine and due to the strong bond he and his family had, he also engaged his family to be involved in the case as well as what is previously described by Suratno.

Halverson, Goodall & Corman(19) defined that there are three kinds of extreme narration within the radicalism process. They are:

Build understanding that extremist massager is a universal accepted understanding (obscuring internal contradiction).

Give an impression that what happened in certain places is a part of global or universal enemy’s scenario (universalizing them within populations).

Create an impression that their perspectives are common sense (naturalizing their claims as “common sense”)

Physical Condition of Perpetrators

Ahmad Faiz Zainuddin, one of Dita’s friends, revealed that Dita’s family came from a good family. He was not stressed. His educational achievement was great. He had an educational background as a chemistry graduate. He was also from a wealthy family, he was a loyal friend and gentle.

The defendant of the terrorism case Aman Abdurrahman, at a hearing at the South Jakarta District Court, Friday, May 25 2018, said that those who carried out or taught family involvement in the two incidents of bomb terror in Surabaya were mentally ill people and frustrated with life. According to him, two mothers who brought their children to be suicide bombers were emotionally and mentally ill(20).

The Bali Bombing 1 perpetrator, Umar Patek, when invited to be a guest speaker at the Mata Najwa program, gave his response to the Surabaya Bombing. According to Patek, this recent suicide bombing were irrational. This could not be accepted in Islamic point of view, because it involved children and women in their actions(21).

According to the Head of the East Java Regional Police Psychology Section, AKBP Said Rivai, someone who experienced this situation needed to keep the mission secret. The children-suicide-bombers were forced to do this because he got psychological and psychological stress(22).
Furthermore, Ali Fauzi, the former head of the East Java Jamaah Islamiah (JI) bomb assembly instructor and founder of the Peace Circle Foundation, said that the suicide bombing by one family was not purely due to an ideological process. According to Fauzi, the perpetrators were overdose brainwashing so that his thoughts experience anomalies.\(^{(20)}\)

Thus, Dita Aprianto and her family did not experience any abnormalities or suffered from mental illness as a reason for them to commit suicide bombings. However, they were psychologically ill after experiencing a long process of indoctrination. These thought and psychological anomalies occurred and caused them to sacrifice their children and families. This would not be experienced naturally without religious indoctrination.

### Motivation of the Perpetrators

Chief of National Police, Tito said the family head of the suicide bombers in the Wonocolo apartment, Sidoarjo, was a close friend of the one who was responsible for the suicide attack in three churches in Surabaya. Anton Febrianto \(^{(47)}\) was killed along with his wife, Puspita Sari \(^{(47)}\) and his first child, LAR \(^{(17)}\). While the other three children, LAR \(^{(15)}\), FP \(^{(11)}\), GHA \(^{(11)}\) suffered injuries and were treated in Bhayangkara Hospital. Normal mental conditions would not be able to make someone sacrifice their family for an absurdity. Anton was found dead while holding a bomb switch\(^{(23)}\).

According to the Director of the Institute for Policy Analyst of Conflict (IPAC) Sidney Jones, suicide terror bombings in Surabaya on May 13 and 14 2018 by utilizing cells radicalized through indoctrination. Suicide bombers in Surabaya and Sidoarjo have the same indoctrinator, impersonating the same teacher of recitation, Khalid Abu Bakar. While Khalid has a linked-network in Syria, named Gana\(^{(24)}\).

According to Erick Shaw\(^{(25)}\), there are four stages of a common developmental pathway of thought: first, the process of early socialization; second, narcissistic injuries, for example negative life events and negatively affect self-image or self-esteem; third, escalation events (often confrontations that cause perceived provocation). This developmental pathway of understanding was no longer normal. The psychiatric conditions of suicide bombers in Surabaya had changed dramatically over a long period of time, therefore, the perpetrator believed something immoral as a good principle.

Their post-indoctrination motivation was to maintain self-esteem or honor and revenge for escalation events. These people actually had a normal thought process but their psychological conditions were like robots who were ready to be ruled anytime and anywhere although it harmed many people.

### Conclusion

It can be concluded that before becoming a terrorist, Dita Aprianto and his family had experienced indoctrination since Dita was in high school. Dita underwent the third phase after graduating from high school, by evolving into a belief that killing other people whose perception and belief are different is an obligation.

Dita Aprianto and his family had no medical record of any abnormalities or mental illness before and when they committed suicide bombings. This mental and psychological disorder was not recorded because this pattern of indoctrination was veiled, but this could be seen from their suicide bombing actions.

The head of the East Java Regional Police Psychology Section, Said Rivai, argued that this psychological disorder was a form of expression of his mental pressure. This happened because they carried suicide bombings, leaving behind their lives and families. This suicide bombing was also in secret. Dita and her family committed suicide bombings because of indoctrination factors that influenced their psychological and mental thought.

Bacterial Contamination of Cell Phones of Health Care Providers at a Tertiary Care Centre

Deep H. Wankawala¹, Satyajeet K. Pawar², G.S. Karande³
¹Under-Graduate Student, M.B.B.S, Krishna Institute of Medical Sciences, Karad, Maharashtra, ²Associate Professor, Department of Microbiology, Krishna Institute of Medical Sciences, Karad, Maharashtra, ³Professor and Head, Department of Microbiology, Krishna Institute of Medical Sciences, Karad, Maharashtra

Abstract

Introduction: Health Care Associated Infections (HCAI) caused by Multidrug Resistant (MDR) bacteria are an emerging risk factor in many institutions; cell phones being a convenient mode of communication and an easy mode of carrying patient information are used extensively by Health Care Workers (HCWs). Their cell phones can be a potential reservoir for harmful pathogens that can cause nosocomial infections. Further more, the extensive use of cell phones can easily transmit these pathogenic bacteria towards both the ends of the health care hierarchy.

Objectives:

To isolate the aerobic bacterial pathogens present on cell-phones of the Health Care Workers at a Tertiary Care Centre.

To assess the antibiotic sensitivity pattern of these isolates.

Materials and Method: In this study a random sampling of cell phones of 30 HCWs was carried out from wards of the hospital. Swabs were collected and processed as per standard techniques. AST was carried out according to CLSI 2018 standard guidelines.

Results: Bacteriological analysis of 30 samples yielded a total of 42 isolates. Of these 42.8% isolates were pathogenic of which 14%(6) were Pseudomonas aeruginosa, 17%(3) Staphylococcus aureus, 7%(3) Enterobacter cloacae complex, 5%(2) Acinetobacter spp., 2%(1) Diphtheroids, 2%(1) Klebsiella spp., 2%(1) Aeromonas salmonicida, 2%(1) Acinetobacter baumannii complex. Remaining 57.2% isolates were non-pathogenic of which 12%(5) were Sphingomonas spaucimobilis, 10%(4) Staphylococcus hominis, 10%(4) Staphylococcus warneri, 7%(3) Kocuria varians, 2%(1) Kocuria rosea, 2%(1) Pseudomonas stutzeri. The antibiotic sensitivity pattern of the pathogenic isolates revealed a few alarming results.

Conclusion: The results of our study reveal that cell phones are contaminated with bacteria and can act as a reservoir for harmful pathogenic bacteria that can cause HCAI.

Key Words: - Cell Phones, Contamination, Hospital Acquired Infections, Drug Resistance.
termed as Health Care Associated Infections (HCAI). Such healthcare-associated infections or nosocomial infections add to the morbidity, mortality and costs that one might expect from the underlying illness alone.¹,²

The routes of transmission of microorganisms or cross-contamination that cause infections include ariel, oral, contact and parenteral route.

The main focus here being the contact route, because the rates of adherence to hand-hygiene recommendations are abysmally low. Reasons cited include inconvenience, time pressures, and skin damage from frequent washing. Use of alcohol rubs is highly effective except when the hands are visibly soiled.³

Today, India has about 287 million mobile phone users, in health care setting, they are essential for quick and easy access to laboratory and imaging reports, for consultations, and sometimes for life threatening emergencies.⁴

Studies have shown that both Gram-negative as well as Gram-positive bacteria can survive for months on dry surfaces, with longer survival rate when in humid and lower-temperature conditions, which are provided by the sweat from a person’s body and the warm body of cell phones.⁵ In today’s health care system, the use of cell phones has reduced the morbidity rate drastically, by helping in fast communication within hospital settings and spreading medical knowledge at an unbelievable speed, causing a visible decrease in morbidity rate. However, one of the most concerning factor regarding heavy use of cell phones is that they can act as reservoirs of pathogenic bacteria and other microorganisms. People rarely clean their mobile phones, as they are uninteresting to clean. Hence, the cell phones have the potential of being contaminated with a variety of bacteria. Many studies have been conducted on cell phone contamination among healthcare workers that is clinicians, nurses, ward assistants and in community. But, very few projects have been conducted in this part of the world based on bacterial contamination of cell phones used by health care workers.⁶ ⁷

Thus, minimum required number of health care workers with cell phones is:

\[ 29 \]

So, a minimum of 29 health care workers with cell phones will be required.

Samples were collected randomly from cell phones of 30 resident doctors and nursing staff posted at different wards at the Tertiary Care Centre.

**Materials and Method**

After the clearance from institutional ethical committee the study was conducted at the tertiary care center. Then an informed consent was taken from the health care provider participating in the study. The confidentiality was maintained about the identity of participants, by giving them an identification code. A questionnaire of 4 questions related to knowledge, and 3 questions related to their practices were requested to be answered which included “Yes” or “No” questions and one-line answers. While samples were collected from the participant’s cell phone, which they use dominantly at their work place, covering the surface area of their cell phone (screen, sides and the back and if present, the backside of the cover) using a sterile swab dipped in sterile peptone water, using standard aseptic precautions. The swabs were then transferred to microbiology laboratory for inoculation on blood, chocolate and MacConkey’s agar, which were incubated overnight, the culture were then processed for identification and speciation of aerobic bacterial growth using standard methodology, identification and antibiotic sensitivity of these growths were processed using Vitek 2 Compact as per CLSI Guidelines.¹⁰ The data collected from the questionnaire and laboratory results were be analyzed using Microsoft Excel software. Descriptive statistics were used to calculate percentage of each response given.

**Study Design: Cross-Sectional Study**

**Study Setting:** Krishna Hospital and Medical Research Centre. (KH & MRC)

**Study Population:** Health Care Providers working at the Institutional Hospital

**Inclusion Criteria:** Health Care Providers who are willing to give an informed consent and carry and use a cell phone.
Findings

Bacteriological analysis of 30 samples revealed that a total 42 organisms were isolated, of these 42.8% isolates (n=18) were pathogenic of which 14% (6) were Pseudomonas aeruginosa, 17% (3) Staphylococcus aureus, 7% (3) Enterobacter cloacae complex, 5% (2) Acinetobacter spp., 2% (1) Diphtheroids, 2% (1) Klebsiella spp., 2% (1) Aeromonas salmonicida, 2% (1) Acinetobacter baumannii complex. (Fig. 1) Remaining 57.2% (n=24) isolates were non-pathogenic of which 12% (5) were Sphingomonas paucimobilis, 10% (4) Staphylococcus hominis, 10% (4) Staphylococcus epidermidis, 7% (3) Staphylococcus arlettae, 5% (2) Staphylococcus haemolyticus, 5% (2) Staphylococcus warneri, 5% (2) Kocuria varians, 2% (1) Kocuria rosea, 2% (1) Pseudomonas stutzeri. (Fig. 2) A total of 42.8% (n=18) organisms were pathogenic, can be potentially harmful in a hospital setup (Fig. 1). Their antibiotic sensitivity pattern (Table. 1) revealed that the pathogenic bacteria showed significant isolates were having resistance towards penicillin group, beta-lactam and beta-lactamase inhibitor combination, lincosamide, and macrolide groups. But, the major alarming point was that 30.8% of the pathogenic isolates were even resistant to colistin.

The questionnaire that was used for the study reported that 53% (n=16) participants wash their hands in between using their cell phone and patient contact and 47% (n=14) did not wash their hands in between interpatient contact. (Fig. 3) It was also reported that 70% (n=21) participants clean their phone regularly or had cleaned it recently and 30% participants (n=9) had never cleaned their phone till date. (Fig. 6) The questions based on participant’s knowledge revealed that 97% (n=29) of them think that their phone is contaminated, where as 3% (n=1) participants were of the view that their phone is not contaminated with bacteria (Fig. 4) and of these 83% (n=25) of them think that their phone can transmit any disease where as 17% (n=5) (Fig. 5) think that their phone cannot transmit bacteria or organisms. The participants have used hand sanitizer frequently as a cleaning agent, followed by use of spirit, and few participants only used cotton ball.

Discussion

The main aim of the present study was to assess the bacterial profile of contaminated cell phones of health care workers associated with a Tertiary Care Center and the results of our study show that the a number of cell phones harbor pathogenic bacteria and are hence a potential threat in spreading Health Care Associated Infection (HCAI). This study showed 100% rate of contamination of cell phones as compared to other studies which showed S. Zakai et al.11 (96.2%), Heyba et al.12 (74%), J. Lavanya13 (56%), Bhumbla et al.14 (92%), Sedighi I et al.6 (99.2%), Shakir et al.8 (83%) contamination of total samples tested. In this study it was reported that 70% samples showed monomicrobial growth, whereas 30% samples showed polymicrobial growth.

Education of health care workers regarding infection control can be a part of staff health care programs, which can increase awareness about transmission of potentially pathogenic bacteria. Continuous visual stimulus can help decrease spread of HCAI’s in the form of hand hygiene posters and leaflets. About 17% participants (Fig. 5) were unaware of the fact that their cell phone can transmit bacteria which in certain scenarios can be potentially harmful, and even if the participants are aware of potential transmission of bacteria about 70% of them have never cleaned their cell phone. Further studies can be carried out to pull up the most effective and convenient method of disinfection without causing any harm to the Health Care Worker’s skin and their cell phones.

Conclusion

To conclude, our study reveals that the cell phones of Health Care Workers can get contaminated with pathogenic bacteria and some bacteria showed alarming antibiotic sensitivity patterns with resistance to penicillin, cephalosporins and even carbapenem and polymyxin groups, and could serve as a reservoir for hospital acquired infections. Significant percentage of health care workers does not wash their hands in-between interpatient contact after cell phone use. Regular hand washing might be a single most effective preventive method to avoid transmission of these potentially pathogenic bacteria.

Transition Mutations of Interleukin-4 gene 590C>T in Patients with Type-2 Diabetes Mellitus

Intisar Hussein Ahmed

Department of Biology-College of Education for Pure Science-University of Wasit –Iraq

Abstract

Background: The regulation of immune system at multiple levels is related with IL-4. Diabetes is a global health problem and plays an important role in the high mortality rates in the world.

Aim: In current work the mutational changes related with of IL-4-590 C>T gene polymorphisms were analyzed among 64 type -2 diabetic patients (T2DM) and 26 individuals as control group. Patients and controls were from Wasit province in Iraq.

Study design: The study design was case –control study.

Materials and Method: The allele-specific PCR (ARMS-PCR) technique was used to detect the IL-4-590 C>T gene polymorphism (rs2243250). PCR products for IL-4-590 C>T and primers were prepared for sequencing analysis in order to detect mutations and alterations in IL-4 -590 C>T gene of T2DM patients.

Results: After alignment of product amplification of IL-4 590C>T CC or CT genotypes, there are nine transition substitution mutations in patients with diabetes mellitus. Transition substitution mutations: Transition substitution mutations: six transition substitution mutation adenine to guanine in site 721, Guanine to adenine in site 858, and, guanine to adenine in site 858.

Conclusions: We conclude that different transition mutations at IL-4 gene 590C>T are associated with type-2 diabetes mellitus.

Keywords: Interluekin-4, diabetes mellitus, polymerase chain reaction, transition, mutation.

Introduction

The regulation of immune system at multiple levels is related with IL-4. IL-4 is considered as survival and growth factor of lymphocytes. It has important role in the differentiation of B cells in addition to regulation of T cells differentiation in immune response. The resting T cells after antigen exposure are differentiated to Th1 and Th2. These processes depend on cytokines. Furthermore, protection of lymphoid cells from programmed cell death is also by IL-4. Diabetes is a global health problem and plays an important role in the high mortality rates in the world. The complexity of this disease is linked to several factors including genetic heterogeneity, interactions between genes and the environment. The pathophysiology of T2DM is associated with inflammation and immunological phenomena (e.g. antibodies of anti-islel cell, high levels of cytokines and conventional related with type 1 diabetes are emerging in many patients with type 2 diabetes, chemokines) and obesity, that has a strong relationship with resistance to insulin and T2DM. interleukin-1 gene family of cytokine proteins has a pathological role in diabetes. Diabetes is associated with alleles of genes that encode to immune or inflammatory mediators. Eighteen Previous studies showed that secretion of IL-4 can be affected by its polymorphisms in -590 region. Rare studies investigated the association of IL-4-590C>T with T2DM in Iraqi patients. The current study is aimed to analyze the mutational changes related with IL-4-590 C>T gene polymorphisms among Iraqi cases from Wasit province.
Materials and Method

Two groups of subjects were included in this study: 64 type-2 diabetic patients (T2DM) and 26 individuals as control group. Patients and controls were from Wasit province in Iraq. Blood samples (5ml) were collected from patients and controls, then transferred into EDTA tubes for DNA extraction. Genomic DNA was isolated from blood samples using Quick-gDNA™.

Agarose gel electrophoresis of DNA

Agarose gel electrophoresis of DNA using agarose gel was used to detect. The DNA fragments after extraction and to investigate the interaction results of PCR by the presence of the standard DNA to differentiate the bundle size resulting from the reaction of PCR on the agarose gel.

Genotyping of IL-4-590 C>T

Detection of IL-4-590 C>T gene polymorphism (rs2243250) was done using allele-specific PCR (ARMS-PCR) technique. Two primers were used in two reactions for every subject.

Table 1: Specific primers of IL-4

Five μL of each primer in reactions, 10 μL of Dream Taq Green PCR Master Mix (2X) (Fermentas, K 1081, USA) to a final volume of 25 μL. Thermal cycler was used to carried out the amplification reactions with 1 min at 96 followed by 10 cycles, of 95° for 15 s, 65° for 50 s, 72° for 40 s, and 72° for 40 s; 20 cycles then 20 cycles of 95° for 50 s, 59° for 50 s, and 72° for 50 s. Products of PCR were electrophoresed, visualized and photographed.

PCR products sequencing

PCR products for IL-4-590 C>T and primers were sent to Macrogen company /South Korea for sequencing analyses in order to detect mutations and alterations in IL-4 -590 C>T gene of patients with T2DM.

Sequencing of IL-4 590C>T gene

Samples of amplified PCR-products of IL-4 590C>T CC or CT genotypes from patients with T2DM by direct sequencing to detect SNPs within these sequences. Our sequences were compared with reference sequence of IL-4 590C>T CC or CT genotypes in national center biotechnology information (NCBI) Gene Bank. The sequencing appeared 100% compatibility with Homo sapiens IL-4 590 C>T gene CC or CT genotypes. Homo sapiens haplotype HHF*4 interleukin-4 (IL-4) gene, promoter region and partial cds. Sequence ID: GQ892017.1 Length: 1340 Number of Matches: 1

The results of IL-4 590C>T of CC genotyping are shown in Figure 1.

CT genotyping results of IL-4590C>T are shown in Figure2.

Sequencing of IL-4 590C>T gene of patients with type 2 DM with CC or CT genotypes compared with genotypes of IL-4 590 C>T obtained from gene bank as follows:

**Discussion**

Type-2 DM is multifactorial disease and is related with several mutational changes. There are numbers of polymorphic loci that exist in the IL-4 gene promoter. These sites have been reported as the vulnerability of several diseases including the IL-4-33C/T, IL-4-589C/T, and IL-4-590C/T specifically frequencies of the genotype and allele of IL-4-590C/T were well investigated and noted to be related with different diseases. The IL-4 one of the hematopoietic cytokines, play an important role in regulation and stimulation of T-lymphocytes. In allergic conditions and infections, the naturally mechanism of protection is due to IgE. Moreover, it perform an important role in T2DM pathophysiology. In this study, after alignment of product amplification of IL-4 590C>T CC or CT genotypes, there are nine transition substitution mutations in patients with diabetes mellitus. Transition substitution mutations: six transition substitution mutation adenine to guanine in site 721, Guanine to adenine in site 858, and Guanine to adenine in site 858. To our knowledge this is the first study of sequencing analysis in the -590 region of IL-4 gene in patients with type 2 DM. The transition mutations which are associated with hyperglycaemia can be considered as a new biomarker for genetic material damage and possibly due to oxidative stress. The regulation process of the next exon may be associated with the substitution mutation in the intron region. DNA mutations that reserve the rings same number in the nucleotide base are transition mutations. In contrast, transversion mutations include changing the nucleotide base from a pyrimidine to a purine or vice versa. In the protein-coding regions of human genome, transition mutations are fortified over transversion mutations. Transversion mutations result in amino acid substitution and that is the reason that these mutations thought to be depleted in exons. The rate difference between these two types of mutations is an essential evolutionary studies at molecular basis. Transversion mutations result in disruption of transcriptional factors binding, lead to great alterations in gene expression. We conclude that different mutations at IL-4 gene 590C>T are associated with T2DM.

Relaxation Intervention and Counselling Models in Controlling Stress in Cancer Patients

Zamli¹, Muhammad Syafar², Sukri Palutturi², Suriah², Ahmad Yani³

¹Postgraduate Doctoral Program Students Hasanuddin University, Makassar, Indonesia, ¹Akademik Keperawatan Reformasi Makassar, ²Public Health Faculty, Hasanuddin University, Makassar, Indonesia, ³Faculty of Public Health Universitas Muhammadiyah Palu, Indonesia

Abstract

Cancer causes virus infections such as Hepatitis B/hepatitis C and human papilloma virus which has contributed 20% of cancer mortalities in the low-middle income countries. More than 60% of new cases and around 70% of cancer deaths in the world occur annually in Africa, Asia and Central and South America. It is estimated that annual cancer cases will increase from 14 million in 2012 to 22 million in the next two decades. The intervention program against cancer risk factors not only aims to reduce new cases of cancer, but also reduce the possibility of other diseases caused by risk factors. Almost all studies found that psychosocial interventions had a significant effect on the recovery of cancer patients. Psychological interventions accompanied by motivation for healing provide suggestions to cancer patients to have more spirits of life. Hence, various studies made recommendations for handling cancer by involving psychological interventions, giving motivation, and spiritual support to cancer patients. This study allowed researchers to combine the two methods to see the effectiveness or influence in reducing and controlling stress in cancer patients through counseling and deep breathing relaxation. This study aimed to identify models of counseling interventions and relaxation to control stress in cancer patients. In this study, it is concluded that most of the concepts and results of previous studies recommend an intervention model in the form of counseling and relaxation to control stress in cancer patients.

Key Words: relaxation and counselling, stress control, cancer

Introduction

Cancer is one of the leading causes of death in the world. Approximately 8.2 million deaths are caused by cancer. Lung, liver, stomach, colorectal and breast cancers are also the biggest causes of cancer mortalities every year. More than 30% of cancer deaths are caused by five behavioral and dietary risk factors, those are: high body mass index, low consumption of fruit and vegetable, lack of physical activity, cigarette smoking, and excessive alcohol consumption. Smoking is one of the main risk factors for cancer which causes more than 20% of cancer deaths in the world and around 70% of deaths from lung cancer worldwide⁴

Cancer that causes infections of viruses such as hepatitis B / hepatitis C virus and human papilloma virus contributes to 20% of cancer deaths in the low-middle income countries. More than 60% of new cases and around 70% of cancer deaths in the world occur annually in Africa, Asia and Central and South America. It is estimated that annual cancer cases will increase from 14 million in 2012 to 22 million in the next two decades.⁵

In the United States and several other developed countries, cancer is now responsible for around 25% of all deaths. Within a year, about 0.5% of the population is diagnosed with cancer. In adult men in the United States, the most common cancers are prostate cancer (33% of all cancer cases), lung cancer (13%), colon and rectal cancer (10%), bladder cancer (7%), and cutaneous melanoma (5%). The most common cause of death is lung cancer (31%), followed by prostate cancer (10%), colon and rectal cancer (10%), pancreatic cancer (5%)

Correspondence Author:
Ahmad Yani

DOI Number: 10.5958/0976-5506.2019.02071.0
and leukemia (4%). Meanwhile, for adult women in the United States, breast cancer is the most common cancer (32% of all cancer cases), followed by lung cancer (12%), colon and rectal cancer (11%), endometrial cancer (6%, uterus) and non-Hodgkin’s lymphoma (4%). Based on cases of death, lung cancer is most common (27% of cancer deaths), followed by breast cancer (15%), colon and rectal cancer (10%), ovarian cancer (6%), and pancreatic cancer (6%). Statistics can vary greatly in other countries.

A diagnosis of cancer can cause feelings of fear, anxiety, depression, despair, and doubts in carrying out future plans. Cancer can significantly increase a patient’s spiritual needs. Because of self-esteem and spiritual beliefs are threatened and personal relationships are disrupted due to lack of self-confidence, previously adaptive mechanisms become insufficient. Meanwhile, hospital care can trigger feelings of loneliness and eventually, a spiritual crisis arises in them. This crisis can cause imbalances in the mind, body, and soul. In dealing with critical illness, such as cancer, patients bring out special needs, the most important of which is spiritual needs. These patients depend on spiritual aspects, and spiritual adjustment is the strongest method they use to deal with the disease.

Most studies found that psychosocial interventions had a significant effect on the recovery of cancer patients. Psychological interventions accompanied by motivation for healing provide suggestions to cancer patients to have more spirits of life. Therefore, various studies made recommendations for handling cancer by involving psychological interventions, giving motivation, and spiritual support to cancer patients.

Research on the implications of mental health in bladder cancer patients included 11 prospective studies and 8 retrospective studies. This study reviewed mental health problems, such as depression and anxiety, which often accompanied the diagnosis of bladder cancer with a worse prognosis associated with a greater psychological burden. Bladder cancer patients also have an increased suicide risk especially in older male patients who are not married with advanced disease status. Poor mental health can affect treatment outcomes such as postoperative complications and survival-related outcomes similar to physical health. While awareness of the importance of mental health in bladder cancer patients is growing, further studies are needed to assess the role of interventions such as cognitive behavior therapy or pharmacotherapy to optimize treatment.

The high incidence of cancer cases and around 40% of cancer deaths are likely related to risk factors of cancer that should be prevented. The risk factors of cancers are among behavior and eating patterns, including high body mass index; Less consumption of fruits and vegetables; Lack of physical activity; Cigarette smoking; Excessive alcohol consumption; other cancer risk factors, are due to exposure: physical carcinogens, such as ultraviolet (UV) and radiation; Chemical carcinogens, such as benzo (a) pyrene, formalin and aflatoxin (food contaminants), and fibers, for example asbestos; Biological carcinogens, such as virus, bacterial and parasitic infections.

The intervention program against cancer risk factors not only aims to reduce new cases of cancer, but also reduce the possibility of other diseases caused by these risk factors. Smoking, one of which, causes around 1.5 million deaths from cancer each year (60% of deaths occur in low-middle income countries). Overweight, obesity and lack of physical activity cause 274,000 cancer deaths every year; Excessive alcohol consumption causes around 351,000 cancer deaths each year; Sexual transmission of human papilloma virus (HPV) causes around 235,000 cancer deaths each year; Air pollution (outside and indoors) causes around 71,000 cancer deaths every year; Carcinogens in the work environment cause at least 152,000 cancer deaths each year.

Previous research examined the effect of training in relaxation techniques to reduce anxiety in primary caregiver breast cancer patients at home. The results of quantitative analysis using Wilcoxon nonparametric statistics and visual inspection graphs showed a significant difference score between before and during training with Z = -2.023 and p = 0.0215 (p <0.05).

Regarding to the learning model by Bandura (social cognitive theory), previously there was a model of this research that was counseling on the efficacy of adopting a behavioristic bandura learning model as conducted by researchers (Lev & Owen, 2000) with the research title Counseling women with breast cancer using principles developed by Albert Bandura. This study found that counseling interventions to promote self-efficacy can improve quality of life and reduce pressure for women diagnosed with breast cancer.
In this study design the researcher combined the two methods to examine the effectiveness or influence in reducing and controlling stress in cancer patients through counseling and deep breathing relaxation.

Based on the given facts, this study aimed to examine intervention counselling and relaxation models to control stress in cancer patients.

**Research Methodology**

This paper used a two-stage methodology for the formation of the initial model and conceptualization. This study collected several concepts, theories and some research results that were relevant to counseling and relaxation of stress control in cancer patients.

**Results & Discussion**

The results of this study found that cancer is caused by hormonal irregularities resulting in the growth of neoplasms in normal body tissues or often known as malignant tumors. In addition these symptoms are also known as malignant neoplasms and are often characterized by typical cell cycle abnormalities that allow cells to: grow uncontrollably (cell division exceeds normal limits), attack nearby biological tissues, and migrate to other body tissues through blood circulation or lymphatic system, called metastasis.

This disease is often known by the public as a tumor, but not all of them are cancer. Tumors are all abnormal lumps, and are divided into 2 groups, namely benign tumors and malignant tumors. Cancer is a general term for all types of malignant tumors. This disease can affect everyone, in every part of the body, and in all age group, but more often affects people who are 40 years old.

Cancer causes many different symptoms, depending on the location and character of the malignancy, and the presence or absence of metastasis. Diagnosis usually requires microscopic examination of tissue obtained by biopsy. After being diagnosed, cancer is usually treated with surgery, chemotherapy, or radiation. Most cancers cause death.

Commonly, cancer is referred to based on the type of organ or cell where it occurs. For example, a cancer that begins in the large intestine is referred to as colon cancer, whereas cancer that occurs in basal cells of the skin is referred to as basal cell carcinoma. Cancer classification is then carried out in more general categories.

Most cancers are recognized through visible signs or symptoms or through screening. Both of these methods do not lead to a clear diagnosis, which usually requires a biopsy. Some cancers are discovered accidentally during medical evaluation of unrelated problems. Because cancer can also be caused by methylation of certain gene promoters, early detection can be done by testing genes that become biomarkers for cancer. Some types of cancer have known the status of the biomarker methylation. For example for breast cancer BRCA biomarkers can be used, whereas for colorectal cancer can use Sox17 biomarkers.

Individual counseling is a counseling service organized by a counselor to clients in solving problems experienced by cancer patients. A counselling can be made through communication or face-to-face discussion between counsellor and client to discuss about past and present problems as well as unsolved problem in cancer patients. Discussion of problems in counseling is comprehensive and in-depth and touches on important things about the client (very likely to touch the client’s personal secrets). But it is also specific in the direction of problem solving.

Relaxation techniques are independent nursing interventions to reduce pain intensity, improve pulmonary ventilation and improve blood oxygenation. Skeletal muscle relaxation is believed to reduce pain by relaxing the muscle tension that supports pain, plenty of evidences show that relaxation is effective in relieving pain. The purpose of respiratory relaxation is to improve ventilation of the alveoli, maintain gas exchange, prevent lung attenuation, relax muscle tension, increase cough efficiency, reduce stress both physical and emotional stress which is to reduce pain intensity (control or reduce pain) and reduce anxiety.

Patients who carry out relaxation techniques achieve a greater focus of attention using Jacobson techniques and increased emotional control using visualization of surveillance and lifestyle are associated with stronger intentions, higher perceived needs, and lower concerns than kemoprevisi. Strong predictors of intention are women’s beliefs about risk reduction methods, especially for lifestyle and chemoprevention.

Cancer deaths are highly related to cancer risk factors that should be prevented. Cancer risk factors that consist of risk factors for behavior and eating patterns,
including high body mass index; Less consumption of fruits and vegetables; Lack of physical activity; Cigarettes smoking; Excessive alcohol consumption; other cancer risk factors. (7)

Conclusions

This study concluded that most of the previous concepts and studies recommend intervention model in a form of counselling and relaxation to control stress in cancer patients.

Ethical Clearance: Our study was not directly applied on human, hence ethical clearance was not required.

Abstract

Background: Identification of factors associated with short-term survival of ischemic stroke patients (survival <30 days).

Research Objectives: to analyze the relationship of blood pressure, pulse, respiratory frequency, GCS, instantaneous blood sugar, LDL cholesterol and triglycerides, history of hypertension, history of diabetes mellitus and a history of heart disease.

Method: This study used an observational analytic method with a retrospective design. Sampling uses purposive sampling. 258 samples were taken from medical record data from January 2016 - December 2017.

Results: Blood pressure, level of consciousness, momentary base sugar levels, triglycerides and history of DM that were significantly associated with the dependent variable (survival) in ischemic stroke patients. This can be seen from the ρ-value variable systolic blood pressure (ρ = 0.001) and diastolic blood pressure variable (ρ = 0.000), Awareness Level (GCS) (ρ = 0.000), instantaneous blood sugar (ρ = 0.015), triglycerides (ρ = 0.033), and history of DM (ρ = 0.005).

Conclusion: Ischemic stroke factors that are significantly related to short-term survival are blood pressure level of consciousness, instantaneous basic sugar levels, triglycerides and history of DM

Keywords: ischemic stroke factor, short-term survival

Introduction

Stroke is one of the causes of long-term mortality and disability throughout the world, and a number of 5.7 million people die each year. Stroke is the second leading cause of death worldwide. According to the WHO in 2015, strokes are a sudden neurological symptom caused by brain disorders and circulatory disorders that last more than 24 hours. Stroke mortality and disability continues to increase, also increasing the burden of stroke globally. Based on 1990-2013 Global Burden of Ischemic and Hemorragic Stroke data, around 13 million new stroke sufferers each year, and 4.4 million of them die within 12 months. The average percentage of stroke cases is 22.9% per month.

The biggest increase in stroke incidence occurred in Southeast Asia. Based on the results of the South East Asian Medical Information Center (SEAMIC) data, the largest stroke death rate in Southeast Asia is described in Indonesia. Stroke cases in Indonesia are estimated at 500 thousand people experience a stroke each year, 2.5% of them die while the rest experience mild disability to severe disability. This is also supported by the results of the 2012 Balitbangkes (Health Research and Development Agency) Ministry of Health of the Republic of Indonesia that nationally, the largest distribution of deaths in Indonesia is stroke with a percentage of 15.4%. In Indonesia, stroke is the number one cause of death in hospitals. The prevalence of stroke in East Java is ranked fourth, which is 16% based on the diagnosis of health workers. In Kediri Regency the number of stroke patients reached 1,431 people with male sufferers as many as 669 people and women with 762 lives.

Determination of minimum hospital service standards in 2008, one of which was to assess hospital mortality, namely the mortality rate of less than 48 hours and more than 48 hours. The Net Death Rate (NDR)
is death that is more than 48 hours after the patient is admitted to the hospital [7]. Calculation of Net Death Rate (NDR) is a mortality rate of 48 hours after the patient is treated for each 1000 patients out with a standard NDR value tolerated by the Indonesian Ministry of Health which is <25 per 1000 [8]. Based on the results of a preliminary study in the hospital. Kediri Baptists get the results of the number of ischemic stroke patients who entered the ED in 2015 amounting to 293 patients per year, in 2016 it increased by a number of 375 patients per year while in 2017 the number of stroke patients in the ED was 355 patients per year. The NDR of ischemic stroke patients in 2015 was 31.06 ‰, while the NDR of ischemic stroke patients in 2016 had decreased by 26.4 ‰ and NDR in stroke patients in 2017 increased by 26.6 ‰. Based on these data indicate ischemic stroke mortality in hospitals. Kediri Baptists are a concern because they exceed the NDR standard limits according to the provisions of the health ministry.

The American Heart Association in the initial management guidelines for patients with ischemic stroke is one of them by doing general supportive care which includes handling airway, breathing and oxygenation (oxygen saturation, pulse, and respiration), assessment of consciousness level, assessment of blood pressure, and blood sugar levels on emergencies. Diagnostic examination to determine risk factors including assessing blood sugar levels, cholesterol levels. Nurses can also conduct studies by analyzing the history of stroke patients such as a history of hypertension, diabetes mellitus and heart disease.

Method

This study used an observational analytic method with a retrospective design to look at several risk factors, by using medical record data from January 2016 to December 2017. The researchers conducted observations to determine the relationship between variables, namely blood pressure, pulse, respiration, GCS, blood sugar for a moment, blood cholesterol, history of hypertension, history of diabetes mellitus and a history of heart disease, then looked at the relationship to survival. 258 samples, taking samples with purposive sampling. Data collection is carried out for approximately 1 month. Data uses frequency distribution and multivariate tests using multinomial regression tests.

<td>0.481</td>
</tr>
<tr>
<td>History of P. Heart</td>
<td>3,623</td>
<td>0.163</td>
</tr>
</tbody>
</table>

Table 3 shows a partial test that among the nine independent variables there are five variables (systolic blood pressure, diastolic blood pressure, level of consciousness, momentary base sugar levels, triglycerides and history of DM) that are significantly associated with the dependent variable (survival). This can be seen from the $\rho$-value variable systolic blood pressure ($\rho = 0.001$) and diastolic blood pressure variable ($\rho = 0.000$), Awareness Level (GCS) ($\rho = 0.000$), instantaneous blood sugar ($\rho = 0.015$), triglycerides ($\rho = 0.033$), and history of DM ($\rho = 0.005$). All of these variables have a value of $\rho \leq 0.05$. The conclusion that can be drawn is that the variables that are significantly related to survival are systolic blood pressure, diastolic blood pressure, level of consciousness, triglyceride momentary blood sugar levels and history of DM.

### Table 4 Multinomial Logistic Regression Analysis

<table>
<thead>
<tr>
<th>VARIABLE</th>
<th>Short-Term Survival</th>
</tr>
</thead>

</tr>
<tr>
<td>Triglycerides</td>
<td>0,007</td>
</tr>
<tr>
<td>History of DM</td>
<td>0,003</td>
</tr>
</tbody>
</table>

Table 4 shows the results of the multinomial regression obtained is that the variable ischemic stroke patients who have DM contribution in the short term who survive has an odd ratio value of -1,779 which means it is more appropriate than the short term compared to medium-term survival. Conclusions that can be drawn from ischemic stroke patients with DM participation have a chance of 1,779 times greater short-term survival compared with stroke patients.

### Table 5 Test the Goodness of the model

</table>

Table 5 shows the Nagelkerke value of 0.706, which means the diversity of data on independent variables
(systolic blood pressure, diastolic blood pressure, level of consciousness, momentary base sugar levels, triglycerides and history of DM) in this study was able to explain the survival of 70.6% while the remainder is explained by other independent variables that are outside the research model.

**Discussion**

Based on the results of multinomial logistic regression, it was found that the dominant or most associated variables with short-term survival in ischemic stroke patients were blood pressure, level of consciousness (GCS), instantaneous blood sugar, triglycerides and a history of diabetes mellitus. The results obtained showed that strongest factor associated with survival was a history of diabetes mellitus with p value 0.003 and a coefficient of -1.777 which showed that the direction was negative. The meaning of the coefficient that is ischemic stroke patients who do not have diabetes mellitus (DM = 0) will cause a tendency to experience long-term survival. Ischemic stroke patients with a history of diabetes mellitus have a chance of 1,779 times greater experience of short-term survival compared to ischemic stroke patients who have increased systolic, increased diastolic, decreased GCS, increase in instantaneous blood sugar and increased triglycerides.

Based on the results of the coefficient, the strongest variable associated with short-term survival is a history of diabetes mellitus. The history of diabetes mellitus has a negative coefficient (B = -1.779) with p = 0.003 significant at α = 0.05. This explains that patients who do not have a history of ischemic stroke patients will tend to experience long-term survival. This is because diabetes mellitus has a hyperglycemia that can cause several events, namely atherosclerosis, aggregate platelets, and increased blood viscosity which triggers an increase in blood pressure and a buildup of plaque which will become an ischemic stroke. If these conditions occur in the long term / chronic, it will increase the deterioration of the patient’s prognosis and reduce survival, so patients tend to experience short-term survival. The results of studies that are in line convey that the history of diabetes is a risk factor associated with death in stroke patients. The Italian study showed that ischemic stroke patients increased the risk of in-hospital mortality and death by less than 30 days, so patients tended to experience short-term survival.

Blood pressure has a positive coefficient (B = 0.0074) for systolic blood pressure with p = 0.000, and for diastolic blood pressure (B = 0.118) with p = 0.000 significant at α = 0.05. This shows that the higher the blood pressure value of ischemic stroke patients it will cause the tendency of patients to experience short-term survival. Uncontrolled blood pressure and tend to increase can cause vasoconstriction of blood vessels, giving rise to the degree of constriction of blood vessels and trigger atherosclerosis. Weiss et al., (2018) explained in his study that systolic blood pressure which increased by > 160 mmHg had a relationship with an increased risk of short-term death to long-term death in ischemic stroke patients with elderly age. Based on this study systolic pressure ≥ 160 mmHg and diastolic ≥ 100 mmHg, ischemic stroke patients are at risk of experiencing short-term survival. Other studies that support a decrease in systolic blood pressure of 10 mmHg can reduce stroke incidence by 41%. (10)(12)(13)

GCS has a negative coefficient (B = -1.052) with p = 0.000 significant at α = 0.05. This explains that the higher awareness (GCS) in ischemic stroke patients will cause the tendency of ischemic stroke patients to experience long-term survival. Ischemic stroke patients have a greater chance of survival compared to hemorrhagic strokes. One reason for this is that patients with ischemic stroke tend to have moderate levels of consciousness good GCS > 8, so the recovery process does not need time which tends to be long. The Glasgow Coma Scale (GCS) is used to determine the level of awareness and severity experienced by stroke patients. The lower the GCS value indicates the more severe sensory, motoric and coordination disorders in the body. Shamshirgaran et al., (2014) explained a decrease in the level of consciousness factor influences independent predictors of early death of less than 30 days (short-term mortality). This can be concluded that the lower the level of awareness of patients, the more likely they will be to experience survival.

Momentary blood sugar (GDS) obtained a positive coefficient (B = 0.001) with p = 0.006 significant at α = 0.05. This shows that the higher the GDS value it will cause the tendency of ischemic stroke patients to experience short-term survival. The condition of hyperglycemia in the metabolic process affects mitochondrial function in the ischemic area of the penumbra. Hyperglycemia can lead to hypertension, atherosclerosis, heart disease and stroke. Uncontrolled hyperglycemia can worsen...
the prognosis of stroke patients, increasing the risk of only experiencing short-term survival. According to Wan-Arfah et al., (2018) in ischemic stroke patients with diabetes mellitus will tend to experience short-term survival compared to those without diabetes mellitus.⁹

Triglycerides obtained a positive coefficient (B = 0.011) with p = 0.007 significant at α = 0.05. This shows that the higher the triglyceride value it will cause the tendency of ischemic stroke patients to experience short-term survival.⁰ Based on the theory of increased triglyceride levels can be associated with an increased risk of vascular disease. Increased triglycerides in the blood associated with an increase in cholesterol and LDL in the blood can trigger atherosclerosis make LDL cholesterol in the arterial wall toxic and reduce the beneficial effects of HDL. Increased LDL cholesterol and triglycerides can trigger vascular diseases such as heart disease such as atrial fibrillation, can increase embolism which results in the expansion of infarction so that it can worsen the prognosis in stroke patients. Patients atrial fibrillation experience low survival and tend to experience short-term survival.

Conclusion

The dominant factors in short-term survival (<30 days) included increased blood pressure, hyperglycemia, decreased GCS, increased triglycerides and a history of diabetes mellitus can have a relationship with the incidence of short-term survival.

Relationship between Type of Dysphonia and Quality of Life Based on Voice Handicap Index

Ribka A. Toding ¹, M. Amsyar Akil ¹, Abd. Qadar Punagi ¹

¹Department of Otorhinolaryngology-Head and Neck Surgery, Medical Faculty, Hasanuddin University, Indonesia (Email: todingribkaaryanti@gmail.com)

Abstract

Dysphonia has a significant impact on patients’ quality of life including psychological, social, physical, occupational, and communication to others. Voice Handicap Index is the most widely used instrument for measuring the quality of life for patients with dysphonia. The purpose of this study was to assess the relationship between type of dysphonia and quality of life based on voice handicap index. This study was conducted using cross sectional analysis to 12 normal subjects, 26 structural dysphonia subjects, and 10 neurogenic dysphonia subjects. Every sample had undergone video-stroboscopy examination to assess anatomical abnormalities of the larynx and vocal cords, and then we measure the Voice Handicap Index score. The result of the study showed that VHI scores on physical, functional, emotional and total scores were higher in neurogenic dysphonia compared to structural dysphonia subjects with p-value < 0.001. This indicated that the quality of life for patients with neurogenic dysphonia are worse than patients with structural dysphonia.

Keywords: dysphonia, video-stroboscopy, quality of life, voice handicap index

Introduction

Dysphonia is a terminology used for abnormalities characterized by changes in quality of sound, either by high and low pitches of sound, loudness, or efforts needed to produce sound that causes communication disturbance and associated with decreased quality of life. This condition can caused by abnormalities in phonetic organs especially larynx, both organic or functional. Dysphonia is not a disease, but a symptoms of disease or abnormalities on larynx (1).

In 2001, United State of America reported the prevalence of dysphonia about 0.98% (536,943 dysphonia patients per 55,000,000 total patients), in which they found more women patients compared to men (1.2%; 0.7%) with occurrence on the age of more 70 years old. In UK, around 50,000 patients per year came to ENT departement with dysphonia(2). Cohen et al (3) found that the prevalence for dysphonia was 0.98 from total study subjects with population of women 63.4% and male 36.5%.

A variety of disorders that can cause dysphonia such as nodules or vocal cord polyps, laryngo-pharyngeal reflux (LPR), vocal abuse, vocal cord paralysis, trauma, allergies, stress or depression, and congenital abnormalities. In 2015 Reiter reported that the most common cause of dysphonia were acute laryngitis (42.1%) and chronic laryngitis (9.7%), functional dysphonia (30%), benign (10.7%) and malignant tumor (2.2%), and neurogenic factor such as vocal cord paralysis (2.8 to 8%). Gusmarini et al have conducted a research at RSUP DR. M. Djamil Padang in 2010-2013, and the result showed that the most common cause of dysphonia was Gastroesophageal reflux disease (GERD) with 33.8% cases.(4,5)

There are several system that can be used to classify voice disorder. One of them divided voice disorder into 2 large groups, namely:...
Organic voice disorder: voice disorder which is physiological results from changes in the respiratory tract, laryngeal, or sound formation mechanism. Organic dysphonia is further divided into two groups:

Structural voice disorder is organic voice disorder caused by physical changes in sound formation mechanisms, for example changes in vocal cord tissue such as edema or vocal nodules, structural changes in the larynx due to aging.

Neurogenic voice disorder is organic voice disorder caused by disturbance of the central or peripheral nervous system to the larynx which affects sound.

Functional voice disorder is voice disorder caused by a disturbance in sound formation without any abnormalities in the larynx, for example vocal fatigue, muscle tension dysphonia.

Dysphonia have a significant impact on psychological, social, physical, work, and communication. The World Health Organization (WHO) defines disability (handicap) as limitation of participation from activities normally carried out by person due to physical impairment or injury. Severity of dysphonia and how dysphonia influence patient’s daily life is difficult to measure because that needed self evaluation in dysphonia management. (7)

Dysphonia impact on patients’ quality of life can be assessed by using some instruments. There are several instruments that have been developed to assess sound outcome such as Voice Handicap Index (VHI), Voice Outcome Survey (VOS), Voice Symptom Scale (VoSSS), Vocal Performance Questionnaire (VPQ), Voice-Related Quality of Life (V-RQOL), and Singing Voice Handicap Index (SVHI) (8). VHI is the most widely used instrument, which aim to evaluate dysphonia psychosocial impact. In 1997, Jacobson et al developed the Voice Handicap Index (VHI) which consists of 30 questions known as VHI-30, and on 2002 it has been validated by the Agency for Health Care Study and Quality. Quality of life assessment is very helpful in providing appropriate treatment for people with dysphonia. Patients who met the inclusion criteria were then asked to complete VHI questionnaire.

The VHI questionnaire was conducted to assess patients’ quality of life. The VHI score consists of 30 statements representing three subgroups, which reflect the functional, physical, and emotional aspects. Each statement must be read carefully and patients must be able to determine the frequency according to daily life, starting from 0 (never), 1 (rare), 2 (once in a certain period of time), 3 (often), to 4 (always). The range of VHI scores is between 0 and 120. VHI can be interpreted as mild (VHI score 0–30), moderate (31–60), and severe (61–120). Statistical tests were performed to determine the relationship between type of dysphonia and the VHI score.

Materials and Method

Research Time and Location

This study was conducted at ENT Head-Neck Surgery outpatient clinic of Hasanuddin University Hospital and Wahidin Sudirohusodo Hospital from January 2019 to March 2019.

Research Design and Variables

This study design is an analytical cross-sectional study. The variable is independent variable (type of dysphonia), dependent variable (Voice Handicap Index).

Population And Sample

The population in this study were all dysphonia patients who was admitted to ENT Head-Neck Surgery outpatient clinic of Hasanuddin University Hospital and Wahidin Sudirohusodo Hospital from January 2019 to March 2019. The samples were all subjects from the population who met the inclusion criteria.

Data Collection Method

Data collection was carried out by taking demographic data including, sex, age, job and routine otorhinolaryngology examination such as otoscopy, anterior rhinoscopy, pharyngoscopy, and laryngoscopy. Patients who are willing to take part in the study are asked to fill out informed consent, then video-stroboscopy is performed to assess abnormalities in the larynx and vocal cords. Patients who met the inclusion criteria were then asked to complete VHI questionnaire.

The VHI questionnaire was conducted to assess patients’ quality of life. The VHI score consists of 30 statements representing three subgroups, which reflect the functional, physical, and emotional aspects. Each statement must be read carefully and patients must be able to determine the frequency according to daily life, starting from 0 (never), 1 (rare), 2 (once in a certain period of time), 3 (often), to 4 (always). The range of VHI scores is between 0 and 120. VHI can be interpreted as mild (VHI score 0–30), moderate (31–60), and severe (61–120). Statistical tests were performed to determine the relationship between type of dysphonia and the VHI score.

Results

A cross sectional study was conducted to assess the
relationship between types of dysphonia and quality of life based on Voice Handicap Index (VHI). This study was conducted on people with dysphonia in ENT Head-Neck Surgery outpatient clinic, Hasanuddin University Hospital, Makassar from January 2019 - March 2019.

During this period, we obtained 48 samples consists of 22 men (45.8%) and 26 women (54.2%) with 11 patient in age group < 31 years old (22.9%), 20 patient in 31-40 years age group (41.7%), and 17 patients > 40 years old (35.4%). Based on work, we obtained 5 professional user (10.4%) and 43 non-professional user (89.6%).

Figure 1. Type of Dysphonia Based On Video-stroboscopy Examination

Video-stroboscopy showed that the most common type of dysphonia was 26 structural dysphonia (54.2%), 12 normal (25.0%), and 10 neurogenic dysphonia (20.8%) (Figure 1). Table 1 shows that the proportion of subjects with a severe VHI score was found to be higher in women (26.9%) compared to men (13.6%). Table 2 shows that the proportion of subjects with severe VHI scores was found to be highest at 31-40 years of age (35.0%) and the lowest at <31 years old (9.1%).

Discussion

This study shows that there is a relationship between type of dysphonia and quality of life based on the voice handicap index.

Gender distribution is more common in women than for men. This result is not very different compared to Caroline’s study with a comparison of men (35.5%) and women (64.5%), as well as Hummel’s study with total men (35) and women (51). However, this result was different to Gusmarini which showed that the incidence of dysphonia is comparable to men and women 1: 1. Based on the results of these studies, we concluded that gender does not affect the incidence of dysphonia. (5,11,12)

The highest frequency of patients with dysphonia is between of 31-40 years with 20 (41.6%) patients, followed by the age group above 40 years with 17 (35.4%) patients, and the lowest is < 30 years age group with 11 (22.5%) patients. This result is different from study reported by Caroline, et al showed that the highest frequency of patients with dysphonia is in age group above 40 years, and Haryuna who reported the highest percentage of patients with dysphonia is in age group over 60 years. This is due to the fact that in that study the cause of dysphonia was laryngeal malignancy whereas in this study more cases were caused by laryngopharyngeal reflux. (11,13)

In this study the most common laryngeal disorder was structural dysphonia (54.2%). The results of this study is likely due to Wahidin Sudirohusodo Hospital and Hasanuddin University Hospital being a reference center in Eastern Indonesia, so that structural abnormalities that require more operative treatment are referred to both those hospitals. This study is in line with the study from Kiakojoury et al. (14) which also found that the
most common cause of voice disorders was organic dysphonia (85.78%), functional dysphonia (8.6%), and dysphonia due to neurological disorders (5.6%). Cohen, et al reported that the most common diagnosis for patients with voice disorders was LPR (3). Gusmarini stated that the underlying causes of dysphonia were LPR (33.8%), vocal cord paralysis (23.5%), and Laryngeal TB (10.3%5).

Comparison between male and female VHI scores was found to be higher in female. This shows that the quality of life in female is worse than that of male. This study result is supported by a study reported by Bogusz, et al which stated that VHI scores were significantly higher in women than men with p-value < 0.05 (15). According to the literature there is a difference between men’s and women’s quality of life, where men’s quality of life tend to be better than women. Both men and women have differences in roles and access to and control of various sources so that the needs or things that are important for men and women will also be different. This indicates a different aspect of life related to quality of life in men and women, for example communication. Women are more likely to socialize and use sounds, so they feel more disturbed when there is a change in their sound.

The highest VHI score was found at the age group 31-40 years (35.0%) . This is due to the age group 31-40 years is still in productive age, which is still active in social and economy. The results of this study are parallel with study conducted by Caroline (11) who reported that at the age of < 40 years, total VHI score was higher than in those aged more than 40 years.

Comparison of VHI scores based on the type of dysphonia using Kruskal-Wallis test shows that the highest mean functional score were found on neurogenic dysphonia (23.8). The highest mean physical score were found on neurogenic dysphonia (23.2). The highest mean emotional score were found on neurogenic dysphonia (23.2), and mean total VHI score were found highest on neurogenic dysphonia (70.2). The results of the total score and subscale have significant differences with p values < 0.001. Patients with vocal cord paralysis have poor quality of life that may be caused by the impact of vocal cord paralysis not only causing voice impairment, but also disturbing other daily activities such as lifting, straining, and swallowing. This results showed that overall severe quality of life disturbances were related to neurogenic dysphonia abnormalities.

Bogusz et al (2011) stated that the highest total VHI score and subscale were found in patients with vocal cord paralysis, and the lowest score in patients with benign vocal cord tumors. While the comparison between scales found that the highest average VHI score was recorded in the physical subscale and the lowest in the functional subscale (15). Amir, et al (2006) reported that patients with neurogenic dysphonia had the highest total VHI score, and the lowest score was found on dysphonia that were caused by inflammation compared to other pathological abnormalities with p-value < 0.05 (16). Study conducted by Lam, et al (2006) states that in both VHI-30 and VHI-10, the total score of neurogenic group is significantly higher than in the structural group, and that the structural group has higher score compared to the inflammatory group (17). It shows that abnormalities in the larynx that cause speech disorders have an impact on patients’ quality of life both physically, functionally, and emotionally. Therefore the treatment of patients with dysphonia must be done in a multidisciplinary approach by looking at the scores of each subscale. Physical disorders can be treated with surgical and medical treatment, functional disorders can be treated with vocal rests and speech therapy, and emotional disorders can be handled by counseling.

**Conclusion**

This study result shows that the most common cause for dysphonia based on video-stroboscopy examination is structural dysphonia. The value of the voice handicap index score on neurogenic dysphonia is higher than structural dysphonia both in functional, physical, emotional, and total scales. This shows that the quality of life in patients with neurogenic dysphonia is worse than structural dysphonia, so it can be concluded that the assessment of quality of life using Voice Handicap Index can be used as a supporting tool in choosing the right treatment for people with dysphonia.

Factors Affect the Quality of Health Services of National Health Insurance Participants (Studies Public Health Center Benteng in The City Palopo)

Nilawati Uly¹, Marissa²
¹Associate Professor, ²Graduate Study program, Institute of Higher Health Education, Mega Buana Palopo, Indonesia

Abstract

Public Health Center as the first level health facility is expected to improve and enhance public health. Where workers or health workers in Public Health Center has a role and a great responsibility on public health issues. Especially in terms of providing quality health services to the community. To determine the factors that affect the quality of health services of national health insurance participant in the public health center Benteng Palopoin 2016. The type of research was a survey research that used a structured or systematic question to many people, and then all of the answers that obtained are recorded, processed and analyzed by using a cross sectional research design. The results of statistical analysis obtained by value $\rho = 0.000 < \alpha = 0.05$ means that H0 rejected and Ha accepted that there is an influence on the technical competence of health care quality of national health insurance participants. Results of statistical analysis obtained by value $\rho = 0.004 < \alpha = 0.05$ means that H0 rejected and Ha accepted that there is an influence on the effectiveness of health care quality of national health insurance participants. Results of statistical analysis obtained by value $\rho = 0.000 < \alpha = 0.05$ means that H0 rejected and Ha accepted that there was an effect on the efficiency of health care quality of national health insurance participants. Factors that affect the quality of health services of national health insurance participant in the public health center Benteng Palopoin 2016, namely technical competence, effectiveness, and efficiency.

Keywords: quality of service, technical competence, effectiveness, efficiency.

Introduction

Based on data from the Palopo City Health Office in 2015, the number of contribution recipients (PBI) JKN from the regional expenditure (APBD) budget was 51,000, the recipients of contributions from the state expenditure budget (APBN) were 45,614 ¹. Based on data from the Benteng Kota Palopo Health Center in 2015, the number of JKN beneficiary beneficiaries (PBI) participants was 7,307, and there were 9,000 independent JKN participants, of which there were 18,603 residents of Benteng Community Health Center². Then, out of this total, 51% did not claim to be dissatisfied with doctors’ services, while the rest were not satisfied with hospital services³. Especially for efforts to develop service quality in hospitals and health centers also known as Clinical Gofernance⁴-⁶. The JKN program was underway at the Benteng City Palopo Health Center. Seeing the number of patient visits has decreased in the last three years, it is necessary to know how the quality of services at the Benteng Health Center. Based on the background of the above thoughts, the researchers were interested in examining the factors that influence the quality of health services for participants of the National Health Insurance at Benteng Kota Palopo Health Center in 2016

Materials and Method

Research Design

Research design is a method used by researchers to conduct a study that gives direction to the course
of research. The type of research used is a survey that is a study that uses the same structured or systematic questions to many people, then all the answers obtained by researchers are recorded, processed and analyzed. By using a cross sectional study design that is the type of research that emphasizes the time of measurement or observation of data of independent and dependent variables only once.

**Research Location**

This research was conducted at the Puskesmas Fort Palopo.

**Research Time**

This research was conducted in May to June 2016.

**Population**

The population in this study were all outpatients who used the National Health Insurance who came for treatment at the Benteng Health Center in January-March 2016, which was 2,700 people.

Samples. The sampling technique carried out in this study was simple random sampling by randomly drawing out the numbers and that was used as a sample of 96 people.

**Results**

a. Quality of Service

**Table 1. Distribution of Respondents Based on Quality of Service at the Benteng City Palopo Health Center, 2016**

Uji Regresi, Crosstab

From the results of statistical analysis using linear regression obtained value $\rho = 0.000 <\alpha = 0.05$, means that H0 is rejected and Ha is accepted so that there is an effect of effectiveness on the quality of health services for participants of the National Health Insurance in Benteng City Palopo.

**Discussion**

Effect of Technical Competence on Quality of Health Services

The distribution of respondents based on technical competency in Benteng Health Center in 2016 was obtained by 96 respondents studied, the number of respondents who said that competent technical competence was 93 respondents (96.9%) and respondents who said they were incompetent were 3 respondents (3.1%) Many respondents agreed that all this time the services provided by Benteng Community Health Center in terms of technical competence were very good, both in terms of the readiness, appearance and skills of officers in providing services.

The influence of technical competence on the quality of health services for national health insurance...
participants at Benteng Kota Palopo Health Center in 2016 the results of statistical analysis using linear regression obtained a value of $\rho = 0.000 < \alpha = 0.05$, meaning $H_0$ was rejected and $H_a$ was accepted so that there was influence technical quality of health services for participants of the National Health Insurance. This is because patients feel that the technical competencies possessed by doctors, nurses, and other non-medical officers in serving patients at Benteng Health Center are good because the respondent answers to technical competencies that have the responsiveness / speed of health workers in handling patient complaints and provides solutions, the availability of doctors and nurses to serve patients and routinely control the patient’s condition, in addition to the attitude of the health staff, the complete condition of the equipment at the Benteng Health Center is still standard, but this is not too significant, because the equipment in the puskesmas is appropriate with service operational standards.

Effect of Effectiveness on Quality of Health Services

The respondent’s distribution based on effectiveness at Benteng Kota Palopo Health Center in 2016 was obtained from 96 respondents studied, the number of respondents who said that the effectiveness was 89 respondents (92.7%) and respondents who stated ineffective were 7 respondents (7.3%). Judging from the dimensions of effectiveness as many as 89 people (92.7%) owned by health workers in the Puskesmas are already in the effective category which illustrates that health workers have provided maximum service based on their scientific background ability and satisfaction. The dimensions of effectiveness in this study are based on the assessment of patients on aspects of patient examinations carried out regularly, giving explanations at the beginning before carrying out the action, giving encouragement in terms of healing, deft in carrying out various actions and being able to complete the task independently.

The effect of effectiveness on the quality of health care services for national health insurance participants at Benteng Health Center in 2016, the results of statistical analysis using linear regression obtained a value of $\rho = 0.000 < \alpha = 0.05$, meaning $H_0$ is rejected and $H_a$ is accepted so that there is an effectivity on service quality health of participants of the National Health Insurance.

The results of this study are in line with the research conducted by on the analysis of inpatient satisfaction at Lanto General Hospital. Pasewang where there is a significant relationship between human relations (effectiveness) and patient satisfaction with and the results of statistical tests obtained a value of $\rho = 0.001$, his research explains that good human relationships will instill trust and credibility by respecting, keeping confidential, respectful, responsive and giving attention, listening to complaints and communicating effectively are also important. Relationships between good people will have a big contribution in effective counseling. Poor human relations will reduce the effectiveness of technical competencies in health services. Patients who are treated poorly tend to ignore the advice and advice of health workers. The presence of patients who are satisfied with the services of the officers is that they are quickly served by the clerk.

Effect of Efficiency on Quality of Health Services

The distribution of respondents based on efficiency at Puskesmas Benteng in 2016 was obtained from 96 respondents studied, the number of respondents who stated efficient efficiency was 88 respondents (91.7%) and respondents who stated inefficient as many as 8 respondents (8.3%) . This can be caused by patients feeling that health workers provide services according to the procedure with the promised time right in providing good service when doing registration, drug collection and health workers provide an explanation of the rules for using drugs according to the prescription given by the doctor. While respondents who stated the efficiency of the dominant inefficient staff were also distributed to the quality of health services in the quality category as much as 5 (5.2%). If reviewed in more depth, the achievement figures need special attention. The lack of efficiency possessed by health workers at the health center including nurses who provide services to patients can affect the quality of services held.

On table 7 the effect of efficiency on the quality of health care services for national health insurance participants at Benteng Kota Palopo Health Center, the results of statistical analysis using linear regression obtained a value of $\rho = 0.000 < \alpha = 0.05$, meaning $H_0$ was rejected and $H_a$ was accepted so that there was an effect of efficiency on service quality health of participants of the National Health Insurance with the interpretation
that there is an influence of the efficiency of officers on the quality of health services where the number of responsive officers in providing services is an element that influences the patient’s assessment of the quality of services held. Suprapto’s research\textsuperscript{13} states that the ease of administration with the accuracy of working hours of health workers in providing services has a significant effect on patient satisfaction at Sragen District Hospital.

The results of this study are in line with the research conducted by Nur Ifah Intan Suaib\textsuperscript{14} with the title Relationship between the quality of health services and satisfaction of BPJS patients in Luwu District Hospital. The results of statistical tests using fisher’s exact text obtained a probability value ($\rho = 0.000$). The probability value obtained is $\rho <0.05$, then the null hypothesis is rejected or there is a significant relationship between efficiency and satisfaction of BPJS patients in Luwu District Hospital.

**Conclusion**

Based on the results of data analysis and discussion of the results of research on factors that affect the quality of health services for participants of the National Health Insurance at Benteng City Palopo Health Center in 2016, conclusions can be drawn as follows:

1. There is an influence of technical competence on the quality of participant health services National Health Insurance at Benteng Community Health Center in Palopo City. The results of the linear regression statistical analysis, the value of $\rho = 0.000 <\alpha = 0.05$ means that $H_0$ is rejected and $H_a$ is accepted.

2. There is an effect on the effectiveness of the quality of health care for participants in the Guarantee National Health at Benteng Community Health Center in Palopo City. The results of the linear regression statistical analysis, the value of $\rho = 0.004 <\alpha = 0.05$, means that $H_0$ is rejected and $H_a$ is accepted.

3. There is an effect of efficiency on the quality of health services for participants of the National Health Insurance at the Benteng Health Center in Palopo City. The results of the linear regression statistical analysis, the value of $\rho = 0.000 <\alpha = 0.05$, means that $H_0$ is rejected and $H_a$ is accepted.

Policy Concept of Public Health Services on Regionalization of JKN Referral Systems in Border Areas

Amir Mahmud Hafsa¹, Alimin Maidin², Sukri Palutturi³, Stang⁴

¹Doctoral Student Program, Faculty of Public Health, ²Dentistry Department, Faculty of Dentistry, ³Hospital Management Department, Faculty of Public Health, ⁴Health Administration and Policy Department, Faculty of Public Health, ⁵Health Biostatistic Department, Faculty of Public Health, Universitas Hasanuddin, Makassar, Indonesia

Abstract

The purpose of this study was to examine and analyze the concept of public health service policy offerings for the regionalization of the national health insurance referral system in the district / city border area in South Sulawesi Province. Research methods. This study used qualitative and carried out in three government agencies, namely the South Sulawesi Provincial Health Office, Daya Regional Hospital and Wahidin Sudiro Husodo Hospital as Tertiary Hospitals. Data retrieval was carried out from September 2016 to May 2018 with in-depth interviews as primary data and retrieving documents as supporting data in related institutions as secondary data. Determination of informants with purposive sampling technique. Data collection is done by in-depth interviews, observation, focus group discussions (FGD). Data analysis was carried out qualitatively descriptive by obtaining data / information from informants, describing data records, then preparation of analysis by reducing data to meaningful and more concise information, the way is to do coding or code then summarize again in the form of categories and relationships between categories, studies This uses 4 ways to increase trustworthiness, namely; thick description, negative case analysis, triangulation, member checking. Results. The community considers the regionalization of the referral system makes it difficult for people in border areas, besides very far access, sometimes it is very difficult to reach, the costs incurred are far more expensive, seem complicated, if people follow queues sometimes for long periods, in primary services such as clinics / health centers.

Keywords: Health Referral System, Regionalization, National Health Insurance

Introduction

Government policies, especially health policies, can be influenced by the political, economic and cultural conditions of the community in accessing health services with a tiered service system, especially in border areas between provinces and between districts / cities, one region or another region. Health insurance is a guarantee in the form of health protection so that participants get the benefits of health care and protection in meeting basic health needs given to everyone who has paid contributions or fees paid by the government. The National Health Insurance as a National Health Sector Program which was enacted on January 1, 2014 as an effort to overcome various problems related to health services. According to Ribot and Peluso access is the ability to benefit from something or the right to obtain something power. Whereas according to Schlager and Ostrom. Definition of access is the right to enter, use, and utilize certain regions or zones. Increased access to health services is one proof of the government’s seriousness in improving the quality of public health services. Organizational climate is very influential on the support of team performance, motivation, and values of the community and the government as a motivator, regulator of the implementation of health services for every citizen. Facilitating chronic disease sufferers in accessing health services by reducing queues for chronic disease participants. Complementing health facility needs and increasing the competence of health workers.
in all regions of Indonesia, so as to be able to handle cases according to the level of service, one of which is to reduce unnecessary referral cases. Primary health care or primary health care acts as a gate keeper where first person or community contact with health services occurs.

Materials and Method

The research method used is qualitative research. This research explores more about access to hospital referral systems in the border areas in South Sulawesi. The focus of this study is on developing a tiered Hospital Referral System Regionalization Model on the National Health Insurance (JKN) in border areas for medical and non-medical staff in regional hospitals and tertiary hospitals, as well as provincial health offices. The Basics of Qualitative Research is constructivism which assumes that reality is plural, interactive and an exchange of social experiences interpreted by each individual.

Results and Discussion

General description of the people of South Sulawesi

South Sulawesi Province is located at 0° 12' - 8° South Latitude and 116° 48' - 122° 36' East Longitude. The area is 62,482.54 km². Administratively, the boundaries of the South Sulawesi Province: North side with Central Sulawesi Province, West side with Makassar Strait, East side with Bone Bay and South side with Flores Sea. The area is 62,482.54 km² (42% of the total area of the island of Sulawesi and 4.1% of the total area of Indonesia). South Sulawesi has a strategic location in Eastern Indonesia allowing South Sulawesi to function as a service center, both for Eastern Indonesia and internationally. The Makassar tribe itself consists of several sub-tribes that are widespread in the southern part of Sulawesi island, spread from Makassar City, Gowa Regency, Takalar, Jeneponto, Bantaeng, Bulukumba, Selayar, Maros, and Pangkep. The sub-tribes are, for example, the Makassar Lakiung tribe, Turatea (the Jeneponto and Bantaeng tribes), the Konjo Tribe (Bulukumba and Part of Maros), and the Selayar Tribe.

Geographical Location / border problems of an area

The regionalization of the referral system is the answer that indeed this program has long been issued by the Government of South Sulawesi long before there was a central government program called JKN, which was the first and best South Sulawesi and JAMKESDA service model to be in line with the time of cultural development. Current cultural socialization with regionalization, some people consider, this is no longer appropriate, there needs to be a model development, even some informants say the regionalization of the JKN referral system violates human rights, the problem for regions where development is approaching prosperity, because the system is limiting and not give the same rights to each region both in the development of health facilities and human resource development so that everyone to do, provide services, get the same health services. Based on the results of interviews with informants R1, R2, as stated in the following:

Informant R1 assumed that the information provided was data in accordance with the objectives of the hospital referral system realization during the Jamkesda period, Jamkesmas, better known as Pergub (governor’s regulation) South Sulawesi Number 15 of 2008, which had an JKN referral system supported by interviews with informants. R2, which states that:

The Jeneponto community that borders Bantaeng prefers Bantaeng to seek treatment, feeling secure, fast, access to services is far better the consequences are not borne by the BPJS because it does not follow the tiered SOP referral system, hoping that in the future there will be a joint rule or MOU region wherever, whenever he is sick, it is important that he is registered as a member of the BPJS and has fulfilled his obligations according to Universal Health Coverage (R26)

The concept of American health policy is that every border area must have Hospital Post, which is a hospital that serves the community between two border areas far from one district to another, our country has not yet been able to make policies, conceptualize integrated referral system policies or Joint MOU that communities near other cities can do hospital services such as Barru patients with Pare pare, Takalar near Gowa, where health facilities are closer, as well as other areas throughout South Sulawesi (R13 45 years)

The distance and travel time of my research and your research and supporting theories or refute my results. Furthermore, distance and travel time, based on the results of interviews in research obtained or found through the South Sulawesi provincial Health Agency, Wahidin Hospital Sudirno Husodo (Ka UGD), and Daya Hospital and experts assume and argue almost
the same as the social phenomenon in health services. The following is an interview quote from the informant R1, R2: To break the distance chain very far so that public health services are faster to health facilities, automatically the community benefits more, transportation costs, expenses and financing for the patient’s family are reduced, the Pergub continues to run in the BPJS shutter and provides quality and high quality health services. there is an MOU between two regions (R1, R2), because access is easier, the people of Soppeng who want to be referred prefer to go to Pare-pare Hospital compared to Bone Hospital as well as distance, have arrived at Pare Pare Hospital, but have not traveled to Bone (R26) Hospital.

The same thing was said by R2 and 3 other informants who also objected to the policy on regionalization of hospital referral systems due to research that said the program did not work in accordance with the objectives of the flagship program than Governor Sahrul Yasin Limpo as the following: There is no analysis of distance and travel time when determining the region in the regionalization policy of the referral system so that the distance between one region to another is very far in one region, causing the community to choose the closest health facilities even though it is risky because they have to pay for the services they receive or become a general patient (R2, R3, R5, R7).

He was the former head of the health department for 5 periods, he was very critical of the policies issued by the Governor of South Sulawesi and his statement: The Tolo community in Jeneponto Regency to the mountains prefers to cross to Bantaeng because it is close and the feeling of comfort is handled directly by a specialist doctor, even though it is not borne by the BPJS to be a general patient (R13, R14).

**Accessibility of Health Services**

The limited facilities, infrastructure, governance of human resources of health workers are a classic problem in health services, especially in South Sulawesi and in Eastern Indonesia and in Indonesia as general as possible. The government has carried out various efforts to improve access to health services both from the aspect of infrastructure, strengthen the health care system through financing mechanisms, referral systems, human resource development and distribution of health personnel.

Health service access is then linked to the concept of equity (fairness) or the concept of justice in health services is defined as eliminating the difference in health services provided to all communities regardless of RAS social status and religion and belief flow. Equity means that all communities have the right to get equality in accessing health services according to their needs, the equality of utilization of health services in common health outcomes.

The term equity is divided into two, namely horizontal equity and vertical equity. Horizontal equity related to health services in the community by that in certain cases the community must get the same treatment for the same needs. Whereas vertical equity is the fulfillment of rights to health services must be adjusted to the proportion and needs, in accordance with the diagnosis of the disease they suffer or assuming that people who need complex treatment means entitled to more perfect health services.

A figure as well as Head of the South Sulawesi Provincial Health Office and at the same time the initiator of the issuance of Pergub No. 15 of 2008 on Hospital Regionalization of the Referral System at the time of the Free Health health service is still in terms of what we call JAMKESMAS and JAMKESDA. yes it was made and still applied after the health service system from JAMKESMAS integrated into JKN as which was assumed by the informant R1 and 11 following:

Besides the reasons for being closer and very young to reach, the people of the western part of Soppeng Regency, Soppeng Batu Batu, are adjacent to Sidrap Regency, assuming referrals to Pare Pare Hospital are younger, compared to Bone City, as well as in Luwu with characteristics of Luwu region. walenrang and the characteristics of all of South Sulawesi which are not owned by other regions or other provinces in Indonesia (R1 59 years, R2, 45 years). The pros and cons of the regionalization of the current JKN referral system are as stated by the informants as follows:

If there is no in-house room, Sisrute is looking for, communicating throughout the hospital that is collaborating with Wahidin and Sisrute Hospital which plays a role until there is a response, because the patient arrives at the referral but there is no treatment room so there must be info on facilities and infrastructure even certain things if there is a patient who needs a specialist,
sisrute can help so that it can improve the quality of hospital services (R14).

To be able to access the referral, the BPJS policy must be permitted, because the quota system in an area such as Rp. 99 thousand is paid here means that the money is here if it is to be serviced within a month or not. those who come don’t care who they will be treated the same, so, the policy is that people must be able to report to BPJS or other parties (R18).

**Conclusion**

Actually regionalization of the referral system needs to be revised, there is no need for regions in terms of health services, wherever whenever an important sick community is registered with BPJS participants the BPJS is obliged to serve it, so regionalization of the JKN referral system is only for health facility development and health HR development. The concept of health policy in America, every border area must have a health post or hospital post, namely hospitals that serve the community between two border areas that are far from one district to another, our country has not yet been able to conceptualize regionalization system integrated referrals or Joint MOUs such as Barru patients with Pare pare, Takalar near Gowa, where health facilities are closer, as well as other areas throughout Indonesia (R45)

Microbiome Alterations on Incidence Chronic Rhinosinusitis with Nasal Polyps of Indonesians

Muhammad Fadjar Perkasa1, Amelia Dian Utami1, Riskiana Djamin1
1Department of Otolaryngology Head and Neck Surgery, Medical Faculty, Hasanuddin University, Makassar, Indonesia

Abstract

Background: Affects approximately 10% of general population, leads to decrease quality of life, lost productivity as well as increase financial burden to society. Chronic rhinosinusitis with nasal polyps (CRSwNP) recognize as a benign nasal growths that usually arise as a result of chronic paranasal sinuses inflammation. Alteration of microbial composition may cause increasing the incidence of allergic disorders and contribute to the development and chronicity of inflammatory disease

Objective: Investigate histopathology of nasal polyps and nasal microbiome in chronic rhinosinusitis with nasal polyps of Indonesians

Materials and Method: This study was conducted using the case control technique on 10 patients of CRSwNP. All of the samples examined by next generation sequencing technique and nasal polyps histopathological examination.

Results: The non eosinophillic type is a dominant in CRSwNP while Actinobacteria, Bacteroidetes, Cyanobacteria, Firmicutes, Fusobacteria, and Proteobacteria were the dominant phylum in CRSwNP with variation number of percentage.

Conclusion: This study highlights alteration of microbial composition of CRSwNP and its histopathological examination.

Key Words: Chronic Rhinosinusitis, CRS, CRSwNP, Microbiome, Proteobacteria, Histopathology, Dysbiosis

Introduction

Chronic rhinosinusitis (CRS) is a chronic inflammatory disease of the nose and paranasal sinuses around 8-12 weeks defined by two symptoms, nasal blockage/obstruction/congestion, nasal discharge, facial pain/pressure, and/or reduction or loss smell with endoscopic examination or relevant CT scan changes.1,2 Affects approximately 10% of general population, leads to decrease quality of life, lost productivity as well as increase financial burden to society and causing to a further than a million operative interferences per year worldwide.3

Two main category of chronic rhinosinusitis based on absence or presence of nasal polyps (CRSsNP; Chronic rhinosinusitis without nasal polyps and CRSwNP; Chronic rhinosinusitis with nasal polyps)1,3

Chronic rhinosinusitis with nasal polyps (CRSwNP) recognize as a benign nasal growths that usually arise as a result of chronic paranasal sinuses inflammation.4 In Western countries, most of the nasal polyps are eosinophilic while in East Asian countries are noneosinophilic types.

Despite late research evidence that conduces to advance revealing the pathophysiology of these chronic...
airway conditions, the cause remains badly understood and seems to be multifactorial. The microbiome concept emerged to be one of the mechanisms contributing to the inflammation of CRS. Numerous studies indicate that changes in the airway microbiota may be affiliated with inflammatory process.\(^5\)

It is generally considered that the presence of microorganism on airway mucosal surfaces may compromise health. Microbiome has major roles in a healthy environment, the more bacteria existence as a richness, diversity and evenness, the healthier will be. Alteration of microbial composition may cause increasing the incidence of allergic disorders and contribute to the development and chronicity of inflammatory disease.\(^6\)

Here, we investigate histopathology of nasal polyps and nasal microbiome in chronic rhinosinusitis with nasal polyps of Indonesians.

**Material and Method**

**Ethics Statement, Study Design and Patient recruitment**

Diagnosis of Chronic rhinosinusitis was made according to The European Position Paper on Rhinosinusitis and Nasal Polyps.\(^1\) CRSwNP patients were informed about the study and invited to participated, scheduled for endoscopic sinus surgery on all paranasal sinuses for the treatment of CRS. Written informed consent was obtained from all participants. Diagnosis of CRS was made according to the European Position Paper on Rhinosinusitis and Nasal Polyps 2012. Exclusion criteria included Immunodeficiency, sinonasal malignancies and tumor, Atroficans rhinitis, patients with previous surgical history and age <18 years old.

The study protocol and ethical clearance was approved by Biomedical Research Ethics Committee on Human Faculty of Medicine Hasanuddin University, Makassar, Indonesia (Register number:14/UN4.6.4.5.31/PP36-KOMETIK/2019).

Study participants were conducted in 2019 at Wahidin Sudirohusodo Hospital, Hasanuddin University Hospital and Mitra Husada Hospital Departement of Otorhinolaryngology, Head and Neck Surgery, Hasanuddin University, Makassar, Indonesia.

**DNA Extraction Library Preparation and Sequencing**

Entire genome DNA by samples was elicited using CTAB/ SDS method. DNA concentration and purity was monitored on 1% agarose gels. Conording to the concentration, DNA was diluted to 1ng/µL using sterilised water.

Amplification of the 16S rRNA gene V3-V4 region was executed by using specific primers designed to anneal to 341F and 806R. This resulted in amplicon sizes around ~466bp. All further steps in library preparation were did according to the Illumina “16S Metagenomic Sequencing Library Preparation” protocol.

**2.6 Sequence Analysis**

Sequences analysis were performed by Uparse software (Uparse v7.0.1001) using all effective reads. Sequences with ≥ 97 % similarity were assigned to the same OTUs. Representative sequence for each OTU was screened for further annotation. For each representative sequence, Morthur software was performed against the SSUrRNA database of SILVA Database for species annotation at each taxonomic rank.

**Results**

**Participant Characteristics**
Within the period of study, we recruited ten patients with chronic rhinosinusitis with nasal polyps (CRSwNP). We examined the pathological histology of the nasal polyps and investigated microbiome of the uncinate process. The age characteristic and gender distribution shown in Table 1

Sequencing Result

Single-ends reads was assigned to samples based on their unique barcode. Quality filtering on the raw reads were performed under specific filtering conditions to obtain the high-quality cleans reads. A total of 900,783 raw sequences passed quality filtering steps and after chimera removal, we obtained 753,805 reads, which had passed all quality filters under 97% identify conditions.

Microbial Identification

The microbial communities in the sinuses of chronic rhinosinusitis with nasal polyps subjects were represented in the Phyla *Proteobacteria* (54.86%), *Firmicutes* (21.06%), *Cyanobacteria* (12.51%), *Fusobacteria* (4.15%), *Actinobacteria* (4.05%), and *Bacteroidetes* (3.37%) shown in Figure 1, table 3 and table 4.

Discussion

This study investigated the bacterial microbiome of chronic rhinosinusitis with nasal polyps patients and histopathological examination of nasal polyps.

In this current study, samples was varied from 18 years old to 62 years old. The prevalence of CRSwNP was higher in female (60%) than male (40%). There are variety conditions related to chronic nasal inflammation due to nasal polyps. The age at which nasal polyps be found is variable and not link to any precipitating factors.

The histopathological examination reported dominated by the neutrophilic type (noneosinophilic) (70%). Previous studies founds nasal polyps tissue excised from CRSwNP during surgery in Asian countries, have dominant non eosinophilic type while in western countries tend to have eosinophilic type, the Asians population have a lower incidens of atopy which correlated with eosinophilic polyps. Environmental and genetical factors might influence the histopathological results and considered that may modify the microbial composition.

The predominant phyla in this study are Actinobacteria, Bacteroidetes, Cyanobacteria, Firmicutes, Fusobacteria, and Proteobacteria, with the most abundance is Proteobacteria (54.86%). From ten samples patient that we recruited, 50% had Proteobacteria as a predominant phyla, 4 samples with Neutrophilic type and 1 sample with eosinophilic type of histopathological examination result. Three samples had Firmicutes as a predominant phyla 2 samples with Neutrophilic type and 1 sample with eosinophilic type of histopathological examination result. Three samples had Actinobacteria as predominant phyla with Neutrophilic type and one sample had Cyanobacteria with eosinophilic type.

The research about microbiome of lower respiratory tract still in early start. Some of reports indicate a precense of Proteobacteria in asthmatic patients. Ramakrishnan et al, 2015 found abundance of this phyla was similar among asthmatic and non asthmatic patients with CRS. The study about genera within Proteobacteria phyla found alteration in several genera of moderate abundance. Proteobacteria might contribute to the pathogenesis of CRSwNP disease via eicosanoids and related mediators.

Previous study revealed, the bearing of nasal polyps wasn’t affiliated with alterations in the nasal microbiome. Among patients on CRS, allergic rhinitis was associated with diminished Actinobacteria levels at the phylum level. The Actinobacteria was consist in the healthy nasal microbiota and believed as key species and potentially beneficial microbe that maintain the healthy state of sinonasal environment, previous study has been revealed that it produce bacteriocins which have antibacterial and antifungal activity that may protected against pathogens.

Our study agreed that microbiome alteration seems to happens in this research. The potential microbe that proved maintaining the sinonasal healthy environment was less dominated in this study. It still unclear, and still remains further study whether pathophysiology of CRSwNP had correlation with this altering condition of microbiome or had another myriad factor that contribute to this condition, since the immunological factor remains more dominating inflammation condition of CRSwNP.

Conclusion

Our study showed microbiome alteration and its possibly correlation with histopathological examination. Alteration composition of microbiome in sinonasal cavity might have role in chronic inflammation leading to disease state. Further investigation involved larger participants, include the history of asthmatic and atopy of the participants, and its correlation with proinflammatory cytokins patterns.
Conflicts of Interest: The authors have no conflicts of interest to declare.

Cadre Behavior as Social Capital for the Development of TB Care Community in the Management of Tuberculosis in Medan City

Syarifah¹, Erna Mutiara², Sri Novita³

¹Department of Health Education and Behavioral Sciences, ²Department of Population and Biostatistics, ³Department of Epidemiology, Faculty of Public Health, University of Sumatera Utara, Medan 20155, Indonesia

Abstract

It is estimated that around one third of the world’s population has been infected by Mycobacterium tuberculosis, about 95% of TB case and 98% of death from TB in the world occur in various developing countries. The Incidence Rate (IR) of TB in North Sumatera Province is 501/100,000. Moreover, the Prevalence of TB in Medan has been increasing for three consecutive years. In Strategy 5 of TB Prevention Strategy Plan, it is acclaimed the importance of the community’s role in promoting, case discovering, and TB treatment support, as well as community empowerment through TB integration in family and community-based health effort. To achieve it, the role of cadre as social capital is very essential in developing TB Care community, through mentoring from TB Care community in Higher Education as a Health Department partnership in TB control. For this reason, a study is performed to discover the behavior of cadres after receiving training. The research method is Quasi-Experiment pre-test post-test group design. The population of the study is all health cadres in Helvetia sub-district of Helvetia Community Health Center and Sukaramai Village I of Medan Area Community Health Center of 15 cadres. The training is conducted at the Medan Area Community Health Center, the training methods are lecture, discussion, and role playing (simulation). The analysis or normally distributed data is performed through T test and for the abnormally distributed data, using the non-parametric statistics Wilcoxon signed Rank Test. The result shows that the majority respondents are above 40 years old, with high school diploma, and entrepreneurs, these characteristics will affect their activity as cadres. There is a significant relationship between knowledge before and after cadre training (p < 0.05). The mean value at the pre-test was 40.87 and after being given training, it increased to 50.67, thus the training methods of lecture, discussion, role playing can increase cadre knowledge in prevention, finding, and control of TB and TB RO. There is a significant relationship between attitudes before and after cadre training (p = 0.05). It can be concluded that cadres as potential social capital are used as the development of the TB Care community which will coordinate with the TB Care PT community, in order to improve case finding in the context of TOOS TB.

Keywords: cadre behavior, TB case finding, cadre empowerment, TB Care Community

Introduction

According to the WHO report in 2017, there were an estimated 1,020,000 cases in Indonesia. The 2013 prevalence survey and 2015 global TB report displayed that the IR TB in North Sumatara province was at 501 / 100,000¹ ². In the context of the challenge of overcoming TB elimination there are 6 (six) strategies developed by JEMM (2013). One essential strategy is Strategy 5, which is Increasing Community Independence in TB Control, which includes: involvement of community roles in promotion, case finding, and support for TB treatment and community empowerment through TB integration in family and community-based health efforts³. Health cadres are the members of the community, who can provide promotive services, preventive and curative services appropriate for the needs of local communities⁴. Health cadres are important social capital in the community both in rural and urban areas. Social
capital is a concept that is frequently used to describe social capacity to fulfill life needs and maintain social integration. The definition of social capital that has developed so far leads to the formation of three levels of social capital, namely on the level of values, institution, and mechanism.

Health cadres are the members of the community who can provide promotive services, preventive and curative services according to the needs of local communities. Health cadres provide great support to develop strong commitments and provide more creative solutions to improve CDR. Health cadres participate in the planning, implementation, monitoring, and evaluation of TB programs. Meanwhile, according to Awfeso (2008) the role of cadres in the community is: 1) Conducting counseling to the community; 2) Referring patients who suffer from cough for more than 2 weeks to receive sputum pot at the Posyandu; 3) Supervising the taking of medicine for pulmonary TB; 4) Spreading the awareness of completing the treatment; 5) Describing the efforts to prevent and transmit TB disease to the patients and the community; and 6) Recording and reporting. Furthermore, Holtgrave et al. (2004) reveal that highly educated cadres have the ability and experience as valuable human resources for an organization.

According to the problems above, health cadres are empowered as citizens who are able to motivate the community to discover TB cases, as well as reduce the risk of transmission to the community through the development of the TB Care community. The purpose of this study is to analyze the behavior of cadres in discovering Tuberculosis (TBC) cases, treatment until recovery, knowledge of MDR TB and prevention of transmission to the family. After receiving the training, they are expected to be social capital in the development of the TB Care Community in Medan City.

Materials and Method

The design of this study is Quasi Experiment pre-test post-test design. The population in this study are all health cadres in the work area of Medan Area Health Center and Medan Helvetia Community Health Service. As for the sample, one village is selected as an area with high urban MDR TB cases and one village is chosen with low MDR TB cases in Medan City. The result of the observation showed that Helvetia Village in the Medan Area Community Health Center working area represents as an area with low MDR TB cases, there are 15 cadres in these areas that become the sample and receive the training.

The training is held in the Medan Area Community Health Center Meeting Room on 30-31 October 2018. The materials and training modules provided are modified from the cadre training curriculum of the Indonesian Ministry of Health in 2018. Training materials included: 1) Introduction to TB; 2) Introduction of MDR TB; 3) Cadre Role in TB Control; 4) Case Finding of Active TB through Family / Community Approach; 5) Active Case Finding and Contact Investigation by TB Cadre; 6) Mentoring of TB Patients by Cadre; 7) The Tracking of Absent TB Patient. The training is conducted with lecture method, question and answer discussion, video playback, and role playing especially for Active Case Finding material and Contact Investigation.

The data collection is conducted with questionnaire before the training and at the end of the training to measure the changes in knowledge of attitudes and actions before and after the treatment. Data analysis for normally distributed data use T test, while for abnormally distributed data use the non-parametric statistics Wilcoxon signed Rank Test. The intervention action and questionnaire have received ethical clearance from the Faculty of Nursing No.1319 / III / SP / 2018 of 2018.

Result and Discussion

The Knowledge, Attitudes, and Action of Cadres After Receiving Training as Social Capital for the Development of TB Care Community

The cadre training as respondents has been carried out as the forerunner to the establishment of a village that concern with TB Care which is expected to empower the community in the prevention, finding, and control of TB Care. The following will be describing the characteristics of respondents including: age, education, occupation. As can be seen in the following description.
### Table 1. Proportion Distribution of Characteristic of Cadres as Social Capital for the Development of TB Care Community in Medan City in 2018

</tbody>
</table>

The majority of respondents are above 40 years (53.3%), and the remaining is ≤ 40 years. At this age, cadres are expected to be able to work actively outside, such as in Posyandu and in the community because they no longer have to cater to their children. Furthermore, if associated with the occupation of the cadres who are unemployed and are entrepreneurs, their time can indeed be used to help the community. The result of the study is similar to the result by Chatarina Umbul and Kurnia which reveals that the highest number of cadres are at senior age and they are more active because they have more free time in the morning and to nourish citizens in their environment.

The majority of respondent are high school graduates, education is one of the bases in developing potential and social capital. This study is similar with a study conducted by Katerina Umul that shows that there are more cadres with high school diploma. Education contributes to a person’s behavior because through adequate education it is expected to have a broad thinking horizon so that they are able to quickly receive health information that ultimately can provide the basic capital for behavior change.

### Table 2. The Influence of Cadre Training as Social Capital for the Development of TB Care Community in Knowledge, Prevention, and Finding of TB Cases in Medan City in 2018

<td>Post Test</td>
<td>15</td>
<td>50.67</td>
<td>50.00 (33 – 72)</td>
<td>11.757</td>
<td></td>
</tr>
</tbody>
</table>

In accordance with Table 2, it is known that there is a significant influence between knowledge before and after cadre training (p < 0.05). The mean value at pre-test was 40.87 and after the training it increased to 50.67, it indicates training with lecture method, discussion, and role playing could improve cadre’s knowledge for the development of TB Care Community in the prevention and finding of TB and MDR TB.

After being given training, there are 13 people who answered questions about the role of cadres in 6 activities. This result is consistent with a research conducted by Pratiwi, Betty, Hargono, Widya (2012), which states there is an upgrade in knowledge of 12.5% before and after tuberculosis training. Training with the lecture method effectively increases the knowledge and attitudes of health cadres about tuberculosis. Moreover, a study conducted by Chatarina and Kurnia also demonstrates that after training the cadres, there is a significant difference between knowledge about TB at pre-test compared with post-test (p value < 0.05). Furthermore, a study conducted by Ni Putu Sumartini about strengthening the role of health cadres in the finding of tuberculosis cases through education with the Theory of Planned Behavior approach can increase cadre knowledge. In addition, a study by Azizah on the training to improve the ability of health cadres in handling tubercularosis (TBC) in the work area of Sragen II Community Health Center also displays that there is an 80% increment in knowledge after receiving the training. Followed by a study by Ni Putu Eva Yanti about Controlling Tuberculosis Cases Through TB Care Cadres Group also exhibits that there is an increase in knowledge of TB Care Cadre Group (Kelompok Kader Peduli TB/KKP-TB) in controlling TB after receiving training.
Table 3. The Influence of Cadre Training as Social Capital for the Development of TB Care Community On Attitudes About Prevention, Controlling, and Finding of TB Cases in Medan City in 2018

<table>
<thead>
<tr>
<th></th>
<th>n</th>

<td>0.005</td>
</tr>
<tr>
<td>Post Test</td>
<td>15</td>
<td>133.13</td>
<td>132.00 (105 – 154)</td>
<td>13.092</td>
<td></td>
</tr>
</tbody>
</table>

Refer to Table 3, there is a significant influence between attitudes before and after cadre training (p = 0.05). Judging from the median value, there is an increase in cadre attitudes, before the value was 123.00 then it increased to 132.00 after receiving training. This is in line with a research conducted by Nur Fadilah et al. about the cadre behavior in the finding of TB suspects. Good attitude is generally related to internal behavior.

Through Monopoly Simulation Games, reveals that there are differences in attitudes of respondents regarding TB after good intervention and 1 week after intervention. Next, Ni Putu Eva Yanti on controlling tuberculosis cases through TB Care Cadre Group displays that there is an increase in attitude of the TB Care Cadre Group in controlling TB after receiving training.

Table 4. The Influence of Cadre Training as Social Capital for the Development of TB Care Community On Action Before and After Training in Medan City in 2018

<table>
<thead>
<tr>

<td>11.252</td>
<td>0.001</td>
</tr>
<tr>
<td>Post Test</td>
<td>15</td>
<td>31.87</td>
<td>32.00 (30 – 32)</td>
<td>0.516</td>
<td></td>
</tr>
</tbody>
</table>

In accordance with table 4, with the Kruskal Wallis test it is known that there is a significant influence between the action before and after cadre training (p < 0.05). Based on the median value, there are changes, namely the median value after training is higher (32.00) than before the training (30.00).

Consistent with a research performed by Eko Wahyudi et al on the Relationship of Cadre Knowledge, Attitudes, and Motivation with the Discovery of Suspected Pulmonary Tuberculosis in Sanankulon Community Health Center, there is a positive and significant relationship between cadre knowledge, attitudes, and motivation with the discovery of suspected pulmonary TB at Sanankulon Community Health Center (p-value = 0.00 and R2 = 0.691). Moreover, similar to a study by I Made Kusuma Wijaya et al (2014), there is a significant relationship between knowledge, attitudes, and motivation with health cadre activities; Health cadres with high knowledge are more than 18 times more likely to be active than cadres with low knowledge; Health cadres with good attitudes are 8 times more likely to be active than cadres with less attitudes; Highly motivated health cadres are 15 times more likely to be active than cadres with low motivation.

Conclusion and Suggestion

Conclusion

The majority age of the respondents is above 40 years, are mostly high school graduates, and the majority of them work as entrepreneurs. These characteristics will affect their activity as cadres.

There is a significant influence between knowledge before and after cadre training (p <0.05). The mean value at pre-test was 40.87 and after being given training it increased to 50.67, thus training with lecture method,
discussion, and role playing can increase the cadre knowledge in prevention, finding, and control of TB and MDR TB.

There is a significant influence between attitudes before and after cadre training (p = 0.05). Judging from the median, there is an increase in cadre attitudes, before the value was 123.00 then it increased to 132.00 after receiving training.

The Effect of Video on the Change of Attitude Toward Stunting Prevention among Children in State Senior High School 1 Topoyo, Central Mamuju

Ismail Kamba1, Amran Razak2, Sirajuddin Saifuddin3, Sukri Palutturi4

1Department of Community Nutrition, Mulawarman University, 2Department of Health Policy Administration, Hasanuddin University, 3Department of Community Nutrition, Hasanuddin University, 4Department of Health Policy Administration, Hasanuddin University

Abstract

The reduction of infants stunting is still very limited to pregnant women and Baduta or Children under two years old. Form of education provided to society need to be more persuasive in order to increase action to solve practical problems and improve their health. This study aimed to examine the effect of video compared to video plus explanation on students’ attitude in order to prevent stunting in the State Senior High School 1 Topoyo, Central Mamuju. This research was conducted on January 7th, 2018 until January 7th, 2019 in Topoyo, Central Mamuju Regency, West Sulawesi Province. The population of this study were all male and female students at State Senior High School 1 Topoyo totaled 710. Control sample was decided by using a ratio of 1:1, so that the total of sample are 342 students (171 + 171). The results showed that there was attitude change before and after intervention by watching video and video plus material explanation from instructor about first 1000 days of life (1000 Hari Pertama Kehidupan / HPK) and stunting prevention among children under five years old, which means that the video had an influence (p = 0.000); there was no change found in the control group after intervention (p = 0.713). Furthermore, there was difference between the use of video and the use of video accompanied by explanation (p= 0.000). It is suggested that efforts targeting public attitude change toward stunting prevention should be done earlier, ranging from primary to secondary education. Socialization about stunting prevention need to arrange systematically by government, so that the negative impact of malnutrition will be minimized.

Keywords: Attitude, Stunting, HPK.

Introduction

Based on data from Global Nutrition Report, Indonesia is ranked 15th of back sequence1-3. Hence, Indonesia is considered as the 15th worst stunting case in the world after Madagascar2-4. The worst stunting rank in the world are Timor Leste (57.7 %), Madagascar (49.2 %), Guatemala (48.0 %), Pakistan (45.0 %), Lao People’s Democratic (43.8 %), Republic Mozambique (43.1 %), Nigeria 43.0%, Malawi (42.4 %), the Central African Republic (40.7 %), Ethiopia (40.4), Chad (38.7 %), India (38.7 %), Mali (38.5 %) and Indonesia which is ranked fifteen in the world stands at 36.4 %)1-3.

One third of children in the world who are stunted are in India, and children in rural areas are worst affected5-7. The determinants of stunting among indigenous children in Jharkhand and Odisha Village, India, require intervention and treatment8,9. World Health Organization (WHO) reported that a total of 49.2% of children were chronically malnourished in Madagascar6,10, placing the country suffered the highest prevalence of stunting in the world6, 11. Short children as a result of chronic malnutrition will cause short term and long term adverse consequences if not addressed at an early age5. Short-term risks are susceptible to various infectious diseases such as diarrhea and pneumonia due to a weakened immune system12.

The results of basic health research in West Sulawesi found that the proportion of the national short toddler occurred between 2007 and 2013. This proportion is 19.2 percent of short and 18 percent of very short. Total
stunting of 37.2 percent\(^{(13)}\). West Sulawesi ranked top
5 and stood at a very short category at 22.3 percent,
while short category was 25.7 percent. Toddlers with
nothing short category stood at 52.0 percent. This means
that there are approximately 48.0 percent of children
under five in West Sulawesi who suffered stunting. The
average percentage is much higher than the national
average which the difference in numbers is about 10.2
percent compared to 37.2 percent of national stunting\(^{(13)}\).
As is known, stunted children are not able to reach their
developmental potential, they have weak cognitive
performance and low educational achievement than
those with good nutrition. Children who are chronically
undernourished experience the highest prevalence of
stunting. Stunting due to chronic malnutrition will cause
a short child if not addressed at young age\(^6\). Various
infectious diseases such as diarrhea and pneumonia will
be exist because of weakened immune system\(^{6,11}\).

Learning media as a part of messenger technology
is a tool that can be used for learning purposes. On this
occasion, a research on learning media effectiveness,
especially video, is proposed. This research aims to
find out the impact of video on the change of students’
attitude for stunting prevention among children under
five years old in State Senior High School 1 Topoyo.

**Materials and Method**

The research design uses “Quasi-Experiment”,
namely pre-test and post-test with control group design.

The research was conducted on January 7\(^{th}\), 2018
until January 8\(^{th}\), 2019. The experiment was located in
State Senior High School 1 Topoyo, Central Mamuju
Regency, West Sulawesi Province.

The population of this study were all male and
female students at the schools amounted to 710 people.
By using proportional random sampling, the total of 171
students were included in the experimental group and
171 students were included in control group. Therefore
the total of sample are 342 respondents.

**Results and Discussion**

**Research Results**

Characteristics of respondents include the following:

<td>100</td>
</tr>
</tbody>
</table>
The table above shows that the number of respondents aged 17 years are more than other respondents as many as 113 respondents (66.1%). Female respondents are many more than male respondents as many as 118 respondents (69.0%). Mostly level of parent’s education is primary school as many as 89 respondents (52.0%). Mostly respondents’ parents work as farmer, as many as 125 respondents (73.1%).

The experiment process was conducted by instructional video playback with presenting HPK material. This material lead learners to understand the ways of stunting prevention in children under five. The treatment was given to students in experimental group. The effectiveness of the treatment was seen by measuring the change of students’ attitude from pretest to post-test. Meanwhile, for more objectivity, measurements were also carried out in the control group at Vocational High School 1 Topoyo. There are no intervention in the control group.

This study also included control group to compare attitudes of students toward 1000 HPK material and prevention of stunting among children under five which was not given intervention / treatment. Uptake ability of students toward other information sources may give influences. Therefore, the control group was selected from same area and same level of knowledge to control certain aspects. Vocational High School 1 Topoyo which is located in same district was selected as group control. Pretest and post-test were also conducted in the control without any intervention or treatments.

Attitude of Students Toward Material about Stunting Prevention

Attitude is the value preference that are individually owned by students. The attitude is a form of approval or rejection depending on the values and norms inherent in the students during their development. The improved attitudes of students in learning before and after intervention can be seen in the following table:

Table 2. Students’ Attitude Before and After Intervention (Intervention Group/SMAN 1 Topoyo and Control Group SMK Topoyo) In Central Mamuju Regency, West Sulawesi, 2018

<table>
<thead>
<tr>
<th>Group</th>
<th>Attitude</th>

<td>Total</td>
<td>171</td>
<td>100</td>
</tr>
</tbody>
</table>

The table above showed that in the Intervention Group, Pretest measurement results with Well category was 131 (76.6%) and Less category was 40 (23.4%); and the measurement results of Post Test were 149 (87.1%) for Well Category and 22 (12.9%) for Less Category. The value of p = 0.000 means that there was effect of the intervention on the attitude change respondents in the prevention of stunting in State Senior High School 1 Topoyo. Meanwhile, the Pretest measurement results of Control Group were 128 (74.9%) for Well Category and 43 (25.1%) for Less Category.

Furthermore, the researchers compared the effect of video (without explanation) and video plus explanation on attitude change. The difference of attitude by using the two different video categories can be seen in the following table:
Table 3. Attitude Difference between Intervention Using Video and intervention using Video Plus Explanation in State Senior High School 1 Topoyo, Central Mamuju Regency, West Sulawesi Province, 2018

</table>

The analysis result of attitude difference after watching the video and video plus is $p = 0.000$, which means there is difference in the attitude after watching the two video category. In another word, video presentation accompanied by explanation is more effective in changing students’ attitude for stunting prevention in State Senior High School 1 Topoyo, Central Mamuju Regency, West Sulawesi.

**Discussion**

The measurement result that there was difference result of pretest and post test proved that there was effect of video on attitude change among students in treatment group. Meanwhile, there was no video influence in the control group that showed that there was no significant result from pretest to post test. This is probably because of the formation of attitude which is influenced by many variables, such as trust, credibility, culture, ideology, and so on. In addition to those factors, attitude formation is also influenced by psychological factors, sociological factors and physiological factors. Psychological factors can be recognized when your attitude is affected by your feeling or mood (sad, happy, angry, so on). The sociological factor includes certain social values giving stereotype on person as well as concept or particular aspect of culture gives impact on person attitude. Physiological factors also affect attitude when person is in a state of fatigue or physical unstable.

Students’ attitude may probably predicts whether students show a particular behavior or not. However, it does not mean that if person has positive attitude on learning then he or she will learn well or get good results. Attitude is relatively sedentary mental tendency to react in particular condition.

Video plays that illustrate the risk of children who are malnourished are expected to lead students to the understanding of these events which finally can direct them to a desired direction. The influence of others are considered which we tend to be the same as the main assume for ourselves. This trend arises because of the urge to join in and avoid troubles. This matter causes video plays need to be accompanied by explanation by teachers or instructors who understand about the material broadcast. When comparing both methods of learning using video only and video plus, there was a difference, which video plus is more effective in changing students’ attitude.

Attitude requires in-depth study before it becomes a form of decision. Attitude is manifested in the form approval or rejection on something or someone. Personal attitude can be ambiguous or unambiguous because of some factors. Dishonesty or variability of a person may probably cause the difficulty of making decision. In certain social condition, people sometimes have a different attitude. People sometimes have to declare similarity with other people in order to overcome fear of alienation, isolation or afraid of being hated, and other specific social reasons from social environment. Someone who has different attitude from common people or majority may feel afraid of being extremely different.
The treatment made differently did not make a difference. It is clear that the process of attitude change is a complicated and long process. It is not easy to change attitude because it was born from a personal faith. Faith is the individual human right to express their existence. Attitude is affected by personal values that prevailed at the time. Adolescent has the value reference that comes from peers. It is not really surprising that teenagers are often in conflict with their parents because they want to show their existence. Therefore, to change their attitude quickly to be more positive, students or teenagers should be included in a participatory discussion as a part of learning method. Students are encouraged to initiate and identify their own problems and solutions. Learning should be sourced from the students, not from teachers.

Attitude will be easily formed if the emotional factors involved in personal experience. This personal experience is intertwined in someone’s life and it is need to be raised. The experience will help in forming the understanding toward social stimuli. When the students watch the video, they will require a response on what they have watched. Involvement of teachers or instructors after watching the video will provide reassurance on the material and confirmation on students’ attitude. The influence of someone who is supposed to be important for students or has an authority is more stronger on students’ attitude toward a thing. People who are usually considered as important figure for individuals are the elderly, people with higher social status, peers and close friends, teachers and spouses. Setting the video also requires careful planning by linking the matter with the traditions and culture. For example, mostly Japanese people are relatively short before the Second World War, but there was a change in posture after the revolution of nutrition in Japan.

**Conclusion**

Changes in attitude measured by pretest and post test after intervention by watching videos and video plus showed that there was video effect on students’ attitude (the measurement result p = 0.000). The finding was supported by result that there was no attitude change in the control group that was not given by video intervention (the measurement result p = 0.713). Besides, there is a difference between using video only and using video plus explanation as a medium of learning (the measurement result p = 0.000). Based on the research results, it is suggested that public awareness and attitude related to stunting prevention need to be addressed early, ranging from primary to secondary education. The dissemination and socialization of stunting prevention should be managed systematically by the government in collaboration with many parties including education sector to minimize the negative effect of malnutrition.

Relationship of Individual Attributes with Birth Place: Cross Sectional Study in Muna, East Indonesia

La Ode Muhamad Sety1, Andi Arsunan Arsin2, Darmawansyah3, Muhammad Basir Palu4

1Departemen Epidemiologi Universitas Halu Oleo, 2Departemen Epidemiologi Universitas Hasanuddin, 3Departement Administrasi Kebijakan Kesehatan Universitas Hasanuddin, 4Departemen Administrasi Kebijakan Kesehatan Universitas Indonesia Timur

Abstract

Background: Until now maternal mortality is very high. More than 20 million women worldwide are pregnant each year, 15% of whom experience complications that require attention from trained health workers to prevent morbidity and death. Labor at home nationally in Indonesia is also still high. The aim of the study was to determine the relationship of the attributes of individuals to the place of birth in Muna East Indonesia Method: The study design used a cross-sectional study, starting September 2016 until February 2017. Samples were 730 mothers of babies, spread across 22 regional health centers in Muna Regency. Sampling is proportional to simple random sampling.

Results: Most respondents preferred to give birth at home to 473 people (64.8%). Individual attributes that were significantly associated with the place of delivery were education OR = 2.69, Maternal occupation OR = 1.75, Parity OR = 0.46. Antenatal care (ANC) visit OR = 1.46. Maternal age and history of complications did not show a significant relationship with the place of delivery. Knowledge of mothers had a significant relationship with the place of delivery OR = 2.53. Further analysis with multivariate, significant related variables were education (Adjusted Odds Ratio (AOR): 2.69 [1.66-4.36]), Parity (AOR: 0.47 [0.34-0.66]), and Knowledge (AOR: 2.19 [1.57-3.06]).

Conclusion: Mother’s education and work, parity, ANC frequency and mother’s knowledge have a significant relationship with the choice of place of birth while the age variable and history of complications are not related.

Keywords: Individual Attributes, place of birth, Indonesia

Introduction

Until now maternal mortality is very high. An estimated 830 women die from complications of pregnancy or childbirth every day throughout the world. 99% of all maternal deaths occur in developing countries. Almost all of these deaths are related to low resources, and most can be prevented1. During the 2012-2017 period, almost 80 percent of live births worldwide occurred with the help of skilled health workers, up from 62 percent in 2000-20052. More than 20 million women worldwide are pregnant each year, 15% of whom may experience complications that require attention from trained health workers to prevent morbidity and death3. One of the factors of maternal and newborn death is labor at home4. The labor process is faced with a critical condition for the problem of emergency labor, so it is expected that labor is carried out in a health facility5,6.

In Indonesia too, according to the 2010 population census the main causes of maternal death are bleeding, hypertension in pregnancy, infection, prolonged labor and abortion7. Currently the maternal health status in Indonesia is still far from expectations, marked by the high mortality rate, which in 2015 still shows 305 / 100,000 KH, while the MDGs target 102 / 100,000 KH8 even the 2019 medium-term development plan, Indonesia targets 306 per 100,000 KH9. Hard work must be done to achieve the targets set for sustainable health development (SDGs),...
which is less than 70 per 100,000 KH in 2030\textsuperscript{10}.

The form of concern of the Republic of Indonesia government towards the community was also seen in the era of 1998, when the monetary crisis occurred by providing a special budget for services to disadvantaged people, including mothers giving birth for free through the health safety social network program called JPS-BK. A similar thing in 2004 was the establishment of Poor Health Insurance (Askeskin). In 2008, the Askeskin program was expanded to include the near poor as part of the new Jamkesmas program including incentives for health workers in antenatal care (ANC), childbirth and post-natal care (PNC) and now managed by an institution namely the Health Insurance Agency (BPJS) which is intended not only for the poor but for all Indonesian people. Childbirth claims by the puskesmas for maternity on condition that they give birth in health care facilities\textsuperscript{9}.

Since 2010 the government of the Republic of Indonesia has also declared an active standby village program, in which husbands, families and communities are expected to be active in order to better recognize danger signs and complications of pregnancy and increase births by trained personnel in health facilities\textsuperscript{13}. Until 2013, there were only 70.4 percent of deliveries at health facilities and only 29.6 percent at home / other. Likewise in Southeast Sulawesi it is still far from national coverage, where deliveries at health facilities are only 23.8% and generally at home which is 67.2%. Muna regency, which is the location of the study, has only 39.72% of the coverage in health facilities, the lowest in Southeast Sulawesi\textsuperscript{14}.

Individual attributes in the form of age, education, and occupation of the mother, parity, history of ANC, history of complications and knowledge of the mother are very important in determining the decision of the mother to choose the place of delivery\textsuperscript{15}. Several studies on maternal decisions regarding the place of labor have been carried out in Asian and African countries, but researchers want to see different things in the Indonesian region, especially the eastern part. The purpose of the study is to know the relationship of individual attributes (age, education and maternal occupation, parity, ANC frequency, history of complications and knowledge of mothers with decisions about places of delivery in Muna Regency

**METHOD**

The study design used a cross-sectional study, starting in September 2016 until February 2017. The sample was a total of 730 mothers of babies from 2,222 populations spread across 22 regional health centers in Muna Regency. Sampling is proportional to simple random sampling. Data analysis consisted of univariate, bivariate by classifying variables into two age categories; (at risk; 20 years and\textgreater; 35 years and not at risk; 20-35 years), education (low; elementary or non-school and high; minimum junior high school or higher) mother’s work (not working; not just working or housewife and work; have a job), parity (primipara; child 1 person and multipara; child\textgreater; 1 person) frequency of ANC (less; never or <4 times and sufficient; 4 times or more), history of complications (ever and never), maternal knowledge (less; <median and good score; ian median) and further analysis with multivariate.

**Research Results**

**Characteristics of Respondents**

The number of participants at the end of the study was 730 mothers who had children aged 0-1 years. The description of the research results can be seen in the following table

</table>
Table 1 shows that the majority of respondents preferred to give birth at home to 473 people (64.8%). Mothers are generally not at risk (20-35 years), which is 558 people (76.4%). Of the total who gave birth at home 473 people, more than half in the age range not at risk (20-35 years), which is 361 people (76.3%). Only a few <20 years old are 79 people (10.8%).

Based on the level of education, the largest proportion is high school (SMA) or equivalent, which is 295 people (40.4%) and the smallest is never attended by 5 people (0.6%). The work of respondents is generally only housewives, namely 586 people (80.3%) and the smallest is 2 workers (0.3%). Based on parity, generally the respondents have a number of living children as many as 1 person, namely 238 people (32.6%), the smallest are those who have parity of 7 or more people, 10 people (1.3%). Of the total who gave birth in health facilities, the majority of respondents had 1 parity of 113 people (44%). The number of ANC visits is generally 4 times or more as many as 534 people (73.2%). And even though it is the smallest, there are still 12 ANC visits (1.6%). Most of the respondents had experienced complications during pregnancy or childbirth, namely 414 people (56.7%) and of the total who gave birth in health facilities, in general had experienced complications, namely 147 people (57.2%).

Analysis of factors related to the place of delivery

To see the relationship of variables related to place of delivery (Table 2), bivariate and multivariate analyzes were performed. The results of bivariate analysis showed that age did not have a significant relationship with the place of birth (p> 0.05). Educational factors have a significant relationship with the place of delivery (p<0.05) OR = 2.69. This shows that mothers with low education more likely to give birth at home compared to those who have higher education. Maternal work also had a significant relationship with the place of delivery (p<0.05) OR = 1.75. This shows that mothers who do not work and only as housewives have a 1.75 chance of giving birth at home compared to working mothers. The parity factor also had a significant relationship with the place of delivery (p<0.05) OR = 0.46. This indicates that mothers who have primipara status reduce their chances of giving birth at home rather than multiparas. Antenatal care (ANC) visits also had a significant relationship with the place of delivery (p<0.05) OR = 1.46. Mothers who had ANC visits less than 4 times had a 1.46 chance of giving birth at home compared to 4 or more visits. The history of complications did not show a significant association with the place of delivery (p>0.05). Mother’s knowledge factor had a significant relationship with the place of delivery (p<0.05) OR = 2.53. This shows that the knowledge of poor mothers has a 2.53 chance of giving birth at home.

The results can also be seen in table 2. Women who had less education only graduated from elementary school or not (Adjusted Odds Ratio (AOR): 2.69 [1.66-4.36]), were more likely to give birth at home than those who had a high education category junior high school (SMP) or higher. Primipara category parity (AOR: 0.47 [0.34-0.66]) is more likely not to give birth at home. Poor knowledge about health problems related to the risk of pregnancy or childbirth (AOR: 2.19 [1.57-3.06]) is more likely to give birth at home.

## Discussion

WHO recommends safe delivery should be carried out in health facilities, but in this study more than two-fifths of respondents prefer homes as places of delivery. Most respondents give birth at the age of 20-35 years which is very good for mother’s safety. WHO emphasizes avoiding four too much in pregnancy which is too young (pregnancy <20 years), too old (pregnancy >35 years), too many children (more than 4) and too close (pregnancy distance <2 years)\(^6\).

Maternal education is a variable that significantly determines the use of health facilities as a place of delivery as has been proven in several previous studies (hagos, feyisa, adedookun). Higher levels of education will increase maternal knowledge, increase self-confidence and also increase awareness of the use of health resources in the community for maternal health (kawakatsu, feyissaa, adedokun). The same results were also found in this study, lower education tends to give birth more at home than those who have higher education. Employment is economically capable of empowering women to take responsibility for their own health and facilitate access to facilities\(^7\). Job is able to make. Independent and more capable mothers to use health facilities when giving birth\(^8\).

Appropriate antenatal care (ANC) awareness raises maternal awareness to seek appropriate and safe health delivery services\(^3, 12, 19\). The results of this study indicate that the frequency of ANCs that are less than 4 times tends to give birth at home. Complications during previous pregnancies are predicted to be carried out in health facilities. when problems arise during pregnancy, women report a desire to be in a facility\(^20\). In this study it was found that mothers who had experienced previous complications tended to give birth in health facilities. They worry that complications will occur again so they prefer to give birth in a health facility.

Knowledge of better maternal health is a determinant of delivery in a health facility. A study in Zambia of women who can pinpoint danger signs in pregnancy is more likely to give birth in a health facility than those without such knowledge \(^21\). Knowledge of high maternal health may positively influence women’s service-seeking behavior and enable it to recognize danger signs early. However, this mother’s knowledge may be the result of frequent contact with skilled health workers; therefore a prospective study is needed.\(^4\)
Conclusion

The results showed that maternal education, maternal occupation, parity, ANC frequency and maternal knowledge had a significant relationship with the choice of place of birth while the age variable and history of complications were not related.

Quality of Health Services in Kamonji Puskesmas Palu City

Slamet Riadi¹, Hamaruddin¹

¹Master Program in Public Administration, Tadulako University

Abstract

This research aims to know the Quality of Health Service at Kamonji Public Health Center in Palu City. Analyze to use the theory Zeithaml, Berry And Parasuraman with the descriptive research method qualitative and 5 informants of people determined with the technique of purposive sampling. 3 informant from circle of implementer of executor of health service and 2 informant from circle of goals of group or society paying a visit and medicalize the. Research during 2 month namely mid February up to April 2018. data collected with the observation, interview and documentation. Result of research show that quality of health service still have to be improve repaired and improved, 2 from 5 indicator not yet good. (1). Tangibles the building have to need the repair, column settlement, location of service column. (2). Responsiveness listen carefully the worker and (3). reliability have adequate. (4). Assurance record the sis and make-up of worker interest still require to be improved. Worker (5). empathy assessed by society have good.

Keywords : Service , Tangibles, Responsiveness, Reliability, Assurance, Empathy

Introduction

Health is a basic right of every person and all citizens are entitled to health services regulated in the 1945 Constitution. One of the health care units is Puskesmas. According to Minister of Health Regulation No. 75 of 2014, the function of Puskesmas as one of the first type of health service facility (FKTP) has an important role in national health system, especially health effort subsystem. To achieve the goals of national health development are carried out various health efforts are comprehensive, tiered and integrated. Puskesmas as one of the first-level health service facilities (FKTP) has specificity compared with other FKTP. (first clinic, individual practice place, etc.). There are several things that are the specificity of Puskesmas, among others: carrying out public health efforts (PHE/UKM) and have the concept of territory. With this specificity of course required good management in managing all efforts undertaken, all potential resources that will be different from other FKTP.

The function of puskesmas as a driver of health-minded development and community empowerment center to support healthy sub-districts and aims to create a society that has healthy behaviors that include awareness, willingness and ability to live healthy, able to reach quality health services, live in a healthy environment and have optimal health, both individuals, family groups and communities. In general, health services provided by Puskesmas include curative, preventive, promotive and rehabilitation services. Regulation of the Minister of Health of the Republic of Indonesia Number 75 of 2014 on Community Health Centers (Puskesmas) needs to have good health care and quality by health providers, therefore demanded a high performance from health providers themselves¹-³.

Puskesmas Kamonji has a working area of 7 kelurahan namely, silae, kabonena, lere, baru, ujuna, kamonji and siranindi. Up to the year 2017 the population of 51,209 inhabitants. It is a potential and a challenge and requires good management. The year 2016 recorded 22,042 male visits and 34,549 women, resulting in total visits of 56,591 times, with daily visits of up to 200 patients, excluding the visit of free puskesmas for free during the afternoon as many as 50 patients. However, health services at health centers kamonji still encountered various problems ranging from the form of buildings that have not been in accordance with the mandate Permenkes Number 75 year 2014, the number of rooms and division of poly, the arrangement of space / placement room, including the absence of separation of elderly and not elderly, adequate quantity and comfort, clean water supply, storage and treatment of medical
waste. The layout of service room in Puskesmas building must be arranged by paying attention to Puskesmas zone as building of health service facility.

Another aspect that is the inhibiting factor is the arrangement of medical records that should be an individual confidential document, still outside the room and can be accessed by anyone who is not interested because the placement is in the hall or corridor of the puskesmas. The condition of the registration queue, patient waiting room is relatively narrow and the old queue adds to the problems faced in the service at the counter.

However, there are important factors supporting the effort to improve the quality of health services in improving the quality of services that is the implementation and assessment of health center accreditation in health centers kamonji on 30 October to 2 November 2017. The main purpose of accreditation Puskesmas is to foster quality improvement, performance through continuous improvement of the system management, quality management system and service delivery system and program, and implementation of risk management, and not merely an assessment to obtain accreditation certificate.

Based on this, research on the quality of health services in UPTD Puskesmas Kamonji needs to be done, so that less than optimal service can be improved and service with the best quality can be maintained. By considering the field conditions as well as the support of information that researchers get from the community, then to menyengkapi the fact researchers are interested in raising this issue into scientific research.

In terms of academic research is expected to be a scientific reference, especially matters relating to the Quality of Health Services in UPTD Puskesmas Kamonji. Practically this research is expected to be a recommendation for the Health Office of Palu City, especially Health Center Kamonji in seeing and paying attention to the quality of health services in UPTD Puskesmas Kamonji

Materials and Method

Types of research

This research is qualitative descriptive research with inductive approach that research method by describing the state of research object at the present moment to the facts that appear in particular so that the general picture can be drawn without making comparisons with other variables.

Location And Time Research

The location of the research is UPTD Puskesmas Kamonji Palu with consideration that there are inhibiting factors in improving the quality of service at puskesmas kamonji, including the supporting factor that is the implementation of accreditation of puskesmas on 30 October until 2 November 2017. This research will be conducted approximately 2 month February up to April 2018.

Informant Research

The subjects and informants in this study were the visitors who went to the Kamonji Health Center and the individual health service implementers at Kamonji Community Health Center (Puskesmas Kamonji). The informant is determined by purposive sampling technique where the informant is determined by certain consideration or indicator and is the person or party that is directly related or able to give information about the implementation of health service at Puskesmas Kamonji Palu city.

Types and Data Sources

Primary data

Primary data is data obtained directly from informants by using interview guidelines.

Secondary data

Secondary data in this research is supporting data which is useful for researcher, because this data is obtained from research object, book, journal, internet and also documents containing information about research.

Sources of data in this study are all the results of observation, interview and collection of data that are considered important in determining the quality of service in Puskesmas Kamonji Palu City.

Definition of Operational Concepts

Based on the definition of the literature review, the authors focus on only one variable or independent variable of health service quality in Puskesmas Kamonji Palu with indicators as follows:
1) Quality of service can be identified by comparing patient satisfaction with the service they receive with the service they expect.

2) The health referred to in this study is a healthy state, both physically, mentally, spiritually and socially which enables everyone to live productively socially and economically. “

3) Puskesmas according to the regulation of health minister of the republic of Indonesia number 75 of 2014 is a health care facility that organizes public health efforts and individual health endeavors at the first level, with more prioritize promotive and preventive efforts, to achieve the degree public health as high as possible in its working area.

Results and Discussion

Puskesmas Kamonji is Technical Implementation Unit of Palu City Health Office geographically located in West Palu District but with working area covering two Subdistricts namely Palu Barat and Ulujadi Subdistricts. Kelurahan which is included in the working area of Kamonji Public Health Center consists of seven urban villages namely Kamonji, Silae, Kabonena, Lere, Baru, Ujuna, and Siranindi urban villages. Five urban villages are Palu Barat District while the other two urban villages are Kabonena and Silae sub-districts.

The work area of Kamonji Health Center is 82.53 Km2 which is divided into 41 RW and 136 RT. Puskesmas Kamonji has a network of health services five sub health centers (Pustu) and 7 village health posts (Poskesdes). The entire service network is dedicated to serve 51,537 people or 12,739 families. Most of the population in the working area of Kamonji Puskesmas is 54.2% is the productive age population

Description of Health Service at Kamonji Public Health Center

One of the factors to assess the amount of utilization of health center facilities as public health service facilities, can be seen from the number of visits in health centers. utilization of health facilities at UPTD Puskesmas kamonji in the year 2017 consists of male visits as much as 31,092 and women 50,497. when compared to 2016 and 2015, the number of patient visits medication tend to fluctuate. The trend of patient visits can be seen in the picture below:

![Figure 1. trend of patient visits by sex At Kamonji Health Center 2015 – 2017](source)

Source : Profil Puskesmas Kamonji, 2015,2016, 2017

Quality of Health Services at Kamonji Community Health Center

To analyze the health service quality of Puskesmas at UPTD Puskesmas kamonji, the writer choose 5 dimension the qualities proposed by Zeithaml, Berry and Parasuraman are physical tangibles, reliability, responsiveness, assurance and empathy.

Physical Appearance (Tangibles)

Physical appearance (Tangibles), meaning physical appearance of buildings, equipment, employees and other facilities owned by providers. The writer concludes the result of interview with Head of Puskesmas Kamonji (dr Rohmat Jasin) that the location of puskesmas kamonji is very strategic and easy to reach, however if seen from the physical condition of health center kamonji is now less than adequate and actually need to get the repair / rehab heavy thoroughly with adjusting the current requirement, especially referring to the mandate of RI health minister’s regulation number 75 year 2014. Then the authors conclude from the interview with (dr Meity Salatan) also explained that the health center kamonji get heavy rehab ration for this fiscal year 2018 The explanation of the informant of the implementor shows that there is an indication of the shortcomings and limitations of the Puskesmas building. The physical condition of the puskesmas now needs to get attention and repair as soon as possible, for the improvement and improvement of the quality of health service to the community of service users in Kamonji Community Health Center, which refers to Permenkes number 75 year 2014. Then the authors conclude from the interview with frequent service / patient recipients routinely seek treatment at puskesmas kamonji (mother of Siti Sumarni) that informant description above matching with decision of MENPAN Number 63 Year 2003 mentioned that service implementation must fulfill some
principles as among others completeness of facilities and infrastructure. The availability of adequate facilities and infrastructure, work equipment and other supporting facilities including providers of telecommunications technology and informatics technology\(^5\)\(^-\)\(^7\). Ease of Access Sites and locations and facilities of adequate services, easy to reach by the community, and can be utilized telecommunications and informatics technology. Comfort Environmental service should be orderly, organized, provided a comfortable waiting room, clean, tidy, beautiful and healthy environment and equipped with service support facilities, as well as parking, toilets, places of worship and others. Based on the results of interviews with all informants related to the physical appearance (Tangibles) we can conclude that the health center kamonji from the access side of service coverage, is very possible because it is on the main road, the physical condition of the building needs to get repair\(^8\)\(^,\)\(^9\).

**Responsiveness**

Responsiveness (Responsiveness) is the willingness to help service users and provide services in a sleek and responsive manner. The authors conclude the results of interviews with Kamonji Community Health Center Head (dr Rohmat Jasin) that focuses on improving and improving services to patients and the community as a whole regardless of social status or health insurance coverage at puskesmas. Types of services available in health centers kamonji stipulated in the clinical service guide clinic kamonji. In line with the above that the importance of carrying out every service by setting and applying quality standards as appropriate The same opinion was also shared by the person in charge of the medic record. Similarly, the authors conclude the interview result (doctor meaty) that his message is in line with Article 7 point d permenkes no.75 2014, stating that the provision of health services that prioritizes the security and safety of patients, officers and visitors. In carrying out his duties of energy health needs to obtain or follow activities or efforts to increase the competency of health personnel, all of them to support the achievement of healthy sub-district.

**Reliability**

Reliability is the ability to deliver consistently and accurately promised services. The authors conclude the results of interviews with the Head of the Kamonji Public Health Center (dr Rohmat Jasin) that the Staffing or executive staff is a serious problem in the public service. Not only the amount but also the skill or competence. In Kamonji Health Center, the number of health personnel in the health service effort is sufficient. In the law number 44 of 2009 article 31-32, explains the rights and obligations of patients to be considered in the overall service process that begins from registration. The rights and obligations of patients at UPTD puskesmas kamonji have been on the wall on the wall so that patients know their rights and obligations. Likewise, the rights and duties of doctors / nurses.

Explanation of the reliability delivered by other implementor informants (dr Meity) the authors concluded in improving the quality of public services are primed confronted several obstacles such as; lack of commitment from the service apparatus, they only carry out their tasks without thinking about the needs, desires and satisfaction of the community, lack of understanding of quality management, inability to change culture and behavior, inaccurate quality planning, ineffective human resources development program, facilities infrastructure services, financing, weakness incentive system, short-term orientation, performance information system has not been developed.

**Assurance**

Assurance is the knowledge, courtesy and ability of service providers in providing trust to users of the service From all informants the information can be drawn a conclusion that continuous supervision by the head of puskesmas towards the service provider will give positive leverage to the consistency of service. Evaluation during the service process through weekly briefings will be able to provide improvements to service efforts and increase awareness of officers in performing health services. Such as the appropriate implementation of the SOP, or revisions to the SOP if deemed necessary.

**Empathy**

Empathy (Empathy) is the ability to provide treatment or attention to service users individually / personally. If service indicators are achieved then customer satisfaction will be achieved. In line with the statement of the head of puskesmas kamonji (dr Rohmat Jasin) Based on survey results of community satisfaction index (IKM) conducted at 13 puskesmas in palu city in february - mei 2017, generally the performance performance of its service is categorized as “GOOD”
and “Very Good”. The health center kamonji from 2016 with good category with 71.65 niali become very good category in year 2017 with value 82.20. all elements of service get a perception value above the number 3 where the average element of service is 3.288.

Description of all informants has actually adopted a series of activities in the public service, in the framework of efforts to meet the needs of services in accordance with legislation and regulations for every citizen and residents of goods, services and or administrative services provided by the providers of public services, in this case the health center kamonji. As for the implementation using benchmark of service standard as the reference of service quality as obligation and promise of organizer to society in the framework of quality service, fast easy, affordable and measurable. Law No. 25 of 2009 (article 15-20) describes the rights of the community / organizers, the obligations of the community / organizers, including the prohibition of prohibition that must be obeyed in the provision of public services and One of the assessment criteria in a puskesmas accreditation is obliged to carry out the mandate.

Conclusions

Based on the results of the research note that the five dimensions of service quality used to determine the quality of health services in UPTD Puskesmas kamonji all have good quality trends, it can be concluded that health service Puskesmas in UPTD Puskesmas kamonji quality.

Abstract

Chronic malnutrition is caused by poverty, improper care, and parents’ ignorance of the nutritional needs of children. Providing a balanced menu is a kind of solution that can be applied to overcome nutritional problems in children. Balanced nutrition services are carried out in early childhood to improve children’s nutritional status. This research was conducted in Bangli District, Gianyar Regency, and Denpasar City, using a randomized pre and posttest control group design with a total sample of 88 children (38 controls and 50 intervention groups). Nutritional status was assessed by comparing weight with age using anthropometric standards based on Z-Score. The results of this study indicate that the intervention group experienced a decrease in the number of children with less weight (25.00%) and an increase in the number of children with good nutritional status (2.22%), while in the control group there was no change in nutritional status. The results of the independent sample t test showed that there were significant differences in the pre-data in the control group and intervention (p <0.05) while the post-data showed no significant differences (p > 0.05). Analysis of differences in body weight in the control and intervention groups showed that there were significant differences (p <0.05). Balanced nutrition services in early childhood can significantly improve their nutritional status.

Keywords: balanced nutrition services, early childhood, nutritional status

Introduction

Preschool age is a golden period because the physical and psychological development is hurried that its nutritional needs must be fulfilled and balanced. Nutritional problems occur in toddlers, especially malnutrition, are the effects of maternal conditions during pregnancy, fetal period, infancy, including diseases suffered during infancy. This situation can hamper children’s development with negative impacts that will take place in subsequent lives such as intellectual decline, susceptibility to disease, decreased productivity to cause poverty and the risk of giving birth to babies with low birth weight. Every parent certainly wants a balance between physical growth and optimal mental development in their children.

Data from WHO showed that underweight cases in preschoolers in the world were 15.7% and overweight 6.6%. Nationally, the prevalence of malnutrition in 2013 was 5.7% and malnutrition was 13.9%. The results of Riskesdas from 2007 to 2013 showed that underweight cases in Indonesia increased from 18.4% to 19.6%, Riskesdas 2010 and 2013 showed that births with Low Birth Weight (LBW) <2500 grams decreased from 11.1% to 10.2%. The trend of nutritional problems in Bali in 2015-2017 showed a case of malnutrition decreased from 9.0% in 2015 to 8.6% in 2017, with the highest prevalence in Buleleng Regency 14.4%.

Chronic malnutrition is caused by poverty, inappropriate parenting, and ignorance of parents regarding children’s nutritional needs. The results shown that children’s cognitive abilities were not developing optimally, children easily get sick and have low
competitiveness. The first thousand days of a child’s life are crucial that determine their future, and in that period Indonesian children faced serious growth disorders. The problem is, over 1000 days, the adverse effects of malnutrition are very difficult to treat. To overcome the incidence of malnutrition, especially mothers, need to be educated to understand the importance of nutrition for pregnant women and children under five years old/toddler.

The results from Ariati, et.al., (2018) get malnutrition cases in Bali Province were still high at 35.85% of children with underweight status and 3.77% over weight. Malnutrition cases in children with a Weight / Age index found in pre-school children are high enough that needs special attention. Children are the most valuable assets for the future of our nation.

Based on those description, giving a balanced nutrition service for early childhood is carried out and the knowledge of balanced nutrition is given to parents so that parents can provide a balanced menu by utilizing local food and food diversification to reduce malnutrition in Bali.

**Material and Method**

This study is a quasi-experimental design with different subjects (randomized pre and posttest control group design). This design was a parallel design, there were 2 groups of samples (control and intervention group). The study was conducted for two months from October to November 2018 in Bangli and Gianyar Regency as intervention group and Denpasar City as a control group with consideration:

1) There were still high malnutrition cases in the regency based on Bali Nutrition Problem Trend data for 2015-2017 (Bali Provincial Health Office, 2017) and the results of preliminary studies that have been conducted.

2) The location was easily accessible by researchers.

3) Availability of early childhood education institution, which the management has been ready to provide additional food for their students.

Determination of early childhood education institution as a place for multistage random research side due to: first selected 3 regencies/cities as random research sites, then from the three districts one early childhood education institution was chosen for which the management has been ready to provide additional food for their students. According to this method, the institution which has been selected such as Yudistira PAUD in Gianyar Regency and Handayani PAUD in Bangli Regency as intervention group, then Swadarma PAUD in Denpasar City as a control group.

Giving Balanced nutrition services in early childhood is a service in the form of counseling and education about Balanced Health and Nutrition to the parents and followed by making food menus for school children by utilizing local food followed by supplementary feeding and monitoring the development of children’s nutritional status with index Weight/Age (W/A). Nutritional status with a W/A index was assessed by comparing the child’s weight with age then compared to the standard. Descriptive data analysis includes age, sex, and body weight of the sample analyzed descriptively by means of the mean and standard intersections. The data homogeneity test was carried out by the Levene test at the level of confidence α = 0.05. If the data in the Control and Intervention Groups were homogeneous, then the analysis of the Independent Sample t-Test, and if were not homogeneous, then used the Man-Whitney difference test at the level of confidence α = 0.05. To compare nutritional status data (in the Control Group with the Intervention Group (O1 with O3 and O2 with O4), if the data were homogeneous, a parametric statistical test is performed (Independent Sample t-Test) and if not-homogeneous, a non-parametric statistical tests (Man Whitney at significance level α = 0.05).

**Results**

**Characteristics of Samples**

The samples observed were 88 children with characteristics as shown below in Figure 1, 2 and 3.

![Figure 1. Characteristics of samples based on age](image)

According to Figure 1, the average of samples in the Control Group was 57.13 months and in the Intervention
Group was 58.88 months.

The data in Figure 2 shown that male and female sex in the Control Group and Intervention Group were the same, while in the Intervention Group, male was more than female.

According to Figure 3, it has shown that the weight in the Control Group increased by 0.11%, while in the Intervention Group there was a greater increase of 8.51%.

Nutritional Status of Students based on Index W/A

Nutritional status assessment with weight/age index showed no change in children’s nutritional status in the Control Group between pre and post, while in the Intervention Group there was change significantly. Nutritional status data of the samples based on weight/age Index were presented in Table 1.

The data in Table 1 showed most of the samples had good nutritional status i.e. 84.22% in the Control Group and 92.00% in the Intervention Group. In the Control Group, there were samples with overweight and underweight each one 3 children (7.89%) and no cases of malnutrition were found. In the Intervention Group there was a decrease in the number of samples with underweight by 25%, from 4 people to 3 people. There was an increase in the number of samples with a good nutritional status of 2.22%, namely from 45 to 46 children, and there was no change in children with overweight, only 1 children.

Effect of Balanced Nutrition Services on Sample Nutritional Status

Data on body weight homogeneity test results in the Control and Intervention Groups by using Levene Test at the level of confidence $\alpha = 0.05$ showed $p \geq 0.05$, indicated that the data in both groups were homogeneous, then followed by Independent Sample t-Test at the level of confidence $\alpha = 0.05$. Where as in the control group and intervention differences in weight gain $p < 0.05$, the data in the two groups were not homogeneous so that it continued with the Man-Whitney test at the level of confidence $\alpha = 0.05$.

The results of differential test were pre data in the Control Group and Intervention obtained a value of $p < 0.05$, which showed a significant difference in the child’s body weight data in the Control Group and Intervention. The body weight average of samples in the Control and Intervention Groups was not the same, this can be seen from the difference in mean pre body weight in the Control group (17.54 kg) and pre in the Intervention Group (15.99 kg). Post data (after intervention) in the Control Group and Intervention got a value of $p \geq 0.05$ which showed no significant difference. The mean data of body weight in the Control Group (17.56 kg) and in the Intervention Group (17.35 kg) were the same. The child’s body weight increased significantly after being treated (8.51%). While the analysis of the difference in body weight in the Control and Intervention Groups obtained a $p$ value of $<0.05$, indicated that there was a significant difference in the data of the sample weight in the Control Group and Intervention. Those shown that giving balanced nutrition services can increase child’s weight.

**Discussion**

**Children’s Nutritional Status**

Nutrition intake obtained from food consumed is useful for brain growth (intelligence) and physical growth. Physical growth was assessed by measuring the nutritional status of children, can be seen from their general appearance (weight and height), physical, motoric, functional, emotional and cognition signs. Based on anthropometric measurements, healthy children will get older, gain weight, and height are associated with adequate intake of macronutrients, calcium, magnesium, phosphorus, vitamin D, iodine, and zinc.

Nutritional status assessment in this study used body weight and age measurement, then compared with anthropometric standards based on Z-Score value. Assessment of nutritional status with weight/age index found that most of the samples (in the Control and Intervention Groups) were of good nutritional status. The same was reported by Sa’diya (2015) who found that most of the samples studied were of good nutritional status (76.4%)\(^9\). Kumala (2013) who examined the relationship between feeding patterns and nutritional status of children aged 1-3 years in Sidomulyo Godean Sleman Yogyakarta also reported that most of the samples examined were of good nutritional status (80%)\(^10\).

**B. Effect of Balanced Nutrition Services on Sample Nutritional Status**

A good diet consists of consuming quality foods, namely consumption of healthy and varied foods, and
adequate food consumption in terms of quantity followed by applying the right eating behavior. If this is applied, it will produce a normal nutritional status of the child. Analysis of the difference in body weight in the Control Group and Intervention group obtained a p value of <0.05 which indicated that there was a significant difference. It showed that giving balanced nutrition services in early childhood can improve children’s nutritional status.

Nutritional status is an expression of the state of balance in the form of certain variables. It mentioned that nutritional status as an expression of the state of balance from consumption of food to nutritional needs. Research by Sari, et al., (2016) found that there was a significant relationship between diet and nutritional status of children aged 3-5 years in the work area of the health center Nangalo Padang. Other research that revealed the relationship between consumption patterns and nutritional status was stated by Sa’diya (2015) found that there was a relationship between diet and nutritional status of preschool children at PAUD Tunas Mulia Village in Claket, Pacet District, Mojokerto District, Myrnawati and Anita (2016) who examined the effect of nutritional knowledge, socioeconomic status, lifestyle and diet on children’s nutritional status, and there was a positive direct influence on diet on the nutritional status of early childhood. These studies showed that the eating patterns have a major influence on the growth and nutritional status of children, so that they must get serious attention from parents and the government if we want the children to grow up healthy and optimally.

Playing and schooling at this early age make children often delay their eating time, often asks for food only before going to bed when he is too tired to move all day and just hungry at night. The attention of parents in providing food to children is very important so that children’s nutritional intake is fulfilled and according to their needs. At this age the child also starts playing a lot with his friends so they will catch the disease easily. It is necessary to instill diverse and nutritious eating habits and a clean lifestyle. The percentage of the type of food consumed must also be in accordance with the RDA, which is 50-70% of carbohydrates, 15-30% of fat, 10-15% of protein, the rest are vitamins and minerals. The principle of early childhood food 4-6 years is the same as adult food, it’s just that it needs to be considered an interesting presentation then children are happy and interested in eating.

Conclusion

Giving balanced nutrition services in early childhood are considered to increase child’s weight significantly. The evidence has been shown by the analysis of the differential tests, that there were significant differences (p <0.05) between the body weight before and after intervention in the Control Group and Intervention Group. Further study in balanced nutrition service program for early childhood is needed to continue and develop to achieve 100% children with good nutritional status.

Are Sellers Who Have Low level of Knowledge, Attitudes and Practice Selling Snacks With Harmful Food Additives?
(Study of Street Food Vendors at Tadulako University, Indonesia)

Nikmah Utami Dewi1, Abdul Rahman’ Yusma Indah Jayadi3, Diah Ayu Hartini1, Bohari1, Fendi Pradana1, Ummu Aiman1

Abstract
This study is conducted to analyze the content of preservatives, sweeteners and harmful dyes in snack foods at Tadulako University and find out the knowledge, attitudes and practices of the seller about food additives. This type of research is descriptive with the research sample were three snacks sellers at Tadulako University. The foods studied were meatballs, tofu, tomato sauce and ice syrup. The results showed that all meatballs and fried tofu were not contaminated with borax and formalin preservatives. Tomato snacks tartrazine tainted tomato sauce, sunset yellow, and ponceau 4R. Syrup ice is exposed to sweetener benzoate, sorbate, saccharin and cyclamate. Benzoic sweetener and sorbate are still below the detection limit. Saccharin does not exceed the threshold, while the cyclamic sweetener at one seller exceeds the Indonesia National Standard threshold. Respondents who have lower knowledge scores, attitudes and practices than other respondents sell sweetened drinks more than the allowable Indonesia National Standard limit. Conclusions are tomato sauce and ice food snack syrup sold at Tadulako University which are contaminated with dyes and respondents with low knowledge, attitude and practices sell snacks with higher sweetener content.

Keywords: preservative, sweetener, snack

Background
The substance of preservatives, dyes and sweeteners which should be used in non-food industries because of their substance can be harmful to the human body if used as an additive in food1. Hazardous preservatives used by food producers are namely borax and formalin2. The use of preservatives, sweeteners and dyes in snack foods is strongly influenced by the seller, especially those who are directly involved with the manufacturing process3.

Sellers who are aware of the use of appropriate food additives tend to sell food that is free of hazardous food additives4. However, some studies also show that knowledge is not the only thing that influences sellers to sell food which is free of harmful additives5. This is proven by the fact that sellers who sell snacks with dangerous additives such as borax are still found6.

Research on food safety, especially the use of preservatives, sweeteners and dyes at Tadulako University has never been done. The use of substances that do not comply with the rules can be harmful to health. While the seller’s knowledge, attitudes and practices are also important to know to provide an overview of the practice of using food additives that are inappropriate.

Source and Method
Type of Research
The type of research used was descriptive. This research was conducted at Tadulako University from May to July 2017.
Population and Sample

The research population was all snacks sellers at Tadulako University. The sampling technique used was purposive sampling. As many as one seller in each of the three faculties that have many customers and in demand by students is chosen as a sample. Food snacks taken at each seller to be tested are meatball, tofu and ice syrup.

Method of collecting data

The data collected in this study are data on substance of preservatives, sweeteners and harmful dyes in snack foods. The study was conducted qualitatively in the laboratory using resorcinol method to test saccharin (SNI 01-2893-1992), the schryver method was used to identify formalin, precipitation method to test cyclamate (SNI01-2893-1992), and paper layer chromatography using wool yarn to test the dye (SNI 01-2895-1992).

Interviews with questionnaires contained instruments of knowledge, attitudes and practices carried out on snack vendors. The level of knowledge states the respondents’ knowledge regarding food additives measured by questions totaling 13. The results obtained are then categorized to be good (80-100%), moderate (60-79.99%) and less (<60%). All respondents signed written informed consent and agreed to participate in the study.

Data Analysis

Analysis is done to get an overview or description of the types of snack foods containing preservatives, dyes and sweeteners. Descriptive analysis is also conducted to determine the level of knowledge, attitudes, and practices on the use of hazardous food additives in snack-seller.

Result

Dangerous Food Additives

Table 1 shows that all meatballs and fried tofu do not contain borax and formalin. In meatball sauce, it is known that A1 and A2 sauce contaminated tartrazine and sunset yellow dyes but it is free of methanyl yellow and ponceau 4R while sauce B1, B2, C1 and C2 are contaminated with tartrazine dye, sunset yellow, ponceau 4R but free from methanyl yellow (Table 2).

Table 3 shows that benzoate and sorbate sweeteners on A1 and A2 syrup ice were below the detection limit, while saccharin and cyclamate exposure were 38.05 mg / kg and 513.86 mg / kg respectively. On B1 and B2 syrup, benzoate, sorbate and saccharin sweeteners were still below the detection limit but cyclamate exposure was 499.19 mg / kg. Likewise in C1 and C2 syrup it was found that benzoate, sorbat and saccharine sweetener were exposed under detection, but cyclamate exposure was 368.87 mg / kg.

Knowledge, Attitudes and Practices of Food Sellers

All respondents had moderate knowledge regarding food additives (table 4). All respondents knew that borax is a dangerous ingredient when added to food. All respondents also knew that not all dyes could be used as food coloring agents. However, one respondent claimed he did not know if formalin was not allowed to be used as food additives. All respondents agreed that the snack maker who added dangerous additives on the sale would have been accidental. Respondents also claimed that they did not use artificial dyes and did not add borax to meatballs or knew about the sale.
Discussion

The research shows that all meatballs and fried tofu samples sold are not contaminated with borax and formalin. Borax and formalin are prohibited preservatives according to the Regulation of Minister of Health Republic of Indonesia No. 235 / Menkes / VI / 1984. Borax has the second largest toxic effect after sodium nitrite. However, several other studies have shown that snack foods contain borax and formalin. Research carried out by Saymona and Dewi (2013) at the University of Indonesia, found that 3.8% of the food samples tested positive contained borax chemicals, which came from two meatball samples and one sample of noodles.

In the sample of sauce A1, A2 which was analyzed qualitatively as dye material was obtained a result that the tomato sauce used a mixture of various types of coloring agents. The coloring material is; sunset yellow and tartrazin. Whereas in samples of sauce B1, B2, C1 and C2 tartrazine was contaminated, sunset yellow, and ponceau 4R. The type of dye above is a type of synthetic dye which is permitted based on RI Minister of Health Regulation No. 722 / Menkes / Per / IX / 88. However, in this study, there are no quantitative tests carried out so it is not known whether the number of existing dyes exceeds the limit set by Permenkes. Dyes such as tartrazine, erythrosine and sunset yellow are high among some individuals due to food intake containing high dye concentrations (9.45 and 4.0 mg). Analysis of snack foods using tartrazine coloring mixtures, sunset yellow whose levels are more than 300 ppm. Acceptable Dietary Intake (ADI) for permissible synthetic colors varies from 0.1 to 25 mg per body weight.

Analysis of benzoate and sorbate sweetener in all syrup ice samples showed below the detection limit, while saccharin in syrup samples in Faculty A was exposed to 38.05 mg / kg and cyclamate in all samples of Faculties A, B and C each of 513.86 mg / kg, 499.19 mg / kg, and 368.87 mg / kg. Although exposure to saccharin, the amount of saccharin in syrup in Faculty A does not exceed the maximum limit of 500 mg / kg. While cyclamate exposure in all samples also does not exceed the threshold that is a maximum of 1000 mg / kg. Other studies show that there were 8% samples of School-food (SF) containing sodium cyclamate.

In this study, all respondents were of moderate knowledge and only one respondent had a high attitude and practice score in the use of food additives. Respondents who have high attitudes and practice scores sell snacks that do not contain formalin and borax and use permitted dyes and artificial sweeteners that do not exceed SNI (Indonesia National Standard) limits. Other studies show that there is a correlation between the level of education of traders and knowledge of hazardous materials such as formalin and borax and artificial sweeteners. Research on one Philippine campus found that traders proved not to be very knowledgeable about food legislation and there was a significant gap between knowledge and practice food manufacturing is associated with the tendency of street vendors to compromise food security due to financial problems. Likewise with the practices of respondents, sellers who sell sweetened drinks are more than the standard permitted according to SNI claiming to be forced to use artificial sweeteners due to expensive sugar prices. Sellers tend to look for large profits with small capital so that they sometimes ignore customer health.

Conclusion

Meatball snacks and fried tofu are not contaminated with borax and formalin. Sauce tomato is contaminated by Tartrazine dye, sunset yellow, and ponceau 4R. Syrup ice is exposed to benzoate, sorbat, saccharin and cyclamic sweeteners, but benzoate and sorbate sweeteners are still below the detection limit. Similarly, saccharin does not exceed the threshold. While the cyclamic sweetener on ice syrup in one of the sellers exceeds the SNI limit. Respondents who have lower knowledge scores, attitudes and practices than other respondents do not sell food containing borax and formalin but sell sweetened drinks more than the permitted limits of SNI. Educational efforts for the use of food additives in food vendors are needed.

Dominant Factors of Metabolic Syndrome among a Sample of School Teachers in Jakarta, Indonesia

Qonita Rachmah, Diah Mulyawati Utari

1Departement of Nutrition, Faculty of Public Health, Universitas Airlangga, Jl. Mulyorejo Kampus C, Surabaya 60115, Indonesia; 2Department of Nutrition, Faculty of Public Health, Universitas Indonesia, Jl. Margonda Raya, Depok 16424, Indonesia

Abstract

Metabolic syndrome leading to cardiovascular diseases and type 2 diabetes, is caused by several factors. This study aims to identify the dominant factor of metabolic syndrome. A cross-sectional study was conducted to 138 school teachers. Data collected through anthropometric measurement, blood sample collection and interview. Physical activity level was assessed using GPAQ questionnaire, while teaching activity was assessed using questionnaire. Data were analysed using chi-square for all dependent variables and simple logistic regression analysis for variable of age, BMI, and abdominal circumference. 24.6% teachers were diagnosed with metabolic syndrome. There was an association between age, BMI, abdominal circumference, physical activity, and teaching activity with metabolic syndrome (p<0.05). The analysis further showed no relation but a tendency that teachers with married status, cholesterol intake >200 mg/day, carbohydrate intake >60% of total energy, frequency of vegetables consumption <4x/week, and sleep duration ≤7 hours/day were more likely to have metabolic syndrome. Multivariate analysis showed that BMI was the dominant factor of metabolic syndrome in teachers (OR=14.797; 95% CI -1.73 - 126.35).

Keywords: abdominal obesity, adults, body mass index, metabolic syndrome, obesity

Introduction

Epidemiological transition during modernization nowadays shifted the lifestyle of most of the people and lead to the increase risk of degenerative diseases, worsened by the increase of obese prevalence. Data in Indonesia showed the increase of obese from 21.7% in 20101 to 28.7% in 20132. Even worse, 13.4% cause of death was due to cardiovascular diseases3. The emergence of cardiovascular disease is caused by the occurrence of several risk factors called metabolic syndrome. A study found that person with metabolic syndrome have three times greater risk of having heart attack/stroke and two times higher risk of death compared with those without metabolic syndrome4. In 2001, NCEP-ATP III define metabolic syndrome as an abnormal metabolic including minimal 3 out of 5 conditions (central obesity, elevated plasma glucose level, blood pressure, triglyceride level, and low HDL-C). Prevalence of metabolic syndrome worldwide is 15-30%5 and half of it occurs in developing countries. In Asian population, using the same definition, prevalence of metabolic syndrome was ranged 10-15%6.

Recent studies demonstrated that obesity increase the risk of metabolic syndrome7,8, at least 31.1% respondents with metabolic syndrome is obese9. Obesity is a condition of excess fat mass in the body which known from BMI measurement. Besides BMI, dietary intake and physical activity also contribute to the development of metabolic syndrome. Excessive energy intake which not accompanied by daily physical activity will cause positive energy balance and fat accumulation in adipocyte tissue. Research among the Samoan-American adults showed that modern dietary pattern which illustrated by the increase in energy and

DOI Number: 10.5958/0976-5506.2019.02083.7
cholesterol intake resulted in an increase of triglyceride level\(^{10}\). Another research developed at Padang, Indonesia revealed that people with metabolic syndrome having higher energy and carbohydrate consumption but low in fibre and omega \(^{3}\).

Prevalence of metabolic syndrome in Jakarta reached 28.4\% and it is higher than national prevalence\(^{11}\). The metabolic syndrome in Indonesia counts as a public health problem that need to be addressed because its prevalence was >15\%. However, the study to find the factors related to metabolic syndrome remains limited. According to early observation, teachers spending at least 8 hours per day for sitting in the classroom, means that teachers had lower physical activity compared to others profession. Moreover, we found that 50\% of teachers was obese which made it more susceptible to metabolic syndrome and it is worse considering that teacher is a role model of healthy condition for children. Based on that facts, this research aims to observe the dominant risk factor related to metabolic syndrome among teachers in Jakarta, Indonesia.

**Material and Method**

A *cross-sectional* design was used in this study. The sample size calculated using test for difference in 2 independent proportions, with \(P_{1} 0.07\) and \(P_{2} 0.25\) from previous study of metabolic syndrome determinant\(^{10}\) resulted minimum sample was 128\(^{12}\). One-hundred and thirty-eight school teachers who met inclusion criteria determined by *multistage random sampling* method were recruited in this study. The inclusion criteria including teacher aged >20 years old, while the exclusion criteria were pregnant or sick during the study. Age, marital status, physical activity, teaching activity, and sleep duration were collected through interview using structured questionnaire and validated GPAQ, whereas nutrient intake was retrieved from 2x24hr *food recall* interview and FFQ then analyse using Nutrisurvey. Anthropometric data (weight, height, waist and abdominal circumference) were collected by direct measurements using digital scale, *microtoise*, and elastic bands. As a quality control, all measurements were done by trained enumerator (nutrition students).

Data of HDL-C, triglyceride and plasma glucose were done in standardized laboratory. Every subject suggested to fast for 12 hours, not doing exercise and smoking before the blood sampling. Blood pressure was measured by nursing using *Sphygmomanometer*. Metabolic syndrome was diagnosed using NCEP-ATP III diagnosis criteria\(^{13}\). *Chi-square* test was used to observe the association between metabolic syndrome and independent variables with 95\% CI and \(P\) value <0.05. For multivariate analysis, simple logistic regression was used to observe the independent variable that have highest association to metabolic syndrome.

**Ethical Consideration:** This study has been approved by IRB at Faculty of Public Health Universitas Indonesia (Ref No: 37/H2.F10/PPM.00/2013).

**Findings**

On average, respondents aged 45 years ± 10.07, women (77.5\%) and had been married (89.9\%). Mean of respondent’s waist circumference was 82 cm ± 1.07 (60.55 – 111.00 cm). Central obesity which sign by high waist circumference was the most common criteria found in respondent, accounted for 47.8\%, then followed by hypertension (38.4\%), low HDL-C level (37.7\%), 26.1\% of low triglyceride level and high fasting plasma glucose as much as 12.3\%.

Based on NCEP-ATP III diagnosis criteria, 34 respondents (24.6\%) were having metabolic syndrome and the rest 75.4\% were not having metabolic syndrome. Table 3 shows frequency of nutritional status, nutrients intake, and lifestyle variables. The analysis revealed that two-thirds respondents were overweight and obese and more than two-thirds of them were also having high abdominal circumference. Mean respondent’s BMI was 27.14 kg/m\(^{2}\), while mean abdominal circumference was 91.48 cm. Analysis of food consumption includes carbohydrate, cholesterol, and frequency of vegetable consumption. The result showed that one-fourth subjects were having carbohydrate intake >60\% of total energy and vegetable consumption frequency <4x/week, even more than a half respondent were having cholesterol intake >200 mg/day. Lifestyle variables measured includes physical activity, teaching activity, and sleep duration. Based on physical activity, more than half of respondents were having light to moderate physical activity and only 16\% having intense physical activity. Whereas for teaching activity, proportion between teacher mostly sitting, standing, and walking during teaching were almost the same (±31\%). Lastly, four-fifth respondents have sleeping duration ≤7 hours/day.
Bivariate and multivariate analysis

The association between metabolic syndrome and several risk factors was tested using chi-square analysis and presented in table 3. Results revealed the association between age, BMI, abdominal circumference, and teaching activity with metabolic syndrome (P<0.05). While other variable with P>0.05 did not show any significant association with metabolic syndrome but showing tendency that respondent with married status, cholesterol intake >200 mg/day, carbohydrate intake >60% of total energy, vegetables consumption <4x/week, and sleep duration ≤7 hours/day are more likely to have metabolic syndrome. Multivariate analysis then showed that an individual with BMI >25kg/m² have 14.79 higher risk to develop metabolic syndrome (table 4).

Discussion

The metabolic syndrome prevalence in schoolteachers’ population was 24.6%. Those prevalence was higher compared to other region such as Indonesia (24.4%)9, Semarang (16.6%)14, Depok (23.8%)15, USA (23.7%)16, and Thailand (21.9%)17. High prevalence of metabolic syndrome in teachers was likely due to the respondent’s characteristics that is more than two-thirds aged above 40 years. It is also found that age have strong association with metabolic syndrome and also relevant with some previous studies which describe that risk of metabolic syndrome will increase at age above 407,13.

As the increasing of age, specifically over 30 years old, body fat will increase due to a decrease in the strength of energy combustion up to 10% every 10 years which causes fewer calories burnt and lead more calories stored as fat in the body. The increase of age also causes a decrease in muscle mass while fat tissue increases, both causing the accumulation of free fatty acid (FFA) in the body then increase risk of metabolic syndrome18.

Marital status didn’t show an association but a tendency that metabolic syndrome proportion was higher in the married group. Previous study explained that marriage is the main social relationship in most adults and become unhappy in marriage could lead to potential psychosocial stressor and will increase the risk of metabolic syndrome19. This study found an association between BMI and abdominal circumference with metabolic syndrome. The proportion of metabolic syndrome among respondents with BMI ≥25 kg/m² reached 37.1% and 30.6% among respondents with high abdominal circumference. The results in line with some previous studies8,20,21,22. On the condition of excess fat, adipocyte cell will maintain energy balance by releasing Interleukin-6 (IL-6), Tumor Necrosis Factor-α (TNF-α), and Monocyte Chemotatic Protein-1 (MCP-1). Both IL-6 and TNF-α will trigger the formation of C-Reactive Protein (CRP) in the liver, which, if produced continuously may worsen the inflammatory condition. In addition, obesity condition also followed by an increase in fat metabolism which lead the production of Reactive Oxygen Species (ROS) and results in the increase of oxidative stress. Oxidative stress cause dysregulation of adipose tissue and its a sign of early pathophysiology of metabolic syndrome. Moreover, adipocytes cells in the abdominal area are larger and less sensitive to antilipolysis which impacted on the increase production of FFA and triglycerides, the decrease in HDL-C mediated by CETP enzyme23.

Diet high in carbohydrates, particularly complex carbohydrate causes an increase in reserves glycaemic index24. Subsequently, the excess carbohydrate in the body will convert into fat in the liver then taken to the adipocytes which can store unlimited amounts of fat, causing obesity and higher risk of metabolic syndrome. Increasing in cholesterol intake also elevate the risk of metabolic syndrome through escalation of triglycerides and decrease of HDL-C. Cholesterol and saturated fat will activate LDL-C receptor which can increase LDL-C level and triglyceride in the bloodstream25. Frequency of vegetable consumption ≥4x/week regularly already proved in lowering CRP plasma concentration so it can reduce the risk of metabolic syndrome.

Physical and teaching activity also known as risk factors that significantly associated to metabolic syndrome which parallel with result of previous studies25,26. Light physical activity lead to the decrease of skeletal muscle insulin sensitivity then cause insulin resistance and metabolic syndrome. Besides, more time spending for sitting together with high calorie intake will cause obesity which associate with the increase of FFA in plasma26,27. Lastly, short sleep duration might also play role in the development of metabolic syndrome even though the relationship was not statistically significant. Short sleep duration could increase ghrelin hormone concentration which causes hungry and might lead to higher energy intake28. Besides, shorter sleep duration also triggers changing in glucose metabolism that could cause insulin resistance29. BMI >25 kg/m² as the marker of over-nutrition was found as dominant factor related to metabolic syndrome. Obesity condition marked by higher fat mass mainly affecting the secretion of free radicals including IL-6, TNF-α and MCP-1 then worsen the inflammatory condition and causes metabolic syndrome.

Conclusions

BMI >25 kg/m² was found as dominant factor related to metabolic syndrome. Maintain BMI in normal range is crucial to prevent the occurrence of metabolic syndrome.

Abstract

Background: Holistic care is a comprehensive model of caring. It has been known as bio-psycho-socio-cultural approach.

Objective: This study aims to develop a holistic nursing care model for mental disorder patients in Indonesia.

Method: This study using explanatory design with cross sectional approach. The participants are nurse in mental health hospital in one province in Indonesia. The sample size is 120 nurses. Data were collected using questionnaire then analyzed using Partial Least Square.

Results: Comprehensive modality therapy (path coefficient=0.621; t=11.75), written standard operational procedures for modality therapy (path coefficient=0.749; t=4.107), nurse competency (path coefficient=0.838; t=30.341), hospital policy (path coefficient=0.567; t=10.736), hospital facilities (path coefficient=0.861; t=23.028), community and family engagement (path coefficient=0.797; t=14.252), and cross-sector collaboration (path coefficient=0.756; t=11.326), influenced the implementation of holistic nursing care in treating mental disorder patients.

Discussion: The holistic nursing care model in treating mental disorder patients not only bio-psycho-socio-spiritual approach but also depend on supportive healthcare facility, policy and community.

Keyword: holistic, nursing care, mental disorder

Introduction

Mental disorder is a behavioral syndrome associated with symptoms of suffering, limitations, and inability to perform essential human functions (1,2). Indonesian basic health research which conducted in 2013 shows that 1.7/1000 of Indonesia’s population has severe mental disorder, with 14.3% experienced restrained in home (3). Six out of 100 Indonesians suffer from emotional mental disorders, resulting in poor productivity and quality of life. Mental health nursing goals is to improve and maintain the patient’s adaptive behavior to contribute to their integration function.

Various therapeutic alternatives intervention in treating mental disorder patients has been developed: psychopharmacology drug, electroconvulsive therapy, cognitive and behavioral therapy, group activity therapy, family therapy and psychiatric rehabilitation. Indonesian government roadmap about “Indonesia free restrain” by 2014 has been socialized since 2010. In fact, the case finding of mental disorder patients who are being restrained in home continues to increase. The Indonesian Ministry of Health data showed the case finding of mental disorder patients who are being restrained in 2010 was 383, in 2011 was 1139, and data from January to August 2012 was 803.

Holistic care is a comprehensive care that aim to meet the patient’s physical, mental, social and emotional needs (4,5).

Caring for mental disorder person will cause productivity loss of family member who become their caregiver. That condition will lead to economic potential lost due to mental disorder. The potential economic lost
due to severe mental disorder is equivalent to the number of patients times by regional minimum wage (58,520 people x 2,2 million) around IDR 128,744,000,000 cost.

Preliminary study shows that mental disorders not only a patient problem, but also family, community, health care, including nurses. Nurses should have the competence such as delivering nursing care, implementing standard operational procedures, and conducting modality therapy in caring for mental disorders patients. A number of barriers in giving care for mental disorder patients in hospital include: incompleteness of nursing care documentation, limited service facilities, ineffective of management implementation in the ward, lack of human resources in nurses (quantity and competence), workload (5) and the condition of patients treated (6). Problems concerned to family and community include: family perception that one family member had mental disorder, caring for family member mental disorder, family feeling, stigma from family and community, perceived impact, and family expectation. It is necessary to formulate a holistic model of mental health nursing. Holistic service is a design of a comprehensive model of health care in view of the various healthy responses of illness by taking into account all components such as biological, psychological, social, cultural and even spiritual (7).

The holistic model will involve the contribution of all elements include patient, family, community and health care providers especially nurses. So this study aims to develop a holistic model in giving care of mental disorders patients.

Materials and Method

Study Design

This study uses explanatory method. The population of the study was nurses at mental hospital Menur Surabaya and mental hospital Lawang Malang. The sample was 120 respondents obtained through simple random sampling technique.

Measures

The data quantified using questionnaires that developed based on previous result of our study. The questionnaire is consist of 55 questions dividing in 8 categories that reflect the study variables: the implementation of holistic nursing care, the implementation of modality therapy, standard operational procedures, human resources nursing, hospital policy, hospital facilities, community condition, and cross-sector role. Each questions is rated on four-point of likert scale (always, sometimes, rarely and never).

Data collection

Respondents were completed the study questionnaire individually after obtaining an explanation of the purpose, benefits, rights and responsibilities of the respondent, and provided the inform consent to follow the study. The respondents fill out questionnaires data characteristics of respondents include gender, age, employment, place (unit) work, and level of education and questionnaire research variables. The collected data is then tabulated for analysis.

Data Analysis

The data were analyzed using partial least square variance-based structural equation modeling (PLS-SEM) in order to model for simultaneous relationships among multiple constructs.

Findings

Characteristics of Respondents

Characteristics of respondents based on the results of the description presented in table 1 in the form of frequency and percentage values. The data show that the majority of respondents are at productive age (36-40 years old) with year of services in 11-15 years. Respondents mostly work in in-patient ward and some have educational backgrounds as Nursing and Nursing Diploma 3.

Model test results Analysis of research variables

The holistic nursing care model test in caring for mental disorders patients begins by evaluating the relationship of latent variables with the study variables through validity and reliability tests. Table 3 describes valid latent variables in forming research variables. Reliability of latent variable is shown with composite value of reliability >0.7. While variable validity is indicated by measuring convergent validity and discriminant validity. Convergent validity was achieved after the research variables obtained the average value of extracted (AVE) >0.5.
Structural model analysis

Structural test of holistic model is used to test the research hypothesis. The results of the holistic model structuring test in treating psychiatric patients were performed on valid and reliable research variables. Based on the results of the structural model test as can be seen in table 5 that the modality therapy is built significantly by 3 research variables, namely modal therapy, hospital policy and community situation. The three variables each have a positive relationship, in the sense that the better the nurse modality therapy, the more supportive of hospital policies and the more supportive of the community situation then the application of holistic models in mental patients will be better. These three variables together determine the implementation of the holistic model in treating psychiatric patients by 40.5%, and the rest is influenced by other variables that are not examined.

**Discussion**

This study shows that holistic model in treating psychiatric patients was shaped significantly by the implementation of nursing modality therapy, hospital policy and the situation in the community which in line with previous study (8-11) that the holistic approach consists of two aspects: the patient and the multidimensional which becomes complicated by the patient’s pain situation. The holistic model focuses on the health conditions of psychiatric patients and attempts to the outside aspects of the patient’s system, the hospitals and the community.

Mental health hospital should have supportive policy towards modality therapy implementation for mental disorder patients. The holistic model pays attention to the community’s response and community engagement
to mental disorder patients when back to their home. Mental hospital should develop community-based interventions, family-based interventions, preparing the community readiness to caring for mental illness patients to warrant the continuity of modality therapy implementation.

The results of the study show that the mental health nursing holistic model is applied by performing integrated nursing care starting from the assessment especially in the spiritual aspect, making the diagnosis based on 10 major nursing problems, bio-psycho-spiritual-social problem and individual-based intervention, and implementing intervention based on Standard operational procedure. This model is in line with previous study (12) that stating that holistic nurses will provide care to a patient thoroughly covering the process of assessment, determination of diagnosis, formulating goals and treatment plans, intervening and evaluating. Previous study shows that a holistic nursing approach raises demands for nurses to interact with patients well so as to determine the health status of patients and determine appropriate actions to improve health (11). So the approach of nursing care is an appropriate method in compiling a holistic nursing care model development in caring for mental disorders patients.

Spiritual aspect need to be assess by nurses during hospitalization. Hospital should facilitate the patients spiritual fullfillness, spiritual consultants and the patient’s expectation of his illness (13). Currently the nursing care given to the patient still focuses on the biological, psychological and social aspects, so that the addition to the spiritual aspect will complement the nursing approach in the holistic model of nursing.

Modality therapy is one component of the application of holistic models in treating psychiatric patients. Modality therapy has a varied approach to mental disorder including somatic therapy, psychological therapy, environmental therapy, community therapy and activity therapy (14) and aims to change maladaptive behavior to be more adaptive. Nurses should pay attention to patient characteristics and disease conditions in providing modality therapy, so that the patient is willing and able to follow the therapeutic process.

The holistic model integrates the biological, psychological, social and spiritual aspects in caring for mental illness patients. The biological aspect is manifested in the medication which will help mental patients achieve improved mental functioning (14). Medication intervention should be accompanied by psychological intervention. Psychological therapy focuses on the use of both verbal and non-verbal communication, improving the thought process and helping the patient understand all about mental disorder (15,16). Psychological therapy is delivered simultaneously with social therapy (World Health Organization, 2005).

The holistic model use individual therapy, cognitive therapy, behavioral therapy, psychosocial therapy and group activity therapy to train patients independently. During the treatment process the nurse pays attention to the patient’s verbal and non-verbal responses, with clear outcome. The holistic model adds spiritual therapy as an important part in the application of modality therapy by helping patients to recognize their ability to deal with illness, especially with regard to motivation, positive attitude and optimism (13).

The key of modality therapy is a good therapeutic patient-nurse relationship (17). The relationship should be established so nurses can select the right modality therapy which can help the patient to achieve better outcome.

Hospital policy is the second component that needed to apply holistic model to ensure patients receive holistic services. The results showed that hospital policy related to job description, authority, remuneration, and reward is needed to implement mental health holistic model. Job descriptions are information that describes job standards and task lists to be done in relation to a person’s position in a particular job (18) which relate to the authority in perform an action. Nurses working in health institutions according to Indonesian Law No. 23 of 1992 on health that state that the ability and authority to perform nursing care is based on their education level. The authority of the nurse is the right and autonomy to perform nursing care based on the ability, level of education, and the position held.

Mental health nurses in Indonesia have multiple job including structural position that obstruct to fully carry out the main task of carrying out treatment to the patient. The findings of this study are consistent with Fisher’s (2011) opinion that patient-nurse rasio is high which cause incomplete documentation and could not carry out intensive psychological intervention. The results show
that remuneration and reward systems are an important aspect of hospital policy when implementing holistic model. Inappropriate reward that nurses get will affect the intervention implementation. The holistic model in this study requires a clear policy about job descriptions and authorities and appropriate remuneration and reward systems.

Community is important aspect in applying holistic model in caring for mental illness patients. The results of this study indicate the existence of elements of community empowerment in the mental health nursing holistic model. Patients with mental illness after hospitalization will return to their families and communities, thus requiring favorable circumstances to avoid recurrence. Nevertheless it is well known that the stigma of society is still high on the existence of patients Schizophrenia, so it takes an intensive approach so that people begin to receive and support the patient’s existence in family and society. The stigma that developed in the community is caused by the lack of understanding related to mental disorders, the impact and the way of treatment (19).

The application of holistic models requires a special strategy to manage the stigma in the community. So that the nursing holistic model that has been applied since the patient is hospitalized can be continued with good community acceptance, even the community to support the use of health service facility, will be able to decrease the recurrence rate.

**Conclusion**

The holistic model in caring for mental disorders patients using nursing care approach of the soul which in its implementation pay attention to the patient from biological, psychological, social and spiritual aspects. The holistic model is carried out by applying the treatment of soul-nursing modalities supported by the hospital policy and the existence of a conducive community situation.

Benefits of Standard Therapy with Nasal Irrigation Using NACL 0.9% on Chronic Rhinosinusitis Patients without Polyp

Muhammad Fadjar Perkasa¹, Agusmiani Ahmad², Abdul Kadir³, Burhanuddin Bahar⁴
¹Department of ear, Nose, Throat, Head-Neck Surgery, Medical Faculty, Hasanuddin University, Indonesia, ²Department of Biostatistic, Public Health Faculty, Hasanuddin University, Indonesia

Abstract

Background: Chronic rhinosinusitis is a clinical problem that has a serious impact on patient quality of life. This study was aimed to observe the effect of nasal irrigation therapy with 0.9% NaCl on improving CT-scan and quality of life of chronic rhinosinusitis without polyp.

Materials and Method: It was a prospective cohort study of 24 adult patients. Divided into 2 groups with standard therapy with nasal irrigation and without nasal irrigation. The results were assessed based on a CT-scan imaging with Lund Mackay score and quality of life with SNOT-20 before and after therapy.

Results: There were significant improvements in CT scans (p = 0.002), and quality of life after standard therapy with 6 weeks once daily nasal irrigation, but no significant change in CT scores (p = 0.552) in the group after standard therapy without nasal irrigation.

Conclusion: standard therapy and once-daily nasal irrigation give better outcome for chronic rhinosinusitis without polyp before considering surgical intervention.

Keywords: Nasal irrigation, Lund Mackay score, SNOT-20.

Introduction

Rhinosinusitis is an inflammatory disease of nasal mucosa and paranasal sinus usually caused by viral, bacterial, fungal, dental infection, or due to fractures and tumors. If this rhinosinusitis continues with a period of symptoms of ≥12 weeks characterized by two or more symptoms, one of which is a nasal congestion / obstruction / congestion or nasal secretion (anterior, posterior nasal drip) is referred as chronic rhinosinusitis (CRS).¹,²

The current prevalence of CRS has reached 13.4 to 25 million cases. According to the National Ambulatory Medical Care Survey in the United States in 2001 there were 12.3 million visits to health care each year due to CRS. While in Indonesia precisely at the Cipto Mangunkusumo Hospital (RSCM) has been reported that the incidence of new cases of rhinosinusitis in adult patients who come to the Rhinology Division of Department of ENT in January to August 2005 as many as 435 patients and 300 patients of which suffered rhinosinusitis. In addition, from three teaching hospitals in Makassar City from 2003 to 2007, 4.5% of cases of rhinosinusitis from all cases treated by the Rhinology Department¹,³,⁴,⁵

Furthermore, in the diagnosis of CRS, the symptoms is one of the important things and imaging studies such as CT scan is the gold standard. Some cases of chronic rhinosinusitis generally have to end with surgery. Therefore, proper diagnosis and management is necessary to prevent the severity of CRS. According to the CRS management guidelines recommended use of antibiotics, topical steroids and nasal wash with physiological NaCl solution.²,⁶

DOI Number: 10.5958/0976-5506.2019.02085.0
One that has been known empirically and widely applied to CRS patients in the clinic is irrigation or nasal wash which generally use isotonic saline solution, this nasal washing is believed to be able to relieve symptoms of rhinosinusitis. Wei JL et al 2011, intranasal irrigation with saline or saline + gentamycin is safe and effective in the treatment of chronic rhinosinusitis in pediatrics on CT scan based on Lund Mackay and quality of life. This study aims to examine the effect of standard therapy with nasal irrigation with 0.9% NaCl on improvement of CT-scan score based Lund Mackay (LMK) scoring system and quality of life based on SNOT-20 in chronic rhinosinusitis without polyps patients.

**Materials and method**

**Research site**

This research was conducted in the outpatient unit of ENT department Dr. Wahidin Sudirohusodo Hospital Makassar starting from December 2017 until March 2018.

**Design and research variables**

The design of this study is experimental cohort study. The independent variable in this study was patient with chronic rhinosinusitis without polyp, while the dependent variable was improved symptoms, CT scan and improvement of quality of life after 6 weeks.

**Samples**

The sampling technique was performed randomly. In this study all patients who have been diagnosed as chronic rhinosinusitis based on the history, the ENT diagnostic examination were undergone CT scan of paranasal sinus coronal view and record quality of life by SNOT 20. The sample size is 24 patients were devided into 2 groups. Patients in the first group (12 patients) received standard therapy for 3 weeks and adjuvant therapy once daily nasal irrigation with NaCl 0.9% for 6 weeks, while the second groups received only standard therapy without nasal irrigation. After 6 weeks, Patients from both groups were examined for CT scan of paranasal sinus coronal view and quality of life by SNOT 20.

**Research Ethics Aspect**

The study permit was obtained from Biomedical Research Ethics Committee on Human Faculty of Medicine Universitas Hasanuddin (Register No. 1030/H4.8.4.5.31/PP36-KOMETIK/2017).

**Exclusion criteria**

Patients with sinonasal tumors, nasal polyps, severe septal deviation, septal perforation, maxillofacial fracture, rhinosinusitis with orbital complications, pregnancy and lactation, and patients with a history of Endoscopic sinus surgery.

**Drugs**

The drug that we used is standard therapy cefadroxyl 2x500mg oral, methylprednisolon 2x4mg oral, and tremenza 2x1 oral for (3 weeks) and nasal irrigation is 20 ml NaCl 0.9% each nasal cavity once daily for 6 weeks.

**Statistical Analysis**

Data were analyzed using Statistical Package for Social Sciences (SPSS) software (version 21.0 for Windows; SPSS Inc, Chicago, IL).

**Findings**

The total number of Lund Mackay (LMK) score before therapy appears to be a maximum total score of 22, and a minimum total score of 3, with a mean rank of 7.5. And total score of Lund Mackay after therapy maximum 21 and minimum score 1 with mean rank 4.5.

While the total number of SNOT-20 score before treatment was obtained at a maximum of 78 and a minimum of 21 with mean rank of 44.5, and for after treatment the total score of SNOT-20 was maximum 71 and minimum 7 with mean rank 21.

*Wilcoxon Signed Ranks Test

Table 4. shown that 33.3% of sample had negative rank or having mean (14) of CT scans with Lund Mackay score at pretest to be lower (12) at posttest. 25.0% of sample had positive rank or having mean (5.3) at pretest to be higher (10) at posttest, and 41.7% of sample had ties rank or there was no change of mean at before (7.6) and after (7.6) of therapy standard intervention. Wilcoxon Signed ranks test shown that there was no significant change of disease before and after standard therapy.

For the quality of life the total score of SNOT-20 shown 100% of samples were improved their quality of life after standard therapy. Wilcoxon Signed Rank Test results shown that there was a significant change quality of life before and after standard therapy intervention (0.002).

**Discussion**

In this study, the characteristics of the sample showed similar distributions between male and female sexes. The incidence rate in chronic rhinosinusitis by sex is found to be the same or slightly more in males. However, in this study there were 14 samples (58.33%) of women, and 10 samples (41.67%) were male. This is consistent with another study where the incidence of chronic rhinosinusitis two times more in women than in men.9,10

Age distribution showed that sample age was varied, most of them in 31-40 age group as many as 14 samples (58.33%), and age group 20-30 years 10 samples (41.67%), with mean age of sample 31.45 year. This suggests that chronic rhinosinusitis is more common in young adulthood. This is as reported by Privina Arivalagan, (2013) incidence of chronic rhinosinusitis that occurred in RSUP Haji Adam Malik in 2011 most often in the 31-45 year age range. Characteristics of the sample according to the symptoms in this study were Rhinorrhea (41.7%), Post Nasal Drips and Nasal Obstruction 29.2% respectively.11

In our study, the Lund Mackay Score in Patients with Chronic Rhinosinusitis without polyps Improved in all samples (100%) After Standard Therapy + Nasal Irrigation With Nacl 0.9% once daily for 6 Weeks, with significant changes in Lund Mackay score of 0.002 (p
<0.05). This result is in line with the previous study that the daily use of nasal irrigation for 6 weeks is very effective and safe as chronic rhinosinusitis therapy in children where from the CT scan can be seen a reduction in sinus mucosal thickening and correlated with reduced complaints. In another study, a Lund Mackay score of 4.14 and 4.38 on the left and right sinuses, p <0.001 after nasal irrigation with isotonic saline once daily for 6 weeks in chronic rhinosinusitis children with 65, 9% reported complete resolution and only 12.1% requiring surgical treatment (Wei JL, et al, 2011; Pham Vinh, et al, 2014). It has also been described that nasal irrigation enhances mucociliary function, which reduces usdm and reduces the amount of chemical mediator accumulation, mechanically cleans mucus, provides a mild vasoconstrictive effect that reduces congestion complaints, and nasal irrigation also restores aeration in the sinus, thereby decreasing the progression of excess bacteria. Therefore, nasal irrigation may be recommended as first-line adjuvant therapy in chronic rhinosinusitis without polyps before considering surgical therapy.

This study also showed that quality of life based on SNOT 20 in chronic rhinosinusitis patients without polyps had significant improvement in all samples (100%) after standard with nasal irrigation therapy once daily for 6 weeks with a value of 0.002 (p <0.05). This result is in line with the previous study that the daily use of nasal irrigation provides improved quality of life after 6 weeks. Another study concluded that in cases of allergic rhinitis, salin use improved nasal symptom improvement by 27.6%, reduced drug use by 62.1% and improved quality of life by 27.8%.8,12

In the control group, the change in lund mackay score and quality of life based on SNOT-20 in chronic rhinosinusitis patients without polyps after standard therapy without nasal irrigation once daily for 6 weeks, only 4 (33.33%) samples from 12 samples improved Lund Mackay score, 5 samples (41.66%) unchanged, and 3 samples (25%) experienced worsening Lund Mackay score after standard therapy without nasal irrigation. This shows no significant change in Lund Mackay’s total score on CT scan of patients with chronic rhinosinusitis without polyps.

While the quality of life measured by the total number of SNOT 20 score can be seen that there is a change in SNOT 20 score to be better after the use of standard therapy without additional nasal irrigation in chronic rhinosinusitis without polyps patients, where Wilcoxon Signed Rank Test results showed significant figures 0.002 (p <0.05). The effectiveness of medical therapy on chronic rhinosinusitis in improving complaints and quality of life to 40%.

The limitations of this study are the limited number of samples requiring further study with more samples, patient adherence to both standard medical therapy and nasal irrigation with saline not measured, and not being accurate about how much irrigation is required and at what speed / effective irrigation power.

Conclusions

Management of chronic rhinosinusitis without polyp with standard therapy and nasal irrigation NaCl 0.9% once daily for 6 weeks gave a much better result of a review of the results of Lund Mackay CT scan score and quality of life based on SNOT-20, compared with standard therapy without nasal irrigation.

Once-a-day nasal irrigation may be the first line of additional therapy for chronic rhinosinusitis without polyps thus improving the quality of life before considering surgical intervention.

Abstract

Stunting is a major nutritional problem in children under five that occurs in developing countries. Child health care practices by good parents can prevent stunting in children from an early age. Child health care practices include immunization, sick child care, hand washing, clean water supply and drinking water, and sanitation. The purpose of this study is to analyze the effects of child health care practices on stunting in children aged 12-36 months in Jember Regency, Indonesia. This research was an observational analytic study using case-control design. The population of the study were the mothers with children aged 12-36 months in the sub-districts of Arjasa and Kencong in Jember Regency. The sample were selected using simple random sampling technique, totaling of 220 mothers. The data were analyzed using chi-square statistic tests and multiple logistic regression tests. The results of tests discovered that most of the subjects were poorly educated and as housewives. The significant determinants associated with stunting were completeness of basic immunization, water supply and drinking water, and sanitation (p < .05). Thus, we can conclude that there was a significant effect of child health care practices on stunting in children under five. It should be further investigated about the influence of socio-cultural factors that affect child health care practices.

Keywords: stunting; child health care practices; drinking water; immunization; sanitation

Introduction

Stunting is a major nutritional problem in children under five especially in the developing countries. World Health Statistics data in 2014 shows that one of four children aged less than five years worldwide experience stunting. More than 178 million stunting children are in developing countries and 99% in the region of Southeast Asia and Africa¹².

Stunting can be caused by malnutrition that occurs early from the development of the fetus to two-year-old child. Stunting children tend to have low cognitive development, chronic diseases, infectious diseases, low productivity, and adversely affect social, economic outcomes and increase the risk of future child mortality¹⁴.

Indonesia is at the fifth position of the countries that have the highest stunting prevalence. Based on the results of Basic Health Research, stunting prevalence in Indonesia is 36.8%, 35.6% and 37.2% in 2007, 2010 and 2013 respectively³. East Java Province is a reflection in the achievement of child health outcomes in Indonesia. The prevalence of stunting in East Java has remained stagnant over the last three years of 27.0%, 26.1%, 26.9% in 2015, 2016, and 2017. This means that East Java has not met the national target of 26.2%⁶.

Child health care is one of the determinants of stunting. Good health care practices by parents with attention to child’s condition, completeness of basic immunization, hand washing, environmental hygiene and caring for children during illness may prevent stunting in infants⁷. Children who are not immunized are three times more likely to have stunting⁸. Unsuitable laundry practices by mothers increase the risk of stunting 2.89 times greater. Mothers who are able to care for children better, their children have less risk of illness and malnutrition⁹. Poor water sources, drinking water, and
sanitation also increase the risk of children becoming stunting\(^{10}\).

Jember Regency is at the second position of the districts with the highest stunting prevalence in East Java (39.3\%)\(^{11}\). Therefore, Jember Regency has become one of the stunting priority districts in East Java. Arjasa and Kencong sub-districts of Jember Regency are the highest prevalence stunting areas (39.30\% and 38.78\%)\(^{12}\). The objective of this study is to analyze the effects of child health care practices on stunting in children aged 12-36 months in Jember Regency, Indonesia.

**Materials and Method**

This research was an observational analytic study with case-control design. The study was conducted in Arjasa and Kencong sub-districts of Jember Regency in March till April 2018. A simple random sampling was used to select the sample of 220 mothers with children aged 12-36 months (110 stunting children as a case group and 110 non stunting children as a control group).

The data of immunization completeness was obtained from the attachment of Maternal and Child Health (MCH) book Data on child health care, handwashing practice, clean water sources, drinking water and sanitation were obtained from structured interviews with questionnaires and observations. All of the questionnaires were calculated by the validity and reliability test.

In order to examine the effect of health care practice (completeness of basic immunization, child health care, handwashing practice, source of water, sanitation) to stunting, the data were submitted to the bivariate analysis with chi-square and multivariate analysis with multiple logistic regression with 95\% confidence interval and significance level \(p < 0.05\).

**Findings**

*Table 1* shows that most of the stunting children were male (60.0\%) while most of the non-stunting children were female (50.9\%). Maternal age in stunting and non-stunting children was mostly between 26-35 years (48.6\%). Most mothers of children (63.2\%) had a low education (elementary schools and junior high schools). Most of them (73.2\%) were housewives while most of the fathers were unskilled workers (40.9\%). Most of the number of family members in a single home was less than 4 persons.

</table>
Table 2 shows that the number of children with complete immunization was higher than that of children with incomplete immunization. Most mothers of stunting children did not do child health care so well. The practice of hand washing on stunting and normal groups was largely bad (unqualified). The source of clean water and drinking water in the stunting group and the normal large sections is good. Sanitation in the stunting and normal group is more eligible (good).

The results of the present study have shown that complete basic immunization, child health care, hand washing, drinking water and clean water, and sanitation had significant effects on stunting. Providing immunization to children during early life can improve child immunity so that children are not susceptible to certain infectious diseases which in turn can aggravate health conditions and nutritional status. The results of this study were consistent with other studies showing that vaccination had a significant effect on stunting, children who were not given complete immunization were three times more likely to have stunting than children who were given complete immunization. Most of the respondents's children had a complete baseline immunization history and the immunization proceedings were effective. However, complete basic immunization if not matched with a good intake of macronutrients and micronutrients and the presence of recurrent infections in children can worsen stunting conditions in children.

Table 3 shows that the results of multivariate analysis with multiple logistic regression test, we can see that the sources of clean water and drinking water (p = 0.040; B = 1.914), sanitation (p = 0.007; B = 0.414) and basic immunization completeness (p = 0.000 B = 0.260) were the dominant factors affecting the incidence of stunting in children. However, child health care practices and hand washing practices did not significantly affect stunting for pediatric health (p = 0.888; B = 0.957) and for handwashing practice (p = 0.852; B = 0.939).

Discussion

The respondents of this study were dominated by low-educated mothers. Education is one of the factors that can influence the practice of mother care for children because it is closely related to knowledge. Highly educated mothers generally have an understanding of better child care and nutrition than low-educated mothers. Highly educated mothers also have the ability to read and understand health information media so as to have greater opportunity to be exposed to nutrition and childcare education. The respondents were mostly housewives. Housewives have more time and will spend their daily lives caring for children at home so that they tend to perform better maintenance practices compared to mothers working outside.

The results of the present study are consistent with other studies showing that complete basic immunization, child health care, hand washing, drinking water and clean water, and sanitation had significant effects on stunting. Providing immunization to children during early life can improve child immunity so that children are not susceptible to certain infectious diseases which in turn can aggravate health conditions and nutritional status. The results of this study were consistent with other studies showing that vaccination had a significant effect on stunting, children who were not given complete immunization were three times more likely to have stunting than children who were given complete immunization. Most of the respondents's children had a complete baseline immunization history and the immunization proceedings were effective. However, complete basic immunization if not matched with a good intake of macronutrients and micronutrients and the presence of recurrent infections in children can worsen stunting conditions in children.

The results of the present study is also in accordance with other research results in Nigeria showing that there is a significant relationship between child health care with stunting. Mothers who are able to perform child health care routinely check the health conditions of children in health facilities and understand the actions that need to be done if the child is sick, then the child has a smaller risk to experience infectious diseases and malnutrition.

Hand washing practices also affect stunting in children. Most respondents did not perform good hand washing habits before preparing food, before meals, and before feeding the children. Hand washing practices are associated with stunting and child malnutrition through episodes of infectious diseases in children. The results of this study are consistent with other studies showing that poor handwashing practices in mothers with children younger than 2 years in urban areas with
low socioeconomic levels are associated with higher episodes and duration of diarrhea\(^6\).

Source of clean water, drinking water and sanitation also affects the incidence of stunting in children. The results of this study are consistent with studies in Ethiopia showing that good water quality can reduce the incidence of diarrhea in children\(^7\). Sources of clean water and drinking water is the first route of exposure to infectious diseases and better water sources will not be beneficial to health if not accompanied by improved sanitation and good water storage practices\(^8,9\).

Providing a good source of clean water and drinking water will reduce the incidence of infection in children through the prevention of microbiological contamination or certain chemicals during hand washing, on cutlery, bathing, drinking and cooking. Drinking water from an uncooked spring can result in food borne disease. The ripening process of drinking water for children is needed to minimize child contact with pathogens and reduce the incidence of diarrhea. Other research results in India and Indonesia also show that water consumption with water filters and bottled water use is associated with reduced risk of diarrhea in children\(^10\).

Poor sanitation practices are associated with stunting incidence. This result is consistent with research conducted in India showing that an increase in open defecation by 10% is associated with an increase in stunting events of 0.7%\(^11\). Wastes exposed in open areas with poor sanitation conditions and ineligibility can be a potential spot for flies to spawn and multiply, resulting in faecal borne disease. Poor sanitation practices can result in poor environmental health, thus increasing the vulnerability of children to infectious diseases that are one of the causes of malnutrition including stunting\(^3\).

**Conclusion**

Basic immunizations, sources of clean water and drinking water, and sanitation affect stunting in children. Based on these conclusions, it is suggested to Community Health Centers to improve the socialization of hygiene practices in the community to prevent infectious diseases in children. Further research is needed on other factors that affect stunting incidence in children, especially those related to socio-cultural factors of the local community.

Comparison of Needs and Demand on Health Services: A Cross-Sectional Survey in Indonesia

Asruliasani Fajria
Student of Health Policy Administration Program Study, Faculty of Public Health, Airlangga University, Indonesia

Abstract

Health is a capital to work and live to develop offspring. Demand to be healthy is not the same among humans. In the economic activity of health, learning about the needs and demand is needed to determine the level of consumer demand for a product (not just about goods but also health services) so that by knowing it producers (health facilities) can determine attitudes and actions to meet the needs of the consumer (prospective patient). The research method was an descriptive observation with cross sectional design. Sampling is done by quota sampling technique where the research team determine the sample size for the survey of need and demand of health services. The sample size of this research is 100 people. Samples are taken randomly in some areas of Indonesia in Surabaya, Jakarta, Kalimantan, Sulawesi, Bali and Sumatera areas to meet specified quota. The results obtained comparison between need and demand for health service destination is mean 1,46 %. Comparison between needs and demand for speed of service is mean 5,225 %. Comparison of needs and demand for health information from officers is mean 0,94 %. Comparison of needs and demand for ease of health services is mean 1,44 %. There are still gaps because of the factors where health services need aspect, many respondents make a doctor or dentist general practice as a place of choice of health services, whereas on demand, respondents turned out to come to many private hospitals for health services, none gap on the convenience factor of the health service because there is a gap in the speed factor of service and there is no gap in the health information factor of the officer.

Keywords: Need; Demand; Health Services.

Introduction

Individuals will seek to achieve health status by investing and / or consuming a number of goods and services health. To achieve good health is needed good health facilities. Microeconomic theory of the demand for health care services, if health is a normal good, for an individual in a given health, health care will be normal as well. That is, increases in incomes lead to greater demand for health care services. If the income expansion, the health care is a luxury good, and as income increases, a higher share is devoted to health care.

Generally, need and demand of health services can be described in a concept called ice-berg phenomenon. This concept refers to the notion that the right demand should be part of need. Conceptually, need for health services can form an iceberg which is only slightly peak seen as demand. Demand is goods or services actually purchased by the patient. Demand is influenced by the medical opinion of the physician, as well as other factors such as drug revenues and prices. Demand is different from need and want. Wants (wishes) are goods or services that the patient wants because they are best for them (for example, fast-acting drugs). Wants can be the same or different with need.

Need is the quantity of goods or service that is objectively considered best to be used to improve the patient’s health condition. Need is usually determined by...
the doctor, but the quality of the doctor’s consideration depends on the education, equipment, and competence of the doctor. Demand health services is the actual service purchased by the customer health care, in this case is the patient. Demand is influenced by the medical opinion of the physician, as well as other factors such as drug revenues and prices. Demand health services is a health service needed and desired by patients who are accompanied also with purchasing power owned by the patient.

The formula for demand of health services are as follows:

\[
Q_{dmc} = f \left( \text{disease incidence}, \text{provider} \mid \text{cultural-demographic characteristics, economic factors, etc.} \right)
\]

Increasing demand in health services is currently heavily influenced by: a) Quality of health services provided, b) Postpartum care, c) Performance of health services, d) Ease of use of services, e) Payment system. Several factors affecting consumer demand for medical services both in terms of patients and from the providers of medical services are: 1) the incidence of illness 2) cultural and demographic characteristics consisting of: gender, age, marital status, education, patient preferences, 3) economic factors consisting of income, prices, health insurance, time value.

Based on the explanation of the above problem formulation, the purpose of this paper is to know description about need and demand of the community on health services in several regions in Indonesia.

### Materials and Method

This research is an analytic obervesional research with cross sectional study design. The Population in this research was resident in Indonesia. The samples were a part of the population taken as a data source and is considered to represent the entire population. Sampling was done by quota sampling technique where the research team determine the sample size for the survey of need and demand of health services. The sample size of this research is 100 people. Samples are taken randomly in some areas of Indonesia in Surabaya, Jakarta, Kalimantan, Sulawesi, Bali and Sumatera areas to meet specified quota.

This research was conducted online where the instrument is distributed to respondents through online media. Data collection research uses primary data on community needs in general health services. Instruments used in research need and demand is an online questionnaire.

### Result

According to the survey results, the specific comparison of needs and demand on health services can be seen in the following table 1:

Discussion

Demand embodiment of health services may not be in accordance with what is desired due to many things, such as urgent conditions or factors of trust and comfort. There are several factors that can affect one’s need and demand in the utilization of health services. Based on the results of this study, the most respondents need health service destination is doctors or dentists general practice as a place of health service (24%). The most respondents demand health service destination is non-governmental hospitals as a place of health service (29%). This gap can be motivated by various things such as the belief that people believe more to come to the government hospital with a more complete perception or others. In addition, the need factor where it is possible that the needs of the community for health services are widely available in government hospitals compared to the very limited practice of doctors.

Access to health services must be attainable by the community, not hindered by geographical, social, economic, organizational and language conditions. One of them is the geographical state that can be measured by distance, length of travel, type of transport and or other physical barriers that may prevent a person from obtaining health services. Health services that are located too far from the area of residence is not easy to achieve, so it requires transportation to reach the health service, if this situation to happen, certainly will not satisfy the patient, so called a quality health service if the service can be achieved by service users health services.

Health services can be included in the economic concept so that can be learned about needs and demand in health services. Therefore, we need to know and learn what things are needed and desired by consumers as patients to a health service.

Conclusion

There is still a gap between what is wanted from a health facility and what the health care workers in the health facility meet. The gap is quite striking visible in the purpose of health services and speed of health services. This needs attention so that there are improvements and improvements so that between need and demand is suitable or aligned and there is no gap anymore.

Perception on Lasik Surgery Services in Public Eye Hospital of East Java

Elly Ratnaningsih

Master Program in Hospital Administration, Universitas Airlangga, Indonesia

Abstract

Visiting of lasik surgery patients in Public Eye Hospital of East Java in 2016 is quite low (9%) while in 2017 increased (10%) but still below target. Such low achievements are likely to be influenced by consumer perceptions of lasik surgery services. This study aims to assess the community perception of lasik surgery services in Public Eye Hospital of East Java. Assessment of perception includes price, people, process and physical evidence. This study shows that respondents’ perceptions of lasik surgery rates are cheaper than those in other hospitals. Overall perception of officers and service process lasik surgery is good. While the perception of respondents to the physical appearance has not been good, because respondents feel not satisfied with hospital facilities. This research recommends innovation in marketing efforts lasik surgery service and hospital management need to improve infrastructure facilities.

Keywords: perception, lasik surgery services, Public Eye Hospital of East Java

Introduction

Eyes are the sense of vision that serves to absorb visual information. Impairments to vision include mild disturbances and severe disorders that can lead to blindness. Efforts to prevent and cope with visual impairment and blindness need to get attention both by government and society.

The World Health Organization (WHO) established the Vision 2020 program to address blindness and vision problems. Based on data from WHO, worldwide in 2010 there were 285 million people (4.24%) of the population with visual impairment, 39 million (0.58%) with blindness and 246 million (3.65%) with low vision. The most common causes of vision loss are refractive disorders (43%), cataract (33%), and glaucoma (2%).

In Indonesia, Vision 2020 was launched on February 15, 2000. Indonesia’s population suffered from blindness of about 1.5% or 3.6 million. The incidence of blindness caused by refractive abnormalities ranks first as the cause of blindness in Indonesia. According to Basic Health Research (Riskesdas) in 2013 showed that the prevalence of refractive disorder of 22.1% of the total population and the proportion of glasses or contact lens users over 6 years of age in Indonesia is 4.6%, the proportion of sharp decline eyesight of 0.9%, the proportion of blindness of 0.4%. While the proportion of glasses or contact lens users in the population above 6 years old in East Java province was 4.8%, the proportion of sharp decline of vision by 1.0%, the proportion of blindness by 0.4%.

The data of eye surgery visit in Public Eye Hospital of East Java in 2015 until 2017 shows that cataract surgery trend has increased. Board of National Health Insurance (BPJS) policy which prohibits cataract operation service outside in Public Eye Hospital of East Java and policy of restriction of service area coverage with direct referral letter from primary health facility only in 3 (three) regions Surabaya, Gresik and Sidoarjo no impact to decrease number of cataract surgery. Small operations consisting of pterigium, hordeolum, granuloma, intropion repositioning and others have increased significantly. Meanwhile, the achievement of lasik surgery patients in 2016 is quite low (9%) while in 2017 increased by 10% but still below the target of 480 people per year (100%).

The low utilization of lasik surgery services is influenced by consumer perception. If people have a good perception of lasik surgery service then more and more people use the service. This study aims to assess
the public perception of lasik surgery service in Public Eye Hospital of East Java.

Method

Descriptive observational research involves 72 respondents (32 actual patients and 40 potential patients). Potential patient criteria are aged 18-40 years, only get prescription glasses or medicine and are willing to be interviewed in the filling questionnaire. While the actual patient criteria aged 18-40 years, had done pre lasik examination or lasik surgery in Public Eye Hospital of East Java and willing to be interviewed in filling questionnaire.

Sampling using judgment sampling technique. This study assesses respondents’ perceptions of several aspects including tariffs, service personnel, service process and physical appearance. Data processing includes (1) data editing, checking completeness and suitability of questionnaires that have been filled respondents; (2) coding, coding of each respondent’s answer in the questionnaire; (3) data entry, entering respondent data into Ms. program Excel; (4) cleaning, re-checking data that has been inputted; (5) preparation of frequency distribution tables, merging in tabular form so that the results obtained can be informative; and (7). Preparation of strategic issues.

Results and Discussion

Perceptions of tariffs consist of two indicators: tariff comparison with other hospitals and tariff compliance with patient’s ability. Respondents’ perception of lasik surgery rate is cheaper compared to other hospital tariff with average 3.2 whereas perception of respondents who do not do lasik operation stated that most of respondent less able to do lasik operation with average 2.2. Overall perception of the lasik group of patients was good with an average of 3.2. The lowest average value of the perception of a group of patients who did not perform lasik surgery was the professionalism of the officer with an average of 3.10.

Respondent’s perception on service process of lasik operation have some indicator that is waiting time, clarity of service flow and speed of service of officer. Perception of respondents in the group of patients who did not perform lasik surgery on the waiting time has the lowest average value is 2.3 which means less good. Overall perception of respondents to the process of lasik surgery service in Public Eye Hospital of East Java included in the category either with the average of 3.0. Respondents perception on the group of patients who perform lasik surgery to the comfort and cleanliness of the waiting room and service room has the highest average value of 3.41 and 3.38 with very good category. Respondents’ perceptions of the completeness of hospital facilities such as canteen, and friction payment instruments, etc. are still not good enough with an average of 2.3 whereas toilet hygiene is also not good (2.4).

Utilization Analysis of District Health Account Document in Health Planning and Budgeting Study in West and Central Lombok District

Alya Hazfiarini¹, Ernawaty²
¹Department of Health Policy and Administration, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

Health account is a tool which describes health expenditure systematically, comprehensively and consistently which used in national level (National Health Account/NHA), provincial level (Provincial Health Account/PHA) and district level (District Health Account/DHA). Besides, it can be used as a reference on developing health planning and budgeting in each area. West and Central Lombok District have been developed District Health Account (DHA) since 2006, but they did not utilize it as a reference for health planning and budgeting in district level. This study aimed to analyze awareness, interest, desire and action of stakeholder using AIDA model of hierarchy response in DHA program.

This research was a descriptive observational study with cross-sectional design. This research used purposive sampling technique. The respondents were DHA team, the structural official position of District Health Office and the structural official position of District Development and Planning Agency.

The study found that DHA team, the structural official position of District Health Office, and the structural official position of District Development and Planning Agency categorized into aware and desire category. However, the majority of the DHA team member, the structural official of District Health Office, and the structural official of District Development and Planning Agency in West Lombok District and Central Lombok District were categorized as uninterested and inaction category.

Introduction

Health account is a tool which describes health expenditure systematically, comprehensively and consistently¹. Health account used in national level (National Health Account/NHA), provincial level (Provincial Health Account/PHA) and district level (District Health Account/DHA). West Lombok District and Central Lombok District have been developed DHA since 2006. Although DHA was prepared annually, not all DHA documents were available for every year. During 2010 till 2013, West Lombok District had the documents in 2011-2013 whereas Central Lombok District only had the documents in 2010 and 2013. According to interview with former head of program section at Central Lombok District Health Office, this incomplete archive happened because of the document making process stopped at data collection and analysis.

Data of DHA document can be used as a reference for developing health planning and budgeting. According to Table 1, public health programs in both West Lombok District and Central Lombok District had the lowest percentages of health expenditure in 2010-2013. Moreover, according to report of Basic Health Research (Riskesdas) of West Nusa Tenggara Province in 2007 and 2013, there were five health problems which their percentage and prevalence increased from 2007 to 2013.

The five health problems which their percentage and prevalence increased from 2007 to 2013 in West Lombok District were percentage of stunting toddler, percentage of household which did not use defecation facility, percentage of malnutrition toddler, malaria prevalence and hepatitis prevalence. While the five health problems which their percentage and prevalence increased from 2007 to 2013 in Central Lombok District were percentage of stunting toddler, percentage of household which did not use defecation facility, acute respiratory infections prevalence, percentage of malnutrition toddler, and diarrhea prevalence.

According to Table 1, it can be concluded that DHA document was not used as a reference for developing health planning and budgeting in the districts. This study aimed to analyze awareness, interest, desire and action of stakeholders in DHA program using AIDA model of hierarchy response in West Lombok District and Central Lombok District.

**Method**

This was an observational study using cross sectional design. Data was collected in April 2016. Population of this study was all of the DHA teams, the structural officials of District Health Office and the structural officials of District Development and Planning Agency. The sample of the research was all of DHA team members; head of subsection, head of division, head of section or head of subdivision of the structural officials of District Health Office; and the structural officials of District Development and Planning Agency which covered health sector.

There were 49 respondents interviewed with a set of questionnaire using Likert scale. The questionnaire asked about respondents’ knowledge, perception, awareness, interest, desire and action towards DHA program in their district.

**Findings**

WHO stated that it is needed to form a team to arrange a health account document. Regulation of Ministry of Health No. 971 / 2009 explained that health account is a concept that should be owned by the head of Health Office in order to increase the ability and skill of basic planning and budgeting. According to Republic of Indonesia Government Decree No. 8 year 2003, District Development and Planning Agency was technical institution which responsible for district development plan. Nevertheless, the structural official of District Development and Planning Agency should understand district health account concept in order to develop health
sector development plan.

There were four people in DHA team of West Lombok District consisted of official of district health, official of general hospital, and official of financial management board and asset. On the other hand, DHA team in Central Lombok District consisted of district health official, development planning agency official and District Hospital official. Table 3 depicted the interview result which conducted by DHA team in West Lombok District and Central Lombok District.

</tbody>
</table>

Table 2 depicted that all of the DHA team in both districts was not aware with DHA program in their district. However, all of DHA team was not interested with DHA program. It meant that only 50% of DHA team of West Lombok District and 33% of DHA team of Central Lombok District which was interested with DHA program by trying to find out more information about it. Besides, desire of DHA team to utilize DHA document was higher than its interest.

</tbody>
</table>
There were two indicators of action category of DHA Team which had low score (Table 3). The first indicator was arranged DHA document and the second was dissemination DHA document to other official structure in their office, district government, and district legislative. The indicator of arrangement of DHA document was low because not all of DHA team member in both districts involved in all technical process of DHA document arrangement. Moreover, the data collecting process was very difficult to obtain the data from all of district. The dissemination activity was low because the DHA team did not have authority and was lack of the support from district health office.

</table>

Table 4 showed that all of the structural position of District Health Office in both district were aware about DHA program but only 21% of structural position of District Health Office were interested in DHA program. This meant that they tried to find out more information about DHA. Furthermore, desire level of the structural position of District Health Office more increased than the interest level. There were 95% of official of health office in West Lombok District and 84% of official of health office in Central Lombok District who had desire to utilize DHA document. This circumstance happened because they thought that DHA document was needed to summarize district health expenditure and important to utilize the DHA document. However, there were only 11% of structural official of health office in West Lombok District and none of structural official health office in Central Lombok District who categorized into action category.
