\textbf{Estimation of total gas and methane production \textit{in vitro} (ml/200mg dry matter):} The results of Table 3 showed a significant decrease in the T3 treatment containing mint oil (28.12 and 30.24 mg/200 mg dry) in total gas production after 12 and 24 h. of \textit{in vitro} incubation and T2 and T4 treatments by 31.20, 26.55 and 33.22, 28.42 mL/200 mg dry matter, respectively, compared with control treatment T1 36.80 and 37.87 mg/200 mg dry matter, In the same context, after 48 and 72 h. of \textit{in vitro} incubation, there was a significant decrease(p<0.01) in the total gas production (p<0.01) in the T4 treatment, with an average of 31.50 and 32.05 ml/200 mg dry and T2 and T3 respectively at 35.92, 39.97 and 33.53,32.63 ml/200 mg dry matter, respectively, compared with T1 39.05 and 43.00 mg/200 mg dry matter, which is similar to that obtained\textsuperscript{13} This may be due to the fact that the addition of vegetable oils to feed The process of digestion of carbohydrates in the rumen, which had a clear effect on the reduction of the production and composition of gases in rumen.

For methane, after 12 and 24 hours of \textit{in vitro} incubation, the results showed a significant decrease (p<0.01) in T2 in methane production at 2.42 and 3.78 (ml/200 mg dry) followed by treatment T4 (2.42) And 2.70 mg/200 mg dry matter (finally treatment T3 2.42) and 3.25 mg/200 mg dry matter (respectively) compared with the treatment of T1 (3.55 and 3.77 mg/200 mg dry matter), while the volume of methane after 48 days of \textit{in vitro} incubation at treatment T3 (3.50 mg/200 mg dry) followed by treatment T4 (3.58 ml/200 mg dry matter) compared to T1 (4.20 mg/200 mg dry matter), whereas T4 (p<0.01) in the volume of methane after 72 h. of \textit{in vitro} incubation at 4.05 ml/200 mg dry matter compared to the treatment of T1 (4.62 ml/200 mg dry matter), These findings are consistent with the findings\textsuperscript{13} may be due to the addition of peppermint oil, which reduced the effectiveness of fermentation in the rumen by reducing the activity of microorganisms by encapsulating the feed material with a thin layer of oil, which reduced the susceptibility of microorganisms to adhesion to the material Fodder and secretion of digestive enzymes\textsuperscript{14}.

\textbf{Table 3: Effect of adding peppermint oil in total gas and methane production \textit{in vitro} (ml/200 mg dry matter)}

\end{table}

This may be due to the fact that the addition of vegetable oils to feed The process of digestion of carbohydrates in the rumen, which had a clear effect on the reduction of the production and composition of gases in rumen.
T1: control (Without any addition), T2: diet adding peppermint oil 70 μl/kg dry matter, T3: diet adding peppermint oil 140 μl/kg dry matter, T4: diet adding peppermint oil 280 μl/kg dry matter, N.S indicates not significant ** indicates significant differences at the probability level (P < 0.01).

Measurement of *in vitro* digestion factor for dry matter, organic matter (%) and metabolizable energy (MJ/kg dry matter): The results in Table 4 showed significant differences (p<0.01) in the laboratory digestion of dry matter, organic matter, and metabolite energy by adding different levels of peppermint oil by 0, 70, 140 and 280 μl/kg dry matter, with T1, T2 and T3 (64.18, 63.41 and 62.31%, respectively). High perennial (p<0.01) in *in vitro* digestion of dry matter compared to T4 treatment (60.23%) with 280 μl/kg dry matter peppermint oil. These findings are not consistent with15, This may be due to the fact that the addition of vegetable oils to ruminant diets has given a positive indication of the increase in the *in vitro* digestion coefficient of the dry matter in the bush, there is a relationship between the addition of oil and the *in vitro* digestion coefficient of dry matter.

As for the effect of peppermint oil in the *in vitro* digestion of organic matter, the results (Table 4) showed a high elevation (p<0.01) in the T2 treatment containing (65.07%) compared to T4 (62.08%) while T3 was middle between them (63.31%). These results are not consistent with the findings of the study16. The addition of vegetable oil to alfalfa a hay had positive effect in improving the *in vitro* digestion factor of the organic matter, which gives a clear indication of the destruction of carbohydrates in rumen.

**Table 4: Effect of adding peppermint oil in *in vitro* digestion for dry matter, organic matter and metabolizable energy**

<table>

<td>9.03 ± 0.04 b</td>
</tr>
</tbody>
</table>

The results of Table 4 showed a high elevation (p<0.01) in the metabolizing energy of T1, T2 and T3 containing 0, 70 and 140 μl/kg dry matter of peppermint oil, which reached 9.62, 9.51 and 9.34 MJ/kg dry matter, respectively, compared to T4 (9.03 MJ/kg dry matter), and these results are inconsistent with15, the reason may be that the addition of vegetable oil to the diet has had a positive effect on the improvement of metabolizable energy in forage (T2 and T3) with mint oil, but the high oil content of 280 μl/kg dry matter has caused a negative effect And the *in vitro* digestion factor for the dry matter, there is a direct relationship between the addition of the oil and the estimation of the energy of the feed.

**Conclusion**

Adding of peppermint oil to the ration diet has given better results in reducing the production of total and methane gas and led to a significant improvement in *in vitro* digestibility of dry matter, organic matter and of metabolizable energy.

MEBA: Development Android-based Ecosystem Module for Senior High School Students

Mieke Miarsyah¹, Rusdi¹, Niki Desvidisa Aryani¹, Ilmi Zajuli Ichsan¹
¹Biology Education Program, Faculty of Mathematics and Natural Science, Universitas Negeri Jakarta, Indonesia

ABSTRACT

The purpose of this study was to develop teaching materials in the form of an android-based module on the biology of ecosystem material for students. This research was conducted in February-May 2019 at Universitas Negeri Jakarta. This study used the Research and Development (R & D) method. The results of the study showed that the assessment was carried out by three experts namely media experts, material experts and linguists had very decent results. The percentage of the feasibility of Android-based biological ecosystem material module according to the media experts is 89%, according to the material at 85% and according to the experts at 83% which is categorized as very valid. Assessment of 30 students with a percentage of 80% classified as valid. The conclusion is that MEBA is valid and suitable for use in learning at school.

Keyword: Android-based, Research and Development, MEBA

Introduction

Technology is a whole means to provide goods needed for the survival and comfort of human life. One of the most widely used technologies is the use of smartphones¹⁴. Operating a smartphone requires a mobile operating system (OS). One of the most popular mobile operating systems (OS) today is Android. Android is relatively easy to develop because it is open to be studied, changed, improved and disseminated so that it can be made as needed ⁵⁻⁷.

Learning biology in the 21st century emphasizes students to be able to learn independently. Students must be active in learning and not make the teacher the only source of learning⁸⁻¹¹. Students must be able to be independent in learning activities. The independence of learning affects learning ability so that it can improve student learning outcomes. Of course, there must be a media to facilitate students to be independent. It is impossible for students to be independent without being trained or facilitated¹²,¹³.

Learning media that are considered suitable is one of them is an Android-based module.

Module development is in line with current technological developments. The module developed is a biology-based module on ecosystem material (MEBA) that is practical and has an attractive appearance. The module will also complete animation and video. Also, questions will also be included as evaluation material for students and the score can immediately appear. Students can also learn while playing with the games menu added. The novelty of this research is a module that has a glossary menu that contains biological terms that are relevant to the material and its definitions. Usually, the menu is not found in modules in general. Based on the description, it is necessary to develop the MEBA module. The purpose of this study was to develop MEBA for students in Biology learning.

Method

This research was conducted in February - May 2019 at the Jakarta State University. The research method used in this study is research and development with the design of Borg and Gall¹⁴. The stages in this design are collecting data, planning, developing, tryout prototype, a small group tryout, revise, a trial dissemination field. In the collecting data, stage consists of an analysis of needs and students and learning objectives. The second stage
is the planning stage which consists of the preparation of material and preparation of storyboards.

After all the designs are ready, developing is carried out to develop the biology module based on Android ecosystem material (MEBA) for Senior High School students. After the development stage is done, then the prototype tryout stage is validation to media experts, material experts, and linguists. The next stage is a small group tryout conducted on 10 students and a field trial stage for a whole class trial for 30 students. MEBA validation is done for media experts, material experts, linguists, and students. The media validation criteria refer to Akbar and can be seen in table 1 below.

Result and Discussion

The Android-based biology module (MEBA) was developed in Indonesian Language and consists of 8 main sections including the start page, main menu page, competency indicator page, material page, evaluation page, quiz page, glossary page, and developer information page. The start page is the first display of MEBA which contains the module title and developer name along with the main menu as shown in Figure 1.

The next section on biology modules is based on Android, namely submenu of material and glossary. This menu is a novelty because there is usually a glossary. More details can be seen in figure 2 below.

Based on the assessment of media experts as a whole the biology-based module android gets a percentage of 89% with very valid criteria. Based on the assessment of material experts as a whole the assessment gets a percentage of 85% with very valid criteria. Based on the assessment of linguists the percentage of the overall assessment gets a percentage of 83% with very valid criteria. Meanwhile, the results of validation to students showed a percentage of 81% in terms of the media, 79% for the material aspect, 81% in terms of language so that if averaged got 80% so that it could be categorized as appropriate for use in learning.

MEBA is an innovation in Biology learning in the 21st century. This is in line with technological advances that change the learning paradigm. Now learning doesn’t have to be in class and do face to face. The existence of technological advancements such as this makes teachers easier to deliver material. In addition, the material delivered can be modified by yourself. Just like MEBA that inserts a glossary menu.

This glossary menu is inserted in MEBA to make it easier for students to find scientific terms that are difficult to understand. This is because one of the obstacles for students in learning Biology is because many scientific terms are not familiar in everyday life. This glossary menu will help students find the term. This will also support student learning independence. When students experience difficulties, there is no need to ask the teacher about it.

Even so, the role of the teacher in this matter remains essential. MEBA can indeed help in learning, but that does not mean that biology teachers can just leave their duties. Teachers in the 21st century must still play a role in learning, but still learning remains student-centered. Teachers can continue to provide motivation to create a conducive learning atmosphere. Using MEBA in learning can make learning more active, provided the learning model used also supports students and can discuss.

MEBA aside from being used for students, it has benefits that can also be used by various groups such as undergraduate students or the general public. That is because the operation of MEBA is easy and simple. MEBA can be used on various types of Android devices. We know that the use of Android is very much in the world. Even though MEBA is easy to operate, there must be some modifications if you want to use it for the general public. MEBA has the potential to be further developed so that it can be more relevant to the general public. The community needs MEBA to be able to easily understand the environmental problems around it.

Conclusion

Based on the results of the study, it can be concluded that the MEBA module for class XI SMA is feasible and can be used in the learning process. The MEBA validation score from media experts was 89%, material experts 85%, linguists 83%. While students get a percentage of 80%. This shows that MEBA is an innovation in the learning of 21st-century Biology.

Acknowledgments

Thank you to the validators, media experts, and material experts who have been involved in this research. Thanks also to the Faculty of Mathematics and Natural Science, Universitas Negeri Jakarta for helping with funding from this research. Without support from various parties, this research will not work well.

Conflict of Interest: There is no conflict of interest in this research

ABSTRACT

**Background:** Major surgical procedures lead to perioperative immunosuppression. This study aimed to evaluate the influence of Total intravenous anesthesia (TIVA) on the immune response of oncologic patients undergoing lower limb surgeries.

**Method:** The study included 18 patients with lower limb malignancies scheduled for lower limb-sparing surgery. They were planned to receive Total intravenous anesthesia (TIVA), (n=18). Pain intensity and levels of IL-6 and IL-10 were assessed postoperatively. If visual analogue scale (VAS) scores ≥ 4, a dose of morphine 2.5 mg IV was used.

**Results:** In the study group, IL-6 and IL-10 levels were measured at baseline and 24 hours after surgery. Both IL-6 and IL-10 levels increased 24 hours after surgery. Increase of IL-6 level was significantly higher than that of IL-10 (p < 0.001). The total morphine consumption in TIVA was 17.72 ± 1.32 mg.

**Conclusion:** Total intravenous anesthesia (TIVA) provides effective anesthesia but does not enhance the patients’ immune response by disturbing IL-6/IL-10 balance in patients undergoing surgery for lower limb malignancy.

**Keywords:** Total intravenous anesthesia, lower limb cancer, IL-6, IL-10, immune response.
inflammatory phase to prevent the excessive activation of the systemic inflammation, mainly through the release of IL-10. The balance between the proinflammatory and the anti-inflammatory cytokines limit the spread of infection, tissue injury and promote tissue healing and repair through their local and systemic effects. The number of liver resection has increased, which requires adequate and safe anesthesia provision in this surgery area. Cytokine plasma spectrum is the one of the most important indicators characterizing inflammatory reaction intensity during and after surgery and postoperative period flow prognosis. Immune monitoring gives a notion about operative room features, liver damage severity, anaesthesia adequacy. Interleukin dynamics evaluation during liver resections is a topical theoretical and practical problem. The aim of this research was to evaluate the interleukins intraoperative dynamics in liver resection patients. Anaesthesia protocols were analyzed in 51 patients, 26 (51%)

All forms of general anesthesia have been found to modify the immune system by affecting both innate and adaptive immunity. Presumably by directly affecting the immune system or activating the hypothalamic-pituitary-adrenal axis and the sympathetic nervous system. Along with stress such as surgery, blood transfusion, hypothermia, hyperglycemia, and postoperative pain, anesthetics per se are associated with suppressed immunity during perioperative periods because every anesthetic has direct suppressive effects on cellular and neurohumoral immunity through influencing the functions of immunocompetent cells and inflammatory mediator gene expression and secretion. Particularly in cancer patients, immunosuppression attributable to anesthetics, such as the dysfunction of natural killer cells and lymphocytes, may accelerate the growth and metastases of residual malignant cells, thereby worsening prognoses. Alternatively, the anti-inflammatory effects of anesthetics may be beneficial in distinct situations involving ischemia and reperfusion injury or the systemic inflammatory response syndrome (SIRS). Different anesthetic approaches may modulate the stress response, particularly CK activation. Total intravenous anesthesia is found to inhibit the stress response; many studies showed that total intravenous anesthesia might preserve different immunologic indices better than general inhalational anesthesia.

Many studies have suggested that impairment of the immune response might increase perioperative morbidity and mortality in susceptible patients (e.g., all cancer patients) due to infection, recurrence, and metastasis of the malignant tumor. In oncological patients, the immune status is often impaired by the malignant disease itself and by chemotherapy when administered preoperatively and appears to be worsened as the disease progresses. In this study, we investigated cell-mediated immune status in colorectal cancer patients.

METHOD: Interleukin-2 (IL-2)

This study aimed to evaluate the influence of total intravenous anesthesia (TIVA) on the immune response of oncologic patients undergoing lower limb surgeries for malignancies.

Patients and Method

This study was carried out at National Cancer Institute (NCI), Cairo University. The study was approved by the local anesthesia department scientific and ethical committee (Approval no. MD2010014043.3). All patients were informed about the study design and objectives as well as tools and technique. Every patient provided informed written consent before enrollment in the study.

Inclusion criteria were patients between 20 and 60 years old with lower limb malignancies with no evidence of distant metastasis scheduled for lower limb-sparing surgery not exceeding two hours. Exclusion criteria included hepatic and renal impairment, diabetes mellitus or other endocrine disorders, obesity (BMI >30 kg/m²), immune disorders or immunosuppressive therapy, steroid treatment in the last six months, bronchial asthma, coagulopathy and cardiac diseases. Eighteen patients were planned to receive total intravenous anesthesia.

Method: The routine preoperative assessment was done to all patients. In the operating room, patients were monitored continuously using ASA standard monitoring (ECG, pulse-oximetry, SaO₂, non-invasive blood pressure and capnography). Blood loss was observed every 5 min. An intravenous (IV) access was established with 16-18 G cannula. Preoperative antibiotic prophylaxis, paracetamol 1 gm IV infusion and 30 mg ketorolac intramuscular were given to all patients. All patients received 0.02 mg/kg midazolam intravenously and 100% O₂ via face mask (3-4 L/min) for 3 minutes. Intravenous Ringer’s lactate solution was administered to replace fluid deficit preoperatively. resuscitation equipment and drugs were available.
Anesthesia was induced with propofol 2 mg/kg, fentanyl 2 μg/kg and rocuronium 0.6 mg/kg for tracheal intubation. Anesthesia was maintained with continuous infusion of propofol 3-6 mg/kg/hr, fentanyl 1.5-2.5 μg/kg/hr and rocuronium 0.15 mg/kg/hr. Fentanyl was administrated in increments 0.5 μg/kg guided by hemodynamic and clinical requirements (if more than 20% of standard heart rate and blood pressure).

For postoperative analgesia, all patients received ketorolac 30 mg/12 hrs and IV paracetamol (15 mg/kg) every 8 hours. In case of pain with visual analogue score (VAS) ≥ 4 a dose of morphine 2.5 mg IV was used.

In the two groups, the pain intensity was assessed using VAS score immediately postoperative and at 1, 2, 6, 12 and 24h postoperative. The total morphine consumption was calculated. For patients and surgeons satisfaction assessment, the following rating scale was reported preoperatively and at 24 hrs postoperative: 1 poor, 2 fair, 3 good, 4 very good and 5 excellent.15

Two venous samples were collected from each patient in plain tubes: prior to anesthesia induction (once intravenous cannula was inserted) (T0) and 24 hours postoperative (T24) Laboratory assay of IL-6 and IL-10 procedure followed the basic principle of sandwich ELISA technique. Commercial kits were supplied by Assaypro, USA (EI1006-1) for IL-6 and (EI3010-1) for IL-10. ELISA technique was done using semi-automated ELISA system (TC 96, tecodiagnostics, Austin, Texas, USA).

The sample size was calculated based on the findings of Davies et al.16 that the estimated mean pain score was 55 in the TIVA group, with a standard deviation of around 15, at 24 hours post-surgery. The calculated the sample size with alpha 0.05 and power of 80% was 18 patients in TIVA group.

Statistical Method: Data management and analysis will be performed using the Statistical Package for Social Sciences (SPSS) vs. 21. Numerical data will be summarized using means and standard deviations or medians and ranges. Categorical data will be summarized as percentages. Comparison of numerical variables within the study group was made using t-test or Mann-Whitney test as appropriate. Comparison between categorical data was performed by the Chi-square or Fisher’s exact test. All tests were two-sided. A p-value < 0.05 was considered statistically significant.

Results

The demographic data is shown in Table 1. Table 2 shows that after 24 hours the two interleukins increased. However the increase of IL-6 level (p < 0.001) was significantly higher than that of IL-10 (p < 0.019).

Immediately in PACU, patients of TIVA Group started to experience pain with various degrees (Table 3). All patients of TIVA Group were in need of morphine rescue analgesia during the postoperative period. The total morphine consumption in the studied group was 17.72 ± 1.32 mg.

After Induction of anesthesia mean arterial pressure (MAP) increased significantly in the TIVA Group (p < 0.001) (Figure 1). After that, MAP started to regain the baseline values. Similar changes were recorded in heart rate (Figure 2). However, all readings were within the clinically accepted ranges.

Discussion

The results of this study demonstrated that IL-6 increased in the study group 24 hours after surgery; the levels of IL-6 increased almost 4-fold after surgery in TIVA Group (highly significant). On the other hand, IL-10 increase was less marked. Therefore, total intravenous anesthesia not maintaining the immunological balance between IL-6 and IL-10.

It was demonstrated that the immune response to surgical trauma begins with the release of proinflammatory CKs; the acute phase response mediated mainly by IL-6. Then, this response is balanced by an anti-inflammatory phase to prevent the excessive activation of the systemic inflammation. The most important anti-inflammatory CK is IL-10.

Previous studies suggested that total intravenous anesthesia can attenuate the patients’ anesthetic and surgical stress compared to general inhalational anesthesia.

Moselli et al. demonstrated the immunological superiority of regional anesthesia compared to general anesthesia in patients undergoing major surgery for colon cancer. In their series, Epidural anesthesia (as a type of regional anesthesia) attenuates the IL-6 production...
and the surgery-induced proinflammatory response, while the levels of IL-4 and IL-10 were significantly elevated. Similar findings were reported in comparing spinal anesthesia and intravenous anesthesia.\(^{19}\) Also, preemptive epidural analgesia limited the pro-inflammatory response to surgery in women undergoing elective laparoscopic radical hysterectomy for cervical cancer.\(^{20}\) In patients undergoing primary total knee arthroplasty, a combination of continuous lumbar plexus and sciatic nerve blocks was associated with attenuated postoperative inflammatory response.\(^{21}\) and then were randomly allocated to either patient-controlled analgesia with morphine (n = 6). Also, Davies et al. used Epidural anesthesia and CFSBs as perioperative analgesia for knee arthroplasty. Total morphine consumption was lower in CFSBs group.\(^{16}\)

Wiryana et al. reported that regional anaesthesia (combined spinal epidural technique) had a superior effect of reducing inflammatory response compared to TIVA by suppressing level of IL6.\(^{22}\) In detecting the inflammatory cytokine expression levels in peripheral blood of patients with cervical discogenic pain before and after cervical nerve block, Bai-shan et al. found that peripheral blood inflammatory cytokines TNF-α, IL-1, IL-6 levels decreased at 24 hours and three days after cervical nerve block therapy compared with before nerve block.\(^{23}\)

These effects appear to transient and may be of minor importance in subjects with a healthy immune system. However, in patients with immune dysfunction, multiple organ failure, or other high-risk groups as cancer patients, the influence of anesthetics on the perioperative inflammatory response may have clinical implications.\(^{1}\)

In the current study, we evaluated one type of general anesthesia; total intravenous anesthesia (TIVA). We proposed that (TIVA) may enhance the patient’s immune response by achieving a balance between the proinflammatory and anti-inflammatory CKs; IL-6 and IL-10. This expectation was based on possible good patients’ comfort, good extended postoperative analgesia, low morphine consumption, and good attenuation of neuroendocrinal stress response.\(^{30}\) Similarly, Fekkes et al. suggested that propofol does not inhibit IL-6 release and that longer operating times are paired with increased IL-6 production.\(^{31}\)

Concerning the VAS score at PACU, it was significantly higher at all recorded times in comparison to baseline (P<0.001). That may be due to short duration of action of last dose fentanyl (first dose morphine was required at PACU).

Therefore, the 24 hrs morphine consumption postoperative was high in the study group. The 18 patients in the TIVA Group needed morphine as post operative rescue analgesia when VAS score ≥ 4.

In conclusion, total intravenous anesthesia (TIVA) provide effective anesthesia in patients undergoing surgery for lower limb malignancy. This technique does not enhance the patients’ immune response by disturbing the balance between the proinflammatory cytokine IL-6 and the anti-inflammatory cytokine IL-10. However, it is characterized by hemodynamic stability, high surgeon and patient satisfaction, and low complications rate. Therefore, total intravenous anesthesia (TIVA) is not to be a preferred anesthetic alternative for lower limb surgeries in patients with malignancies or multiple medical co-morbidities.

Surgically Managed Isolated Midgut Malrotation–A Clinical Study of 34 Children

Mohammed Jabbar Kadhem1, Muhammad Albahadili2, Hussein Ali Abed Ahmad3

1M.B.Ch.B., FICMS, Lecturer, 2CABS, HDLM, 3CABS, College of Medicine, University of Wasit Iraq

ABSTRACT

Malrotation is the most common congenital malformation of the small intestine. A prospective study conducted at Alkarama teaching hospital, during January 2017 to December 2018, including 34 children (20 males and 14 females) less than 15 years old who were undergoing a Ladd procedure with a diagnosis of isolated intestinal malrotation confirmed by surgery; cases complicated by volvulus were excluded. Patients were followed up and evaluated prospectively. Findings revealed that the median age was 15 days. About 91% of cases aged less than five years. Almost 70.5%, of them at their first month of life. Classical presentations were mainly found in cases at their first year of life, while a typical presentations were reported in older children. The main and sufficient diagnostic tool for malrotation was the upper gastro-intestinal contrasts studies, it was sufficiently diagnostic in 50% of cases. Postoperative complications reported in 7 cases and unfortunately, 3 cases (8.8%) died of septicemia. In conclusion, The Ladds’ a significant efficient procedure with low mortality and morbidity rates in treatment of children with midgut malrotation.

Introduction

Malrotation is the most common congenital malformation of the small intestine. It is estimated that 1 in 200 live births has an asymptomatic rotational deviation; however, symptomatic malformation occurs less frequently (1 in 6,000 live births) 1-3.

There are several attempts to provide the desired classification based on the etiology, but the incomplete turn indicates a failure that occurs at the final 180 degrees anti clockwise rotation or a reversal of the colon. No rotation occurs when the spin is rotated to the abdominal cavity without turning more than 90 degrees, that is, without turning back from the horizontal surface. Reverse rotation occurs when the post-arterial or caudal portion of the mid-gut or returns to the abdomen from the beginning, not before the pre-arterial part1,2,4.

Symptoms of malrotation and volvulus may include vomiting, flexion of the legs to the abdomen, abdominal pain, inflammatory bowel disease, diarrhea, constipation, rectal bleeding, weight loss, tachycardia, restless breathing. Symptoms of malrotation and volvulus may be similar to other medical conditions 4,5. The diagnostic methods for malrotation and volvulus may include in addition to the physical examination and medical-history, various studies of imaging and laboratory tests 1,6. These are done to evaluate the position of the malrotation and if they are bent or blocked. These tests include blood tests for electrolytes, a test for diagnosis of blood in the stool, plain x-ray, FAST ultrasound and Doppler, computed tomography (CT). Sometimes the diagnostic combined radiological studies used to get better imaging, for instance X-ray and CT scanning to get horizontal and axial views. CT scans accurate images of body parts, including bone, muscle, fat tissue, and limbs. CT scan is more accurate than general radiography, moreover, esophagograh and high GI series 2,6-8. Barium enema x-ray may shows an abnormal small intestine, blockage, and other problems2,7. The high GI series usually examines the small intestine, while lower GI series studying the large intestine. Barium enema performed for intestinal examination to detect abnormalities. Bariums enema X-ray may indicates that the large intestine is not in the normal place2,7. The flexible sigmoidoscopy, usually performed for volvulus, examines
the lower part of the digestive tract, the rectum and the large intestine. This can be used to detect volvulus. However, sometimes the diagnosis is difficult to differentiated in asymptomatic patients.\textsuperscript{9,10}

Malrotation is potentially fatal with the progression of intestinal ischemia. Early surgical intervention is essential and is often a life-saving. Symptomatic malformation often occurs in the first weeks of life.\textsuperscript{1,4} Therefore, to focusing on the surgical care of intestinal malrotation, this study emphasizes presentation, clinical and surgical management, review operative technique, and outcome of the surgery.

**Patients and Method**

This was a prospective study of isolated malrotation conducte in Alkarama teaching hospital, between January 2017 to December 2018. Included 34 patients with age range between 3 days and 14 years; who were presented with various signs suggestive of malrotation, those patients underwent physical examination, radiological study which included plain abdominal x-ray abdominal sonography (FAST US in some cases was performed and others with Doppler US), upper gastrointestinal contrast study, barium enema and CT scan, the finding were compared with result of surgical exploration. After rapid intravenous hydration, broad spectrum antibiotics that administered prophylactically. The Ladd procedure was performed to all patients. Patients were followed up from the first postoperative day to up to 5 months after surgery.

**Findings**

A total of 34 patients were enrolled in this study with a median age of 15 days. They were 20 males (58.8%) and 14 females (41.2%) with a male to female ratio of almost 1.4 to 1. Out of the 34 cases, 32 (94.1%) were full term on labor and only two (5.9%) were preterm, additionally, all patients with normal birth weight except one (2.9%) had low birth weight of 2.1 kg, (Table 1). The Clinical features at presentation of the studied group are summarized in (Table 2). Regarding the radiological studies, all patients examined with plain abdominal X-ray. Doppler ultrasonography performed in 15 cases (44.1%), focused abdominal sonography in trauma (FAST) in 8 cases (23.3%), upper gastrointestinal (UGI) contrast study in 8 cases (23.5%), barium enema in 2 (5.9%) and computed tomography scanning in 3 cases (8.8%), it is worth mentioned that in some patients more than one radiological study was performed, (Table 3).

The operative procedure performed was Emergency laparotomy in 11 cases (32.4%) and Elective laparotomy in 23 (67.6%), (Table 3). The overall postoperative complications reported in 14 cases (41.2%), (Figure 1), these included Adhesive intestinal obstruction, wound infection and septicemia in a rate of (20.6%), (11.8%) and 8.8%, respectively, (Table 4). Unfortunately, 3 patients did not survived giving a mortality rate of (8.8%), (Figure 2).

Our finding revealed twenty boys (58.58%) against fourteen girls (41.2%) which agreed that reported previously as males are relatively more affected than females. While other earlier study found equal sex distribution.

Malrotation can present as an acute surgical emergency or with more chronic abdominal symptoms. In most of the reported cases, the most frequent symptom is vomiting (cyclic vomiting); However, the clinical characteristics in neonates cannot be easily distinguished from those of duodenal stenosis with vomiting of mood and laryngeal contraction that can be resolved after vomiting or aspiration by the infertile gastric tube. Pain or irritability is not a prominent clinical feature in babies, but a common feature in young and older children. Similar findings reported and comparable to that of Strouse et al. Images are essential to eliminate disability as a cause of vomiting. Abdominal pain is less frequent, (41.2%) compared to (55%) reported in literature and usually occurs in older patients.

The chronic presentation is a diagnostic challenge, which was seen in our study in patients above five years, nonetheless, the diagnostic delay is not uncommon, and the symptoms may found for almost 30 years. The chronicity of symptoms could be attributed to the compression effect of the peritoneal bands. The images of a child in our study are suspicious of starting a mal-rotation with an x-ray. The simple abdominal radiography are often normal or non-suggestive in most of our patients as same as result in the study done by Strouse et al, but occasionally the findings can be very confusing, may show double bubble sign, duodenum dilated with a fluid level, and scariness of gas in the distal bowel as reported by this study in (11%) of our patients, compared to (47.5%) found by Ameh EA et al.

The status and association between the superior mesenteric artery and Doppler ultrasound is a characteristic and may be useful in the diagnosis, which done in fifteen (44%) of our patients and suggested in only four (3.5%) of them. Although the contrast study of the upper gastrointestinal tract, is the first option investigation, the choice for each child with IM presented with bilious vomiting should be made immediately, except in cases where the baby is very sick or suspected of having a presence of infarction of the bowel and perforation risk is found, as in some of our patient, this investigation was not feasible for all our patients as it requires appointment and not available as an emergency study in the policy.

Discussion

The majority of patients (70.5%) in this study presented at their neonatal period. This is in line with the report of Mary and her colleagues (75%) but it can presented at any age.
of our hospital. Barium enema was performed in 2 cases (5.9%) of our patients, abnormal cecal position suggested in both. Prasil et al. found that normally positioned cecum in almost 20% of malrotation cases. Ladd’s represented the optimal surgical intervention for all malrotation cases. In our study were (32.3%) with elective laparotomy while (67.7%) had an emergency laparotomy. A laparotomy is performed soon after correction of dehydration, general condition of patients. In a study by Feitz R. et al. reported (23%) with elective Ladd’s procedure, while (74.5%) patients as an emergency procedure. Mortality and morbidity due to malrotation is often attributed to septicemia and adhesions of the bowel. The mortality rate during the operation in this study was due to septicemia (8.8%). In our environment, diseases and mortality are combined with delays and referrals. These problems can be addressed by educating parents, traditional birth-attendants, midwives, general practitioners and pediatricians about the need to suspect mal-rotation in any child with bilious-vomiting and early referral. Tashjian and others recommend that they examine a Ladd’s approach in asymptomatic patients after optimizing their cardiac function which agreed our study. The steps of the Ladd’s method, which was performed in all our patients, increased the handling and manipulation of the intestine and increased the risk of adherence, which, as postoperative complications in 7 patients (20.6%) of patients in our study compared to 10% reported by Mary et al. (5), (14%), (4%) by Strouse et al and (7-15%) rates of postoperative adhesions in previous reports. In this study (11.8%) of patients developed wound infection, of them two with dehiscence, while 8.8% had sepsis. In a study reported by Feitz et al. postoperative complications were wound infections (2.3%) including dehiscence (0.9%), sepsis (1.7%) of all patients.

The length of hospital stay in our study ranged (7-10 days) after the operation compared to (5-7 days) reported by Mary and colleagues, hospitalization duration may depend on different factors such as patient’s general condition and the need for further investigation. Unfortunately, we reported a mortality rate of 8.8%, however, in previous studies, malrotation mortality, ranged 6.9% as reported by Ademuyiwa et al. to 50% as that reported in in Nigeria.

**Conclusion**

Ladd’s procedure remain the surgical treatment of choice in midgut malrotation. With low postoperative complications, morbidity and mortality, which were reported comparable to previous studies. Early presentation, stabilized general condition and covered patient by broad spectrum antibiotics play an important role in reduction of the high morbidity and mortality. A properly performed and interpreted Doppler US and UGI series are the fastest, most accurate method of making the diagnosis.

The Effect of Anaerobic Exercises According to the Distance Traveled in the Game in Reducing the Concentration of Lactate and Improve the Performance of Some Skills for Table Tennis Players

Muslim Mohammed Sabit¹, Wael Abbas Abdulhuseein¹, Husam Abdulkadhim Raheema², Hayder Naji Habash Alshawi³

¹AL-Najaf education Directorate, Ministry of Education, Iraq; ²The Islamic University, Iraq; ³Faculty of Education for Girls, Department of Physical Education and Sports Sciences, University of Kufa, Iraq

ABSTRACT

Through the exercise of table tennis students and their follow-up in training and games as well as their knowledge of the various curricula in the training of table tennis found that there is a lack of anaerobic exercise, according to the distance of the game during the game, which affects the concentration of lactic acid, which contributes to the development of performance of table tennis players, The main problems in the training of players because we know through the distance can put the appropriate exercises contribute to improve the performance of some skills during the game so researchers found it necessary to study this problem and develop appropriate solutions through The aim of the study was to prepare anaerobic exercises according to the distance spent during the match (10-12 years), and to determine the effect of anaerobic exercise on the development of lactic acid concentration and the skills of the upper frontal and rear impact injuries and movements of the two men. Functional and Technical tests the vertical jump test (Sargent) is used to measure anaerobic capacity, measure the concentration of lactic acid in the blood, measure the distance between table tennis and table tennis skills. The researchers concluded that exercise the Anaerobic System has increased the speed of the nervous system to adapt to the high training loads and its resistance to fatigue and improved its ability to quickly receive stimuli and make quick decisions, which was clear from the speed of the performance of players, and the exercise of speed increased the capabilities of players and their capabilities of the endurance of anaerobic muscles and the speed of disposal of acid And the high frequency and repetitive training method had a clear effect on biochemical adaptations due to rotation of work and rest periods.

Keywords: Anaerobic exercises, lactic concentration, basic skills and table tennis.

Introduction

The importance of research into the distance the table tennis player during the game to put the appropriate anaerobic exercises to reduce the concentration of lactic acid, which develops the performance of the table tennis player during the game, and the problem of research through the exercise of researchers to the game of table tennis and follow them in training and games and the multiple approaches to table tennis training have found that there is a lack of anaerobic exercise in accordance with the distance involved in the game, which affects the concentration of lactic acid, which contributes to improving the performance of table tennis players, we found that it is necessary to study this problem and to develop appropriate solutions through this study. The objectives of the research were to prepare anaerobic exercises according to the distance spent during the match. (10-12 years), and the impact of anaerobic exercise on the development of lactic acid concentration and stroke skills in the upper, frontal, posterior, and male movements.¹

Practical Part

Field Research Procedures: The researchers used the experimental method for the suitability and nature of the research on the students of the special school of table
tennis for the province of Karbala in a comprehensive manner. They are (12) children aged 10-12 years and divided the society by successive lots without returning to control and experimental groups and in each group (6) The homogeneity and equivalence processes were performed to ensure homogeneity of the sample of the study using the torsion coefficient and to show that the subjects were homogeneous in weight, age and length variables.

**Determination of measurements, functional tests and technical tests:** After examining the many measurements and tests and the experience of the researchers in this field, the measurements that proved their scientific weight in measuring the research variables were determined as measurements and tests in previous experiments, which can be measured and measured in the measurement of the skill and functional abilities of table tennis players.

**Characterization of tests:**

**First, Functional Test:** vertical jump test (modified Sergent):²

**Objective of the test:** measurement of anaerobic capacity.

**Description of the Performance:** The laboratory does some exercises for the purpose of warm-up before the start of the test for the purpose of configuration and pleasing, the laboratory holds a piece of crayons and then stand by the wall so that the scorpions are adjacent and the position stretched out and the legs are separated and the laboratory extends the arm near the wall to extend it as high as possible To mark the wall before jumping up to determine the level of jump from this signal and after the performance of the player weighted arms down and backward with the bend of the trunk to the front and down and bend the knees to the status of the list is jumping high to reach the maximum height, Chalk on the wall.

**Registration:** The laboratory is given three consecutive attempts to calculate the best results for the nearest (1 cm). The anaerobic capacity is calculated by the following equation:

\[
\text{Anaerobic capacity} = 2.21 \times \text{body weight} \times \sqrt{\text{Jump distance}}.
\]

**Second:** Testing and Functional Measurement: Measuring the concentration of lactic acid in the blood:³

**Objective of the test:** To know the level of concentration of lactic acid in the blood after the effort.

**Tools Used:** Lactate pro 2 manufactured by Arakray of Japan, two needle drill, 2 test strips, medical cotton, sterile materials, and small hand towel (2), registration form.

**Performance description:** After the laboratory has finished performing the speed-bearing test (180 m), performed as quickly as possible, the level of lactic acid concentration in the blood is measured after the effort, after the completion of the test time (5) minutes, Transmission of lactic acid from muscle to blood, followed by following steps for testing:

1. Configure the device to operate by turning it on from the power button and then placing the Test Strip and inserting it into the device.
2. After the blood is out of the finger, a drop of blood is placed on the measuring tape fixed on the device.
3. The device will show a sound after the device will start counting down from (15 seconds) until the result of measurement on the screen of the device in the unit of measurement is (Milli M/L).

**Recording:** The reading recorded by the device is recorded in milli/l.

**Third:** Measuring the distance of the table tennis match:⁴

Several physical games were played with a table tennis game for the respective sample of two speed cameras. Camera 1 was placed on one side at a distance of 4.10 meters from the side scale and at an altitude of 1.1 meters. A camera (2) was placed on the parallel scale of the parallel table (4 m) and the distance between the two lateral scales shall be (4 m) and the rear gauge shall be removed from the rear edge of the table (4 m). And painted clear marks on the ground and a metric scale in the confined area and the video was transferred to the computer to analyze these games by software (Tracker-4.96)

**Fourth:** Testing the skills of table tennis:

**Name of the test:** Test the skill of the frontal blow and the rear strike and the movements of the two men.

**The purpose of the test:** To determine the degree of performance and success of the skill of the frontal strike and rear strike and movements of the two men.

**Tools:** legal play table, legal rackets, legal balls, basket for collecting balls, registration form.
Description of the test: The player stands in the area of the back strike and stands the coach or the person who threw the balls in the Qatari counterpart and put a set of balls next to him and throw (10) balls at appropriate speeds in specific places on the table and hit the above skills with the movements of the two men towards it and three attempts each player and take the arithmetic mean each attempt includes (10) balls.

Pre-test: The researchers carried out the pretest after all the conditions were available for the period from 3/4/2017 corresponding to Friday and Saturday at 9:00 am.

Posttest: The researchers conducted Posttests of the research sample on Thursday and Friday, 13-14/4/2017 at 9 am after the end of the period of anaerobic exercises and the same method of pre testing.

At the level of moral significance ≤ (0.05) and the degree of freedom (5).

Given the specificity of the table tennis game, which depends on the fast and intermittent moves, which depend on training in the training methods of high intensity and repetition is one of the characteristics of anaerobic exercises, so most of the functional adaptations of table tennis players are heading towards these specifications, through the figures obtained from the previous measurements We see that there is a difference in their ratios is almost simple in most of them because the functional adaptations appear clearly in aerobic exercise more than anaerobic exercises, as aerobic exercise depends on the endurance and the severity without the stenosis and occur adaptations in the organs of palpation the researchers attribute the increase in lactic acid (LA) to the extreme effort of a table tennis player with its dependence on anaerobic glycosylation significantly in energy production, which is stored in muscle fibers, 5 Which is rapidly analyzed to provide the muscle needed energy in the rapid effort and for a few periods. The differences were significant between the pre-test and post-control group, which decreased the concentration of lactic acid but very few levels as we observed differences in the circles It should be noted that the percentage of concentrations of this acid increases in the activities that depend on exercise and anaerobic performance as the main source of energy during the maximum effort, noting that “in working muscles, the effect of increased operations Metabolism is localized changes in pH and intracellular fluid components”6.

Through the application of the anaerobic exercises according to the distances in the games that were within the systems of phosphate and Lactic and rationing stressed these exercises and times of hospitalization in proportion to the age and level of performance of the experimental group and the gradualization of the intensity during the training units of training It was clear from the figures shown in the table above that the changes in the measurement of the proportion of lactic Had significant differences for the period in which the exercises were applied. The results showed that the experimental group improved in the above variables with the highest percentages that can be adopted in the future.7

Discussion

We note from table (3) that there is no significant difference in a very important biochemical variable that plays a prominent role in many activities and sports. It is the concentration of (LA) in the blood which is the second source of anaerobic energy after the phosphate source. The preference for the experimental group is to improve this biochemical index. The researchers attribute the reason for this preference to the nature of the anaerobic exercise, which is characterized by anaerobic endurance times that are very similar to the periods of endurance in the run. This convergence of time and intensity of these exercises enabled the experimental group as it is known that athletes can reduce the concentration of lactic acid after exercise by some low-intensity exercises that accelerate the elimination of acid. In addition, it is possible to reduce the concentration of lactic acid after exercise. It is known that table tennis is classified as short- to medium-term, with short negative intervals between points and stages, accompanied by high oxygenation, so that work in most of its points with oxygen deficiency, so the ATP is destroyed and the lack of oxygen is necessary. This training should be carried out under the nature of this feature. This is done in the number of exercises for the experimental group which is distinguished from the control group which was trained a little more than the times and the literal commitment to the training components the reason for their lack of improvement in speed and their lactic system.

Conclusions

Anaerobic exercises have increased the nervous system’s speed to adapt to high training loads and its resistance to fatigue and improved its ability to quickly receive stimuli and make quick decisions, which was clear from the speed of performance of players, and the exercise of speed has increased the capabilities of players and their ability to end the anaerobic muscles and the speed of disposal Lactic acid accumulated by the maximum voltage, and the high frequency and repetitive training method had a clear effect on biochemical adaptations due to rotation of work and rest periods, allowing during the recovery period to restore the composition of energy compounds Depleting during the effort and the ability to perform subsequent iterations itself efficiently, and find out the actual distances traveled in the game contributed to increasing specialization preparation exercises in line with the nature of the energy exerted in the game and thus exercise applied closer performance

Clinical Presentation Factors Associated with Length of Pre-Hospital Time in Patients with Acute Exacerbation of Heart Failure in Blitar

Nabilah Siregar¹, Retty Ratnawati², Tony Suharsono³

¹Postgraduate Program of Nursing, ²Department of Medicine, ³Department of Nursing, Medical Faculty, Universitas Brawijaya

ABSTRACT

Heart Failure was suffered by 26 million people in the world, and 3,083 people in Indonesia in 2013. Clinical presentation of patients leads them to make a decision for seeking medical care that would affect the length of pre-hospital time. The aim of this study was to analyze clinical presentation factors associated with length of pre-hospital time in patients with acute exacerbation of heart failure in Blitar. This study used an observational analytic design with a cross-sectional approach. 60 respondents were selected by using purposive sampling technique. This study was conducted at Ngudi Waluyo General Hospital and Mardi Waluyo General Hospital. Mann Whitney test found that factors associated with length of pre-hospital time in patients with acute exacerbation of heart failure were chest pain (p=0.001), dyspnea (p=0.007), fatigue (p=0.006), number of symptoms (p=0.000), and acute symptom onset time (p=0.005). Multiple linear regression test showed that chest pain was the most dominant factor associated with length of pre-hospital time in patients with acute exacerbation of heart failure (Beta = -0.422).

Keywords: Acute exacerbation of Heart failure, Pre-hospital time, Clinical presentation factors

Introduction

Heart failure (HF) was suffered by 26 million people in the world which about 1–2% in adult population and 10% in elder population¹,². Prevalence of HF in Indonesia was 0.3% (3,083 people) from total population of Indonesia in 2013 based on symptoms and medical diagnosis³. Blitar has high cases of HF as many as 421 patients came at Ngudi Waluyo general hospital emergency unit and 204 patients at Mardi Waluyo general hospital emergency unit in 2017⁴,⁵.

Rehospitalization in patients with HF often characterized by frequent exacerbations⁶. Even there is no time recommendation yet like myocardial infarction, but it is an important thing for patients. Spending time longer in seeking medical treatment for symptoms of exacerbation could make their condition be worse when they arrive at hospital⁷. Patients with HF who go to hospital longer from onset symptom to arrive at hospital (pre-hospital time) would prolong treatment time for exacerbation and results in longer recovery time, length of hospital stay (LOS) was one day longer than who came within 24 hours since onset (11 vs 10 days), and elevation of Brain Natriuretic Peptide (BNP) which indicated decreation of Left Ventricular Ejection Fraction (LVEF)⁸,⁹.

There are many symptoms experienced by patients with HF including fatigue and dyspnea as typical symptoms¹⁰. Fatigue and dyspnea are common symptoms of HF especially in worsening of HF¹¹. Chest pain is also a common symptom of HF which is caused by ischemic heart diseases¹². Previous studies said that dyspnea and fatigue were associated with the length of time from onset to arrived at hospital. On the contrary, another study revealed that chest pain and dyspnea were not factors that affecting length of pre-hospital time (pre-hospital time) would prolong treatment time for exacerbation and results in longer recovery time,
length of hospital stay (LOS) was one day longer than who came within 24 hours since onset (11 vs 10 days), and elevation of Brain Natriuretic Peptide (BNP) which indicated decreation of Left Ventricular Ejection Fraction (LVEF) 8-9. Other studies showed that chest pain was a factor that decreased duration between symptom and presenting at hospital, but there was no correlation between fatigue and pre-hospital time\textsuperscript{14-15}.

Considering to pre-hospital context, nurses also have a role to investigate about factors associated with pre-hospital time in patients with cardiovascular diseases including HF. The result would be as a basic consideration for looking for the solution to reduce length of pre-hospital time.

**Material and Method**

This study used an observational analytic design with cross-sectional approach, which conducted at Mardi Waluyo General Hospital and Ngudi Waluyo General Hospital Blitar in February to March, 2019. Respondents were 60 patients with acute exacerbation of HF who came to Emergency unit and admitted to inpatient ward, and selected by using purposive sampling technique. Data collection used a questionnaire. Inclusion criteria of respondents were: 1) Aged 55 years old or older; 2) Having family when taking data; 3) Live with family or partner; 4) Non referral/ did not use an ambulance; 5) Came from Blitar region; 6) In stable condition (with criteria: full conscious, respiratory rate less than 30x/minutes or not having chest pain, without ventricular arrhythmia, calm and able to speak; 7) Not having anxiety, does not show signs of moderate-to-severe anxiety or depression based on initial observations and assessments, including: fear, anxiety, tension, unwillingness to communicate with others, feeling prolonged sadness and despair\textsuperscript{16-17}; 8) Data was taken within the first 24 hours after the patient got stable condition. Patients who also diagnosed with a pulmonary infection or cancer after further examination in the ward were excluded.

Duration of pre-hospital time was calculated from the first acute symptom onset (symptom felt more severe than before) until arrived at hospital emergency room\textsuperscript{9}. Data were analyzed by using statistical program (SPSS 20). Bivariate analysis used Mann Whitney test (table 3) because data (length of pre-hospital time) was not normal (p Kolmogorov-smirnov=0.001<0.05), with 95% confidence interval (α=0.05). multivariate analysis was conducted by using multiple linear regression test (table 4) with enter method, and the results fulfill all assumption tests.

As can be seen from table 4, factors associated with length of pre-hospital time were chest pain, dyspnea, fatigue, acute symptom onset time. Number of symptoms is a confounding factor, and chest pain was the most dominant predictor of pre-hospital time.

Discussion

Number of symptoms is a confounding factor, and chest pain was the most dominant predictor of pre-hospital time. It is similar to a study conducted by
Darling et al. showed that chest pain was a factor that shortened pre-hospital time in patients with HF, because it was considered as a specific or severe symptom by patients\textsuperscript{14}. Another research also found that chest pain was a predictor of duration time between symptoms and arriving at hospital in patients with HF\textsuperscript{15}. Chest pain was known as a symptom caused by heart disease, so patients will tend to seek medical care immediately. In this study, 24 respondents complained of chest pain as the main complaint and felt burdensome. They said that chest pain felt suddenly, like burned and translucent to their back, could not disappear with taking a rest, and get more severe. It disturbed their comfort despite while they were not doing any activity, so they decided to go to hospital immediately. In contrast, another study showed that there was no difference between chest pain in patients who came >2 hours (delay) after symptom onset and those who came <2 hours (not delay)\textsuperscript{13}. It could be caused of the intensity of pain was not severe before entering the hospital. However, in this study, chest pain of acute exacerbation phase they felt was moderate to severe pain scale and continuously.

In this study, dyspnea reduced 436.187 minutes of pre-hospital time. It is consistent with a research carried out by Darling et al. which showed that dyspnea was a factor that reduced pre-hospital time delay in patients with HF\textsuperscript{14}. Another research also revealed that dyspnea (at rest and during activity) was related to length of time between worsening symptoms and seeking medical care\textsuperscript{11}. Continuous and burdensome dyspnea could increase patient distress and cause inability to carry out activities, so patients and families decided to seek medical care at hospital immediately\textsuperscript{7}. In this study, 56 respondents had dyspnea and it was the main complaint and get more severe than before. They felt discomfort due to dyspnea when they walked only in a few meters, even when they did not do any activity. However, a study explained that dyspnea was the most influencing factor in prolonging of pre-hospital time, which patients with dyspnea had 4.6 times risk to get delay in pre-hospital time, because dyspnea has gradual pattern, so patients and families did not realize that it is a sign of worsening condition and did not seek for medical care at hospital rapidly\textsuperscript{11,18}. This difference in finding might cause of different samples, so the calculation pattern of pre-hospital time was also different. However, the average time of dyspnea onset was 3 days but with a mild or not severe intensity, so they chose to take a rest first to eliminate this symptom. Contrary to this result, another study showed that there was no significant difference of pre-hospital time in patients with HF\textsuperscript{13}.

Fatigue also reduced 254.875 minutes of pre-hospital time. This result is in line with research conducted by Neuwenhuis et al. that showed a relationship between fatigue and length of time between onset to arriving at hospital\textsuperscript{15}. Another research also showed a significant difference between patients who were came \textless;72 hours and who came ≥72 hours from acute symptom till arrived at hospital\textsuperscript{18}. In this research, fatigue often followed dyspnea, so patients also felt it when they were not doing any activity or have a light activity. It made them could not move or do any activity as usual. When it felt burdensome with dyspnea, then they decide to go to hospital. On the other hand, a study said that fatigue was the most common symptom in worsening HF, but usually in elderly people, they would perceive it as a condition that usually occurs in the elderly, so they did not consider it as a serious or threatening condition and waited until the symptoms decreased\textsuperscript{11}. Contrary to this study, other studies found that fatigue was not related to the duration of acute HF patients in seeking medical care to hospital\textsuperscript{13-14}.

In this research, number of symptoms is a confounding factor which patient who had 1-2 symptoms was had 157.320 minutes shorter. 70\% of respondents had 1-2 symptoms (combination between either chest pain, dyspnea or fatigue). It is not in accordance with another study which showed relationship between number of symptoms with pre-hospital time delay\textsuperscript{11}. However, another study said that patients who had ≥3 acute symptoms were more likely to be delay in seeking medical care than those who had fewer symptoms\textsuperscript{13}. In addition, the symptoms were acute and got more severe, so even though 1 or 2 symptoms but it would make patients and families looking for emergency medical treatment immediately\textsuperscript{7}.

Furthermore, acute symptom onset time associated with length of pre-hospital time which acute symptom at 06.00 p.m.–06.00 a.m. reduced 207.003 minutes of the time.. 55\% of respondents had acute exacerbation symptoms onset at night and waited until the next morning. Patients said that they did not want to disturb their families who were sleeping. Patients who did not have private vehicles also did not want to disturb relatives or neighbors at night about borrowing a vehicle for going to hospital, so they chose to take a rest till
Feeling worried or being reluctant to disturb family or health worker at night, do not consider symptom as a serious condition, wait to evaluate any improvement in symptoms in the next morning associated with delay in pre hospital time\textsuperscript{7,14,19}. Contrary to this study, a study showed that onset time at 8.30-17.30 was a factor that prolongs time from symptom to hospital, because this time is busy or working hours\textsuperscript{15}. It is different from the conditions in Blitar, where ambulance service 118 is not available yet. There is no public transportation also like in other cities but inter-city transportation only operates from 6.00 a.m. to 03.00 p.m., so it makes no traffic jam there during working hours. In addition, online transportation is only available in Wlingi and Blitar city, so most of the respondents had to contact other families, relatives or neighbors to loan a vehicle to take patients to the hospital. This is supported by a study that an attempt to contact family or friends first was related to pre-hospital time\textsuperscript{14}. This condition also explained in a review that patients who live in rural area are more have prolonged pre-hospital time because they do not have transportation\textsuperscript{7}.

**Conclusion**

Factors associated with length of pre-hospital time in patients with acute exacerbation of heart failure in Blitar were chest pain, dyspnea, fatigue, and acute symptom onset time, which chest pain is the most predictor. Further research about social support factors is needed to investigate the association with pre-hospital time in patients with acute exacerbation of heart failure.

Transforming Growth Factor β1 in the Different Stages of Breast Cancer Patients

Narjis Hadi Al-Saadi¹, Amer Hasan Abdullah²

¹College of Science, Department of Chemistry, University of Kerbala, Iraq; ²College of Science, Department of Chemistry, University of Al-Mustansiriya, Iraq

ABSTRACT

Background: Transforming growth factor β1 (TGF β1) is one of the proteins which has a multifunctional role in breast cancer. It is considered an inhibitor in early stages and promoter in advanced stages of breast cancer.

Objective: The aim of this study is to know the benefit of using TGF β1 as predictor marker in breast cancer patients in different stages of the disease.

Method: Transforming growth factor β1 were determined from 52 patients with breast cancer in the early stage of the tumor (І+ІІ) 61% and advanced stage (ІІІ+ІѴ) 39% and 25 subjects as a control group by using Enzyme Linked Immunosorbent Assay (ELISA).

Results: The results showed a high level of TGF β1 (p˂ 0.05) in breast cancer patients compared with the control group. Depending on the stage of the tumor, TGF β1 was more level in these patients with stage II than stage I and stage IV (p˂0.03, 0.029) respectively. So this study showed no any significant differences between the early stage of the tumor and advanced stage of the tumor.

Keywords: TGF β1, Breast cancer, serum

Introduction

Breast cancer is one of the most common cancers worldwide especially in Iraq after the war in 1990 and 2003. The radiation of weapons that contain depleted uranium was one of the causes of cancer (1). Many substances as transforming growth factor plays a pivotal role in progression or suppression tumor in the stages of breast cancer (2). TGFβ1 exist as a homodimer and is released as in active form. It is expressed by many normal cells and organs and influences both normal and tumor cells process in the mammary gland (3,4). Very little studies are estimated the circulating TGF β1 as predictor marker in patients with breast cancer. It is increased in the early stage of the tumor and can be used as a predictor clinical marker of breast cancer (5). In early-stage, TGF β1 acts as a growth inhibitor of epithelial cells whereas in the advanced stage of tumor TGF β1 exchange its activity into tumor promoter and effect on cancer metastasis (6). It acts as an inhibitor of tumor angiogenesis in early stage and activator of tumor angiogenesis in late stage (7). This double function puzzled the researchers for many years (8). However, TGF β1 can adjust cancer-related process, like cell infestation, malignant growth, and microenvironment modification (7).

Method

Study Design: The current study was designed as a Case-control study which includes 52 patients with breast cancer their age ranging between 25 to 75 years old and 25 subject their age-matched with the patients as a healthy control group. Patients were enrolled from the oncology unit at Al-Husseini Hospital, Kerbala, Iraq, in the period from October 2017 to April 2018. Those patients were diagnosed as breast cancer by

DOI Number: 10.5958/0976-5506.2019.02173.9
histopathological examination. A questionnaire was designed to obtain information about the patient. It contained the name, age, weight, height, smoking, menopausal, treatment, contraceptive, family history of cancer, abortion, breast feeding, and the living.

Collection of Specimens: Blood samples were drawn from the venipuncture, and then were let it to stand for 30 min. at room temperature. Sera were separated by using centrifuge at 3000 xg for 15 min., and then stored at -70°C until uses.

All samples were taken before surgery.

Determination of TGF β1: The level of serum TGF β1 was measured by using the Enzyme Linked Immuno Sorbent Assay (ELISA). A sandwich ELISA was used and a target-specific antibody has been pre-coated in the wells. Samples, standards, and controls were added into these wells and bind to the immobilized (capture) antibody. The sandwich is formed by the addition of the secondary antibody; a substrate solution was added that reacts with the enzyme-antibody-target complex to produce a measurable signal. The intensity of this signal is directly proportional to the concentration of TGF β1 present in the original specimen (9).

Statistical Analysis: Statistical Package for Social Sciences (SPSS) version 24 was used for statistical analysis. Data were expressed as mean (SD) for normality distribution and median for non-normality distribution. Kolmogorov-Smirnov test displays the non-normality distribution of TGF β1, so Mann-Whitney U test was used. P-value ≤ 0.05 was considered significant.

Results

The characteristic feature of the patient with breast cancer is shown in Table - 1. The statistical analysis showed a significant (p<0.001) elevated level of TGF β1 in those patients with the breast cancer compared with the healthy control group (Table 2). During the tumorigeneses, the level of TGF β1 exchange but not significantly (p > 0.05) between early and advanced stage of the tumor, whereas significant (p < 0.0001) elevation of TGF β1 in subgroups, early stage and advanced stage as compared with control group respectively (Table 3) (Fig.1). Patients were classified into four groups depending on the stage of the tumor. Transforming growth factor TGF β1 was significantly (p < 0.03) elevated in patients with stage I comparing with stage II and significant (p<0.029) elevated level in patients with stage IV comparing with those of stage II of cancer (Table 4).

Discussion

This study focused on the correlation between serum TGF β1 and breast cancer because the physician considered all data which helped him in the prognosis of cancer (10).

Transforming growth factor TGF β1 acts as an inhibitor of mammary endothelial proliferation and regulator of mammary ductal and alveolar development (11).

The results of this study showed the elevated level of TGF β1 in patients with breast cancer compared with the control group. This elevation due to the high expression for synthesis TGF β1 and its association with oncogenic activity (1). Several studies had also the same results and explained the overproduction of TGF β1 in many tumors especially in those with breast cancer. It is related to the tumor progression. Tumor cells produce TGF β1 which enhancing tumor growth through promoting angiogenesis and avoiding immune surveillance (10). Iavanovic´ et al, (2003) approved the significantly elevated level of TGF β1 in breast cancer patients compared with healthy group (12). Also, Papadopoulou et al. (2008) are indicating the highest level of TGF β1 in breast cancer patients in compared to the control group (11). Several projects study these associations between the expression of TGF β1 and breast cancer (13).

This study didn’t show significant differences between the early stages of cancer and advanced stage, although there is a difference in the concentration of TGF β1 between two stages. The reduced level of TGF β1 in stage II may be due to losing the function of TGF β1 protein receptor (14). Palmari et al, (2006) revealed
the increased level of TGF β1 during tumorigenesis and metastasis stage (14). Other studies reported that there is no significant relationship between serum TGF β1 and stages of breast cancer patients (15)(16). This finding was corresponding with the results of this study. Michael et al (2014) study’s showed a significant correlation of TGF β1 and tumor size (15). Nataša et al (2003) explain the overexpression of TGF β1 in early stage of breast tumor. At a certain stage of breast cancer, there is a shift in TGF β1 action (17). The increment expression of TGF β1 in early stages (I/II), it would be an advantage for the host, but not for tumor itself (17). Shim et al (1999) study’s showed a significantly high level of TGF β1 in patients with colorectal carcinoma relative to the healthy group and there is a correlation between the level of TGF β1 and progression of the tumor (18).

Patient with both early stage and advanced stage showed a high level of TGF β1 relative to the control group. This finding was similar to Dave et al, (2012) (19).

The treatment with radiotherapy and chemotherapy can increase TGFβ1 action and then enhancing tumor metastasis. So the inhibition of TGFβ1 promotes sensibility tumor into radiotherapy and chemotherapy (15). Boothe et al. (2011) are confirmed that TGF β1 is related to the increased fibrosis caused by radiation (20).

For women who take contraceptives, studies have shown a low correlation between contraceptives and breast cancer, and this fact matched with the results of the study(21).

Many projects studied another type of cancer which include prostate, thyroid, ovarian, and breast cancer which exhibit a significant elevation in the concentration of TGF β1 in those patients compared with the control group (22)(23)(24)(25).

Conclusion

Transforming growth factor TGF β1 play a significant role in tumorigenoses and can be used as predictor marker in breast cancer.

ABSTRACT

Background: Globally, suicide is a cause of premature death among young people. A survey done in Indonesia’s students revealed that suicidal thought was experienced by around 5%. In Jakarta, a 2015 preliminary study found a higher figure of 18.6% of high school student experienced suicidal ideation. This demonstrated an urgent need for intervention in the prevention and progression from suicidal ideation to suicide attempts. Therefore, this study aims to develop an instrument, named as The Risk Factors of Suicidal Ideation, for early detection of risk factors of suicidal thought in students.

Method: This cross-sectional study was conducted in 2018 in Jakarta Province. A research-based, self-administered questionnaire was developed to assess the risk of suicide in high-school students. The study sample comprised 910 students from 10 high schools; the schools were chosen through stratified random sampling. Some statistical analysis was used to show the validity and reliability of this instrument.

Results: This study produced a Risk Factors of Suicidal Ideation (RFSI) questionnaire consisting of 14 items incorporating four dimensions: belongingness, loneliness, hopelessness, and burdensomeness. The questionnaire achieved an 88.2% Cronbach’s alpha rating, indicating high reliability. Meanwhile, the instrument’s construct validity ranked high by Kaiser-Meyer-Olkin test (.812), and a Bartlett test score of <0.0001 confirmed the integrity of its factor analysis.

Conclusion: The questionnaire is reliable and valid in assessing the risk factors of suicidal ideation among high-school students of Jakarta Province. Screening as part of an intervention strategy for suicide prevention can have an important role in decreasing suicidal ideation.

Keywords: suicide risk-assessment questionnaire, suicidal ideation, high-school students
Research has shown it is important to detect risk factors before they develop into suicidal ideation. Consistently across countries, about 60% of transitions from suicidal ideation to planning and from planning to an attempt occurred within a year of the onset of ideation. Studies also found that adolescents who reported suicidal ideation at age 15 were almost 12 times more likely to make a suicide attempt between the ages of 15 and 30, compared with adolescents who did not have suicidal ideation at baseline, with no sex differences.

By considering the previous data, this current study was conducted to develop a research-based questionnaire to assess the presence of those factors among high-school students in Jakarta. Various self-report questionnaires were evaluated, but they lacked efficiency for this purpose, and Apter has made a convincing argument against the reliability of data self-reported by adolescents. This study’s research questionnaire is more useful in the early detection of behaviors that lead to suicidal ideation. The idea to develop this research began after conducting a document review of a previously developed instrument by the Ministry of Health. In April 2016, the ministry’s Directorate General of Disease Control and Prevention submitted a report on the psychometric characteristics of the government’s Service Evaluation on Mental Health Cases (EPK2J) questionnaire, which was designed in 2015 to research suicidal tendencies among 502 adult respondents in four cities. The directorate recommended further study, both theoretically and empirically, to determine whether five dimensions which overall consisting of 28 items could reliably measure a person’s tendency to suicide. The dimensions were: burdensomeness, belongingness, impulsiveness, hopelessness, and loneliness. The EPK2J questionnaire was developed by combining several instruments to meet the need for Indonesian locality. The instruments were: the Interpersonal Needs Questionnaire, the UCLA Loneliness Scale, the Brief Hopelessness Scale, and the Suicide Behavior Questionnaire – Revised.

Risk factors for suicide include mood disorders and previous suicide attempts. Substantial research has been done to support the connection between major depression and teen suicide. Taking this into account, depression is also examined in this study. Effective adolescent depression-screening instruments include Patient Health Questionnaire-9 (PHQ-9) and -2 (PHQ-2). This research utilizes the PHQ-9 Adolescent.

Method

This cross-sectional study was conducted in 2018 in 10 schools in Jakarta Province. The study population was high-school students aged 14–18. For the purposes of quantitative research analysis, the minimum required sample size was adjusted according to the sample calculation formula for the two-proportion population hypothesis test (two-sided test) with a minimum sample size of 596 samples, which was increased in consideration of the dropout rate of 10%. The acquired sample size was 910.

To determine the sample size in high schools, a list of all high schools in Jakarta Province was prepared. The schools were chosen with stratified random sampling after determining the A-accredited high schools. Five schools were public vocational and five schools were general public. Each school was targeted to get 100 samples with random selection between grades 10, 11 and 12.

The questionnaire in this study is derived from the EPK2J questionnaire for adults in health-care facility settings. This study developed EPK2J into a special questionnaire for adolescents in the school setting. The questionnaire was then tested in schools. The questionnaire included an introduction explaining the importance of filling it out carefully and answering every question, with an additional note emphasizing confidentiality. The assessors or surveyors then brief students on how to answer the questions. Once the students completed the questionnaire, they were gathered and delivered to the researcher.

Data were inserted and analyzed using the SPSS software (version 21.0). Construct validity tests were performed for the items of all components using exploratory factor analyses, which took into account the items’ response format. Factors were extracted using the principal component analysis, followed by orthogonal rotation. Prior to the exploratory factor analyses, the Kaiser-Meyer-Olkin test measure was obtained and Bartlett’s test of sphericity was performed. The reliability analysis was performed using the Cronbach’s alpha coefficients for each factor that emerged from the analysis.

Results

The questionnaire’s content- and face-validity were determined through two focus group discussions. The questionnaire was handed to expert child and adolescent psychiatrists in the Indonesian Psychological Association,
the Child and Adolescent Psychiatry Section in the Indonesian Psychiatric Association, the suicide-prevention NGO Into the Light, the Ministry of Health’s Research and Development Agency, the Ministry’s Directorate of Prevention and Control of Mental Health and Drug Problems, the Association of Clinical Psychologists, and the Indonesian Youth Mental Health Association. After the input from two focus group discussions, the questionnaire started with 28 items and was revised to 27 based on the suggestions made by these experts. Each statement was scored at four levels: Do Not Agree, Somewhat Agree, Agree, and Strongly Agree.

To test the reliability of the questionnaire, the ten schools were selected by random stratification. Students filled out 910 questionnaires; high-school students completed 435 and vocational-school students completed 475. Of the high-school students, 65.4% were girls and 34.6% were boys, with an average age of 16 and a range of 14–18 years. Cronbach’s alpha, estimated on all participants, was 88.2% of the total score (final 14 items). These values were interpreted as having excellent internal consistency. The KMO was 0.812, and significant of Bartlett test was <0.0001.

Of the respondents who took the PHQ-9 Adolescent on depression severity, 28.4% of respondents scored minimal/none, 43.5% mild, 17.7% moderate, 5.5% moderately severe, and 1.3% severe. Additional questions in the PHQ-9 Adolescent were: “Has there been a time in the past month when you had serious thoughts about ending your life?” (5.4% answered “yes”) and “Have you ever, in your whole life, tried to kill yourself or made a suicide attempt?” (8.1% answered “yes”). The suicidal ideation score was used as a proxy for measuring the content validity of the developed questionnaire on suicide risk assessment. With gender differentiation, the results of suicidal ideation utilizing PHQ-9 were 5.5% of females and 5.1% of males. Regarding the suicide-attempt question, the results were 8.7% of females and 7% of males.

Furthermore, the cut-off of suicide risk factors was sought using the receiving operating characteristic curve (ROC) analysis. A cut-off score for the suicide risk-assessment questionnaire was set at ≥ 31 of 56 scales with a sensitivity of 0.776 and a specificity of 0.771. Utilizing the final Risk Factors of Suicidal Ideation (RFSI) questionnaire with cut-off score of ≥ 31, the result showed a higher proportion of students reporting higher risk in girls (28.8%) than boys (20.7%).

**Discussion**

The suicide risk-assessment questionnaire captured a larger number of students than the PHQ-9 Adolescent because it was intended as early detection of suicide risk. It also showed that female students are at higher risk than male students, which echoes the results of PHQ-9 Adolescent. It is hoped a screening for early detection will prevent the development of suicidal ideation, which could lessen the likelihood of an attempt. According to a recent study, school-based mental-health programs must take into consideration a gender-based approach. Eventually, in line with the objective of early detection of risk factors, this developed instrument can be labeled as “Risk Factors of Suicidal Ideation (RFSI)”.

The questionnaire developed through this study was not previously available in Indonesia. So far, one of the instruments used in Indonesia for adolescent mental health programs in schools include the Strength and Difficulties Questionnaire (SDQ), the results of which are recorded in a student’s Health Report Card (Rapor Kesehatan Anak) and School Health Efforts Program (Usaha Kesehatan Sekolah).

As with the SDQ questionnaire, the RFSI questionnaire developed in this study might be incorporated into School Health Efforts programs and make up a part of a student’s Health Report Card. In the instructions for implementing mental-health services in schools that are integrated with the School Health Efforts Program, there is a chapter on mental-health intervention using the SDQ to address problems with learning achievement and/or behavior. The result of the School Health Efforts Program has to be followed up. Educators should patiently and attentively talk and listen to students, involving parents and classmates to help.

Peer counselors from schools are partnered with community health centers to manage services for local teenagers. Peer counselors must also have basic knowledge about the role of a counselor, connecting adolescents with competent healthcare workers who will make the appropriate referrals. This is important if the RFSI indicates a high risk of suicide tendencies. As an example, there was a health center in DKI Jakarta creating an android-based psychiatric or mental-health application called eJiwa; it uses a self-administered questionnaire, an excellent idea, given how many internet-users are teenagers.
Another highlight of the Health Ministry’s program is the Minimum Service Standards that covers the types of basic services in the form of health services at productive age with basic service quality according to the standards of productive age health screening. Basic service recipients are Indonesian citizens aged 15–59. Screening services include the detection of emotional and behavioral disorders, which makes them suitable for incorporating the RFSI. \(^{18}\)

One of the Ministry of Health’s innovations is Sehatpedia application, a form of digital-era health innovation. \(^{19}\) Adolescents must be exposed to digital health services, including the screening process. It is possible that the RFSI questionnaire could also be included in Sehatpedia so that the coverage area is greater than eJiwa, which is only focused on DKI Jakarta.

**Conclusion**

This study found that screening could be applied quickly to detect any disturbances or risk factors that humans did not even realize before. The screening instrument is a self-administered suicide risk-assessment questionnaire, named as RFSI, that can be given to high-school students in school settings to detect the risk factors of suicide ideation.

The Effect of Chlorhexidine Tooth Paste on the Tooth Shade  
(A Comparative Study)

Raed Faisal Al-Huwaizi, Yamama Adnan Al-Rubbaey, Ali Hadi Fahad

1College of Dentistry, University of Kufa, Iraq

ABSTRACT

The objective of this study was to analyze the effect on the tooth shade of a chlorhexidine toothpaste in comparison with three edible toothpastes with the widest worldwide distribution (Colgate, Crest and Signal). The study group was formed of 48 volunteer young adult female dental students (3rd stage) aged 20 years having a fully dentulous anterior dentition and a good oral health status. The shade of the teeth before the study was mostly 2M1 followed 1M1, 2L1.5 and 2R1.5 then 2M2. The majority of the control group subjects (94%) showed no tooth shade changes, 25% of the subjects who used Laculut Aktiv toothpaste showed a mild tooth shade change and no subject showed moderate or severe shade change. Chi square showed these shade differences to be statistically non-significant (p<0.05). Prolonged brushing with Laculut Aktiv toothpaste darkens tooth shade.

Keywords: Tooth shade, chlorhexidine tooth paste, microorganisms, antimicrobial agent

Introduction

Toothpastes are daily oral care products, the chemical composition of which is constantly changing due to manufacturer’s competition. Toothpastes are recognized as the best source of fluoride, and now chlorhexidine which most effectively protects both deciduous and permanent teeth from caries.(1,2)

Toothpaste is classified as drugs not cosmetics because drugs should contain an ingredient to achieve the effect the consumer desires. It is important to determine if different brands of tooth paste contain effective antibacterial ingredient such as fluoride, chlorhexidine and xylitol to reduce bacterial load in human mouth and contribute to dental health. (3)

Teeth are typically composed of a number of colours and a gradation of colour occurs in an individual tooth from the gingival margin to the incisal edge of the tooth. The gingival margin often has a darker appearance because of the close approximation of the dentine below the enamel. In most people canine teeth are darker than central and lateral incisors and younger people characteristically have lighter teeth, particularly in the primary dentition. (4)

The science of colour is important in dentistry with regard to colour perception and description, and can be improved with training. The viewing conditions are extremely important and variables such as the light source, time of day, surrounding conditions and the angle the tooth is viewed from affect the apparent tooth colour. Light is composed of differing wavelengths and the same tooth viewed under different conditions will exhibit a different colour, a phenomenon known as metamerism. In judging tooth colour it is best if the light source used is standardised to reduce the effects of metamerism. It is common to find three sources of light in a dental surgery; natural, fluorescent and incandescent. (5)

Historically, tooth discoloration has been classified according to the location of the stain, which may be either intrinsic or extrinsic. It may also be of merit to consider a further category of internalised stain or discolouration. (6)

Extrinsic discolouration is outside the tooth substance and lies on the tooth surface or in the acquired pellicle. The origin of the stain may be either metallic or non-metallic. (6,7)

The causes of extrinsic staining can be divided into two categories; those compounds which are incorporated into the pellicle and produce a stain as a result of their basic colour, and those which lead to staining caused by chemical interaction at the tooth surface. These organic chromogens are taken up by the pellicle and the colour imparted is determined by the natural colour of the chromogen. (6)
Indirect extrinsic tooth staining is associated with cationic antiseptics and metal salts. The agent is without colour or a different colour from the stain produced on the tooth surface. Interest in the mechanisms of extrinsic tooth staining was mentioned by Flotra et al. that tooth staining increases with the use of chlorhexidine. These non-metallic extrinsic stains are adsorbed onto tooth surface deposits such as plaque or the acquired pellicle. The possible aetiological agents include dietary components, beverages, tobacco, mouthrinses and other medicaments. (8)

The characteristic staining of the tongue and teeth noted by Flotra et al. (8) is not peculiar to chlorhexidine, it has been reported in other cationic antiseptics, the essential oil/phenolic mouthrinse ‘Listerine’(9) and following prolonged use of delmopinol mouth rinses. (10)

The study aimed to compare dental staining associated with chlorhexidine based tooth paste (Laculut, Aktiv) in comparison to 3 brands of regular tooth pastes (Crest, Colgate and Signal).

**Materials and Method**

**Sample:** A sample of 48 volunteer young adult female (3rd stage dental students) aged 20 years having a fully dentulous anterior dentition and a good oral health status was enrolled in the study. They were all non-smokers.

**Grouping:** The participants were randomly allocated to four groups (12 individuals each) depending on the type of tooth paste they would use (Crest tooth paste, Colgate tooth paste, Signal tooth paste, Laculut Aktiv chlorhexidine based tooth paste).

**Method:** All the individuals were asked to brush their teeth three times a day for the whole period of the study (12 weeks), and were instructed not to drink coffee with minimal tea consumption (up to 2 cups a day). The individuals were examined weekly to encourage adherence to oral hygiene measures.

**Shade Measurement:** Tooth shade measurement was done by observation of the middle third of the labial surface of the maxillary right central incisor and comparing its shade with Vita 3D Master Shade Guide. The readings were taken at noon time and on the same dental chair to minimize the effect of surrounding light. In the beginning of the study, efficient scaling and polishing was performed to all the teeth and a baseline tooth shade was registered. At the end of the 12-week experimental period, another shade reading was registered after the patients brushed their teeth. If the teeth become one level darker, this was regarded as mild color change; while two levels darker was regarded as mild color change; and three levels darker was regarded as severe color change.

**Consent Form:** Before commencing in the study, the nature of the experiment was described to each individual outlining the commitment to protocol, risks and benefits, and the right to withdrawal. After answering any queries, a consent form was signed.

**Calibration and Standardization:** All the patients were examined on the same dental chair under fluorescent light. Inter-examiner calibration of shade measurement was performed on 20 subjects and proved to be statistically non-significant. A second intra-examiner reading was taken after 2 weeks to eliminate memory bias and was also statistically non-significant.

**Results**

The shade of the teeth before the study was measured and displayed in figure 1. The most prevalent shade was 2M1 followed 1M1, 2L1.5 and 2R1.5 then 2M2 and lastly 3L1.5.

The majority of the control group subjects (using Crest, Colgate, and Signal tooth pastes) showed the same tooth shade in baseline as after 12 weeks. Only 2 subjects of the 36 showed a mild shade change in groups Crest and Colgate tooth pastes.

On the other hand, 25% of the subjects who used Laculut Aktiv tooth paste showed a mild tooth shade change while no subject showed moderate or severe shade change. However, Chi square showed these shade differences to be statistically non-significant (p<0.05).

Discussion

The present study included only third year dental students based on the availability during the actual study period and keeping in mind the future study compliance.

The present study was an in-vivo randomized clinical trial that evaluated the comparative efficacy of three different very popular toothpastes on the staining effect on the teeth. A chlorhexidine based toothpaste (Luculat Aktiv) was incorporated because of the increased public interest in the usage of alternative health care with more therapeutic efficiency. (11) The addition of antimicrobial agents to conventional toothpastes aims to increase effectiveness in the control or elimination of microorganisms involved in a wide variety of the primary etiological agents of dental caries. (12,13) However, there is not enough evidence about dentifrices with chlorhexidine. (14)

Teeth shade change may be influenced by both intrinsic and extrinsic coloration, being the latter determined by the adsorption of pigments onto the tooth substrate, causing staining. (15,16) Staining observed clinically may be the result of the precipitation of antiseptics, such as chlorhexidine, or of chromogenic dietary substances, such as tea. (17)

In spite of individual variation, the study did not find any change in shade after the use of all three commercial toothpastes in the majority of cases proving their clinical efficiency. This comes in agreement with Ghassemi et al. (18) who found similar results while using Colgate Cavity Protection Toothpaste for six weeks and with Koertge et al. (19) who found no significant tooth shade changes after using Crest Toothpaste for twelve weeks. The minor differences detected may be due to differences in enamel roughness, brushing frequency and technique or consumption of staining food. (20,21).

Three quarters of the subjects who brushed with Laculut Aktiv showed no shade changes and only one quarter showed a mild shade change. It is difficult to compare our findings with previous researches as most of them were carried out in vitro (16,22) or on bovine teeth. (23)

Analysis of Cyclamate Contents in Food/Beverages Snacks Sold in Several Primary Schools in Enrekang Regency

Rahman¹, Prawansa Amran¹
¹Department of Health Analyst Poltekkes Makassar

ABSTRACT

Research has been carried out on the analysis of cyclamate content in snacks/snacks sold in several elementary schools in Enrekang Regency with the aim of analyzing cyclamate content in snacks/beverage samples both qualitatively and quantitatively. The method used in this study is the laboratory observation method with a descriptive approach, qualitative test with Gravimetric method and quantitative test with UV spectrophotometry. The results of the study from 28 samples contained 10 types of snacks and 18 types of snacks. Based on qualitative tests of 10 samples of all snack foods (100%), they were negatively contained cyclamate. Of the 18 samples of snack foods there were 6 (33.3%) samples stated to contain cyclamates and 12 (66.7%) samples stated as not containing cyclamates. From the results of the quantitative test, from 6 samples that were positive for cyclamate with levels of 24.92 - 100.33 mg/kg with an average value of 53.07 mg/kg with a standard deviation of 86.61, all of them still met the requirements according to the Head of the Agency Drug and Food Control is a maximum of 500mg/kg.

Keywords: Cyclamate, food, snacks, Enrekang

Introduction

Food and beverages are very important for humans because they are one of the basic needs for their survival. Foods and beverages that are consumed must be fulfilled by their nutritional needs, hygienic, and safe to avoid diseases. At present the food and beverage industry is growing rapidly, advances in food and beverage processing technology have produced products in the form of processed food and beverages. Food and beverages in addition to having a longer shelf life, practical, also have a color, taste, aroma, and texture that is better than natural foods and drinks.¹⁷ Artificial sweeteners which are now widely used in beverages are cyclamate, which is one of the sweeteners used by small traders and home industries that have a sweet taste without bitter taste. These sweeteners have a sweetness 30 times relatively large than the level of sweetness of sucrose with no calorific value which is usually said to be a nonnuritive sweetener felt for diabetics and obese sufferers. In various small industries, cyclamates are often used to replace sucrose or often we are familiar with sugar or cane sugar with the intention of lowering prices so that they are sold cheaply but the taste remains sweet.²⁰ Cyclamate has a good taste, especially with its sweetness, but the use of cyclamates must be limited because it can endanger health.

Every country has its own rules in limiting the amount of cyclamate consumption. In Indonesia cyclamic sweeteners are still allowed as long as they do not exceed the threshold determined in the decision of the Head of the Food and Drug Supervisory Agency of the Republic of Indonesia. Regarding the use of artificial sweetener food additives in food products Number: HK.00.05.5.1.4547 in 2004, that cyclamates are allowed in drinks and food with a maximum usage limit of 500 mg/kg. The WHO world health organization itself limits the daily consumption of safe cyclamate (ADI) is 11 mg/kg body weight.¹⁹

Based on this, researchers are interested in conducting research with the title Analysis of cyclamate content in snacks/snacks sold in several elementary schools in Enrekang Regency.
Research Method

A. Type of Research: This type of research is descriptive comparative which aims to determine the differences in cyclamate content in snack foods and snacks which are traded in several elementary schools in Enrekang Regency.

B. Population and Samples
1. Population: The population in this study were snacks and snacks that were traded in several elementary schools in Enrekang Regency.
2. Samples: The samples used in this study were snacks and beverages that were bought and sold in several elementary schools in 3 sub-districts, namely: Baraka District, Malua District, and Buntu Batu District, Enrekang District.
3. Sample Size: The number of samples obtained and used in this study were 28 samples consisting of 10 samples of snacks and 18 samples of snacks.
4. Sampling Techniques: The sampling technique in this study was Total sampling.

C. Place and Time of Research
1. Sampling place: Sampling sites were carried out in several elementary schools in 3 sub-districts namely Baraka District, Malua District, and Buntu Batu District, Enrekang District.
2. Inspection Place: This research has been carried out in the Chemistry Laboratory of the Makassar Health Polytechnic Department and the Makassar Health Laboratory Center.
3. Research Time: This research has been carried out:
   a. Sampling was carried out on 3 districts in several Enrekang District elementary schools from August 13, 2018 and September 13, 2018
   b. Laboratory checks are qualitative tests and quantitative tests are held on August 20, 2018 until October 10, 2018.

D. Research Variables:
1. The independent variables in this study were the types of snacks and beverages that were traded in several elementary schools in 3 districts of Enrekang Regency.
2. The dependent variable in this study is the content and cyclamate level.

E. Operational Definition
1. Analysis: Analysis is a method for determining whether or not there is and determining the level of cyclamate in a material.
2. Cyclamate: Cyclamate is an artificial sweetener which is often referred to as sweet juice which is widely used by food and beverage manufacturers as a sweetener.
3. Food/Beverage snacks: Food/Beverage Snacks are a type of soft food/drink produced by housewives or home industries that are traded on traditional markets or in crowded places such as in schools.

F. Work Procedure
1. Pre Analytical
   a. Preparation of tools and materials:
      Tools: Porcelain cup, erlenmeyer, analytic balance, volume pipette, separating funnel, stirrer, measuring flask, beaker, stopwath, waterbath, test tube, suction rubber, chamber chromatography, TLC plate, bottling device and UV-Vis spectrophotometer
      Material: Aquadest, solution of hydrochloric acid (HCl), solution of barium chloride (BaCl2) 10%, Solution of sodium nitrite (NaNO2) 10%, solution of 10% NaOH, sodium cyclamate,
      a. Sample preparation: Piped 100 ml of sample snacks and snacks into a measuring flask, then add 10% NaOH to alkalis. Filter using whatman filter paper (Apriyantono. A. et al.)
   2. Analytic: Ways of working:
      a. Making Standard Sodium Cyclamate Solution
         1. Making 1000 ppm cyclamate mother solution
            Weigh 0.1 grams of sodium cyclamate, dissolved in aquadest, put in a 100 ml volumetric flask, add aquadest to the boundary mark. Then homogenize.
         2. Making standard work solutions: Piped as much as 5 ml (50 ppm), 10 ml (100 ppm), 15 ml (150 ppm), 20 ml (200 ppm), 25 ml (250 ppm), 30 ml (300 ppm), 40 ml (400 ml). ppm, and 50 ml (500 ppm), then each is put in a 100 ml volumetric flask.
3. The absorbance is measured by a UV-Visible spectrophotometer at a wavelength of 420 nm.

b. Qualitative test for cyclamate deposition method
1. Pipette 100 ml of sample solution and inserted into the Erlenmeyer flask. Add aquaest to the boundary mark. Filter on whatman paper.
2. Add 10 ml of 10% HCl solution.
3. Add 10 ml of 10% BaCl2 solution, left for 30 minutes
4. If filter turbidity occurs, use paper whatman. Add 10% NaNO2 as much as 10 ml is done in the acid room.
5. Heat using a waterbath while homogenizing for 20 minutes until white sediment is formed. Then let it cool.
6. If white deposits arise from BaSO4, the sample contains cyclamate

c. Quantitative test spectrophotometer method
1. Pipette 100 ml of sample solution and inserted into the Erlenmeyer flask. Add aquaest to the boundary mark. Filter on whatman paper.
2. Add 10 ml of 10% HCl solution.
3. Add 10 ml of 10% BaCl2 solution, left for 30 minutes.
4. If filter turbidity occurs, use paper whatman. Add 10% NaNO2 as much as 10 ml to do in the acid room.
5. Heat using a waterbath while homogenizing for 20 minutes until white sediment is formed. Then let it cool.
6. The absorbance is measured by a UV-Visible spectrophotometer at a wavelength of 420 nm.

3. Post Analytic: Calculation of cyclamate levels
Calculation of cyclamate content is done by using a linear equation, a graph is made between absorption and concentration for cyclamate, where the absorption values on the Y axis and concentration on the X axis, then drawn lines between points to obtain a straight line equation.

\[ Y = a + bx \]

G. Data Analysis: Data that has been collected from the results of the study will be presented in table form and described in narrative form.

Results and Discussion

A. Research Results: Based on the results of laboratory examinations which were held on August 20, 2018 to October 10, 2018 which were held at the Makassar Health Laboratory Center, the following results were obtained:

Table 1: Distribution of snack foods based on the results of qualitative tests of Siklamat content traded in several Primary Schools in Enrekang Regency

<th>Standard Deviation (SD)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td></td>
<td>53.25</td>
<td>86.61</td>
</tr>
</tbody>
</table>

Based on table 5 above, it shows that from 6 samples of snack drinks that contain positive cyclamates, the average number of cyclamate levels is 53.25 mg/kg sample with a standard deviation value of 86.61.

B. Discussion: Cyclamic sweetener is one type of artificial sweetener or synthetic sweetener which is a type of sweetener that has a sweet taste 30 times relatively large from the sweetness level of sucrose with no caloric value.

In various small industries, cyclamates are often used to replace sucrose or often we are familiar with sugar or cane sugar with the intention of lowering prices so that they are sold cheaply but the taste remains sweet. Cyclamate has a good taste, especially with its sweetness, but the use of cyclamates must be limited because it can endanger health. The result of cyclamate metabolism which is often called cyclohexamin is carcinogenic so that excretion through urine can stimulate tumor growth.

In Indonesia cyclamic sweeteners are still allowed as long as they do not exceed the threshold determined in the decision of the Head of the Food and Drug Supervisory Agency of the Republic of Indonesia. Regarding the use of artificial sweetener food additives in food products Number: HK.00.05.5.1.4547 in 2004, that cyclamates are allowed in drinks and food with a maximum usage limit of 500 mg/kg.

Based on the results of the research for the qualitative test with Thin Layer Chromatography (TLC) method, all 10 food samples did not contain cyclamates, whereas for the snack beverage samples it was found that from 18 snacks samples obtained 6 types of cyclamate samples. Snack drinks sold in several elementary schools in Enrekang Regency, found 6 (21.4%) samples that tested positive for cyclamic sweeteners and 12 (78.6%) samples of snacks that did not contain cyclamates. Of the 6 samples that contained positive cyclamates after being tested with quantitative tests of ultra-violet (UV) spectrophotometric methods, the results were: 24.92 mg/kg, 28.0 mg/kg, 32.54 mg/kg, 32.45 mg/kg, 100.27 mg/kg, and 100.33 mg/kg. This means that from 6 samples not exceeding the standards set by the Head of the Republic of Indonesia Drug and Food Supervisory Agency, which is a maximum of 500mg/kg. Based on these results, the cyclamate level obtained in snacks sold in several bases in Enrekang Regency is between 25.92 mg/kg - 100.33 mg/kg with an average value of 53.07 mg/kg with a standard deviation value (SD) as many as 86.61.

According to the head of the Food and Drug Supervisory Agency (BPOM) said that the safe limit of cyclamate use in snacks or snacks is 500mg/kg, meaning that of the 6 samples of snacks sold in some elementary schools in Enrekang District that are positively cyclical still safe for consumed.

Conclusions and Suggestions

A. Conclusion: Based on the results of the research and discussion about the Analysis of Cyclamate content in snacks/Beverages that are traded in several elementary schools in Enrekang Regency can be concluded as follows:
Based on the results of qualitative analysis of Thin Layer Chromatography (TLC) method, it was found that from 28 types of samples there were 10 samples of types of snacks and 18 samples of types of snacks.

2. Snack food samples from 10 types were stated to be all negative containing cyclamate.

3. Samples of snack drinks from 18 samples obtained 6 (33.3%) samples containing positive cyclamates, and 12 (66.7%) samples did not contain cyclamates.

4. Based on the results of quantitative analysis of the spectrophotometric method, from 6 samples that contain positive cyclamate, all of them are still within the standard limits permitted by the Head of the Republic of Indonesia Drug and Food Supervisory Agency, which is a maximum of 500mg/kg.

B. Suggestions: Based on the results of research and discussion it can be suggested as follows:

1. For the community, it is still advisable to pay attention to snacks/drinks that will be consumed.

2. For household industries to always pay attention to the safety of snacks/snacks sold.

ABSTRACT

Aim: Safe and healthy drinking water is drinking water by which has well controlled and maintained hygiene sanitary. This study aims at investigating the sanitation and hygiene of drinking water found in several refill drinking water depots in Kendari City, Southeast Sulawesi Province, Indonesia.

Method: Selecting the sample was done randomly with a total 32 samples of drinking water refill depots scattered in Kendari City. Data collection uses questionnaires as stated in the Regulation in the Republic of Indonesia’s Minister of Health Regulation No. 492/Menkes/Per/IV/2010 concerning on drinking water quality requirements which includes aspects of premises, equipment and handlers.

Results: The results of the research is hygiene and sanitation conditions in 32 refill drinking water depots scattered in Kendari City showed 66.33% met the eligibility requirements and 33.26% were not feasible. For the parameters of the equipment used in the refill drinking water depots, it is as much as 92.75% meet the eligibility requirements and 5.40% are not feasible, while for the hygiene and sanitation conditions of the handlers, as much as 52.68% are eligible and 47.37% are not feasible.

Conclusion: Hygiene and sanitation requirements in the management of drinking water are very important to prevent the incidence of spreading diseases caused by water and sanitation. Hygiene and sanitation of drinking water refill depots will be able to control infectious diseases and can provide protection to consumers so as to ensure human safety and health.

Keywords: Hygiene, Sanitation, Management of Drinking Water, and Refill Depots

Introduction

Safe drinking water is a very basic need for human life.¹² Accessibility and availability of safe drinking water plays an important role in economic development and human health.³ Drinking water contamination is a serious threat that will cause problems for human life.⁴ Pollution of drinking water is mainly caused by microorganism, organic matter and disinfectants that affect the quality of drinking water and cause disruption to human health.⁵ Therefore, the availability of safe and health drinking water is a challenge faced by the world today.

Refill drinking water quality continues to be a concern as it relates to public health and when it is contaminated, it would be the media spread of infectious diseases that can cause death.⁶ Sanitary and hygienic drinking water is one of the prerequisites for improving the quality of drinking water produced and can provide health security and safety to consume.¹ However, the hygiene and sanitation of drinking water is still a problem that is overlooked. This condition contributes to the high diarrheal diseases listed in Kendari. The survey results in one of the health centers in Kendari city in 2013 that there were 2.915 cases of diarrhea and in 2015, it is recorded 529 cases of the diarrhea disease.⁷ Therefore, it is required periodic monitoring and improvement of drinking water quality management in order to improve public health. In Kendari city, drinking water distributed by several companies of refill drinking water depot and most of them apply hygiene and standard sanitation of drinking water for water safety before distributing to consumers.

Several previous studies have shown that the hygiene and sanitation of drinking water refill depot that is not managed properly can become a medium for
spreading and infectious diseases, as reported in Afrika,
Mali, Bangladesh, and some European countries. If the hygiene and sanitation of drinking water refill depot knowable, then counseling about drinking water sanitation and hygiene management can be approved to maintain the quality of safe drinking water produced.

Although several studies on hygiene and sanitation have been conducted in various countries, such as USA, UEA, Bangladesh, India, Malaysia, and some areas in Indonesia, hygiene sanitary evaluation of drinking water in Kendari, Indonesia still has not been widely publicized. The purpose of this study was to investigate hygiene and sanitation of drinking water refill depot in producing potable drinking water.

**Materials and Method**

This study is a descriptive study conducted to provide an overview of sanitary and hygienic refill drinking water depot with parameters of premises, equipment, and healthy life of refill drinking water depot handler. This research was conducted at several places in Kendari from March to August 2018. Year Determination of the number of samples is done randomly by the number of 32 samples of drinking water refill depots scattered in Kendari. The data collection used questionnaire as contained in the Minister of Health 492/Menkes/Per/IV/2010 concerning on the quality requirements of drinking water in Indonesia.

**Results**

1. Place Water Sanitation Hygiene Refill: Most of refill drinking water depot in Kendari, owned by an individual business with the service’s reach limited to the area around the place of business. Results observation sanitary hygienic refill drinking water are presented in the following table.

It is found that 2 depots of refill drinking waters’ roofs and ceilings are inadequate since the constructions are not strong, do not closed perfectly, the surfaces are uneven, dark in color, difficult to clean and allow rat to enter the processing room. However, all refill drinking water depots in Kendari already have several air vents. Nevertheless, only some refill drinking water depots meet the requirements, for instance, building sanitation and hygiene conditions include access to bathrooms and latrines, sewerage drains, closed trash cans, hand washing places equipped with running water, and buildings that are free of rats, flies and cockroaches (Table 1).

3. Hygiene Officer Water Refill: Results of this study found that the involvement of workers who assist the refill drinking water depot on average employ at least 2-3 people with an area of buildings used as places of business ranging from 5 m² to 70 m². Observation conducted on sanitary hygienic cleanliness handlers include uniforms, using of headgear, the use of aprons, and the use of muzzles to clean nails. It is also seen handlers behaviors such as hand washing, spitting, talking, eating and drinking, smoking, and scratching during work. The hygiene and sanitation observation result in table 3.

Health checks are necessary to prevent contamination of the drinking water produced when employees have a disease that can be transmitted through the air. Therefore, it needs necessary guidance through relevant agencies to increase awareness and knowledge officer of depot refill drinking water to improve the safety of drinking water produced, because even though the condition of sanitary hygienic premises and equipment are eligible
not necessarily produce drinking water that is safe to eat if the hygiene and sanitation handlers/operator do not meet the standards of drinking water management. This is because the handlers/operators are in direct contact with drinking water produced and could potentially be a source of contaminants.

Discussion

Assessment of the quality of drinking water is a great way to ensure the risk of spreading disease through air. This research conducted in Kendari city which aims to measure hygiene sanitation of drinking water produced with a focus on the observation of sanitary premises, equipment and operators. This study is an exploratory study that contributes to a portrait of hygiene and sanitation program undertaken management of refill drinking water depot in ensuring the quality of drinking water production. This is due to the spread of diseases, pathogens and other infectious diseases is largely determined by improving hygiene in sanitation and hygiene measures undertaken by the management of refill drinking water depot.

The findings of this study indicate that the sanitation hygiene of 32 refill drinking water depots in Kendari seems not ideal. This is because only around 66.33% meets the eligibility requirements, while 33.26% has not fulfilled the eligibility requirements. Management of a good place will reduce the risk of transmission of the disease, letting the place that is not hygienic will be a medium for disease spreading so that the water produced becomes unsafe for consumption and increases the risk of infection that can cause death. For hygiene sanitation of the place, the following components contribute to sanitation hygiene which are not massive, such as: (1) unavailability of bathroom and latrine access (2) no closed trash can, (3) no hand washing area equipped with water flow and soap, and (4) not free from rats, cockroaches and flies.

The safety of drinking water equipment is very important in supporting human health, since if the equipment used does not meet water health standards so that it can reduce health benefits for those who consume it. The quality of equipment used makes an important contribution to the quality of drinking water produced, because with equipment that meets the appropriate safety standards, it will guarantee the people who consume the drinking water produced. While the parameters of the handler/operator of drinking water management are 52.68% that fulfilled the requirements and 47.32% which did not meet the requirements.

Based on the data described above, it appears that supervision of drinking water sanitation hygiene towards refill drinking water depots must be carried out continuously and scheduled in order to reduce the amount of pollutants and can provide health benefits for the drinking water production by carrying out continuous and scheduled monitoring of refill drinking water depots which include places, tools and handlers/operators. It will reduce the rate of pathogen/pollutant release into drinking water, as well as minimize the spread of disease among consumers and improve the quality of drinking water so it is safe for consumption.

Assessing the Risk Factors for Diabetes Retinopathy Patients in Al-Nasiriya City, Iraq

Rawaa Kamel Abd¹, Vinoth Raman²

¹Department of Community Health Techniques, Kut Technical Institute, Middle Technical University, Baghdad, Iraq; ²Assistant Professor, Quality Measurement and Evaluation Department, Deanship of Quality and Academic Accreditation, Imam Abdulrahman Bin Fisal University, P.O. Box 1982, Dammam 31441, Saudi Arabia

ABSTRACT

Context: The World Health Organization estimates that by 2030, Iraq will have 2,009,000 new case of diabetes.

Aim: To assess the risk of diabetic retinopathy (DR) among diabetes patients in Al-Nasiriya city, Southern Iraq.

Methodology: A study of cases and controls was presented with a total of 220, of them 110 cases and 110 control. Patients with Diabetes mellitus (DM) attending follow-up check-ups regularly at diabetes and endocrinology center in Nasiriya city from the period March 1, 2018 to May 31, 2018 were considered as our study population. Chi-square tests is applied to analyze the association between visual impairment and risk factors, in addition multivariate logistic regression is used to explore odds ratio and 95% confidence interval for the association among visual impairment and risk factors. p<0.05, identified as statistically significant.

Results: Factors such as age, gender, educational level, BMI, family history, hypertension, treatment type and glycemic control which showed a significant association between cases and control on DR. The significant factors influencing DR were analyzed in multivariate logistic regression. We observed secondary education level, BMI, family history, treatment type and glycemic control occurred as significant independent risk factors for the incidence of DR.

Conclusion: Our analysis reflect the necessity of prevention of the identified risk factors, which appears in our findings. Our study endorsed that a population based study can be conducted in future to examine the risk factors in different parts of Iraq to provide accurate data on the cause of DR and predict the correct result.

Keywords: Association, Diabetics Mellitus, Diabetic Retinopathy, Risk Factors, Visual Impairment

Introduction

In 2035 worldwide it is estimated that 592 million of people with diabetics mellitus (DM) were observed under the age group 20-79.¹ The general pervasiveness of diabetes in Iraq was 21.8 for each 1000 in 2007. The World Health Organization (WHO) estimates that by 2030, Iraq will have 2,009,000 new case of diabetes. ² In 1999, WHO organized a vision 2020 program to reduce the preventable blindness globally by 2020 and discussed the cause and trends of visual impairment.³ By 2020 it has been estimated that the prevalence of visual impairment would be double, if the necessary actions to reduce about 80% reasons of preventable visual impairment are not taken.⁴ From late 1970’s, only very few literature revealed the incidence and prevalence of diabetic retinopathy (DR) in persons with DM.⁵

One of the major feared disabilities that a common person can suffer is visual impairment. Persons with DM observe DR and visual impairment as the most awful problem of diabetes, since they cannot achieve or
DM patients are at higher risk of developing ocular impairment which changes the retina and blindness that leads to an eye complication i.e. DR.[8] It’s a microvascular complications of DM influence the small blood vessels that connect eye’s veins to arteries, it occur secondary due to elevation of blood sugar and consider as the most important cause for impairment of vision and blindness in diabetes patients. Over one third of DM patients will develop some form of DR in their lifetime and the risk increase with duration and uncontrolled diabetes.[9,10] Management of DM should not only depended on reduction of blood glucose level but also should concentrate on monitoring and treatment of any associated risk factors such as hyperlipidemias, smoking, obesity and treatment hypertension. The prime motifs of diabetes treatment are identified as diet with exercise, oral hypoglycemic therapy and insulin treatment because the previous factors have an important role on the occurrence of DR.[11,12] Therefore, this research aim to assess the risk of DR among diabetes patients in Al-Nasiriya city, Southern Iraq.

Materials and Method

A study of cases and controls was presented with a total of 220, of them 110 cases (with eye diseases related to diabetes) and 110 control (without eye diseases related to diabetes). Patients with DM (Type 1 or Type 2) attending follow up check-ups regularly at diabetes and endocrinology center in Nasiriya city from the period of 1 March 2018 to 31 May 2018 were considered as our study population. Among the study population, those who suffered from DM with the age group of 35 years and above were included in this study. Besides, an ethical clearness and approval were taken from each patient prior to the commencement of the study.

Definition of DM: DM is a metabolic trouble characterized by entire (Type 1) or proportional (Type 2) insulin deficiency.[13] Type 1, DM is known as insulin-dependent DM or adolescent beginning diabetes. It represents around 5% of all cases of diabetes. Type 2, DM also named as non-insulin dependent DM or adult-onset diabetes is the most widely recognized type of DM, which accounts for 90% to 95% of every diabetic patient.[14]

Data Collection

A closed questionnaire method was investigated by the first author. We collected the information on socio-demographic (age, gender, education level) which is first part of data collection. Associated conditions of DR (smoking, Body mass index (BMI), diabetic type, family history, duration, hypertension, treatment type, glycemic control) constitutes the second part of data collection. BMI was measured as weight kg/height m². The patients were classified into subgroups according to WHO BMI measures as underweight (<18.5 kg/m²); normal weight (18.5-25 kg/m²) and overweight (25.00-29.99 kg/m²).[15]

Statistical Analysis: In this study, Chi-square tests is analyze the association between visual impairment and risk factors (age, gender, education, smoking, BMI, diabetic type, family history, duration, hypertension, treatment type and glycemic control). In addition, multivariate logistic regression analysis is used to explore odds ratio (OR) and 95% confidence interval (CI) among visual impairment (dependent variable) and risk factors. p<0.05 (two tailed), identified as statistically significant. All statistical tests were done using the software Statistical Package of Social Science (SPSS) IBM version 20.

Results

The results on descriptive characteristics of study sample and chi-square tests were reviewed and described as follows. With regard to age group, 41.8% of cases and 43.6% of control are observed between the age of 55-64 years. A significant association (p<0.05) was observed between cases and control with regard to age group. The gender wise distribution indicated that 46.4% of cases and 67.3% of control are males. The association between cases and control is found statistically significant with respect to gender (p<0.05). The Majority of study sample from control 60% are belonged to university group and 40% from case are illiterate. Furthermore, there is a significant association between education level and DR (p<0.05). In case of smoking status, no statistical association (p>0.05) is observed between cases and control. Besides, 61.8% of cases 67.3% of
control are observed non-smokers. When reviewing the results related to BMI, the majority of study cases group was observed as normal weight (53.6%) whereas the majority of control group observed as overweight (75.5%), a significant association between BMI and DR is observed (p<0.05).

Moreover, a significant association (p>0.05) is found between cases and control with respect to the type of diabetics and 91.2% cases and 85.5% control were presented under type 2 diabetic. With regard to family history of DR 73.6% of cases and 50.9% of control had family history of DR. There is a statistical significant association between cases and control (p<0.05). The duration of DR reveal that higher percentage of 57.3% cases and 51.8% control were found with above 10 years, while lower percentage was observed in patient having less than 5 years. However, the association between duration type and DR was found as non-significant (p>0.05). Oral intake of insulin as treatment was observed in 65.5% of cases and 85.5% control. Results showed that there is a statistically significant association between cases and control (p<0.05). Oral intake of insulin as treatment was observed in 65.5% of cases and 85.5% control. Results showed that there is a statistically significant association between cases and control (p<0.05). Older induction of insulin as treatment was observed in 65.5% of cases and 85.5% control. Results showed that there is a statistically significant association between cases and control (p<0.05).

Furthermore, the factors such as age, gender, educational level, BMI, family history, hypertension, treatment type and glycemic control which showed a statistically association between cases and control were analyzed to find out their statistical significant influence on DR using multivariate logistic regression model. The significant factors influencing DR were identified based on the values of odd ratio (OR), confidence interval (CI), Wald value and p-value in multivariate logistic regression model [Table 1]. Results showed that age group of 45-54 years (CI of 0.005-1.637) had 0.086 times of higher risk of prevalence evolving DR (Wald=2.664, p>0.05) when compared to other age groups, however all age groups showed non-significant. In education level, primary education showed 17.324 (CI of 3.264-69.436) times of higher risk of evolving DR (Wald=6.913, p>0.05), but only secondary education is found to be significant on evolving DR. BMI and Family history were identified as the main risk factor with (p<0.005), the OR showed a high risk value in multiple logistic regression. Treatment type and glycemic control seemed to be a statistically significant risk factor for the incidence of DR. The OR was very less with statistically significant. However, the gender showed no statistical significance on evolving DR (Wald=0.622, p>0.05) with OR=0.377 (CI of 0.033-4.261). Likewise, hypertension was not found to produce statistically significance on evolving DR (Wald=0.045, p>0.05). Therefore, secondary education level, BMI, family history, treatment type and glycemic control occurred as significant independent risk factors for the incidence of DR.

In this study the factors influencing the prevalence of DR such as age, gender, educational level, smoking, BMI, diabetic type, family history, duration, hypertension, treatment type and glycemic control were examined. In our study age, gender and hypertension were not found as significant risk factor for DR. Our study revealed that prevalence of DR tend to increase with increasing level of education (p<0.05). It is observed that the patients having secondary education are more likely to have retinopathy when compared to those who are illiterate and having primary education and these patients are also likely to be unemployed, thereby unable to afford the eye care service. The findings of our study is consistent with the results of previous studies.\textsuperscript{[16,17]} In our study, BMI showed a significant association with DR as underweight and normal weight are the main risk factors for DR. Likewise, several other studies have found an association between DR and BMI presence.\textsuperscript{[18,19]} Karter et al.\textsuperscript{[20]} identified in north California that the majority of population had a family history of DM. In our study, family history showed a statistically significant association with DR, this findings is consistent with the study by Le et al.\textsuperscript{[21]} Treatment type with oral and insulin showed a significant association with DR, which agreed with the results of El-Haddad and Saad.\textsuperscript{[22]} Our study showed that the 14.5% of control had the insulin injection, this result is in accord with the results of McCarty et al.\textsuperscript{[23]} A study by Katulanda et al.\textsuperscript{[24]} in Sri Lanka stated that the prolonged coverage of population with hyperglycemia as a risk factor for complications in DR. This could explain the significant association between glycemic control and DR observed in our present study, and the previous studies also highlighted the same association.\textsuperscript{[25,26]}

### Conclusion

Our analysis reflect the necessity of prevention of the identified risk factors, which appears in our findings as education level, BMI, family history, treatment type and glycemic control. Our results focused the growing urgency of DR prevention in the study area as well as the necessity for awareness. Our study endorsed that a population based study can be conducted in future to examine the risk factors in different parts of Iraq to provide accurate data on the cause of DR and predict the correct result.

The Principle of Lived Body Experience of Public Safety Center (PSC) 119 Officer in Conducting Integrated Emergency Response Systems in Malang, East Java, Indonesia

Retno Tri Astuti Ramadhana¹, Indah Winarni², Heni Dwi Windarwati²
¹Master Program of Nursing. ²Lecturer, Faculty of Medicine, Universitas Brawijaya

ABSTRACT

Background: The officer of PSC (Public Safety Center) 119 in Malang is spearheading of health services outside of hospital. PSC officer was expected to remain on duty well even though they are faced with problems related to educational background and infrastructure.

Objective: This study aimed to explore the sense of physical and psychological experiences (lived body) from PSC 119 officer in carrying out Integrated Emergency Response Systems in Malang.

Method: This study was qualitative research with an interpretive phenomenological approach and data analysis using IPA (Interpretative Phenomenological Analysis).

Results: Themes that found were based on lived body principle included grateful to be a member of PSC, love of working in helping others, and proud of being a member of the PSC.

Conclusion: The officer of PSC 119 Malang did not only work physically but also bring a positive emotional dimension in helping patients of pre-hospital emergency.

Keywords: Experience, PSC officer, SPGDT

Introduction

The government of Indonesia develops a program for the safety of community that known as Safe Community Program (SCP) in 2000. The aim of this program is to provide health care for people in the towns and villages(1). The kind of SCP implementation was application of Emergency Ambulance (EA) 118 that conducted in 18 cities, including Jakarta, Palembang, Yogyakarta, Surabaya, Makassar, Denpasar, and Malang(2). The implementation of EA only serves approximately 5 years. The obstacle of AE system included the lack of financial support from the government, the public would have to pay if they want to use the service and the increasing prevalence of infectious diseases, thus the government prioritize in this case(2).

Indonesia does not have an integrated pre-hospital service for 10 years, thus the government established the Regulation of Minister of Health number 19 in 2016 about Integrated Emergency Response Systems called as Sistem Penanggulangan Gawat Darurat Terpadu (SPGDT)(3). SPGDT implemented by establishing the National Command Center (NCC) in the Ministry of Health and Public Safety Center (PSC) in each district and town with call center number 119(4). The early establishment of PSC 119 service has been implemented in 27 locations across the island of Java(5).

Malang is the second largest city located in East Java, and being the largest city in Indonesia according to their population. Malang is also the second largest city in the southern part of Java island after Bandung(5). Malang has had PSC 119 since June 22, 2017 that consisted of 10 members. The result of interviews with PSC 119 officer Malang obtained three main phenomena. First, the PSC 119 members consisted of 2 health workers and 8 others are commoner. Second, the recruitment process of PSC 119 officer is not conducted in a series of tests. Third,
the officer of PSC 119 who has helped traffic accidents victims revealed the feelings of panic and fear in helping victims due to the lack of educational background and infrastructure.

The existence of human is consisted of four basic structures that known as “existentials”, they are lived space/spatiality, lived body/corporeality, lived time/temporality, and lived relationship/relationality. Existential help the human to develop as an approach to explore the experiences that experienced such as the human is exist in the world in terms of time, space, body, and relationships with other human beings. Lived body in phenomenology has the sense that the human being in the world physically and psychologically. Physical presence reveals something about us and unconsciously we always hide things at the same time(6).

Method

The methodology of this research used an interpretive phenomenological approach that developed by Heidegger (1962). This study was emphasized the deeper interpretation of relevant experience and not only described a person(7). The sample selection using purposive sampling based on inclusion criteria. There were five PSC 119 officers who met the criteria and were willing to be a participant. Data collection used in-depth interviews and data analysis used IPA (Interpretative Phenomenological Analysis)(8).

Findings

Data of study result analyzed by using IPA which consisted of six steps, they were reading and re-reading, initial noting, developing emergent themes, searching for connection a cross emergent themes, moving the next cases, and looking for patterns across cases(9). The analysis data result from five participants that related with lived body experience of the PSC 119 officer in implementing SPGDT in Malang obtained three themes, they were:

Grateful to be a member of PSC: Grateful according to Indonesian dictionary has the meaning of gratitude, giving thanks. Context grateful in this regard was the grateful of participant for the work they had. This theme was made up of three sub-themes, they were self-gratitude, thankful for the work situation, and gain the trust of co-workers.

The first sub-theme was self-gratitude, it was expressed by participants in the statement:
“... I’m so grateful to be one of the member of PSC...” (P1)
“... I’m very happy all the time (elected to be the member of PSC) and I’m so glad of all because I don’t want to lie to my conscience that I’m a social person. I like working in social field ...” (P3)

The second sub-theme that was thankful for the work situation. It expressed by participants such as:
“... I feel this is my place (PSC) because I’m easily to feel bored. The point is I get easily bored and don’t get tied. That means, if the work is monotonous, I get bored quickly. When passing the first month to the second months I feel PSC is my place...” (P4)

The third sub-theme gained the trust co-workers. The following was the statement of participant:
“... Department of Health may have already known our performance in the field. Our speed in the field, how to help people...” (P5)

“... yes I’m so grateful, but also we don’t know about the assessment of leader on our services. But why do they directly elect us? because the assessment of Department of Health against our handling in the field, both reports and also our courtesy, attentiveness to the patient or the patient or his family ...” (P2)

Love of working in helping others: Love of working in helping others according to Indonesian dictionary meant using compassion to help the others. This theme emerged from the two sub-themes such as working in the PSC was a call of the heart and feel comfortable working in the PSC.

The first sub-theme was working in the PSC was a call of heart. Statements of the participants were:
“... I want to channel the potential of my social soul, I fixed in this PSC...” (P1)
“... this is where my social work from birth, it may be appear in social environment, including my Father also embed social towards other human beings ...” (P3)
The second sub-theme that was comfortable working in PSC. This was expressed by the participants in the statement:

“... actually I didn’t have thought about to be here in PSC 119, I join this organization from my heart. I was only a volunteer, joined because I like social activities... I have an experience on dealing with the ambulance. There, my heart was touched and I join as volunteer of PSC 119 Malang... “(P1)

**Proud of being a member of PSC:** Proud according to Indonesian dictionary was having a great hearts, feel manly (because they had the advantage). This theme had two sub-themes, namely satisfied with themselves as an officer of the PSC and feel needed by others.

The first sub-theme was satisfied with themselves as an officer of PSC. This expressed by the following statement:

“... I want to help the others... the main point I wanted to help people, I want to help people no matter what happens to me. I tried to save, I tried to help and share to others ... “(P1)

“... If I become the helper, I will be happy even though I can’t give (material) at least I could give a solution ...” (P4)

The second sub-theme was feeling needed by others. Statement of the participants were:

“... I am feeling quite pleased and very happy when we can help who need us, even though in the morning hours or night we got calling, we should serve with full of responsibility...” (P1)

**Discussion**

Grateful to be a member of PSC contextually meant that participants felt grateful for their work achievement. In this study, grateful was self-gratitude, thankful for the employment situation, and thankful for gaining the trust of co-workers. Two researchs mentioned that thanks consisted of two stages: happiness feeling perceived by individual and happiness that connected to an external source. This was supported by other research that mentioned that gratitude was feeling happy to do what they received. Fourth this research had several similar aspects related to gratitude that associated with internal and external aspects. Gratitude meant the perceived happiness of individuals and this was an internal aspect. Gratitude that was connected to the external factors in this research was thankful to the work situation and gaining the trust of co-workers.

Behavior of gratitude shown by the PSC officer was by saying *hamdalah* for favors to be one member of the PSC, was chosen because that had ability, and got a sense of co-workers over working conditions in two places. This was supported by research that the most important behavior of grateful was grateful through say *hamdalah*. Moreover, the behavior thankful it went through the hearts and deeds. Thankful through the heart of each event was realized with the meaning of life and grateful by works diligently to practice their religion. Participants in this study also shown grateful behavior through heart and action that indicated by participants felt proud to be a PSC officer, become a better person, and improved themselves by learning about life after joining PSC 119 Malang. Grateful behavior through actions indicated by the behavior of participants to consider a job in the PSC was not boring, familiar with the work at the PSC, and entrusted to carry out the mandate in the PSC.

Love working in helping others contextually meant that duty as the member of PSC come from their heart. Love, in this study was love to help others by working in the PSC was a call of heart and feeling comfortable working in the PSC. Love was an attitude that consisted of feelings, cognition, and behavior that focuses on caring, concern, tenderness, willingness to help and understand others. Both studies had the same thing related concept of love that begins from feeling, cognition, and behavior. PSC officer loves the work he had started with their inner calling to help people in need. Furthermore, PSC officer think that working in the PSC is the right place to channel social life. PSC officer who have loved his job it will be reflected in the form of behavior that is using compassion when dealing with victims and serve on the PSC to help others.

The experience of loving others is a powerful reason to provide assistance to foreigners and people nearby. This love compassion for others allow individuals leads to prosocial behavior. The motivation to help others is divided into internal motivation is influenced by the value of the inwardly and externally influenced by external factors such as fear of punishment and the desire to get a prize. Internal motivation is associated with positive outcomes such as persistent in work, have an
interest in doing the job, and achievement of the general welfare. This study shows that the internal motivation that comes from the heart of Malang 119 PSC officers more prominent than external motivation. If a larger internal motivation to help others then it is associated with higher life satisfaction, positive effect on his life, and high self-esteem. It is also perceived by PSC 119 officer Malang.

Proud to be a member of PSC contextually means that the participants felt to have advantages over others that participants have a job in PSC 119 Malang. In this study, feel proud is satisfied with himself as an officer of the PSC and feel needed by others. Feeling proud to be elected as an officer of PSC is human nature. This is in accordance with the Theory of the Hierarchy of Needs by Maslow (1954), which states that if the physiological needs, security, and love have been met, then people need recognition (esteem needs) of others. Humans need stability, assertiveness, self-esteem high level, and the respect of others. When these needs are met, then someone feels confident and valuable as a person in the world.

Pride and respect for the work of self-consciousness that make up a person would devote all his attention to itself than any other person, object or event. Pride will increase the confidence of someone and make someone realize that her behavior is very useful for others. This is consistent with research that says that participants felt proud of his work as being needed by others. Someone has a sense of pride when they can thrive in the job. An agency that provides a satisfying work environment and supporting its employees will create satisfaction and make someone loves and is proud of his work.

Research showed that reputation from outsiders is a source for creating a sense of pride in the work. This is consistent with Social Identity Theory (SIT) that the views of external parties associated with the pride of staff within an institution and it is the same with job satisfaction. SIT by Tajfel and Turner (1979) states that individual would categorize themselves according to their interests or something. In addition to self-categorization, individuals evaluate groups that they consider to be a part and the group that they do not consider to be a member. An individual constantly categorize themselves by evaluating groups inside and outside and then comparing that value exists. The self-concept consisting of a social category, the evaluation group, and group membership value is the individual’s social identity. The positive social identity rewarded with positive self-esteem. This study showed that participants already categorization against themselves that as an officer of PSC 119 Malang.

Conclusion

According to lived body of four phenomenology principal on the experience of PSC 119 officers in implementing SPGDT in Malang City, East Java, Indonesia obtained the theme of being grateful to be a member of PSC, love of working in helping others, and proud of being a member of PSC. The three themes emerged as a form of psychological dimensions of PSC 119 officers. Another reason was that there was only one 119 PSC in Malang that provided pre-hospital emergency services.

ABSTRACT

Cigarettes are objects that contain more than 4,000 toxic substances and are very healthful for those who consume them actively and those who are exposed to smoke generated from smoking activities. The highest prevalence of smokers every day released by Riskesdas in 2013 was found in workers as farmers/fishermen/laborers at 44.5%. This study aims to explore smoking behavior in fishermen in Kodingareng Island, Sangkarrang Islands District, Makassar City. The method used is qualitative Phenomenology approach to explore smoking behavior on fishermen on Kodingareng Island. Data is collected from August 2018 to February of 2019 in an independent interview. The selection of informants used a Purposive Sampling Technique consisting of 10 fishermen 3 smokers, 3 community leaders and 1 Puskesmas officer. Data analysis with Content Analysis.

The results of the study revealed that in general fishermen did not know the ingredients and content of cigarettes, they only felt pleasure from consuming cigarettes, but there were also those who knew that they were limited to the appearance of reading on cigarette packs. Fishermen think that smoking behavior is not a problem when smokers themselves are able to find good money, a work culture that conditions them to smoke even as a child makes their attitude of thinking that smoking is common on Kodingareng Island. Smoking habits of fishermen based on smoking time, smoking function and intensity of smoking. Conclusion The smoking behavior of fishermen is different from smoking behavior in the general population, so a special approach is needed to control smoking behavior.

Keywords: Smoking Behavior, Fishermen, Kodingareng Island.

Introduction

Cigarettes are one of the addictive substances that can be bad if consumed. The effects of tobacco use or consuming cigarettes, not only on health but also on the economy. Studies conducted in America found that a smoker will incur higher costs than non-smokers, in the form of health care costs and death costs from smoking1.

More than 80% of the 1.3 billion smokers worldwide live in low and middle income countries2. Indonesia still ranks third which has the highest number of active smokers after China and India2,4, and ranks first for most male smokers from 22 countries at 67%3. The highest prevalence of smokers every day released by Riskesdas was found in workers as farmers/fishermen/laborers at 44.5%4.

The initial survey conducted on Kodingareng Island showed there were 1179 people who were fishermen, 844 fishermen were smokers, namely 19.65% and 63% passive smokers, of which 36.98% were all male sex. The high rate of passive smoking in the Island causes high rates of hypertension and ARI each year5.

Smoking behavior is caused by several factors including; lack of knowledge, cigarette advertisements,
the influence of parents who smoke, lack of parental control over children, the existence of norms or values in society and the influence of peers. Whereas a research found that causes a person to be affected to become a smoker, namely occupation, marital status, education level, location of residence, condition of residence, age and level of income.

Based on the background above, the researchers were interested in exploring smoking behavior in fishermen on Kodingareng Island.

**Material and Method**

This study used a qualitative research method with a phenomenological approach to explore smoking behavior in fishermen on Kodingareng Island, Sangkarrang Islands District, Makassar City. Data is collected for 6 months, starting in August 2018 to February of 2019 in an Independent Interview. The taking of informants used the Purposive Sampling Technique which consisted of 10 fishermen 3 family smokers, 3 community leaders and 1 Puskesmas officer. Data analysis with Content Analysis and data validity using Triangulasi Source.

**Findings**

**Knowledge:** The results of in-depth interviews with fishermen regarding their knowledge of cigarettes, varied answers were obtained.

**Knowledge of Materials and Substances in Cigarettes:** Some informants did not know the ingredients and contents of cigarettes. The informant only consumes cigarettes because of the pleasure of taste and has become his habit.

“If that is not so learned that we feel just pleasure, this is just smoking habit”.

Apart from taste pleasure, informants felt negative effects on health (such as coughing) if they consumed cigarettes without being balanced with adequate drinking.

“That’s all if we don’t drink coughing.”

Informants know the ingredients and content of cigarettes (e.g. tar and nicotine) as limited as the appearance read on cigarette packs without knowing the effects.

“What we know is what we read in the packaging, nicotine with tar but we don’t know what is nicotine and tar”.

**Knowledge about Hazard of Cigarette for Health:** Informants do not know the dangers of smoking, so it does not affect smoking behavior. Informants get information only through warning pictures of the dangers of smoking on cigarette packs, which cause fear. But that doesn’t have an effect, because there is no evidence or negative effect on the health it feels.

“Not afraid to see pictures of cigarette wrappers’’.

“The warning is not obscure, it is horrifying but there is no proof”.

Informants know the dangers of cigarettes but do not affect smoking behavior. The dangers of smoking are known to include sore throats with coughing complications, leading to cancer.

“You know, smoking often hurts the throat, especially the usual coughing’’.

“Bringing cancer”.

Informants know the dangers of smoking and influence smoking behavior. The impact of smoking affects the intensity of consuming cigarettes. The more symptoms that are felt (e.g. coughing), the lower the intensity of smoking.

“That was before I said, but I wasn’t too active if smoking didn’t have any impact, but sometimes there was also a cough when I coughed and stopped again”.

**Attitude**

**Attitude of Seeing People Smoking Around Many People:** Not knowing and not aware of the dangers of cigarettes because there is no concrete evidence of smoking-related diseases witnessed directly by informants.

“It’s not normal, but I don’t know that because I haven’t seen it with my own eyes”.

Fully aware of the dangers of cigarettes that can interfere with the health of children for example resulting in coughing

“Danger, because cigarette smoke is very dangerous for small children”.

**Attitude of Seeing Small Children Smoking:** Some informants do not allow children to smoke due to the dangers of smoking for health. The heart of a healthy
child must be protected from exposure to cigarettes, because young children are considered not yet able to regulate their breath properly, so that cigarette smoke can enter and blast the heart.

“Little children should never smoke, they are still small, their hearts are still healthy, this is still small, suction goes into the heart, you don’t know what to do”.

In addition, informants consider children and adults not a measure to limit smoking behavior, as long as they are able to make their own money to buy cigarettes.

“If money seekers are not papaji, if they don’t look for money, how about when they run out of cigarettes, don’t let them think about anything else.”

The informant considered the coastal communities primarily parents who work as fishermen to have a work culture that conditions them to smoke even as a child.

“Here, there are still small children who smoke teachings from the parents of fishermen if there are also small fishermen.”

**Smoking Attitudes in the Home:** Informants allow smoking in the house, because smoking is considered normal, and is not a cause of disease. For example the example of lung disease, where the disease is not only suffered by smokers, but also by non-smokers.

“If I don’t ji, I don’t get sick because there are also people who don’t smoke on X-rays because of lung disease, smoking is also there, that means cigarettes are just like that, don’t make people sick because I have experienced so much, no Broken smoking is also the same as the lungs are smoking “.

**Smoking Habit:** From the results of in-depth interviews, informants’ smoking habits can be grouped based on smoking time, cigarette function and the intensity of smoking. Based on smoking time, informants consume cigarettes after eating, drinking coffee, staying up late, playing cellphones and hanging out. Informants smoke at these times to increase the taste pleasure from previous activities.

“It depends on the smell, but if you eat less, if you don’t eat, you have to drink coffee, days”.

When feeling dizzy and a lot of thoughts, informants consume cigarettes to reduce negative feelings.

“After eating, I’m confused about smoking”.

Smoking habits based on cigarette function, informants consume cigarettes to relieve cold and refresh the body after diving.

“We will dive, if the sailor uses our lifeboat to dive, so if you dive in cold, that’s the advantage of smoking fresh when you finish diving, it doesn’t feel cold anymore”.

In addition to eliminating the cold when in the sea, cigarettes also function to relieve sleepiness while at sea.

“Get used to if you go 2 to 3 fishing nights a day so that I’m not sleepy if smoking”.

Smoking habits based on the intensity of smoking, more when in the sea, which is as much as two packs, compared to when on land informants only consume less than one packet.

“There are more in the sea because if I go, usually two packs I carry for one day, on one land do not run out”.

**Discussion**

Knowledge is the result of knowing someone through their senses through vision, hearing, smell and so on. In general, fishermen only know the ingredients and content of cigarettes according to what they feel and what they read in cigarette packs. On the cigarette pack is a warning about the dangers of cigarettes and their contents. However, there is no deeper explanation about the effects of substances on health.

Consuming cigarettes, giving pleasure to smokers. Nicotine is addictive which can make someone who consumes it addicted. When nicotine enters the body, smokers will feel pleasure. The result is smokers will feel calmer, more brilliant thinking power, and able to suppress hunger. Psychological satisfaction contributes very highly to smoking behavior, which is 40.9%. This illustrates that smoking behavior is considered to provide pleasure and pleasure. Cigarettes are believed to be able to bring effects on positive emotions that affect the psychology of smokers who feel pleasure due to smoking.

Viewed from any angle, cigarettes still have a negative effect. Eating cigarettes has a negative effect on health. Nevertheless, fishermen still consume cigarettes, because
for them, nothing they see directly affects them so they don’t smoke anymore. The negative effects that are felt in the form of coughing are a disease that is easily eliminated and is not considered dangerous so they continue to enjoy cigarettes. Knowledge of substances, cigarette ingredients and the danger of consuming cigarettes for health that is still minimal in fishermen causes them to maintain their smoking behavior. This study is in line with the results of a study said that a smoker who has a good knowledge of the health hazards of smoking has a positive attitude to refuse to become a smoker\textsuperscript{16,17}.

The attitude of fishermen in general considers smoking behavior is a natural thing, but smoking behavior to children for them is not a problem as long as the child is able to make their own money. Children who do not smoke are considered as lazy children because there is no reason to encourage them to work. Another case for children who smoke will try to work to find cigarette money. In addition, the work environment that makes children have to smoke causes them to assume that smoking is a natural thing, even though there are a small number of fishermen who consider smoking behavior in children inappropriate, because the child’s heart and lungs are still considered too weak and dangerous for his health. The negative attitude shown by the fishermen is supported by the results of a research stating that there is a significant relationship between attitudes and smoking behavior\textsuperscript{18}. In line with another research which states that there is a relationship between the attitude and smoking practices\textsuperscript{19}.

Cigarette fishermen are friends when at sea. The smoking habit of fishermen is based on smoking time, cigarette function and smoking intensity, namely the number of cigarettes consumed per day. The smoking times of fishermen such as after eating, drinking coffee, staying up late, and fishing. Smoking habits based on the function of cigarettes are to reduce sleepiness, and cold when in the sea, and to eliminate dizziness or stress. Various psychological factors that influence a person to become a smoker are the presence of pleasure, relaxation and can reduce stress\textsuperscript{20}. Women in Hong Kong despite knowing the health hazards caused by smoking, they continue to consume it because smoking is used as a strategy to reduce stress and other negative emotions\textsuperscript{14}.

Based on Management of Affect theory, smoking behavior can divide into four types: the type of smoker who is affected by positive feelings, where a smoker consumes cigarettes to increase his positive feelings such as feeling happy and so on. Addictive smoking behavior. This type of smoker is caused by a heavy addiction so that smokers want to add to the dose of cigarettes every time the effect of the previous cigarette consumed starts to decrease. And smoking behavior that has become a habit. The purpose of smoking in this type is not to increase the dose, get positive feelings or eliminate negative feelings but smoke because it has become a habit\textsuperscript{21}.

**Conclusion**

1. Knowledge of fishermen is minimal about the ingredients and content of cigarettes and the danger to the body, they only know the extent of the appearance of cigarette packaging and the experience they have felt.

2. The attitude of fishermen considers smoking behavior is a natural thing both for children and adults.

3. Smoking habits based on smoking times (after eating, drinking coffee, eating and fishing/fishing), based on the function of cigarettes (to relieve cold, eliminate drowsiness and stress), and based on the intensity of cigarettes.

**Suggestion**

An effort to control smoking behavior is needed in fishing communities by taking into account the characteristics of the region, their environmental conditions and culture.

The Role of MgO and CaO Nano-Particles on Staphylococcus Epidermidis Isolated from Catheter Indwelling Patients

Rita N. N. Rammo
Department of Biology, College of Science, Kirkuk University, Kirkuk, Iraq

ABSTRACT

The role of nano-particle metal oxides MgO and CaO as inhibitors to bacterial growth has been evaluated. The bacterial samples collected from catheters at a number of medical centers are diagnosed by culturing and biochemical tests to yield 18 isolates of S. epidermidis. Identification and particle size of the received MgO NPs, and CaO NPs are analyzed by X-ray diffraction. These are then examined for their antibacterial activity against S. epidermidis by the agar diffusion method, biofilm inhibition and minimum inhibitory/bactericidal concentration (MIC/MBC). The outcomes of the inhibition zone show that both MgO NPs and CaO NPs spread similar zone activity of (25 mm ± 2 mm) at 10 µg/ml concentration. For the biofilm inhibition, MgO NPs had (82 %), and CaO NPs had (76 %) at 10 µg/ml indicating good inhibition to biofilm formation. The test of MIC/MBC showed that MgO NPs are more efficient at lower concentration (1.25 µg/ml) in comparison with CaO NPs (2.5 µg/ml). Above these concentrations, complete inhibition of S. epidermidis is observed as an indication of the efficacy of these inorganic nano-particles in suppressing the growth of bacterial invasion.

Keywords: Staphylococcus epidermidis, Nano metal oxide, Catheter, Antibiofilm.

Introduction

Inorganic nano-particle compounds have drawn much research interest by their unique characteristics at the macromolecular, molecular and atomic levels as reducers of microbial infections 1. Some of the metal oxides compounds, such as MgO and CaO nano-particles (NPs) are considered as bacterial inhibition agents and as safe materials to humans 2. Many biologists have increasingly focused their attention on these materials for being as effective inhibitors of resisting pathogenic strain 3.

The mechanism of antibacterial activity of NPs can be interpreted by interacting with bacterial surface and then entering inside the cell, which eventually led to its destruction. Occasionally, these materials can have bactericidal impacts that are essential in different antimicrobial applications 4. The small size or large surface area of NPs had high active contact with the microbial cells raising the penetration and interaction through the cell membrane promoting their antimicrobial activity 5.

As being antimicrobial agents, the effectiveness of NPs has been tested for their ability to restrain bacterial colonization on different surface devices, like catheters 6. Chronic infections caused by pathogenic bacteria are difficult to treat because of their ability to destroy host tissue causing resistance to antibiotics 7. Therefore, strategies have recently been implemented in the next-generation of agents or drugs to restrain bacterial infections from inorganic or natural substances, safe to human beings as having relatively less toxic and endocrine disruptive effect 8. S. epidermidis infections caused by the use of medical devices (catheters), can be colonized by micro-organisms that form an adherent biofilm on the surface of the device 9, and is the most common concerns of the line associated bacteremia and other polymer-related infections among UTI patients 10, 11. Catheter encrustation and blockage are reported as a common complication in the care of patients undergoing long-term indwelling bladder catheterization 12, 13.

Few studies have been carried out to assess the efficacy of MgO and CaO NPs against virulence factors of S. epidermidis in vitro. Therefore, for UTI patients, this study aims to evaluate the role of MgO and CaO NPs as antibacterial active agents towards S. epidermidis isolated from indwelling catheters.
Materials and Method

Collection of specimens and Growth Conditions: Eighteen specimens of S. epidermidis in this study were isolated from the surfaces of infected intravenous catheters taken from both sexes. We enrolled patients aged 20-70 years visiting hospitals in Baghdad and Kirkuk city for six months through 2017-2018. Strain diagnosis was verified by biochemical characterization tests 14,15.

Bacterial growth samples were transferred via sterile loop into nutrient broth media and were incubated at 37 ºC for 24 h. Then 0.1 ml of each sample was transferred into sterilized test tubes containing 0.9% NaCl solution.

Identification and Preparation of NPs dilutions: White powders of MgO NPs with purity 99.5% and CaO NPs with purity 99.95% were obtained from the Nanografi Nanotechnology (Turkey). For confirmation, material identity and particle size measurement of the powders were analyzed by X-Ray diffraction (XRD) techniques.

In 10 ml of dimethyl sulfoxide (DMSO), about 10 mg of each powder was suspended to prepare a stock solution of 1 mg/ml. Lastly, we again diluted 1 ml of the solution by 10 ml of DMSO that yield a solution of (100 µg/ml) concentration for the next steps.

Antimicrobial activity of MgO and CaO NPs: The antimicrobial activity of MgO and CaO NPs vs the isolates of S. epidermidis was calculated using the agar diffusion method as follows:

Hollow wells were cut into the solidified nutrient agar (NA) in Petri dish plates by cork borer of ~ 5 mm diameter and used to test all bacterial isolates. 0.1 ml of MgO NPs or CaO NPs suspended in (DMSO) taken from various concentrations namely 2, 4, 6, 8 and 10 µg/ml were put to these wells. The plates were incubated at 5-8 ºC for 2 - 4 h to achieve good diffusion and then incubated at 37 ºC for 24 h. Then, the inhibition zone diameter (mm) formed around the wells was calculated and compared with the activity of (DMSO) alone without MgO NPs or CaO NPs which showed no impact on these bacteria 16,17.

Microtiterplate Assay: Biofilm production was obtained using a microtiter plate assay as previously described 19. Briefly, S. epidermidis were incubated overnight in 10 ml of Tryptic Soy Broth (TSB) and 0.25% glucose at 37 ºC with continuous shaking.

After that, the cultures were diluted 1:100 and 200 µl of this dilution was transferred to each well in the plate and subsequently inoculated aerobically for 24 h at 37 ºC. The culture was washed three times using 200 µl of phosphate buffer saline (pH= 7.4) to eliminate nonadherent cells, and then, dried in an inverted position. Adherent bacteria were fixed with 95% ethanol and stained with 1% (Wt/Vol) crystal violet for 10 min. Excess of unbound crystal violet was removed by gentle washing three times with of sterile distilled water. After clearing the water, the microtiter plate was air dried for 2h. The optical density (OD) at 590 nm was measured, and a mean value was calculated from three replicates. Finally, this value was considered to be (adherence positive) at ≥ 0.12, (adherence negative) < 0.12.

Biofilm inhibition: Biofilm inhibition was carried out in microtiter plate assay adopting the method of biofilm formation 19,20. Different dilutions of NPs were added to the wells containing cell suspension of the prepared isolates, and the procedure was continued as described already with the same concentrations of MgO and CaO NPs sited earlier. Percentage of inhibition was calculated according to the following formula 20:

\[ \% \text{ of inhibition} = \frac{\text{OD in control} - \text{OD in treatment}}{\text{OD in control}} \]  

Minimum inhibitory/bactericidal Concentrations: The minimum inhibitory concentrations (MIC) were analyzed in MgO, and CaO NPs toward S. epidermidis isolates according to 21 by the following steps: 1) We put 1 ml of medium (i.e.nutrient broth) in a test tube. 2) 1 ml of test solution was added to it. 3) 0.1 ml of bacterial isolates that prepared in 0.9% of NaCl were inserted to the test tube consisting of test and media solution.

For each NPs, five serial dilutions of 10, 5, 2.5, 1.25 and 0.625 µg/ml were performed followed by incubation at 37 ºC for 24 h. The positive occurrence of turbidity was compared with a sample of 0.5 McFarland standards. At the same dilutions, the control test was included as broth samples inoculated with DMSO only which had no impact on the bacterial growth.

Also, we obtained the minimum bactericidal concentration (MBC) by sub-culturing 50 µg/ml to each test group which revealed that no evident growth
occurred. Thereby, for no growth, this concentration would be deemed as MBC. Statistical information was conducted by analysis of variance (ANOVA) and T-test at significance P values below 0.05.

Results and Discussion

X-ray Diffraction: Figure 1 illustrates the X-ray diffractograms of MgO and CaO NPs taken with Cu Kα radiation. The indexed peaks match with the PDF2 - ICDD files for MgO and CaO. Particle size was analyzed by Scherrer’s method to give a nano-size of 18 nm for MgO and 45 nm for CaO.

![Caption (M) and Caption (C)](Figure 1: X-ray diffractograms of (a) MgO NPs and (b) CaO NPs)

Bacterial Growth Diffusion: Isolates from indwelling catheter-related bacteriuria grown by the agar diffusion test are indicated by the illustrations shown in Figure 2, regarding the inhibition zone manifested by the effect of MgO and CaO NPs. The antibacterial activity of these nano-particles is probably to be related to exhibiting smaller particle size in comparison to bacterial cells thus facilitating adherence to its cell walls leading to their destruction and death.

![Caption (M) and Caption (C)](Figure 2: Inhibition of S. epidermidis growth in agar diffusion test by 10 µg/ml concentration of MgO NPs and CaO NPs)

Measurements of the inhibition zone for S. epidermidis growth against different concentrations of MgO and CaO NPs are given in Table 1. It is noted that the total biomass of S. epidermidis was decreasing in the setup concentrations of nanoparticles studied compared to control (without NPs), and MgO NPs had higher diffusional activity (27 mm zone diameter) in comparison to CaO NPs (23 mm zone diameter) at the same concentration of 10 µg/ml. The role of nanoparticles as antimicrobial active agents can be understood by their chemotherapeutic nature to control and reduce infections and can be employed in bacterial infections treatment.

Biofilm Inhibition Percentage: Biofilm formation of S. epidermidis was studied by overnight grown culture in 96- wells of a polystyrene microtiter plate. Adherent biofilm is then determined by the occurrence of dark staining material on the wells’ bottoms. The manner in which the antibiofilm effect is noted may be explained as dose-dependent. The inhibition of biofilm in the microtiter plates has shown the formation of S. epidermidis biofilm to decrease with the concentration of nano-particles manifested by the measured optical density shown in Figure 3. The calculated inhibition percentages (%) of biofilm due to the efficacy of nanoparticles are tabulated in Table 2.

As listed in Table 2, MgO NPs recorded a slightly better antibiofilm effect in comparison with CaO NPs for all concentrations. Moreover, both NPs show a significant decrease in the formation of biofilm due to the presence of MgO NPs (82%) and CaO NPs (76%) at (10 µg/ml) concentration. Similar behavior is observed with Ag NPs in the biofilm inhibition of *Escherichia coli* and *Pseudomonas aeruginosa*.

The results of MIC (Table 3) show that *S. epidermidis* is inhibited at concentration 1.25 µg/ml for MgO NPs and 2.5µg/ml for CaONPs. MBC has also demonstrated similar behavior for both NPs, and these results indicate that cells treated with 2.5µg/ml of MgO NPs and 5.0µg/ml of CaO NPs were no longer culturable suggesting their lethality on bacterial pathogen common in catheter-acquired infections.

The better antibacterial activity of MgO NPs may be due to its smaller particle size compared with CaO NPs. Their antibacterial activity is a consequence of the potency to insinuate the walls of the bacterial cell and lead damage to its cytoplasm. The MIC value of CaO NPs studied by Roy et al. on *S. epidermidis* is found to be 2mM which is comparable to what has been found in this study an indication that the route of producing these nanoparticles had no significant effect on antimicrobial activity especially regarding dose concentration.

Similar behavior to these results has been observed by Kadhum in studying the effect of nanoparticles of ZnO and SiO2 on various kinds of bacterial growth including *S. epidermidis*. Interpretation of antibacterial activity of MgO and CaO NPs reported from several citations rely on the generation of active oxygen as having a primary role, in addition, to increase in pH of the medium as another influencing factor. The overall picture of the use of inorganic nanoparticles as a counterpart of adherence suggests their usefulness in influencing bacterial suppression by a mechanism that causes the bacteria to coagulate by the break of the microbial cell membrane in nanoparticle suspension.

**Conclusion**

The antibacterial role of MgO and CaO nanoparticles as active agents towards *S. epidermidis* is evaluated. The in vitro incorporation of these nano-particles against the growth of *S. epidermidis* has provided robust scientific evidence that they are effective antimicrobial agents and that eventually inhibit bacterial adhesion and biofilm formation.

Lactobacillus Casei Strain Shirota: Overview of Blood Sugar Levels and Blood Fat from Children Obesity and Fatting

Rudy Hartono¹, Aswita Amir¹, Adriani Adam², Agustian Ipa¹, Rusli³, Sudirman Katu⁴

¹Department of Nutrition, Makassar of Health Polytechnic, Indonesia, ²Department of Nutrition, Mamuju of Health Polytechnic, Indonesia, ³Department of Pharmacy, Makassar of Health Polytechnic, Indonesia, ⁴Internist, Central of Public Hospital Wahidin Sudiro Husodo, Makassar, Indonesia

ABSTRACT

Some survey results show that the prevalence of obese and fatty children is increasing rapidly both in the world and in Indonesia. Impacts that can occur for obese and fatty children in the future are degenerative diseases and decreased productivity. Probiotics are natural microorganisms found in the digestive system, which are deliberately bred as food/beverage supplements which if consumed in balanced amounts will have a positive impact on health. One good probiotic for health is Lactobacillus cassee strain Shirota is a type of bacteria that is resistant to the reaction of stomach acid, and has many important roles in the human body in the intestine, and its important role is to help digestion. The purpose of this study was to prove the effect of supplementation of L. casei strain Shirota on the profile of blood sugar, total cholesterol, triglycerides, LDL, and HDL in obese and fatty children. Type of experimental research with pre-post test only design. Samples are children aged 6-12 years, obese and fatty, cooperative. The results showed that there was a significant effect of L. casei strain Shirota supplementation on total cholesterol (p = 0.005), but not significantly on when blood sugar, triglycerides, LDL and HDL (p> 0.05). Conclusion there was an decrease in total cholesterol levels after L. casei supplementation. Similarly, there was no significant increase in when blood sugar, decrease triglycerides, decrease LDL and decrease HDL levels. Suggestion L. casei needs to be given to obese and fatty children every day to improve digestion and reduce total cholesterol levels.

Keywords: Lactobacillus casei, blood sugar, cholesterol, triglycerides, LDL and HDL

Introduction

The rate of obesity in children in Indonesia has tripled, according to a global study released in the New England Journal of Medicine. They have the potential to suffer from various types of diseases as adults, including diabetes, heart disease and cancer. Based on the 2016 National Health Indicator Survey data, as many as 20.7% of Indonesia’s adult population are overweight. This number increased from 15.4% in 2013¹,²,³,⁴. The Global Burden of Diseases study published in the scientific journal, Lancet, in 2014 placed Indonesia at number 10 in the list of countries with the highest obesity rates in the world. The rate of obesity in children grows much faster than adults⁵,⁶,⁷.

Some research findings have found evidence that obesity has an important role in cases of death in as many as four million cases in 2015. This has a greater global problem. This study proves that there is no country in the world that has succeeded in reducing the number of people with obesity, even though the economic losses caused are not small. Ironically, obesity cases are also increasing in countries that are threatened by food insecurity such as in Africa⁸,⁹. According to the study, Burkina Faso is the country that records the highest obesity growth in the world. While Egypt has the highest number of adult obesity sufferers.

The rate of obesity among children in Indonesia shows a sharp increase. The indication is an improvement in the family’s economic conditions which causes easy access...
to various forms of food. However, there are external factors that also influence it. Some cases indicate that some children were asked by their mothers to play with their friends outside the home\textsuperscript{10,11}. Moreover, after school, children of the same age are busy doing activities around the housing complex. But, the child prefers to be at home, spending time with his electronic game device. According to the mother, the child does not tend to be picky when eating, or enjoy whatever food is available. But on the other hand, he doesn’t have much physical activity\textsuperscript{12}.

His parents’ encouragement to take part in extracurricular activities in schools that burn calories, such as taekwondo or swimming, is only a few times. Not surprisingly, he was much heavier than his own brother who was 3 years older. The child has not been picky about food, anything eaten. Her pants are now wearing size number 34, because of the large circumference of her abdomen. The school uniform, if the older sibling can replace the new four years, if the child is only two months old, he has to change, because he is getting bigger\textsuperscript{3,12}.

According to experts obesity continues to increase, due to unhealthy consumption patterns. In Indonesia, children from families with middle to upper economic conditions experience this, because of the ease of accessing various types of food. Parents tend to want their children to eat a lot, and choose the types of high-calorie foods. This type of fast food is also popular and popular with children, including menus that contain high sugar. At the same time, children, especially in urban areas, began to lack physical activity, due to the increasing hobby of playing games. About 30 percent are obese in the adult group. Children and adolescents are in the top ten percent who are obese. However, in this group of adolescents this is not only a problem of obesity, because blood pressure also starts to rise\textsuperscript{5,10,11}.

In several studies found evidence also that the symptoms of high blood pressure among adolescents, as a follow-up impact of obesity, excessive salt consumption, high stress levels and lack of physical activity. Not surprisingly, now, various diseases such as sugar and heart have been found in the age group of 30 years. This phenomenon occurs because the actual trigger factors have been initiated and saved since the age of the children. One of the probiotics that are widely used today is L. casei with various advantages including improving metabolism\textsuperscript{14,15,16}.

Research purposes analyzing changes in profile of blood glucose levels, total cholesterol, triglycerides, LDL and HDL after receiving supplementation L. casei for obese and fatting children.

**Material and Method**

This type of research is an experiment with a pre-post test only design. Research locations at SD Inpres Perumnas I and IV Makassar City. Time of study in March - August 2018. Population: all students at SD Inpres Perumnas I and IV Kota Makassar

Samples: all obese and obese students. The sampling used was simple random side which was chosen by 12 people, but on the trip of the 1rd week of intervention resigned for technical reasons. So the end of the study only got 11 samples. The sample was given L. casei strain Shirota for 1 month. Data analysis using t-test 2 samples in pairs with normal data distribution requirements.

Blood sample results, a serum examination was performed to determine the blood sugar levels, total cholesterol, triglycerides, HDL and LDL. Examination of the variables under study was carried out at the Community Eye Health Laboratory, Tajuddin Chalik Hospital, Makassar City.

**Findings**

Based on the results of this study shown in the table below:

**Table 1: Effect of L. casei strain Shirota on Blood Sugar while and Blood Fat of Obesity and Fatting Children in 2018**
Based on table 1 above shows that L. casei supplementation increases when blood sugar levels and blood fat levels. When blood sugar levels increased from 96.73 ± 7.66 mg/dl to 97.09 ± 17.45 mg/dl but were not significant (p> 0.05), this implies that when blood sugar increased with L. casei supplementation, total cholesterol levels decreased significantly (p = 0.005), ie from 173.91 ± 32.18 mg/dl to 156.73 ± 29.76 mg/dl, it was proven that L. casei supplementation reduced total cholesterol levels.

Triglyceride levels decreased not significantly (p> 0.05), ie 147.00 ± 67.69 mg/dl to 119.91 ± 49.29 mg/dl. LDL levels decreased not significantly (p> 0.05) from 100.09 ± 26.84 mg/dl to 92.36 ± 22.01 mg/dl. HDL levels decreased not significantly (p> 0.05) from 45.09 ± 6.20 mg to 42.27 ± 6.05 mg.

Table 1 also shows that the average increased in when blood sugar levels is 0.36 mg/dl, total cholesterol levels decreased by an average of 17.18 mg/dl, triglyceride levels decreased by an average of 27.09 mg/dl, LDL levels decreased by an average of 7.73 mg/dl, HDL levels decreased by an average of 2.82 mg/dl.

**Discussion**

Cholesterol is a fat-shaped compound that is mostly produced by the body in the liver from fatty foods consumed which are needed by the body to make cell membranes, wrap nerve fibers, make various hormones and body acids. Cholesterol cannot be circulated directly by blood because it is insoluble in water. To circulate it, a “transport” molecule called lipoprotein is needed. There are two types of lipoprotein, namely high density lipoprotein (HDL) and low density lipoprotein (LDL)\(^{1,5}\).

The mechanism of cholesterol reduction can occur because lactic acid can degrade cholesterol into coprostanol. Coprostanol is a substance that cannot be absorbed by the intestine. Thanks to coprostanol and the remaining cholesterol can be removed with feces. In other words, the amount of cholesterol absorbed by the body becomes low. A report on this matter explained that the reduction in cholesterol by lactic acid bacteria (Lactobacillus) could reach a range of 27-38%\(^6\).

High fat consumption will increase sterol in the large intestine and increase the secretion of bile salts, which will then be metabolized by bacteria in the intestine to produce carcinogenic compounds (cancer triggers). Cholesterol in food ingredients through the stomach to the duodenum and in the intestine in the triacylglycerol oil phase\(^15,16\).

Bile acids are absorbed from the bottom of the ileum and return to the liver. This is the hepatic circulation. The collection of bile acids in the liver is approximately 3.5 grams circulated 6-10 times per day. Each time 1%, which is around 500 milligrams/day, escapes absorption and is excreted through the stool. Furthermore, body cholesterol is secreted through the intestine by the intestinal wall. Bile salts are wasted through the stool and result in more cholesterol needed to synthesize bile salts and reduce the body’s cholesterol levels\(^10,12,14\).

The process of forming cholesterol and carcinogens (compounds that trigger tumors) starts from fat that will turn into bile acids which then become a series of enzymes. Then change the procarcinogen into a carcinogen, which among others triggers colon, breast, prostate, and pancreatic cancers\(^3,5,6,8\).

The process of forming bile acids from fat is stimulated by faecal bacteria or coli bacteria originating from feces or feces. But with the presence of lactobacillin, the faecal bacteria become inactive so that the process of changing fat into bile acids is also stopped\(^8\). Another compound of lactic bacteria is NI (not yet identified or unknown)\(^8\). However, this compound has a known role in inhibiting the formation of cholesterol. NI works to inhibit the enzyme 3-hydroxy 3-methyl glutaril reductase which will convert NADH to nevalonic acid and NAD\(^4,8,12\). Thus, a series of other compounds that will form cholesterol are also inhibited. Therefore, it can be said that the presence of foods and beverages naturally acidified with lactic bacterial fermentation can help prevent cholesterol and cancer from arising\(^5,16\).

**Conclusion**

1. L. casei strain Shirota supplementation in obesity and fatting children causes an not significant increase in when blood sugar levels.
2. L. casei strain Shirota supplementation in obesity and fatting children causes a significant reduction in total cholesterol levels
3. L. casei strain Shirota supplementation in obesity and fatting children caused a not significant decreased in triglyceride, LDL and HDL levels but the highest decreased in triglyceride levels.
Conflict of Interest Statement: This research without conflict of interest between researchers and subjects.

Source of Funding: This study uses funding from the Ministry of Health Polytechnic and also to PT Yakult Indonesia who have volunteered to provide L. casei strain Shirota products in the research that has been conducted.

Ethical Clearance: Research ethics was obtained through the ethics commission of the research of the health and health polytechnic of Makassar with No. 467/KEPK-PTKMKS/VII/2018.

Role of Manual and Powered Tooth Brushes in Plaque Removal and Oral Health Status (A Comparative Study)

Salah Mahdi Ibrahim¹, Sattar J. Abdul-Zahra Al Hmedat¹
¹Department of Periodontology, College of Dentistry, University of Kufa, Iraq

ABSTRACT

Aim of the Study: Evaluate the plaque and calculus removal during the manual and powered brushing of teeth and To compare manual and powered toothbrushes in everyday use, principally in relation to plaque removal.

Materials and Method: A randomized blinded controlled trial with 50 healthy human volunteers of age group 18-25 years was carried out. The subjects were randomly assigned to 2 groups i.e., groupA - manual brushing with and without dentifrice, Group B - powered brushing with and without dentifrice. Plaque accumulation and gingival condition were recorded using plaque index. The test treatments were brushing with 2 oscillating rotating electric toothbrushes, a manual toothbrush and a rinse with a toothpaste slurry (3 g/10 ml water).

Results: Mean plaque and gingival scores was reduced over the 3 week trial period for all groups manual Brushing with or without a dentifrice resulted in a mean plaque reduction of 49% and powered brushing with or without a dentifrice resulted in a mean plaque reduction of 60%

Discussion: the efficacy of plaque removal has been emphasized more with powered tooth brush rather than manual tooth brush, and as brushes with hard bristles may precipitate adverse changes associated with brushing, like, abrasion of tooth surface as well as traumatizing the gingival margin, the need of hard bristled toothbrushes in the market is questionable.

Conclusion: the plaque and calculus has removed during the manual and powered brushing of teeth. powered tooth brush has more effect than manual tooth brush in removing plaque and calculus.

Keywords: Manual, powered tooth brushes, gingivitis, oral hygiene, plaque index.

Introduction

It is widely agreed in dentistry that plaque consist of a combination of pathogenic microorganisms and host cells. Which consider is the principal etiological factor associated with periodontal disease. Since Loe’s experimental gingivitis, [1] thorough plaque control has been essential to control and prevent gingival and periodontal disease. Supra gingival plaque control is dangerous in preventing both initial gingivitis and periodontal disease in all stages. [2] Mechanical tooth cleaning by means of a toothbrush and a dentifrice remains the most effective and common method for controlling supra gingival plaque. [3,4].

Dentifrices are supposed to prevent plaque buildup, strengthening teeth against caries, elementing stains, removing food debris, and control the oral mouth. [5,6] Dentifrices containing anti-plaque and anti-inflammatory agents would also elemental plaque and help in overcoming the manual or mechanical shortcomings of brushing. [7].

Most of the studies that evaluate the role of a dentifrice in plaque removal and those that assess different toothbrush designs, were done by making comparison of the result product with the control. In such studies, the obtained plaque removal score could be due to the use of toothbrush and dentifrice, it was difficult to distinguish the contribution of either toothbrush or dentifrice.

There are several studies that attempted to define the role of dentifrices in plaque removal during mechanical tooth brushing. One study [8] stated that brushing with a dentifrice removed more plaque than brushing alone. Another study [9] found no difference between brushing
with or without a dentifrice; in another studies done by Binny et al.,[10] and Paraskevas et al.,[11] brushing without a dentifrice found more plaque reduction when brushing without dentifrice than brushing with a dentifrice. A recent study [12] showed that the use of a dentifrice is not cause additional plaque removal during manual tooth brushing and concluded that the mechanical action provided by the toothbrush is crucial in plaque control. Although each study differs in factors related to the study methodology, the overall result is important.

The present study was undertaken in order to view the conflicting role of dentifrices and the effect of its role when used in associoted with tooth brushing. The aim of the present study is to detect the actual role of the dentifrice and demystify its effect when associated with use of tooth brush.

**Efficacy of Tooth Brushing:** Previous studies showed of plaque accumulation and removal with daily tooth brushing during a 28-day period following a dental prophylaxis. On average about 60% of the plaque was left after the self-performed brushing. Morris et al.[13] reported on the 1998 UK Adult Dental Health survey and observed that the mean proportion of teeth with plaque deposits was 30% in the 25–34-year age group and 44% in those aged 65 years and above. At the Academic Centre for Dentistry Amsterdam (ACTA) a study was conducted which assessed the efficacy of a single 1-minute brushing exercise in subjects adhering to their customary brushing method Van der Weijden et al.[14] It was observed that after 1 minute of brushing, approximately 39% of the plaque had been removed. The results of the studies described above indicate that most subjects are not effective brushers and that they probably live with large amounts of plaque on their teeth, even though they brush once every day.

**Electric Toothbrushes:** To invest the necessary time and effort to well instructed and motivated and properly instructed individuals who are doing, international toothbrushes and adjunctive manual (interdental) devices, mechanical measures are effective in removing plaque. Maintaining a dentition close to plaque-free is, however, not easy. Plaque removal and patient motivation where doing by The electric toothbrush. Electric toothbrushes were making to the market more than 50 years ago. Bemann & Woog in Switzerland, The first toothbrush powered by electricity was developed by them and was introduced in the United States in 1960 as the Broxodent. General Electric, In 1961 a cordless rechargeable model was introduced by Studies of the use of these early electric toothbrushes showed that there was no difference in plaque removal when compared with a manual toothbrush and they had mixed effects on gingivitis [15].

**Aims of the Study:**

This study has used to

1. detect the effect of plaque and calculus removing during the use of manual and powered brushing of teeth.
2. we make comparison by manual and powered toothbrushes in everyday use. Principally in relation to plaque removal and gingival health. Stain, calculus removal.
3. compare the role of using the manual and powered brushing of teeth in the reduction of gingivitis and plaque.

**Material and Method**

**Study Design:** The group study consisted of 50 student of College of dentistry, Kufa, Iraq. Male and female in age range (20-23) years. the volunteers were examined in perfect study with suitable time to indicated severe cases in relation to periodontal disease and restorative-related problems. Data collected by the use of dental mirror, probe and The study period lasted for 10-week.

Single-examiner blind was used for examination A group of 25 subjects participated in this, randomised, crossover design. Subjects had fair oral hygiene and the electrical tooth brush never used previously. Subjects were plaque free in 7 days by the use of rotating electric toothbrushes, a manual toothbrush and a rinse with a toothpaste slurry (3 g/10 ml water).

**Brushing Exercise:** Before starting, the patient was asked to wet the brush head with tap water and the brushing time was two minutes for the whole mouth. [16,17] 30 seconds per quadrant, 15 seconds for the buccal side, and 15 seconds for the lingual side. When dentifrice was used for brushing, 2 ml of dentifrice was adding onto the toothbrush using a syringe with dentifrice (sensodyne). The supervision of the brushing procedure was done by a different examiner. A stop viewing was used and a signal was given to the subject to change the brushing surface.
The Clinical Parameter

![Plaque index](image)

**Figure 1: Plaque index**

**Results**

Fifty two students (volunteers), 10 students didn’t participate after the first phase, either due to their college examination or because of their sickness. The remaining 42 students were divided into two groups (1 and 2) of 21 each and they use tooth paste randomly. The mean of the total plaque indices by manual brushing with and without dentifrice are tabulated in [Table 1]. the mean of the plaque indices by powered brushing with and without tooth paste are tabulated in [Table 2]. Manual Brushing with or without a dentifrice resulted in a mean plaque reduction of 49% and powered brushing with or without a dentifrice resulted in a mean plaque reduction of 60%. This 11% difference is highly significant (P≤0.0001).

**Figure 2: means of plaque related to the time of diagnosis by manual tooth brush normal**

**Figure 3: means of plaque related to the time of diagnosis by powered tooth brush normal**
Discussion

The primary tool in overall plaque control in The toothbrush alone has long been considered. Adelivery vehicle such as fluoride, tartar, consider as breath control components of The dentifrice, the bacterial plaque consider as amain etiologic factor of periodontal disease. The studies of Loe and his associates have clearly demonstrated that bacterial plaque is a major etiologic factor in inflammatory periodontal disease.

The use of the toothbrush is not effective with a high standard of oral hygiene. Adults, with suitable method, appear not to be as effective in their plaque removal as might be expected. Most individuals only elemenating about 50% of plaque by tooth brushing.

The plaque has been reduced to almost 49% for brushing by manual tooth brush {P-value >0.05} and 60% by powered tooth brush {P-value >0.05}. highly significant differences were noted between these groups. The efficacy of plaque removal has been approved more with powered tooth brush rather than manual tooth brush.

I could agree with Dr. Perry, but I would appreciate comments from anyone on the panel. the way that we have analyzed the literature in the field I have some concerns. The results of some 60 studies favored the powered brush, and there was no difference in another 40 studies. In this particular field. We all know how much more difficult it is to publish studies which show no differences between the test groups.

Dr. Heasman, I could not agree more. In the Rotadent study, the way that we have analyzed the literature in the field there were no surrogate markers, only tooth loss at the end of the 10-year period. More studies are how effective these brushes are in maintaining dentitions intact and keeping dentitions functional and aesthetic needed over a longer period to provide a clearer view.

Conclusion

This study showed that This program conducted 10 weeks s were more effective than those conducted at six-week intervals in improving oral health knowledge, regarding plaque index, powered tooth brush has more effect than manual tooth brush in removing plaque and calculus. People buy tooth brush with or without dentifrice not only to clean the teeth, but also for its content of an anti-caries action, desensitizing effects, for the feeling of freshness and to reduce malodor.

Prevalence of Gram Negative Bacteria Isolated from Patients with Burn Infection and their Antimicrobial Susceptibility Patterns in Kirkuk City, Iraq

Sarah Ahmed Hasan¹, Kasim Sakran Abass²
¹Department of Basic Science, Faculty of Dentistry, ²Department of Pharmacology and Toxicology, College of Pharmacy, University of Kirkuk, Kirkuk, Iraq

ABSTRACT

Burn injury compromises the skin barrier and enables bacterial infection, hence delaying burn wound healing. This study aimed to determine the microbial profile of burn wounds, and resistance patterns of microbes with respect to the source of the injured patient’s wound. From 130 wound swab samples were collected from burn patients at Azadi Teaching Hospital, Kirkuk/Iraq. Sterile swabs moistened with sterile saline were used to swab burn wounds. The swabs were plated on blood agar and MacConkey agar for 24 hrs at37°C. Biochemical tests were carried out on the representative isolate on each plate, and antibacterial sensitivity pattern was determined using the Kirby-Bauer disc diffusion method. The study revealed that the main source of burns was gas flames (60%) and scalds (29.23%). Out of the 130 samples analysed, (72.3%) were culture positive and 27.7% were culture negative for bacteria. The predominant gram negative bacteria isolated were, Pseudomonas aeruginosa 40(42.5%) followed by Klebsiella pneumoniae 23 (24.46%), Enterobacter cloacae 21 (22.34%) and Escherichia coli 10(10.63%) were the least frequently isolated bacteria. These isolates showed high resistance towards Beta lactam antibiotics and showed varying resistance levels towards non beta lactam antibiotics (Ciprofloxacin Amikacin and Gentamicin). Resistant gram negative bacteria are the most common isolates associated with burn wounds. Hence a careful selection of antibiotics to control the wound infection is required for proper management of burn wounds in order to help reduce morbidity and mortality.

Keywords: burn wounds, gram negative bacteria, antibiotic resistance, Flame.

Introduction

Burns wounded considered as a suitable site for multiplication of bacteria and are more frequently sources of infection than surgical wound, mostly because of larger area involved and longer duration of stay in hospital¹. Approximately 75% of the mortality after burn injuries is concerned with infections rather than hypovolemia and osmotic shock². The infection patterns are various from hospital to hospital; the varied bacterial flora of infected burn wound may change significantly during the healing period³. Hence such studies are too important for providing suitable and efficient treatment for reducing the rate of morbidity and mortality in Burn Units. Universally, burns are destructive forms of trauma in patients with significant thermal injury⁴,⁵. They can be caused by thermal, scalds, electrical, chemical agents or gas⁶. Patients with such burn injuries require urgent specialized care to decrease bacterial infection, which is considered as critical cause of morbidity and mortality for burn patients⁷.

Much progress are made to infection control systems and burn injury management, in spite of that, burn infection still constitutes a serious clinical challenge in most developing countries, where wound site infections considered as major source for infections, causing post-operative illness and mortality for burn patients⁸. There are significant effects on burn wounds that are...
contaminated with pathogenic bacteria that can delay the wound healing, because of herniation, breakdown or complete dehiscence of the wound\textsuperscript{9,10}.

Almost, the source of contamination is the patient’s normal flora or exogenous contamination from the hospital environment; different groups of bacteria have been reported to be related with wound infections\textsuperscript{11}.

Antibiotic susceptibility patterns for pathogenic isolated bacteria from hospitalized patients are constantly evolving, and this can constitute a significant challenge for clinicians treating burn injury victims\textsuperscript{12,13}. Therefore, this study was made to determine the microbial profile of burn injuries, the antibiotic susceptibility patterns of bacteria associated with the source and degree of burn, age, and sex among burn wound patients at Burns Unit of Azadi Teaching Hospital in Kirkuk city in Iraq.

**Methodology**

The investigation was a cross-sectional study carried out at the Burn Unit of Azadi Teaching Hospital in Kirkuk, Iraq. All consenting burns patients admitted to the Burn Unit from January–July, 2017 were recruited and included in the study.

**Sample Collection:** A total of 130 burn wound swabs were collected, using a sterile cotton swab, and immediately transferred under aseptic conditions to Microbiology Laboratory where they were processed. Data on gender, age and type of burn also collected from the patients.

**Laboratory Analysis:** On arrival at the laboratory, the wound swabs were immediately cultured onto blood and MacConkey agar then incubated at 37°C for 18-24hrs. After 24 hrs, the colonial morphology of the color, shape and general appearance of the individual colony on each of the plates was examined.

A representative single colony on the blood and MacConkey agar was gram stained and tested with citrate, indole, urease, Triple Sugar Ion test (TSI), and oxidase were performed to identify which bacteria species were present\textsuperscript{14}.

**Susceptibility Testing:** Antibiotic susceptibility testing done by Kirby Bauer disc diffusion method as per CLSI\textsuperscript{15}.

Each gram-negative isolate tested using ten antibiotics:

- Amoxicillin (10μg), Augmentin (10μg), Cefotaxime (30μg), Ampicillin (10μg), Ceftriaxone (30μg), Ceftazidime (30μg), Imipenem (10μg), Ciprofloxacin (5μg), Amikacin (30μg) and Gentamicin (10μg).

**Data Analysis**

The data obtained from the study were analysed using descriptive Statistics generated with the help of Microsoft Excel. The quantitative data analyzed using GraphPad Prism software, version 6. In all cases, P-values less than 0.05 considered statistically significant.

**Results**

130 samples collected from the burn patients, 50 (38.46%) were from males and 80 (61.53%) were from females (Table I). The greater number of patients were within the 21-30 age group (32.3%), followed by 0-10 (30.76%), 11-20 (16.92%), 31-40 (6.62%), 51-60 (6.15%), 41-50 (3.84%), and the 61-70 age group had the least number of patients (3.07%). Gas (flame) were the main cause of burn injuries in 78 (60%) patients, followed by Scalds 38 (29.23%) and electricity 14 (10.76%).

Table I: Demographic characteristics of recruited burns patients
Out of the 130 samples cultured, 94 (72.3%) were positive for bacterial growth, while 36 (27.7%) showed no growth in cultures. The majority of positive bacterial growth were from second burn degree 56 (59.57%), followed by third burn degree 35 (37.23%) and first burn degree 3 (3.19%) (Table II).

In this study 4 different predominated isolates of gram negative bacteria were identified (Table III), Pseudomonas aeruginosa 40 (42.5%) followed by Klebsiella pneumoniae 23 (24.46%), Enterobacter cloacae 21 (22.34%) and Escherichia coli 10 (10.63%) (Table III).

Four main isolates of gram negative bacteria were high resistant to beta lactam antibiotics (Amoxiclavulanic acid, ampicillin, amoxicillin, ceftriaxone, ceftazidime, cefotaxime and imipenem) except 5 (23.8%) of Enterobacter cloacae isolates and 1 (9%) of Escherichia coli isolates were resistant towards imipenem.

Also the bacterial isolates were resistant to aminoglycosides antibiotics (amikacin and gentamicin), except 8 (38.09%) of Enterobacter cloacae isolates were resistant towards amikacin and all isolates of Escherichia coli were sensitive towards it (Table III).

Discussion

This study reports for the prevalence of burn injury and associated resistant bacteria in patients in Azadi teaching hospital in Kirkuk, Iraq.

In this study, the prevalence of burn injuries was higher in females: 80 (61.53%) compared with 50 males (38.46%). This agreed with a study proceed by Forson in Ghana which also reported a higher prevalence of burn injuries in females (64%) than in males (36%). The relatively higher rate of burn injuries in females may be due to their greater participation in kitchen activities. However, our results are in contrast to a study by Ekrami and Kalantar from India, which showed a higher rate (59.3%) of burn injuries in males than in females (40.6%)16.

The studied patients’ age ranged from 1 to 62 years of age, the 21-30 age group was the most burn injured age group - which agreed with the study by Chaudhary et al. in Nepal17. This could be because of the fact that the 21-30 group is the most active group, and most involved in outdoor activities. Seventy-eight (60%) of the studied patients had flame injury, while 38 (29.23%) had scald injury and 14 (10.76%) had electrical injuries. These findings were agreed with a study by Shahzad et al in Pakistan18, which reported the main burn cause was gas flame (76%), followed by scald (14%), contact (6%), electrical (3%) and chemical (1%).
Among the patients cultures 94 (72.3%) were positive cultures, most of them 36 (27.7%) were from second degree burn patients.

The most predominant gram negative bacteria associated with burn injuries were *Pseudomonas aeruginosa*, *Klebsiella pneumonia*, *Enterobacter cloacae* and *Escherichia coli*. *Pseudomonas aeruginosa* was the most common bacteria associated with the burn injuries. The high prevalence of *Pseudomonas aeruginosasa* in this study may be because of the fact that it thrives well in a moist environment. Our findings agreed with the studies by Forsan and Lakshmi et al. from Ghana and India respectively, which also reported *Pseudomonas* sp. as the most common isolate in burn injuries with a prevalence of 33.6%. This study, however, is in contrast to study by Srinivasan et al. in India that reported *Klebsiella* sp. (33.91%) to be the common isolate associated with burn injuries. The differences in isolated bacterial isolates in burn wounds may be because of the variation in treatment practices in various geographical locations of burn victims.

In this study, the antibiotic susceptibility pattern of various gram negative isolates from the burn patients showed high resistance toward B-lactams antibiotics, this has emerged through production of β-lactamase, alterations in the targets of antimicrobial agents, the penicillin-binding proteins also through alterations in outer membrane permeability of the bacteria toward the drugs.

Also the isolates emerged high resistance toward aminoglycosides, this emerged through three mechanisms: production of aminoglycoside modifying enzymes, alterations at the ribosomal binding sites or reduced uptake or decreased cell permeability. While bacterial resistance toward ciprofloxacin can occur through various mechanisms: alterations of the cell permeability, changes or alterations in the site of action leading to loss of susceptibility to the antimicrobial drugs mediated by the increment of the efflux pump activity and by enzymatic degradation of the antimicrobial agents.

**Conclusion**

Findings of this study were that multidrug resistant gram-negative organisms are the most common isolates from burn patients. So the study suggest a careful selection of antibiotics to treat burn wound infection is required for proper management of these wounds to reduce morbidity and mortality associated with multiresistant bacteria.

The Intensity of Pain in Neonates Undergoing Venipuncture Procedures in the Neonatal Ward

Siti Yuyun Rahayu Fitri¹, Mohammad Juffrie², Lely Lusmilasari³

¹Department of Pediatrics Nursing, Faculty of Nursing, Universitas Padjadjaran Bandung Indonesia; ²Department of Pediatrics, Faculty of Medicine, ³Department of Pediatric Nursing, Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada

ABSTRACT

A pilot survey is needed about the level of pain due to painful procedures in neonates in order to develop pain treatments in neonates. This study aimed to know the level of pain intensity in neonates underwent blood collection procedures in the neonatal ward. The design of this study was descriptive observational. Instrument used The Premature Infant Pain Profile-Revised (PIPP_R). The samples were neonates who underwent venipuncture procedure treated in the neonatal ward with 88 babies. The results showed that most babies performed moderate pain levels (89.8%). The experience of recurring pain in the neonatal period has potential physiological and psychological problems both in the long and short term. Based on this study, it is important for clinicians in the neonatal room to anticipate pain and develop pain management in neonates who have invasive procedures.

Keywords: neonates, pain, venipuncture

Introduction

Survey research in various countries has been conducted to identify the prevalence of pain in neonates during treatment. A survey of 14 NICUs in Canada showed that each neonate received an invasive procedure of 2 to 8 procedures every day (1). In another study it was shown that 144 neonates experienced more than 7,000 procedure procedures since being treated until returning home (2). In France, of the 430 neonates who were treated, they experienced painful procedures totaling 30,018 procedures, and 30,951 procedures that caused stress, the condition occurred in the first 14 days of treatment. Furthermore, still in France, based on a multicenter prospective study related to epidemiology of neonatal pain, it was shown that the most invasive procedure was heel stick, which is an average of 16 times per baby for 14 days of treatment (3). Another study reported that there were 20,000 painful procedures in 151 neonates for 14 days treated at the NICU, or an average of about 196 procedures per neonate (4).

According to the International Association for the Study of Pain (IASP), pain is an unpleasant sensory and emotional experience related to actual or potential tissue damage (5). Pain that appears in neonates can have an impact on various aspects both short and long term. The impact of pain in neonates began to be investigated in 1996, after the previous years were only seen in experimental animals (6). Pain that occurs in neonates can have an impact on increasing physiological pain sensitivity, intra vascular hemorrhage (IVH) or Ischemia Leading to Periventricular Leucomalacia (PVL), sequelae in neurodevelopment (7) neurobiological changes (CRF, HPA, brain activity), behavior changes in the future such as emotions, depression, reactions when playing, even psychopathology (8). Developmental changes in cognitive and motoric abilities that were poor at 8 and 18 months of age were also associated with the experience of getting invasive procedures that recur during neonates (9). Then it is generally said that pain in the neonatal...
period has an impact on aspects of neurobiology, HPA axis and behavior \(^{(10)}\). Poorly managed pain has an effect on brain development and stress systems of premature neonates, but pain management is still a challenge \(^{(9)}\).

Prevention and treatment of pain in neonates is very important given the impact of short-term and long-term pain in various aspects. But in fact, of the many procedures that cause pain, management of pain carried out by health workers is still very limited \(^{(3,9,11)}\). The average administration of analgesia in neonates with invasive measures is only about 27.4% and further studies have reported that administration of analgesia in neonates given invasive both pharmacologically and non-pharmacologically is only about 20.8% \(^{(12)}\).

In Indonesia, attention to research on pain in neonates began to develop. However, there are no data on the level of pain in infants that has been formally measured. This research is a pilot to survey the level of pain of neonates who performed blood collection procedures. Based on observations in the neonatal ward, blood collection procedures (venipuncture) are invasive procedures that are most commonly performed on treated neonates. This pilot study will be the basis for pain management as well as an overview of the quality of life for neonates who are undergoing treatment at the hospital.

**Material and Method**

This was a descriptive observational study. The pain was measured by use of the Premature Infant Pain Profile-Revised (PIPP-R) instrument which assesses pain from behavioral and physiological aspects and modification variables \(^{(13)}\). Pain indicators include (i) Behavior aspects: brow bulge, eye squeeze, nasolabial furrow, (ii) Physiological aspects: heart rate and oxygen saturation, (iii) Contextual: gestational age and behavioral state. Within the scale, a score of 0-6 points indicates mild pain, 7-12 points indicates moderate pain, and 13-21, points indicates severe pain \(^{(14)}\).

Before the use of this instrument, the translation process was first conducted, namely the process of obtaining devices in different languages with the original language to achieve the same targets in various countries or cultures.

Procedure: Before the venipuncture procedure was carried out, the nurse begins to attach the oximeter to the baby’s soles of the foot, after the oximeter shows the display, then the nurse in charge of blood sticks the needle to get the desired blood sample. To assess the intensity of the pain, a PIPP-R scoring form has been provided. To assess the aspect of the behavior according to the indicator, the nurse observes the behavior and uses the stopwatch for its duration, then for the physiological aspects the measurement of HR and SaO2 uses a non-painful neonatal Oximeter according to the principle of atraumatic care, and for the contextual aspect (gestational age and behavioral state) by looking at medical records and observations. The suitability coefficient between rater was calculated and showed a good level of suitability (ICC = 0.968, p = 0.001).

The sample in this study was the babies who were to take blood sampling procedures in the period June - August 2018 and it was recruited 88 babies.

**Findings**

Babies who were the subjects in this study were all babies who were treated in the neonatal ward at the above 32 week gestational age and were not restricted based on maturity because the use of PIPP-R measuring instruments would correct the effect of age (table 1). The results showed that the level of pain in newborns undergoing venipuncture procedures was mostly at the Moderate level (table 2). When described in the scores obtained, the pain score range is between 6 to 13 points and most are in score 9 (diagram 1).

Discussion and Conclusion

This study was the first study to investigate pain scores using PIPP-R in infants who underwent venipuncture procedures in Indonesia. The results showed that the majority of infants who received venous blood collection procedures were at a moderate level, which was between the scores of 7 to 12. Then based on the distribution of the obtained score data, the lowest pain level was at the highest limit for that category, i.e. score 6 of a maximum of 6 mild category. For the severe category the score is at the lowest limit for that category which is 13 points. The results of current study are generally in accordance with previous studies which showed that venipuncture procedures without analgesic treatment were at moderate and severe levels (15).

Invasive procedures in infants including venous blood sampling (venipuncture) are often performed on infants repeatedly for various purposes at different times. Even in one procedure, the newborn vein is usually not always getting blood so the stabbing is done several times to get the required blood sample. Epidemiological studies in France showed that in a period of 14 days of treatment, 430 infants received a heel stick procedure of 8396 measures and a venipuncture of 757 (12). Then another study showed that within 14 care days 6832 infants received 42,413 invasive procedures with an average of 7.5-17.3 per neonate per day (10).

The experience of repeated pain in infants if not given treatment can cause problems both in the long term and in the short term. The effects of the pain include decreased infant weight and head circumference, reduced white matter and subcortical gray matter, increased heart rate, reduced brain size, mostly in frontal and parietal regions, elevated cortisol levels, neurological behavior and psychological (17–20).

Invasive action is not possible at all and pain will still be felt by neonates. This study can provide an overview to clinicians and health staff working in the neonatal space to become the foundation in developing interventions that can reduce pain, implement it and make policies that support the provision of analgesia in neonates who undergo painful procedures both pharmacologically and non-pharmacologically.

ABSTRACT

This study aimed to analyze and formulate a strategy to improve quality of service at the inpatient care unit of Anuntaloko Parigi Hospital based on a servqual approach. This research was an analytical study with a cross-sectional design, where the data analysis is derived from facts that have occurred or are taking place in the study population. The method used in this study was a survey on 96 patients and 24 officers. The results showed that the level of quality of service at the inpatient care unit at Anuntaloko Parigi Hospital was very low or not qualified. There was a significant relationship in 5 (five) dimensions of quality of service experienced by patients, there was a significant relationship in 2 (two) dimensions of quality of services, namely, reliability and responsiveness, between the services expected by patients and quality of service, and on the dimensions of tangible, there was no significant relationship regarding to reliability and empathy. There was a negative gap between the services expected and perceived by patients. Last, the service dimension that affected the quality of service was responsiveness.

Keywords: Quality of Services, Servqual Approach, Hospital

Introduction

Health state is the will of all parties, not only by person or family, but also by groups and even by all members of the community. Health is a healthy condition, both physically, mentally, spiritually and socially, which enables everyone to live productively socially and economically.(¹,²)

Quality must begin with customer needs and end with costumers’ perceptions. The same is true for services provided by hospitals as providers of health services. Hospital quality can be valued based on patient perceptions. (³) Factors evaluated by consumer which are the key factors determining the quality of services are access, communication, competence, courtesy, credibility, reliability, responsiveness, security, understanding, and tangibles. Based on the study, there is a strong correlation between communication, competence, courtesy, credibility, security which eventually are combined into assurance dimension. (⁴–⁶) Likewise, there is a very strong correlation between access and understanding, which eventually are combined as empathy dimension. (⁷) Consequently, there are five dimensions of quality of service used to evaluate a service, namely reliability, assurance, tangible, emphaty, and responsiveness (RATER). (⁸,⁹)

The aforementioned indicators of hospital service performance may illustrate that there is a tendency to decrease the level of performance, possibly due to the lack of efficiency of services provided to patients. (¹⁰,¹¹)

Based on data from Anuntaloko Parigi Hospital, the number of inpatients in 2008 was 6,429, with an average of 536 patients per month. The number of hospitalized patients in 2009 was 6661 people, with an average of 555 patients per month. The total number of patients in 2010 was 22,215 people, and the number of hospitalized patients in 2010 was 6,597 people, with an average of
549 patients per month. Meanwhile, the data for 2011 from January to July were 3397 with an average of 485 patients per month. Based on data from inpatients from 2008 to 2010, it was found that there had been a decline in the number of inpatients as many as 168 people.

Considering the decrease in utilization rates in Anuntaloko Parigi Hospital which might be affected by patient/customer dissatisfaction to the low quality of perceived service, it was necessary to make an analysis of the quality of services at Anuntaloko Parigi General Hospital, especially in inpatient services with a servqual approach which will then be made into a strategy for service improvement using the importance and performance matrix.

Method

This study was quantitative with cross sectional study approach. The study was done at the inpatient care unit at Anuntaloko Parigi hospital from December 2016 to March 2017. The population was all hospitalized patients at inpatient care unit of Anuntaloko Parigi hospital as well as all the officers working in service units at Anuntaloko Parigi hospital. A purposive sampling technique was employed with a sample size of 24 officers respondents and 96 patient respondents which was calculated through an estimated proportion formula:

\[ n = \frac{(Z_{1-\alpha/2})^2 \cdot (P)(1-P)}{d^2} \]

The data were collected by means of questionnaire for each officer and patient and were analysed using chi square and logistic regression analysis.

Results

The most influential dimension toward the quality of service

Table 1: Logistic regression analysis between patients’ willingness and quality of service at inpatient care unit at Anuntaloko Parigi hospital

</tr>
</tbody>
</table>

Table 2 shows the biggest negative gap was true for empathy dimension (-1.17) and the least was responsiveness dimension (-0.89). These results indicated that of the five dimensions, the quality of perceived services was lower than what was expected at the inpatient care unit at Anuntaloko Parigi hospital.
Table 3: The gap between perception of officer and services provided to the patients based on five dimensions of the quality of service at the inpatient unit at Anuntaloko Parigi hospital

</tr>
</tbody>
</table>

Table 3 shows the biggest negative gap was true for reliability dimension (-2.37) and the least was responsiveness dimension (-1.29). These results indicated that the quality of services provided by officer was lower than what was perceived by patients.

The importance–performance analysis: Regarding to strategic plan to improve the quality of services, the average scores of importance and performance of all five dimensions were made into the following importance-performance matrix.

![Graph 1: The analysis matrix of importance and performance at the inpatient unit of Anuntaloko Parigi hospital in 2012](image)

Graph 1 shows there were 7 attributes of the quality of services in quadrant I, 4 attributes in quadrant II, 3 attributes in quadrant III and 8 attributes in quadrant IV.

Discussion

Over expectation of patients toward the health service was among the factors influencing the low quality of services. However, the most influential factor of the quality of services perceived by the patients was the low performance of officer. According to the interview made by the researcher, the quality of service perceived by patients was lower that what was expected, for instance the unfriendly attitude of officer and the absence of officer in the room when needed.

Analysis of the influence of experience and patients expectation over the quality of service: The quality of service that was significantly related to expected service quality and tested by logistic regression analysis was the responsiveness dimension. This means that only the attributes in the service dimension are the main indicators to measure the quality of health services in the inpatient unit of Anuntaloko Parigi Hospital. On the
other hand, service improvements in the dimensions of reliability, assurance and tangible did not have a large leverage to the high perceptions of patients toward the quality of service.\textsuperscript{(18)}

Improving service attributes in the dimension of responsiveness, therefore, must be a top priority to improve quality at the inpatient unit of Anuntaloko Hospital, Parigi. Graph 1 shows the service attributes that should get priority on responsiveness, for instance; officers must be responsive to each patient’s complaints, having an attitude of always wanting to help patients, providing information to patients that must be clear and understandable and not making any burden of any complaints or wishes of patients.

\textbf{The gap analysis of the quality of services:} The difference between actual performance (perceived services) and consumer perception on the expected quality of service was based on five service dimensions in service quality model (servqual), namely tangible, reliability, responsiveness, assurance, and empathy.\textsuperscript{(8,19)}

The results of the study showed that attributes such as service procedures which are fast and easy, on time services, sincere attention and the ability of officers to provide services without errors are very important and expected by patients. Other important service conditions are expected by patients, namely the special attention of officers to patients, officers are not discriminatory in providing service and always treat patients well.\textsuperscript{(20–22)} Ironically, the officers could not perform better performance on these dimensions. This means that there was a dimension of service that was importantly expected by the patient, however the officer actually showed poor performance on that dimension and vice versa there was a dimension that was not too expected and emphasized by the patient but precisely the officers showed good performance on that dimension.

The aforementioned gaps arose due to management/officer misperception of the service expected by the patient (gap 1).\textsuperscript{(23,24)} As is shown in Table 4, there was a gap between the perceptions of officers on the services expected by patients and actual patient expectations. Another reason is because the hospital service quality indicator instrument (hospital accreditation system) has not been oriented to customer satisfaction, the quality of service cannot be assessed from the service provider’s point of view but must be based on the customer’s assessment (voice of customer).\textsuperscript{(25,26)} However, these four factors can actually be controlled by service providers, indicating that the occurrence of a negative gap between services received and those expected by patients is highly dependent on the performance of the officers.\textsuperscript{(15,18)}

Understanding the problem, therefore, the strategy to improve the quality of service in the inpatient unit of Anuntaloko Parigi Hospital must be prepared based on the expectation of patients. In addition, management must always improve the quality of officers, especially those related to service management, development of attitudes and characteristics of officers so that they are able to understand better and feel about what is felt by patients.

\textbf{Strategy to improve the quality of services at the inpatient unit of Anuntaloko Parigi hospital:} The results implied determination of position to assign research attributes with a Cartesian diagram. The strategy for improving services in this paper was based on the importance and performance matrix consisting of 4 quadrants as follows:

1. The attributes included in quadrant I located in the upper left (service attributes that were considered very important, but hospital management had not implemented it according to the expectation of the patient) are:
   a. The hospital yard is clean and beautiful
   b. The hospital layout and furnitures are clean, neat and comfortable
   c. Officer service provides security to the patients
   d. Officers are able and willing to give appropriate answer toward questions and complaints of patients.
   e. Officers care to the patients and their family
   f. Officers provide equal services without any discrimination to the patients
   g. Officers always treat patients well
2. The attributes included in quadrant II located in the upper right (service attributes that were considered very important by patients and had been implemented by hospital management and met patients satisfaction) are :
   a. Medical equipments are complete, clean, and ready-to-use
b. Services are fast and punctual  
c. Officers are polite and friendly  
d. Officers patiently and carefully treat the patients

3. The attributes included in quadrant III located in the bottom left (service attributes that were not considerably important by patients and the implementations by hospital management were mediocre and less satisfying) are:
   a. Officers give error free service  
b. Officers provide clear and understandable information  
c. Officers do not make burden of any complaint of patients

4. The attributes included in quadrant IV located in the bottom right (service attributes that were not considerably important by patients but the implementations by hospital management were excessive/less important but very satisfying) are:
   a. Officer appearances which are clean and tidy  
b. Patient admission procedures are fast and precise  
c. Services procedures are easy  
d. Officers provide sincere service to any complaint of patients/their family  
e. Officers quickly respond to patients complaint  
f. Officers always want to help patients  
g. Knowledge and ability of doctors to diagnose diseases  
h. Officers provide special care for each patient

Conclusions

This study concludes that the level of quality of services at inpatient units at Anuntaloko Parigi Hospital is very low or not qualified. There is a significant relationship on the 5 (five) dimensions of quality of services experienced by patients. There is a significant relationship in 2 (two) service quality dimensions, namely (reliability and responsiveness) between the services expected by patients and the quality of services. With respected to the Tangible, Reliability and Empathy dimensions, there is no significant association is found. There is a negative gap (gap-) between services expected and perceived by patients. Responsiveness has the most influence on the quality of service.

This research recommends the need for developing cooperation among professional institutions in research and improvement of customer-oriented management. The rationalization of the price rates of Anuntaloko Parigi Hospital is based on the ATP/WTP study.

Serum Vitamin-D Levels in Bronchial Asthmatic Patients in Baghdad City

Sura O. Yousif¹, Jasim Mohammed Muhsin²
¹Technical Institute, Suwaira-Middle Technical University, Wasit, Iraq; ²Health and Medical Technology College, Middle Technical University, Baghdad, Iraq

ABSTRACT

Objective: Several preceding reports have indicated the association between vitamin-D levels and bronchial asthma. Nevertheless, a small number of studies in Iraq had concentrated on vitamin-D serum concentration in a such population. The presented study will examine the main association between bronchial asthma and vitamin-D levels in a randomized asthmatic individuals.

Method: Cross-sectional study included 61 asthmatic patients (26 females and 35 males) who attended Chest Diseases Department in AL-Zahraa Center (Baghdad) for Asthma and Allergy between August 2017 and April 2018, their ages ranged from 6 to 18 years. All subjects were submitted to estimation some of anthropometric measurements including; body mass index (BMI), full medical history, routine laboratory investigations and clinical examination by qualified physician, serum samples of the participants had been analyzed using ELISA for IgE level and ELFA for vitamin-D levels.

Results: Asthmatic participants revealed a significant difference (p<0.05) between levels of vitamin-D according to the genders, both IgE and vitamin-D reflected a significant difference (p< 0.05) among all the four BMI scales that had been used in the recent study and high significant relation of the vitamin-D deficiency with IgE levels among the asthmatic participants (p< 0.001).

Conclusion: Our recent outcomes indicated that there was a vitamin-D deficiency in Iraqi asthmatics patients. Furthermore, deficiency of vitamin-D has been related with elevated abnormal IgE level among asthmatic subjects. So, serum vitamin-D level in asthmatic patients should be surveillance constantly.

Keywords: Asthma, Immunoglobulin-E, Vitamin-D

Introduction

Highly occurrence of asthma and allergic diseases draws a considerable deal of worry¹. There are a lot of impacts related to vitamin-D on innate immune system and the adaptive immune system which could be useful in the primary protection from asthma, modulation of the severity of asthma exacerbations, and reduction or protection against asthma morbidity. Vitamin-D deficiency is detected more and more in general population, and it is mainly based on behavioral, lifestyle and dietary changes.

A novel of studies is firmly established of asthma relates to subnormal of vitamin-D levels. The immune system is very complicated with multiple interfering pathways of vitamin-D as a contributor to the outcome of immune responses in asthmatic patients.²,³ Furthermore, the effect of vitamin-D on airway epithelium, immune cells, bronchial smooth muscles is vital to the asthma pathogenesis.³ Through inhibiting Th17 production or vitamin-D prevent asthma exacerbations as an effective modulator related to the immune system.⁴,⁵ By regulating immune cells differentiation and proliferation.⁶ There is an assumption that vitamin-D change the release of smooth muscle’s chemokine’s in airways via inhibiting the expression of steroid resistant gene. Yet, the assumption has not been proved.⁷ Previous studies indicated that kids experiencing mild to moderate asthma with low vitamin-D concentration had more exacerbations.

DOI Number: 10.5958/0976-5506.2019.02187.9
with less asthma control. With low lung functions, more hospitalizations in past year, decreased response to inhaled corticosteroids (ICS), and thus, increased use of ICS. Furthermore, vitamin-D is inversely related with increased airway response to glucocorticosteroids and airway remodeling. Our suggestion is that the patients who experience asthma might have low vitamin-D levels which could be a risk factor and no more details regarding the impact of seriousness of Vit.D insufficiency in patients experiencing asthma. The main goal of the current study was to explore the possible relation among critical deficiency of vitamin-D, BMI and IgE with patients experiencing asthma in Iraqi patients.

Materials and Method

Participants and Study Design: Cross-sectional, study has been performed in AL-Zahraa Center for Asthma and Allergy/Baghdad, Iraq. The study was conducted between August 2017 to April 2018, which consisted of 61 patients experiencing asthma (26 females and 35 males) who have been admitted to Chest Diseases Department.

Questionnaire was set to evaluate the bronchial asthma medical history, anthropometric measurements that involved BMI, height (cm) and weight (kg) by qualified physician for each patient. A local Ethical Committee reviewed and approved the study.

Measurement of IgE and vitamin-D serum levels: Briefly, venous blood sample had been taken from all subjects and centrifuged for collecting sera. All samples tested for serum IgE by the following of manufacturer instructions of commercial enzyme linked immunosorbent assay of (Demeditec Diagnostics GmbH. Germany) with standard range: 5–1000 IU/ml, and serum vitamin-D by the following the instructions manual of enzyme linked fluorescent assay of (BioMerieux. France) using minividas instrument with range: less than (20ng) and more than (100ng).

Statistical Analysis: Chi-squared test was used to assess the association with qualitative variables. Fisher exact was used when Chi –squared test was not suitable. The differences between observations have been significant at p ≤ 0.05.

Results

In table 1, a summarization will be presented regarding the major demographic characteristics related to the participants of the study, stratified vitamin-D levels based on gender. (78.68%) with deficient Vit.D between genders with significant difference (p = 0.04). In contrast, IgE levels had been detected with insignificant difference (p = 0.069).

Discussion

The current study examined the acuteness of vitamin-D inadequacy. The results indicated that very severe deficiency of vitamin-D in all the subjects were 6.6% and 37.7% as sever vitamin-D deficiency. While, 32.8% (optimal), and 6.6% (normal).

Communication between the hereditary elements and nature of the general population causing the noticeable irritation in air ducts (12,13). Different elements could be had diverse effects for example; allergens, foods, indoor allergens, such as creature allergens, growths, bugs, or open-air regular allergens (dust of trees, grass, and so forth.); synthetic substances; ozone (O3); tobacco smoke; paints; cold air; climatic changes in temperature and barometric weight; lack of hydration; work out; air quality; cold and warmth (14). As referenced, the consequences of the current study have been unmistakably affirmed the connection between asthma and deficiency of vitamin-D. In clarifying discoveries, vitamin-D function in the keeping up the homeostasis related to impact of connection between serum dimensions of vitamin-D with asthma.

Furthermore, there is a suggestion that vitamin-D immunologically interferes with separation and multiplication of B & T cells and keeps emission of immunoglobulins or anti-inflammatory cytokines (14-19). Accordingly, vitamin-D demonstrate sort of inflammatory and immunomodulatory property like in a study which demonstrated that vitamin-D supplementations decreases aggravation of air channels and activation route of high responsive in murine model.
of susceptible asthma, study revealed; inadequacy of vitamin-D connected with less blood T-regs, expanded proinflammatory cytokines, high bronchoalveolar lavage liquid eosinophilia and decreased BALF interleukin 10 levels in lung tissue. In a different study for assessing the impact of vitamin-D intake on neutrophilic and eosinophilic activation route aggravation in patients experiencing non-atopic asthma demonstrated that Vitamin-D lessens eosinophilic aggravation of air ducts and could be useful in treating asthma. In addition to, study demonstrated that vitamin-D has effect onto the airway renovating. Possibly, via expanded sensitivity to corticosteroids drugs, then vitamin-D will decline the eosinophilic aggravation of airway inflammation. Regarding to these issues, different studies demonstrated that the insufficiency of vitamin-D expands the danger of airway hyperreactivity and decreases lung work.

Commonly, the inadequacy of vitamin-D on the planet is epidemiologically pervasive, also high predominance exists in territories with bottomless sun introduction; by taking vitamin-D level of less than (20 ng/ml) as lack of vitamin-D, a study revealed a percentage of inadequacy of vitamin-D in American newborn children/toddlers. Another research in USA indicated the rates of vitamin-D inadequacy and vitamin-D lack in individuals of age between (0 – 21 years) have been accounted for (21%) and (28%), respectively. Iranian, matched results with current study which has been directed with the point of inspecting the insufficiency of vitamin-D in kids of age between (9-12 years) demonstrated that 72.4% contemplated kids experiencing deficiency of vitamin-D.

In this study, highly significant relation has been seen between the IgE serum levels with vitamin-D deficiency. It appears that the connection between vitamin-D and hypersensitive marker (IgE) is autonomous from other powerful factors such as; BMI and genders. A study founded the connection between vitamin-D and indicators of childhood asthma in more than 600 teenagers in Costa Rica. In multiple linear regression study, the outcomes demonstrated an invert and critical connection between IgE levels and vitamin-D. However, a study shows no distinction has been spotted between deficiency of vitamin-D with IgE level. Small sample size was one of the restrictions of the current study, our hypothesis needs further investigation studies to establish the association between the studied biomarkers in asthmatic patients.

The results of the current research propose that serum vitamin-D level of patients experiencing asthma did not follow a typical range. So that, serum vitamin-D level in patients experiencing asthma should be examined constantly.

Micro RNA 141 as a Biomarker for Ovarian Cancer

Thaer Ali Hussein

Southern Technical University, Thi-Qar, Iraq

ABSTRACT

Ovarian cancer, especially ovarian carcinoma, is a very dangerous form of cancers that affected women and causes severe losses among them. The microRNAs or (miRNAs) are RNA transcripts class that commonly consisted in its length from ~19–22 nucleotides. Those nucleotides altered the miRNA pattern that is responsible for its pathological conditions. The highly stable transcripts are miRNAs-141. Those transcripts are observed from formalin-fixed paraffin-embedded (FFPE). FFPE samples are used to identify microRNAs-141. They are usually used for the purpose of diagnosis and detection of tumors, especially for detection of a very severe malignant tumor, the ovarian cancer. This study was designed for evaluation of the role of miRNA-141 and the importance of miRNA-141 patterns in FFPE samples. Those patterns were obtained from the patients suffered from ovarian cancer. The PCR-array technology was also used for the detection and the comparison of the miRNA-141 differential expression pattern of ovarian cancer. This study concluded that, the miRNA-141 can be used effectively and successfully for predication and detection of the ovarian cancer that facilitated its treatment and curing.

Keywords: microRNAs-141-Ovarian cancer- Formalin-fixed paraffin-embedded (FFPE).

Introduction

Ovarian cancer (epithelial carcinoma) considered as the major and dangerous cancers that affecting women health and its life. The mortality rate of ovarian cancer considered as the highest percent in all gynecological cancers of malignant characters, and its prognosis is commonly poor in its characters (1).

The study conducted by (Zou et al., (17) concluded that the drug resistant was related to microRNA microarray dataset GS54665. The mRNA dataset were obtained from the Gene Expression Omnibus database that involved GSE33482, GSE28646, and GSE15372. The screening of dysregulation of microRNAs was with GEO2R. By real-time quantitative PCR (qRT-PCR), they further obtained in A2780 (A2780/DDP) and SKOV3 (SKOV3/DDP) cells. The drug resistant were associated and analyzed through comprehensive bioinformatics analyses. The differentially expressed microRNAs (microRNA-141) in drug-resistant ovarian cancer cells reached to 10 fragments.

Another study conducted by Keller et al. (8) on microRNA-141. They reported that microRNA-141 altogether involved in the drug resistance regulation in ovarian cancer. They further reported that the nine microRNAs and thirty-eight genes identified numerous signaling pathways related to drug resistant from the annulation of the biological process together with pathway enrichment analysis. A relationship of regulatory between the nine microRNAs and nearly all thirty eight genes was also revealed from the interaction of microRNA-mRNA. By qRT-PCR in SKOV3/DDP and A2780/DDP cells, the expression of nine microRNAs and seven genes indicated consistency in expression profile with the microarrays. Among those, the PI15 and EPHA7 expressions were inversely related with the expressions of microRNA-141, as well as acknowledged as essential targets of microRNA and microRNA-mRNA interaction.

The main method which is currently used for the treatment of ovarian cancer is the surgical interference. This treatment is considered as the primary treatment because it is supplemented with chemotherapy that is delivered to the patient. Platinum-based combination chemotherapy improves many things in women suffering from ovarian cancer i.e. the overall response, clinical relevant, and survival rates. The multiple drug resistance (MDR) primarily considered as the main problem in clinical practice that obstruct the medical treatment of ovarian cancer (11).
Recently, by the using of bioinformatics approaches like biochip data extraction, visual mapping, biological data clustering, promoter prediction, sequence alignment, statistical analysis and pathway analysis, the data about the molecular level can be identified. For examining the molecular pathogenesis of several diseases as well as tumor, several research ideas were provided by those analyses. For example, Yin et al. (16) identified 25 genes through a comprehensive bioinformatics analysis. Those genes (including AKT1/2D) were linked to drug resistance in ovarian cancer. In the research, microarray data detailing microRNA expression profiles and the messenger RNA (mRNA) in drug-sensitivity and drug-resistance which were used in the treatment of ovarian cancer. The ovarian cells of cancer were extracted from the Gene Expression Omnibus (GEO) database (3). The data was analyzed to differentiate the gene expression and microRNAs associations. In the drug-resistant or drug-sensitive against ovarian cancer, the correlation between differentially expressed genes and microRNAs usually investigated by a comprehensive bioinformatics analysis that, included biological enrichment pathway, biological annotation, mRNA-microRNA interaction analysis and differentiation and protein-gene interaction analysis.

The postoperative chemotherapy was considered as the main method for full ovarian cancer treatment. On the other hand, the multiple drug resistance process was considered as the main reason for the failure of the treatment of chemotherapy and curing of ovarian cancer (5).

Previous studies have shown that factors, including differential expression of microRNAs, genes, and microRNA-controlled were linked to the multiple drug resistance in ovarian cancer (4 and 15). The screening, identification of the microRNAs and investigating the relationships between microRNAs differentially expressed and the genes may throw the light on the molecular mechanisms and guide the clinicians by choosing the type of drug treatment protocol and prognosis (9).

By using qRT-PCR, Zou et al. (2015) defined 9 differently expressed microRNAs. They noticed that the microRNA-18b, microRNA199a-3p, microRNA-335, microRNA199a-5p, microRNA199b-3p, microRNA-645, and microRNA-141 expression during analysis in A2780/DDP and SKOV3/DDP cells have similar results as that of microRNA chip obtained by (Yin et al., 16).

Braicuet al. (2), reported that, through MicroRNA-141 regulation and adjustment of Kelch-like ECH-associated protein 1 (KEAP1), microRNA was responsible for adjustment of the drug resistance in treatment of ovarian cancer.

The microRNA-141 and the gene characters can be predicted as the regulatory negative correlations between each other. 2780 ovarian cancer cells were predicted by the microRNA-141 which was characterized by its highly positive expression in drug-resistant. The MicroRNA-mRNA interaction analysis explained that, the potent target genes of microRNA-141 were EPHA7 and PI15. Additionally, the study conducted by (Muresanet al., 13), reported that regulation and adjustment of the drug resistance in treatment of ovarian cancer was significantly associated to the microRNA-141.

Therefore, the objective of the current study was to assess the role of miRNA-141 as a biomarker to identify the ovarian cancer, especially in ovarian carcinoma and dealing with it.

**Method and Materials**

**Study Design and patients:** The present study constituted a multiple stage design, retrospective, nested case-control study for the determination of the serum miRNA levels that either they may be used for predicting EOC development. The patients were separated into screened, trained, as well as validated sets. Total of 100 samples of plasma were included from which 60 were affected cases and 40 were controls.

All the EOC patients exposed to histopathological diagnosis with primary ovarian cancer. The patients included in the current study did not receive chemotherapy or radiotherapy before obtaining the blood sample.

Before surgery, blood samples were obtained from the patients. The patients as well as the controls that were genetically unrelated and free from digestive, respiratory, cardiovascular, reproductive, urinary, and endocrine diseases were included in the present study. On the other hand, the individuals who suffer from those diseases were excluded from the study.

In this study, the protocol was according to the ethics of Center review committees. From all the participants, informed consent was taken. Personal interview was conducted with each participant and informed them. The pre-tested questionnaires were used to get the information about demographic, menstrual history,
reproductive history, family history of cancer, women life style, and environmental exposure. After that, about 3-ml sample of blood was taken from each control and women with disease.

By the use of quantitative reverse transcription-polymerase chain reaction (qRT-PCR), the miRNAs identified in the screening set were examined on the sample of 60 EOC patients and 40 normal controls.

The collection of blood in anticoagulant EDTA tubes was done. The blood then further proceeded for isolation of plasma. At air temperature, blood was centrifuged at 1200 g for 10 minutes. After the centrifugation of blood, the supernatant plasma transferred into another fresh tube. At −80°C, that supernatant plasma was reserved. From all the plasma samples, RNA was separated.

Briefly, 250 µl of plasma was melted and rotated for removing lymphocytes at 14000 g at 4°C for 10 minutes. After that, lyse 200 µl of supernatant fluid.

For screening ovarian cancer biomarker, the plasma pools were used. Samples of pools were created by joining 100 µl of ten samples. At 14000 g, the pool was mixed and rotated for 10 minutes. For RNA isolation, supernatant fluid of about 1 ml was transferred to another tube. 5 µl of 25 fmol synthetic Caenorhabditis elegans miRNA cel-miR-39 was joined to denature every sample for normalization.

MiRNeasy Mini (Qiagen) following the manufacturer’s protocol was used to isolate the RNA. Besides that, in pre-heated 30 µl free of nuclease water, RNA was eluted.

By using TLDA, MiRNA expression of sample of pool was described. The TaqMan miRNA reverse the TaqMan miRNA multiplex RT assaysand transcription kit. Human Pool Set were used for reverse transcription of RNA. Plasma RNA solution of about 9.16 µl was transcribed in RT mixture of about 15 µl. At 16°C, the tubes were incubated for 30 minutes, and then further incubated for 30 minutes at 42°C, following for 5 minutes at 85°C. Before using the TLDA, the TaqManPreAmp master mix kit (Applied Biosystems) increased the number of cDNA obtained for analysis.

By using 15µl final reaction volume the triplicate wells were measured with the following series i.e. at 95°C for 10 minutes, followed by 50 cycles for 15 seconds at 95°C and for 1 minute at 60°C. To compute the relative differences in expression by the method of 2−ΔΔCt having confidence of 95%, the 7900 Sequence Detection System 2.4 software defaults were applied.

Statistical Analysis

The statistical analysis was done on a software i.e. SPSSPC+-version 24. The Independent Sample t-test was applied to measure the control and affected group differences. All statistical tests were two-sided. A P value of <0.05 was regarded as significant.

Results

Patient Characteristics: The samples included in this study reached to 100 plasma samples (60 cases of patient women and 40 control women), the clinical and demographic characters of them were obtained about the women used in the samples and all historical characters were obtained that useful in the diagnosis and useful in the identification of the role miRNA-141 (Table, 1).

Evaluation of miRNA-141 relative expression in ovarian cancer: 10 ovarian cancer tissue samples and 5 normal ovarian tissue samples by using macro dissected specimens were used. The ovarian cancer patients’ average age was 59.55 ± 3.34 years, whereas, the age of control group was 62 ± 4.49 years.

* = Significant at (P < 0.05).

In the current study, the first step was to do a comparative analysis of miRNA based on method of ΔΔCt for ovarian cancer tissue and normal control
women. The interest on miRNAs as a cut-off level had 1.5-fold expression difference and a P-value of <0.05 in tissue of ovarian cancer. Ten miRNAs differentially expressed (4 over-expressed and 6 down-regulated).

By using interpretative program Ingenuity Pathway Analysis (IPA), the expression of miRNA proved as statistically significant, that lead to sum up the biological significance and identification of miRNAs and their related target gene interaction.

**qRT-PCR data validation:** MiR-141 had an expression level in ovarian cancer of 203.1 ± 275 for good sensitivity and specificity. The miR-141 proved as excessive expression in ovarian cancer patients. As compared to the other types of cancer, the level of expression was greater in ovarian cancer. The Fold change of ovarian cancer was 26.19 ± 30.59. In findings, the PCR-array data agreement was significant. The value of 0.84 AUC for ovarian cancer patients was revealed by ROC curves of miR-141.

**Discussion**

The present study revealed that, the miRNAs were responsible for the expression in ovarian cancer vs. normal tissue. They were also responsible to identify the differentially expressed miRNAs in ovarian cancer. The miRNAs were also used for prognostic and diagnostic markers, as well as for predicting ovarian cancers and its severity level. They emphasized the functional differences, used to regulate the incidences of ovarian cancers. The pattern of miRNA expression might differentiate and distributed from the incidences of endometriosis from normal tissue. The detection, analysis of the miRNAs and altered pattern of expression were included in malignant incidences and transformation. By qRT-PCR validated miRNAs, the sensitivity and specificity were noticed. The panels of miRNAs may take into account for potential usage as markers of prognosis and diagnosis. Especially used for ovarian cancers and procedures of surgery (7).

In modulation and favoring proangiogenic mechanism, the ovarian-related miRNA had an important role to play. Therefore, in the selected pathologies, the miRNA can be taken into account as a prognostic as well as a therapeutic target. By angiogenic mechanism, those ovarian-related miRNAs were prone for activation. On ectopic sites, they can affect the implantation of endometrial cells (10).

Davis et al. (3) explained that, there was a high resistance for cisplatin with respect to the expression of miR-141. It was found to be in accordance with positive aberrancy of transcript ‘grade. In ovarian cancer, members of the miR-141 have also been identified. Those transcripts were proposed as biomarkers. The expression was correlated between tissue samples and its values from blood samples.

The cooperation and relationships between ovarian carcinoma remained a controversial issue, but it is sustained by miRNAs. Simultaneously, a particular miRNA signature was identified as capable discrimination between ovarian cancers. The findings lead the ground for further researches for the purpose of miRNAs role in endometriosis and malignancies (12).

The differentially expressed miRNAs-141 might play significant role in regulating functions of pathological processes which sustained cell proliferation. Now it is understandable that miRNAs played an essential part in pathology and can be linked to malignant transition of the ovarian cancer (6).

According to the panel of identified miRNAs, the dysregulated miRNAs discovery can perform as accurate biomarkers for the applications of diagnosis and prognosis. It also assesses the risk factors involved in the changing from benign to malignant (14).

The study demonstrated that differentially expressed miRNAs especially miRNA-141 contributed significantly in regulation of pathological processes that sustain cell proliferation of ovaries. The miRNAs-141 related to regulating the ovarian tumor. During ovarian cancer treatment, they can contribute to malignant transformation with its effect for drug resistance.

Experience of the Nurses on Family Involvement in the Care of Patients with Acute Coronary Syndrome (ACS) at the Intensive Cardiovascular Care Unit

Titin Andri Wihastuti, Septi Dewi Rachmawati, Ayu Wahyuni Lestari, Yulia Candra Lestari, Kumboyono Kumboyono

1School of Nursing, Medical Faculty, Brawijaya University; 2School of Nursing, Kendedes Institute of Health Sciences

ABSTRACT

Background: Family involvement in the Intensive Cardiovascular Care Unit (ICCU) is still controversial as it is a room with a high level of care. The policies of each hospital on this matter vary.

Objective: The purpose of this study is to explore the experience of the nurses on family involvement in the care of patients with Acute Coronary Syndrome (ACS) at the ICCU.

Method: This study is descriptive qualitative research with 24 participants (nurses) who have experience working in ICCU at least 1 year.

Results: This study results in finding of two themes: making a work environment crowded and interfering with the nursing activities.

Conclusions: Therefore, it is necessary to prepare a manual of family involvement procedures in the care of ACS patients in ICCU so as not to interrupt the treatment process.

Keywords: Acute Coronary Syndrome, Caregiver, Intensive Cardiovascular Care Unit, Nursing

Introduction

Acute coronary syndrome (ACS) is an ischemic heart disease and patients are treated in the Intensive Cardiovascular Care Unit (ICCU). Family involvement in ICCU can improve patient safety and satisfaction and is accepted in nursing practice in general.[1] However, family involvement in ICCU is still a controversy of every health service provider because it is a room with high levels of care, rigorous monitoring, and the use of complex medical procedures in the context of the health status of patients, a decrease is often experienced and things can go unpredictable. Based on a literature out of 892 screened articles, 124 article analyses are eligible and the results show 5 components of differences in patient and family involvement including attendance, support, communication, decision makers, and contribution to care.[2] Therefore, it is necessary to have an internationally relevant policy regarding the extent of family involvement in the ICCU in improving service quality in patients.

Patients in critical condition need moral support from the nearest person or family. Families in this context are defined as people who are intimately and routinely close to the patients throughout the process of nursing care. These people experience anxiety because of the entry of patients to critical areas and require support from the surrounding environment.[3] Based on research by family members play important roles in medical care in the Intensive Cardiovascular Care Unit (ICCU) as one of the most important progress units in the treatment of patients with Acute Coronary Syndrome.[4,5] The role

publikasikoe@gmail.com
of the family includes decision makers, intermediary communications between patients and health workers, and they also provide psychological safety for patients. Based on the research, there are 5 components of differences in patient and family involvement including attendance, support, communication, decision makers, and contribution to care. Patients believe the presence of family members will help to lower anxiety levels and increase comfort levels. Research by Neill says that the involvement of family members in critical patients in the intensive care unit can benefit patients and families where families will provide moral support to patients and help nurses provide holistic services with family-centeredness.

However, restrictions on family involvement and policy limiting ICCU visits encourage confidence that visitors can impede medical care and treatment, making patients exhausted, and may interfere with the treatment process or healing. This is consistent with the theory that there is a negative psychological effect on patients due to the presence of visitors as this increases risk of infection, unsafe working environment, and jeopardize the privacy of patients undergoing treatment at the ICCU. Given that patients treated at ICCU are high-risk patients and may experience a sudden change of condition. Critical care activities require specialized care and effective equipment and highly trained nurses, doctors, and other supporters.

The purpose of this study is to explore the experience of nurses on family involvement in the care of ACS patients in the ICCU. The benefits of this study are expected to be an evaluation material for hospital management in determining family involvement policy in the care of ACS patients in ICCU.

**Material and Method**

**Design of Study:** The design of the study is a descriptive qualitative.

**Population and Sample:** Participants in this study were 24 nurses working in the EDs general hospital in East Java Province, Indonesia. Participants were selected from population using purposive sampling approach based on inclusion criteria including having experience working in ED at least 1 year, having experience treating patients with ACS, and have followed Basic Cardiac Life Support and Intensive Care Nursing Training.

**Data Collection:** The study was conducted by a team of researchers led by a research nurse with high integrity and cardiovascular expertise. Prior to the data collection process, participants would get an explanation on the objectives, benefits, and research procedures. There was no relationship between researchers and participants. Researchers held 2 to 3 meetings, this was done as to ensure participants to share their experiences on family involvement in ACS patients in ICCU openly and honestly.

The researchers explored the nurses’ perception of the family involvement of the ACS patients in the ICCU through a semi-structured in-depth interview. The interview process was conducted face-to-face in the ICCU nurses’ room. Participants were interviewed one by one. Interviews lasted from 30-50 minutes per participant. Statements submitted by the participants were recorded into audio (MP3). The research results are kept anonymous and confidential.

**Data Analysis:** Interview data were analyzed manually using thematic methods, where one cannot proceed to the next phase without completing the previous stage. The stages are: a) familiarisation with the data, done by reading repeatedly the results of interviews; b) coding, executed by making categories of words considered important and answering research objectives; c) searching for themes, organizing categories according to their groups for subthemes and themes; d) reviewing themes, checking the suitability of themes and categories; e) defining and naming themes, defining themes for obtaining the main idea of each theme; and f) writing up, writing the results of research as a report after associated with the existing literature.

**Results**

Based on the results of interviews, two themes were identified: a crowded work environment and disruption to the nursing activities.

**A crowded work environment:** This is a condition where there are a lot of visitors causing the room to be full and crowded. This happens due to the non-compliance of visitors to policies or regulations that have been set by the room. This sub-theme has three sub-themes: many visitors, the violation of rules, and non-compliance to visiting time.

Participants state that a large number of visitors are caused by not obeying the rules submitted by nurses.
This usually makes nurses feel disturbed in the process of providing nursing services to patients. Increased number of visitors not only interfere with the activities of nurses but will disturb the comfort of nearby patients.

The question was, “what do you think about the patient’s visit to ICCU?”, and the answers from participants are as follows;

“...the rule seems a bit lost. We have told them that the patient can only have one visitor at a time, well yeah another one follows. As time goes by, there are too many people coming, too many are entering the room, so we have to remind them continuously...” [P3]

Participants state that families often violate the rules in the room although the nurses have repeatedly reminded them about the rules. Family members react differently to rules set in the room.

The question was, “according to your experience, what is the patient’s family attitude about the limitations of visitors in this room?”, and the answers from participants are as follows;

“...sometimes, when the patient is a health worker or the staff of the hospital itself, we find it difficult to remind the visitors that they can only visit the patient one by one, or the main family member, well yeah it is a bit problematic, we find it rather difficult to stick to the rules.” [P4]

“Well, some people just do not listen to what we say, to the rule. People are different. And yes, there are families disobeying the rules, no matter how many times we explain the rules, they keep breaking them.” [P5]

“we sometimes forget that there is one family that makes him feel uncomfortable, maybe because of a conflict or a problem, it’s one of the things that makes the patient uncomfortable, the patient looks calm but thinks his heart is still working hard” [P16]

Participants revealed that the nurses find it difficult to remind the family members to leave as soon as the visiting time is over. To make people obey the visiting time, the nurses often leave it to the security guards.

The question was, “What actions do you take to deal with a family that violates visiting rules?”, and the answers from participants are as follows;

“Yeah, it is rather difficult. After the visiting time is over, they simply do not want to leave the room. We just call the security guard, ask for help to remind the visitors to leave.” [P7]

Disruption to the Nursing Activities: This theme shows that nursing activities cannot be optimally done as there are too many people in the room. There are 2 sub-themes that describe the activities of nurses that cannot run optimally disrupt the actions performed and cause more stressors. Participants revealed that a large number of families can disrupt the actions performed by the nurses so services provided are not maximal and this has an impact on the patients’ healing process.

The question was, “what impact did you feel due to too many patient family visits?”, and the answers from participants are as follows;

“We have many tasks to do, and there are many family members around, we just find hard to perform the actions needed.” [P4]

“more stressors in the ICCU than in the treatment room, here the stressors are sometimes from colleagues, our doctors, patients, and their families” [P24]

Discussion

The results show that many family members present in the ICCU can disrupt the activities of the nurses making them find it hard to perform their duties optimally. Given that the ICCU is a room that requires high maintenance and is accompanied by numerous measures and highly complex medical equipment to support patient care, and that patients treated at ICCU are high-risk patients and may experience a sudden change of condition, this situation must be avoided.

The intensive care unit is a specially designed and fully furnished facility with experts to provide effective and safe care for life-threatening patients or possibly life-threatening health problems. Critical care activities require special care and effective equipment and highly trained nurses, doctors, and supporters. The number of actions and equipment installed in the ICCU accompanied by the visit of family members caused the room to become crowded so the nurses could not provide optimal service. The duty of nurses is not easy because they are dealing with many parties, both patients and their families; thus, their job requires not only skill but also high patience in facing all kinds of situations and conditions.
The environment and situation in the ICU are certainly very different from the usual treatment room. Four informants stated that the family members’ disobedience greatly disturbs the activity. Patience is needed in the communication between the nurses and the patients’ family considering the nurses are directly related to them. Nurse work is not easy because they must be able to control emotion even when the patients’ family members shout at them. Nurses are required to always be professional in any situation and condition including facing complaints from both patients and family members.

The results show that families often violate the visiting time. The disobedience of family members and relatives during the visit results in a negative interaction between the nurses and the family members. The nurses complain that visits made by family members outside the visiting hours interfere with their work, other patients, and threaten patients’ privacy. Thus, it is necessary to limit the involvement of the family and the policy to limit the ICU visit is based on the belief that visitors may hinder the care and medical treatment as well as making patients fatigue which finally may affect the healing process. This is consistent with the theory that there is a negative psychological effect towards patients on the presence of visitors as it increases the risk of infection, leads to an unsafe working environment, and jeopardizes the privacy of patients undergoing treatment at the ICU.

This study, however, contradicts research stating that family members’ involvement in critical patients in the intensive care unit can benefit patients and families where families will provide moral support to patients and assist nurses in providing holistic, family-oriented care. Family members play important roles in the medical care of patients in the ICU. This role includes acting as an alternative caregiver, meeting patients’ wishes, assessing the suffering of patients, as an informant in communicating between patients and physicians, and a source of hope and comfort. Because of the key family role in patient assessment, support, and decision making, providing family-centered care is a key component in providing patient-centered care.

In the research, two important sub-themes have been found that family involvement in the ICU makes the room crowded and interrupted the activities of the nurses. However, the role of the family in involvement in the ICU is needed in the case of decision makers, as an informant in communicating between patients and health personnel, as well as providing moral support to patients. Family involvement must be tailored to the conditions and situations in the ICU room and the patients’ condition so as not to interfere with the activities of the nurses. It is hoped that there will be guidance on family involvement in the ICU and future research is expected to examine the extent to which family members are involved in intensive care to improve optimal services in patients with Acute Coronary syndrome treated at the ICU.

Source of Funding: The researchers would like to thank the Medical Faculty of Brawijaya University who has funded this research.

Conflict of Interest: The authors declare they have no competing interests

Ethics Approval and Consent to Participate: This study has obtained the approval of ethics from Medical Faculty, Brawijaya University, Number 216/EC/KEPK/06/2017.

ABSTRACT

Indonesia’s territory is in a condition with a high risk of natural disasters. On average every day five disasters occur in Indonesia. Disaster is a phenomenon that can appear anywhere, anytime, and to anyone with a sudden process of occurrence. Reducing the impact of disasters requires preparation through disaster management activities in the pre-disaster phase. Nurses have a big role in the pre-disaster phase to reduce the risk of health problems caused by disasters. This study aimed to know the relationship between experience and training with nurses’ knowledge in the pre-disaster phase. This study used cross-sectional. The population of this study was nurses in Ngudi Waluyo Hospital Blitar, East Java, Indonesia. 152 respondents were selected using a simple random sampling technique. Data was collected for 2 weeks after using a questionnaire. The collected data of this study were analyzed using Chi-Square (α = 0.05) with SPSS 20 program. There was no significant relationship between experience and knowledge (α = 0.121) but there was a significant relationship between training and knowledge (α = 0.00). Training is very important to ensure the readiness of individuals ready to face disasters

Keywords: experience, training, knowledge, nurses, pre-disaster phase

Introduction

The territory of Indonesia is in a condition with a high risk of natural disasters. The level of disasters in Indonesia is very high, with 1,500-2,000 times per year recorded. There were 1,967 disasters in 2014 and 1,582 disasters in 2015 in Indonesia. On average every day a disaster occurred in Indonesia.1. Disaster is a phenomenon that can appear anywhere, anytime, and to anyone with a sudden occurrence process. It can result in fatalities, environmental damage, property losses and psychological impacts.3. Reducing the impact of disasters requires preparation through disaster management activities in the pre-disaster phase. According activities in pre-disaster are aimed at reducing the impact of preventive disasters, namely the ability to avoid and prevent disasters, and to reduce the impact of disasters4.

Critical facilities including community health centers must be able to protect affected communities and disaster victims, especially when the disaster response phase occurs. The hospital will be the last destination in the process of handling victims so that hospitals are expected to be able to make good preparations. Nurses have a big role in the pre-disaster phase to reduce the risk of health problems caused by disasters. Nurses are expected to have the ability to provide disaster management servants at all stages starting from pre-disaster (mitigation and preparedness), emergency response (response) and post-disaster (rehabilitation) through nursing activities, implementing programs from the government and coordinating with parties related to disaster management. The series of activities carried out by nurses in disasters are in accordance with their role, namely nursing care providers, disaster preparedness educators, coordinators and developers of disaster management programs as well as researchers5.

Research in Hong Kong with a sample of 164 Register Nurse (RN) explained to support nurses’ abilities in disaster management activities, needed competencies that must be fulfilled by nurses, namely: First aid, Basic Life Support (BCLS), Advanced Cardiovascular Life Support (ACLS), infection control, field triage, pre-hospital trauma life support, advanced trauma care nursing, post-traumatic psychological care, and peri-trauma counseling. Competencies that must be possessed by nurses according to ICN & WHO (2009) are competency as first medical responder, direct care provider, care coordinator, information center and educator, mental health consultant and triage officer. In more detail ICN & WHO divides nurse competencies in disasters into four classifications, namely mitigation competencies (prevention), preparedness competencies (preparedness), response competencies (disaster response) and recovery and rehabilitation competencies.

Current conditions in the field show that nurses’ knowledge about disaster management is still lacking starting from knowledge about disaster preparedness, disaster response and recovery after disasters. This study aimed to know the relationship between experience and training with nurses’ knowledge in the pre-disaster phase.

Method and Material

The method used in this study was cross-sectional design. The research was conducted in February 2019 at Ngudi Waluyo Hospital at Blitar East Java, Indonesia. The population in this study were 152 nurses were selected using simple random sampling technique with inclusion criteria: nurses who are registered as employees of Ngudi Waluyo Hospital at Blitar and willing to be a research respondent.

The research instrument used a knowledge questionnaire of 20 questions. Validity and reliability test of questionnaire were conducted involving 20 respondents with the same characteristics as the research subject. Validity and reliability test are indicated by corrected item-total correlation > r table (0.3809) and Cronbach’s alpha value of 0.901. The data were tested by the Chi-Square test and statistical analysis was carried out using the SPSS 20 program.

Results

Table 1: Characteristics of respondents by age and gender (N:152)

</table>

Table 6 shows the relationship between training about disasters and knowledge competence in the pre-disaster phase of nurses at Ngudi Waluyo Hospital at Blitar. The result of Chi-Square test showed that p = 0.000 (p-value <0.05), it can be concluded that there is a difference in the proportion of knowledge competency in the pre-disaster phase of nurses between respondents never with those who have attended disaster training (there was a significant relationship between disaster training and knowledge competency in the pre-disaster phase of nurses).

Finding

a. The relationship between experience in disasters and knowledge competence in the pre-disaster phase of nurses at Ngudi Waluyo Hospital at Blitar: The results of the statistical test of the relationship between experience variables in disasters and knowledge competencies obtained p = 0.121 (α <0.05) with a value of r = 2.478. So it can be concluded that there was no significant relationship between experience in disasters and knowledge competencies in the pre-disaster phase of nurses at Ngudi Waluyo Wlingi Hospital. In the study that entered the category of good knowledge for respondents who had experience in disasters amounted to 11 respondents (61.1%) out of a total of 18 respondents, while those who did not have experience in disasters amounted to 52 respondents (38.8%) of a total of 134 respondents. Only a small percentage of nurses have been directly involved in disaster activities.
Experience according to Notoadmojo (2012) is included in factors that influence knowledge. Xu & Zeng (2016) mentioned that nurses who have participated in the rescue process in disasters have gained adequate experience and good psychological endurance. Nurses are able to understand the characteristics of activities that must be carried out in the rescue process. So that the relevant knowledge and skills of nurses are able to increase capacity in disaster nursing. Knowledge and skills to increase the capacity of disaster nursing. Li & Zang (2013) stated that the process of rescuing on the ground during a disaster can increase awareness of the importance of improving one’s abilities in rescue activities to increase their awareness and motivation to learn.

Tzeng et al. (2016) revealed that nurses who work in emergency and critical care units have good capture and response in disaster management. This shows that nurses who work in an emergency have response experiences and self-confidence in managing crisis situations such as disaster situations but Martono et al (2018) in the study stated that experience is not significantly related to nurses’ knowledge in disaster management.

b. The relationship between training about disasters and knowledge competence in the pre-disaster phase of nurses at Ngudi Waluyo Hospital at Blitar: The results of the statistical test of the relationship between training and competency variables of knowledge obtained a value of \( p = 0.000 \) (\( \alpha <0.05 \)) with a value of \( r = 11.852 \). So it can be concluded that there was a significant relationship between disaster training with competence (knowledge) in the pre-disaster phase of nurses at Ngudi Waluyo Wingi Hospital. In the study included in the category of good knowledge for respondents who had attended disaster training amounted to 36 respondents (80%) of a total of 45 respondents, while those who had never attended disaster training amounted to 27 respondents (25.2%) out of a total of 107 respondents.

Training part of the education process and receiving information. Notoadmojo (2012) stated that education and information are factors that influence individual knowledge. The results of this study indicate that respondents with their last education S1 Nursing + Nurses have a better level of knowledge compared to respondents whose education is DIII/D4 Nursing. Training is one of the factors that influence knowledge because training is an implementation activity in the field. Training using the case simulation method can stimulate respondents to think critically and creatively so they can increase knowledge. The results of this study are comparable to Xu & Zeng (2016) that disaster training influences the competence of nurses in China about disaster preparedness. Alim et al. (2014) stated in the study that training and disaster simulation can improve nurses’ knowledge and abilities in disaster management.

Ahayalimudin & Osman (2016) from the results of his study revealed that training is very important to ensure the readiness of individuals ready to face disasters because there was a significant relationship between the presence of education/training participants and practices related to disaster management. Individuals who have attended disaster education or training and are directly involved in disaster response have good self-confidence and increased self-awareness regarding the importance of disaster management. Training creates readiness to manage the impact of disasters. It requires training facilities and provision of opportunities by health care authorities to enable emergency care and medical personnel to participate fully in training.

**Conclusion**

There was no relationship between experience in disasters and knowledge competencies and there is a relationship between disaster training and knowledge competencies. This finding proves that the training is one of the factors that can affect individual knowledge because training is an activity in the form of direct implementation in the field. It is recommended to do further research to investigate the knowledge, attitude and practice retention for nurses at hospital. Organizing training activities on training management can have a good influence on the level of knowledge for nurses. Nursing education institutions and related agencies responsible for disaster events so that they can organize disaster training activities for nurses in hospitals.

Outpatients’ Attendants Knowledge Regarding Antibiotics Use and Antibiotics Resistance in Al- Najaf Al-Ashraf City Health Institutions

Zaman Kareem Kadhim¹, Fatima Wanas Khudair²
¹B.Sc. Nursing, M.Sc. Nursing, ²B.Sc. Nursing, M.Sc. Nursing, PhD. Nursing, Asst. Prof, Community Health Nursing Department, Faculty of Nursing, University of Kufa

ABSTRACT

Antibiotics are important drugs that affect bacteria either kill or stop the growth of bacteria; appearance of the so called antibiotics resistance threatens its effectiveness on the therapeutic level. The level of knowledge regarding the antibiotics use and resistance of people provides them adequate protection against the risk of resistance whenever the assessment is good. The importance of the subject in Iraq invited us to choose this subject, which affects the lives of the human. This study focuses on assessing outpatients’ knowledge regarding antibiotics use and antibiotics resistance and the effect of some demographic variables and source of information on their knowledge. A descriptive design, survey study was carried out in al-Najaf City hospitals for the period from September 24th, 2018 to May 1st, 2019, nonprobability sampling technique convenience sample of 451 respondents. Questionnaire consists of socio-demographic information, and 34 questions for the knowledge of use, and resistance. The overall knowledge of outpatients’ knowledge was fair and affected by age, gender, educational level, occupational status, and residency of participants.

Keywords: outpatients’ attendants, knowledge, antibiotics use, antibiotics resistance.

Introduction

The entire world, antibiotics cannot be dispensed within the field of medicine and this is considered an evolutionary revolution. In medicine, especially in modern medicine, the treatment of bacterial infections is the basis of all other treatments, especially in surgery, internal medicine, chemotherapy, and others. Antibiotics used by most people without knowing the magnitude of the risk behind this use and the global public health problem. Appropriate and scientifically required antibiotics use, according to the known pharmacological policies of antibiotics which ensure better health and low costs for public health. Antibiotics resistance is most important global public health problems, which indicate that antibiotics are not affected by bacteria for several reasons, are the most important of which misuse, inappropriate use, and taking over-the-counter antibiotics. The challenges that affect the treatment of infections are the obvious causes of bacterial resistance to antibiotics, which in turn lead to the length of stay in the hospital (prolong stay), and the high rate of morbidity and mortality and also increase in cost to the individual, family, and community and also affect in one way or another Public Health System of the State.

Objectives of the Study:

1. To assess Outpatients level of knowledge concerning Antibiotics use and antibiotics resistance.

2. To find out the relationship between outpatients level of knowledge regarding antibiotics use and resistance and certain variables; age, gender, residency, marital status, monthly income, educational level, and sources of previous information, access the antibiotics, number of medical visits, and safely use of antibiotics.

Method

A descriptive design, survey study was carried out, to attain the stated objectives, during the period from September 24th, 2018 to May 1st, 2019. The study was conducted in the Najaf Health Directorate in four main hospitals in Al-Najaf AL-Ashraf City, Iraq.

Instrument of the Study: Questionnaire by interview, after reviewing literature related to antibiotics use and resistance. Used modified on an original instrument which that constructed previously (6) (7). The slight modification according to supervisor and expert’s direction to suit the study population. The questionnaire consists of first part, which deals with sociodemographic data, and second part, information about antibiotic. The third and fourth part deals with questions about knowledge consist of 34 questions.

The Statistical Analysis: The data of the (451) participants were entered and analyzed by means of the statistical package for social sciences (SPSS), V.23, 2015.

Findings

The total number of the studied group was 451 patients with a mean age of (32.7 ± 8.5) years range (20 - 65 years). About two-thirds, (63.4%), of them were married, more than one-third,(36.4%), of the participants had primary level of education. As for the occupation status, housewives represented (41.5%). Regarding the economic status, (53.4%), claimed it is sufficient to some extent. The distribution of the sources through which the participants got their knowledge, more than two-thirds participants (68.7%) got their knowledge from their friends, however, some patients showed overlapping in their source of information and got more than one source. The main source of antibiotics that the participants got was Pharmacies which was reported as a source by (69.2%) of participants, and other sources contributed in different rates. Majority of the study participants,(76.5%), claimed that they had number of medical visits during the year on need. When the participants asked about the easiest mode of administration of antibiotics, (41.9%) reported intravenous injection, intramuscular injection (IM) reported by (40.6%), while only (17.5%) said that oral mode of administration was the easiest way to take antibiotics,(Table 1)

The respondents’ assessment about antibiotic use and antibiotic resistance and overall means score revealed a fair overall knowledge, with a mean score of 1.71, (Table 2). Further distribution of the study participants according to their level of knowledge revealed that only (4.2%) had good knowledge, (31.5%) fair knowledge and (64.3%) had poor knowledge (Figure 1).

The analysis using cross-tabulation for the relationship between overall knowledge about antibiotics use and resistance and sources of information about antibiotics revealed a statistically significant association with source of information (P < 0.05). Patients who get their information from their friends had the lower knowledge score and majority of them had poor knowledge. More than one-third of the participants buy antibiotics from private pharmacies (34.4%) they had fair knowledge. About half of the participants visit the hospital or outpatient clinics when needed (49.2%) had poor knowledge. More than a quarter of respondents say that the easiest way to take antibiotics is IV injection (28.6%) are also poor class, (Table 4)

**Discussion**

Total questionnaires 470 respondents, 19 were excluded the total number of participants was 451. Samples were collected from January 6th, 2019 to March 21th, 2019.

The current study indicated that about a quarter of respondents at an average age of (27 years). This age may be more susceptibility due to a lot of work responsibility, this result similar to the study conducted by Mouhieddine et al. 2015.

Regarding gender, the current study indicates that males are more than females at 55.9%, which is different with most previous studies. Previous studies indicate that the percentage of females is higher than that of males. In residence, the current study indicates that urban participants 59.9% more than rural, this in our study is normal because of the sample taken from hospitals that are in the center of the city. A study conducted by Jifar and Ayele, 2018 is consistent with the current study.
Marital status in this study, about two-thirds of the respondents was married (63.4%). This result is normal in our study matched with age previously and this age is acceptable in our society for marriage. This result stated by another study that marrieds are the highest category of respondents.

Educational level of the participants in the current study, the educational level of respondents was more than one-third at the primary level (36.4%). The previous studies opposite of the current study can be interpreted by the social and economic conditions that surround led to a large segment of Iraqi society not complete study.

Occupational status of the participants, housewives being more than one-third (41.5%) may be the majority of female participants in the current study do not have an occupation because the time the sample was part of the official working most of the staff of the males and females was in their jobs. Previous studies differ from the current study by the occupational status, where the majority of respondents in the previous studies are from the employee class.

Economic status, the description in the current study that more than half of respondents said sufficient to some extent (53.4%) taking into consideration most of the Iraqi people are middle-class economic. A study conducted by You et al., 2008 supports the current study.

Results in the current study showed that the total assessment of knowledge related to the use of antibiotics poor and the mean of score (1.66). And Results in the current study showed that the total assessment of knowledge related to the resistance of antibiotics fair with mean of score (1.84).

Our results showed that the total assessment of knowledge related to the antibiotics use and resistance was fair with mean of score (1.71), Can be explained by a lack of health awareness about antibiotics and the seriousness of resistance to antibiotics as it is not included in the school curriculum. Our findings showed that there is a high significant between the overall level of knowledge about antibiotic use and resistance of age, educational level, occupational status, gender, and residency (P > 0.01).

Current results indicate that there is a high statistical significance between overall the level of knowledge about antibiotics use and resistance and sources of information about antibiotic (p>0.01).

Conclusion

The majority of outpatients who visit hospitals were male with age range 25-29 years. The participants’ overall knowledge of the antibiotics use and resistance was fair. This can be explained by the frequent visits to hospitals as well as the question between peers, which indicates that the study community has knowledge but there is a gap in application. The socio-demographic characteristics have a high statistical significance with the knowledge regarding antibiotics use and resistance except for the economic status. Maybe because of homogeneity the sufficiency to some extent is mostly on the sample and for this reason, it does not create a difference of about the same economic level almost.

The Prevalence of Serum and Seminal Fluid Antisperm Antibody in Couples with Unexplained Subfertility in Kirkuk City

Eman I Fathi¹, Salih Ibrahem²

¹Department of Obstetrics and Gynecology, ²Department of Biochemistry, College of Medicine, University of Kirkuk, Kirkuk, Iraq

ABSTRACT

Unexplained infertility occurs in many couples of reproductive ages; immune mechanisms have been postulated in this disorder for the last few decades. Antisperm Antibody (ASA) present in serum and seminal plasma has been implicated. Many researches have been devoted to studying autoantibody in males. However, too little attention has been paid in females. For this aim, 127 couples with unexplained infertility are involved in this case-control study. Enzyme-linked immuno-sorbent assay (ELISA) test is used to detect ASA in serum specimens of both male and female. The same technology is also applied for detecting ASAs in male seminal fluid qualitatively. The results demonstrate that 22.8% of infertile women with unexplained subfertility have IgG-ASA in their serum an. Furthermore, seminal fluid analysis is carried to their partner. Consequently, the results show that out of 127 male patients with unexplained infertility 56 male (44%) and 18 (14.1%) have positive ASA in the seminal fluid and their serum, respectively. Additionally, four couples have positive ASA in the blood of both partners, and two had positive ASA in the blood of the female partner and in the blood and semen of the male partner. Statistically, the outcomes demonstrate that the presence of ASA in the female is not associated with its positivity in the male partner seminal fluid or blood (P>0.05). Accordingly, the study concludes that other causes rather than autoimmune mechanism are more likely implicated in unexplained subfertility.

Keywords: Antisperm Antibody, infertility, serum specimens.

Introduction

Infertility is a worldwide couples issue arises at reproductive age, and it can be likely occurred in one out of five couples ¹. It is defined by World Health Organisation (WHO) as a concern of the reproductive system happens by the failure to get a clinical pregnancy after one year (or more) of regular unprotected sexual intercourse ². The most important cause of subfertility (especially in ageing patients) is bad quality of oocytes. It is important mentioning that it is hard to identify the quality of oocytes ³. Furthermore, in infertile couples, Immunological factors in the form of ASA are deemed as infertility cause in a considerable ratio ⁴,⁵.

The presence of ASA is firstly documented by Samuel Meaker in 1922 ⁶. More specifically, ASA is immunoglobulins of IgA, IgM and or IgG which are pointed the antigens od sperm. Additionally, it can be identified in cervical mucus, ejaculate, follicular fluid, and the serum of male and female partner or both of them ⁷. Furthermore, these antibodies can also occur in 4 % (1 to 2.5%) of fertile females (males). However, the occurrence of ASA in the fertile persons infers that not all ASA leads infertility ⁸. The risk factors of ASAs development in men consist of the breakdown of the trauma and surgery, blood-testis barrier and orchitis ⁹. Additionally, transtubal passage of sperms to the peritoneal cavity (which occurred after vaginal intercourse) may produce ASA formation through presentation and macrophage phagocytosis ¹⁰.

In the literature, ASAs act by capacitation, fertilisation, blocking sperm movement and prevention of implantation of embryos ¹¹. Furthermore, it has been proven that the development of ASAs is not affected by sexual practices ¹². Acrosin antibodies occur in the infertile female sera prevent sperm-zona pellucida binding through the activity of protease ¹³.

Aim: our aim is to find a correlation between unexplained subfertility and autoantibody in partners (for both female and male) with unexplained subfertility.
Patients and Method

A cross-sectional study carried out at the infertility centre at the Azadi teaching hospital in Kirkuk, Iraq during October 2016 - February 2018. Five hundred and thirty-one couples who attended the unit for primary or secondary infertility are included in this study and considered as Initial Study Population (ISP).

The female age of the ISP range from 19-4 year, while the male partners were from 19-60 years, a complete questioner form prepared for each person and included: name, age, date of marriage, occupation and both medical and surgical history. We applied previously set up strict criteria to define an infertile couple as have Unexplained Infertility. The couple who had no identifiable cause of infertility as proved by normal male seminal fluid analysis results and the female partner showed normal ovulation and patent bilateral tubes and uterus as confirmed by hormonal studies and ultrasound and hysterosalpingogram. In 2010, seminal fluid analysis and reporting were done for each male according to the WHO laboratory. Lastly, we excluded from this work those who did not match the above-mentioned criteria.

By applying our strict criteria, 127 patients met them and were our Final Study Population (FSP). ASA was assessed in the sera of both partners of the FSP using ELISA technology (Enzyme-Linked Immunosorbent Assay using Biotek® Machine) used for detection ASAs of the IgG type in the serum of both males and females. The same technology was applied for detection ASAs in male seminal fluid qualitatively.

Statistical analysis was done by SPSS Statistics for Windows, Version 22.0. Armonk, NY: IBM Corp. We used Chi-Square to study the correlation between the presence of ASA in male and female in different biological fluids. Finally, A P value of less than 0.05 was considered statistically significant.

Results

Our initial study population was composed of 531 couples who attended the fertility unit at Azdi teaching hospital in Kirkuk, Iraq, during the period October 2016 until February 2018. The females were 19-45 year while the males’ partner had a wider age range extending from 19-60 years (Table 1). Only 127 (23.9%) couples of the initial study population met the inclusion criteria and were eligible to be entitled as Final study population.

The remaining couples 404 had various pathologies either in the male 73 (18%) or female partners 149 (36.8%) or in both of them 182 (45%) as clarified in details in Table 2. Oligospermia was the most frequent cause of male infertility Figure 1. The spectrum of female pathologies was wide, and Polycystic Ovarian Syndrome (PCOS) was on the top of the list 81 (54%). An example of the ultrasonic features of PCOS is shown in Figure 2. Tubal pathologies came second 23 (15%), and hysterosalpingography (HSG) was our tool to identify them as shown in Figure 3.

As mentioned previously, our goal is to assess the role of immunology in unexplained infertility, of those 127 couples who were assigned as having unexplained infertility. The majority 98 (77.1%) of the female patients had negative ASA, while the remaining 29 (22.8%) of them had positive ASA in their blood as listed in Table 3.

As outlined in Table 4, 20 patients (68%) their age was more than 35, while distribution of male age among infertile couple, 8 (14.2%) patients their age were below 25 years. Additionally, 9 patients (16%) their age were between 25-34 years. Furthermore, 17 patients (30%) their age was 35-39 years, 14 patients (25%) their age was 40-45, and 8 patients (14.2%) their age was ≥ 45 years.

Discussion

The WHO has classified infertility as a global problem and distressing issue to both partners and their relatives. Yet, no conclusive results have been reached with regard to the prevalence of the angiosperms antibody and to what extent their presence jeopardises the fertility capacity. Most of the couples (>70%) who have sought consultation...
for the infertility problem were investigated for infertility and were found to have a pathological cause(s). This is a nearly consistent finding in all other studies despite geographical and demographic variations. PCOS is the main culprit in female infertility. This finding is not surprising that the high prevalence of this pathology at reproductive age group.

The percentage of unexplained infertility among infertile couples was about 23%, and this agrees well with other studies that found the incidence of unexplained infertility is in a range from 5-20% . It is well known that ASA can impair the fertility capacity of couples through different mechanisms such as damaging sperms transport. Additionally, it inhibits sperm penetration of the cervical mucus. This means more they jeopardise capacitation and acrosomal reaction.

It has been suggested that ASA may form in women because of a decrease of one or more immunosuppressive factors in her husband’s seminal fluid as sperm cells may possess protective mechanisms that inhibit immune reactions. However, there is no convincing evidence to aid this hypothesis. Additionally, the mechanism of ASA development in male still not very clear as some ASA are attached to the sperms or circulating in the serum. Therefore, the epididymis is likely to be the critical site of antibody generation, especially in the setting of obstruction. In the literature, several studies have found lower prevalence which reflects a trend toward an association between demographic factors and ASA formation. This might be explained on the bases that older age means more marital sexual exposure and possibility of more damage to the male sexual organs due to physical trauma or other types of damage such as caused by varicocele. Despite all the researchers that have been investigated on the relation between infertility and ASA presence, it is not clear that why some people with positive ASA are still fertile and had no consequence to these antibodies.

**Conclusion**

In this study, we studied the correlation between unexplained subfertility and autoantibody in partners (for both female and male) with unexplained subfertility. 127 couples with unexplained infertility are involved in this case-control study. The results showed that out of 127 male patients with unexplained infertility 56 male (44%) and 18 (14.1%) have positive ASA in the seminal fluid and their serum, respectively. Statistically, the outcomes demonstrated that the presence of ASA in the female is not associated with its positivity in the male partner seminal fluid or blood (P<0.05). Accordingly, we concluded that other causes rather than autoimmune mechanism are more likely implicated in unexplained subfertility.

Nevertheless, we admit that our study has some limitation such as not including fertile couple to see the prevalence of ASA. In addition, the study would have more informative if we treated those patients with immunosuppressive therapy and observed if a reduction in the concentration of the ASA would have resumed the fertility capacity of the couple. Thus we leave these questions for future work.

Description of Transformational Leadership of Head Room in the Provincial Hospital in Pariaman Padang Indonesia in 2018

Helmanis Suci¹, Yuliasri², Deswita³
¹Master of Nursing Faculty, ²Faculty of Economy, ³Faculty of Nursing, Andalas University Padang Indonesia

ABSTRACT

Data obtained from a hospital nurse turnover figures for the year 2017 by 4%. Turnover figures showed that the rate of retention of nurses in HOSPITALS Pariaman is quite high. Results of a study with nurses implementing obtained that level of involvement working nurses in HOSPITALS Pariaman is quite high, but the dimensions of work involvement includes vigor, dedication, and absorption showed different results. This research aims to look at the relationship with the head of the transformational leadership involvement of nurses in HOSPITALS work Pariaman Year 2018. This research is descriptive research analytical, cross sectional design. The sample numbered 105 nurses, taken using a purposive sampling technique. The chi square test results obtained there is transformational leadership relations head with the involvement of the nurse working with the implementing p-value = 0.000 with the OR = 8.735. The hospital is expected to sustain the transformational leadership style of head room and recommends implementing the nurse to continue her career so that further enhance the competencies and career nurse.

Keywords: Transformational Leadership Nursing, Involvement, Leadership.

INTRODUCTION

Marquis and Huston (2010) mention five management functions, namely planning (planning), organizing (organizing), workforce (staffing), direction (actuating), and control (controlling) (1). The fifth function is known as a management process. Some of the literature discusses workforce function (staffing) in more detail in the concept of human resource management (HR). Human resource management is the efficient use of human resources in the Organization through management functions (2). In human resource management (Human Relationship) has developed the concept of engagement work (work engagement) (3).

Work engagement is defined as a positive process of intrinsic motivation (4)and a satisfactory working condition related thoughts that are distinguished by three dimensions, namely strength (vigor), dedication ( dedication), and absorption (absorption) (4). Employees with involvement of interns were able to feel the pleasure, excitement, enthusiasm, physical and psychological health, improve performance, and being able to move their involvement to others (5). According to Mercure, Demerouti, Schreurs, Schaufeli & Bakker (2009), conceptualized as a State work involvement affective-motivational-related jobs that are characterized by strength, dedication and absorption. They define the dedication as the strong commitment and a sense of significance (sense of significance), enthusiastic, inspiration, pride, and challenges in the work. This study explores the work engagement among nurses (4).

In Taiwan, Wu (2010) studied the perceptions of nurses related engagement work. Wu found that nurses who have a work engagement feel happier and find the meaning of life through the process of patient care (6). Therefore it is necessary to grasp the dimensions of the sustainability of developing employees in the workplace. The results of the study showed that employees who develop shows better performance, where 32% of employees demonstrate high organizational commitment and 46% reported job satisfaction. In contrast, employees who did not develop tend to exhibit such negative psychological Burnout (burnout) and fatigue work (7).

Work involvement is a positive State of mind related work that includes the dimensions of spirit (vigour), dedication (dedication), and absorption (absorption) (4). Leadership is a key element in the operational organizations to perform management functions (8). Leadership is the process of influencing another person...
or a group to achieve a common goal (8). The role of leadership of head room as the Manager at the front lines is very important. Leadership places emphasis on increasing productivity by maximizing the effectiveness of work (1). Leadership is important in the nursing work environment as it has effect on the climate and work environment of the Organization (8).

Related research leadership is continuously performed for their ability to induce the employee to have motivation and engagement work (9). At this time the organization requires managers and leaders who are able to develop the level of commitment and enthusiasm of employees associated with the job showing the behavior and characteristics of such a charismatic personality, ability to affect others and had a vision of the future that will bring all resources to achieve the objectives of the organization. The leader is called transformational leaders (10). Transformational leaders are able to encourage employees to enhance the value of the Organization include higher productivity, service quality and solve social problems (11).

MATERIAL AND METHOD

This type of research is descriptive analytic method used is the approach of cross sectional. This research was conducted at the PROVINCIAL HOSPITAL of the city of Pariaman, West Sumatra. The sample in this research totalled 105 people nurse, taken using a purposive sampling technique with inclusion criteria: (1) implementing the PROVINCIAL HOSPITAL nurses all over the Pariaman, (2) implementing the Nurse not being off work and learning tasks, (3) managing Nurses who have served at least 12 months or not within its orientation, because the nurses have been able to identify the model of leadership of head room after interact within 1 year, (4) are willing to be the respondent.

RESULTS

Table 1: Distribution Characteristics of nurses Implementing based on Age, marital Status, and the Long work at the PROVINCIAL HOSPITAL in Pariaman April 2018 (n = 105)

<table>

</tr>
</tbody>
</table>

In table 2 illustrates the transformational leadership comprises four subvariable that is the dimension of the influence of idealism, inspirational motivation, intellectual stimulation and individual consideration. Based on the table can be known that more than half of nurses implementing transformational leadership said the head of the room good (59%), more than half the dimension of the influence of idealism (58.1%), more than half the dimension of the inspirational motivation good (53.3%), more than half the dimension of intellectual stimulation (57.1%) and more dimensional considerations individual good (50.5%) HOSPITALS in Pariaman.

DISCUSSION

Based on table 1, obtained by implementing the PROVINCIAL HOSPITAL nurse Pariaman more half aged ≥ 30 years (53.3%), more than half are married (60%) and more than half of nurses work long executor < 5 years (52.4%). The results of this research is also

Conted...
supported by research Fajri (2016) that more than half the age of nurses implementing the PROVINCIAL HOSPITAL in Pariaman > 36 years (62.2%). Based on this it can be concluded that the age of implementing existing nurses in hospitals are there in Indonesia are on different age categories.

Based on table 2 it can be noted that more than half of the nurse perceives the transformational leadership style of head room in the PROVINCIAL HOSPITAL in Pariaman is good (59%). From the research results obtained are also transformational dimension whereby the influence of both categories of idealism 58.1% good inspirational motivation, dimensions of 53.3%, dimensions of intellectual stimulation either of 57.1%, and the dimension of Eng. considerations iVIDU fine of 50.5%.

Employee performance can be enhanced through engagement work. Work engagement is positive energy in maintaining the sustainability performance of employees. Work engagement implies that employees will be focused, dedicated and energetic when they started working, which will improve its performance (4). This the engagement work potentially increase the success and competitiveness of an organization that is so needed at this time (12). Transformational leadership is a leader who gives consideration to its individual and intellectual stimulation, as well as having the charisma (13).

Based on the results of implementing questionnaire to the distribution of nurses in HOSPITALS Pariaman indicates that the dominant component is shown by the head of the room is a component of the influence of the idealism of 58.1%. The influence of ideal, also known as charismatic, where these attributes can be observed through the behavior of leaders in the form of confidence, strength, ethical, high standard exceeds the initiator. The manifestation of the charisma of the leaders in the form of values, beliefs, and the Mission in harmony with the objectives of the organization. Transformational leaders with influence often serves as the ideal role model because such leaders admired, trusted, and respected.

Based on the results of the questionnaire also obtained that the nurses say the style of transformational kepemimpinan Head Room either, it is evident that more than half of nurses (57.1%) says that the head of the room there is helping its members in solve problems that are there in the room and provide a solution if there is indeed a problem occurs. This typifies the Head has a high stimuliasi. With the stimulation of intellectual leaders of his creativity to stimulate thinking about the relevance of manner, value system, the trust hopes to mengahasilkan idea – the idea as well as a new innovation for the Betterment of the organization.

CONCLUSION

The multivariate results of individual consideration dimensions are most prominent in relation to nurses’ involvement. Hospital management need to maintain nurse unit manager’s transformational leadership style to increase nurse’s work engagement which are finally increase hospital outcomes.

Conflict of Interest: No conflict of interest arose in this study

The Influence of Application of Nursing of Spiritual Nursing to Patient Satisfaction in Regional General Hospital of Palembang and Regional General Hospital of Martapura

Aris Citra Wisuda¹, Meri Neherta², Ira Kusumawaty³

¹Master of Nursing Faculty of Nursing, ²Faculty of Nursing, Andalas University of Padang Indonesian; ³Polytechnic Ministry of Health Republic of Indonesia Province of South Sumatra Indonesia

ABSTRACT

Background: The application of religious nursing care can enhance the peace of mind and patient satisfaction
in care then speeding up the healing process.

Aim: this study aims to determine the effect of the application of spiritual nursing care to patient satisfaction.

Method: This research is a type of quasi experimental research through pretest-posttest design with control
group design with total sample 44 respondents. The sampling technique uses total sampling. Data were
analyzed by using T test. This study was conducted from June 2017 to May 2018. Place of study in the
inpatient room of public hospital Palembang BARI.

Results: this study obtained that age of the respondents are mostly age range 37-65 years (old age) that is
as much 72.7%, the education of the respondents is mostly low education that is as much 79.5%, for patient
satisfaction on pre test is known mostly dissatisfied as much 70.45% and at post test patient satisfaction
change that patient satisfy as much 72.7%. The result of T test is known that p value <0.05 is 0.000, it means
that there is influence of applying spiritual nursing care to patient satisfaction.

Conclusion: the influence of application spiritual nursing care to patient satisfaction.

Suggestion: it is hoped that the head of the hospital provides training to all nurses about spiritual nursing
care so as to improve patient satisfaction.

Keywords: Spiritual Nursing Care, Patient Satisfaction.

INTRODUCTION

Patient satisfaction is an absolute must be met by
every health or hospital service provider. The hospital
will survive if it is always oriented to patient satisfaction
¹. One indicator that supports patient satisfaction is
the optimal service in running care nursing. There is an
increasing tendency of nurse model trends that require
more professional nurses. One of them is holistic
caring with spiritual nursing care to be one part of the
implications of the nursing process ². In practice, nurses
should have an active role in providing spiritual nursing
care. The ability of nurses in applying spiritual nursing
care should be supported by optimal nursing knowledge.

Meeting the needs of spirituality is something that can
not be ignored. The need for spirituality has been proven to
give patients strength in the face of their illness ³. Patients
who are in a state of course need spiritual reinforcement
and assistance during the treatment, it takes the active
role of nurses in the fulfillment of the spiritual needs of
patients while in the hospital ⁴.

METHOD

Research Design: This research is a type of quasi
experimental research with the design used is pretest-
posttest with control group design, ie there are two
groups one as the control group and one as the
experimental group ⁵. Test of research analysis using
T test. The design of this study experimental group
received the intervention while in the control group did
not intervention. Before the experimental group was
given an intervention, a pre test was conducted in the experimental group and the control group to determine the initial capability. Furthermore, in the experimental group conducted intervention in accordance with the planned, while the control group did not intervention. The experimental group was given treatment in the form of the application of spiritual care.

Population and Sample

1. Population: The population of this study is the overall object of research. The population used as research subjects are inpatients, namely in the internal medicine room and surgery room of the general hospital of Palembang BARI, which is 22 patients. While the population that became the control group were inpatients, namely in the internal medicine room and surgery room of the general hospital of Martapura area was 22 patients.

2. Sample: The sample is part of the population selected in a certain way so it is considered to be representative of the population. The sampling technique in this research is total sampling. The sample taken from this research is patient. The number of patient samples consisted of 22 experimental groups and 22 control groups.

RESULTS

Based on table 5 above shows that the average value of satisfaction in the post-test of experimental group average of 98.59 while in the post-test control group obtained an average value of 83.14. It can be concluded that there is a difference in mean value of post test satisfaction of control group and experimental group. Value p value 0.000 <α (0.05) thus concluded there is influence between applying spiritual care with patient satisfaction.

**DISCUSSION**

**Respondents Characteristic**

1. **Age of Respondents**: The result of this research is the age of 35 years old (old age), the experimental group is 81.8% and the control group is 63.6%. The explain that at the stage of late adult development has an increased spiritual need, so that nurses have an important role in completing the spiritual needs in the nursing process of the patient (7). A
The result of the research conducted that the higher of someone age then the level of expectation of the spiritual will be higher (8). The higher the level of expectations, then the level of desire to be satisfied higher, so this condition that causes the number of patients who feel dissatisfaction during the treatment took place.

2. Education of Respondents: The result of the research shows that patient education mostly is low education, the experimental group is 72.7% and control group is 86.4%. A research that high intellectual experience can provide a broader spiritual outlook that affects the health of his soul(9). In contrast to other research that there is no relationship between education level and patient satisfaction(10). According to that one outcome of higher education is satisfaction or dissatisfaction with the product or service(1). 

Description Patient Satisfaction on Pre Test and Post Test of Spiritual Nursing Application Implementation in Experiment Group and Control Group: The result of the research showed that the satisfaction of the patients before the intervention (pre test) was found mostly in the experimental group and the control group declared dissatisfied that the experimental group was 68.2% while the control group was 72.7%. Patient satisfaction in post test mostly in experiment group stated satisfied that as much as 90.9% while control group mostly stated not satisfied as much as 54.5%.

Spiritual help is an activity that a person does for help and help from the Most High. Limitations of patients caused by hospitalization cause the limitations of patients in worship one of them pray. A research which explains that hospitalized patients experience a condition of spiritual distress (11). The explain spiritual distress is a condition in which a person experiences a lack of connection with living with his or her beliefs(10). When a person is sick, feels pain or loss attacks someone, spiritual power can help a person to heal(12). The nurses need to consider certain religious practices that will affect nursing care, such as patient beliefs about birth, death, dress, prayer, and nurses need to support the patient’s spiritual. The explanation shows that religious practice is one of the needs needed by a person as an indicator of satisfaction in nursing services in the religious aspect during hospitalization (13).

Explains the existence of the relationship of spiritual needs fulfillment with patient satisfaction because it can improve coping behavior and expand the sources of strength in patient. Spiritual needs as an important factor for maintaining or maintaining a person dynamic personal relationship with God, by helping the patient in fulfillment and support in religious practice can help improve patient coping during a crisis (14). The research conducted in a study of the relationship of spiritual needs with apsient satisfaction in patients in the treatment period, 76% of respondents said they were satisfied because they have religious elements in every act of nursing, because it shows that belief or belief can give life meaning, strength, and coping for the patient (15).

Difference Patients Satisfaction on Pre Test and Post Test Implementation of Spiritual Nursing Care of Experimental Group and Control Group at the Regional General Hospital of Palembang BARI and Regional General Hospital of Martapura: The results showed that the average score of satisfaction on control group pre test was 81.32 and the control group post test became 83.14. It can be concluded that there is an increase in the average patient satisfaction score on pre test and post test.

The average satisfaction score in the experimental group pre test was 81.59 and the experiment group’s post test became 98.59. It can be concluded that there is an increase in the average patient satisfaction score on pre test and post test. The value of significance 0.000 less than 0.05 thus concluded there is a significant difference in patient satisfaction in pre test and post test experimental group.

The difference of satisfaction score scores in the intervention group according to the researcher is caused by the intervention in the form of spiritual care. Fulfillment of spiritual needs is important but in reality the fulfillment of the spiritual needs of patients is still far from being expected. The results of the current situation analysis of some literature indicate the fact that spiritual care has not been given by the nurses competently due to various factors. One is that the lack of nurses’ ability to fulfill their spiritual needs is due to the lack of nurses who have mastered the concept of spiritual nursing that nurses should have obtained since their education(16).

Implementation of spiritual care in the hospital is influenced by many factors, one of them from the nurse itself. A research obtained the result of the difference between the spiritual ability of nurses before and after given the understanding of spiritual concepts (18). The
proves that there is a significant difference of nurse knowledge in pre test and post test of experimental group\textsuperscript{(19)}.

**The Effect of Implementation of Spiritual Nursing Care on Patient Satisfaction at the Regional General Hospital of Palembang BARI and Regional General Hospital of Martapura:** The result showed that the average value of satisfaction in control group post test was 83.914 and in group of post test experiment got value equal to 98.59, it can be concluded that there is difference of mean value of post control group satisfaction satisfaction and experiment group. Value \(p\) value 0,000 < \(\alpha\) (0.05) thus concluded there is influence between applying spiritual care with patient satisfaction.

Providing intervention in the form of spiritual care shows hospitals trying to provide comprehensive and quality nursing care includes biological, psychological, social, and spiritual aspects. The nursing care affects patient satisfaction during treatment. This explains that the quality of service provided by the hospital will give a great influence for patient satisfaction, so to give kepuasaan for patients, every hospital must provide satisfactory service \textsuperscript{(19)}.

Spiritual aspect is one of the most important aspect that need to be paid attention by nurse, therefore nurses are demanded skillfully and able to do guidance of worship of patient, so hopefully when patient can perform obligation worship patient get peace of soul, enlightenment, and sense of comfort \textsuperscript{(20)}.

**CONCLUSIONS**

There is a description of the low value of spiritual satisfaction before the nursing spiritual intervention (pre test) most patients expressed dissatisfaction of 68.2\%. After the implementation of nursing spiritual intervention (post test) has increased the satisfaction of patients mostly stated satisfied that as much as 90.9\%. There was an increase in satisfaction from an average score of 81.59 to 98.59 in the experimental group after a nursing action. There were differences in outcomes performed in the intervention and control groups where the intervention group had a higher satisfaction score than the control group. In the control group with an average score of 83.14 and the intervention group 98.59 with \(p\) value 0,000.

Work Motivation Description of Nurses at South Sumatera Hospital Indonesia

Citra Suraya¹, Yulastri Ari², Vetty Priscilla²
¹Master of Nursing Faculty, ²Faculty of Nursing Andalas University Padang

ABSTRACT

Work motivation of nurses is still one of nursing service problem at hospital. Low work motivation will affect the performance of nurses who are not good. This study aims to analyze the description of work motivation of nurses at South Sumatera hospital. This research type is quantitative with analytic descriptive approach. The sample of the study was 92 implementing nurses determined using proportionate random sampling technique. The data source is the nurses at South Sumatera hospital. The results of this study are known from 92 nurses can be seen 55.4% who have not good achievement, 54.3% nurses with a bad appreciation, 53.3% nurses with the development of potential individuals who are not good, 51.1% nurses with work itself is not good and 56.5% nurses with bad responsibility. More than half of work motivation factors include achievement, rewards, individual development, job self and responsibility. It is expected that the field of nursing can improve the motivation of nurses work by supervising the performance of nurses.

Keywords: Motivation, Work, Nurses, Performance and Factor.

INTRODUCTION

Motivation of nurses work is still one of nursing service problem in hospital. The motivation of nurses work at hospital III level of Ambon which have low category of 64.29% (¹). The same study conducted also showed a low motivation of nurses worker 60.1% at Bali Mental Hospital (²). Different research results reported Putri and Rosa (2015) hospital wards PKU Muhamadiyah Yogyakarta Unit II where the work motivation of nurses is low proportion is less that only 13.80% (³).

The factors that influence work motivation are fundamentally different according to the theoretical view of motivation. Motivation is influenced by basic human needs including physiology, sense of belonging, appreciation and self actualization (⁴). The job motivation based on employee type that is X employee type which is high in work motivation otherwise Y type employee is low motivated employee (⁵). Focuses on work motivation is sourced to the wishes of employees include ruling, achievement and affiliation (⁶). According to the theory of Herzberg (1950) there are two factors that affect the motivation of the nurses work namely hygiene and motivation factors. The superiority of Herzberg theory can identify whether internal and external work motivation factors affect most nurses performance. Therefore in this study the researchers used the theory of two factors.

Results of interview on September 19, 2017 with 16 nurses at South Sumatra hospital. Two nurses (12.5%) said that work motivation is categorized quite well, such as the selection of the best nurses are held every year. However, four nurses (25%) said the nurses motivation may affect performance degradation, such as the presence of late arriving nurses, returning prematurely, leaving the room during working hours, lack of cooperation with peers. As for 10 nurses (62.5%) stated that the low work motivation of nurses is due to the low appreciation in overtime and low support in career development of nurses. Based on these interviews it can be concluded that most (> 50%) work motivation of nurses in of South Sumatera hospital is low still categorized.

The above data is supported by observations made by researchers on September 23, 2017 with 16 nurses at South Sumatra hospital. The researcher found that there are still four nurses (25%) who are not on time in work, three nurses (18.75%) still lack of nurses to attitude and empathy in giving nursing service and nine
nurses (56.25%) still not complete in filling nursing care. This indicates that the work motivation of nurses at South Sumatera hospital has not been high. Based on the above phenomenon, this study aims to determine the description of work motivation of nurses at South Sumatera hospital.

**METHODS**

This research uses quantitative research design with analytic descriptive approach. Respondents in the study were 92 implementing nurses working at hospital. The sampling technique in the research by using proportionate random sampling methods where sampling will be chosen at random.

Data collection using checklists and questionnaires made by researchers based on various literature that suits the purpose of research. Measurements performed on nursing work motivation data instruments obtained by using a questionnaire. Questions of the questionnaire include achievements, awards, individual development, the work itself and responsibility performed using the likert scale in its measurement with a rating range of 1 - 4. Assessment of answers to respondents questions are 1 = strongly disagree, 2 = disagree, 3 = agree, 4 = strongly agree. This study uses questionnaires which is a references from previous research conducted so that researchers do not test the validity and reliability (7).

**RESEARCH PROCEDURE**

Procedures in the implementation of this research had previously been conducted ethical testing with no 62/kepkrsmhfkunsri/2018 and approved by the Ethics Commission Faculty of Medicine Sriwijaya University. Principles of ethics based on ethical health guidelines issued by the National Commission on Health Research Ethics. Furthermore, it is also equipped with an Informed Consent sheet that contains an explanation of the purpose of the researcher about the overall implementation of the research to participating nurses as research subjects.

**DATA ANALYSIS**

Data obtained from the results of research done data processing and data analysis, data processing is done based on four stages of editing, coding, scoring and entry data to then be analyzed by using a computer. Researchers then do an analysis of the data that has been collected. Data analysis includes univariate analysis, can be done to identify frequency distribution of nurses work motivation factors include achievement, reward, individual development, job itself and responsibility at hospital. The results are presented in the form of frequency distribution tables.

**RESULTS**

Table 1: Frequency Distribution of Working Nurses Motivation Factors at South Sumatera Hospital (n = 92)

Table 1 shows that of 92 nurses can be seen 55.4% which have not good achievement, 54.3% nurses with bad appreciation, 53.3% nurses with the individual development, 51.1% of nurses with poor self employment and 56.5% of nurses with unresponsibilitity.

Table 2 shows that of 92 nurses most have low work motivation that is as much as 57.6%.

**DISCUSSION**

Pursuant to univariate analysis result got unfavorable work performance showed that nurses with proportion more than half that is equal to (55.4%). This result is in line with the same research conducted in RSUD Kota Tidore Kepulauan also found that most of the nurses
researchers analysis that good work will be achieved with good work motivation, the greater the work performance of the nurses, the greater the productivity and the creativity of the nurses.

In this study nurses who have awards are not good with the proportion of more than half that amounted to (54,3%). The same research that the awards are not good in hospitals dr. Rasidin Padang that is equal to (71,2%) (10). Other research that the lower the award the less productivity to the achievement of a nurses achievement. This is because appreciation is one of the factors that affect the work motivation of nurses. The researchers analysis that appreciation is needed for nurses to improve nurse performance. This is because appreciation is one of the important factors in motivating nurses work (11).

Based on the result of characteristic of individual development it is known that the percentage of nurses is not good that is equal to (53,3%). This research is in line in RSUD Senopati Bantul Yogyakarta that the development of individual potency is not good that is equal to (72,3%) (12). The Research in RSUD Raa Soewondo Pati states that every nurse needs clarity in career development respectively can be obtained through formal and non formal education in face of its future. According to the researchers analysis that the development of nurse potential is very much needed by giving opportunity for the nurses to follow the education to the higher level and get the training so that it can improve the work motivation of the nurses (13).

Univariate analysis found that the nurses who owns the work itself is not good with the proportion of more than half that is equal to (51,1%). The same research conducted in RSUD Haji South Sulawesi Province which has the job itself is not good that is as much (69,1%) (14). Other research in RSUD Sekarwangi Sukabumi District argued that where if someone feels his job itself is considered good enough, then he will feel satisfied and will automatically work well. According to the researchers analysis that good work will be supported by good work motivation because the higher work motivation will increase the spirit for the nurses to his work (15).

More than half of nurses have unfavorable responsibilities (56,5%). The same research was conducted in RSUD Tugurejo Semarang which has not good responsibility as much as (63,1%) (16). According to the theory of Mc Gregor (1960) argues that most nurses are not ambitious to achieve optimal performance and always avoid responsibility. Research in dr. Rasidin Padang stated that work motivation will create a nurses awareness of her role, responsibility and work performance of a nurses. Researchers analyze that the higher the work motivation of the nurses will be the greater responsibility in the role of work so that will form an optimal performance (10).

The result of univariate analysis shows that the low nurses work motivation is known that the percentage of nurses with the proportion is more than half that is equal to (56,5%). The same study was conducted in the inpatient ward of RSUD Raden Mattaher Jambi that the motivation of low nurses work was found as much as (63,5%) (17).

The motivation of the nurses work has the driving factors such as achievement, reward, work itself, responsibility and individual development so that it can work productively because of interest and pleasure with work, feel its work gives meaning, satisfaction and happiness but otherwise if the worker is considered a burden as coercion, something to do or as a burden, one is inclined to do the work not maximally according to Herzberg (1950) theory. According to the researchers analysis, the work motivation of the nurses can shape ones attitude in facing the situation in the workplace. High motivation to work can shape a persons attitude to be positive. Because work motivation can affect a nurses performance.

CONCLUSION

Result of research, analysis and discussion hence can be taken conclusion that more than half of motivation factors work in this research include achievement, appreciation, individual development, work itself and responsibility which is not good. It is expected that the field of nursing can improve the motivation of nurses work by supervising the performance of nurses. The researcher recommends that the next researcher can continue on the research that analyzes the relationship between the independent variable and the dependent variable by involving more variables.

ABSTRACT

Nursing career path is a role for nurses to work in accordance with their own clinical authority. This study aims to explore the experiences of clinical nurses in implementing career path. Design of this research is qualitative methods through phenomenology approach, with in-depth interview technique. Participants in this study were the old nurses who were taken by purposive sampling and the number was seven people. Data analysis was done by using Collaizi method. The research result got five themes; implementation career clinic nurse hampered because of the quantity of human resources, work is not suitable with authority clinical and quality of human resources, the determination of the level of career of the old nurse in Hospital Padang Panjang is based on education, experiences and special skills certificate, socialization is not optimal, the expectations of nurses to implementation of career path, and support that expected by the nurse in implementing career path.

Keywords: career path, experience, clinic nurse

INTRODUCTION

Implementation of nursing career path has been started since the issuance of regulation that regulate the nurse system of career nurse in Indonesia. According to Kornela, Hariyanto and Pusparahaju (2014), the application of nursing career level in hospital has not been done based on competency test but still situational (based on need). Implementation of the clinical nurse career path is hampered by the lack of human resources, the work is not in accordance with the clinical authority, and the low quality of human resources and special skills certificate 3) socialization is not optimal enough, 4) nurses expectation on career path implementation, and 5) Support in career path implementation in the form of managerial support and competence support.

MATERIALS AND METHOD

This study used qualitative research design through phenomenology approach with the aim to obtain a description of the meaning of the individual experiences of clinical nurses on the implementation of career path.

RESEARCH RESULT

The results of the this research are: 1) the implementation of the clinical nurse career path is hampered because of the lack of human resources, the work is not in accordance with the clinical authority, and the low quality of human resources, 2) the recognition career of old nurses based on education, work experiences and special skills certificate 3) socialization is not optimal enough, 4) nurses expectation on career path implementation, and 5) Support in career path implementation in the form of managerial support and competence support.

Theme 1: The implementation of the clinical nurse career path is hampered by the lack of human resources, the work is not in accordance with the clinical authority, and the low quality of human resources

a. Quantity of less human resources in RSUD Kota Padang Panjang.

The result of the research shows that the nursing career level of clinical nurses has not been implemented well caused by various aspects, one of them in terms of quantity of human resources, namely the lack of manpower in each room is one obstacle in the application of career nurse level in RSUD Kota Padang Panjang. This is revealed from the statements of two participants as follows:

“Difficult to apply ....becauseofthatlack of energy.... sometimeswe are his official partner with the same level of PK ... “(P.1)
“Because our power is limited... it’s hard for us to sharing the work in the room,”........ the current constraint due to less of energy (P.6).

Lack of energy perceived by the room nurse due to the distribution of nurses who are not in accordance with the needs. Distribution of nurses became ineffective because it did not take into account the workload of nurses and BOR in each room(7). Conceptually Susanto (2009) revealed that the achievement of BOR (Bed Occupancy Ratio) has a significant effect on the need of nurses staff so that the need of nurse staff needs to be taken into account through BOR level(8).

b. The division of work has not been in accordance with the clinical authority.

During this time they work using the principle of cooperation and help each other. As disclosed below :

“... Now this is not implement yet ... to serve the patients, the time is not enough ..... we do anything in our room ....” (P3)

“... When in the implementation not yet according to clinical authority .... I also do other work .... which is not my authority .... we work together to help each other ....” (P4)

“During this time we work together ..... if there are actions yaa done together ...... clinical authority ... yaaa ... not referring to it ....” (P7)

Nurses in hospitals Padang Panjang has not worked in accordance with the clinical authority due to the function of management is not optimal yet, including supervision by the supervisor, monitoring the implementation of the authority SOP clinical nurses, and there is no evaluation of the implementation of nursing career path that has been implemented.

c. Low quality of human resources in RSUD Kota Padang Panjang.

The result of the research shows that the participants have not understood the career path of the nurse. Clinic nurses only know the current level of his career, but not yet know the essence of the career path itself. This is revealed in the following participants statement:

“...not know and understand as a whole for what exactly the career path ... that I know ... I am in the career path PK II, I have not seen its function for what .. the excess is for what ,” (P2)

“... I do not know what is the use of PK-PK ...” (P3)

One cause of low knowledge of nurses in hospitals Kota Padang Panjang of the implementation of career paths due to the lack of socialization and training related to career nurses.

Theme 2: Confession of old nurse career path based on education, work experiences and special skills certificate.

a. Based on education level, working period, and special training certificate.

The result of the research proves that the nurse acknowledges the level of long career nurse career based on education, working period and special training certificate that is owned. A participant stated that the determination of the career level of the nurse clinic is based on years of service:

“Just calculated the workload and working period .... there is a certificate of training the surgical room .... so I am PK II ....”(P3)

“...... skill .... have certificate of special skill training yeah ... Ayuk join ICU adult training .... now it is Ayuk in PK II ... whereas my friends are still in PK I ... in terms of work experiences .... “(P7)

“...... now the level of PK II ...... is based on the level of education ni ... work experiences ....” (P1)

The nursing career level have taken into education, working period and special training certificates. It is already in line Minister of Health of the Republic of Indonesia (2017) that mapping or mapping is a process of determining the level of the old nurse in accordance with career prerequisites determined according to the policies of each hospital and based on the requirements of each rank by the nursing team team to determine the eligibility of the nurses at PK level according to their competence(13).

b. Not yet based on experiences

In contrast to the previous opinion, two from seven participants had a perception that career
recognition was based on educational level rather than experience. So that participants are at the level of career PK I already have experience of working long enough. perception of a participant.

“... because it was taken based on SPK education ....my experience SPK was not worth the experience of nurse D III now, ... more experience when I followed SPK in the past ....”(P4)

“Still pKI, it’s a diploma of SPK ...education...
“.... it feels if from experience is not appropriate in PK I ... but because the diploma SPK yaaa ... received ... adjustment for the diploma Ners not yet because not have STR ...” (P.5)

Career nursing mapping implemented in RSUD Kota Padang Panjang is based on the rules set by the health ministry of Indonesia, but in its application, the percentage of working period and education is too little to cause naive for nurses, nurses feel that their work experience is less appreciated. It will also have an impact on the nurse’s work spirit and performance of the nurse itself.

Theme 3: Thesocialization is not optimal yet

a. The frequency of socialization only once

The result of the interview was a statement from the participant that the frequency of socialization was once:

“previously we followed the socialization, but socialization be left socialization. If is socialized....... then applied we will know “(P1)

“Ever socialized .... before the test just that ....” (P5)

“Before the credential exam has been done socialization, but only once ... It should be in time with regular frequency.... with the socialization of course we will understand the implementation of career path” (P2)

The success of the career path program needs a strong commitment from the leadersto take steps in the implementation of the levels. One of them by doing socialization to all nurses in the hospital. Coordination of career team with committee nursing and hospital leaders are also necessary done intensively (16). According to Furedi (2009) socializations is a process that helps individuals learn and adapt about how the way of life and how to think group, so that he can play a role and functioning in groups(17).

b. Socialization does not exist yet

The following participant’s statement stated that there has been no socialization of career path application:

“There is no socialization .... I do not know what is the use of PK-PK ...” (P3)

“there is no directly notice to us .... at the time it was a test ... socialization only through ni Esi (head of the room) ..” (P4)

socialization related to the implementation of career nurse in RSUD Kota Padang Panjang has not been implemented maximally. One cause is the dual role of nursing committee members.

Theme 4: Theexpectation of the nurses on the implementation of the career path with financial and non-financial rewards

a. Non-financial rewards

The result of the research shows that the participants’ expectation is non financially, this is the following statements of the participants related to the non financial expectation who want the award based on their competence:

“Working in accordance with my authority ... work more directed ... what is my responsibility ...” (P.7)

“my hope ... can work according to the authority I have ... not the work that is shared with ...” (P1)

“Equal rewards ... eexample point credit points ....” (P.4)

The participants also hopes that there will be awards in recognition of his competence.

“The appreciation in a professional manner .... a kind of confession....in admit if we are competent in this field ... “(P.6)

“There is a professional differentiator ni ..... work according to competence and also appreciated according to competence....each competence is also diringi with their respective responsibilities ... so there seems to be differentiator professionalism ni ...”(P2)
One participant expressed his expectation on the implementation of career path in the form of self-esteem:

“Working according to my authority ...... what is my responsibility ...do not always nurse blame and considered trivial ...“(P7)

Non-financial rewards can be in the form of recognition of the competence of the nurse, the award is given based on the career development of the nurse itself. In line with the opinion of Muis (2012) said that Developing a career can be determined through non-financial rewards, the number of awards it can identifying a the right job performance so that it can be proposed to be promoted to a higher position(18).

b. Financial rewards

The results shows that the nurse has hope for the application of career path to be rewarded financially over the career level that has been owned. Some participants said they wanted different wage to be differentiated based on their career level:

“Financial may ... there are differentiators between PK I and PK II ... PK II receives more than PK I ....” (P.1)

“.... acceptance of wage in accordance with career level .. higher PK greater services received” (P.4)

“Differences of wage .. there are classes of wage ... just distinguished ..” (P.3)

Other participants expressed wanting welfare and remuneration based on their career level:

“.. There is a differentiation of professionalism, where there is professionalism in there wage ... with the PK we expect also there is a wage differentiation between PK ....” ... direction to remuneration .. “.(P.2)

“we can consider with working period......... prosperity, remuneration as at other hospitals in accordance withinitsPk” (P.5)

The financial rewards expected by the nurses in RSUD Padang Panjang is in the form of remuneration in accordance with career level or career achievement. Sarwar and Abugre (2014) in his research argued that financial rewards in the form of salaries and incentives greatly affect job satisfaction(19).

**Theme 5: Support is needed in the form of implemnetasi career managerial support functions and support competence**

a. Support from management functions

Some participants said there is already regulation but there is no control from the management:

“Regulation (SPO) ...... from the Director just a regulations... policy also exist, from the field was already there .... but the controlling that does not exist”(P.1)

One participant said there was a policy but the participants did not know whether the evaluation was carried out

“Not in the evaluation whether this is good for the patient or not,authorityclinical signature .......not only asked to work .... “(P6)

“.... We had never been asked by the management about implementation tasks in accordance with the clinical authority in the room.” (P3)

Two participants also said no preformance support a form of monitoring from the leader .... “(P6)

“Usually there is a monitoring ..... for now the case managers who do ... how we work in the room ....... how the condition of the room ..... but monitoring related to the implementation of career path not yet exist ....” (P.7)

A participant said there was no direction from management

“Maybe from the leader, from who in the higher position, for example from the management that has not been done .... guidance....... direction..... this is the problem that is managing management “(P.4)

Lack of support for the application career path in the hospital can be understood because the implementation of career path in RSUD Padang Panjang city has been began in 2015. Hospital organization has not commitment and efforts in the implementation of the career path. The career team that has been formedbut it has not done any activities to start the career path.
b. Competence support

Two participants said that they lacked the opportunity to develop their knowledge through training during their working period:

“To improve competence.....we lack the training and development of science ... I feel like a frog in a shell ....,”

“I already followed a basic training in surgical operation room .. but not the cost of the hospital .. i also have the right to attend training, to seek new sciences” (P.3)

“If the training is based on skills we can find by ourselves ...because we who need .....find by yourself...after 12 years I work have never had a chance, except for the needs of the hospital ...for example accreditation because there must be a certain certificate .. “(P.5)

“Upgrade is our science .... after4 years working there is no training .... itsimporatant for the satisfaction of science” (P.6)

Participants also said they have not had the opportunity to improve their competence through special training:

“The training opportunity has started, but for the special rooms ... if I am last BTCLS .... I am looking for myself .... other special trainings have not been thereyet .... there is no chance” (P.7)

Gorda (2004) states that education and training is a process of activities to improve and develop attitudes, behaviors, skills, knowledge and intelligence in accordance with the wishes of the company concerned[22].

CONCLUSION

The calculation formula of energy needs is less suitable because the calculation of needs is not based on the workload of nurses. This has an impact on the distribution of nurses who are not in accordance with the needs in the room so that the room with a high workload of nurses feel short of energy.

Conflict of Interest: No conflict of interest arose in this study.

Description of Patient Satisfaction with Communication of Nurse Practitioner at the Hospital Dr. Rivai Abdullah Palembang Indonesia in 2018

Isrizal¹, Meri Neherta¹, Ira Kusumawaty²

¹Faculty of Nursing, Andalas University, Padang, Indonesia; ²Polytechnic Ministry of Health of Republic Indonesia

ABSTRACT

Background: Therapeutic communication against the patient in regard to support the healing of patients not only to provide information about her/his health but heard the complaints of the patients, such as a sense of empathy that is always followed by education in friendly service, will strongly influenced in the satisfaction of the patient.

Purpose: This research aims to know the description of the implementation of the therapeutic communication at the Dr. Rivai Abdullah’s Hospital Palembang.

Methodology: design uses a descriptive analytic design with samples of research 88 patients. This study was carried out for 6 months form 2017 June - 2018 May. This research with cross sectional approach.

Result: The result of the research it is known that from 88 respondents aged amounted to 47 people (53.4%), while it is known that education is the most respondents is low numbered 60 men (68.2%). Orientation phase amounted to 44 people (50.0%), work phase amounted to 45 people (51.1%) and termination phases totaled 53 people (60.2%).

Conclusion: the implementation of therapeutic communication at Dr. Rivai Abdullah’s hospital in the implementation of therapeutic communication with disgruntled 51.1 %. Suggestions: Expected to especially in the hospital inpatient nurses in the room to be able to maintain the communication stage therapeutic-starting from the stage of the orientation, and work towards termination of the patient being treated.

Keywords: Nurse, Therapeutic communication, quality of service, hospital

INTRODUCTION

Therapeutic communication is done always at the time of serving patients in the event of service nursing care of each patient to achieve patient satisfaction. It is really in the need to speed up the recovery and healing of patients and to avoid a condition that can cause misunderstanding between the nurse, patient and family. Therapeutic communication is very necessary at all nurses especially inpatient nurses (1). It means that patients will not feel satisfied with the service provided in a communication from the nurse is not good. It is evidenced by the results of research that has been done in the PROVINCIAL HOSPITAL of Yogyakarta data obtained more than 50% of patients who are admitted are less satisfied with the communication therapeutic committed against the nurses.

Inpatient nurse at the hospital must use therapeutic communication against patients who are hospitalized, from assessment to evaluation of the patient. Therefore, the nurse needs to develop a strategy to improve therapeutic communications against patients (2). The satisfaction of patients treated at home can impact positively in the service of the hospital to the community(3).

Very friendly service given to the hospital by nurses towards patients health care can be given not only to the patient but also given to families and communities. To
achieve optimum healing nurse must be able to meet the needs of the patient. When the nurse meets the needs of these patients there are several stages of the interaction that must be done by nurses, such as introduce myself to the patient, explain the action that will be performed, the work process, and evaluation of nursing (2).

METHODOLOGY

The design of this study used descriptive analytic design with 88 patient samples. Sampling technique using proptional random sampling method. This research was carried out for 11 months from 2017 June to 2018 May. Data were collected using questionnaires and the hospitals. The location of this research was conducted in Dr. Rivai Abdullah Hospital Palembang.

RESULT

The results of the study it is known that from 88 respondents aged (41 - 65 years) amounted to 47 people (53.4%), young (18-40 years) 41 people (46.6%). Education of the Most respondent is low (SD - SMP) amount 60 people (68,2%). High education amounted to 28 people (31.8%) on patient education. Therapeutic communication with orientation phase was found by some unsatisfied respondents as much as 44 people (50.0%) and therapeutic communication with work phase was found most of the unsatisfied respondents were 45 people (51,1%), whereas communication teraupetik with termination phase got most of the satisfied respondents were 53 people 60.2%.

DISCUSSION

The results of research on the distribution communication frequency, the age characteristics and education of nurses at inpatient care obtained from 88 respondents aged old amounted to 47 people (53.4%), while it is known that education is the most respondents is the low numbered 60 men (68.2%).

Age is the time that the existence of an object or creature either living or dead human age life is said to be fifteen years in the measure since he was born until the time the age count. So that age in the measure from birth until the present (4). Education is the process by which the community through other institutions deliberately transforms knowledge heritage and the values and skills and generation to generation (5).

The results of this research are in line with daughter of Anjana (2016) (6), which discusses the description of elderly care in meeting the social needs of personal care in Lotus werdha tresna. On the results of his research that most respondents aged 60 – 74 years totalling 33 people (45.8%), whereas those aged 45 – 59 years amounted to 22 people (30.6%), ages 75 – 90 years amounted to 13 people (18.1%) and the age of 90 years old totaled > 4 people (5.6%). Most respondents low education educational ELEMENTARY SCHOOL – JUNIOR totaled 42 people (58.3%).

According to Febriani (2014) shows that the number of respondents most patients are women with 24 (55.8%) respondents and most education is the number of patients with ELEMENTARY education as many as 20 people (46.5%) (7).

According to Potter & Perry (2005) the number of elderly in age groups increased dramatically, so that many patients admitted to health-care professionals take the time to age 50 years in health care because they should focus to identify and meet their needs (8). Whereas the communication of therapeutic in communication between patients and nurses form a therapeutic relationship, the relationship of mutual trust and make it easier for nurses to take informed decisions in addressing the health concerns. Therapeutic communication generally performed in the nurses room inpatient public hospital sultan syarif Muhammad area alkadrie, Pontianak is already good and supported by research conducted rahayu (2013) communication conducted 100 nurses % good (9).

Based on research results, related theories and related research then the researcher argues that age affects on the service in the hospital especially at the satisfaction of the patient because in old age showed low knowledge on respondents in terms of. It’s a great pain in the Home Ministry badly needed human resources to achieve the satisfaction of patients who are treated at home sick. While education affects on the quality of service at home sick to achieve satisfaction patients. because of low education showed low levels of knowledge of the patient.

In the results of research on the frequency distribution of communication teraupetik the stage orientation obtained most of the respondents are not satisfied of 44 people 50.0%, while the working stages obtained the majority of the respondents are not satisfied totalling 45 persons i.e. of 51.1% and at the stage of termination obtained most of the respondents are satisfied of 53 people 60.2%.
According to the theory that there is an orientation phase is the phase that began when the nurses meet the patient for the first time. It was the first time an patients seek help that will affect relations between nurses and patients. This phase of work is to give a chance on patients to ask, inquire, main complaint start activities in a good way and according to plan and the termination phase is the Phase in which to communicate the activities of the therapeutic conducted on nurses was summed up the results of the interviews, did the contract time, place and topics as well as ended the interview with a good way.

The results of this research line with Kusumo (2017) that discusses the influence of therapeutic communication nurse against the patient’s satisfaction at hospital. On the results of his research therapeutic communications on phase orientation numbered 57 respondents with percentage (38.14%) said it was not satisfied and therapeutic communication On the stage of the work amounted to 47 respondents with percentage (33.57%) said it was satisfied whereas the communication of terapeutik phase termination amounted to 51 respondents with percentage (36.43%) said satisfied.

Based on research of results, related theories and related research then the researcher believes that therapeutic communication on nurses with orientation phase, work and the planned termination by nurses committed to help healing patients who are treated at home and to encourage patients to work between nurses and patients in terms of satisfaction in patients.

CONCLUSION

From the results of research that has been done it is evident that the implementation of therapeutic communication in the inpatient room can heal the patient’s healing process. However, for the implementation of communication not solely in the room hospitalization but could be used in outpatient room. Therapeutic communication is communication that consciously planned aims and activities were concentrated to cure the patient. To overcome nurses who did not communicate with therapeutic then the hospital can conduct training communication therapeutic during three weeks. Then the hospital can apply inpatient room and outpatient space.

Conflict of Interest: No conflict of interest arose in this study.

ABSTRACT

Background: Therapeutic communication is very important role in nursing service, because therapeutic communication is an absolute and decisive activity for the relationship or interaction of nurses and patients in supporting the recovery of patients and find solutions to the problems that are being experienced client.

The Aims: This study aims to determine the picture the implementation of therapeutic communication by the executing nurses in the inpatient wards of Ernaldi Bahar Hospital Palembang in 2018. Methods and samples

Research: This research is descriptive with quantitative methods. Technique that used in choosing the samples was Total Sampling method. The sample size was 52 people from 5 inpatient rooms of Ernaldi Bahar Hospital Palembang for 11 months from June 2017 until May 2018.

The Result: Based on the result of research it is found that from 52 nurses, 44.2% are 36-40 years old, 78.8% female sex, 36.5% vocational education, 63.5% nurse implementing therapeutic communication well.

Conclusion: The implementation of therapeutic communication at Ernaldi Bahar Hospital Palembang in 2018 with good category.

Suggestions: Hospitals need to pay attention to nurses’ therapeutic communication in nursing service by conducting routine room head supervision to nurse executing to assess therapeutic communication performed by nurse executor to patient.

Keywords: Nurse, Therapeutic Communication

BACKGROUND

Communication plays a very important role in nursing services, because communication is an absolute and decisive activity for the relationship or interaction of nurses and patients in supporting the healing of patients. Communication within the nursing area is a process for creating relationships between health personnel and patients to recognize patient needs and determine action plans and cooperation in meeting those needs. According to Stuart and Sundeen (2001), communication is very important between nurses and clients. Communication between nurses and clients has the advantage of finding solutions to the problems the client is experiencing, and this communication is called therapeutic communication.

Therapeutic communication according to Gombong (2012) is a way to foster a therapeutic relationship where there is information and the exchange of feelings and thoughts in order to influence others. According to Kusuma (2016) Therapeutic communication is a conscious, purposeful and focused communication for the patient’s healing. Meanwhile, according to Suryani (2005), Therapeutic Communication is a communication performed or designed for therapeutic purposes. A helper or nurse can help clients to solve their problems encounter through communication. Darmawan and Andriyani (2014) found that in Mental Hospital of West Java Province found that most nurses are not in applying therapeutic communication that is 55.3%. Meanwhile, according to research that conducted by Arifin (2015) in RSUD Kota Salatiga found that as many as 72.5% nurses with therapeutic communication level is enough, less as much as 25.5% and nurses with a good level of communication only 2% this is not in line with the
results of research in RSUD Dr. Rasidin Padang, who got that 81.4% nurses are able to communicate therapeutic. Based on research Siti (2015) at RSU Rajawali Citra Bantul Yogyakarta get 49.1% nurse who communicate therapeutic well, while therapeutic communication nurse less good as much 22.8% (8).

METHODOLOGY

This research is a quantitative research. The type of research used is descriptive analytics with Cross Sectional approach. The Population in this study amounted to 60 nurses and the sample in this study amounted to 52 people that used in choosing the samples is Total Sampling method with exclusion the criteria of head of room and nurse who was on leave. This research was conducted in the hospital ward of Ernaldi Bahar Palembang. The Data were obtained from the questionnaire distribution. The data analysis includes univariate analysis; it is conducted to identify distribution of frequency of therapeutic communication implementation in the hospital room of Ernaldi Bahar Hospital Palembang

RESULT OF THE RESEARCH

</tr>
</tbody>
</table>

Based on table 2 it can be seen that from 52 respondents who were researched in Inpatient Room Ernaldi Bahar Hospital Palembang, most of the nurse implementing good therapeutic communication (63,5%).

DISCUSSION

The age of respondents in this study is mostly at the age of 36-40 years (44.2%). Productive age is in the career stabilization period. Age is related to maturity and one’s ability to behave. The addition of age in the assumption of the researchers is directly proportional to the addition of the ability to take precautions, control the emotions and ability to interact or communicate. At the age of entering adulthood, usually the individual achieves mastery of mature knowledge and skills

The sex of nurses in this study was dominated by women (78.8%). This is in accordance with the general perceptions of the community that nurse jobs are more identical to women’s work. Work as a nurse requires patience, patience and affection. According to the researchers’ analysis, nurses are social work in accordance with the nature of women is sabra, able to communicate, have affection, high commitment to the service so that the nurse profession is played by women.

Nurse education in this research is mostly D III Nursing (36,5%). According to the researchers’ analysis, the largest number of nurses in the hospital is the advocacy nurse associated with the service needs and the ability of the hospital to meet the number of staff. Education becomes an individual’s ability to take responsibility for his work. The application of therapeutic communication by the nurse as a whole is good in categorical (63,5%). From the data it can be seen that most of the implementing nurses at Inpatient Room Ernaldi Bahar Hospital Palembang have done a lot of therapeutic communication well.
The implementation of therapeutic communication is not the same as social communication. Social communication does not have a specific purpose and usually the implementation of this communication just happens. Whereas therapeutic communication has a purpose and serve as a therapy for clients. Therefore the implementation of therapeutic communication should be well planned and structured. The structure of the therapeutic communication process consists of four stages: pre-interaction or preparation stage, orientation or introduction stage, stage of work, and termination stage.

CONCLUSION

From the results of this research that has been done can be concluded that the characteristics of nurses mostly aged 36-40 years, female sex dominated, the level of education is still largely DIII Nursing and most nurses implementing therapeutic communication well.

ABSTRACT

Conflict in health services occurs both in Indonesia and abroad. The head of the room plays an important role in resolving conflicts in the nursing area. If the conflict is not resolved soon will have an impact on the service. So it is needed a way or strategy head of the room in resolving the conflict. The purpose of this study is to obtain in-depth information about the headroom experience in resolving conflicts. This research design using qualitative with phenomenology. The number of participants in this study were nine participants. Data collection method in this research is with indepth interview and field notes. Method Data analysis using Collaizzi approach. The research got five main themes: Understanding the head of the room about the conflicts that occurred in the nursing room, the way the head of the room resolved the conflict, the stages in conflict resolution, barriers in resolving conflicts, Feelings in resolving conflicts. This study can be concluded that the head experience in resolving conflicts vary so quickly in resolving conflicts in the nursing home.

Keywords: Head of Room, Resolving Conflict, Experience

INTRODUCTION

Most health workers at hospital services experience conflict in work. In Switzerland, on average, every health worker has at least two conflicts with the supervisor, whereas in the United States there are more healthcare conflicts among colleagues¹ (²). In Indonesia, the exact data on this conflict in health care not yet, but Arini research (2012) at Ibnu Sina Padang Islamic Hospital as many as 90% of nurses have experienced conflicts. Therefore almost all hospitals whose health workers experience work conflicts, the leaders of hospitals and all health workers must manage this conflict well so as not to harm organizations and individuals³ (⁴).

The causes of conflicts are often found through research conducted by several researchers. According to Smith, Mazzarella and Piele (2008) there are 3 factors that cause conflict that is communication problems, organizational structure and human (⁴). Suharno (2012) reported that there are two dominant factors causing conflict, namely communication and human factor (⁵), while Margiraharjo research (2016) and Wahyudi (2015) reported the dominant cause of conflict only communication. From the above studies show that communication is the most dominant cause of conflict in many ways (⁶) (⁷). This implies that poor nurse communication has the potential to lead to conflicts in nursing services, one of which is interpersonal conflict.

RESEARCH METHOD

The method of research using qualitative research with phenomenology, participants in the study amounted to 9 headroom with the technique of taking parsisipan using purposive sampling. Data analysis Information obtained by recorded, recorded with mobile phone and voice recorder application. A verbatim transcript was made (making the interview result in written form), and the researcher interview form was obtained with the participants. Analysis of phenomenological research data can use the Colaizzi method.

RESEARCH RESULT

Based on the results of in-depth interviews about the experience of head of space in resolving conflicts in the hospital nursing room in South Sumatera Year 2018 got five themes.
Theme 1: Understanding the head of the room about the conflicts that occur in the nursing

Room Conflict is often faced by the head of the room that has been completed.

“... I think the conflict is a condition in which there are different ways of thinking of individuals .. because every human being does not have the same thoughts that will cause conflict if it happens ...” (P1)

“.. conflicts occur the thought of a different mind. because the thinking of someone gives a different picture .. well of education, ethnicity and ethnicity. “(P6)

“.... the conflict took place between one person and another person different in thinking .. if not mistaken it had happened to my staff ... the conflict was also a feeling that would be right alone .....” (P3)

Them 2: Experience the way the head of the room resolve conflicts in the nursing room Doing a discussion:

“.... at that time the problem that occurred in our room, I finish by calling the conflict and membahasa what is the problem .. I ask the conflict .... what’s wrong? .... what’s wrong? ..... the point is I ask all the problems. And doing shorts to tell them “(P3)

“The problem that nurse took place yesterday, I solved by asking what the problem was .... I instructed those in conflict to tell me everything. Dealing with the problems that exist in them. “(P7)

“.... if no one way I do together to tell what the problems that have happened .... what problem .. when happened .. that’s what I asked all the problems .. alhamdulillah they tell .. only communicative problems .... “(P9)

Them 3 : The experience of the head of the room performs the stages in the settlement of conflicts in the nursing room

Conduct assessment or analysis prior to troubleshooting

“.... at that time before brother .. hmmm .... do before resolving the conflict where I do the collection of facts in the conflict .. like the facts of the witnesses at the time or evidence that there is a sms they are the cause of the conflict ... “(P1)

“...... there was once happened, for example the nurse’s problem ... I wait for a good situation and do not talk in a crowded place in solving the problem .. we see the condition also the deck .. not good if again discuss about their problem in front of the crowd or in front of the patient .... “(P6)

“.... before the way I described earlier ... in solving the conflict first to seek evidence of the conflict .... to examine the condition of the room not to interfere or the conditions must be safe ..” (P7)

“... we collect duhulu existing information ...... before we do the settlement of the conflict, because we must know first information why the problem happened so we are not wrong in solving the problem ......” ( P9)

Theme 4: The headroom experience about the obstacles experienced by the head of the room in resolving the conflict.

Hampered by work as head of the room

“... as my head of the room a lot of work ... have not taken care of the room, staff, and patients also ... every day that we meet from 8 to 10 or 11 noon ... back room at 11 just do the chores of the room ..absen and the patient .. continue the break .. sometimes sometimes meeting again during the day .... “(P2)

“... there is a delay that I experienced is tu workload problem .. that’s often hampered if there is a problem in our room..the problem yesterday at the time of hospital accreditation .. so the meeting continued no time to sit in the room .. sometimes a lot of work outside room “(P6)

Our work is stout .. a lot of that in thought ... that’s hamabatanny .....help the staff and patients ...not meeting with kavid or ka.instalasi. not to mention yesterday there was a conflict with the hospital anniversary event so on busy busy .... “(P8)

Them 5: Feelings that have been felt by the head of the room in resolving conflicts in the field of nursing

The feeling of calm that is felt after the conflict in the room has been completed

“After the conflict is over ... the feeling is calm and
relaxed” .. in the sense that there is no more burden of mind ... my feelings feel safe (P3)

“...... I feel happy after I solve that problem .... the pleasure that everyone must feel .. because will be in our job ..” (P5)

“Conflicts after completion ... i feel calm ... can reduce our workload .. . akek ...... but i feel like happy ... calm ... no more thoughts ......” (P7)

“... it feels calm if the problem is over ... that’s the feeling that I feel .. there is also if successful in doing a job will feel calm .... workload minimize ..........” (P9)

DISCUSSION

1. Understanding the head of the room about the conflicts that occur in the nursing room: Based on the results of research on the experience of the head of the room in South Sumatera hospitals in the face of conflicts in the nursing room because of differences in thinking, differences of ideas and disputes. This is the same as explained by Marquis & Huston (2010) conflicts that occur in the workplace because of internal or external disputes where the difference of ideas between two or more people (11). Conflict occurs as a contradiction to the balance situation occurring in individuals or in the wider order, such as differences in ideas between individuals, between groups, or between communities (12). Based on the above research can be concluded the conflict can be expressed as a state of a person or group of people in a social system that has a difference in looking at a thing and manifested in behavior that is not or less in line with other parties involved in it when achieving certain goals.

2. Experience the way the head of the room to resolve conflicts in the nursing room: The results showed that the way the head of the room in resolving conflicts in the nursing room to do a way of discussing between the head of the room, katim and who have a conflict or people in conflict in the room. The results of the study are in line with Israel and Africa with in resolving conflicts with compromise styles(13) (14) (15). Compromise works towards partial satisfaction, all parties seek an acceptable solution and not an optimal one thus no one wins or loses absolutely (16). The results above can be concluded how the compromise is this action can be done if to both parties feel that both things are the same important and good relationship become the main. Each side will sacrifice some of its interests to get a win-win situation (win-win solution).

3. The experience of the head of the room performs the stages in the settlement of conflicts in the nursing room: Based on the results of the study explaining that the head of the room in resolving conflicts in the nursing room to conduct the assessment of the situation first to know the type of conflict to determine the time required and do the data pengumulan or choose the right time to resolve the conflict. Collect information / facts, where the facts collected must be complete and accurate, but also should be avoided mixed with opinions or opinions. Opinions or opinions have been entered into subjective elements. Therefore, the collection of facts must be done with caution (10). According to Vestal (1994) in Nursalam (2015), situational assessment is where identifying types of conflicts or determining the time required, after collecting facts and validating all estimates through in-depth assessments. Then who is involved in the conflict and the role of each where the situation may change (17). Based on the results of the above research can be concluded that before making a conflict resolution to collect accurate facts do not let the opinions or opinions are less clear that will cause the less obvious.

4. Headroom experience about the obstacles experienced by the head of the room in resolving conflicts: Based on the results of the study found that the obstacles that are often faced by the head of the workplace problem where the busy head of the room to resolve the conflict. The head of the room has limited time due to the responsibilities of a large room head. This is in line with the results of research conducted by Muspawi (2014) explains that in conflict management there are frequent barriers, especially work problems or busyness which is characterized by high job and high work load (18). Then it can be concluded that the obstacles in resolving conflict in the workplace or health service delivery is influenced by work and motivation. Where such barriers are often found by the leader or head of the room in resolving conflicts that occur in his staff.
5. Feelings that have been felt by the head of the room in resolving conflicts in the field of nursing: Based on the research results found that the head of the room feel happy after solving the problems that occurred in the nursing room where the head of the room felt has succeeded in his duties as a leader to take responsibility for the conflict occurred in the nursing field. The above statement is in line with the results of research conducted by Usman (2004) that happy feeling is owned by every individual where the feeling will arise if the individual feels what he has done has been successful or successful (20). Similarly, the results obtained are considered very good in the actions that have been done. The above statement in line with the results of research Indriyatni (2010) explains that the pleasure of a person seen from a positive action to others where the success of the business made by the person itself. Based on the results of the above research can be concluded that every human being in a job has a feeling happy when the problem at his work has been completed therefore Hospital in East Java said happy if the conflict has been completed (21).

CONCLUSION

1. Understanding the head of the room in resolving conflicts in the nursing room explains that the conflicts that are often faced by the head of the room in the form of differences in thoughts, ideas and disputes in which the existence of different thoughts between individuals.

2. The experience of the head of the room on how to resolve conflicts in the nursing room by discussing to discuss the problems that occur in the room, discuss the causes that occur in the room to the conflict, and choose or decide the best solution to achieve the same goal.

3. The experience of the head of the room in resolving conflicts in the nursing room has a stage of assessment, where the room kepela to identify the situation and time in mnyesai conflict

4. The headroom experience in resolving conflicts often finds barriers. Job factors can also hamper conflict resolution where the workload is overwhelming.

5. The feeling of head of the room before the problem that occurred in the nursing room after the problem has been completed the head of the room feel happy, relieved and grateful for the effort and responsibility as the head of the room has succeeded and can run amanah as head of the room.

ABSTRACT

The performance of a good nurse is an illustration of the level of hospital service success, which indirectly illustrates the nurse’s ability to provide nursing care. This study aims to identify the relationship of nurse career application level with the performance of nurse executor at Inpatient Room of RSUD Palembang BARI year 2018. The research design used is analytic descriptive with cross sectional approach. The sample was 92 nurses and 92 SKP documents. The results show that there is a relationship of career rewards with work behavior \((p = 0.002)\), there are career development relationships, career recognition, career awards with job performance \((p=0.026, p=0.007, p=0.035)\), there is a career rewards relationship, career promotion with performance \((p=0.000, 0.027)\). The most dominant factor is career awards \((p=0.004)\). This study recommends the need for application of career nurse level that can improve the performance of nurse implementing in giving nursing care.

Keywords: Nurse Performance, Application of Career level

INTRODUCTION

Good nurse performance is the hope of all patients. According Mangkunegara (2015) performance is the result of work in quality and quantity achieved in carrying out the duties and responsibilities given to him \(^{(1)}\). The performance of the nurse is measured by the services provided to the patient so that the patient feels satisfied or dissatisfied \(^{(2)}\). So the performance of nurses is the productivity of nurses in providing nursing care in accordance with the authority and responsibilities that can be measured in quality and quantity. Assessment of nurse’s performance is a form of quality assurance of nursing service.

Performance assessment is an effort to assess the performance of nurses in the work. Work assessment is a formal system for reviewing and evaluating the performance of a person periodically serves as information about nurses’ individual abilities and helps leaders make decisions in personnel development \(^{(3)}\). The performance assessment is a tool that can be trusted as the control of human resources and productivity, but the fact is the performance of nurses into the problems in all nursing services.

The performance of nurses is influenced by various factors. According to Gibson (2008) there are three variables that affect the individual’s performance that is 1) the individual variables consist of skills, psychological variables consisting of perceptions, attitudes, personality, learning and motivation, while organizational variables consist of resources, leadership, rewards, structure and job design \(^{(4)}\). According to Ilyas (2013), factors affecting performance include personal characteristics consisting of age, gender, experience, orientation and communication style, motivation, salary, environment, organization, supervision and career development. From some references above the performance of nurses can not be separated from factors that influence it \(^{(5)}\). The optimal performance of nurses will certainly contribute to nursing services.

The nurse’s performance appraisal component is set out in Government Regulation no. 46 Year 2011 on the assessment of work performance of Civil Servants (PNS) include Employee Work Objectives (SKP), work behavior and work performance. Assessment of the achievement of Employee Work Objectives (SKP) can be seen in two aspects, namely: 1) Quantity aspect is the achievement of Employee Work Objectives (SKP) of planned target output, 2) Quality aspect is the assessment of work
behavior. From these two aspects will get the value of work achievement which is the sum of 60% x Work Objectives Employees (SKP) and 40% x work behavior. This performance appraisal is expected to improve the performance of nurses. One effort to maintain the performance of nurses remains good by applying a system of career level in the hospital. The application of career level is expected to spur the nursing profession to improve the quality of its work. In every career level nurse clinic increase has competence complexity.

RSUD Palembang BARI is a Local Government Service Agency (BLUD) of Palembang city government with Type B which is committed to improve the quality of quality health services with accreditation plenary. Currently RSUD Palembang BARI is one of the hospitals in the southern part of Sumatra province which has implemented a career-based system based on SK Menpan no. 25 years 2014. Preliminary study conducted on February 22, 2018 with respondents 20 nurses in the inpatient care unit of performance assessment components include the average score of nurse SKP of 85.03 means that nurses in nursing care is in the standard criteria, while the average nurse job behavior of 78.26 in good category and value of work performance when combined SKP score with work behavior hence got value of work performance of nurse in hospital equal to 82.71 mean value of work performance in RSUD Palembang BARI in good category.

**RESEARCH METHOD**

This research is a quantitative research. The research design used is descriptive analytics with cross sectional approach. The population in this research is nurse of executor in PDL, Class I & II, Children, Surgery, ICU, ICCU, PICU and VIP which amount to 120 people. The results of the calculation of the number of samples in this study were 92 implementing nurses and 92 of their documents Employee Performance Objectives (SKP). Determination of sample size used is proportional random sampling. Data analysis included univariate, bivariate and multivariate analysis.

Table 2 shows the value of p value <0.05 that is career reward variable (p value = 0.004) which means the most influential variable to nurse performance is career reward variable.

DISCUSSION

A. Relationship Implementation of Career Level with the Performance of Nurse Executor in the Inpatient Room of RSUD Palembang BARI: The result of bivariate analysis shows that there is a significant relationship of career awards with performance. The results of this study are in line with the research conducted by Marsudi (2013) in Fatmawati General Hospital; the result is that there is a meaningful relationship between career levels with the performance of nurse executor (7).

In the study there is a meaningful relationship between career awards with the performance of nurses at RSUD Palembang BARI. The award is a nurse’s perception of increased authority and income based on clinical nurse career level.

The most basic career development is a financial planning program that is likely to benefit employees. In addition, organizations are required to not only provide work to workers for their lives, but organizations or companies can offer useful skills and enable employees to survive in critical conditions. The rewards in the form of financial and non-financial planning will be given differently at each level in the clinical nursing care system. So according to the researchers, if the career level system implemented, then the new will appear a greater influence between the award with the performance of nurses in RSUD Palembang BARI.

The results showed there was a significant relationship between career promotions with the performance of nurses at RSUD Palembang BARI. Promotion in this research is the nurse’s perception of promotion, placement in a more interesting and beneficial position according to care nurse clinic. The reassignment to a higher position or promotion is usually followed by a raise. Promotion in nurse clinical career network system is more focused on the aspect of the competition.

According to the researchers, if the career level system implemented in RSUD Palembang BARI it will be more clear and fair in preparing nurse promotion policy. From the questionnaire it can be seen that as many as 93.5% of nurses responded well in reward items tailored to the responsibilities and 92.4% nurses responded well in career promotional items improve performance.

B. The Most Dominant Factor Relates to the Performance of Nurse Executor in the Inpatient Room of RSUD Palembang BARI: The result of
multivariate analysis shows that p value <0.05 is career reward variable (p value = 0.004) which mean from 3 variable of career tracking that entering in modeling, which have the most influence to the performance of nurse executor in RSUD Palembang BARI is career reward variables. The OR value of career reward variable that is 0.034 means that good rewards have a chance of 0.034 (CI95%: 0.003-0.349) to improve the performance of nurse in RSUD Palembang BARI hospital ward compared to bad career award.

The result of this research is in line with the research conducted by Sari (2011) of Haji Hospital in Medan, it is found that there is a significant relationship between the award and the performance of the nurse of Haji Hospital in Medan (8). The results of this study is different from the research conducted by Suroso (2011) in RSUD Banyumas, obtained the result that the career challenge is the factor most related to the performance of the nurses in RSUD Banyumas(9).

Nursing performance is based on the guidelines and standards that become the reference in nursing service. The Indonesian National Nurses Association (2010), endorsed the standards of the nursing profession as stated in Law No. 36 of 2009 consisting of competency standards and standards of nursing practice. The performance of the nurse is measured from the services provided to the patient so that the patient feels satisfied or dissatisfied (2).

The award is a nurse’s perception of increased authority and income based on clinical nurse career level. The most basic career development is a financial planning program that is likely to benefit employees. With the existence of financial planning program so employees or nurses will be encouraged to take action as possible and provide the best service, so that will impact on the performance of nurses to be increased.

CONCLUSION

There is a significant relationship between the applications of nursing career level with the performance of nurse executor. This study recommends the need for the application of career nurse level which has a positive impact in improving the performance of nurse implementing in giving nursing care. It is expected that the hospital can prepare a competency-based clinical career system that includes flow, model, and competency test.

¹Health Administration and Policy, University of Indonesia, Department of Public Health, Kampus Baru UI, Depok 16424

ABSTRACT

Background: Indonesian contextual circumstances pose various potential threats to the safety of the country. These threats are the primary cause for developing a good defense system in the country that is able to tackle real and potential threats. Defense Ministry Regulation Number 19 year 2015 classifies threats into three based on the type and duration, including hybrid threats, which one possibility is the use of biological agents as weapons in bioterrorism. Currently, bioterrorism does not receive adequate attention, owing to the fact that it has not occurred in Indonesia. Therefore, there is no defined law or programs with regards to bioterrorism.

Method: This is a qualitative analytic study. Informants were chosen using a purposive approach. It was done under the consideration that detailed information regarding readiness of the National Defense Component of Republic of Indonesia in the face of bioterrorism threats is crucial. Data collected from informants is supported by expert judgment for triangulation purpose.

Result: The results show that there are many obstacles in the implementation of the Ministry of Defense Regulations in the environment of the primary and supporting state defense components. These include no direct socialization of the primary policies which leads to poor coordination and integration between defense components. Hence, the primary aim of integrating the entire primary and supporting strength components are not well achieved.

Conclusion: Coordination between the primary and supporting state defense components overcoming the threat of bioterrorism have yet to be defined in a clear roadmap as there are obstacles in communication, coordination, and synchronization between sectors. The next step is to determine the urgency of bioterrorism, to form a consideration across sectors regarding the importance of forming regulations to encompass overcoming bioterrorism in Indonesia.

Keywords: Bioterrorism; state defense components; Indonesia;

INTRODUCTION

Regulations of the Republic of Indonesia Number 28 on Basic Human Rights states that rights to personal protection, a feeling of safety, and protection from threats is a basic human right that should be provided by the country. Based on the Ministry of Defense Regulation Number 19 Year 2015, Indonesian contextual circumstances pose various potential threats to the safety of the country. These threats are the primary cause for developing a good defense system in the country that is able to tackle real and potential threats as national security from various threats is an important pillar to the existence of the country.

The dynamic development of the global, regional, and national strategic environment, the geographical positional, natural human resources, industrial growth, and the large population of Indonesia bring changes to the spectrum of threats that are complex and affect security of the country. This causes a change in the dimension of threats, both physical and non-physical. Regulation of the Ministry of Defense Number 19 in 2015 classifies threats into three groups based on the type and duration,
including military threats, non-military threats, and hybrid threats. Continuous existence of the Indonesian Republic is greatly affected by the development of multiple threats, including hybrid threats. One possible manifestation is the use of biological agents as weapons of bioterrorism.

Bioterrorism is the deliberate release of pathological agents, such as viruses, bacteria, or other agents used to cause illness or death in humans, animals, plants, and other organisms that may affect the government or cause intimidation to a community. Bioterrorism affects the political, economic, social and culture conditions. The impact and damages caused by bioterrorism is not directly visible, as it may cause damage after some time. Furthermore, bioterrorism may lead to the collapse of administration, and the governance of the country, not only because it is highly infectious and highly effective, but also because it is very difficult to control once released.

According to the World Organization of Animal Health (OIE), 60% of bacterial diseases among humans are caused by zoonosis, bacterial diseases from animals that may infect humans, and vice versa. A more serious fact was expressed that 80% of microorganisms used as agents for bioterrorism come from zoonosis bacteria. In recent times, the world has recorded many incidence of intermittent use of biological agents especially zoonosis to perpetuate terrorism act. Center for Disease Control and Prevention (CDC) classifies biological agents that may be used as weapons into three categories: A, B, and C. This classification is based on the degree of spread of the microorganism and its ability to cause disease. This shows that the trend of biological weapon usage has been dealt with seriously at an international level.

History has noted the occurrence of bioterrorism as weapons of terror, including the use of smallpox virus, anthrax bacteria, and other organisms for terror attacks. In the United States of America, the first known bioterrorism is reportedly in 1984. An actual anthrax attack occurred in the widely remembered 2001 October postal contamination incident. The U.S. Homeland Security Department received reports of anthrax spore exposure, including 11 inhalational cases, 11 cases of cutaneous anthrax, and caused five deaths. As recently as April 2013, letters that tested positive for ricin were reportedly sent to many important figures in the U.S., one of them was to the U.S. President, Barack Obama.

It is suspected that bioterrorism has occurred in Indonesia. This was stated because few scientists believed that the H5N1 bird flu virus found in Indonesia was one hundred percent identical to the one found in Guangzhou, China. Minister of Health, Republic of Indonesia year 2004 – 2009 also called for efforts to change the mechanism of virus sharing by the World Health Organization (WHO). She emphasized that bioterrorism and agricultural terrorism is a form of modern warfare that is asymmetrical. This war is aimed at consumption and disease spread, which destroys national security, because it compromises food and health.

Firm punishments are given by international laws towards bioterrorism. This is because international laws have several different conventions that deal with this issue, which include: first, the Geneva Protocol year 1925 regarding violations to the use of chemical weapons and humanity; second, the Biologic Weapons Convention (BWC) year 1975 regarding the use and development against the production and distribution of biologic weapons; and third, Chemical Weapons Convention 1993 which emphasized on the punishments toward countries that violate the regulations. The U.S. military has compiled and published many regulations for every operation and for those employed in the field. Of these manuals, the Field Manual (FM) 3-11 is the most specific to biological agent preparation and reactions. This multi-service tactics, techniques and procedure manual focus on chemical, biological, radiological, and nuclear (CBRN) agents.

The Minister of Defense of the Indonesian Republic stated in the White Book of Indonesian Defense (2015) that the development of knowledge and technology in the field of chemistry, biology, nuclear, and explosive devices (CBRNE) increases the ownership, use, and spread of CBRNE which in reality may be important to the well-being of humans. However, these dangerous substances may have the potential of becoming threats to the security and safety of mankind if obtained by irresponsible groups of people. Moreover, it is assumed that there are several countries still producing these substances illegally and causing a threat of CBRNE to other countries. If not handled appropriately, or not controlled well, it has the potential of becoming a threat to community health, which also represent a threat to security of the country.

Successfully facing the challenges of bioterrorism threats need a multifaceted response. Based on the
Regulation of the Defense Ministry Number 19 in 2015, as mentioned above, in the face of hybrid threats, a specific pattern of defense is implemented which places the national guard (TNI) as the primary component supported by the ministry or other associated Non-ministry Government Organizations and other components of the country’s strength, including regional governments, to take strategic steps in the face of this threat in accordance with their professional and proportional abilities.

The policy on the Implementation of National Defense is not a simple process. Grindle stated in the book titled Politics and Policy Implementation in the Third World that implementation is a political and administrative process affected by two variables, including context and content. From a contextual point of view, this policy is crucial considering the complexity of hybrid threats, especially bioterrorism, which may not be accomplished by the National Guard alone as the first line of defense. On the other hand, with regard to content, the role of the National Guard is the primary line of defense and leaders of the ministry and other governmental organizations act as supporting factors in the processing of bioterrorist threats.

METHOD

This is a qualitative research study, conducted based on the consideration of the researcher to obtain detailed information regarding the preparedness of the Indonesian Republic National Defense Component in the face of threats of bioterrorism. The collected information is supported by expert judgment and documents finding for triangulation purpose.

Informants were chosen using the purposive technique, which is based on the principle of appropriateness and adequacy. Appropriateness refers to the fact that the informants are chosen based on their knowledge of the topic being researched. While adequacy means the number of informants that have been chosen is appropriate to the type and detailed information required. The purposive method was chosen as the researcher wanted a representative sample based on their anticipated richness and relevance of information in relation to the study’s research questions. Digital recordings of the interviews were translated into written transcripts, which were then simplified into a matrix based on the questions asked. Data were validated using four criteria into levels of trust, including credibility, transferability, dependability, and confirmation. This research maintained data validity through a data triangulation approach, including primary triangulation through data collection by in-depth interviews, secondary triangulation of resources through data collection from informants and comparison of data obtained from the informants. Another method of maintaining data validity is through evaluation on adequacy of references to be analyzed or evaluated as a comparison. Collected data was analyzed to identify the readiness of the Indonesian Republic defense component in the face of bioterrorism.

RESULTS

This research was performed over a span of approximately four months, beginning at the end of February until the end of May 2018. It included three phases: pre-research phase in preparation for all the requirements for data collection in the field, research phase, and data analysis phase. The analysis of the implementation of Ministry of Defense Regulation Number 19 Year 2015 among the supporting units in the face of threats of bioterrorism revealed the use of implementation theory as developed by Edward III (1980).

The research was conducted involving four primary informants from Indonesian National Military Health Center, Indonesian Army Health Center, Indonesian Ministry of Health, and Eijkman Molecular Biology Laboratory. In addition, interviews were conducted with two expert informants from the Faculty of Veterinary Medicine Airlangga University and Bogor Institute of Farming, and several associated documents were analyzed.

Communication Factors: From the communication aspect, implementation of the Ministry of Defense Regulation Number 19 Year 2015 in the informants’ institutional bodies as the primary and supporting units in the face of threats of bioterrorism have not received detailed socialization from the initiators of this policy. This was revealed by informants during the in-depth interviews conducted at different times and places.

“...never, according to me not many know about this even in the ministry, but in the faculty of veterinary medicine not yet...” (EI-2)

Most of the informants mentioned that they have not received socialization regarding the Ministry of Defense
Regulation Number 19 Year 2015. While one informant mentioned that they have received the socialization in 2017, in the form of simulation but there was no any proofs or documents about the details of the program. We can only find one news that mentioned that the simulation of Influenza pandemic has been done in 2017 and also involved other stakeholders, included Indonesian National Military.

**Resource Factors:** Resources play an important role in the implementation of a policy. Based on the research, the cooperation does not go well among the components of the national defense components and has not been planned properly in a structured manner. One supporting informant stated that resources are not a major issue. The most important is awareness and good understanding among the community regarding bioterrorism. With that understanding, then support of resources will automatically become available.

“...I don’t view resources as an issue, instead it is understanding. If understanding of this is not united, then all resources will be depleted. Resources, finances, it can all be created if there is potential, that is the context...”

*(EI-1)*

**Disposition Factors:** Based on the results, disposition factors include commitment, attitude, and tendencies in the face of bioterrorism among the involved components are stand alone and not yet integrated. One informant mentioned that the derivation of the Ministry of Defense Regulation has been compiled into TNI Commander Regulation to handle nuclear, biological, and chemical threats, and will be accomplished by the end of this year. The informants from veterinary health faculty mentioned that they inserted bioterrorism topics in the syllabus of the veterinary faculty students.

**Bureaucracy Structure Factors:** It may be concluded that the bureaucracy structure among the supporting components participate actively as defined by their job requirements in their internal areas. However, a roadmap is needed to integrate and explain this entire defense system. This roadmap becomes their guide in the future to face threats of bioterrorism.

“...So far, the components, as I mentioned, they are there but not integrated. They can be collected in the roadmap...” *(PI-3)*

**CONCLUSION**

Based on the results of the study and discussions regarding the readiness of the national defense component in the face of bioterrorism, it can be concluded that:

1. The components of the Indonesian State Defense Components are not yet ready to face overcoming threat of bioterrorism, because there are obstacles in the implementation of this regulation in the community. Therefore, the primary aim of integrating the entire primary and supporting strength components are not well achieved.

2. Health is an integral part of a country’s defense system. Thus, it requires teamwork with all aspects of national health in the efforts to support national security. To attain synergy, integrated coordination and cooperation is required, along with comprehensive policies that refer to national laws, and synergy between all aspects of national security. The Indonesian government can increase the awareness towards bioterrorism among the military and increase cooperation between military groups with important leaders in the field of community health.

3. Coordination and integration between all the involved components in overcoming the threat of bioterrorism have yet to be defined in a clear roadmap.

**Conflict of Interest:** The authors have no conflicts of interest with the material presented in this manuscript.

**Source of Funding:** The authors would like to show our gratitude to the Directorate of Research and Community Service University of Indonesia for the supports of this research.

**Ethical Clearance:** The authors declare that there is no any ethical issues that may arise after the publication of this manuscript.

ABSTRACT

Background: Human resources are an important component of success. The success of the hospital is strongly influenced by the performance of employees including nurses. One of the supporting factors of nurse performance is job engagement. Objective: the aim of this research is to find the correlation of nurse engagement with Performance index in ICU nurse activity at Surabaya Hospital. Method: This research is a quantitative analytic research and use descriptive design with cross sectional research method. The sampling technique used in this research is the total sampling technique that is taking data of all nurses who are in ICU. Result: The results of this study indicate that nurse engagement has a correlation with performance index.

Keywords: Engagement, Performance, Nurse

INTRODUCTION

In a hospital organization, human resources are an important component of success. Human resources need to be managed well and professional in order to create a balance between the needs of human resources with the demands and progress of the company’s business. The development of the company’s business is very dependent on the productivity of labor in the company. Every company wants a good performance from every employee. Employee performance is a factor that can determine the success or failure of the company in reaching its vision. Jex and Britt argue that performance (job performance) is a behavior of employees involved in the job. Performance (job performance) has two major categories, namely in-role (task) performance and extra-role (contextual) performance. In-role performance refers to the technical aspects of employee work. For example, a nurse is required to perform tasks such as checking blood pressure, injecting, and installing an IV. Meanwhile, extra-role performance refers to non-technical skills such as the ability to communicate effectively, show motivation and enthusiasm for workers, and help co-workers who have difficulty in doing their work. According Agustina (2009) defines performance as a result of work over a certain period compared with various possibilities, such as standards, targets / goals or criteria that have been agreed upon. Performance appraisal has an important role in improving work motivation. This performance appraisal is basically a key factor in developing an organization effectively and efficiently. According to Haryono (in Faizin and Winarsih, 2006) the performance of nurses is nurse activity in implementing the best of an authority, duties and responsibilities in order to achieve the goals of the main task of profession and the realization of the goals and objectives of the organizational unit.

In addition to good performance employees are expected to have engagement, an engagement, a desire to contribute and a sense of ownership of work and company. In general engagement is defined as the attachment of both physical, intellectual and emotional to contribute to the improvement of company performance. Gallup defines engagement as participation and enthusiasm for work. Gallup also associates employee engagement with positive emotional attachment and employee commitment.
(in Nusatria and Suharmono, 2013) gives the definition of employee engagement as a positive attitude that employees demonstrate to the organization and the value of the company9. While Schaufeli and Bakker (2010) states that work engagement as a positive thing that must be met in work and has some characteristics that are marked by the spirit (vigor), dedication (dedication) and absorption (absorption)10. The attachment that workers perceive in each characteristic will encourage the creation of a personal attachment. Workers with high levels of engagement will have a high emotional attachment to the organization, which will have an effect on completing the work and are likely to have a satisfactory quality of work11. The bound worker will be motivated to increase his productivity, accept the challenge and feel his work gives meaning to him. It will have a positive impact on worker performance, as well as for organizational productivity and growth. So it can be said that work engagement can provide changes for both individuals, teams and organizations.

Based on data from the HR department, the performance of nurses as much as 72.5% has good performance, 21% medium and 6.5% bad performance. While the target of the hospital as much as 85% nurses with good performance and no nurses with poor performance. Therefore conducted research to see one of the factors that affect the performance of work engagement. The expected result is to know the relation of engagement with nurse performance in hospital, hence can be done the work engagement improvement so that can improve the performance of nurse in hospital.

**METHOD**

This research is a quantitative analytic research and use descriptive design with cross sectional research method. Cross-sectional research method is one of the most frequent observational (non experimental) study. In a broader sense, the cross-sectional study includes all types of research whose variable measurements were performed only once at one time12. This research is to know correlation of nurse Engagement relationship with nurse performance by approach, observation or data collection. Data taken in the form of Primary Engagement nurses data in ICU which have been taken by interview using questioner following Gallup theory. Nurse performance data using hospital secondary data. This study was conducted at Surabaya Hospital in February 2018. The number of respondents who used as many as 12 nurses ICU which is Total Sampling.

**RESULT**

Based on Primary Data of nurse Engagement and Secondary Data of Performance of ICU Hospital nurse of Surabaya then got the following data.

**Table 1: Distribution of Respondents Frequency Based on Nursing Engagement in ICU Room Surabaya Hospital 2018**

<table>
<thead>
<tr>
<th>Engagement</th>
<th>Frequency (n)</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not engaged</td>
<td>5</td>
<td>41.7</td>
</tr>
<tr>
<td>Engaged</td>
<td>7</td>
<td>58.3</td>
</tr>
<tr>
<td>Total</td>
<td>12</td>
<td>100.0</td>
</tr>
</tbody>
</table>

Based on Table 1. it can be learned that most of the implementing nurses (58.3%) in the ICU Hospital Surabaya Room include employees who are engaged.

**Table 2: Distribution of Respondents Frequency Based on Performance of Nurses in ICU Room Surabaya Hospital 2018**

<table>
<thead>
<tr>
<th>Nurse Performance</th>
<th>Frequency (n)</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Good</td>
<td>8</td>
<td>66.7%</td>
</tr>
<tr>
<td>Fair</td>
<td>4</td>
<td>33.3%</td>
</tr>
<tr>
<td>Poor</td>
<td>0</td>
<td>0%</td>
</tr>
<tr>
<td>Total</td>
<td>12</td>
<td>100 %</td>
</tr>
</tbody>
</table>

Based on Table 2. shows that of 12 nurses, most of the nurses in the ICU Hospital Surabaya had good performance of 8 people (66.7%).

**Table 3: Nursing Engagement Relations with nurse performance in ICU Hospital Surabaya Hospital 2018**

<table>
<thead>
<tr>
<th>Engagement</th>
<th>Nurse Performance</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Fair</td>
<td>Good</td>
</tr>
<tr>
<td>Not engaged</td>
<td>4</td>
<td>20.0</td>
</tr>
<tr>
<td>Engaged</td>
<td>0</td>
<td>100.0</td>
</tr>
<tr>
<td>Total</td>
<td>4</td>
<td>33.3</td>
</tr>
</tbody>
</table>

According to Table 3. it can be learned that the more engaged nurses in ICU Hospital Surabaya, the higher the tendency of nurses to have a good performance in performing their duties in the ICU Hospital Surabaya. The results of cross-tabulation in this study indicate that nurse engagement tends to have a relationship with the performance of nurses.
DISCUSSION

Based on the results of analysis in ICU Surabaya Hospital with field observation and nurse performance data, nurses with good performance of 66.7% while the standard set by the hospital is 85% good performance. Based on cross tabulation, there is a positive correlation between work engagement and nurse performance. This means the higher the nurse’s work engagement the better the nurse’s performance, and the lower the work engagement the worse the nurse’s performance. This is in line with previous research conducted by Wahyudi (2017) stating that nurse engagement at Pariaman hospital has a positive relationship with the performance of nurses\(^1\). Another supporting research is a study conducted in Malang with a sample of 102 nurses stating that nurse’s Engagement significantly affects nurse’s satisfaction which then affects the performance and turn over intention of the nurse\(^2\). Engagement of employees is very important in improving employee initiatives in performing their duties. For example, compliance with 5 times wash-hand, when compared to forcing employees with regulation, improving engagement proves more successful in increasing employee compliance rates in hand washing\(^3\). This supports the results of table 3. Where the nurses are not Engage, the performance of the nurses is not good.

CONCLUSIONS

Based on the results of the analysis of research that has been done then it can be concluded that there is a positive relationship between employee engagement with the performance of hospital nurses ICU. In relation to the results of this study, the suggestion for the Hospital to design a training where the training can improve employee engagement and performance. Training is more directed to off-site training (training that is not related to work skills) where the training is able to revive motivation and as learning for nurses to be more familiar with their potential.

Correlation of Mercury (Hg) Levels in Blood With Level of Crystatin C Serum in Traditional Gold Mining Area in Sekotong Village of West Lombok District

Syamsu Rijal¹, Soedjajadi Keman²

¹Lecturer of Institute of Environmental Engineering (STLL) Mataram; ²Department of Environmental Health, Faculty of Public Health, Airlangga University, Surabaya Indonesia;

ABSTRACT

The presence of gold miners in Sekotong village of West Lombok has attracted public attention since the beginning of 2008, even many who come from outside of Sekotong. Almost 50% of the 40,000 Sekotong residents are involved in activities related to unlicensed gold mining and processing. This study aims to analyze the heavy mercury (Hg) equipments in blood with serum cystatin C in West Sekotong Village of Sekotong Subdistrict, West Lombok District, West Nusa Tenggara. This research was an analytic observational study with cross sectional study design. The sample size was 18 people consist of 9 people exposed group, and control group was 9 people using simple random sampling technique. Exposed groups live in West Sekotong village and the control group lives in Kekait village. The data were collected through interviews using questionnaires and mercury test in blood using Mercury Analyzer method while Cystatin C vapor and serum test using method of Turbidimetry Immunoassay (PETIA). Data analysis using Spearmen Correlation. The results showed that mercury (Hg) content was no correlation with Cystatin C (Spearmans, p = 0,546). This study is mercury (Hg) levels have exceeded the standards in the exposed group. The levels of mercury (Hg) were not associated with levels of serum Cystatin C.

Keywords: Level of Mercury (Hg), blood, Level of Cystatin C

INTRODUCTION

The presence of gold miners in the West Sekotong village of West Lombok district has attracted public attention since the beginning of 2008, even many who come from outside Sekotong district. Almost 50% of the 40,000 Sekotong residents are involved in activities related to gold mining and processing¹. Illegal mining is difficult to stop because for local people, mining is their current livelihood, but if mining activities continue to be done then more and more mercury is wasted into the environment and cause environmental pollution around.

The mercury content of the waste gold mining waste in June 2015, it is known that the mercury content in the waste reservoir is 34,65-82,72 ppm². The high content of mercury is feared will pollute the environment. Based on Government Regulation Number. 82 of 2001 on water quality management and water pollution control, mercury content for first class water quality standard is 0,001 ppm.

The biotic component can give an idea about the physical, biological and chemical a waters. Heavy metals that often pollute the environment are lead (Pb), cadmium (Cd) and mercury (Hg) because these three heavy metals are used by most industrial production processes³. When heavy metals (Hg, Pb, Cd) enter the body, most will collect in the kidneys, liver, and some will be excreted through feces and urine⁴.

Test of Serum cystatin C has been used as one of the methods to evaluate renal function. This protein is not affected by bone mass, gender, age, or race, unlike creatinine. When the kidneys are functioning normally, serum cystatin C concentrations in the blood are stable.
But when kidney function is impaired, its concentration begins to increase. An increase in when GFR decreases and can often be detected before any measurable GFR reduction can be measured. Although much data and literature support the use of serum cystatin C.

**MATERIAL AND METHOD**

This research was an analytic observational study with cross sectional study design because of all research variables at the same time, there is no time difference between the measurement of potential risk factors and their impacts and involves measurement of exposure and its effects simultaneously on specific groups of individuals. This research was conducted in West Sekotong Village, Sekotong Subdistrict of West Lombok District, while the comparison location (negative control) in Kekait Village, Gunung Sari Subdistrict of West Lombok and testing of Hg and Cystatin C serum blood samples were conducted at Prodia Clinic Mataram. This research was conducted in December 2017 until January 2018.

The population in this study consisted of two groups: the exposed group population living in Sekotong village and unexposed groups living in Kekait Village of Gunung Sari subdistrict, West Lombok District. The sample size was 18 people consisting of 9 people from the exposed group and 9 groups unexposed. The sampling technique using simple random sampling. The data were collected through interviews using questionnaires and mercury test in blood using Mercury Analyzer method while Cystatin C vapor and serum test using method of Turbidimetry Immunoassay (PETIA). Data analysis using Spearmen Correlation to determine the correlation of mercury content with cystatin.

**FINDINGS**

**Level of Mercury (Hg) in Blood:** The test of mercury (Hg) levels in Blood was done by Atomic Absorption Spectrophotometer (AAS) method. The distribution of Hg levels in blood of respondents was shown in the table below.

<table>
<thead>
<tr>
<th>Groups</th>
<th>Hg Levels in Blood (ug/dL)*</th>
<th>Total</th>
<th>Mean</th>

* Threshold Limit Concentration of Hg in blood (WHO)

Table 1 showed the groups exposed to Hg levels in blood >5 ug/dL were 9 people (100%) with mean of 10.96 ug/dL and deviation standard 5.73. While in the unexposed group had Hg levels in blood ≤ 5 ug/dL were 2 people (22.22%) with mean of 13.46 ug/dL and deviation standard 12.10 and negative control had Hg levels in blood <5 ug/dL were 8 people (88.88%) with mean of 2.94 ug / dL and deviation standard of 1.36.

**Level of Crystatin C Serum in Blood:** Cystatin C levels in Blood were analyzed using ELISA method with a reference value of 0.57 to 0.96 mg/L. The distribution of Cystatin C counts on the respondents was shown in solid table below.

<table>
<thead>
<tr>

</tbody>
</table>

* Threshold Limit Concentration of Cystatin C in blood (WHO)
Table 2 showed exposed group had Cystatin C levels in blood > 0.96 mg/L were 4 people (44.44%) with mean of 1.2477 and deviation standard 0.0966. While unexposed group had Cystatin C levels in blood 0.57 - 0.96 mg/L were 6 people (66.66%) with mean 0.8255 and Deviation standard 0,1250.

**DISCUSSION**

The results showed that there was a difference of mercury (Hg) levels between exposed group and unexposed group (kruskal Wallis, p < α.). In the exposed group all respondents had mercury (Hg) above 5 ug/dL. This is because these respondents work as laborers in gold miners without permission and are indicated to come from gold miners without permission either as workers or from consuming marine life and vegetables. Unlike the unexposed group, almost all of the respondents had mercury (Hg) levels below 5 ug/dL.

The results showed that there was a difference in Cystatin C levels between exposed and unexposed groups (Kruskal Wallis, p<α.). This was supported by research conducted in Kokap Kulon Progo of Yogyakarta that gold miners (PETI) had Cystatin C levels in the blood between group exposed at an average of 1.07 mg/L and an unexposed group of 1.10 mg/L (excluding the standard 0.53-1.01 mg/L).6

Correlation of mercury (Hg) levels with Cystatin C Serum levels: Results of laboratory test of Hg levels in blood had mean 27.36 ug/dL with Deviation Standard 19.19 with range 5-10 ug/dL whereas for Cysatin C serum average 3,0620 mg/L with Standard Deviation 0,4162 with range 0.57 - 0.96 mg/L.

Furthermore, the correlation of blood Hg levels with serum Cystatin C based on analysis with Correlation Spearmens rho showed that blood Hg levels did not have a correlation with serum Cystatin C level with p = 0.546. Another research said that Cystatin C levels are not only affected by heavy metals but can also be affected by nutritional status (p=0.012) in the positive direction of the relationship.7 Internal dose is the presence of a number of xenobiotic materials in biological media interacting with the subcellular, cellular and target tissues that are influenced by genetic factors, nutritional status, sensitivity markers and immune status.3

**CONCLUSION**

Mercury (Hg) levels in blood on exposed group exceeded the standard set by WHO and the mercury (Hg) levels in blood were not associated with cystatin C serum levels.

Environment and Forestry Agency (DLHP) to take action against Unlicensed Gold (PETI) in the use of mercury (Hg) in the effort to minimize the normal weight of mercury (Hg), Agency for Health Research and Development (Balitbangkes) to conduct monitoring, Society or consumers pay more attention to the pattern of consumption of marine biota to lose weight metal and minerals (Hg) in the body and also through the air to help reduce mercury (Hg) levels, and For researchers it can be used for the things that are needed in this study and other vegetables such as fish, shrimp, crabs.

Relationship Analysis of Head Competency Competency in Implementation of Management Functions with Nurse Performance in The Application of Patient Safety Objectives in General Hospital Mayjen HA Thalib Kerinci Indonesia 2018

Thirisia Monica¹, Meri Neherta², Fitra Yeni²
¹Master Program of Nursing, Faculty of Nursing, ²Faculty of Nursing, Andalas University,

ABSTRACT
The managers ability to motivate, influence, and communicate with the will determine the effectiveness of the manager. Implementation of management functions Requiring competence of the head nurse as first-line managers in the inpatient unit. This study was cross sectional among 103 nurses in the RSUD Major General HA Thalib Kerinci. This study aimed to determine the relationship of head nurse competency in performing management functions and nurse’s performance in the implementation of patient safety. This research results that the competence heads of the organization are (p = 0.007, α = 0.05) and directing (p = 0.014; α = 0.05), with most of the factors associated with the performance nurses in the implementation of patient safety was organizing (p = 0.022; α = 0.05). Head Nurse need to constantly improve competency in performing nursing management functions primarily on organizing and directing function in improving the performance of nurses in the implementation of patient safety goals.

Keywords: competence Head of the room, the nurse performance, patient safety

INTRODUCTION
Patient safety is part of the quality of health services that can be seen as an organizational system (structure and culture), management, human resources, scheduling and equipment availability. The management of the treatment room can be done well, if the head of the room has managerial ability and professional ability in managing the implementation of care services where the manager or head of the room arranges and plans room management for the management of the patient (Terry, 2013). The results of Chase (2011) study in US Hospital using descriptive study focusing on the measurement of nurse managers’ competence in 81 first-line nurse managers from 3 types of hospitals found that the competence of nurse managers play a very important role in determining the extent to which nurses play a role in all House arrangements General Illness Mayjen HA Thalib Kerinci is the only referral center hospital in Kerinci.

Hospital with type C has 16 inpatient Room From interview result about ability of head of room in carrying out management function, conducted by researcher to head of room in 6 inpatient room obtained that management function not maximal implemented, head of room and execute its management function only few item aja that is executed that is at the time of operand only, even then operan night service to morning, head of room always conduct visit with doctor, but supervision and direction to nurse executor not yet optimal, never follow activity of head room ward management, planning guidance on patient safety goals because they do not have guidelines. where the activities performed by the head of the room only report the event only if an unexpected event occurred to the Hospital Patient Safety Committee. The head of the room does more work, which often happens to be medication errors, surgery errors, procedures and nosocomial infections (Classenet al, 2011). Based on the above background, to improve work productivity, performance and effectiveness is closely related to the competence of the head of the room in running the nursing management function.

METHOD
This research is a quantitative research with approach cross sectional. The population in this research is all the nurses in the inpatient ward that amounted to 139 people in RSU Major General ThalibKerinci Technique.
The sampling of the research using proportional random sampling with the sample number of 103 nurses, where the criteria inclusion in this study is the
1. Nurse executor in the inpatient room
2. Not being on leave/education
3. Willing to be the respondent

The research was conducted in June 2017.

RESULTS

The characteristics of age nurse yang have age ≤ 35 years more that is 83 (80.6%) than age 35 years old. The respondents were dominated by 70 (68%) female nurses with the highest level of vocational education (D3 nursing) of 77 (74.8%), the working period of most ≤ 5 years was 60 (58.3%), and the respondents who had attended the training sebanyak 89 (86.4%).

Based on table 3 indicates that there is no correlation between the head room’s competence in the planning function and the performance of the nurses in applying the patient’s safety objectives (p = 0.0499) there is relation of head room competence in organizing and directing with nurse performance in patient safety target (p = 0.007 and p = 0.0014), and there is no relationship of competence in supervision with the performance of nurses in the target of patient safety (p = 0.0492).

Final Modeling of Logistic Regression Results on Competency Head Nurse in Implementation of Management Function with Nurse Performance in Application of Patient Safety Target in Major General H. Thalib Kerinci Hospital 2017 (n = 103)

The variables that have a significant relationship with the performance of nurses in the implementation of patient safety goals is the function of organizing and directing function (p < 0.05: α 0.05). The results of the analysis obtained the highest OR is the direction (OR = 2.317) so it can be concluded that the competence of the head of the room in the function of direction is the most influential factor on the performance of nurses in the application of patient safety sasran. The result of OR can be interpreted that the executing nurse who evaluates the competence of the head of the room in a good briefing function will have the opportunity to perform a good performance in the application of the patient’s safety target of 2.317 times higher than the nurse who assessed the less directed function after controlled by the organizing function.

**DISCUSSION**

1. **Relationship of Head Competency Room in Function of Planning with Performance of care in applying patient safety target:** Based on the result of research, there is no significant relation between competence in function of head of room planning with nurse performance in applying patient safety target (p = 0.499), where p > 0.05. This result is in accordance with Darwito research (2012), that there is no significant correlation between the implementation of head room planning function with nurse performance (5), and Kusumas research (2015) there is no correlation between the function of headroom planning with the performance of nurse executing (p = 0.89) (6). This is because the nurse in providing nursing care is still fragmented on certain types of tasks, so that the work performed by nurses is still routine and not well planned. This is also because most nurses are vocational (74.8%) where the operational nursing personnel in the targeting of patient safety target with the most working period is 5.3% as much as 58.3%, where the experience is still less including the sense of responsibility answer.

2. **Relationship of Head Competence Room in Organizing Function with Nurse Performance in the implementation of patient’s safety objectives:** Based on the result of research, there is a significant relationship between competence in head organizing function with nurse performance in the implementation of patient safety target (p = 0.007), where p < 0.05. The results of this study are not in accordance with the research Kurniadi (2013) there is no relation between the function of organizing the head of the room with the performance of nurse executor (p = 0.83) (6).

Organizing is the determination of the work to be done. Grouping tasks and handing out work to every staff, establishing departments and establishing relationships. According to the researcher’s assumption, the competence of the head of the room in the organizing function needs to be improved to achieve the objectives systematically so that there is clear division of tasks, there is good coordination, there is one command unit, and there is a division of responsibilities and authority in accordance with the abilities and skills of the nurse so that a relationship exists between the nurse and the head of the room.

3. **Relationship of Head Room Competence in Direction Function with Performance of nurses in the implementation of patient safety goals:** Based on the results of the study, there is a significant relationship between competence in
the function of head direction of the room with the performance of nurses in the implementation of patient safety goals \((p = 0.014)\), \(<0.05\). The results of this study in accordance with research Craven (2012) that there is a significant relationship between the head direction of the room with the application of patient safety \((p = 0.008)\).

The direction function is for the nurse or staff to do what they want and should do. Elements in direction consist of mutual motivation, problem-solving, delegation, effective communication, collaboration and coordination (Terry & Rue, 2010) \(^1\). The results of this study are not in accordance with the research Kurniadi (2013), that there is no relationship of head direction function with the performance of nurses \(^6\). According to the assumption that the competence researchers must have in the direction function requires the head of the room to communicate with the nurse implementer for the purpose can be achieved. Briefing can create a good working climate.

4. **Connection Head Competency in the Supervisory Function with Nurse Performance in the application of patient safety goals:** Based on the result of research, there is no significant correlation between head room competence in supervision function with nurse performance in applying patient safety target \((p = 0.492)\), where \(p > 0.05\). The results of this study according Wibowo (2013) that there is no relationship control function with the implementation of nursing care \(^8\). Similarly, research Kurniadi (2013) that there is no relationship of head room supervision function with the performance of nurses \(^6\).

**Conflict of Interest:** No conflict of interest in this study

Nutrition Education Using my Plate Media to Improve Self-efficacy and Parental Support towards Children in Full-day Primary School and Non-Full-day Primary School

Calista Segalita¹, Triska Susila Nindya¹, Qonita Rachmah¹, Trias Mahmudiono¹

¹Departement of Nutrition, Faculty of Public Health, Universitas Airlangga, Jl. Mulyorejo Kampus C, Surabaya 60115, Indonesia

ABSTRACT

Nutrition education approach is one of many ways that can be done to change people behavior, mainly regarding in health. There is still lack of nutrition education towards school children by the school because of human resource, facilities, and financial matters. Nutrition education using MyPlate media can help children to choose nutritious food. Nutrition education were given by attractive counseling using audio-visual and cooking demo based on MyPlate food guide. Balanced meal nutrition education using MyPlate are expected to be internalized inside children’ mind. Participants of this study were 50 students from public and private primary school in Surabaya. Data for this study were gathered using pretest and posttest. Pretest was given before and posttest was given after nutrition education process in order to evaluate the result. To compute the data ANOVA statistical test was used. The use of ANOVA statistical test revealed that after nutrition education, students’ knowledge towards MyPlate concept significantly increase in each food group: main food (p-value=0.004), vegetable (p-value=0.002), and water (p-value<0.001). Moreover, nutrition literacy score and literacy about MyPlate also significantly increase with each of it has p-value<0.001. This study showed that there was significant improvement in children literacy about MyPlate food concept before and after nutrition education process has given.

Keywords: Children-school age, MyPlate, nutrition education, balanced nutrition

INTRODUCTION

Children around the world suffering malnutrition. More than 25% children in third world countries are stunted(1). Stunted children cannot grow well. Stunted children have shorter height compare to normal children in their age. Moreover, stunted in children associated with sub-optimal brain development causes weakening in brain cognitive development, study and career achievement in the future(2). The majority of developing country experienced nutrition phenomena known as nutrition transition. Nutrition transition happened when the population adopting modern lifestyle while social-economy, urbanization, and acculturation aspect are emerging(3). Popkin (2002) suggested that double burden of malnutrition in household correlated to urbanization. When urbanization occurred, household family income increased and affected their ability to buy more food, there is an increase in quantity but not in quality. Energy-dense food but low micronutrient and protein effect children’s growth, especially in children height. Meanwhile in the side of mothers, if mothers eat high-dense food but do low physical activity then the risk of obesity and weight-gain will be higher. As the fourth most populated country, Indonesia undergo double burden of malnutrition. Prevalence of stunted children in Indonesia was 36,8%, 35,6%, and 37,2% consequently in 2007, 2010, and 2013(5).

Mothers play important roles in supporting family nutritious intake. It is important, in a way that most
of mothers are known to prepare and arrange food for their family. In the early stage of life, children are not able to choose their own food, therefore mothers play role in here, to help them choose the right and nutritious food. Savage et al. (2008) stated that parents powerfully shape children’s early experiences with food and eating, providing both genes and environment for children. Children’s eating patterns develop in the early social interactions surrounding feeding(6). In Indonesia, balanced food recommendation previously socialized in 2009 by the Ministry of Health. Specifically, they promote MyPlate concept which regulated in PERMENKES. However, people especially mothers are still lack of understanding in implementing MyPlate concept. MyPlate is a reminder to find our healthy eating style and build it throughout our lifetime. MyPlate emphasizes five food groups: fruits, vegetables, grains, protein, and dairy products. Consuming balanced each of these food groups as recommended in MyPlate helps to build and maintain healthy bones(7).

Nutrition education is one thing that can be done to changes one’s behavior especially towards health. We see that it is important to introduce nutrition education to young people especially children school-age. Nutrition education in school age best given when collaborates with community who interact mostly with the kids, which is school. In line with Bezerra et al. (2017) statement that school can act as an enabling environment for the promotion of healthy eating behaviors and the practice of physical activity. Unfortunately, in Indonesia, there is still lack of nutrition education towards school children because of the lack of school resources such as human resource, facilities, and financial matters. The involvement of the school community represents a main role in social support to children and adolescents(8).

Al-Muslim school is one of institution that served full-day school concept and had been declared as ‘Healthy Promoting School’ since 2008. They applied green education concept and nutritious food implementation to their student. Meanwhile, SDN Sidotopo Wetan I is a public school run by the government of Surabaya. This school is not full-day school thus they don’t provide any lunch activity together. Therefore, MyPlate concept never been socialized in SDN Sidotopo Wetan I. Compare to Al-Muslim, the number of student in SDN Sidotopo Wetan I is larger. Hence, activity to improve student’s literacy about MyPlate concept is needed importantly, looking at large number of students in SDN Sidotopo Wetan I who unfamiliar with MyPlate concept.

The objective of this study is to improve children self-efficacy, MyPlate and nutrition literacy also parents support towards nutritious food intake for their children using MyPlate concept. To improve and change ones’ behavior, especially children, the programs must be fitted into the family, school, and community setting, in order to improve effectiveness(9,10). To effectively promote healthy nutrition in children school age, we must better understand the determinants of their behaviors and change in these behaviors. One important theory of behavior change is Bandura’s Social Cognitive Theory (SCT). Bandura’s SCT is an interpersonal theory that emphasize mutual interactions of persons, behavior, and environment(11). The SCT is relevant to health communication. SCT provides a framework for designing, implementing and evaluating programs. Evaluating behavioral change depends on the factors environment, people and behavior. The SCT includes all constructs that are both internal to individual (e.g., self-efficacy, goals) as well as external (e.g., social support, environmental influences)(12). All of the three factors, environment, people, and behavior are constantly influencing each other. Behavior is not simply the result of the environment and the person, just as the environment is not simply the result of the person and behavior(13). The theory deals with cognitive, emotional aspects and aspects of behavior for understanding behavioral change. The concepts of the SCT provide ways for new behavioral research in health education. Ideas for other theoretical areas such as psychology are welcome to provide new insights and understanding.

In this study, we try to improve children self-efficacy to change the behavior to consume nutritious food. Self-efficacy is fundamental to the process of behavior change in that confidence in ones’ abilities can provide the motivation necessary to follow through with a change in behavior. Self-efficacy conceptualizes a belief in personal capabilities to organize and execute the courses of action required to attain a behavioral goal(14). Additionally, self-efficacy is important because it influences several other SCT variables(13). Consistent evidence indicates that self-efficacy is a mediator of behavior change Bandura suggested four specific antecedents of self-efficacy beliefs: enactive mastery experience, vicarious experiences verbal persuasion and physiological/affective states(15). According to Bandura (1997) nutrition interventions will be more successful if they strengthen individuals’ knowledge of the topic,
improve environmental factors, encourage self-efficacy, develop the use of self-regulatory, and the interventions are appropriately prepared for demographic groups. In this study, we highlighted three antecedents in Bandura’s SCT to improve self-efficacy in Al-Muslim and SDN Sidotopo Wetan I, mastery experience, verbal motivation, and vicarious experience. These three strategies then elaborated into education activities given to students. We expected there will be positively correlation between nutrition educations about MyPlate and student’s improvement in self-efficacy and also parental support.

MATERIAL AND METHOD

Site and Subject of Study: This study done in two different places, Al-Muslim Fullday Private School and Sidotopo Wetan Non-Fullday Public School. The participants of this study were 50 school-children in each school who divided into 5 groups consist of 10 students. In each group, there was one nutrition educator as a guide during education process. This nutrition educator played a role to help and ensure children to be aware and understand about MyPlate concept. Students and mothers who participated in this study in informed consent. This study has been approved by The Health Research Ethics Committee of Faculty of Public Health Airlangga University with registered number 159-KEPK and date of approval 26 April 2017.

Pre and Post-Test: The design of this study is using single-group pretest and posttest design. Assessment of pretest was done before intervention given. Assesment of posttest given after the children received nutrition education. To determine initial associations among the nutrition education, student’s self-efficacy and parents support, Pearson product-moment correlations were estimated using SPSS (v.21.0). Afterward, to compute the data t-test and ANOVA statistical test were used.

FINDINGS

The result of ANOVA statistical test showed significantly improvement in students’ food grouping competence and literacy after the nutrition education intervention was delivered. The p-value result of the variables showed positive correlations. Students’ ability in classifying different food groups was improved. As can be seen in table 1, in main meal food grouping the p-value=0.004, vegetable p-value=0.002, and water p-value<0.001. Moreover, nutrition literacy score and MyPlate literacy score was significantly increase with each p-value<0.001.

</tbody>
</table>
Al-Muslim had higher average score rather than Sidotopo Wetan I considering most of the Al-Muslim students were already aware about health information. Posttest assessment in Sidotopo Wetan I was increase significantly, more students acquired better score in MyPlate literacy. This result might be affected because of participants’ characteristics. In Sidotopo Wetan I, most participants were 6th grade which could contribute to better comprehension. Meanwhile, Al-Muslim participants had more disparity from 3rd until 6th grade students.

For the posttest in nutrition literacy, the average score of nutrition literacy in Al-Muslim students were higher compare to Sidotopo Wetan I. The average score in Al-Muslim was in 3 meanwhile Sidotopo Wetan I was in 2. Therefore, we can conclude that there was significant improvement from pretest to posttest score about nutrition literacy.

Al-Muslim score was increase into 5, which was the maximum score and so did as Sidotopo Wetan I which improve into 4. There was significant improvement in Sidotopo Wetan I meanwhile Al-Muslim did not increase as significant as Sidotopo Wetan I. Nutrition literacy in both school were significantly improved after nutrition education was given.

Outcome of this study is to change students’ behavior with parental support to be able to consume nutritious food based on MyPlate food guide. To start eating healthy from such early stage of life will reflects in adolescent health status. Healthy eating habit will help dealing with the complexity of the health problems in adolescents’ life stage.

Both school improved in before and after intervention showed on pretest and posttest score. However, Sidotopo Wetan I public school showed more significant improvement in pretest and posttest score compare to Al-Muslim private school. It may be related because before intervention, Sidotopo Wetan I students were less aware about health, compare to students in Al-Muslim private school who were previously familiar about health. Al-Muslim private school had practicing eco-green education as a health promoting program since 2008. Therefore, Al-Muslim’s students will likely have better comprehension about nutrition literacy rather than Sidotopo Wetan I public school. Thus, when education was given, Sidotopo Wetan I showed more significant improvement. However, in posttest result, Al-Muslim had higher score rather than Sidotopo Wetan I.

It is related to Al-Muslim healthy school practices since 2008, it encourages students to be more aware about health and it is reflected in posttest score compare to Sidotopo Wetan I.

Although there was score improvement with self-efficacy but there was no association between the intervention given and the improvement. It might be occurred because of the duration of intervention was not long enough to give the impact. In this study, nutrition education was given for one-month long. Meanwhile, some studies gave longer duration. Study conducted by Murimi et al. (2017) occurred for 5 months and succeed in improving self-efficacy in school children. Also, study by Jarpe-Ratner et al. (2016) found that ten-weeks nutrition education to student was effective in improving children’s self-efficacy. Thus, in the future researchers can considered to give longer duration to increase and improve self-efficacy towards school children.
CONCLUSION

Nutrition education based on social cognitive theory is an effective model from which to explore influential construct of health behavior. Intervention using nutrition education with MyPlate media and attractive activities give significantly improvement in nutrition literacy and MyPlate literacy of students in private and public school. Longer duration of intervention might be needed to significantly improve children’s self-efficacy,

Medication Error Based on Nurse Knowledge at Inpatient Unit of Surabaya Private Hospital

Wahidah Rachmaniyah¹, Bima Pramundita¹, Djazuly Chalidyanto²
¹Department of Administration and Public Policy, Public Health Faculty, ²Lecturer of Public Health Faculty, Airlangga University, Surabaya

ABSTRACT
Medication error is one of the factors that cause the incidence of medical error. The parties who were responsible for these cases are nurses. The purpose of this study is to describe the incidence of medication error based on the knowledge of nurses at the inpatient unit of Surabaya Private Hospital. This is an observational descriptive research. Based on the time of study this was included as cross sectional study. The respondents were 63 nurses. The data were collected by questionnaires and observational guidance. Data analysis was conducted by cross tabulation analysis. The results of this study are most of the respondents were in the age range of 20-40 years old. Most of the respondents were female. The last education of most of the respondents was Diploma-III. The most of respondents have worked for more than 10 years. The respondents who have good-knowledge are in Class 2 room, while the respondents who have poor-knowledge are in Kids room. In overall of the room, the knowledge levels of respondents are poor. The conclusion of this study is the incidences of medication error are more happening in the room with poor level of respondent’s knowledge and fair level of respondent’s knowledge.

Keywords: medication error, knowledge, nurse, inpatient

INTRODUCTION
Medication error is an incident that can be detrimental to patients which can actually be prevented. This medication error is the result of drug use, action, and treatment as long as the patient is handled by health personnel.¹ Medication error itself is one of the common factors that can cause a medical error.²

These incidents are most common in hospitals. According to Kinninger (2003), about 7000 people were died annually due to the medication error. Another study conducted in United States, found that the incidence rate of medication error between 2-14% of the number of patients treated in hospital. This was happened because the wrong prescription is about 1-2% and it was causes losses to the patient. Another study says that about 7000 patients were died every year in United States due to medication errors. According to a recent report from the National Audit Commission Report on Patient Safety, medication error (7% of all medical error incidents) is the second most common factor of incidents that endanger to patients after a patient falls.³ Based on the Rule of MOH RI Number 129/Menkes/SK/II/ 2008 on Minimum Service Standards of Hospital mentioned that the incidence of medication error should be 100% not exist or not happen. This means that in providing health services, medication error should not be happened at any.

This case of patient safety is also still found in Surabaya Private Hospital. The place of highest incidence of patient safety is in the inpatient unit. The increases were happened from 2016 to 2017 is from 24% to 33.8%. In period of January-March 2017, inpatient unit of Surabaya Private Hospital has the highest number that contributes the number of patient safety incident. While the most frequent patient safety incidents in period of January-March 2017 in the inpatient unit were the incidents of medication error-related, that is 78% of the total patient safety incidents at inpatient unit of Surabaya Private Hospital.

Medication errors can happen in every stage of treatment. According to the National Patient Safety Agency 2004, medication error in the administration error stage is the type of error that gives the worst impact compared to other types of errors. These errors are also common. The party that has a role in this case is nurse. Nurse should be aware on drug delivery safely including safe doses, side effects of medication, alertness to drugs that have similarities of both name and appearance and the ability to educate patients and their families about medication.3

Based on these data, the research problem found is the incidence of medication error at Inpatient Unit of Surabaya Private Hospital by 78% in period from January to March 2017. Thus, this study aims to describe the incidence of medication error based on nurse knowledge at Inpatient Unit of Surabaya Private Hospital.

METHOD

This study is an observational descriptive research with the cross sectional approach. Samples of this study were 63 nurses. This research was conducted at inpatient unit of Surabaya Private Hospital and conducted in April - December 2017. Technique of data collection is conducted by questionnaire and observation for primary data. While secondary data was collected from report document of patient safety incident in period from January to December 2017. Data analysis is conducted descriptively.

RESULTS

Based on the data of the research results it can be seen that the characteristics of respondents based on age, gender, last education and length of working at Surabaya Private Hospital are as follows:

Based on Table 1, it can be seen that most of respondents are aged between 20-40 years as many as 46 respondents (71.6%). This range of ages is included in the early adult age category. Most of respondent’s genders are female that was 91%. Most of last educations of respondents are DIII that was 56.7%. Most of respondents have been working in the inpatient unit of Surabaya Private Hospital for more than 10 years that is 55.2%.

Source: Primary Data, 2017
Based on Table 2, it can be seen that most of respondents are have good level of knowledge that are as many as 27 respondents (40.3%). Respondents who have good level of knowledge about medication error and drug delivery are in Class 2 room. While respondents who have poor knowledge level related to medication error and drug delivery are in Kids room.

Results of research about score of respondent’s knowledge on medication error and drug delivery that concluded based on each room are described in following table:

Based on Table 3, it can be seen that the room that has good level of knowledge is Class 2. There are two rooms that have fair level of knowledge, that are Class 1 and VIP. While there are three rooms that have poor level of knowledge that are Class 3, Class 3B and Class 2. This is indicates that most of rooms in Inpatient Unit of Surabaya Private Hospital have poor level of respondent’s knowledge about medication error and drug delivery.

Table 4 shows that Class 2 room is a room with no medication error during year of 2017. While in 5 other rooms there are incidences of medication error with a various number. It can be concluded that most of rooms in Inpatient Unit of Surabaya Private Hospital have medication error incidents during year of 2017.

Table 5: Cross tabulation between Respondent’s Knowledge on Medication Error and Drug Delivery with Medication Error Incidents at Inpatient Unit

Source: Primary Data, 2017
Based on Table 5, it can be seen that the whole rooms with poor level of respondents’ knowledge (100.0%) and the rooms with fair level of respondents’ knowledge (100.0%) are the rooms which medication errors are happened. The room with good level of respondents’ knowledge (100.0%) is the room which medication errors incidents are not happened. It can be concluded that the incidents of medication errors are more prevalent in the rooms with poor and fair level of respondents’ knowledge on medication errors and drugs delivery.

**DISCUSSION**

Knowledge is the result of “know” that has happened after someone held a sensing on particular objects mainly through the eyes and ears. If someone can answer questions shortly about particular fields fluently, both written and oral then it can be said that they knew some of these fields. A set of replied answers is called knowledge.

According to Hurlock in Jersild, *et al* (1978), 11 human life spans, that are prenatal (from conception to birth), neonatal period (born to 2 weeks), infancy (2 weeks-2 years), early childhood (2-6 years), late childhood (6-10/11 years), puberty (10-12/13 years), early adolescence (13/14-17 years), late adolescence (17-21 years), early adulthood (21-40 years), middle age (40-60 years) and old age (60 years and over). So the respondents in this study are included on early adulthood category.

The results of study indicate that most of respondents are have D-III educations. This means that respondents had fulfilled the requirements set in PERMENKES No.148/2010 on Nurse Practice Permit which stating that a nurse can doing nursing practices after obtaining Nurse Practice Permit and have minimum education of D-III on nursing.

Based on the results of study it is noted that most of respondent’s length of working is more than 10 years. The longer a person working, the more experience he or she has, so that he or she has the skills to work. This is in accordance with Prabandari (2003) stated that the longer a person’s length of working the higher the level of skill for the work that became his duty. The supports of adequate capability and experience will demonstrate the quality of his work.

Based on the results of study it can be seen that the nurse’s knowledge is still poor. Nurse’s knowledge is very important. Knowledge is influenced by several factors, one of them is a person’s education level. It can be said the higher level of person’s education the better level of knowledge. The higher level of person’s education, the easier one receives information and the more knowledgeable. If one’s knowledge is poor, it will hinder his performance because it is difficult to accept newly introduced information and values.

Comprehensive knowledge is very important for nurses. This is needed as the basis of any nursing action that was undertaken. If the nurse has adequate knowledge related to medication, then the nurses can take appropriate and safe medication to the patient. Likewise, the nurse’s knowledge related to medication error, the higher level of nurse’s knowledge then the identification of error in the service could be done before the error was happened to the patient.

The research conducted has the results that from 3 rooms that have poor level of nurse’s knowledge, the whole are rooms wherein medication error was happened. From 2 rooms that have fair level of nurse’s knowledge, the whole are also rooms wherein medication error was happened. This means that the incidence of medication error is more prevalent in a room with poor level of nurse’s knowledge.

Nurses with the poor knowledge will more often to make mistakes when performing health services. This is in line with the study conducted by Amik (2014) which explains that nurses with the better levels of knowledge, will make a few mistakes when taking medication and more able to identify errors before they happened to the patients. Another study that was in line with this study is study conducted by Budiharjo (2017) which states that the better the level of nurse’s knowledge the less the incidence of medication errors that happened in the room.

**CONCLUSION**

Based on the discussion it can be seen that the incidence of medication error was happened in the room of Inpatient Unit of Surabaya Private Hospital. In general, the nurse’s knowledge in the room of inpatient unit is still poor. Medication error was happened in a room with poor level of nurse’s knowledge and fair level of nurse’s knowledge.

Association of Human Leukocyte Antigen-(HLA-B 27) Gene Polymorphism with Vitiligo Disease

Mona N. Al-Terehi, Zainab Abbas Al-Talebi, Abbas Hussein Mugheer, Ali H. Al-Saadi, Fathia ATeeq Rajab

1College of Science, 2College of Basic Education, University of Babylon, Iraq; 3Omar Al-Mukhtar University, El-Gubba

ABSTRACT

Vitiligo have been recorded in different ages in population it is appeared by interaction between different factors causes de-pigmentation in skin, the present study conducted to estimate HLA 27 gene polymorphism in vitiligo patients using single specific primer-polymerase chain reaction (PCR-SSP), DNA was extracted from whole blood for patients and control, then amplification was implemented, the results of demographic show that the means of age were 33.093 and 32.809 for patients and control, disease was recorded in female than male 79.54%, 18.18%, about 36.36% of patient had family history and 56.81% of them, their parents had family related. High percentage of patients had dispersive sites of de-pigment sites 54.54% while 40.90% of them in hands and legs. The genotyping results show that there was no association between HLA B27 and vitiligo disease, HLA – was 95.83% in patients while it was 85.71% in control in non-significant differences

This study concluded that there was no association between HLA B 27 and vitiligi disease in Iraqi population.

Keywords: vitiligo disease, of Human Leukocyte Antigen- (HLA- B 27), PCR-SSP.

Introduction

Vitiligo is an autoimmune disease resulted from melanocytes destruction which caused depigmentation in some part of skin and hair. The real cases of vitiligo have been studied, all reasons of vitiligo were based on the Loss of melanocytes function, However, some factors like autoimmune, genetic polymorphism and mutation,viral infections and oxidative stress may be contributed in vitiligo incidence and development. There were three theories for explaining the mechanisms of vitiligo pathology, the convergence theory is that stress, toxic compounds accumulation, autoimmunity, genetic mutations, changes in cellular environment and melanocyte migration and proliferation impaired have major role in varying features of vitiligo etiopathology.

Studies reported association between MHC class I region SNPs and vitiligo in the vicinity of the HLA-A gene found high-risk allele when they analysis DNA sequence encoding to canonical HLA-A2 specificity, which also present in variety of auto-antigens derived from melanocyte proteins like tyrosinase, TRP2, OCA2 and MART-1/melan-A.

Materials and Method

Study Design: Case-control study was carried out at the DNA lab/Babylon univ./in Babylon province/Iraq.

Study Population: The study subjects enrolled 44 patients suffer from vitiligo that diagnostic by specialist physician and these patients under biological therapy randomly selected from Karbala teaching hospital. All subjects in this study were taken written consent before participation in this study according to ethical approval of Iraqi ministry of health. Questionnaire taken from the patient included age, sex smoking habit, alcohol intake, and family history, past medical history.

Blood samples were collected in EDTA tube for DNA extraction, DNA was extracted from whole blood using (Genaid extraction kit) accoding to, After DNA extraction; consternation and purity of DNA
were estimated using nanodrpe. PCR conditions were performed as a following.

PCR Amplification single specific primer-polymerase chain reaction (PCR-SSP) using, a set of primers including (forward primer: 5F: 5'- GCTACGTGGACGACACGCT-3', R:5'-CTCGGTACGTCTGTGCTT -3'), R:5'-TCTCGGTAAAGTCCTGTGCTT A-3' (149 bp) and HgH as positive control F5'- TGCCTTCCCAACCATTCTTA-3'M (434bp) 10.

PCR conditions it performed as a following; per-denaturation for 5 min at 94˚C, then 35 cycles (60s at 94˚C, 2 min at 65˚C, 60 s at 72˚C, and finally 10 min at 72°C). PCR products were determined by electrophoresis pattern in agarose gel (1.5% agarose, 70 V, 20 mA for 45 min) with ethidium bromide staining, the results were statically analysis using X² and odd ratio at CI 95% And p value <0.05).

PCR Amplification single specific primer-polymerase chain reaction (PCR-SSP) using, a set of primers including (forward primer: 5F: 5'- GCTACGTGGACGACACGCT-3', R:5'-CTCGGTACGTCTGTGCTT -3'), R:5'-TCTCGGTAAAGTCCTGTGCTT A-3' (149 bp) and HgH as positive control F5'- TGCCTTCCCAACCATTCTTA-3'M (434bp) 10.

Results and Discussion

Vitiligo is depigmentation disorder disease caused by interaction of different factors, one of these is genetic polymorphisms and mutations, present study was conducted to detection HLA -27 gene polymorphism in vitiligo patients using PCR-ARMS technique. according to data that collected from patients and control the demographic the distribution of study groups show in table 1, there is no significant differences between patients and control in age mean (33.093 and 32.809) years at p value 0.928.

The prevalence of diseases in present study was in high in males than females, about 79.54% of samples were males several studies show that females were more frequent than males as in 11 for three years respectively in koria. In Indian 12, recorded that the ratio of females to males was 1.5:1, other study deal with present results that males more frequent than females 13,14, on the other hand there was equal incidence between male and female. This distribution depending on different factor like life style, genetic predisposition, genetic of gender, nutrition, and environmental factors.

Table 2, show chractisitc of patients, 36.36 % of patients had family history while 63.63 didn’t have family history, 16 mention in their study that vitiligo in the family history is caused by autosomal dominant inheritance. 17 clarified the relation between family history and children vitiligo, the earlier onset of pediatric vitiligo is linked to a family history. The information’s of family history of disease in Iraq was poor, especially genetic mutation and polymorphism in addition of other factor which contribution in disease incidence. In addition of family history about 56.81 % (table 2) of patinas their parents were related, this because culture of relative marriage in population.

| Yes | 56.81 |
| No  | 43.18 |

About 54.54% of patient had dispersive depigments area while 40.90 % of them the de-pigment area in terminal and 2.27 % in the abdomen and face 12 explained this phenomena that de-pigmentation occurs simultaneously or subsequently at various unrelated distant sites.
The results of DNA extraction was in figure (1, A) all of patients and control had high concentrated and pure DNA.

Figure 1: Electrophoresis pattern of A, DNA extracted from patient and control (70 V, 20 mA, 30 min, 0.5 X TBE buffer). B PCR- SSP products for of hela - 27 genotyping in patient and control. lane 1, 7 line and 8,15 HLA +.

Table 3 and figure (2, B) show results of HLA genotyping, HLA – was more frequent in patients 95.83% than control 85.71% while HLA + was high percentage in control 14.28% than patients 4.166%. these differences were non-significant at p value 0.2921, odd ration 0.265 (CI 0.0214 to 3.1778). A study implemented by 18 didn’t deal with present study, they improved association several HLA alleles like B 27 with vitiligo disease especially in familial history. the association of HLA alleles with vitiligo were diverse among population, B27 was associated with this disease in Italian population 19.

As a results of HLA alleles role in immune response against viral infected cells in serious pathways, it may be contributed in response to vitiligo caused by viral infection which improved by detected CMV in DNA of de-pigments cells 20,21.

Investigators consider HLA gene polymorphism as genetic marker of vitiligo disease and predisposition because of closed association between HLA alleles and disease incidence in different population 22,23 also the strongly linkage between HLA loci and other sites in the region of major histocompatibility complex (MHC) in chromosome 6p. 24,25.

Angiotensin Converting Enzyme Gene Polymorphism in Hypertension Patient Detection

Mona N. Al-Terehi*, Alyaa Aziz Al-Mosawei†, Zahraa H. Al-Qiam‡, Hiader Kamil Zaidan§, Ali H. Al-Saadi

*College of Science, University of Babylon, Iraq; †Ibn Hayan University College, Kerbala, Iraq; ‡Al-Mustaqbal University College, Iraq; §Cultural Attache, Embassy of the Republic of Iraq, Amman, Jordan

ABSTRACT

Hypertension is one of the important health problems in last decade in Iraqi population, high percentage of its incidence have been reported in different ages, hypertension is blood pressure which effected by different factors. The pressure of the heart does not stay at the same level at all times. It varies based on activities at a particular point in time. The present study aims to estimate Angiotensin converting enzyme gene polymorphism with Hypertension disease in females, samples collected from females had age mean 25-70 years with duration period rang 1month-15 years and BMI mean 30.30. DNA was extracted from whole blood then PCR-ARMS used to detect Deletion/Insertion sequence, results show that non-significant differences between patients and control in age and BMI, there was 45.45 of patients were obese, 42.42 were overweight while 12.12 were normal weight. Patients had age range 35-55 was more frequent it was 58.62%, while age category <35 years was 12.06% and 29.31% of patient had age >55 years. Deletion insertion genotyping was non-significant differences between study groups in all genotype (p value 0.05) the frequents of DD genotype was same for patients and control in percentages 50 % with odd ratio 1. DI is more frequent in patients than control it was 25%, 22.22 % respectively with odd ratio 0.1 while genotype II was high in control 27.77% and in patients was 25%.

The present results concluded that no association between ACE gene polymorphism with Hypertension disease in female of Iraqi population

Keywords: Hypertension, Angiotensin converting enzyme, gene polymorphism. PCR-ARMS

Introduction

Hypertension has been the global problem which growing in the world it is correlated with some pathophysiological conditions (1) such as ventricular hypertrophy, dysfunction of endothelial, metabolic syndrome, chronic kidney disease, inflammation, oxidative stress and a genetic predisposition to cardiovascular events (2), in developing countries high prevalence of hypertension have been recorded which contributed in pandemic of cardiovascular disease (CVD) and renal failure (3,4). Multi factors have major roles in incidence hypertension like genetic and environmental factors which causes elevation of blood pressure, investigators used these factors in classification disease as a complex and multifactorial disease, other Factors like sedentary lifestyle, stress, diseases, smoking and alcohol intake also contributed in hypertension development (5-8).

Angiotensin Converting Enzyme (ACE) gene is located on chromosome 17q23 and consist of 25 introns and 26 exons, from 63,477,061 to 63,498,380 base pair (9). It is part of the renin-angiotensin system, which balance of salts and fluids in the body also it regulates blood pressure, By cleavage angiotensin I protein at a particular location, to converted it this protein to angiotensin II which causes constrict blood vessels to increased blood pressure (10). The insertion/deletion (I/D) polymorphism of ACE gene have been determined in the WBCs and tissue in addition to its levels in plasma and tissue(11,12).
Materials and Method

Case-control study was carried out at the DNA lab/Babylon univ./in Babylon province/Iraq.

The study subjects enrolled 55 females patients suffer from hypertension that diagnostic by specialist physician, these patients under biological therapy randomly selected from Mrjan teaching hospital. All subjects in this study were taken written consent before participation in this study according to ethical approval of Iraqi ministry of health. Questionnaire taken from patients included : BMI, age, occupation, past medical history.

Exclusion Criteria: pregnant women, smokers were excluded from present study.

Blood samples were collected for DNA extraction, its extracted from whole blood using (Genaid extraction kit) with modification according to (13), consternation and purity of DNA were estimated using nanodrpe. ARMS-PCR Amplification used for Angiotensin converting enzyme genotyping by set of primers including (forward primer : 5F: 5’-CCCATC CTT TCT CCC ATT TCT C-3’ R- 5’-GTT TTC ACC GTT TTA GCC GGG A-3’), R:5’-CCA TGC CCA TAA CAGGTC TTC A-3’ used to amplify the gene segment which produced 190bp (in deletion polymorphism) and 490bp (in insertion polymorphism) PCR conditions it performed as a following; per-denaturation for 5 min at 94˚C, then 35 cycles (30 s at 94˚C, 30 s at 67˚C, 30 s at 72˚C, and finally 10 min at 72˚C). PCR products were detected by electrophoresis pattern in agarose gel (1.5% agarose, 70 V, 20 mA for 45 min) with ethidium bromide staining, the results were statically analysis using $X^2$ and odd ratio at CI 95% And p value <0.05).

Results and Discussion

The results of present study that focused on polymorphism of angiotensin converting enzyme gene in hypertension patients show that patients ages mean was 49.0323 while control age mean was 46.3182 there was no significant differences between study groups. Body mass index in patients was higher than control group but in non-significant differences it were 30.3000 and 27.9545 respectively (table 1), figure 1 show distribution of patients according to BMI, obese patients were more frequent than overweight and normal BMI, the percentages were (42.42,45.45 And 12.12%) respectively, patients that had age range 35-55 was more frequent than other categories 58.62%, low percentage was found in the age category <35 years it was 12.06% while 29.31% of patient had age > 55 years, the Mozaffarian et al., (14) found that the prevalence of hypertension was increased with age. in other study which found a positive correlation between age and blood pressure for males and females (15). Also the same study improved that overweight/obese individuals were more likely to have hypertension than those with normal BMI. Vuvor et al., (16) concluded that increment in BMI was influenced blood pressure among adults’ population.

The distribution of D and I alleles in patient and control were approximated. D was 0.625, 0.676 in patients and control respectively, allele I was 0.324 in patients and 0.375 in control group. This results show that no associated between ACE gene polymorphism with hypertension in females, a study deal with ACE gene polymorphism in Indian patient show that this gene correlated essential hypertension (17). He et al. (18) found that the ACE polymorphism was significant associated with hypertension, while expression level didn’t important factors associated with hypertension in this Chinese population. Rasyid et al., (19) deal with present results that no significant difference in genotype distribution and allele frequency between study groups. Present study need more investigation about other factors which effected in hypertension incidence in Iraqi population, like life style, other genes polymorphism, and genetic predispositions in Iraqi individuals.

**Conclusion**

The present results concluded that no association between ACE gene polymorphism with Hypertension disease in female of Iraqi population.

The Incidence of Breast Cancer in Women with Thyroid Dysfunction in Al-Najaf Province

Zainab S. Mohammed¹, Radhwan M. Hussein¹, Alaa A. Ali¹, Hasanain J. Kadhim²

¹College of Pharmacy, Ahl Al-bait University, Kerbala, Iraq; ²Pathological Analysis Techniques Department, AL Tousi University College, Najaf, Iraq

ABSTRACT

The problem of B.C. is growing in both established and developing states, and in many provinces of the domain, it is the utmost frequently arising malignant sickness in females; it is including (18 percent) from the all cancers that effected woman, and the global, B.C. is the 5th greatest public cause of death with cancer. In year (2008), almost (1.4) m. female were established with B.C.in universal with a consistent about (460.000) demises.

Thirty Participants were included in this study; they were attendants of Al-Sadder Medical City, breast cancer unit and Middle Euphrates Cancer Center in AL- Najaf province.

The results of the present study revealed positive family history of breast cancer in 60% of malignant cases, while negative cases comprise 40 %. In benign cases; positive family history was less frequent comprises only (26%) while negative cases was of higher frequency (73%), and such difference was highly significant (P < 0.05).

A.B.O. blood group phenotypes in B.C. female patients in both type malignant, and benign and healthy woman (married, single and infertile women) revealed no insignificant alteration, where as an improved incidence of blood group phenotype B (64%), and a decreased frequency of blood group AB (10%) in evil (malignant) unhealthy person as matched with healthy assemblies, infertile, solitary, wedded (30%, 30%, 22% independently), and however an improved frequency of blood group O (43%) and a decreased frequency of blood group A (13%) in benign patients as compared with control groups infertile, solitary, married.

The present research advocated an elevation occurrence of goiter synchronized with extraordinary frequency of autoimmune thyroiditis, established mainly by A.b. positivity, in woman breast cancer persons. Hyperthyroidism was found in high percentage 6 cases (20%) in malignant breast cancer and 4 cases (10%) in benign cases when compared with control group 1 (4.0%), (P<0.05). The present study revealed high percentage of hypothyroidism, Nontoxic goiter was found in 20 patients in malignant breast cancer group (67 %) and 23 in benign breast cancer patients (77 %) controls 6 (96 %) and such difference was highly significant (P < 0.05).

Keywords: Breast cancer, thyroid, Najaf

Introduction

Breast cancer is a collection of cells that proliferated abnormally and formed a lump in the breast area, and is characterized by it’s ability of cancer cells to spread from one place to another and this means that if they left and not treated as soon as may lead to the spread of the disease in the body and then death (1).

Breast cancer utmost commonly arising of disease within malignant woman; comprising about eighteen
percent of all female cancers, and worldwide, breast cancer is the 5th most communal cause of cancer death, the encumbrance of B.C. is increment in established and evolving states, and in a various regions of the world \(^{(2)}\). In the year of 2008, approximately (1.4) M. of female were established with B.C. Worldwide with corresponding of (460.000) death \(^{(3)}\).

Cancer of breast in woman patients are the public phenotype of woman carcinoma, secretarial for about (1: 3) of the recorded female cancer consistent with the modern Iraq C.R. (Iraqi -Malignant tumor- Documentation)/(2010) \(^{(4)}\), and the supplementary causes of tumor interrelated demises \(^{(5)}\). In our countries according to Ministry of health/Iraq- Cancer archive (2006), of B.C. was most often cancer among women also it was the commonest in Kirkuk city. It forms (15-32 %) of total cancer patients with severe rise in occurrence of this tumor type in youngest age person, typical year old of person with breast-carcinoma in Iraqi female is (45) y.\(^{(6)}\).

There are unknown reasons etiological issue of tumors type had been advocated with epidemiological, also dissimilar B.C. -associated harmful influences have been recommended by the studies of epidemiological; for example, period, menstruation, equality, woman with menopause, breast-feeding by using of exo-genous hormones or oral contraceptive, fatness, lack of the employment, nourishment, smoldering, whisky, malt ingestion and family history of B.C. or other tumors \(^{(7)}\), these may be risk issues have been publicized to have different relatives to tumor of breast in different national populaces of the biosphere \(^{(8)}\).

Binding or rejection of the natural levels of hormones in the body accountable for the preservation of homeostasis of the body and the instruction of metabolic process of developmental, and may consequence in the demonstration of tumor in breast tissue of woman \(^{(9,10)}\).

Genetic anomalies in breast tumor have been obstructed concluded a different of the genomic lines also, one of them is genomic unpredictability evaluated. Genomic uncertainty in cancer can be observed as instability of chromosomal, and in which a popular of the cancers revealed the irregular karyotype including both rearrangement of chromosome and, or aneuploidy and are categorized as tumors. In this respect, different research stated an irrelevant increase in chromosomal aberrations (C.A.s) in cultured (P.B.L.s) of cancer patients with solid cancers \(^{11,12}\).

### Materials and Method

**Patients:** Our study convoluted about (ninety) of women patients, also dispersed into two type of groups of unhealthy groups of person and three groups of healthy person. unhealthy woman who had a breast tumor, and permitting to the tumor type and they dispersed as malignant and benign assemblies, and each group contain about (thirty) of woman patients. Malignant tumor group comprised patients with age range: (25 and 70 y.), though such variety in benign tumor groups were (20- 65 y).

Patients of Breast Tumor at center of tumor in AL-Furat Al-Awsat and Al-Sader Teaching Hospital (Najaf) during the period (March 2017 to February 2018). Three groups of women were registered in our previous research, included married woman, also had children, (Married woman group), married woman but with problem of primary infertility (Infertile group) and single women (Single group); each with (ten) subjects.

**Blood Sample:** The study enrolled by collection of 10ml of venous blood from each case using disposable syringe under aseptic conditions and divided into three aliquots; 2 of them with 4 ml. They were distributed in tube, and let for fifty min., formerly, they were putting in centrifuge at 3000rpm, for 10min. for serum collection. The third part of blood about 1.5- 2 ml in EDTA tube for hematological tests.

**Blood Phenotype:** About 1.5- 2ml of blood used, this way based on the method of agglutination reactions in the groups of blood with particular antiserum from company (Bio-test-Germany).

**Thyroid Function Test:** Serum T3, T4 and TSH was determined by using the extracted serum from the 1st 4 ml of blood and analyzed by ELISA equipment, it is provided by alpeco-analytic, United State of America\(^{(13)}\).

**Determination of T.P.O.:** The test of T.P.O. by using the ELISA kit is a semi-quantifiable of enzyme-interrelated immune-osorbent analyze that used for the exposure of antithyroid peroxidase Ab in the serum of human in both groups.

**Bio-statistical Analysis:** Mean ± standard deviation were used. One way analysis of variance (ANOVA) monitored by least significant difference, analyses at (0.05%) probability of levels was used, the difference will be major when (P <0.05) value \(^{(14)}\).

The results in figure (1) revealed increase of levels of T3 in malignant and benign cancer according to age of breast cancer patients when equaled with healthy persons such dissimilarity were extremely substantial (P < 0.05).

Figure 1: T3 levels in benign and malignant breast cancer women patients according to age

The results in figure (2) showed comparison between benign and malignant breast cancer cases according to levels of T3, the difference was highly significant (P < 0.05) when compared with healthy woman.
Results that showed in the figure (3) revealed levels of T4 in benign and malignant cancer according to age of patients with B.C, the difference significantly was highly (P < 0.05) when compared with control group.

The results in figure (4) showed comparison between benign and malignant in breast cancer woman patients according to levels of T4, the difference was highly significant (P < 0.05) when compared with healthy woman.

The results of present study in figure (5) revealed levels of TSH in benign and malignant cancer according to age of patients with B.C, the difference significantly was very highly (P < 0.05) when compared with control group.
The results in figure (6) showed comparison between benign and malignant breast cancer woman patients according to levels of TSH such difference was highly significant (P < 0.05) when compared with healthy women (control group).

The results revealed levels of anti-thyroid peroxidase in benign and malignant cancer according to age of patients with B.C., the variance was highly significant (P < 0.05) when compared with control group.

The results comparison between benign and malignant breast cancer woman patients according to thyroid peroxidase. The variance was highly significant (P < 0.05) when compared with control group.

**Discussion**

Aggregation of familial incidence can be recognized both to segment the mental surroundings, genes, and lives, and it consumes been confirmed the hazard of the breast cancer developments was twofold such as highly percent in the female with an precious relative of first - degree than, female in common inhabitants (15). The modest of the risk vulnerability alleles, it is conversing small percent of the danger in sequestration, but have reasonably a insignificant consequence with combination (16).

The reason behinds such not significantly differences, also may be interrelated to small size of control samples. The significantly differences were generally paid with an increased the incidence of the
phenotype of B blood group for patients with malignant, O phenotype of patients with benign (64% vs. 43%), also a reduced the occurrence of the phenotype AB of patients with malignant, and phenotype A of blood group of patients with benign (10% vs. 13%) in the B.C. this study has been agreement with current research that obtained by (17-19).

Dissimilarities of the geography in the occurrence of B.C. have been accredited to alterations in the iodine intake with diet, and a consequence of the iodine on the breast has been assumed (20,21). The receptors on the tumors of breast, have been assumed for accountable for the accident of thyroid gland complaints and mammary (22).

Conceivable of the relations between the tissue of thyroid gland and tissue of the breast are centered on the public property of the epithelial cell of thyroid gland and mammary to quintessence of iodine by the mechanism of active transport across cell membrane of tissue, in addition to on the occurrence of the receptors TSH in adipose tissue, that is rich in mammary gland (23, 24).

Modern study that recommended well prediction for B.C. with patients and improved the ranks of hormone (T.P.O.) (22). That suggested the response of immune system might be focused both by tumor and by thyroid tissue. The high percent of (T.P.O.) levels has been revealed to be a very significant factor in Ab-reliant cell cyto-toxicity in the tissue of thyroid gland, and may be a conceivable relationship between the immune system, and autoimmune thyroiditis this revealed no arrangement on the significance of its suggestion with woman with cancer type of breast in woman (25).

Comparison between the Effectiveness of Combination of Letrozole with Misoprostol and Tamoxifen with Misoprostol in Medical Termination of First Trimester Missed Miscarriage

Hanan N. Ibrahim¹, Zuhud M Mustafa¹, Hassan K Rajab¹
¹College of Medicine, University of Tikrit, Salah Al-Deen, Iraq

ABSTRACT

The missed miscarriage was similarly named as silent miscarriage. The aimed of this study was to compare the efficacy between letrozole with misoprostol and tamoxifen with misoprostol for medical termination of first trimester missed miscarriage. The study was conducted as a randomized comparative trial from January 2015 to November 2015 at Tuzkhurmatu general hospital in Salah Al-Deen government (Iraq). A total of 120 women with missed miscarriage at (6-13 weeks) gestation were randomly divided in to two groups: (60 women) were received 7.5 mg of letrozole orally for two days, and (60 women) were received 60 mg of tamoxifen for two days. After two days 600 misoprostol administrated vaginally in all women, if they had no vaginal bleeding a second dose of 800 misoprostol was given after 24 hours. The results shown that many woman prefer a less invasive way of terminating their pregnancy in case of missed abortion (and legal medical abortion), and also wish to be awake during the treatment despite the fact that they might experience more pain and longer bleeding compared with woman undergoing primary surgical evacuation and over (25%) of medically treated women undergo secondary surgical evacuation.

Keywords: Miscarriage, letrozole, Tamoxifen.

Introduction

The missed miscarriage was similarly named as silent miscarriage. The good purposes of you won’t knowledge the normal alert of hampering or hemorrhage, however particular indications, such as the sensitive breasts or biliousness, may start facilitation up. A missed miscarriage is a gestational sac containing dead embryo or fetus before 24 weeks gestations without clinical symptoms of expulsion (¹). The missed miscarriage was a reason of apprehension both for the patients and the gynecologist. The gynecologist worry was determining the technique of concluding pregnancy. The difficulty was as of locked cervix, bulk of creation and the opportunity of devotion of produces to the uterine partition. This devotion enlarges Hazard of incomplete removal and uterine (²). Over the historical from three eras, medical approaches of abortion had been advanced during the world, medical abortion that were include the use of medications to stimulate an abortion, while the technique was most frequently used up to 63 days of development (estimated from the first day of the last menstrual dated), the management also operative after 63 days of gestation puncture (³).

Mifepristone is synthetic anti-progesterone; Mifepristone have been displayed to be an operative abortifacient after when collective by a prostaglandin administrated two days later (⁴). Misoprostol is a synthetic analogue of prostaglandin; it has been found that the oral pill can be used in promoting cervical ripening and uterine contraction (⁵). Methotrexate is a folic acid antagonist it has been used in combination with misoprostol for early abortion up to (⁷) weeks in some countries when mifepristone has not been available (⁶).

Tamoxifen is selective estrogen receptor modulator used in treatment and prevention of breast cancer. Ingestion of tamoxifen followed by misoprostol would be

Corresponding Author:

Email: Mohammednaife123457@gmail.com
an effective medical method of termination of pregnancy (7). Letrozole is non-steroidal aromatase inhibitor may be another effective option for medical abortion but more research is need regarding this regimen (8).

The management of abortion is an important issue in gynecology. Medical abortion has been considered as a non-invasive option for first trimester pregnancy termination as it avoids the risk of anesthesia and surgical trauma to the cervix and uterus and other organs. The aim of this study was to compare the efficacy between letrozole with misoprostol and tamoxifen with misoprostol for medical termination of first trimester missed miscarriage.

The study was conducted as a randomized comparative trial from January 2015 to November 2015 at Tuzkurmatu general hospital in Salah Al-Deen government (Iraq).

Materials and Method

A total of 120 women with missed miscarriage at (6-13 weeks) gestation were randomly divided in to two groups: (60 women) were received 7.5 mg of letrozole orally for two days, and (60 women) were received 60 mg of tamoxifen for two days. After two days 600 misoprostol administrated vaginally in all women, if they had no vaginal bleeding a second dose of 800 misoprostol was given after 24 hours. The main outcome measure was the complete abortion rate. The secondary outcome measures included complete abortion rate according to misoprostol the records were then analyzed by the use of SPSS version 22.

Inclusion Criteria:

1. Age older than legal consent>18 years.
2. Primigravida or multigravida.
3. Missed miscarriage (6-13weeks)
5. No history of chronic diseases
6. Closed cervical OS.

Exclusion Criteria:

1. Woman age less than 18 years.
2. Gestational age more than 13 weeks.
3. Intrauterine contraceptive device.
4. History of vaginal bleeding or abdominal pain.
5. Breast feeding.
6. Hemoglobin level less than 10 g/dl, abnormal coagulation screen, abnormal liver or renal function test, viral hepatitis positive.
7. Allergy to misoprostol, letrozole, tamoxifen.
8. History or evidence of disorders that represent contraindication to the use of letrozole, tamoxifen, misoprostol.
9. Ovarian or uterine pathology.
11. Any evidence of infection.
12. Patient’s refusal to participate in the study.

All women had uneventful history with normal general examination. Gynecological examination revealed enlarged uterus, with no vaginal bleeding, and no dilatation of cervical OS. Investigation included blood group and Rhesus factor, complete blood count, random blood sugar, general urine examination, hepatitis screen, liver and renal function test, and blood coagulation profile. The diagnosis of missed miscarriage and the gestational age was confirmed by a reliable menstrual history and ultrasound examination. Total of hundred twenty women had met the selection criteria randomly divided in to two groups:

i. Letrozole groups (60 women) were given letrozole 7.5mg as an oral dose (three tablets of 2.5 mg, FemaraR, NOVARTIS) for two days.

ii. Tamoxifen groups (60 women) were given tamoxifen 60mg as an oral dose (three tablets of 20mg, AstraZeneca Company, UK) for two days.

Results and Discussion

A total of (120) women presented with missed miscarriage (6-13) weeks gestational age were enrolled. 60 women were allocated for medical termination of their pregnancies with letrozole and misoprostol and the others 60 women with tamoxifen and misoprostol as shown in Table 1.

(NS= No statistical significance)

The numbers of women with age between (20-25 years) in letrozole group were 17(28.3 %), and in tamoxifen group were 21(35%), age between (26-31years) in letrozole group were 21 (35%) women, and in tamoxifen group were 20 (33.3%) women, age between (32-37 years) in letrozole group were 14 (23.3%) women, and in tamoxifen group were 10 (16.6%) women, age between (38-43years) in letrozole group were 8 (13.3%) women, and in tamoxifen group were 9 (15%) women. P value for all above results was more than (0.05), which was statistically not significant.

The number of women with gestational age between (6-9weeks) in letrozole group were 54 (90%) women, and in tamoxifen group were 52 (86.6%)women, gestational age between (10-12 weeks) in letrozole group was 6 (10%) women, and in tamoxifen group were 8 (13.3%) women. P value was more than (0.05), which was statistically not significant. The numbers of primigravida in letrozole group were 7 (11.6 %), and in tamoxifen group were 10(16.6%), the numbers of multigravida in letrozole group were 53(88.3%), and in tamoxifen group were 50 (83.3%), with no statistical significance between two groups.

In letrozole group the numbers of women with previous abortions were 33 (55%) and in tamoxifen group were 28 (46.6%) and the number of women with previous C/S in letrozole group were 7(11.6%), and in tamoxifen group were 8(13.3%). p ≤ (0.05), which was statistically not significant.

As shown in Table 2, 40 women were aborted completely in the Letrozole group given a complete abortion rate of (66.6%), compared to 53 women in tamoxifen group given a complete abortion rate of (88.3%). 12(20%) women were aborted incompletely in the letrozole group, compared to 5(8.3%)women in the tamoxifen group. 8(13.3%)women were failed to abort in letrozole group, compared to 2(3.3%) women in tamoxifen group, these results were statistically significant.

There are three reasons for searching for a medical alternative:

First that many woman prefer a less invasive way of terminating their pregnancy in case of missed abortion (and legal medical abortion), and also wish to be awake during the treatment despite the fact that they might experience more pain and longer bleeding compared with woman undergoing primary surgical evacuation.

Second, even though approximately (25%) of medically treated women undergo secondary surgical evacuation, they may still have a lower infection risk as compared to woman primarily undergoing surgical evacuation.

Third, the waiting time for the operating theatre may sometimes be days, whereas medical treatment may be initiated immediately after diagnosis.

Several clinical trials have evaluated the use of misoprostol alone for termination of early pregnancy failure, highest abortion rate was found in a study done at 2007 by Hertzen et al, who found that complete abortion rate was (84-87 %) up to 63 days gestation after administration of 800mg of misoprostol vaginally or sublingually every three hours for three doses. However in combination of misoprostol with others drugs was more effective (9).

The main outcome from this study was the complete abortion rate which is (88.33%) in combination of tamoxifen with misoprostol compared to (6.66%) in combination of letrozole with misoprostol, which is statistically significant.

The results of the present study demonstrated that complete abortion rate in letrozole group was 66.66% which is lower than previous mentioned studies, these variation may explain by difference in numbers of women, gestational age, period of letrozole management, and dissimilar amounts of it. All 5 patients (8.33%) in tamoxifen collection were terminated totally before the management of misoprostol. The whole abortion ratio afterward chief dose of misoprostol in tamoxifen collection were meaningfully upper than letrozole group, that were (58.31%) and (18.31%), correspondingly.

The changes of hemoglobin from baseline to one month after induction of abortion were (0.558 + 0.308)
in letrozole group and (0.432 + 0.248) in tamoxifen group, which indicate it has no much more blood loss in both groups. This agrees with study done by (10), who found that the median decrease in hemoglobin level was 0.50 g/dl (+2.2 to -4.7 g/dl).

**Conclusion**

We conclude that tamoxifen and misoprostol is more effective than letrozole with misoprostol as a medical method of termination for first trimester missed abortion, it is associating with higher complete abortion rate after single misoprostol dose and with gestational age up toward 11 weeks. We mention that the assistance of tamoxifen with misoprostol in health dissolution of chief trimester missed abortion.

The conflict of interest was summaries in failure of the sample in terms of number and geographical distribution, where the study on the number of 120 women, and in the area of Tuzkhurmatu only.

The ethical was asked patients to own an eleven minutes rest before measure of their pressure level of blood. Ethics Committee of Tuzkhurmatu general hospital in Salah Al-Deen government (Iraq) and AHAPs permitted the analysis method, and printed consent were attained from all of the members before beginning of the study.

Serological Detection of Hepatitis B Virus by Rapid Test Compared to Elisa in Kerbala Province, Iraq

Zahraa M. Al-Qanbar¹, Mohanad Mohsen Ahmed², Mohammad J. Al-Jassani³
¹Department of Laboratory Sciences, College of Nursing, ²Department of Medical Microbiology, College of Medicine, University of Kerbala, Iraq; ³DNA Research Center, University of Babylon, Iraq

ABSTRACT
There are more than 240 million Hepatitis B virus (HBV) carrier cases and more than 600,000 deaths annually worldwide. Hepatitis B may cause acute hepatitis (AHB) or chronic hepatitis (CHB). Patients with CHB have elevated complications involving cirrhosis and liver cells carcinoma.

This study aim to detect HBV in Kerbala province by ELISA and Rapid test.

All samples were taken from outpatients attending Imam Hussein Medical City Hospital, Kerbala Province and Central Public Health Laboratories, Kerbala Province, Iraq, during the period from October 2017 through April 2018. Total of 50 HBV suspect patients were subjected to ELISA (Bioelisa HBsAg Kit, Spain) and then retested by HBsAg Rapid Test Cassette (OnSite HBsAg Rapid Test Cassette, USA). The number of females was (23) and the number of males was (27). The age groups ranged from (16-70) years.

All samples were showed positive results by ELISA and by Rapid test.

Rapid test proved to be fast, reliable and economic test for HBsAg detection in routine HBV investigation tests.

Keywords: Hepatitis B virus, ELISA, rapid test, HBsAg.

Introduction
One of the major global health problems is Hepatitis B virus (HBV). More than two billion people are infected where more than 240 million Hepatitis B virus (HBV) carrier cases and more than 600,000 deaths, with liver cirrhosis and hepatocellular carcinoma, annually worldwide (1-3). Hepatitis B may cause acute hepatitis (AHB) or chronic hepatitis (CHB) (4). HBV incubation period is about 75 days on average, but can up to 180 days (5). HBV can be detected by serological methods like ELISA and rapid test as the most common, fast and economic methods to detect different virus markers such as HBsAg, anti-HBsAg, anti-HBcAg, HBeAg and anti-HBeAg (5,6).

ELISA is a biochemical assay that uses antibodies and an enzyme-mediated color change to detect the presence of antigen with high sensitivity (7).

Rapid diagnostic test (RT) strip is a lateral flow chromatographic immunoassay where HBsAg can be detected. The immune-complex is captured on a membrane by the pre-coated non-conjugated HBsAg antibody (6). RT have several advantages, it is easy to perform, fast, economic and can be done on a case-by-case (9,10).

This study was conducted since the presence of HBsAg in serum or plasma is the most important indicator for the diagnosis of a hepatitis B virus (HBV) infection.

Materials and Method
Study Subject: A total of 50 HBV suspected patients, 27 males and 23 females aged from 16-70 years. They were outpatients attending Imam Hussein Medical City Hospital, Kerbala Province and Central Public Health
Laboratories, Kerbala Province, Iraq, during the period from October 2017 through April 2018. They were pre-operation, routine marriage test or pregnant women cases.

**Specimen Collection and Processing:** Total of 50 intravenous blood samples (5ml) were collected. The blood sample was poured into a clean tube without anticoagulant and centrifuged at 3000xg for 5 minutes. The serum was stored in clean tubes at (-20°C) until use.

**Detection of HBsAg**

**ELISA screening test:** Samples were approved infected with HBV by ELISA (Bioelisa HBsAg Kit, Spain) at Imam Hussein Medical City Hospital and Central Public Health Laboratories, Kerbala Province. This test is based on a one-step “Sandwich” principle. In brief, HBsAg coupled with horseradish peroxides (HRP) serves as the conjugate, Tetramethyl Benzedrine (TMB) and peroxide as a substrate. Upon completion of the test, a color develops which is directly proportional to the amount of HBsAg in the sample. The method done according to the manufacturer recommendations. Blank was read at 450nm and the absorbance was read, of each well, within 30min. It is recommended to read using a 620-630nm reference filter.

**HBV Rapid Test:** All samples were tested using HBsAg Rapid Test-Cassette (OnSite HBsAg Rapid Test Cassette/ USA) for qualitative detection of HBsAg at a ≥1ng/mL.

About 200μL of serum was transferred to the specimen well then started the timer for 15min.

The results were read according to the manufacturer’s instructions. The positive result is with two colored lines appeared, one in the control region (C) and the other in the test region (T). The negative result, one colored line should appear in the region (C) only.

**Results**

**Distribution of HBsAg positive patients:** Total of 50 patients were distributed according to their gender and according to their age. When distributed according to their gender founded that males were more than females with a ratio of (1.17:1) and percentage of 54% males and 46% females (figure 1).

**Distribution of HBsAg positive patients according to gender**

**Distribution of HBsAg positive patients according to age:** When distributed HBsAg-positive patients according to their age (table 1), were found that the age ranged between 16-70 year with a mean age (40.16), and found that most of the patients were located within fifth and sixth decade 51-60 year with a percentage of 34%.

**ELISA and rapid tests:** The result of ELISA showed the presence of HBsAg in all patients’ serum. Moreover the result of HBsAg Rapid Test were showed all samples were positive too and the results showed some patients had weak positive result where other patients had strong positive result (Figure 2).
Discussion

Since HBsAg appear the first during acute HBV infection, HBsAg is the most critical serological marker to detect and remains detectable upto six months (11,12). So that we used two methods to detect HBsAg in patients, the first method by ELISA and the second by rapid test the results were compatible using both methods. Although ELISA is 10 times more sensitive (0.15 ng/ml), the result of HBsAg Rapid test showed some specimens had weak positive result where other specimens had strong positive result (see figure 1). The specimens had weak positives result because they are from patients in early stages of infection or inactive carriers (13-16), and the level of HBsAg in serum ≥1ng/mL. While the specimens, which showed strong positive result had HBsAg in serum higher than 1ng/mL.

Conclusion

Despite its less sensitivity, Rapid test is fast, reliable, economic test with much less effort and instrument usage for HBsAg routine investigation and HBV detection on a case-by-case basis.

Prognostic Evaluation of $KRAS$ Gene Mutation in Colorectal Cancer Patients

Ibrahim A. AL-Tememi$^1$, Osamah Abd Ali Nassr$^1$

$^1$University of Al-Qadisiyah, IRAQ

ABSTRACT

Background: Colorectal cancer is the most common malignant tumor of the lower gastrointestinal tract (colon and rectum) of epithelial origin, perhaps the only cancer that starts as a benign adenomatous polyp, which can last a few years to become cancer. The RAS gene family is among the most studied and best characterized of the known cancer-related genes. Of the three human ras isoforms, KRAS is the most frequently altered gene with mutations occurring in 17%–25% of all cancers. The aim of current study was to develop a highly sensitive method for detecting somatic mutations of KRAS gene for genotyping CRC patients.

Method: The present investigation included 20 control group and 40 patients with Colorectal Cancer with ages between (26–82 years) for the identification of KRAS gene by symmetric PCR technique (RT-PCR). The risk of mutant KRAS genotype in association with colorectal cancer was assessed in terms of Odds ratio.

Results: Current study showed that persons harboring mutant KRAS genotypes are at two-fold risk for developing colorectal carcinoma than the general population.

Conclusions: On the basis of current study findings, significant over productions of KRAS mutations seemed to have potential role in colorectal cancer progression and worse prognosis when compared with healthy people.

Keywords: Colorectal Cancer, KRAS gene, genotyping, mutations, prognosis.

Introduction

Colorectal cancer is the most common malignant tumor of the lower gastrointestinal tract (colon and rectum) of epithelial origin, perhaps the only cancer that starts as a benign adenomatous polyp, which can last a few years to become cancer. Colorectal carcinoma considered the fourth most common malignancy affecting gastrointestinal tract (1). The RAS gene family is among the most studied and best characterized of the known cancer-related genes. Of the three human ras isoforms, KRAS is the most frequently altered gene with mutations occurring in 17%–25% of all cancers. Approximately 30%–40% of colon cancers carry a KRAS mutations. The latter have been associated with poor survival and increased tumor aggressiveness. Additionally, KRAS mutations in colorectal cancer lead to resistance to selected treatment strategies. The detection of KRAS mutations has been associated with decreased response rates to selected chemotherapeutic agents. Therefore, KRAS mutational status is a critical factor when considering the use of targeted therapies. The association of KRAS gene mutation and response to therapy was first reported in patients with metastatic colorectal cancer, who were treated with anti-epidermal growth factor receptor (EGFR) agents. The link between the KRAS gene mutation and decreased response to anti-EGFR agent was first reported by (2). The KRAS oncogene is mutated in approximately 35%-45% of colorectal cancers and KRAS mutational status testing has been highlighted in recent years. The most frequent mutations in this gene, point substitutions in codons 12 and 13, were validated as negative predictors of response to anti-epidermal growth factor receptor antibodies. Therefore, determining the KRAS mutational status of tumor samples has become an essential tool in managing patients with colorectal cancers (2). The aim of current study was to develop a highly sensitive method for detecting somatic mutations of KRAS gene for genotyping CRC patients.
Material and Method

Study Samples: The study population consisted of 40 patients (25 males and 15 females) with age ranged (26–82 years) diagnosed with Colorectal Cancer in diseases teaching hospital during the period from March 2018 to the end of May 2018. In addition, 20 normal healthy subjects were selected as controls.

DNA Extraction: Whole blood samples (5mL) were drawn via vein puncture into tubes containing EDTA and samples were stored at −20°C until DNA extraction. Genomic DNA was extracted from whole blood using Quick-gDNA™ Blood MiniPrep/Zymo/U.S.A.

KRAS gene by symmetric PCR technique (RT-PCR): The following primers for genotyping positive strand for KRAS gene F-5’-AGG CCT GCT GAAAA TGA CTG -3’ R-5’-TTG GAT CAT ATT CGTCCA CAA-3’ and Cy5 (Probe 1) 5’-CTT GCC TAC GCC ACC AGC TCC AACT-BHQ2-3’, while genotyping negative strand for KRAS gene F 5’-AGG CCT GCT GAAAA TGA CTG-3’ R-5’-TTG GATCAT ATT CGTCCA CAA-3’ and ROX (Probe2) 5’- AGT TGG AGC TGG TGG C GT AGG CAAG-BHQ2 - 3’. The mixture for the PCR reaction contained 10 μL of tGoTaq Probe qPCR Master Mix, 0.2 μL Probe, 0.4μL (Forward and Reverse primer), 4.0μL Nuclease-free water, and 5μLDNA Sample Volume. PCR conditions for these amplifications were: 5 minutes at 95°C, denaturation 15 sec at 95°C, alignment Annealing/Extension 10 sec at 55°C, Detection (Scan) 15 sec at 72°C and Melting curve of 15 sec at 55–95°C.

Results and Discussion

The following genotypes related to KRAS, GC (wild genotype) and AC, AT and GT (mutant genotypes) were studied and the results were shown in Table (1). The rates of the wild genotype (GC) were 24 (60.0 %) and 15 (75.0 %), in study and control groups, respectively. The mutant genotype (AC) was more frequent, 8 (20%), in study group than in control group, 3 (15.0 %). However the difference did not reach statistical significance (P= 0.724).

The mutant genotype (AT) was equally frequent in study and control groups, 2 (5.0 %) versus 1 (5.0 %), respectively, P= 0.724. The mutant genotype (GT) was more frequent in study group, 6 (15%), than was in control group, 1 (5.0 %), however, the difference did not reach statistical significance (P= 0.394; Table 3). Overall, the frequency of mutant genotypes was more in study group, 40%, than in control group, 25 %, but the difference was not significant in statistical terms (P= 0.251; Table 2).

The risk of mutant KRAS genotype in association with colorectal cancer was assessed in terms of Odds ratio which was 2.0 (95 % confidence interval of 0.61 - 6.60). This implied that persons harboring mutant KRAS genotypes are at two-fold risk of developing colorectal carcinoma than general population and the etiologic fraction (EF) of these mutant genotypes collectively accounted for 0.38 (Table 2). The results of the HRMA (amplification and melting curve) showed the melting curve results of only 35 samples (Figure 1). An advantage of performing HRMA analysis on a real time PCR machine with HRM capability, is that the PCR amplification and HRM analysis are performed in the same run and the results are available for analysis at the end of the run. In addition, Figure (2) showed the difference between two types of KRAS mutation melting curve.

In this study the aim was to develop a highly sensitive method for detecting somatic mutations of KRAS gene for genotyping CRC patients. The high resolution melting analysis technique (HRMA) applied to mutation scanning is often implemented in high-resolution format. Upon the completion of amplification, PCR products are subjected to the melting procedure in the presence of fluorescent probes. Characteristic changes in DNA melting curves indicate the presence of mismatched bases in the duplexes and, therefore, the presence of mutations (3).

Since TaqMan probes were present in the incubation medium at both steps of the analysis (amplification and melting curve), the analysis can be carried out in the closed tube format. This was a 1.5–2h assay in a single tube without any intermediate or additional procedures that minimize not only time and labor expenditures, but also the probability of the cross contamination of samples which is the most important. As a results, the HRMA method is much more sensitive than Sanger sequencing (3). Our results agreed with (4,5) who revealed that codon 12AC mutations were more frequent in patients followed by codon 13 mutation.

Conclusions

On the basis of current study findings, significant over productions of KRAS mutations seemed to have potential role in colorectal cancer progression and worse prognosis when compared with healthy people.

Ethical Clearance: The research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq.

Evaluation of Malondialdehyde and Glutathione in the Treated and Newly Diagnosed Iraqi Patients with Type 2 Diabetes Mellitus

Hamsa Faisal Najim¹, Zianab Muayad Saber¹, Alaa Mohamed Shaheed¹
¹College of Dentistry, Al-Bayan University, Baghdad, Iraq

ABSTRACT

Background: Diabetes mellitus is a group of metabolic disorders that is characterized by elevated levels of glucose in blood and insufficiency in production or action of insulin produced by the pancreas inside the body. Current study was aimed to investigate the biochemical profiles of Iraqi obese patients with type 2 diabetes mellitus.

Method: Fifty treated diabetic patients with type 2 diabetes mellitus, twenty five newly diagnosed diabetic patients and thirty healthy individuals as control subjects were included. The biochemical analysis included measurements of malondialdehyde and glutathione in all the subjects.

Results: Data from current study revealed highly significant increase in serum MDA in both newly diagnosed T2DM (P<0.01) and treated T2DM patients. Furthermore, serum GSH levels were significantly reduced in these groups as compared to those in control group (P<0.05). In addition, higher GSH level was observed in treated T2DM patients as compared to the newly diagnosed group (P<0.05).

Conclusion: Abnormally high levels of lipid peroxidation and the simultaneous decline of antioxidant defense mechanisms can lead to damage of cellular organelles and oxidative stress.

Keywords: T2DM, oxidative stress, anti-oxidants, MDA, GSH.

Introduction

Diabetes mellitus (DM) is a chronic endocrine disorder characterized by hyperglycemia resulting from absolute or relative insulin deficiency with disturbances in carbohydrate, fat and protein metabolism due to the defects in insulin secretion and/or insulin action. Diabetes mellitus is classified into Type 1, which refers to a condition where there is chronic progressive beta cell destruction (¹), and Type 2, which is the most common type of diabetes that occurs due to the decreased biological response to insulin (²).

Corresponding Author:
Hamsa Faisal Najim
College of Dentistry,
Al-Bayan University, Baghdad, Iraq
Email: hamsa_phdmax2012@yahoo.com

In the early stages, beta cells respond to insulin resistance by secreting increased quantities of insulin and thus maintaining blood sugar at normal levels. However, gradually beta cells begin to fail and insulin levels decrease resulting in rising of blood sugar (³).

The term antioxidant has been defined as any substance, exogenous or endogenous in nature that delays or inhibits oxidative damage to a target molecule and protects biologically important molecules such as DNA, proteins and lipids from oxidative damage and, consequently, reduces the risk of several chronic diseases. Common antioxidants include the glutathione and the enzymes superoxide dismutase, catalase and glutathione reductase (⁴). The highest concentration of glutathione is in the liver making it critical in the body’s detoxification process (⁵).

Taken together, the aim of current study was to investigate the homeostatic alterations at biochemical levels in Iraqi patients suffering from Type 2 diabetes mellitus.
Materials and Method

This case control study was carried out at AL-Khademiya Hospital during the period from June-December 2017. The study was conducted on 105 obese Iraqi subjects with type 2 diabetes mellitus (T2DM). They were recruited into the following groups:

**Group (A):** Included 65 patients whose age ranged from 42 to 71 years (mean ± SD age was 57.3 ± 1.35). These patients were already treated with metformin 500mg three times daily and glibenclamide 5mg twice daily.

**Group (B):** Included 40 patients (newly diagnosed with T2DM). These patients did not receive treatment for DM. Their age ranged from 39-67 years with mean ± SD age of 51.82 ± 2.5 years. Diagnosis was made by consultant physicians for patients as having T2DM depending on patient’s history and clinical examination laboratory investigations.

**Group (C):** Thirty normal healthy individuals (controls) were enrolled in this study. Their age ranged from 40–61 years with mean ± SD age of 54.6 ± 1.07 years.

**Measurement of serum Malondialdehyde (MDA) level:** Blood samples were collected by drawing 2.5ml of blood from each subject. Test was conducted according to (6). The assay was based on the reaction of a chromogenic reagent, 2-thiobarbituric acid, with MDA at 25°C. One molecule of MDA reacts with 2 molecules of 2-thiobarbituric acid to yield a chromophore with absorbance maximum at 450nm.

The concentration of serum Malondialdehyde (MDA) in each sample was extra plotted from MDA standard curve (Figure 1).

**Measurement of serum glutathione (GSH) concentration**

**Principle of Assay:** The general thiol reagent, 5-5’-dithiobis [2-nitrobenzoic acid] (DTNB), reacts with GSH to form the 412nm chromophore, 5-thionitrobenzoic acid (TNB) and GS-TNB. The GS-TNB is subsequently reduced by glutathione reductase and β-nicotinamide adenine dinucleotide phosphate (NADPH), releasing a second molecule (TMB) and recycling the GSH; thus amplifying the response (7). Any oxidized GSH (GSSG) initially presents in the reaction mixture or formed from the mixed disulfide reaction of GSH with GS-TNB is rapidly reduced to GSH (8). The concentration of serum glutathione in each sample was extra plotted from GSH standard curve (Figure 2).

**Results and Discussion**

Table (1) revealed highly significant increase in serum MDA in both newly diagnosed T2DM (P<0.01) and treated T2DM patients. Furthermore, serum GSH levels were significantly reduced in these groups as compared to those in control group (P<0.05). In addition, higher GSH level was observed in treated T2DM patients as compared to the newly diagnosed group (P<0.05). The present result was in agreement with Biplab et al. (2010) who pointed that MDA (as an oxidative stress marker) plays a significant role in the pathogenesis of T2DM and its complications.

</tr>
</tbody>
</table>

* ANOVA: new diagnosed or treated T2DM vs. control: * P<0.05, ** P<0.01)

MDA: Malondialdehyde, GSH: Reduced glutathione

MDA levels were reported to be significantly increased in both groups with complicating T2DM cases. This explains the generation of reactive oxygen species (ROS) during disease process. The generation of ROS has been potentiated by the marked increase in lipid peroxidation product (MDA) in the disease process (9).

The significant hyperglycemia along with raised plasma MDA level in diabetes groups explained their contribution towards free radical production as well as generation of oxidative stress (10).

Abnormally high levels of lipid peroxidation and the simultaneous decline of antioxidant defense mechanisms can lead to damage of cellular organelles and oxidative stress. Many reports are available with regard to oxidative stress and antioxidant status of type 2 diabetic patients (10). High levels of MDA with decreasing in GSH concentration in serum of type 2 diabetic patients is widely reported. Also, this depletion of GSH is considered to be indicative of increased oxidative stress (12).

Presentations of Congenital Heart Disease in Children

Rahman K. Al-Jeboori¹, Shaima’a Dakhel Abdul Hassan¹, Thuraya Habeeb Farhan²

¹Department of Pediatrics, College of Medicine, University of Al-Qadisiyah, Iraq; ²Maternity and Children Teaching Hospital, Al-Diwanyia, Iraq

ABSTRACT

Congenital heart disease (CHD) is the utmost widely recognized class of natal defects. CHD involves wide scope of cardiovascular deformities from basic structures exhibiting in the prompt infant time frame to mellow imperfections, for example, bicuspid aortic valve, which might not be predictable till parenthood. Early finding for those below 1yr of age having critical congenital heart disease (CCHD) diminishes both mortality and grimness while postponed analysis has been appeared to prompt noteworthy mortality.

This study aim for study age, gender distribution and frequency of clinical presentation of CHD.

A prospective study accompanied through 3 years since 1st of July 2015 till 1st of July 2018 & encompass 198 patients with CHD consult the outpatient clinic in Al-Diwaniyah city, Al-Qadisiyah, Iraq, each patient was recorded the 1st time diagnosed as CHD; with history, examination, send for x-ray of chest, ECG, & ECHO study & also record the cause of presentation at 1st time when he was diagnosed as CHD.

In our study, total cases were 198, male 118 (60%), female 80 (40%). Age of presentation, in acyanotic CHD results were {<1month 26%, 1-3m 38%, 3-6m 21%, 6-12m10%,.>1year 5%}, in cyanotic CHD results were {<1month 73%, 1-3m 27%}.According to causes of presentation in acyanotic 47% were presented with chest infection, 18% had heart failure & failing to thrive "HF+FTT", 35% had murmur discovered on routine examination of baby at outpatient clinic while in cyanotic type 100% the cause of presentation were cyanosis.

Many patients with CHD discovered by routine physical examination, so full cardiac examination must be done for all patients as a routine role after delivery before discharge from hospital.

Keywords: Congenital heart disease (CHD), ventricular septal defect (VSD), tetralogy of Falot (TOF), patent ductus arteriosus (PDA), pulmonary stenosis (PS), atrial septal defect (ASD).

Introduction

(CHD) had been happen roughly in 0.8% of live birth. The frequency is greater in stillborn (3-4%), unconstrained abortions (10-25%), and untimely newborn children (about 2% barring PDA). The determination is built up by 1wk of age in ~40-50% of patients with CHD and by age of one month in~50-60% of patients¹)

CHD is the utmost well-known class of natal defects²,³ CHD contains wide-ranging scope of cardiovascular abnormalities from basic structures showing in the prompt infant time frame to mellow imperfections, for example, bicuspid aortic valve, which might not be predictable till parenthood. Regardless of noteworthy advancement in clinical consideration for influenced people, CHD relics the main source of baby death amongst natal anomalies ⁴ For babies that surviving early period, there were a great proportion of comorbidities, together cardiovascular and extracardiac & predictable life expectancy was as yet lessened ⁵

In newborn children with a CCHD, the danger of ill health & mortality increments when there is postponement in the determination & opportune referral to tertiary unit⁶

Newborn children with (CCHD) necessitating invasive or catheter intercession within 1st year of lifespan are in danger for cardiovascular breakdown

Corresponding Author:
Shaima’a Dakhel Abdul Hassan

Al-Diwanyia, Iraq
Email: dr_sh_d@yahoo.com
or else passing whenever released from the birth emergency clinic deprived of a CCHD conclusion (7) If not recognized instantly, CCHDs may have calamitous outcomes (8,9). This postponed finding has been appeared to prompt huge mortality just as generous short-and long morbidity for survivors (6,7).

The previous 3 decades have seen generous walks in managing heart disease by a 39% decrease in death due to CHD somewhere in the range of 1979 and 1997 (10). Stagnant, CHD relics a huge reason for natal and baby death in the United States (US), representing 29% of passings because of birth deformities and 5.7% of all newborn child passings. (11) Neonates represent 57% of newborn child death as a result of CHD (12). CHD that necessitates obtrusive intercession within 1st month of life had been named CCHD.

Unrecognized neonatal CHD conveys a genuine danger of preventable death, dreariness, & impairment (13) Clinical examination earlier to release from hospital and of newborn children at about 45 days of age for any sign of CHD is suggested in Health for All Children (14).

Upgrades in diagnosing, treating, & surgical repairing are changing the survival arrangement of CHD. As of late the survival of progressively complex sorts of inborn CHD has enhanced, prompting an expanding remaining task at hand for development, reinvestigation, and reoperation. Over a similar time, the consideration of grown-ups with CHD has started to create as a different subspecialty (15). It appears to be likely that everything except those with the least difficult types of CHD will require authority development, & this would be the principle development territory in consideration of those having heart disease (16).

Materials and Method

A prospective study accompanied through 3 years since 1st of July 2015 till 1st of July 2018 & encompass 198 patients with CHD consult the outpatient clinic in Al-Diwaniyah city, Al-Qadisiyah, Iraq, each patient was recorded the 1st time diagnosed as CHD; with history, examination, send for x-ray of chest, ECG, & ECHO study & also record the cause of presentation at 1st time when he was diagnosed as CHD.

Results

In our study, total cases were 198, male 118 (60%), female 80 (40%), as showing in figure-1.

![Figure 1: Sex Ratio](image1)

Sex distribution in acyanotic CHD was male 92 (60%) & female 62 (40%), while in cyanotic CHD was male 26 (59%) & female 18 (41%), as showing in figure 2.

![Figure 2: Sex Distribution & Type of CHD](image2)

Sex distribution in each specific type of CHD & their percent from total cases as showing in figure 3.

![Figure 3: Types of CHD & Sex](image3)

According to age of presentation, in a Cyanotic CHD results were {<1month 26%, 1-3m 38%, 3-6m 21%, 6-12m10%>,>1year 5%}, in cyanotic CHD results were {<1month 73%, 1-3m 27%} as showing in figure 4.
According to causes of presentation in acyanotic type, 47% were presented with chest infection, 18% had heart failure & failing to thrive "HF+FTT", 35% had murmur discovered on routine examination of baby at outpatient clinic while in cyanotic type 100% the cause of presentation were cyanosis, as showing in table 1 & figure 5.

In our study VSD, ASD & PDA account for 69% which similar to study in the Hospital das Clínicas at Maternity Unit joined the Latin-American collaborative study of congenital malformations, where the results of all clinical presentations of heart diseases were analyzed together (ASD), (VSD) & (PDA) accounted for 62.6% of all imperfections recognized, the results to some extent higher in our study (23).

The most common CHD in our study were VSD & TOF, similar results in study in Iran 2006, also similar results in M:F ratio in both studies CHD higher in males 1.5:1, also in this study results were CHD presented more frequently during infancy (46%), while in our study 96% of presentation at age< 1yr. A cyanotic disease was noticed in 58 (69 %) cases, in our study 95% whereas cyanotic disease was noticed in 26 (31%), in our study 100% of cyanotic discovered at age cases <1yr.

Among cyanotic disease, (VSD) was found in (58.3%) while in our study 60%, (ASD) (4.8%) in our study 3%, defect of endocardial cushion in 2 patients (2.4%) while A.V Canal defect in our study 3%. Amongst cyanotic disease, (TOF) accounted for 13.1% in our study TOF about 20%. These higher results in our study due to new advances occurred in last years in detecting & diagnosing the disease when we in doubt.

**Discussion**

Cardiovascular anomalies are the most widely recognized gathering of congenital abnormalities. Later planned investigations, with prepared accessibility of timely echocardiographic checkup, have appeared higher of pervasiveness of alive conceived heart anomalies, practically which is all represented by the discovery of even more little ventricular septal defects (17-19). These results similar to results in our study where VSD represent the higher prevalence 60%.

Early acknowledgment of these anomalies is essential in light of the fact that clinical introduction and crumbling might be abrupt (20) and specific curable imperfections might even reason for mortality beforehand diagnosing them (21,22).

Figure 4: Age of Presentation of CHD

Figure 5: Causes Of Presentation CHD.
In this study, the furthermost communal clinical arrangements were developmental delay & "failure to thrive" (FTT) (86.9%), shortness of breath (69%), chest infection (52%), heart failure (46%), cyanosis (20.2%), while in our study results were chest infection (36%), HF + FTT (14%), on routine exam (27%), cyanosis (22%); according to these results cyanosis similar percent while previously FTT was higher which may be due to delayed diagnosis previously in comparison to early diagnosis in recent years (24).

So on the routine cardiac examination must be done at delivery room, before discharging baby from neonatal care unit & in those visiting outpatient clinics for any purposes or visiting a health center for routine checkup or for receiving vaccine, because high percent of CHD that discovered on routine checkup (murmur), chest infection, cyanosis or FTT that blamed to CHD.

The importance of early diagnosis for early intervention before missing patient because duct dependent disease or shunt dependent CHD which can lead to death even before diagnosis.

**Conclusion**

Many patients with CHD discovered by routine physical examination, so full cardiac examination must be done for all patients as a routine role after delivery before discharge from hospital.

Sero Levels of Lipocalin-2 in RA Patients

Sahar Abdul Sattar Alwan1, Mayada Noori Iqbal1, Ali Hussein Al-Hafidh2

1Department of Medical Laboratory Technology, College of Health and Medical Technology,  
2College of Health and Medical Technology, Middle Technical University, Baghdad, Iraq

ABSTRACT

Rheumatoid arthritis (RA) is a constant systemic autoimmune seditious disease. Although the precise etiology of disease is not known, but up to date studies demonstrate that lipocalin-2 (LCN-2) is a recognized seditious biomarker, LCN2 is involved in innate immunity by sequestrating iron that in turn limits bacterial growth that has an optimistic relationship with body mass index and a variety of metabolic syndromes.

Study intended to look the level of lipocalin-2 and their relationship with Body Mass Index BMI among patients with RA.

Patients with RA (103) that divided in to two groups(56 new early diagnosis group;47 early diagnosis with treated group), were included diagnosis according to American College of Rheumatology (ACR) criteria and 25 subjects as healthy control group. All demographic (Age and Gender), clinical data (Body Mass Index BMI) and serological data (serum lipocalin-2, ACPA, CRP and RF investigated by ELISA methods. Rheumatic Arthritis of both groups divided according to RF results in to two subgroups (seropositive 36, seronegative 20 at new early diagnosis RA group) and (seropositive 32, seronegative 15 early diagnosis RA with treated group). Mean and SE of serum lipocalin-2 level in patients with RA (9.44±1.620ng/ml), as compared to healthy control individuals (7.28±1.055ng/ml) were significantly higher. Positivity result of Anti-CCP in patients groups 94 (91.3%), as compare with positivity Anti-CCP 0 (0.00%) at healthy control group. No significant difference of lipocalin-2 between RF+ve and RF-ve (P>0.05) at both groups, but high significant deference among Anti-CCP and ESR between RF+ve and RF-ve of new early diagnosis RA group and high significant deference of CRP and ESR at early diagnosis RA treated group. Present study had no important correlation between lipocalin-2 levels and BMI in both groups, except among RF-ve (early diagnosis RA treated groups). These consequences point to that serum LCN-2 levels may be used as a pathogenic pointer in the early on period of the sickness but do not able to be used to pointer in the analysis of RA.

Keywords: Serum Lipocalin-2, New early RA diagnosis, Body Mass Index BMI.

Introduction

Rheumatoid arthritis is an autoimmune disarray which affects mostly small joints hand and feet and has a lot of systemic manifestations (1). The auto antigens recognized by autoantibodies include cartilage components, chaperones, enzymes, nuclear proteins and citrullinated proteins (2). A biomarker is defined as organic marker, usually refers to a assessable pointer of a number of natural condition or state. Discovering original biomarkers in RA studies attract scientist to know the input roles in a variety of stages of development, leftovers a subject matter of attention for RA. Since destructive factor such as lipocalin-2 known as inflammatory biomarker, it is a 25kDa protein that have monomeric, homodimeric, and heterodimeric forms, this a protein that found in humans is priarranged by the LCN2 gene (3); it is more often than not synthesized as of the adipose tissue and liver cells (4). After additional explore, LCN-2 was recorded to be spoken from a variety of other cells. As, throughout irritation it is synthesized from epithelial cells. LCN-2 plays a position in different cellular proceedings, as well as immune response, differentiation, and tumorigenes (5). With greater than before LCN-2 gene expression in the livers and fatty tissue of the
hereditarily heavy animals \(^{(6)}\). So study aimed to give the impression about level of lipocalin-2 in RA patients and its significant difference between seronegative and seropositive RF and study their relationship with Body Mass Index BMI among patients with RA.

**Materials and Method**

Data collected during the period from March – September 2017. This study includes group of (103) patients with early rheumatoid arthritis of less than 1 year duration that classify according to (ACR) criteria (56 patients with new early diagnosis without treatment group and 47 patients early diagnosis RA treated group) and (25) healthy control subjects and patients divided in to two subgroup (seropositive 36, seronegative 20 of new early diagnosis RA group) and (seropositive 32, seronegative 15 of early diagnosis RA with treated group). Questionnaire form formulated which involved name, age, sex and BMI by (Kg/m²).

**Specimen:** Venous blood spacemen’s (5ml) that were collected from patients and healthy controls; 3 ml of each sample for serum separation, and the other part remains of whole blood were collected for ESR test by westregren method.

**Study Protocols:** Quantitative measurement of lipocalin-2, Anti-CCP, C-reactive protein (CRP), rheumatoid factor(RF) by Enzyme Linked Immuno-Sorbent Assay (ELISA),according to the manufactures protocol (R&D Systems USA, Chorus Italy, Agappe Switzerland and Chorus Italy, respectively). Body Mass Index (BMI)=Kg/m².

**Statistical Analysis:** Statistical analysis was performed using the SPSS 10 statistical package. Mean, SD and SE were used to express variables. The outcome of study were evaluated using a nonparametric and parametric statistical methods for information with non-normal and normal distribution, respectively. T test was second-hand to contrast the differentiation in mean among two incessant numeric variables, differences that were considered significant statistically at \(P<0.05\).Between-group comparisons were complete the Spearman’s rank association coefficient process for non-normally distributed data and Pearson’s product-moment correlation for normally distributed variables \(^{(7)}\).

**Result**

**Demographical and clinical characteristic of studied groups:** Demographical characteristics variables, patients information such that age and gender were recorded. Clinical parameter such as body mass index (BMI). The mean age patients \((42.22\pm11.23\) years) while \((36.40\pm11.15\) years) of healthy controls, gender of patients comprised female \((74.8\%)\) and male \((25\%\)\), body mass index BMI results showed (normal weight \(28\) (27.2 %), over weight \(31\) (30.1%), obese \(44\)\(42.7\%\) patients vs (normal weight \(12\) (48.0%), over weight \(4\)\(16.0\%), obese \(9\) (36.0%) in controls. The study showed that the number and percentage of studied groups according to positively results of ESR, RF, CRP and ACPA, elevated results of ESR patients \(82\) (79.6%), while healthy control group \(2\) (8.00%), positivity RF,CRP and Anti-CCP of patients results showed \(67\) (65.0%), \(89\) (86.4), and \(94\) (91.3%), respectively. Parameter which represents biomarker such as lipocalin-2 was measured in patients and compared with controls, the results showed that mean and SE of Lipocalin-2 was \((9.44\pm1.620\) ng/ml) vs \((7.28\pm1.055\) ng/ml) of patients with RA and healthy control group, respectively.

**Distributions of markers among studied groups according to RF subgroups:** Studied different parameter’s readings along all different of RF groups, which proved of having normal distribution function, since probability levels of significant through testing goodness of fit are accounted \(P>0.05\).

**Table 1: Mean levels of lipocalin-2, Anti-CCP,CRP and ESR among studied subgroups of RA patients**

Respect to subject of BMI and patient’s groups, some studies markers has accounted strong and significant relationships in at least at p< 0.05 concerning early diagnosis RA treated groups with RF-ve, while negatively relationships with the leftover groups (i.e. Treated RF+ve, and RF-ve). Briefly in early diagnosis RA treated group who have RF-ve, the results showed significant correlation between BMI and level of lipocalin-2(p= 0.006), but no significant relationships between BMI and (Anti-CCP, RF, CRP and ESR) among studied groups.

**Discussion**

The present study revealed that prevalence of RA was more in female patients than male patients similar to result in 2014 showed (75.25% vs 24.75%, respectively) and this study suggests that augment aging can show the way to constant inflammation and resistant mediated tissue injure (8). Other study have shown opposite result more frequent in men than in women (72% versus 55%, respectively) (20).

Anti-CCP, RF, CRP and ESR in present study showed high positive result compare with control, similar to study recorded that RF, Anti-CCP, CRP and ESR with high levels was obliging for the confirmed diagnosis of RA (10). In present study patients with positive RF and Anti-CCP more than with negative RF and Anti-CCP test results. Thus, these parameters could be worn as exact serologic markers for RA (11). In present study found the
strength relations of Anti-CCP and RF, indeed, results of present study in antibody discordant patients suggest that RF may be more closely connected with augmented level of Anti-CCP at RA patients, agree with study showed RF and Anti-CCP had highest autoantibody concentrations at RA patients (12). Present data reveals that LCN-2 levels are superior in patients with RA than in healthy individuals, likewise to consequence establish in their data that serum LCN-2 levels were elevated in RA patients than in healthy controls (13). There was not a meaningful difference between serum LCN-2 levels between RF(+) and RF(-) patients and serum LCN-2 levels of RF(−) patients more than in RF(+), agree with study by Gulkesen and his coworker who recorded serum RF and CCP levels did not correlate with LCN-2 levels (14). However, contrary results were also reported with no increase level of lipocalin-2 in RA patients (15). Tissue allocation and appearance of LCN-2 in neutrophils, bone marrow, and tissues bare to germs, such as the trachea, lung, stomach, salivary gland, and colon (3) point to its taking part in seditious responses. In neutrophils, LCN-2 secretion is very keeping pace by infection and the commencement of frustration (16).

Obesity comprised (42.7%) of patients RA and this agree with study recorded about 66% of patients with RA are obese, extreme overweight leads to superior manufacture of provocative proteins that augment the joint irritation due to the illness itself (17). So, numerous factors connected with RA may be probable penalty of disease quite than related to illness danger, however, fat individuals had a considerably augmented risk of RA disease (18).

The involvement of body mass index (BMI) with parameters levels at RA patients, recorded important relations between events of BMI and lipocalin-2 among RF-ve at (early diagnosis RA with trated group). Nevertheless, not showed significant correlation between BMI and others markers (Anti-CCP, RF, CRP and ESR) among studied group. Study reported Lipocalin-2which has a positive relationship with body mass index, and a variety of metabolic syndromes (19). Jon and his co-workers reported major relations between every one events of adiposity, chiefly truncal fat, and CRP levels in women (20), but study showed like the result in present study that BMI had negative correlation with CRP and ESR (21).

Conclusion

These consequences point to that serum Lipocalin-2 levels increased in RA patients compared in healthy control. Perhaps used as a pointer for structural injure like erosions in the early on period of the illness but do not able to be –used to checker in the analysis of RA disease. An intensify of body mass index can give lipocalin-2 and show the way to a superior danger for RA progress. However, the judgment as well places of interest the require for research on the relationship between body mass index and RA risk with alteration for more confusing factors.

Comparative Study for the Diagnostic Features of BNP and HS-CRP in Patient with Heart Failure

Salam H¹, Raid M¹, Adnan T.²

¹Chemistry Dept., College of Science, ²College of Medicine, University of Thi-Qar, Iraq

ABSTRACT

A large number of diagnostic tests are used to confirm the presence of heart failure (HF) disease including symptoms and clinical signs of HF, radiological examinations, echocardiography, electrocardiography and laboratory blood tests. Also in recent years, in 1988, a new cardiac natriuretic peptide [B-type natriuretic peptide (BNP)] with excellent diagnostic characteristics was discovered. Wherefore, in the next years was appeared to have prognostic properties and later likewise seemed to have symptomatic properties in the outpatient settings and emergency department.

In this research we completed work with participants, part of them patients with heart failure to varying degrees and another part do not suffer from heart failure to be a control group on which to build the results of the research. We pulled the blood from them, turned it to serum, estimated concentrations of certain chemical agents that are under research such as (BNP, hs-CRP, T-Chol, HDL-cholesterol, TG, LDL-cholesterol and VLDL-cholesterol) and compared these concentrations with another factor (EF %). Generally, we found a clear increase in concentrations of BNP and hs-CRP (Percentage increase in BNP and hs-CRP concentration level is estimated at 497%, 332 % which is 5, 3.32 times as much as the BNP and hs-CRP concentration in control group D respectively), with the greater decline in the value of EF%. As well as compared to other factors (Percentage increase in T-Chol, TG, LDL-cholesterol, VLDL-cholesterol and percentage decrease in HDL-cholesterol.). Therefore, the BNP and hs-CRP are the two best factors of the total factors studied in the research to diagnose heart failure disease.

Keywords: Heart Failure (HF), Brain Natriuretic Peptide (BNP), Lipid Profile

Introduction

Heart failure (HF) is a complex clinical disorder and the end phase of all diseases of the heart that happens when the heart decreases its ability to supply sufficient blood stream all through the body. Furthermore, there is numerous reasons for HF with the goal that coronary artery disease, hypertension, cardiomyopathy, valvar and congenital heart disease, arrhythmias, alcohol and drugs, “high output” failure, pericardial disease and primary right heart failure [1]. Also chronic heart failure (CHF) rate and transcendence increases with age. As well as it is an imperative cardiovascular issue foreseen that would augment all through the accompanying 25 years as its recurrence will significantly increment and its power will grow 10 crease from age 60 to age 80 [2, 3]. HF is the main source of hospitalization in individuals more than 65 years [4, 5].

ProBNP is delivered from heart muscle cells, basically in the left ventricular myocardium response to ventricular dilation and pressure overload. Moreover proBNP is split to [B-type natriuretic peptide (BNP1-32 or BNP) and N-terminal proBNP (NT-proBNP)] [6]. Also BNP displays several physiologic functions including vasodilation, advancement of natriuresis and diuresis, inhibition of the sympathetic nervous system and several hormone systems such as the renin-angiotensinaldosterone system, also inhibitory and useful impacts on the physiological mechanisms associate with the cardiovascular system [7]. BNP has a half-life of 22 minutes [8]. For such a serious situation view, the aim

Email: salamhe64@gmail.com
of this research is to measure the concentration of BNP, hs-CRP and lipid profile in the blood of heart failure patients and healthy people with no heart failure, to compare between them and identify the best agent to diagnose the heart failure disease.

Materials and Method

About 8ml of blood was withdrawn from the participants in the research, the blood was allowed to clot by left it undisturbed at room temperature for 15-30 minutes and the clot was removed by centrifuging at 2200-2500 rpm for 15 minutes in a refrigerated centrifuge. The resulting supernatant is designated serum, the liquid component (serum) was transferred immediately into a clean polypropylene tube by using a Pasteur pipette. The isolated serum was saved at -20°C for subsequent analysis. Elisyys uno was used to measure blood BNP concentration (Abcam’s BNP Human ELISA Kit (ab193694) is an in vitro enzyme-linked immunosorbent assay (ELISA) for the quantitative measurement of Human BNP in serum, plasma and cell culture supernatants), Cobas Integra 400 plus, and Spectrum Spectrophotometer used to measure the other factors.

The number of participants in the research was 110, the males were (57; 52%) and females (53; 48%). The number of patients who took the blood samples was 70 patients, conditional the ejection fraction was 49% or less and they were divided into three groups [group A with an EF % of ≤ 30%, group B with an EF % (31% - 40%) and group C with an EF % (41% - 49%)] and a fourth group D of 40 healthy people with no heart failure.

Results and Discussion

Relationship between BNP and EF %: Table (1), general average in Table (2) and percentage increase in Table (3), when compared with the concentration of BNP in control group D, the difference is clear that there is a significant increase in the concentration of BNP in groups A, B and C for control group D. Also from the above paragraph and Figures (1), (2) and (3) note that BNP is an excellent factor for diagnosing heart failure patients and the relationship between it and EF % is inverse relationship.

Moreover, several studies have been found a strong negative relationship between BNP and EF %[9,10].

Generally, Brain Natriuretic Peptide (BNP) is delivered essentially from the ventricle in light of volume expansion, pressure overload and elevated diastolic pressure [11]. The net impact of these peptides is a decline in blood pressure because of the reduction in systemic vascular resistance and along these lines afterload [12].

As for an ejection fraction (EF %) is typically ascertained by partitioning the volume of blood pumped from the left ventricle per beat, otherwise called stroke volume, healthy individuals typically have ejection fractions between 50% and 65% [13].

Legend as in table (3)

Relationship between T-Chol, HDL-cholesterol, TG, LDL-cholesterol, VLDL-cholesterol and (BNP, EF %): Table (1) and General Average in Table (2), when compared with the concentration of lipid profile in control group D, we note a small difference between the groups A, B and C for control group D, this does not give us any evidence or help of diagnose patients with heart failure. From the above section and Figures (1), (2) and (3) we find that the relationship between T-Chol, TG, LDL-cholesterol, VLDL-cholesterol and BNP is a direct and inverse relationship with EF %, And vice versa for HDL-cholesterol.

Furthermore Linssen found a positive relationship between the left ventricular hypertrophy (LVH) and total cholesterol and those results indicate a positive relationship between BNP and total cholesterol [18]. As for total cholesterol is required for some functions for example, to keep up uprightness of cell membranes, creation of vitamin D on the surface of skin and generation of bile acid and steroidal hormones [19].

As well as Qin Zhao found a positive relationship between HDL and EF% [15]. Also high density lipoprotein (HDL) cholesterol is regularly known as the ‘good’ cholesterol, the part of HDL-cholesterol is to transport overabundance cholesterol from the tissues (counting the arterial wall) to the liver for disposal [20].

Moreover, Mona found a positive relationship between BNP with (TG and LDL) [21]. As well as triglycerides are a form of fat and the main molecules that make up animal fats and vegetable oil, they are also a major human skin component of oils (sebum) [22]. Likewise low density lipoprotein (LDL) cholesterol, the conviction that low-density lipoprotein (LDL) cholesterol causes atherosclerosis and resulting coronary illness is a basic statute of current solutions [23].

Very Low Density Lipoprotein (VLDL) cholesterol, elevated amounts of VLDL-cholesterol have been related with the improvement of plaque deposits on artery walls, which limit the entry and confine blood stream [24].

Conclusions

There is a significant increase in the levels of concentrations of BNP and hs-CRP in the blood when the value of EF % decreases, also there is a negative relationship between EF % with (BNP and hs-CRP) and vice versa for BNP and hs-CRP, likewise the relationship between EF % and HDL-cholesterol is a positive and vice versa for BNP and HDL-cholesterol, the amount of decrease in HDL-cholesterol concentration is slightly reduced when the value of EF % decreases, as well as the relationship between EF % and (T-Chol, LDL-cholesterol, TG, VLDL-cholesterol) is a negative relationship, vice versa between them and BNP, where there is a small increase when the value of EF % decreases. From the above and from Figure (3) we conclude that the best diagnostic factors for heart failure patients are BNP and hs-CRP compared to lower value of left ventricular blood pumping (EF %).

A Phylogenetic Study of *Entamoeba Histolytica* Isolated from Patients in the Babylon Hospital of Iraq Based on 18S Ribosomal RNA Gene

Saba Fadhil Ali Malaa¹, Rasha Amer Noori Al Tufaili², Dhamiaa Maki Hamza³, Raad Ajem¹
¹Al-Furat AL– Awsat Technical University, Iraq; ²University of Kufa, Iraq; ³Collage of Medicine, Kerbala University, Iraq

**ABSTRACT**

About ten percent of the world’s people are infected with *Entamoeba histolytica*, which representing over fifty million people annually. Sequences of 18S ribosomal RNA gene have been obtained for five new isolates of *Entamoeba histolytica*, which is represented new insights into the evolution of phylogenetic analyses of this parasite in Iraq. In the current study, the phylogenetic relationships between five local isolations of *Entamoeba histolytica* and eight *Entamoeba* spp global isolates were studied by using the 18S rRNA gene sequence.

The analysis of multiple sequence alignment and the adjoining phylogenetic tree analysis was carried out by using ClustalW multiple sequence alignment online based analysis of 355bp 18S rRNA gene was amplified by Polymerase Chain Reaction.

Phylogenetic analysis results of these gene sequences revealed that *Entamoeba histolytica* local isolations were closely related to *Entamoeba histolytica* two Japan isolation (AB282660.1) and (AB485592.1) more than other countries. Accession No: KT253450, KT253451, KT253452, KT253453 and KT253454, these isolates are unique, and a new strain, this is the first report on the usage of molecular phylogeny to classify *Entamoeba histolytica* which is found in Babylon Province of Iraq.

**Keywords:** *Entamoeba histolytica*, phylogenetic tree, Polymerase Chain Reaction, 18S rRNA gene sequence.

**Introduction**

In parasitic diseases, Amoebiasis is the most reason of death After Malaria and Schistosomiasis [1]. Although *Entamoeba histolytica*, *Entamoeba moshkovskii* and *Entamoeba dispar* are morphologically identical but they are biochemically and genetically different [1,2,3].

Over the previous different long time, it has become clear that amoebae appear a highly diverse and polyphyletic aggregation. Other than their form of movement, no phenotypic features unite the group [2,4,5,6]. The illumination of molecular techniques modulating gene signaling and virulence is pay great attention for Scientists working with *Entamoeba histolytica* in order to recognize parasite biology and be able to identify biochemical objects or vaccine applicants that could help to management amoebiasis [7,8].

The information on the host range of any Entamoeba species does not verification, but it is clear that some of them can infect different hosts. *Entamoeba dispar* is separated from a wide diversity of ancient and new world primates as well as humans [9,10].

The features and synonyms of *Entamoeba polecki* are not known because it is originated in pigs and humans. The main criteria of Entamoeba are that many types of morphology level with cyst size and the number of cyst nuclei [11,7].

This illustrates a problem which is increasingly facing molecular information correlation with morphological features. Most similar instances have including ___

**DOI Number:** 10.5958/0976-5506.2019.02216.2
environmental scanning, and no connection to the parasite is usually probable \cite{8}. In addition, in the past qualified primers for the discovery Entamoeba spp. are not specified as previously assumed, which can be demonstrated by the different small sequence in the first areas.

These studies on 18S ribosomal RNA definite that the human pathogenic \textit{Entamoeba histolytica} parasites in several areas of the world and defined their phylogenetic relationship. In addition to that, the case of \textit{E. histolytica} of Iraq remained unclear. The current study was observed and analyzed the small subunit ribosomal RNA genes for production of phylogenetic trees of Iraqi \textit{E. histolytica} parasite in comparison of another species Entamoeba spp. In this study, there are new understandings into the phylogeny of \textit{E. histolytica} provided by the analysis of new Babylon isolation.

**Materials and Method**

Forty \textit{Entamoeba histolytica} isolates were collected from the patient’s fecal samples with gastrointestinal discomfort symptoms referred to the health centers and hospitals in Babylon, in 2017. Then, the samples were sent to the Research Laboratory of Intestinal Protozoa in the Department of Parasitology of Hilla General Teaching Hospital of Medical Sciences for further examination.

**Genomic DNA Extraction Originate:** DNA was extracted from stool samples by using the (Stool DNA Extraction Kit Bioneer-Korea). The components of the kit were prepared and the steps were carried out according to the manufacturer’s instructions.

**Primer Design:** The primer was designed with the service of the Gene bank-NCBI site in order to obtain a complete sequence of the 18S ribosomal RNA gene (Gene bank sequence) by using the program Primer 3plus to design primers which is used in the PCR assay \cite{12}. The Primer has been equipped by the Korean company Bioneer.

**Polymerase Chain Reaction (PCR):** PCR technique was carried out by using a specific primer which was designed by \cite{13}. And Supplied by (company Bioneer. Korea).

**DNA Technics Sequencing:** DNA sequencing method was done for confirmative detection and a Phylogenetic relationship of \textit{Entamoeba histolytica} which is based on 18SrRNA gene by analyzing Phylogenetic tree using ClustalW multiple sequence alignment programs. The 355bp PCR product has been purified with agarose gel (EZ. EZ-10 Spin Column DNA Gel Extraction Kit, Bio basic, Canada). The purified 18S rRNA gene samples of PCR products were sent to Bioneer Company in Korea for DNA sequencing using 18SrRNA forwarding primers (AB DNA sequencing).

**Results and Discussion**

Out of 40 fecal samples of clinical suspected \textit{Entamoeba histolytica} were tested by conventional PCR assay, only thirty samples were appeared positive for \textit{Entamoeba histolytica} at 355 bp PCR product of 18S rRNA gene on 1.5% agarose gel electrophoresis (2h., 5V/cm, 1XTris-acetic buffer).

The five positive samples Sequence analysis of \textit{Entamoeba histolytica} was performed to confirm the PCR results. These sequences of the 18S ribosomal RNA genes of the parasite can be found under the accession numbers: KT253450, KT253451, KT253452, KT253453 and KT253454 at NCBI-Gen Bank submission.
Analysis of DNA sequencing of the 18S rRNA gene 355 bp PCR product by multiple alignment (ClustalW2) showed specific detection of *E. histolytica*, the results of Phylogenetic sequence alignment of (*E. histolytica* local Iraqi isolation) was 100% identity to *E. histolytica* strain (KF429800.1) more than other Entamoeba spp.

The phylogenetic tree was constructed based on five *E. histolytica* Iraq isolation, eight Entamoeba spp and out group sequences including *Entamoeba ecuadoriensis*

The identity percent of *E. histolytica* Iraq local isolates to other *E. histolytica* AB282660.1 (Japan), KJ870211 (Cameroon), Y11272.1 (India), GQ423749.1 (Philippine) was 100% and with *Entamoeba nuttalli* (AB485592.1), were 99%, Table(3):

The 18S ribosomal RNA gene is the most abundant component of nucleic acid with a eukaryotic RNA transcription unit in any parasitic organism. The sequenced rRNA gene was study from a diversity of various organisms and leading to a large sequence comparison database [8,10]. Moreover, the 18S rRNA gene is valuable for phylogenetic analysis due to its high levels of conservation [14,10].

In the Illustrate Entamoeba spp relationships. Parasites which show their previous classification of taxonomy was not clear. Molecular manners such as sequencing 18S rRNA gene described in this study are promising tools to classify this parasite.

For a clearer taxonomic description of *Entamoeba histolytica* parasite, however, basic information based on life-cycle variations, methods of transmission, virulence and genetic compatibility is essential [15,10].

Designing tree of phylogenetic based on sequencing the 18S rRNA gene of the Iraq isolation (*Entamoeba histolytica*), and other species of Entamoeba available in GenBank *E.histolytica* (Iraq isolation) was near to *E.histolytica* (AB282660.1).

In the constructed tree which is depended on available two Entamoeba spp are pathogens, but the others organism in this paper are either free-living or commensal. *Entamoeba histolytica* is the cause of the human amoebic dysentery but *Entamoeba invadens* source fatal infections in some reptiles. Both of these pathogenic species are memberships of distinguished well-supported clades [15,16].

Our trees yield no guide of coevolution between *Entamoeba histolytica* and their hosts. Species from
primates and mammalian sources are scattered in our phylogeny, which suggests that host switching has been a common event in this lineage [16]

Furthermore, more than one host can infect by *Entamoeba histolytica*, which causes a problem in diagnosis and epidemiology. In this study, the fragment of 18S rRNA gene sequences of *Entamoeba histolytica* 355bp was amplified to examine.

The data nucleotide sequence identity demonstrated that the five *Entamoeba histolytica* Iraq isolation are nucleotide identity percent of 100% with *E. histolytica* (AB282660.1 japan) and with *Entamoeba nuttalli* (AB485592.1japan) was 99%, *Entamoeba dispar* (AB282661.1) was 98%. Outcome, significant genetic diversity is present among morphologically different parasites, and it is also probable that exact morphological variations do not influence species-level [15,17,18], but it is evident that some Entamoeba can infect diverse hosts.

Other aspects of the parasite population genetics have been classified, such as population substructure, geographical and host recognition, and chosen and propagation of genetic lineages, all of them must be studied together.

**Conclusion**

Our understanding of *E. histolytica* pathogenesis at both the molecular and DNA sequencing level, as well as its ability to transmit, adapt to diverse conditions, overcome host barriers and emerge as infective trophozoites, will provide targets for therapeutic interventions.

**Recommendation**

More study to detection other aspects of the *Entamoeba histolytica* population genetics.

Histological Effect of the Alcoholic Extract of *Nerium Oleander* in the Heart and Brain in Mice and its Effect on the Lymphocytes (*In Vitro*)

Zinah Ibraheem Khaleel¹, Zeinab Hashim Mohammed², Marwan Q. Al-Samarraie¹

¹Department of Pathological Analysis, ²Applied Chemistry Department, College of Applied Sciences, University of Samarra, Iraq

ABSTRACT

The study consisted of two axes: 1 - Knowledge of the toxic effect of leaf extract *N. oleander* on the histology of the heart and brain of the extract of the leaves in mice.

The plant was extracted with alcohol and the specific chemical data were calculated and the detection of some plant compounds by analytical methods. The animals were then divided into four groups. The first group was the control group, which were vaccinated with distilled water and the second group pumped the extract at a low concentration 1mg/ml and the third group dose extractor. The concentration 1.5mg/ml and the fourth group were pumped with a concentration extract of 2mg/ml. The results of the examination of the tissue of the heart for all groups for month and, edema with spasticity in the muscle cells, and fragmentation and infiltration of the cells of single-nuclei in the heart muscle. We conclude that the extract of the leaves has a toxic effect on the heart muscle. After a month of the dosage, focal necrosis was observed and in other samples of the brain samples were seen infiltration For the inflammatory cells of the nuclei and lymphocytes around volatile regions. 2- the second axis to know the effect of the extract on lymphocytes by studying extracellular (*in vitro*), The results of the *N. oleander* highly inhibitory effect on human lymphocyte mentioned.

**Keywords:** *N. oleander*, Brain, Heart

Introduction

*N. oleander* is one of the most important medicinal plants since ancient times. Despite its high toxicity, about 10 leaves are sufficient to kill a horse and 8 leaves of cow killing. However, humans were able to benefit from this quality in the treatment of many diseases.

The Arabs were the first to discover the therapeutic ability of this plant against cancer and skin tumors as well as in the treatment of back pain and joints (¹). In addition to other compounds such as Oleandrinigenin, gentiosylolandrin, Diginose, and Digitose, they are not medically active. The leaves contain glycosides and digitoxigenin (²). A recent study also found that oleander was used in the treatment of hyperglycemia and high blood pressure (³). A recent study has concluded that oleander flower extract protects nerves and nerve cells from damage (⁴).

Materials and Method

**Extraction of *N. oleander***: The extract was prepared with 20 g of dried leaves powder and was dried by spreading green leaves on a floor covered with clean leaves, while stirring them daily in a dark place with good ventilation and then dissolved in 200 ml of 95% ethyl alcohol. Well and leave it for 24 hours after the mixture was sprayed through several layers of gauze and take the leachate produced in Soxhlet extractor (which works on the basis of vaporization under pressure and temperature not more than (45) m, After evaporation of all the alcohol in the mix was dried to obtain dry matter With dark green color and softened with distilled water Harm the required dose (⁵).
Chemical detection of some active substances found in Samples of the leafy plant:

1. Detection of alkaloids: 10 g of plant sample was boiled in 50 ml of distilled water with 40% hydrochloric acid. The solution was then filtered after cooling. 0.5 mL of leachate was tested in a test tube with the following reagents:

<table>
<thead>
<tr>
<th>Tube</th>
<th>0.5 ml of the detector</th>
<th>The color of the precipitation that</th>
<th>Purpose of detection</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Third</td>
<td>Waknar</td>
<td>brown</td>
<td>alkaloids</td>
</tr>
</tbody>
</table>

2. Detection of Glycosides: Mix two equal parts of the flank detector with the plant extracts and then leave the mixture in boiling water bath for 10 minutes and indicate the positive examination through the emergence of red deposit is a proof of the presence of sugars. To confirm this result was added 1 ml of plant extract to 5 ml of Benedict detector Where the appearance of brown color on the presence of sugars.

3. Detection of flavones: The first solution was to dissolve 1 g of plant sample in 5 ml of 95% ethyl alcohol, then the solution was filtered after 6 hours. The second solution was to add 10 ml of ethyl alcohol at 50% to 10 mL of 50% potassium hydroxide solution. Mix equal amounts of the above and yellow color, indicating the presence of flavones.

Laboratory Animals: In this study 16 mice from Swiss white mice were used, ranging from 25 to 28 g. Obtained from Pharmacology Department/General Pharmaceutical Company for General Industries.

Group Design: The animals were randomly divided into four groups in plastic cages. Each cage contained four mice, treated as follows:

The First Group: Control group: consists of 4 mice, normal saline solution, 0.1 mg/ml.

The second, third, and fourth groups were reintroduced at a concentration of (1), (1.5) and (2), respectively, for a period of one month on a daily basis. The dose was determined according to the weight/ml/kg ratio of body weight.

Preparation of tissue sections: After dissecting the animals and placing (heart and brain) in the Formalin 10% solution, the samples to be studied were converted to ethyl alcohol at 70% concentration. The following steps were taken:

- a- Dehydration, b- Clearing, c- Infiltration, d- Embedding, e- Sectioning, f- Staining, g- Mounting.

Preparation of the extract to study its effect on lymphocytes

Preparation of Concentrations: The amount of powdered extract was oleander 0.8 g (8% of the original weight).

The following concentrations were prepared immediately prior to the experiment. N. oleander concentrations were prepared by thawing 1 g powdered powder in 10 mL of serotonin medium and concentrations (150, 75, 37, 18, 9.35, 4.68, 2.34, 1.17) were prepared. These concentrations are prepared before use.

Lymph Node: Lymphocytes were obtained from the blood of people with liver cancer. The lymphocytes were examined for each of the different total white blood cells and the lymphocytes were separated by Neutral Red.

The effect of cellular toxicity of the purified N. oleander extract extracted from the N. oleander on cell line was assessed by assessing its effect on the HEPG2 cell line (lane 18) at the time of exposure for 48 hours at different concentrations of N. oleander extract (150.0, 75.0, 37.5) 18.75, 9.37, 4.68, 2.34, and 1.17 μg/ml) using the neutral red test. The optical density measured in transmission wavelength is 450nm and 492 nm.

The neutral red assay is a cell survival test/viability based on the ability of viable cells to integrate and bind a neutral red dye. The neutral red absorption test provides one of the most commonly used cytology tests with many biomedical and environmental applications. Therefore, he was selected to determine cellular toxicity.

After exposure, cells are incubated in a neutral red dye. The dye easily penetrates cell membranes and accumulates intracellularly into the lysosomes. Neutral red is also a vital stain, and has been used to
color live cells. Cell changes resulting from the action of the purified *N. oleander* extract cause a reduction in the absorption of Red Neutral. After washing the cells with PBS and treating them with an alleged solution to release any increase in the dye taken, the cell damage was evaluated by measuring the visual density of the treated cell solution and comparing it with the untreated negative control samples. Microtiter panel reader equipped with 450 and 492 nm filter.

**Results and Discussion**

**Effect of the extract on the histological lines of the heart and brain**

**Heart:** The current study revealed acute myocardial infarction from the beginning of the treatment of the follicle and may indicate these plants to toxic effects on the heart muscle. Which lead to disturbance in the cellular ions pump associated with an increase in intracellular fluid accumulation. may lead to fibrillation and death. These were consistent with (10) who showed that these plants contain cardiac glycosides, which can cause direct poisoning of the sodium and potassium pump in the myocardium and the occurrence of vagotonia associated with heart failure. Changes in the current study of the myocardium that appeared in the post-dose phase. These observations were consistent with (11) who showed that these plants occur changes in the heart and digestive system after four hours of plant oleander.

These results may indicate that the toxic effects of these plants have been progressive over time due to the accumulation of large quantities Heart glycoside (12). The occurrence of myocardial infarction with the inflammatory cell sequence may be that these instruments were consistent with (13). While the road (10) that this plant carries very toxic substances to animals because of their heart-hearted content. The observed infiltration of neutrophils and necrosis of the myocardial fibers may indicate that these extracts cause toxic stress, which is associated with the production of pro-inflammatory cytokines such as TNF alpha that attract neutrophils to the site of tissue damage. This guide was agreed with note (13) that the release of free radicals plays an important role in degenerative and necrotic changes. Also, (14) proved that the toxic effects of extracting leaves of the plant can be activated by the production of free radicals that cause tissue damage,
The Brain: After a month of the dosage, focal necrosis was observed and in other samples of the brain samples were seen infiltration For the inflammatory cells of the nuclei and lymphocytes around volatile regions.

If these changes continue for a long period, causing necrosis or death of the neuronal cell, the cause may be attributed to it, as well as lack of food and oxygen resulting from irritation in the vessels. The necrosis of the brain cells and tissues may be due to the presence of proteins in the blood cells of the egg, especially the neutrophils, which are more likely to leak in response to inflammatory reactions in the tissue. Some immune reactions may also cause necrosis and death of nearby cells. Reaction by the cytokines separated by macrophages and Monocytes nucleus.

As for the deposition of hemoglobin in the brain tissue, as seen in the present study, which is attributed to the increase in red blood cell decomposition and its local presence, the tissue has suffered from local hemorrhage as the macrophages at hemorrhage sites ingest the red blood cells (15).

Results of the effect of the extract on extracellular lymphocytes: On the other hand, results indicated in table (3) showed that cell survivals (%) of human lymphocyte measured at 450 nm after 48 hour of treatments with N. oleander extract reaches the maximum reduction (72.0%) after treatment with N. oleander extract at a concentration of 4.68 µg/ml, while the remaining activity of tumor cells was 71.6% at concentration 37.5 µg/ml. Activity of N. oleander extract was determined in cell suspension of human lymphocyte after the treatment with N. oleander extract at concentration 75 µg/ml for 48 hours of incubation. According to these results, the concentration 75 mg/ml of N. oleander extract was selected due to its highly inhibitory effect on human lymphocyte (39%).

</table>

The immune system is affected by the immunological parameters of stress in humans and animals, such as white blood cell toxicity, natural killer cell activity, leukocyte distribution, cytokine production, pharyngeal maturation, yeast activity and lymphopenia. The aim of this study was to investigate N. oleander for acute cytotoxicity in the laboratory on lymphocytes of human peripheral blood. As the approach to reducing the number of lymphocytes leads to the opening of a place to treat many deadly diseases such as leukemia and other diseases associated with blood. On the other hand, when normal lymphocytes attack by any active compound can lead to apoptosis, excess lymphocytes can increase from Bcl-2 known as antiapoptotic protein, Also, lymphocytes when exposed to an active compound (the internal toxin model) can prevent apoptosis by activation (16).

Conclusion

The extract of the leaves has a toxic effect on the heart muscle. After a month of the dosage, focal necrosis was observed and in other samples of the brain samples were seen infiltration For the inflammatory cells of the nuclei and lymphocytes around volatile regions. 2- the second axis to know the effect of the extract on lymphocytes by studying extracellular (in vitro), The results of the N. oleander highly inhibitory effect on human lymphocyte mentioned.

The Impact of the Learning Strategy by Means of Aids to Develop the Spike Performance from Rear Area for Students

Zaid Abbas Hassan¹, Hayder Mahmood Abdullah¹, Nagham Saleh¹

¹The College of Physical Education and Sports Sciences, University of Babylon, Iraq

ABSTRACT

The learning strategy is learning, for understanding or meaning-based learning, by linking the learner’s past experiences with his or her subsequent experiences, the formation of links and relationships between them, and learning through generational processes used to modify alternative perceptions and concepts in the light of the correct scientific knowledge. As well as to recognize the impact of the learning strategy of birth by helping to develop and perform spikes from the rear area for students.

The researcher followed the experimental approach by designing the two parallel groups with the pre and posttests, and on the main research sample of (28) students of the third stage in the Faculty of Physical Education and Sports Sciences- Babylon University for the academic year (2017-2018). The sample was divided into two groups, (14) students per group. The experimental group followed the work of the obstetric learning strategy by means of assistance, while the control group followed the curriculum of the teacher of the material.

Keywords: learning strategy, aids and rear area.

Introduction

The learning strategy is one of modern learning strategies. It is both a learning and a learning method. Students engage in activities and exercises very effectively by linking the learner’s past experiences with his or her subsequent experiences, and learning through generating processes is used to modify alternative perceptions and concepts In the light of proper scientific knowledge. It also helps to remember and speed learning or training and install it, and works to take into account individual differences between learners.

Through the follow-up of the researcher and his observations of most of the educational units for students of this stage, noted a lack of clear in the performance of basic skills, especially the skill of spike overwhelming and the adoption of its performance in a simplified form without taking multiple forms that may be exposed to the learner during the game play, we find weak in dealing with these forms of skill spike overwhelming Especially the spikes of the rear area. In light of this, the researcher suggested introducing the obstetric learning strategy by means of assisting in the development of the spike of the from rear area for students.

The game of volleyball is based on basic skills as an important base for upgrading skill level. The learning of basic skills is the most difficult but necessary stage to achieve optimum performance. The importance of research is the importance of the aspect that addresses its study. Contribute to the development of the spike of the volleyball rear area, as well as to help the existing educational process in the faculties and departments of physical education and sports science in the transfer of various tasks or educational tasks and delivery to the learner to develop the skill of spike Overwhelming area of the rear and mastery, which may help him interact positively with the learning environment.

Research Aim: Identify the impact of the learning strategy by means of aids in performing spike from rear area for students.

Research Hypothesis: Strategy generative learning means helping a positive influence in the development of spike from the rear area volleyball for students.

Research methodology and field procedures

Research Methodology: The researcher followed the experimental method of designing the two groups with pre-pre and post-test to suit the nature of the research
Research Community: The research community determines the students of the third stage in the Faculty of Physical Education and Sports Sciences at the University of Babylon for the academic year (2017-2018) of (154) students.

Sample design tests the accuracy of some of the overwhelming batches: The sample consisted of (30) students. They were randomly selected from the homogeneous research community who did not participate in the main research sample, and constituted a percentage of (19.48%).

Main research sample: The main sample of the sample (28) was randomly selected by the lottery method. The experimental group consisted of 14 students. The experimental group is considering the learning strategy and the control group is studying the teacher’s approach. Thus, the main research sample represented 18.18% of the research community, which is a good percentage of the representation of the society in real and real representation.

Sampling homogeneity: The researchers conducted homogeneity of the research sample in the variables of total length, age and mass, as shown in table (1).

Research Method

The researcher used the following research tools:
- References and Arab and foreign sources.
- Observation.
- The resolution.
- Interviews.
- Tests.

Used tools and devices: The researchers used the following tools and devices:
- A legal volleyball court with its accessories.
- Aircraft balls legal number (15).

Field Research Procedures:

Determination of the rear spike test in the volleyball: To select the technical performance tests for some form of volleyball, the researchers relied on the virtual construction of these skill forms (the preparatory section, the main section, the closing section), and a special questionnaire was prepared containing a set of divisions concerning technical performance evaluation. The plane was presented to a group of experts and specialists to choose the appropriate division to evaluate the technical performance. After collecting the questionnaires, the results were based on the percentages of the agreement of the experts and specialists who were presented with the questionnaire.

To calculate the discriminative ability of the tests, the researcher applied these tests to a sample of the research community (the design sample) of (30) students.

Characterization of tests:

Test the spike of the back line:

Test Name: Test the technical performance of the spike of the back line of the students.

Objective of the test: Measuring the technical performance of the crushing blow of the back line.

Tools used: Legal volleyball court, legal airplane balls (3), a camera with drugs, pre-prepared evaluation form.

Performance specifications: The student in the lab (6) and the spike of the crushing from the back line, the student is given laboratory (3) consecutive attempts.

Total score of the test: (10) degrees. - Test the accuracy of the crushing performance of the back line:

Test Name: The accuracy of the crushing spike performance of the back line of center (6).

Purpose of the test: Measure the accuracy of the crushing performance of the back line.

Tools used: Legal volleyball court, legal plane balls (5), pre-prepared assessment form.

(3) prepares the next ball to the student in the center (6), which blows the crushing of the back line and the performance of crushing blows towards the three areas (C, B), (A) and painted in the middle of the defensive zone rear dimensions of each area (1 m × 2 m).

Total score of the test: (18) degrees.

Main experience:

Pretests: Pretests of the technical performance were conducted by the spike of the volleyball rear of the members of the research sample (the control and experimental groups) on 6/11/2018 at 10:00 am at the outdoor volleyball court at the Faculty of Physical Education and Sports Sciences - Babylon University.

Experimental group (experimental and control groups) were conducted on 7/11/2018 at 10:00 am at the outdoor volleyball court at the Faculty of Physical Education and Sports Sciences - Babylon University.

Implement the vocabulary of the learning strategy by means of aids: After reading the many references and sources, the researcher prepared the vocabulary of the learning strategy by means of assistance, and after consultation with the supervisors to choose the most methods, methods and methods affect the variables of the target in the main experiment, and the implementation of the vocabulary as follows:

1. The implementation of the vocabulary of the learning strategy by means of aids on 12/11/2018 during the educational units, and in part of the main section only, on Monday and Wednesday of each week, at the outdoor volleyball court in the Faculty of Physical Education and Sports Sciences - University of Babylon.

2. The duration of the total implementation (6) weeks. The number of units per week (2) units. And the total number of training units (12) units. The training module (90) minutes.

3. Assistive measures have been developed that have developed the spike of the volleyball rear.

4. Follow the students of the control group in the development of the perception of the spike of the volleyball rear area, the educational method followed by the teacher of the article same, and the number of educational units themselves and the time of the unit as well.

Posttests: Pretests for the technical performance were carried out by the spike of the volleyball rear of the members of the research sample (the control and experimental groups) on 24/12/2018 at 10:00 am at the outdoor volleyball court at the Faculty of Physical Education and Sports Sciences - Babylon University. Pretests of the spike accuracy of the volleyball team were conducted on 25/12/2018 at 10:00 am at the outdoor volleyball court at the Faculty of Physical Education and Sports Sciences, Babel University.

All calculated values (t) were greater than their tabular value of (2.06) below the level of significance (0.05) and at the degree of freedom (26), indicating significant differences in the post tests between the control and experimental groups.
Discussions

The researchers point out that the results of differences in post-tests and the superiority of the experimental group in all variables to the strategy of learning by means of aids contributed to increase the ability of students to generate ideas and this was evident in the development of mental perception by linking the relations between concepts and what they have reached. This is what has been achieved in the main section of the educational unit, especially in the educational part. The group adopted a number of aids: data sheets, illustrations and educational booklet, which helped them to create the correct images of skill performance, this helped to give students the opportunity to modify their previous concepts and acquire new concepts.

These methods were designed and selected on scientific bases that suit the students’ abilities, tendencies and desires, as well as attracting their attention and linking their previous information with the new information. The result of the interaction between what he learns and his current ideas, and this is what is indicated in the students that “students come to the classroom and possess some of the prior knowledge and misconceptions and the most influential and most important factor is what students already know within the learning strategy Molding.

The follow-up of the experimental group members and the use of a range of auxiliary means for use in the course of the exercise of the skills, “There are several ways to motivate the learner towards the effectiveness of the game to learn and practice her skills. These methods are to facilitate the learning opportunities of the motor and the clarity of the appropriate goal to learn and develop the skill, as well as balance to satisfy the needs of the learner, because motivation is a necessary condition for learning, as the learner’s motivation is stronger as he approaches the good performance that does not require much effort and time, which is confirmed in the “The number of attempts with the use of tools, which increased the enthusiasm and motivation of the students, which reflected on the development of the performance of spike from the rear area Volleyball and various places of the stadium, supported by continuous encouragement of the teacher of the material and this is consistent with what was mentioned in the “commitment and encouragement and diversification in performance helps to learn or acquire skills.

Conclusions

The technical design has been designed to test the accuracy and spike of the volleyball rear area of the students. For the learning strategy of birth by means of helping a large role in the development of the spike performance of the area of the rear volleyball students.

The Effect of Relative Muscle Speed Exercises and Absolute Improvement of Some Receipt Parameters, Delivery and Achievement 4 × 100 Meters Relay for Youth

Sadeq Abdul Ridha Atiayah¹, Hussein Mardan Omer¹

¹The College of Physical Education and Sport Sciences, University of Al-Qadisiyah, Iraq

ABSTRACT

That the real race (4 ×100) meter is to cut the distance in the minimum possible time for a team of four runners, which requires, Players Selection on according to the converging times that the tests indicate Private run linked to the relative speed of the Players and the extent of their convergence and this is one of the most important problems that has not been studied previously, applied to a sample of the players of the Olympic champion project in Alnajaf-Al Shraf And with the number of (8) contestants, the researchers conducted the relative velocity tests and specified the time tests of the switch area kidney and speed of the Muslim player and the recipient and the place of switching as dependent variables is affected by The quality of the proposed exercises, and they found that this exercises based on relative speed has achieved the aim of developing variables for the switching area.

Keywords: Drills, Parameters delivered and achievement.

Introduction

Many mechanical laws have entered into field applications for sports training, which require the conduct of field experiments in accordance with the correct scientific basis in order to be successful choice of the type of the appropriate player in the specific competition, especially in the race for individual games and from them Ran (4 × 100 m) relay as it is known that there is a discrepancy in the time of the distances for each player during the total distance of the race and that the time of cutting these distances depends on the ability of the player to accelerate high speed and maintain the maximum velocity (regular speed) and the amount of speed tolerance in the last meters in each Distance. This means that the player must be efficient according to the abilities of the recipient so that the process of receipt and delivery on high accuracy and one speed between both players with the minimum time possible during the switching area, and at high accuracy, so the knowledge of each player’s level and the abilities of a positive acceleration and regular acceleration and The relative speed between both the contestants has become a necessity for the matching players to be identified with capabilities to ensure that the temporal and spatial field is matched at the moment of receipt and delivery and to achieve the minimum time possible and thus achieve high achievement.

The relative velocity is one of the types that the players should be distinguished from and this type of velocity has to do with the velocity of an object relative to another body that has changed motion taking into consideration the direction of each body’s velocity, and the Law (First body speed - Second body speed).

Therefore, the importance of this research is to demonstrate the importance of relying on the relative velocity index in determining the sequence of the contestants and conducting the tests and their measurements and their impact in reducing the instantaneous times when delivering and receiving, and controlling the appropriate distance in which delivery is made and delivered in order to achieve the achievement that The real goal of this contest is.

In addition, this effectiveness is and up to 110 m hurdles) in order to form a team (4 × 100)meter relay and define the period pre-competitions for the purpose of training on receipt and delivery without considering
the relative speed between the contestants which is the real standard to suit the speed. The recipient player with the speed of the Muslim player and the possibility of discovering the value of this relative speed through special tests to determine the right player in his abilities which delivers the stick with the abilities of the player who receives the stick and this is one of the scientific problems that were not studied previously for this contest as the researchers wanted to go into To develop scientific solutions and to improve the level of achievement (4 × 100) meter. Continue to note that the level of Iraq in this competition still requires many studies that contribute to the development of this competition. Therefore, the aim of the research is to recognize the time (30 m) of the delivery distance and the handover of stability and movement. To recognize the total time of the delivery and receiving area, and learn about the impact of the exercises in the development of the spatial and temporal areas of delivery, handover, completion and determination of the sequence of contestants and speed Relative.

The table shows us the sequence of runners (racers) through the speed of the first and the last 30 meters within the races distances, showing that the sequence (6) possesses the best speed when starting from stability as well as the best speed when starting from movement, which means that it is appropriate to be the first runner that starts the race. Also followed by the first sequence with the same specifications, and so the players were put serialized correct according to the speed indicator they cut 30 meters The first and last. The results have indicated that every player has the possibility of cutting all the distance within the three test distances in order to harmonize the speed at which the Muslim runner arrives with the speed at which the recipient runner starts, and so that there is no delay or no downtime at the time of switching, the researcher used the relative speed indicator to determine this sequence scientifically as shown in the following table (4).

Shows that there is a decrease in the relative velocity between the sequence (6) of the sample of the search and sequence (4) of the same sample, In the dimensional test, this means that there is compatibility synchronization of the arrival of the recipient runner to the maximum speed with the speed at which the Muslim runner reaches the delivery point, and this has to do with the good distance of the delivery area and as What said no In the previous discourse with regard to the spatial and temporal areas that evolve In the Telexed, its development was consistent with the evolution of relative velocity. As velocity of the fourth sequence with the velocity of the second sequence of search sample members according to their relative velocity index, while the velocity of the second sequence was consistent with the velocity of the first sequence of the search sample by the relative velocity index also between them. Table (6) also shows the sequence between the velocities of the remainder of the sample, as the compatibility appeared according to the relative velocity index between sequence 3 and 5, sequence 5 and 7, and sequence 7 and 8.

Thus, the researchers conclude that the adoption of the RSI between the speed of the players is a scientific indicator that gives high precision in the selection of players according to their speed, both when the Muslim player arrives and has a certain velocity expressed by the tests of the last run time 30 meters within the distances of the tests adopted by Researchers N, at the start of the runner received from fortitude and expressed by the tests of the first run time 30 meters. This indicates the effectiveness of the exercises of speed and relative speed based on the scientific basis in the development of relative velocity and its adoption in determining the sequence and capabilities of the relay runners, Training must be (using the lowest speed of the maximum speed, taking into account that it does not lead to muscular contraction, and that kinetic performance is timely, streamlined and relaxed).

**Conclusions**

Acceleration may evolve as a result of the training applied by the sample (the first 30-meters time See). The speed of the research sample has evolved as a result of applying special exercises on them (the last 30-meters time), speed tolerance for distance of race distances has been improved. The harmony between the spatial and temporal sphere was demonstrated by the tests applied Speed integration between the Muslim player and the receiving player. I said differences in the relative velocity between the members of the search sample. There is a convergence in the relative speed values of the players in the delivery and receiving areas due to the exercises applied. The relative velocity index helped to determine the sequence of players and their standing in the switching areas and in accordance with the best receipt and delivery process and without Decreased Of the total time of the competition.

ABSTRACT

Background: Nanotechnology is a discipline that manages, constructs, analyzes and deals with application of materials that have diameter from 1 to 100 nanometers. Gold nanoparticles are defined as stable colloid solutions of clusters of gold atoms with sizes at this minuscule.

Objective: The objective of current study was to treat breast cancer using gold nanoparticles capped with drug molecules in specific quantities to reduce the harmful side effects.

Method: The gold nanoparticles were prepared by method of Brust-Schiffrin. These nanoparticles were capped with type of drug (Glutathione) used to treat cancerous tumors. These gold nanoparticles were uncapped with drugs at (526nm) when capped with the glutathione drug at (589nm).

Results: The resulting evidence suggested that Glutathione-capped Gold nanoparticles were non-toxic up to the maximum recommended dosage. Therefore, the demonstrated biocompatibility offers the potentials of Glutathione-capped with Gold nanoparticles. The candidate is considered as a medicine for cancer therapy.

Keywords: Gold nanoparticles, PDT, MCF-7 cell, glutathione, breast cancer.

Introduction

Nanotechnology is a discipline that manages, constructs, analyzes and deals with application of materials that have diameter from 1 to 100 nanometers. Gold nanoparticles (AuNps) are defined as stable colloid solutions of clusters of gold atoms with sizes at this minuscule. They possess different physicochemical characteristics when compared to the bulk gold, the most obvious example being the color change from yellow to ruby red when bulk gold is converted into nanoparticulate gold. The surface plasmon resonance (SPR) peak is positioned at 520nm and this peak is responsible for the ruby red color displayed by conventional gold colloids. This ruby red color of AuNps is explained by a theory called “surface plasmonics”. According to this theory, when the clusters of gold particles are hit by the electromagnetic field of the incoming light, the surface free electrons (6 electrons in case of AuNps) present in the conduction band of AuNps oscillate back and forth, thus, creating a plasma band which has an absorption peak in the visible region at 530-540nm. The surface plasmon band (SPB) of AuNps is used as an indicator for formation during the synthesis of AuNps from their precursor salts. Physical properties of AuNps in turn depend on the size, shape, particle-particle distance and the nature of the stabilizer used to prevent the agglomeration of nanoparticles. According to Mie theory, Surface Plasmon Band (SPB) is absent for AuNps less than 2nm and greater than 500nm. Gold nanorods have two SPB’s, one longitudinal wavelength band at 550-600nm and one transverse wavelength band at 520nm. The longitudinal wavelength band is very sensitive and changing the aspect ratio of Gold nanorods

DOI Number: 10.5958/0976-5506.2019.02220.4
changes the absorption region from visible to near infra-red (NIR). This unique optical property of Gold nanorods is used in near infra-red ray therapy [26] and can be used as a therapeutic means to eradicate diseased cells which forms the basis for cancer treatment using Photodynamic therapy (PDT). It is a minimally invasive technique for cancer therapy.

The use of laser in medical applications has grown enormously from the time of its invention in 1960 to present days [15,16]. In this regard, the use of laser in photodynamic therapy (PDT) has gained increasing interest in medicine representing an experimental tool for the detection and treatment of tumors located in the lung, esophagus, colon, peritoneum, pleura, genitourinary tract, brain, eye and skin [17].

Current study was aimed to treat breast cancer using gold nanoparticles capped with drug molecules in specific quantities to reduce the harmful side effects and the use of lasers as an additional means to kill cancer cells through what is known as the Photodynamic therapy (PDT).

Materials and Method

Glutathione-capped gold nanoparticles (GSH-AuNPs) synthesis: The gold nanoparticleas (AuNps) were prepared by method of Brust-Schiffrin [19]. A volume of 1ml of 0.1M HAuCl₄ was added in 500ml deionized water by a stirring device. Then, 0.06g NaBH₄ placed in 10ml deionized water. Prepared 10ml of NaBH₄ solution. The solution changes from yellow to dark red. The dark red disappears by stirring for 1.5h. Then, adding 0.1g of glutathione to AuNps solution with continuous stir for 2h to obtain AuNps solution to larger size of particles due to glutathione capped. The obtained nanoparticles were subjected to centrifugation at 13000rpm for 15min.

Lasers for heating Gold nanoparticles: The lasers used as a source of heating for AuNps with Glutathione and AuNps with cisplatin in the cell lines, were two continuous lasers; model MGL-III-532-110mW (532nm), and MRL-III-650 and 41mW output power.

Methyl Thiazolyl Tetrazolium (MTT) solution: MTT is a yellow-colored water soluble tetrazolium dye. Mitochondrial lactate dehydrogenase, produced by metabolically active cells, reduces MTT to water-insoluble Formosan crystals. When dissolved in appropriate solvent, these Formosan crystals exhibit purple color. The intensity of the purple color is directly proportional to the number of viable cells and can be measured spectrophotometrically at 570nm. In order to prepare a 5mg/ml concentration of the dye according to [24], 0.5g of MTT was dissolved in 100mL of PBS. The solution was filtered through 0.2µm syringe filter to remove any blue Formosan product and then stored in sterile, dark, screw-capped bottles at 4°C. The solution was used within no longer than 2 weeks of preparation.

Characterized gold nanoparticles: The particle size and zeta potential of AuNps were measured using transmission electron microscope (TEM) before being capped with glutathione by transmission electron microscopy (TEM). Light absorption measured by UV spectrophotometer at wavelength 400-800nm before and after glutathione capped.

Cells viability assay

MCF-7Cells:

Organism: Homo sapiens, human Tissue of mammary gland, breast; derived from metastatic site: pleural effusion, Cell Type of epithelial, Product Format of frozen, Morphology: epithelial, Cultural Properties: adherent, Disease: adenocarcinoma, Age: 69 years adult, Gender: female, Ethnicity of Caucasian, Complete Growth Medium: The base medium for this cell line is ATCC-formulated Eagle’s Minimum Essential Medium, Catalog No. 30-003. To make the complete growth medium, add the following components to the base medium: 0.01mg/ml human recombinant insulin; fetal bovine serum to a final concentration of 10%. Culture conditions: Atmosphere: 95% air, 5% carbon dioxide and 37°C temperature.

The viability of melanoma cells treated with chemical agents was determined via the MTT assay. The cell viability was determined before assessing the cytotoxic effect of AuNps, AuNps+GHS, GHS, and Laser green time on cell lines. Seeding of trypsinized and suspended cells for any cell line in a microtiter plate should be in the range of 21–22 cell/well for the cytotoxicity assay as mentioned by [23]. Viable cell counting was accomplished by using trypan-blue exclusion. Dead cells take up the dye within a second making them easily distinguishable under the microscope from viable cells which remain unstained. The following protocol was conducted:

Cell suspension was prepared MCF-7 cancer cell. The hemocytometer with its cover slip fixed on its place was prepared (for counting soon). Adding 0.2ml of cell suspension to 0.2ml trypan-blue and 1.6ml PBS. Then, adding 20µl from the mixture to the edge of the cover
slip, allowed to run into the counting chamber. After 1-2 minutes viable and dead cells counting started with light microscope at 40X magnification. Cells concentration (cell/ml), total cell count and cell viability (%) were calculated as in the following equations:

\[ C = n \times d \times 10000 \]  
\[ \text{Where } C= \text{Cell concentration (cell/ml), } n= \text{number of counted cells and } d= \text{dilution factor= 10.} \]

Total cell count= \( C \) (cell/ml) \( \times \) the original volume of fluid from which the cell sample was taken.

Cell viability (%) = 
\[ \frac{\text{Total viable cells (unstained)}}{\text{Total cells counted (stained & unstained)}} \times 100 \]  
\[ \text{...}(2) \]

**Treatment conditions and experimental groups:** To investigate the potential effect of hyperthermia on cell growth and survival, cell viability was assessed by the MTT assay. In brief, the cells were seeded into 6-well plates at a density of 5-105 cells/well and were exposed to MW exposure for 24h. Then they were allowed.

For each exposure time (5, 10 and 15 minutes) the irradiation experiments (6 replicate wells for each group) were done in dark room including the:

**Experimental groups for in vitro study** including the following groups:

Group (A): this group was considered as control group.
Group (A1):This group was treated with AuNps.
Group (A2): PDT group was treated with AuNps.
Group (A3): this group was treated with AuNpsGHS.
Group (A4): this group was treated with AuNpsGHS + Laser Green.

After the irradiation, the plates were sealed with self-adhesive transparent film then incubated at 37°C.

**Results and Discussion**

**Characterization of Gold Nanoparticles (AuNps):**

The volume drawn from AuNps stock solution was 125µl. From the curves in Figure (1) when the volume ratio is increased, the surface Plasmon resonance shifts to the right or red shift and increased intensity occurred. These results agree with [63] and become more broadening which indicate a different size or the size of AuNps increased, while the size of AuNps become monodisperse when the volume ratio decreased. This was in agreement with [43, 47].

Table (1) showed the value of the wavelength where the peak of the observance of surface plasmon resonance of gold nanoparticles for different volumes of HAucI4 solution, represents SPRs of Glutathione capped-gold nanoparticles (GSH-AuNPs). From the UV–visible spectra of both AuNPs and nanoglutathione drug capped the gold nanoparticles made the wavelength peak of surface Plasmon resonance slight shift to higher wavelength (red shift). These results are in agreement with [63] and indicated that the size of the gold nanoparticles is increased [37].

Figure 1: Effect of Glutathione-capped gold nanoparticles (GSH-AuNPs) on Surface Plasmon Resonance results revealed the shift of maximal absorption peak to 589 nm after surrounding gold nanoparticle surface with glutathione.
Shape and size of Gold nanoparticles (TEM and SEM): Figure (2) showed a transmission electron microscopy (TEM) which was used to take an image to the gold nanoparticles, with or without coating by nano and GHS, used for measuring the size of gold nanoparticles. The 0.333μM of Chloroauric acid solutions were used to synthesized the gold nanoparticles with or without coating by nanoparticles. The TEM device showed a monodisperse and spherical shape. These results were in agreement with those reported by [20] for the solutions of 0.333μM of AuNps prepared by Brust-Schiffrin.

Figure 2: a: TEM image with X92000 magnification power and b: the granulate accumulation distribution chart for AuNps

Figure 3 showed gold nanoparticles Glutathione-capped (AuNps-GSH) prepared by Brust-Schiffrin. It can be noticed the increase in the size of nanoparticles from 5nm to 15nm.

Figure 3: a: Represents Glutathione-capped gold nanoparticles TEM image with ×250000 magnification power and b: The granulate accumulation distribution chart for AuNps and capped glutathione (GHS).

The Effect of Gold Nanoparticles concentration on cancer cells (MCF-7): Different concentrations of uncoated gold nanoparticles of sizes 5nm and 15nm were used to determine the lethal or cytotoxic concentration.

Effects of AuNps cytotoxicity on MCF-7 cell line (MTT assay): Figure 4 showed that the viability percentages
of MCF-7 cell line in the presence of different concentrations of AuNps (1, 0.5, 0.25, 0.125, 0.0625 and 0.03125mg/ml) after 24h incubation, ranged from 58.9% to 92.5%. It can be seen that a significant decrease in cell viability was observed when cells were incubated with 0.03125mg/ml GNPs (survival rate = 92.5%). This effect increases as GNPs concentration increased to 1mg/ml (survival rate = 58.9%). In Figure (4), GNPs with consecrations (1, 0.5, 0.25, 0.125, 0.0625 and 0.03125µ/ml) did not show any significant difference compared to GNPs with consecrations (1, 0.5, 0.25, 0.125, 0.0625 and 0.03125µ/ml) (P = 0.0527). We can calculate the IC50 (the concentration that induced 50% viability) of AuNps for 24h to be 0.253µg/ml. Data revealed that the viability percentage of MCF-7 cell line in the presence of different concentrations of GHS (Glutathione) (1, 0.5, 0.25, 0.125, 0.0625 and 0.03125mg/ml) ranged from 95.95% to 102.6% after 24h incubation. We can calculate the IC50 to be 0.664µg/ml. Cells viability after treatment with Glu-AuNPs (1µg/ml) was reduced to 38.7% after 24h incubation. We can calculate the IC50 to be 0.174µg/ml.

**Figure 4: Effect of different concentrations on GHS-AuNps and capped AuNps and GHS on cancer cells**

**Effect of laser Exposure time on cancer cells:** Using green laser of the wavelengths 532nm and output power of 110mw, but the laser exposure times were used in minutes (5, 10 and 15). Plano Convex lens at focal length 3cm at distance 17.5cm from laser aperture has been used as a beam expander to produce a beam diameter of 15mm to cover the area for each well (24 wells). Plates were seeded with MCF-7 cell line. The results showed that the viability percentage of MCF-7 cell line in the presence of different concentrations of AuNps and Glutathione (1, 0.5, 0.25, 0.125, 0.0625 and 0.03125mg/ml) was ranged from 23.06% to 56.3% at 15-minute time, while at 10- and 5-minute times, it ranged from 16.83% to 65.6% and from 26.2% to 85.8%, respectively (Figure 5).

**Figure 5: Effects of different concentrations and Laser green and AuNps on cancer cells**
Moreover, Figure (6) showed that the viability percentage of MCF-7 cell line in the presence of different concentrations of AuNps and Glutathione (1, 0.5, 0.25, 0.125, 0.0625 and 0.03125mg/ml) ranged from 18.51% to 40.4% at 15-minute time, while at 10- and 5-minute times, it ranged from 23.5% to 82.6% and 45.4% to 83.8%, respectively.

![Graph showing effects of different concentrations and Laser green-capped AuNpsGHS on cancer cells](image)

**Figure 6: Effects of different concentrations and Laser green-capped AuNpsGHS on cancer cells**

**Conclusions**

The resulting evidence suggested that Glutathione-capped AuNps were non-toxic up to the maximum recommended dosage. Therefore, the demonstrated biocompatibility offers the potentials of Glutathione-capped AuNps as a medicine for cancer therapy.

Study of Immunological Parameters and Epidemiology Features to Rheumatoid Arthritis Frequency in Kerbala City, Iraq

Alyaa Aziz Gubiar Al-Nasrallah
Ibn Hayyan College University, Kerbala, Iraq

ABSTRACT

Rheumatoid arthritis (RA) is one common currently disease within the world. The study exhibited relation between the elevated levels of Anti-CCP which has more specify and RF with RA disease activity.

Anti-Cyclic Citrullinated Peptide (Anti-CCP) and Rheumatoid Factor (RF) analysis are the best and crucial parameters for diagnosis rheumatoid arthritis because their different levels in circulated system in patients with rheumatoid arthritis about controls give important indicators for diagnosis this disease together with the symptoms.

Immunologic and demographic study including (100) samples classification in (50) patients with rheumatoid arthritis in the aging groups ranging from (>30 - <50 yr.), (18) male and (32) female compare with (50) controls samples and measured levels of Anti-CCP by (CHORUS-Anti-CCP kit) based on the ELISA principle in addition to measuring RF levels by (Nephelometry kit) in the serum.

Age and gender represent risk factors, increase development of (RA) disease with aging, increase appear (RA) in female than male. Elevated Anti-CCP and RF antibodies in the serum of (RA) patients compare with healthy in Karbala city. The concentration of Anti-CCP and RF are elevated with aging, and in female more than male.

Keywords: Anti-Cyclic Citrullinated Peptide, Rheumatoid Factor.

Introduction

Rheumatoid arthritis (RA) is referred as an inflammatory condition in the joints unknown etiology (1), characterized with most symptoms including pain, redness, swelling, with Moderate rise in temperature in the area swollen joints (2). Rheumatoid arthritis is autoimmune disease with progression inflammatory happen as a hyper response of the immune system in the body to some diseases such as some inflammatory (3). (RA) do not infected joints only it can be evaluation progressing effects on other organs such as the heart, kidneys, eyes and nerves (4). RA causes to inflammation of articular membrane of the joints and then being the joints erosion and lose its functions (5). (RA) is a common disease in the world, Average of infected with (RA) arranged between 0.5% for 1% (6). (RA) often appear on the people aged between (20-50) years old (7). The incidence of the disease is twice as high in woman than men (8). The appearance of symptoms varies and depending on the effect of the disease it may appear slow and be progressive with age limitation and some appear to be fast (9). Based on the apparent clinical symptoms, RA is diagnosed in different ways. X-rays are usually performed on the hands and feet, MRI, ultrasound, immune tests in laboratory (10). There are different types of antibodies in sera patients with (RA) (11). The process of rheumatoid examination includes (RF) analysis should be initiated when rheumatoid is involved during the clinical examination which depending on agglutination reaction. Anti-CCP analysis developed for the diagnosis of (RA) because the analysis of (RF) is not a qualitative or specific analysis of the disease. Anti-CCP analysis is often positive in 70% of rheumatoid patients (12). First discovery of Anti-CCP antibodies in (RA) sera patients by Nienhuis et al in 1964 (13-15). Rheumatoid Factor (RF) isotype have different affinity. RF antibodies represent one class of immunoglobulins (16). First described by Rose 1948 in patients with RA (17). Although they first

DOI Number: 10.5958/0976-5506.2019.02221.6
described in RA but it can be found in another patient’s sera such as systematic lupus erythematosus (18). The elevated concentration RF in AR disease using in the diagnosis (19). Two types of medical treatments are recommended in the body, in patients with MS. Such as cortisone, can be used for a long time (20).

Materials and Method

Samples were collected (n=50) patients, of different age groups ranging from (>39 -<50 yr). The collection of samples occurs during the period from October 2018 to February 2019 from the joint and orthopedic consultation at Al Hussein Educational Hospital in Karbala city. According to the demographic data (Age, Sex): Patients classification in (n=18) males and (n=32) females compared to the apparently healthy control group, noting that they were free of any symptoms based on the clinical diagnosis by the physician and their healthy life history of (n=50). excluding the group of patients with hepatitis Interference between patients and the effect of this on study parameters as measured body levels. parameters have been determining were CHORUS-Anti-CCP in addition to measuring RF levels in the serum after the blood has been collected and centrifuged at 3000p for 15 min and stored at -80 °C until using. serum counted rheumatoid factor (were determine by Rheumatoid Factor Detection Kit (Nephelometry), Genrui-Biotech Inc China) according to the manufacture instruction positive result 0-201U/ml and determined anti- CCP (CHORUS ANTI-CCP, REF 86094- REF 86094/12, Disease Diagnosis Senese S.P.A Via delle Rose,10-53035 Monteriggioni (Siena) Italy) by using a disposable device on the chorus and chorus TRIO instruments the test based on the ELISA principle the result is positive when concentration in the sample is > 18 AU/ml.

Statically analysis by X² test, students’ independent T test, L.S.D test And p value (<0.05) and ANOVA appropriate.

Results and Discussion

Results of the current study on Rheumatoid Arthritis (RA), All patients underwent serological and radiological tests. The demographic distribution of research samples are (100 samples 50 patients:20 male, 30 female) and summarized in table (1) which divided the study samples into three age groups depending on age, the first category have more frequently was >39 years 28 (56.0%) compare to control at same category 32 (64.0%), followed by the category < 50 years 12 (24.0%) while the control 10 (20.0%), then the category 40-50 years 10 (20.0%) to control 8 (16.0%). The results show P. value 0.68. The results show (18 (47.4%, 32 (51.6%)) in male and female respectively compare to control (20 (52.6%), 30 (48.4%)). Many advance analysis was used to detect the important the dependent variables (Questionnaire data) and independent variables such as Age, Gender, Duration, Disease history and another patient data). The results refer the data (Age, Gender, Duration, Disease activity) more related to loss physical ability in the body, where disease activity have effects on physical body functions (21). The demographic data distribution show relationship between Rheumatoid and aging, During this study more categories that affected by Rheumatoid disease are >39 years, then <50 years. The frequency of disease is high in older patient. The pervious study demonstrated relation between (RA) and infected by another disease (22). (RA) is one of the inflammatory disease that distributing in older. Currently the pathogenicity of (RA) increase up to 85 years old. The percent of prevalence of (RA) in 60 years old and older reach to 2% (23). With refer to gender researches have been suggested that women with (RA) worse than male (24). The reasons are worse in female patients to the fact that the muscles mass and strength is greater in the male that allow them to prevent functional losses (25). many autoimmune disease affected on female more than male one of this disease AR where the sex ratio around 3:1 (26). The passive response in women relation to the genetic etiology (X-linked) factor, hormonal and immune response (27).

The results at this chart showed that the percentage of disease is clear in females compared to males. The percentage of disease in patients female have 32% compared to control female which have 30%. As regards to the male has different from the female, the percentage of patients from the male is less than control, they have 18%-20% respectively.

![Figure 1: The distribution of kidney failure patients according to Gender compare to control](image)

The Outcome in table (2) recorded differences in levels of Anti-CCP parameter in sera of (RA) patients (38.67 ± 10.65, 52.3 ± 2.21, 64.39 ± 3.27) (U/ml) respectively compare with control which have (4.84 ± 1.24, 7.15 ± 0.25, 8.04 ± 0.25) (U/ml) respectively according to age. The differences between the groups were examined below the level of significance (p<0.05) for all the criteria. The results show that the differences in biomarkers levels were statistically significant. The recorded results according to measuring RF factor are indicated to the means of RF factor in rheumatoid patients have different in statistically significant at (p≤0.05). The highest level of RF factor in <50 years (64.39 ± 3.27) (U/ml) compare with category of control 8.04 ± 0.25(AU/ml) and low level in > 39 years (38.67 ± 10.65) (U/ml) which have different from control 4.84 ± 1.24 (U/ml) significantly. The present study show after we analyzed the data that the value of biomarkers Anti-CC, RF factor are increased in the serum of Rheumatoid Arthritis patients in Karbala city in Iraq, This refer for correlation with Rheumatoid disease activity.

Researches refer Anti-CCP have higher positive value to Rheumatoid disease (28). Anti-CCP is a specific antibodies have height sensitivity in Rheumatoid disease (29), Anti-CCP antibodies induced by special enzymes that coded by (PADI) Type 4 genes, the research suggested Anti-CCP antibodies have inflammatory role Rheumatoid disease (30). One of the important criteria that affected on (RA) developments is age. Age is represent important risk factor lead to development many disease such as inflammatory immune disease, cancer diseases and Rheumatoid Arthritis. Aging can be caused damage to the DNA, different in body buffers and affected on many physiologic process in the bodies (31). Results refer that (RA) may developed in the young ages but can development with age increasing. RF factor play important role in RA diagnosis (32) so that RF testing have been used as one classification of criteria for RA diagnosis, there levels increase with aging (33). In addition to RF testing, Anti-CCP can be used for analysis (34). Anti-CCP more specify than RF factor (35).

The results shown in table (3) the effect of gender on the immunological parameters under study and their relationship with Rheumatoid disease. Here, the statistical analysis examined the study of male patients compared with male control group show that the average group of patients have different in the means between male and
female. In the same way there are different between patients and control. The different was significant at \((p\leq0.05)\). The levels of Anti – CCP Antibody increase significantly in the female \(50.89 \pm 13.66 (U/ml)\) about male \(41.67 \pm 11.62\), as well as there are significant different between the control \(6.18 \pm 1.99 (U/ml)\) in the female group. The study carried out a comparison between the female Rheumatoid patients and the female control group, the mean reached \(40.22 \pm 12.95(U/ml)\) in female patients about control \(7.31 \pm 1.35(U/ml)\) the different is statically significant between them. The results show the average of RF factor are increase in female patients \(40.22 \pm 12.95(U/ml)\) and decrease in male \(35.02 \pm 02(U/ml)\), reached in control \(6.62 \pm 0.73(U/ml)\) and \(7.31 \pm 1.35(U/ml)\) respectively at \((p\leq0.05)\). Through this study found relationship between Anti-CCP, RF and gender, the parameters are increase significantly in female compare with male. Gender represent another risk factor influences on the results of (RA) development \((36)\). (RA) in woman have higher and faster disease activity and progressive over time. some researchers suggested there are relation between gender and severity of pathogenicity \((37)\).

Bloodstream Bacterial Infections in Children Inpatients

Ruqayah Qubtan Taha¹, Omar Abdulkareem Ali¹

¹Department of Microbiology, College of Medicine, University of Anbar, Iraq

ABSTRACT

Bloodstream bacterial infections are one of the most common health-care associated issues, and its lead to a high mortality rates, detection of bloodstream infections in children and infants as soon as possible could prevent reaching of causative agents to other organs like kidneys, heart or brain. In spite of a significant and serious number of cases, there are few studies of bloodstream infections in pediatric patients, therefore, this study was undertaken to detect the bacteria causing bloodstream infections in pediatric inpatients and study their antibiotics susceptibility profile.

Total 380 blood specimens were collected from hospitalized children, 19.5% of them developed positive blood culture. Staphylococcus aureus caused 25.67% of total infections, followed by CoNS 22.97%, K. pneumoniae 18.90%, P. aeruginosa 16.25%, E. coli 12.16%, Acinetobacter sp. 2.70%, and Strep. pyogenes (1.35%), Whereas Ceftazidime, Amikacin, Ceftriaxone, and Vancomycin were most effective antibiotics, while maximum resistance was to Erythromycin, Penicillin G, and Cefotaxime. Regarding to the age groups and gender, 31 days – 12 months age group and male were more likely to suffering from bloodstream infections.

Keywords: Bloodstream infections; Blood culture; Antibiotics susceptibility; Pediatric.

Introduction

Bloodstream infections defined as invasion of microorganism into the bloodstream and occurs when viable microorganism enter the bloodstream either nosocomial or community-acquired. Some asymptomatic systemic fungal infections were reported that have important clinical concerns. Blood stream bacterial infections are one of the most common healthcare associated issues, and its lead to a high mortality rates (20% – 50%) 

Common bacterial causes of bloodstream infections include Staphylococcus aureus, Escherichia coli (E. coli), Coagulase Negative Staphylococci (CoNS), Enterococcus species, Pseudomonas aeruginosa, Klebsiella pneumoniae, Enterobacter cloacae, Proteus sp. and β-hemolytic streptococci. CoNS had been considered as nonpathogenic blood culture contaminant, but it had regard as a noticed cause of nosocomial blood stream infection as a result of increasing use of intravascular devices and an increase in number of hospitalized immune compromised patients.

The infections with multi antibiotics resistant bacteria are associated with nosocomial cases, almost in all cases, antibiotic treatment is started before the results of blood culture are available, thus, antibiotics susceptibility pattern of frequently isolated bacteria help the clinicians to use effective as well as empirical antibiotics. Most of studies related to bloodstream infections focus on the adult population, in spite of high levels of mortality regarded to bloodstream infections among hospitalized children and newborn especially in developing countries, in addition to immature immune system of neonate, there are many factors predisposing to neonatal bloodstream infections like maternal infections during pregnancy, delivery outside the hospital, material used in cutting and dressing the cord, prematurity, prolonged membranes ruptures, asphyxia, and length of period spent in hospital.

Because of all above, the purposes of this study were to detect the bacteria causing bloodstream infections in pediatric inpatients and study their antibiotics susceptibility profile.

Materials and Method

Three hundred and eighty blood specimens were collected from hospitalized children in Al-Ramadi teaching hospital of gynecology and pediatric since march/2017 to Feb./2019, 2-5 ml of specimens inoculated into blood culture bottle containing 45 ml of brain heart infusion broth, then incubated overnight at 37 Celsius. After 24 hour, a sub culture was done on Mac-Conkey agar Blood agar, and Chocolate agar plates and incubated overnight at 37 Celsius, re-subcultures were performed on day 3, 4 and 7 in case of no growth observed on plate by first day [9]. Identification of growth was based on colony morphology, Gram staining and Vitek-32 system (BioMerieux).

Antibiotics susceptibility test was done via Kirby Bauer method. The pH of Muller Hinton agar was 7.4 and sterilized by autoclaving at 121 Celsius for 15 min and poured into plates, single isolated colony was transferred into peptone water and incubated at 37 Celsius for 4 hour, the density was adjusted to approximately 10 CFU/μL by comparing its turbidity with that of 0.5 McFarland standard opacity tube. Then the Muller Hinton agar plate was inoculated by spreading, via cotton swab, three times over the entire agar surface and allowed for 3-5 minutes before adding of antibiotic discs via sterile forceps, then plates were incubated overnight at 37 Celsius, the antibiotics susceptibility was determined by diameter measuring of inhibition zones [10].

Statistical analysis was done by Microsoft Excel 2010.

Results

Three hundred and eighty blood specimens were collected from hospitalized children in period of approximately two years, seventy four (19.5%) of them developed positive blood cultures. Most predominant isolate was *Staphylococcus aureus* (25.67%) followed by CoNS (22.97%), *Klebsiella pneumoniae* (18.90%), *Pseudomonas aeruginosa* (16.25%), *E. coli* (12.16%), *Acinetobacter sp.* (2.70%), and *Streptococcus pyogenes* (1.35%).

Male (72.34%) were more likely to be infected than female (27.66%), While the highest rate of infection was in the age group 31 days – 12 months (48.64%) followed by age group 2 - 5 years (37.83%), and age group 1-30 days (13.53%).

Antibiotics susceptibility profile for Gram positive bacteria were as follows: *Staphylococcus aureus* was susceptible for Cefuroxime (83.33%), Amikacin (80.28%), Cefuroxime (81.75%), Ceftriaxone (77.15%), and Ciprofloxacin (74.60%). CoNS isolates were susceptible for Cefuroxime (90.33), Amikacin (89.14%), Vancomycin (85.5%), Cefazidime (84.21%), and Ceftriaxone (82.73%), while *Streptococcus pyogenes* isolate was susceptible for Amikacin, Cefuroxime, Cefotaxime, Cefazidime, Norfloxacin, and Ceftriaxone. (Table 1)

Antibiotics susceptibility profile for Gram negative bacteria were as follows: *Klebsiella pneumoniae* was susceptible for Ciprofloxacin (86.12%), Vancomycin (83.45%), Ceftriaxone (82.66%), and Amikacin (81.22%). *Pseudomonas aeruginosa* was susceptible for Ciprofloxacin (83.33%), Ceftazidime (81.24%), and Ciprofloxacin (77.65%). *E. coli* isolates were susceptible for Amikacin (100%), Vancomycin (89.3%), Cefuroxime (86.73%), and Cefotaxime (85.44%). While the tow isolates of *Acinetobacter sp.* Were susceptible for Amikacin, Cefodizime, Vancomycin, Cefotaxime, Cefazidime, and Ciprofloxacin. (Table 1)

Maximum susceptibility was to Ceftazidime, Amikacin, Ceftriaxone, and Vancomycin, while maximum resistance was to Erythromycin, Penicillin G, and Cefotaxime. (fig. 2)

**Note:** Antibiotics susceptibility results of *Acinetobacter sp.* and *Strep. pyogenes* were excluded due to the low number of isolates.

**Discussion**

Detection of bloodstream infections in children and infants as soon as possible could prevent reaching of causative agents to other organs like kidneys, heart or brain. In spite of a significant and serious number of cases, there are few studies of bloodstream infections in pediatric patients. A gold and standard way to detection the etiological agents of infectious diseases is blood culture and it is an only way to help in choice of appropriate and effective antibiotic.

Positive cases of bloodstream infections in children inpatients was 19.5%, and this is close to the results of studies carried out by Jyothi P. *et al.*, Jhajhria A. *et al.*, Kante M. *et al.*, Vijaya D. A. *et al.*, Qureshi M. *et al.*, and Mehta M. *et al.*, Who reported the following percentage respectively 19.2, 18.75, 17, 16.8, 16.6, and 16.4, many of the inpatients may be received antibiotics before specimen collection is the most effective reason could be explained the low percentage of isolation, in spite of that, Bhatt S. K. *et al.*, and Bolat F. *et al.*, reported high
percentages of bloodstream infections (55.6% and 43% respectively), at the time that, lower percentages were reported via Raheja P. et al (8%) and Pratham R. et al. (10.93%).

A male was predominance with male:female ratio of 2.5:1, other studies by Mythri H. and Kashinath K. R., Raheja P. and Jyothi P. reported 3.5:1, 2.8:1 and 1.9:1 respectively, the fact of attention given to the male infants and also because of greater number of male births in contrast to female maybe can explain the high rates of infection among male children (14).

Most of the bloodstream infections cases were in 31 days – 12 months (48.64%) than other age groups. High rates of infections in infants reported by Jhajhria A. et al (57.3%) and Bichitranaanda S. et al. (50%). The high rate of infections in infants may be due to their weak immune system and most infants take medication intravenously, that may introduce bacteria into their blood stream via medical devices, (2) bottle feeding and birth at home are sensible reasons to contaminate the infants easily and get infections.

In current study, common bacterial causative agent was Staph. aureus followed by CoNS, Klebsiella pneumoniae, Pseudomonas aeruginosa, E. coli, Acinetobacter sp., and Streptococcus pyogenes. (fig. 1) These results were consistent with previous local studies published by Al- Saqar et. al, and Arabi N. & Mojahid R. Increasing CoNS isolation in blood culture may also reflect a change of regarding CoNS as normal flora. Many factors such as prolonged use of intravascular devices, prolonged hospital stay, or other underlying co-morbidities might be increasing bloodstream infections due to CoNS. (9) Gram-negative bacteria have been reported as the commonest cause of bacteremia in hospitalized patients, the probable reason for that could be because it commonly found in the hospital environment, which might be contaminate among inpatients and increase the infection rates (11).

Because of increasing and randomly use of antibiotics, there has been emergence of antibiotics resistance among bacteria. Therefore, the second purpose of this study was to determine antibiotics susceptibility levels among bacteria causing bloodstream infections to commonly used antibiotics. Figure 2 shows that maximum susceptibility was to Ceftazidime, Amikacin, Ceftriaxone, and Vancomycin, while maximum resistance was to Erythromycin, Penicillin G, and Cefotaxime. Staph. aureus was highly susceptible for Cefuroxime, Amikacin, and Cefuroxime, and the high resistance value of it was to Cefotaxime and Vancomycin. CoNS isolates were susceptible for Cefuroxime, Amikacin, Vancomycin, Ceftazidime. while Streptococcus pyogenes isolate was susceptible for Amikacin, Cefuroxime, Cefotaxime, Ceftazidime, Norfloxacin, and Ceftriaxone. Klebsiella pneumoniae was susceptible for Ciprofloxacin, Vancomycin, Ceftriaxone, and Amikacin, and there was high resistance value to Cefotaxime. Pseudomonas aeruginosa was susceptible for Ciprofloxacin, and Ceftazidime, and it was resistant to Cefodizime, Cefuroxime and Cefotaxime. E. coli isolates were susceptible for Amikacin, Vancomycin, Cefuroxime, and Cefotaxime. While the tow isolates of Acinetobacter sp. were susceptible for Amikacin, Cefodizime, Vancomycin, Cefotaxime, Ceftazidime, and Ciprofloxacin. As articulate from the results of current and previous studies, (8,14,15,20,21) injudicious and widespread use of antibiotics had been increased the risk of emergence of multi-drug resistant organisms and furthermore spread of such strains, which not only increases the total cost of treatment but also morbidity and mortality.

Conclusions

The predominant causative agents of bloodstream infection in children inpatients was staph. aureus and CoNS followed by K. pneumoniae and P. aeruginosa. Whereas Ceftazidime, Amikacin, Ceftriaxone, and Vancomycin were most effective antibiotics, while maximum resistance was to Erythromycin, Penicillin G, and Cefotaxime. A male and 31 days – 12 months age group were more likely to suffering from bloodstream infections.

Association of Follicle Stimulating Hormone Receptor Gene Asn680ser Polymorphism with Polycystic Ovary Syndrome in Iraqi Women

Zainab Kadhim Abed1, Estabraq AR. Al-Wasiti2, Ban Abbas Abdulmajeed2
1Um Al-Baneen Centre, AL-Imamian AL-Kadhimiyain Medical City, Iraq; 2College of Medicine AL-Nahrain University, Iraq

ABSTRACT

Polycystic ovary syndrome (PCOS) is a polygenic multifactorial status affecting millions of females worldwide. It is a common cause of anovulatory subfertility.

This study aim to investigate the potential association between the follicle-stimulating hormone receptor (FSHR) gene Asn680Ser (rs6166) single nucleotide polymorphism with PCOS in Iraqi women.

A case-control study including 135 Iraqi women of Arab ethnicity (75 PCOS patients and 60 age-matched control women). The age of subjects ranged from 18 to 38 years. PCOS diagnosis was established by Rotterdam consensus criteria. FSHR gene (Asn680Ser) variant was tested by polymerase chain reaction–restriction fragment length polymorphism followed by deoxyribonucleic acid (DNA) sequencing.

In the present study, the A (Asn) allele and homozygote AA (Asn/Asn) genotype of the FSHR gene Asn680Ser polymorphism had significant risk (P=0.004 and p= 0.005 respectively) of developing PCOS in Iraqi women. On the contrary, the G (Ser) allele and the heterozygote AG (Asn/Ser) genotype gave a significant (P=0.004 and P=0.026 respectively) protective factor from developing PCOS in Iraqi women. Sequencing analysis of DNA confirmed restriction fragment length polymorphism analysis.

The variant Asn680Ser of the FSHR gene is associated with risk of PCOS development and may consider as the causal factor of PCOS in Iraqi women.

Keywords: FSH receptor, Asn680Ser (rs6166) polymorphism, PCOS, Iraqi women.

Introduction

Polycystic ovary syndrome (PCOS) is a polygenic multifactorial condition affecting millions of women worldwide. It is a common cause of WHO group 2 ovulation disorders that accounts for 80% to 90% of anovulatory subfertility(1). PCOS prevalence is specified, by the diagnostic criteria, ethnicity, and population of women studied (1, 2). Diagnosis of PCOS is based on Rotterdam consensus criteria (3). The pathogenesis of PCOS is multifactorial and far from being fully understood. It has been deduced that PCOS can be a familial in origin resulted by a mixture of genetic with environmental agents (4, 5). A major collection of studies has been dedicated to fixing the genetic causes of PCOS looking, especially, the release and action of gonadotrophin, secretion and action of insulin and other genes that had interest with regard to PCOS (6–8). Since follicle-stimulating hormone receptor (FSHR) has been identified as an important vulnerability locus in many genome-wide association studies, there have been multiple researches on FSHR polymorphisms (6, 8, 9).

Follicle-stimulating hormone (FSH) is an important agent in human reproduction, boost proliferation and discrimination of the granulosa cell in addition to the estrogen production (10). It acts by joining to the FSHR that found on the ovarian granulosa cell surface. The FSHR is encoded by the FSHR gene that present on the short arm (p) of chromosome two (2p21-16) (11, 12).

Various single nucleotide polymorphisms (SNPs) of the FSHR gene have been found in different populations. Of these, two SNPs present in exon ten at nucleotide position 919 (Thr307Ala) and nucleotide position 2039 (Asn680Ser) are widely studied to determine the FSHR response to FSH stimulation and to portend the risk of PCOS development (13). In particular, the Asn680Ser SNP has received special attention. The Asn680Ser (rs6166) is situated in intracellular domain of FSHR at codon position 680 which can be taken either by asparagine (Asn=AAT) or by serine (Ser=AGT) (11). Because of the prevalence of PCOS and clinical features and the frequency of FSHR polymorphisms vary among different races of population (2, 14), So, the aim of this study was to investigate the potential association between the FSHR gene Asn680Ser (rs6166) SNP with PCOS in Iraqi women.

**Materials and Method**

A case-control study was conducted at the Higher Institute of Infertility Diagnosis and Assisted Reproductive Technologies/Al-Nahrain University (Baghdad, Iraq) from February 2017 to February 2018. This work was approved by the Local Medical Ethical Committee of the High Institute of Infertility Diagnosis and Assisted Reproductive Technologies/Al-Nahrain University. Each woman that participates in the present study signed a consent form. A total of 135 Iraqi women were studied. All women were of Arab ethnicity and were matched according to age. The age of subjects ranged from 18 to 38 years. Two groups were enrolled in this study. The first was seventy five PCOS patients group were chosen from those women who attended the Higher Institute of Infertility Diagnosis and Assisted Reproductive Technologies. The PCOS women were chosen based on the Rotterdam criteria (3). The enrolled women were only those who had polycystic ovaries on transvaginal sonography to ensure that the phenotype was definitely PCOS.

The second group was the control group, which included 60 healthy women were chosen from those women who attended the Higher Institute of Infertility Diagnosis and Assisted Reproductive Technologies and Al-Imamian Al-Kadhimiya in Medical City (Baghdad/ Iraq), with normal menstrual cycles, no clinical appearance of hirsutism, acne and alopecia, normal basic endocrine detection results, transvaginal sonography revealed no polycystic manifestations and no family history of PCOS.

**Genotype Analysis:** For DNA isolation from all the subjects, two and half milliliters of venous blood were collected in K2-EDTA collecting tube containing EDTA as anticoagulant. According to the protocol of G-spin™ Kit (Intron - Korea), genomic DNA was isolated from venous whole blood. After genomic DNA extraction, agarose gel electrophoresis was selected to confirm the presence and integrity of the extracted DNA (15) (Figure 1.A). In addition, all the extracted DNA samples were tested to estimate the genomic DNA concentration and purity by BioSpec-nano spectrophotometer (Shimadzu/ Japan). Restriction fragment length polymorphism (RFLP) technique was used to detect Asn680Ser SNP (2039 G>A) (16). A 520 base pair (bp) fragment of FSHR was magnifying by conventional polymerase chain reaction (PCR) utilizing the next primers (Integrated DNA technologies/USA):

**Forward primer:** 5'-TTTGTGGTCATCTGTGGCTGC- 3'

**Reversed primer:** 5'-CAAAGGCAAGGACTGAATTATCATT - 3'

Conventional PCR was done by using a MultiGene™ OptiMax Thermal Cycler (USA- Labnet), in overall volume of 25 μl mixture including: 1.5 μl of DNA; 1 μl of every primer, 5 μl Maxime PCR Premix (i-Taq) manufactured by (Intron/Korea) and 16.5 μl double distilled water. The Thermal Cycler was adjusted for PCR status as the following steps: an initial denaturation step of 3 min at 95°C followed by 34 cycles of denaturation at 95°C for 45 sec, annealing at 62°C for 35 sec and initial elongation step at 72°C for 45sec and a final elongation step at 72°C for 7 min.

All PCR products (Figure 1.B) were subjected to restriction enzyme digestion. The 520 bp amplified PCR product was digested with BsrI (Biolab/New England). Digestion was performed in 10μl reaction volume containing 4.5μl reaction buffer, 0.5 μl of restriction enzyme and 5 μl of purified PCR product, incubated at 65°C/45min.

The evaluation of PCR and enzyme digested products were done by gel electrophoresis (2%) that visualized by UV trans-illuminator illuminator (Vilberlourmat-France). Digestion with restriction enzyme Bsr I gave
3 diverse patterns for 2039 G→A substitution: bands of 520 bp in case of Asn680Asn (AA) genotype, 413/107 bp in Ser680Ser (GG) genotype and 520/413/107 bp in Asn680Ser (AG) genotype were observed (Figure 1.C). To verify genotyping results in RFLP, 20 samples (randomly selected from all samples processed) of PCR products and forward primers were sent to South Korea (Macrogen Company) for DNA sequencing.

Figure 1: (A) Gel electrophoresis of genomic DNA extraction from blood. 1% agarose gel, 70 volts, and 65 ampere at 1 hour, visualized under UV light after staining with red safe staining. (B) Agarose gel electrophoresis of PCR products for FSHR Gene (Asn680Ser). The PCR amplified fragment of molecular size of 520 bp. (C) The PCR products after digestion with Bsr I: (AA genotype = 520 bp); (GG genotype = 413 bp and 107 bp); (AG genotype = 520 bp, 413 bp and 107 bp). The PCR and enzyme digested products were electrophoresis on 2% agarose for 1:30 hours. M=DNA ladder 100bp.
Data and Statistical Analysis: Statistical analysis was performed utilizing SPSS Statistics Version 23.0. Fisher exact test was utilized to show the significance of difference among the frequencies (alleles and genotypes) of study groups. Odds ratio (OR) and 95% confidence interval (CI) were achieved to estimate the association among the groups. Significance of tests was specified at P value $\leq$ 0.05.

Results

In the current study, the Asn680Ser variant of the FSHR gene was screened among 135 women (75 PCOS patients and 60 healthy controls). The age range for both PCOS patients and controls was 18 to 38 years with a mean of 26.0 ± 0.51 (mean ± SE) for PCOS and a mean of 26.7 ± 0.51 (mean ± SE) for controls. In the present study, no significant difference (P>0.05) in the age was observed between the two groups.

The allele and genotype frequencies of FSHR Asn680Ser SNP in all subjects were assessed (Table 1). In the present study, there was a significant (P value=0.004) difference in distribution of alleles, Asn (A) and Ser (G) between PCOS patients and control groups. The A allele frequency was (82.7% in PCOS patients versus 67.5% in control group), the OR for such a positive relation was 2.3 with etiological fraction (EF) = 0.46. The genotypes analysis of Asn680Ser SNP showed that the homozygote mutant AA genotype showed a significant (P value=0.005) higher frequency in PCOS patients than in controls (80.0% and 56.7%, respectively), the OR for such a positive relation was 3.06 with EF was 0.53. On the contrary, the G allele and heterozygote AG genotype significantly (P=0.004 and P=0.026 respectively) more frequent in the control group than the PCOS patients group, the OR for such a positive relation were (0.44 and 0.25 respectively) with preventive fraction (PF) = (0.18 and 0.13 respectively). No significant (P value = 0.187) difference was observed in the distribution of the homozygote wild GG genotype among the PCOS and controls (14.7% versus 25.0%, OR=0.52, 95% CI=0.22-1.22). Sequencing analysis of DNA confirms RFLP analysis as shown in Figure 2. The exon ten sequence of the FSHR gene was submitted to the Gene Bank National Center Biotechnology Information (NCBI) under the accession number (MH910500.1).

![Figure 2: Sequencing analysis for exon ten of FSHR gene (Asn680Ser): (AA genotype=one peak), (AG genotype=two peaks) and (GG genotype=one peak) as indicated by arrows.](image)
Discussion

Since the cause of anovulation in PCOS may be due to defects in the early stages of folliculogenesis (17). Therefore, the correlation among FSHR gene SNPs and this syndrome has been widely investigated across different races with inconsistent results. In the present study, the A allele and homozygote mutant AA genotype gave a significant risk of PCOS development among women in Iraq. On the contrary, the G allele and the heterozygote AG genotype gave a significant protective factor from developing PCOS in Iraqi women. This is in agreement with previous studies conducted between different races and also confirmed a significant increase in frequency in the Asn680Ser variant. Sujatha et al. have stated that the A allele and homozygote AA genotype gave a significant risk of PCOS development among women in India (18). In addition, the presence of significant differences in the allele distribution of Asn680Ser SNP in women with PCOS was proven between Iranian women (19) and Korean women (20, 21). On the contrary, the presence of significant risk of PCOS development was not proven between Turkish population (22, 23), Northern Chinese Han women (24) and among Bahraini Arab women (25).

The differences of results that observed in multiple studies may be due to a different PCOS definition and sample size. Moreover, PCOS is a complex and diverse disorder which results from interaction of genetic and environmental agents (26, 27). Therefore, the prevalence and the differences in phenotypes in PCOS women in various populations may be affected by regional and ethnic setting (27-29).

Conclusion

The A allele and homozygote AA genotype of the Asn680Ser variant of the FSHR gene is associated with risk of PCOS development. On the contrary, the G allele and heterozygote AG genotype is a preventive one. So the Asn680Ser variant of the FSHR gene is associated with risk of PCOS development and may consider as the causal factor of PCOS in Iraqi women.

Optimization of L-Glutaminase Enzyme Production by 
Staphylococcus Aureus Clinical Samples

Mustafa Gh. AL-Juhaishy¹, Asma A. Husain¹
¹College of Biotechnology, Al-Nahrain University, Iraq

ABSTRACT

L-glutaminase produced from staphylococcus aureus. Where, a 108 sample of bacterial isolates collected from clinical source. S. aureus identified by biochemical test and differential medium. The ability of these isolates for L-glutaminase production was examined. Results showed that of S. aureus isolate were L-glutaminase producers with different degrees. Among them S. aureus S22 was the most efficient in enzyme production and the specific activity of L-glutaminase in its crude was 4.1 U/mg. Upon studying the optimum condition for enzyme production.

Keywords: clinical samples, L-Glutaminase enzyme, Staphylococcus aureus

Introduction

L-glutaminase (L-Glutaminate amidohydrolase EC 3.5.1.2), L-glutaminase occur in wide range of living organism both microorganism (bacteria and fungi) and higher organism (plant and mammalian) (²). L-glutaminase acts to breakdown l-glutamine and converted it to glutamic acid and ammonia group) (¹, ³). The amino acid l-glutamine is considered as very important essential amino acid for cancer cells since these cells lose the mechanism of l-glutamine synthesis which present in normal cells (¹, ³, ⁶) the proliferation of cancer cells blocked when the L-glutamine Depleted from cancer cells environment. The anticancer activity of L-glutaminase tested on multi types of cancer such as breast cancer (³, ⁷), liver cancer (⁷) and others. In addition to l-glutaminase anti-cancer activity, this enzyme used in food industry as flavor enhancer and in biosensor for monitoring glutamine level in mammalian cell culture (⁴). In biosensor L-glutaminase used for healthy monitoring and clinical diagnostic which achieved by analysis of glutamate and glutamine level in body fluid. L-glutaminase used as both free enzyme of immobilized form as biosensor for monitoring glutamine and glutamate level (⁵).

Materials and Method

Sample Collection: Bacterial samples (108 isolates) of burns, wounds and urine infections were collected aseptically from Al-Sader hospital, private analyzer laboratory in Baghdad and AL-Najaf city. Swap specimens transferred to laboratory under cooling conditions. Specimens were inoculated to mannitol salt agar (MSA), chrome agar, and blood agar media then incubated for 24-48h at 37°C under aerobic conditions. All the primary screened isolates then subjected to various morphological and biochemical tests to ensure their identity⁸.

Semi Quantitative Screening: The isolated S. aureus were subjected to rapid screening for L-glutaminase production by agar plate assay. Bacterial isolates were grown on minimal salt medium (KCl.7H₂O 0.5g/l, MgSO₄.7H₂O 0.5g/l, ZnSO₄.7H₂O 1.0 g/l, KH₂PO₄ 1.0 g/l and L-glutamine 5.0 g/l in pH 6.7) with 2.5% phenol red dye and incubated for 48h at 37°C. Change in pH caused change the color of plate from yellow to pink, which indicated a positive result (⁹).

Quantitative Screening of L-glutaminase

Preparation of cell free supernatant: S. aureus was grown in 250 ml minimal salt media at 37°C for 48h. The culture was centrifuged for 30 minutes at 6,000 rpm, and cell free supernatant was used as crude enzyme.
L-glutaminase activity assay method: L-glutaminase activity was assayed as follows: A reaction mixture containing 10 μl of 0.04 M L-glutamine, 10μl of 0.5 M Tris buffer, 10 μl of enzyme, and D.W to a final volume of 40 μl. The mixture was incubated in water bath for 30 min at 37 °C and the reaction was stopped by adding 10μl of 10% trichloroacetic acid (TCA). Blank was prepared by adding TCA before the addition of enzyme. Mixture reaction (25μl) was taken and the volume was completed to 1ml using D.W, then 50μl of Nessler’s reagent was added. The mixture was kept for 20 min at 25°C, then the absorbance at 450 nm was measured, and the amount of released ammonia was determined [21]. One International Unit (IU) of L-glutaminase is the amount of enzyme which liberates 1μmol of ammonia per minute per ml [μmole/ml/min].

Determination of protein concentration: Protein concentration was determined according to the method of Bradford (10).

Optimum conditions for L-glutaminase production: Optimum conditions for L-glutaminase produced by selected isolate were determined by inoculating 100 ml of the minimal salt medium pH 6.7 with 1.0 ml of fresh culture (OD =0.6) of the bacterial isolate and incubated for 24 h at 37°C, then L-glutaminase activity and protein concentration in crude extract were estimated. Optimum factor when reached was used in the next experiment of optimization.

Optimum carbon source: Various carbon sources (starch, glucose, maltose, sucrose and sugar) were added, individually, to the production medium. The final concentrations of all these carbon sources were 0.1 %. L-glutaminase activity, protein concentration and specific activity were determined.

Optimum Nitrogen Source: Various nitrogen sources (casein, meat extract, yeast extract, tryptone) were added individually to the production medium supplemented with optimum carbone source from the previous step at a final concentration of 0.1%. As in the previous step, L-glutaminase activity, protein concentration and specific activity were determined.

Optimum pH: Optimal pH for production of L-glutaminase was determined by adjusting the pH of the production medium to different values (5, 6, 7, 8, 9, and 10), then incubated for 24 h at 37°C. L-glutaminase activity, protein concentration and specific activity were determined.

Optimum temperature: The production medium was inoculated with the selected S. aureus and incubated at different temperatures (25, 30, 37 and 42°C). The optimum temperature for L-glutaminase production was used in the next experiment of optimization.

Optimum incubation period: Effect of incubation period on L-glutaminase production by S. aureus was studied by incubating the production medium at various periods of time (24, 48, 72 and 96 hr.) to determine the optimum period for enzyme production.

Results

Isolation and identification of Staphylococcus aureus: A total of 108 clinical samples were collected from burns, wounds and urine infections, of which 95 isolates produced yellow colonies on MSA media which is typical characteristic of S. aureus [11]. and gray colonies were observed for the same isolates when cultured on chrome agar which is differential media prevent the growth of all bacterial isolates except S. aureus [12, 14]. When these bacterial isolates grown on blood agar media β-hemolysis around their colonies were produced [11]. The primary biochemical test for these isolates showed in table (1). These characteristics came in accordance with cultural characteristics of S. aureus [8].

Semi quantitative screening: The semi quantitative screening for l-glutaminase production was done by agar plate assay method. Results showed that the pink color directly related to the quantity of enzyme produced. However, among the 95 bacterial isolates, four isolates showed positive result, S. aureus S22 can be considered as the highest l-glutaminase producer which gave clear pink zone when compared to the other isolates (Figure 1). In minimal glutamine agar, l-glutamine amino acid was the only carbon and nitrogen source, so the organisms capable of producing L-glutaminase would be able to grow on this media. The pH indicator shows colour change from yellow to pink. Appeared of pink zone around colonies related with l-glutaminase enzyme action that disrupted l-glutamine amino acid and release ammonia, which raised pH number (9, 13).

A. The plate that inoculated with S22 and incubated for 48 h at 37°C.

B. Blank plate uncultured and incubated 48 h at 37°C

Quantitative screening of *S. aureus* isolates producing l-glutaminase: Upon qualitative screening, the specific activity of L-glutaminase in the crude of the four local *S. aureus* isolates was determined. Result (Table 2) showed that all the isolates were L-glutaminase producers with variable degree of production. The isolate S22 gave the highest specific activity (4.1U/mg) protein. Moreover, isolate S25 showed the lowest specific activity (0.9 U/mg) protein. According to these results, the isolate S22 was selected to be used for improving its ability in L-glutaminase production by optimization.

The differences between isolates in the ability for enzyme production could be due to genetic variations of the genes responsible for the production of this enzyme15.

Optimum conditions for l-glutaminase production: The production of l- glutaminase by the most efficient *S. aureus* isolate S22 was optimized using one factor at a time variable and keeping the other factors constant

Optimal Carbon Source: Five carbon sources (starch, glucose, maltose, sucrose and sugar) were used as a optimum source for carbon and energy to determine the optimum for production of l-glutaminase by *S. aureus* S 22. All these carbon sources were added separately to minimal salt medium in a concentration of 0.1 % w/v. Results showed that, the maximum production of l-glutaminase by *S. aureus* S 22 was achieved when starch was used as a source for carbon and energy which gave highest L-glutaminase specific activity of (13.8 U/mg) followed by glucose (10.9U/mg), maltose (9.3 U/mg), sugar (7.6U/mg) and sucrose (5.2 U/mg) figure (2).

![Figure 2: Optimum carbon source for L-glutaminase produced by Staphylococcus aureus S22 after incubation at 37°C for 48 h.](image)

Optimum Nitrogen Source: Nitrogen sources includes yeast extract, meat extract, casein and tryptone were added to the production medium separately in a concentration of 0.1%. Maximum production of l-glutaminase was achieved when the production medium was supplemented with meat extract because enzyme specific activity reached 18.3U/mg protein when this nitrogen source was used (Figure 3). This result related to the fact that meat extract is easier to utilized by this bacterium than the other nitrogen sources to achieve requirements for growth, cell division and production of l-glutaminase and different metabolites. Another previous studies showed that tryptone was the optimum nitrogen source for *Providencia sp.* L-glutaminase production (16).

![Figure 3: Optimum nitrogen source for L-glutaminase produced by Staphylococcus aureus S22 after incubation at 37°C for 48 hrs.](image)
Optimum pH: The initial medium pH was adjusted in a range between pH 5 to pH 10, the maximum L-glutaminase production was obtained when the pH value of the production medium was adjusted to 8, at this value the enzyme specific activity recorded 24.6 U/mg protein (Figure 4).

The three-dimensional structure of proteins related with hydrogen ions (H+) concentration because any change in H+ and/or OH-compete with hydrogen bonds and ionic bonds in an protein, resulting in protein denaturation (17). Also, the pH effect on the stability of the produced enzyme, solubility of the nutritional materials and substrate ionization (18).

Optimum incubation temperature: Different incubation temperatures used in this study (25, 30, 37 and 42°C) to determine optimum temperature for L-glutaminase produced by S. aureus, the results showed that maximum production of L-glutaminase was occurred when the microorganism was grown at 37°C for 48h, with specific activity of 24.9 U/mg (Figure 5). At any enzymatic reaction temperature above or below the optimal will drastically reduce the rate of reaction. This may be lead to enzyme denaturation or to losing its three-dimensional structure. Denaturation of a protein means the breakage of hydrogen bonds and non-covalent bonds (17). Z. rouxii produced L-glutaminase at the same temperature too (16). The optimum temperature for synthesis of the enzyme from P. fluorescens was 37°C (19).

Optimum incubation period: L-glutaminase production by locally isolated S. aureus S22 was determined after different incubation periods (24, 48, 72 and 96hrs). Results in Figure (6) indicated that the enzyme production started at 24 hours, with specific activity of 11.4 U/mg. until it reached to the maximum enzyme production at 48 hours, and the specific activity of 26.3 U/mg. After that, activity of enzyme was decreased to 6.3 U/mg after 96 hours of incubation.

The possible reason for decrease in L-glutaminase production after 72 hr may be due to reduction of nutrients in the medium, assemblage of excess acid in the media because of sugar utilization and developed oxygen tension. or maybe attributed to assemblage of acetate which is inhibitory to cell growth and generation of toxic products that often decreased protein yields (20).

Conclusion

L-glutaminase production was increased when the medium supplemented with 0.1% starch and 0.1% meat extract (pH 8.0) and incubated at 37°C for 48 hours. Under
these conditions, the specific activity of L-glutaminase produced in culture medium was to 26.3 U/mg protein.

Serologic Study to Detect a Relation between Myocardial Infarction Diseases and *Helicobacter pylori* Infections in Baqubah City, Iraq

Saif Ali Mohammed¹, Duaa Adnan Kadhum¹, Mohammed Khudhaier Abbas²

¹Department Pathologic Analysis Techniques, ²Department Public Health Techniques, Baqubah Technical Institute, Diyala, Iraq

ABSTRACT

Myocardial infarction (CAD) is known as the main cause of death in developed and developing countries. A relation between this disease and *Helicobacter pylori* has been displayed in several studies. The purpose of this study was to determine the relationship between *H. pylori* infection and myocardial infarctions diseases.

Methods: 72 myocardial infarction patients as well as 20 Control samples. Levels of serum IgM antibodies against *H. pylori* were measured by ELIZA technique while IgG antibodies by Rapid Cassette test (CAS), also the blood samples were collected sent to rapid tests of CRP – Latex test as an indicator.

From 92 participants, 72 were patients and 20 were control subjects. The percentage of IgM positive cases against *H. pylori* was 86.11% in the case group and 45% in the control group (p: 0.29), while (52.7%) in the case group and (60 %) in the control group were positive to antiHP IgG (p=0.53). according to statistical data, this study showed no significant association between myocardial infarction disease & *H. pylori* infection (P > 0.05).

Keywords: *H. pylori*, Myocardial infarction (MI), antiHP IgM, IgG.

Introduction

*Helicobacter Pylori* was imparted to the world consideration 1983 by Warren and Morshall, it is now recognized that *H. pylori* gastritis is the commonest chronic human bacterial infectious diseases. Although *H. pylori* are asymptomatic they are thoroughly causally related with benign stomach disorders such as peptic ulcer, gastritis disease and malignant gastric conditions such as gastric mucosa-associated lymphoid tissues (¹) Serological signs indicate that 50 % of the adults in developing and developed populations are infected. *H. pylori* colonize the less acidic antrum of the stomach¹², ³. *H. pylori* infections have been recognized to play a vital part in the pathogenesis of diabetes mellitus type two⁴, ⁵.

The effects of *H. pylori* in the pathogenesis of myocardial infarction diseases still remained controversial. In recent years, Several epidemiologic and clinical evidence have recommended the roles of sustained and severe inflammations in emerging atherosclerotic lesions⁶. Inflammations as a response to irritation, oxidative degradation of lipids, or infections are considered majors cardiovascular risk factors⁷. It has been suggested that determined low-grade inflammatory responses that resulting from chronic gastritis *H. pylori* disorders may increase the level of some coagulation factors, such as fibrinogen, which are the indicator of ischemic heart diseases⁸. *H. pylori* with other microorganisms have a main role in the atherosclerotic plaque development by specific and nonspecific mechanisms such as increased clotting ability, increased the formation of adhesion molecules⁹. *H. pylori* is helicoidally spiral-shaped, a gram-negative rod, a unipolar and microaerophilic bacterium. it is characterized by the production of urease, via ammonia production, thus have the opportunity to survive by creating a pH more than that of gastric mucous¹⁰.
Materials and Method

Blood Collection: This study enrolled 92 samples (60 male and 32 female), 20 individuals control study (No history of Cardiovascular diseases) 72 myocardial infarction patients their ages between (40-80) years old, all of them attending the Emergency room and consultation clinics of Baqubah Teaching Hospital and Balad Ruz general hospital at Diyala province from 5/9/2017 to 5/4/2018. Patients with the myocardial infarction in the common clinical forms (unstable angina UA, hypertension diseases), A questionnaire was directed to those patients entered including the history of hypertension, diabetes mellitus, smoking, and coronary artery diseases and Negative history of (gastritis, duodenal ulcer, and gastric ulcer). The blood samples were collected sent to rapid tests of CRP – Latex test. Blood samples (5 ccs) were obtained and sent to the refrigerator at -20°C at the test time.

Detection of H. pylori antibodies: ELISA IgM kit DEHELO3 designer for the quantitative detection of IgM class antibodies against H. pylori in human serum or plasma. Microtiter strip wells are precoated with H. pylori antigen to bind matching antibodies of the specimen.

Statistical Analysis: Statistical Descriptive analysis (Mean, SD, SE, and percentage) was done to describe data, two independent samples T-test, (F-test), correlation analysis was applied (12).

Results

A total of (72) patients were enrolled in the study, 60 (65.12%) male and 32 (34.7%) female (Figure 1).

Table 1: The Percentage of CRP test in all patients

</tbody>
</table>
The table (3) as shown about 48.3% of patients with Anti IgG and IgM positive results was within fifth decade of life.

**Discussion**

Since *H. pylori* infect the individuals induces the formation of antibodies. Sero-diagnostic tests provide the rapidity, sensitivity, and specificity detection of *H. pylori* (13, 14). *H. pylori* incidence differs in relation to various factors such as geography, age, and economic factors — high in developing countries and lower in the developed world (15, 16). Some studies have shown male predominance in infection (17-19). The incidence of Anti *H. pylori* was highest in the youngest group of <30 years (96.7%), Which may indicate the acquisition of hostility during childhood. In our study, no significant difference in *H. pylori* IgM levels was presented between cases and controls (p=0.29). Patients with MI with positive antiHP IgM was (86.11%) while (52.7%) for antiHP IgG. MI compared with positive antiHP IgM and IgG were statistically no significant differences showed. In Iraq to date, very little studies that show the association between H pylori infections and myocardial infarction disease, so this result was Converged from Azarkar, et.al. that revealed antiHP IgG positivity was (57. 5%) and different from a study was performed by Altaae that revealed antiHP positivity was 38.57 % in CVD. (20, 21). *H. pylori* infections upsurge the production of several metabolites, such as cytokines, that affect the blood flow in vessels and Resulting in its endothelial dysfunction and shrinkage of tiny vessels (22-24). Increase the proportion of fibrinogen lead to in the gastric mucosa of *H. pylori*-infected individuals could increase serum fibrinogen and leukocytes, It appears that the immune response and related reactions in patients with *H. pylori* infection can be demonstrated Accompany this infection and some cardiovascular diseases (25, 26). Finally, this evidence may be consistent with the increase observed in our study of the prevalence of *H. pylori* antibodies among MI patients.

**Conclusions**

1. The prevalence of positive antiHP antibodies was higher in patients Myocardial infraction.
2. Gender disparities are present in our study of patients with positive antiHP patients.
3. The prevalence of antiHP antibodies increases with the rise in the average age.

Assessment of Some Hematological Parameter in People with Hair Loss

Huda Mohammad Kadhim Al-asady1, Naeema Hameed Al-dulaimy1
1Department of Pathological Analysis Techniques, Al-Safwa University College, Kerbala, Iraq

ABSTRACT
Hair loss is a common problem in the Iraqi society. To study its causes, 30 people suffering from hair loss were selected, with ages ranging from 18-50 years and of both sexes compared to 10 healthy people. Blood samples were collected from the persons under investigation; some tests were conducted on them, including: Total white blood cells, Hemoglobin (Hb) and level of Ferritin was measured. The study found that the highest percentage of hair loss is found in females by 73.3% compared to males by 26.6%. The result shown there was not significant decrease in WBCs in people suffering from hair loss by $7.115 \times 10^3/\mu l$ compared with control to $7.74 \times 10^3/\mu l$, while shown there are significant decrease level Hb which a record $11.18 \text{ g/dL}$ in people suffering from hair loss While in control about $13.2 \text{ g/dL}$. There was also a not significant decrease in the proportion of Fe in people suffering from hair loss by Ug/Dl 55.29 compared with the healthy group who recorded the ratio of Ug/Dl 59.29.

Keyword: Hair loss, Hemoglobin, ferritin

Introduction
Hair loss is a common problem that affects both males and females of all ages [1]. Hair loss is not just an aesthetic issue; the condition can also cause a great deal of psychological pain. While hair loss sufferers have long attributed their condition to factors like hormones and genetics, immunity [2].

Hair is a keratin protein filament that grows from follicles found in the dermis of skin [3]. The healthy adult scalp contains about 100,000 hairs, of which 90% are actively growing, hair follicles cycle through anagen, catagen and telogen phases showing in figure (1), since the vast majority of patients with hair disorders suffer from an undesired alteration of hair follicle cycling [4-6]. Thus, in a normal adult scalp, there are around 80-90% of hair in the anagen phase, 10-20% in the telogen phase and 1-2% in the catagen phase [7].

Figure 1: Hair Growth Cycle[4]

Reduction in hair thickness and density leads to a reduction in the overall hair volume (average hair thickness x number of hairs) due to many season such as endocrine causes, stressful events, nutritional causes, intoxication, drugs and Inflammatory scalp diseases, Iron deficiency & other, these causes a disruption in hair growth cycle and hair loss [8].

To study some of hair loss causes, we selected 30 people suffering from hair loss, with ages ranging from 18-50 years and of both sexes compared to 10 healthy people and that is through:

1. Blood samples were collected from the persons under investigation.

2. Determination of hematological parameters
   A. Total white blood cells (WBCs).
   B. Hemoglobin (Hb).
3. Quantitative determination of Fe serum.

**Materials and Method**

**Samples:** The study method include 30 patients suffering from lost hair and 10 healthy as control with mean age of (50 ± 18) from both sex.

**Collection of Blood Samples:** About 5 ml of blood was withdrawn from the vein of the patients under this study by syringes, and the blood was divided into two parts. It placed 2 ml in the EDTA tube for CBC test and the remaining 3 ml from blood was placed in the gel tube and left the tube at room temperature for 15 minutes, then placed in the centrifuge for 10 minutes at 3000 rpm to separate the serum that was pulled by a pipette and used to measure the Fe ratio.

**Blood Test**

**Determination of hematological parameters:** The full count of blood (CBC) factory determine by Complete blood count (Sysmex Kx2In – Japan) Hematological analyzer.

**Quantitative determination of Ferritin serum:** The level of Fe measured by using i- CHROMA (Bodi Tech Med – Korea) device.

**Statistical Analysis:** Statistical analysis was performed of data using excel program in the computer where the mean value, standard deviation and Statistical significant of difference LSD and between two means were calculated at the level of probability of 0.05.

**Results and Discussion**

**Samples:** A total of 30 samples of people with hair loss were collected after being diagnosed by dermatologists at Hussein Teaching Hospital in the city of Karbala, 10 samples of healthy people were also collected for control with mean age of (50 ± 18) from both sex.

The study found that the highest percentage of hair loss is found in females by 73.3% (22 sample) compared to males by 26.6% (8 sample) as shown in the figure (2). Hair loss among women is a challenging common problem for Dermatologists; Hair loss affects more than 25% of women in developed countries \(^9\). In general, the main risk factors of loss hair are major illness, stress, nutritional deficiencies, medications, androgen and genetics basis in its etiology \(^10,11\).

![Figure 2: Percentage of hair loss among males and females](image)

**Determination of hematological parameters**

**Total white blood cells (WBCs)**

<table>

<td>0.991</td>
<td></td>
</tr>
</tbody>
</table>

The results for WBCs showed not significant decrease P-value> 0.05 (in these number of patient with hair loss by 7.115*10^3/µl compared to 7.74*10^3/ µl control, As shown in the table (1). According to a recent study, researchers found a correlation between certain immune system cells and the skin cells that enable hair to grow, macrophages a type of white blood cells can signal skin cells to produce hair. In a recent PLOS Biology study involving mice, researchers found that administering anti-inflammatory drugs had an effect on hair growth. By treating the macrophages, scientists were able to manipulate the cells into reactivating hair\(^{12}\).

In experiments in mice, UC San Francisco researchers have discovered that regulatory T cells a type of WBCs directly trigger stem cells in the skin to promote healthy hair growth. Without these immune cells as partners, the researchers found, the stem cells cannot
regenerate hair follicles, leading to baldness or hair loss, the other study suggests that defects in T-cell could be responsible for alopecia areata, a common autoimmune disorder that causes hair loss, and could potentially play a role in other forms of baldness, including male pattern baldness\textsuperscript{[13]}.

Table 2: concentration of Hb in study group

<table>
<thead>

<td>13.2</td>
<td>± 1.24</td>
</tr>
<tr>
<td>LSD</td>
<td>1.32</td>
<td></td>
</tr>
</tbody>
</table>

According to the results shown in table (2), there was a significant decrease (P-value<0.05) in the level of Hemoglobin (Hb) in people with hair loss 11.18 g/dL while in healthy people 13.2 g/dL, the results of this study were close to those found Elethawi & Jabbar in 2012 [14] which level a to Hemoglobin was ranged from 12.37 g/dl compare with control group by 12.19 g/dl, Hemoglobin (Hb) level may be within normal limits in women with iron deficiency and hair loss. This is because decreased iron stores in body will lead to hair shedding before the development of microcytic anemia\textsuperscript{[15]}.

Quantitative determination of Ferritin (Fe) serum:
Results showed that there was a not significant decrease (P-value> 0.05) in (Fe) serum by 55.29 Ug/Dl at people with hair loss compared to healthy people by 59.29 Ug/Dl. As shown in the table (3).

Hair follicles contain ferritin, decline of ferritin stores in the hair follicle affects the ability of the hair to grow and cause hair loss. Low ferritin levels also causes the hair to exhibit structural changes, dryness, an inability to hold curl or color well, and breakage\textsuperscript{[16]}.

Iron deficiency anemia is the most prevalent nutritional risk factor that faces the dermatologists in daily clinical practice\textsuperscript{[17]}. A serum Ferritin level is using for hair loss assessment and iron supplement is used routinely for hair loss treatment. In spite of this, other authors failed to prove that the iron has an effect on hair loss\textsuperscript{[18]}. Many observational studies have found the association between decreased Ferritin levels and hair loss\textsuperscript{[19-23, 1]}. The reason may be due to a fact that hair follicle matrix cells as the most rapidly proliferating cells in the body appear to have lower levels of Ferritin and higher levels of free iron\textsuperscript{[24]}.

Conclusions

1. There is a relationship between the level of ferritin & Hemoglobin in blood of people suffering from hair loss.

2. It also shows that the people with hair loss there decrease in the immune.

Group A B-Hemolytic Streptococci Infection among Children in Primary School in Samarra City

Asmaa Easa Mahmood

Department of Pathological Analyses, College of Applied Sciences, University of Samarra, Iraq

ABSTRACT

Three hundred children aged (3–12) year (160 males and 140 females), presenting with acute pharyngitis to the pediatric and ear, nose, throat (ENT) departments of Samara general hospital.

The study population was examined clinically for the presence or absence of signs and symptoms of pharyngitis, throat swab culture and the isolation of group A and other groups of β-hemolytic streptococci was confirmed using serogrouping strep test. The result of this study show that the isolation rate of β-hemolytic streptococci was 47.66% and of group A was 23.66% among the study population. The isolation was higher in the following situations (4–8) year olds, among children lived in crowded conditions, among children with recurrent tonsillitis. The antimicrobial susceptibility testing revealed that the highest sensitivity rate of the group A streptococci was to Azithromycin (80.3%) followed by Penicillin G (77.5%) and Ceftriaxone (74.7%). Gentamycin was the least effective antimicrobial agent tested.

Keywords: Group A β-hemolysis Streptococci, tonsillitis, Bacitracin, antimicrobial susceptibility patterns

Introduction

The genus Streptococcus which belong to the family streptococcaceae comprises a large and heterogeneous group of organisms, has broad significance in medicine and industry. Various Streptococci are important ecologically as part of the normal microbial flora of animals and humans; some can also cause diseases that range from subacute to acute or even chronic [1]. Streptococci are Gram positive organism, spherical or ovoid, and no larger than 2 μm in diameter [2].

The type of hemolytic reaction displayed on blood agar has long been used to classify the Streptococci. β-hemolysis is associated with complete lysis of red cells surrounding the colony. Serological subdivision of the Streptococci exploits differences in the group- specific polysaccharide antigens in the cell wall. Lancefield thus identified different groups of β- hemolytic Streptococci and her scheme includes 20 serogroups designated sequentially with the letters A-H and K-V [3]. According to this classification, Streptococci will be considered as follows: (i) Pyogenic streptococi (Lancefield groups), (ii) Pnumococci, (iii) Viridans streptococci, and (iv) Other, principally non-hemolytic streptococci [4].

Penicillin remains the drug of choice for group A streptococci, it is safe, inexpensive, and of narrow spectrum and there is no direct or indirect evidence of loss of efficacy [5]. The reason for the lack of penicillin resistance is not known. However, some strains have developed penicillin tolerance by inhibiting the bactericidal effects of the antibiotic [6]. Erythromycin is often used when allergy to penicillin is suspected or when a decision is made to treat a carrier. This may happen when there are recurrence of tonsillitis despite penicillin treatment [7]. GABHS are also susceptible to other macrolides like clarithromycin and azithromycin and also susceptible to cephalosporins [8].

There are significant resistance of GABHS to certain antibiotics in defined geographic areas; this has been temporally related to increased or excessive use of specific antimicrobial agents, the best example of this,
the macrolides resistance [8]. During the last few years, erythromycin-resistant \textit{S. pyogenes} has been reported in different parts of the world. Two distinct mechanisms of erythromycin resistance are described among group A streptococci. One consists of target site modification by erymethylase strains that express the MLSb phenotype of resistance; the other consists of an active drug efflux that pumps 14-and 15-membered macrolides out of the cell [9].

This study is conducted in order to determine the rate of isolation and antibiotic susceptibility of group A \(\beta\)-haemolytic streptococci among children with acute pharyngitis.

Materials and Method

The study was carried out during six months (October 2017 to March 2018) in Samarra general hospital located in the center of Samaraa city, 120 Km north of Baghdad. Three hundred children with acute pharyngitis were examined, aged 3–12 year from different areas of Samaraa city. Throat swab was taken by disposable cotton swab. The throat swab was rolled on two types of Selective media, the first was crystal violet blood agar (HiMedia/india) which is selective for GABHS and other streptococci and inhibit the growth of \textit{staphylococci} and some other bacteria [10]. The second selective medium was blood agar supplemented with sulphamethaxazole (23.75 \(\mu\)g/ml) and trimethprim (1.25 \(\mu\)g/ml) [11] which suppresses the growth of normal flora and growth of groups of C, F and GBHS. After inoculation, the plates were incubated aerobically at 37\(^\circ\)C for 18-24 hours.

Lancefield grouping of BHS: The lancefield serological system for identification of BHS is based on the immunological differences in their cell wall polysaccharide. After enzyme extraction, these group specific polysaccharide antigen are demonstrated when the enzymically extracted antigen is mixed with latex particles coated with the corresponding antibody and agglutinate it [12].

Antimicrobial susceptibility test: In this study, the disc diffusion method was used to assess the sensitivity of GABHS isolates to a number of antibacterial agent according to [13].

Results and Discussion

\(B\) \textit{hemolytic streptococci} were isolated from 143 (47.66\%) throat cultures, and 157 (52.33\%) of throat culture show growth of one or more of other bacteria. Isolation rates BHS groups are shown in table (1). Seventy one (49.65\%) of isolated BHS were group A and Seventy two (50.35\%) were non\_group A, among these group C from the highest isolation rate 28 (19.58\%) followed by group G 26 (18.18\%). Group A\(\beta\)-hemolytic \textit{streptococcus} associated pharyngitis is an important infection in children because of its potential to complicate into rheumatic fever and rheumatic heart disease. Despite progress in streptococcal vaccine design, there is no specific prophylaxis of group A streptococcal infection now, which determines the high value of antiepidemic measures [14]. So the primary prevention of spread of streptococcal pharyngeal infection and developing their sequelae depends on identifying children with GABHS in their throats. The results of this study show that BHS were isolated from 143 (47.66\%) throat culture and 52.33\% of our samples were negative throat culture to BHS. Similar results were reported [15,16].

That illustrates the large proportion of pharyngitis that is caused by bacterial pathogens in this population of children. The proportion GABHS among the BHS was 49.65\% which represent 23.66\% from the total examined children. This result was in agreement with that reported by [17] in AL_Tameem (21.3\%) and [18]. The reasons for this difference in solution rates of GABHS among different population are due to the age, population size, season, socioeconomic statutes, geographic location, environmental factors, residence and personal hygiene.

**Susceptibility to bacitracin:** Bacitracin susceptibility test was used as a presumptive method for differentiation of group A from other BHS. Table (2) show that the false positive result was 13.9%, i.e. Other group of BHS which were bacitracin sensitive, and false negative result was 7.40%, i.e. Serologically identified group A that were bacitracin resistant.

In our study, a presumptive differentiation of group A from other groups of BHS based on inhibition of the growth of group A by the use of bacitracin disc (0.04 unit). A false negative result of 7.04% and a false positive of 13.9% were detected when bacitracin sensitivity test compared with the Lancefield serogrouping test. The validity of bacitracin test in this study indicate sensitivity of 95% and specificity of 90%. Thus the bacitracin test was of value to differentiate between group A and other groups of BHS since it was with high sensitivity and specificity. Age has with high been reported to be an important factor in the microbiological, Etiology of pharyngitis[19].

Sensitivity = 95%; Specificity = 90%

**Age Distribution:** Table (3) show the isolation rate of BHS was highest in the 4-8 year age groups (67.2%) compared with 32.8% in other age group and same thing for GABHS (70.45%) in the 4-8 year age groups. In our study the age distribution of children according to throat culture results was 67.2% of BHS isolated from throat of children aged 4_8 year age groups compared with 32.8% in other age groups and 70.45% of GABHS was also isolated in children in same age group.

Type specific immunity that developed with age to the most serologic types of GABHS may explain why group A are isolated less frequently from human as they get older. In our study GABHS isolated more from children in age 4-8 years may be due to variation in number of children in different age group e.g. children in these age groups were more than other [20].

Crowding Index: The association between isolation rate of GABHS and crowding index is shown in table (4). Group ABHS was predominant (91.7%) in children with crowding index of three and over.

Several epidemiologic studies in developing countries have demonstrated that crowding index, poverty and low education are interrelated of diseases. In this work GABHS was predominant (91.7%) in children living in crowded conditions. This result was in agreement with that reported by [21]. It was possible that traditional behavior of mothers, poor personal hygiene, in adequate caring practices and poor sanitation may favor development of streptococcal pharyngitis.

The pattern of bacterial susceptibility to different antimicrobial agents varies considerably with different factors like geographical area, environmental conditions, and virulence of the organism [22]. Increased or excessive use of antimicrobial agents in treating all cases of throat infections although a high percent of these infections are viral rather than bacterial, this leads to significant appearance of antimicrobial resistance and treatment failure. For this reason susceptibility of GABHS were tested against ten antimicrobial in practice.
for the treatment guide lines have advocated for the use of penicillin as first line and the use of a macrolide in penicillin allergic individuals who are suspected to have GABHS pharyngitis. Although this believing that GABHS are uniformly highly sensitive to the action of penicillin, it is found in this study that 22.5% of the isolated group A were resistant to penicillin.

Our result was in disagreement with [23]. Who showed no penicillin resistance among BHS isolates. In our study a high resistant rates of GABHS were reported to gentamycin (63.4%) followed by lincomycin (46.5%) and ampicillin (42.3%).

Macrolides including erythromycin and lincomycin have been widely used for treatment of acute pharyngitis and invasive infection of GABHS. In our study the azithromycin resistance was 19.7% which is higher than (5.2%) that reported by [23].

Conclusion
The result of this study show that the isolation rate of GABHS, was age related crowding index and child history of tonsillitis. Group A form the highest isolation rate among other groups of B_haemolytic streptococci, group A strep isolates show highest rate to Gentamycin followed by Lincomycin and ampicillin.

ABSTRACT

Breast cancer is the commonest cancer affecting women worldwide. Different studies have dealt with the etiological factors of that cancer aiming to find a way for early diagnosis.

This investigation was carried out on 74 patients (all were females) who received satisfactory therapy. The present study investigated the relationship between BMI and evaluation of some etiological risk factors among breast cancer patients in Iraq.

They were confirmed for breast cancer by histopathological examinations at Nanakali Hospital in Erbil. All women were between 20-72 years. Ages, Weight, height, stage (II, III), hormone receptors ER, PR and Her2 were taken into account as risk factors.

Among the breast cancer patients, 45% were pre-menopausal and 28% were menopausal and 27% were post-menopausal. Body mass index (BMI) is widely used as a measure of obesity. We investigated the relationship between obesity (BMI ≥ 30 kg/m²) and outcomes in women with ER-positive early stage breast cancer.

Women with high BMI presented with more aggressive stage at the time of diagnosis. Their tumor usually show positive hormonal status (ER/PR), HR+/Her2- being the most Predominant molecular subtypes. most of obese women have tumor hormonal status positive with favorable molecular subtype (ER+/Her2-), thus Decreasing weight will mainly contribute to decrease tumor exposure to high endogenous estrogen especially in postmenopausal age dramatically effect response to treatment in return.

Keywords: BMI, Breast cancer, Risk factor

Introduction

Breast cancer is the commonest malignancy found in women in Europe and the United States, and the incidence continues to rise slowly (1). Breast cancer is the most common cancer among women in Arab countries with a younger age of around 50 years at presentation. Locally advanced disease is very common and total mastectomy is the most commonly performed surgery (2). In Iraq, breast cancer is the commonest type of female malignancy, accounting for approximately one-third of the registered female cancers according to the latest Iraqi Cancer Registry. This shows that the breast is the leading cancer site among the Iraqi population in general, surpassing even bronchogenic cancer (3).

Worldwide, at least 2.8 million people die each year as a result of being overweight or obese, and an estimated 35. 8 million (2.3%) of global Disability –Adjusted Life Years (DALYs) are caused by overweight or obesity. Overweight and obesity lead to adverse metabolic effects on blood pressure, cholesterol, triglycerides and insulin resistance. Risks of coronary heart disease, ischemic stroke and type 2 diabetes mellitus increase steadily with increasing body mass index (BMI), a measure of weight relative to height. Raised body mass index also increases the risk of cancer of the breast, colon, prostate, endometrium, kidney and gall bladder (4).

It was shown from studies that obesity is associated with the incidence of breast cancer (5-7). Overweight patients with breast cancer often have higher mortality rate than patients with normal weight. Obesity is a factor leading to poor prognosis in breast cancer (8-10). At present, body mass index (BMI) is applied to measure whether a person is obese or not. Both the weight and the height of the body are considered in BMI, which reflect the relationship between body mass and height. BMI is
easy to measure, and it is currently the standard index used internationally to measure the extent of obesity and to evaluate the overall fitness.

Materials and Method

Patients: This study was a retrospective-prospective study, carried out at Nanakali hematology/oncology hospital of Erbil on a sample of 74 cases, who were diagnosed with breast cancer (stage II and stage III).

Collected data included full questionnaire regarding (age, weight, height, body mass index) and clinic-pathological assessment (such as TNM staging, histology grade, ER/PR and HER2 status).

Body Mass Index (BMI): BMI was calculated as weight in kilograms divided by height in meters squared and rounded to the nearest tenth, according to the following equation (11).

\[
\text{Body Mass Index (BMI) = } \frac{\text{Weight (kg)}}{\text{Height m}^2}
\]

Following current recommendations, normal weight was defined as a BMI of 18.5-24.9, overweight as BMI of 25.0 to 29.9, and obesity as a BMI of 30.0 or higher (12).

Data Analysis: The relationship of BMI to the stage of breast cancer at diagnosis was evaluated using the x² test for frequency tables of BMI by stage of breast cancer. The Pearson correlation test was used to determine any association between BMI and age.

Results and Discussions

A total of 74 breast cancer patients (age range = 20–72 years) were included in the present study (Table 1).

Table 1: Menopausal Distribution of Breast Cancer Patients

We classified them into three age groups:

1. Premenopausal: women less than 45 years of age (45% of patients)
2. Menopausal women between 45 - 50 years of age (28% of the patients)
3. Postmenopausal those greater than 50 years of age (27% of the patients).

(81%) of our breast cancer patients had positive ER, (82%) of breast cancer patients had positive PR. About one third (38%) of our breast cancer patients had positive HER2 and 62% of them had negative HER2. These findings are shown in Table 2. This was similar to studies done in Iraq and Turkey (13, 14).

As regards the staging of breast cancer, according to AJCC staging, stage II and III breast cancer were found in 66.2% and 33.8% of the patients (Table 2).

They were classified according to BMI into three groups Normal (9.4% of the patients), Overweight (36.4% of the patients) and Obese (54.2% of the patients). Mean BMI of the studied breast cancer patients was 32.9 Kg/m² (Table 3).

</table>

There was a significant association between breast cancer patients with positive ER and obesity (p≤0.05), as showed in Table 4 and a significant association was also observed between Breast cancer women with positive PR and obesity. These findings are consistent with results of Peng Xing, et al study (15).

There was significant association between BMI categories and breast cancer patients regarding stage of tumor (Nottingham Grading System) (p <0.05). Data are shown in Table 4. Breast cancer patients in our study with TNM stage II and III were associated significantly with obesity (p≤0.05), see Table4. This finding agreed with results of study done by Eichholzer M. et al study and Cui y. et al study which suggested that higher body mass index was associated with advanced stages of breast cancer (16, 17). There may be several reasons for the observed association between body mass and stage of breast cancer at diagnosis. First, this association could be due to a delay in diagnosis among obese women. Overweight/obese women have larger breasts, and thus tumor detection may be more difficult in these women simply because tumors are more difficult to palpate in larger breasts. This hypothesis is supported by several studies that show a positive relationship between breast size and stage of breast cancer. (18) Second, obesity is associated with advanced breast cancer at diagnosis, high tumor proliferation rates, and more triple-negative phenotypes, indicating that it may adversely contribute to prognosis. (19) Some studies suggest that locally increased estrogen levels promote tumor growth. (20) Obesity causes an increased production of the estrogen known as estrone via the aromatization of androstenedione in peripheral adipose tissue. In addition, obesity is associated with low levels of sex hormone-binding globulins, which results in a significantly higher level of the biologically active, unbound form of estrogen known as estradiol. (15) Therefore, it is possible that obesity leads to an overall increase in the active levels of estrone and estradiol and that the high levels of these hormones promote the growth of breast tumors in obese women.

There is significant association between obesity and hormonal receptor subtype ER+/PR+ (P≤0.001), as shown in Table 5.

There is strong association between high BMI and ER+/PR + hormone receptor subtype in our study (p ≤0.001), as shown in Table 5. These results are somewhat similar to results of 9 cohort and 22 case-control studies comparing the highest versus the reference categories of relative body weight showed that the risk for ER+PR+ tumors was 20% lower (95% CI = −30% to −8%) among premenopausal (2, 643 cases) and 82% higher (95% CI = 55–114%) among postmenopausal (5, 469 cases) women (21). Current study found a significant association between obese postmenopausal breast cancer patients and HR+/Her- subtype (p<0.001) and this finding was more significant in postmenopausal obese women (p=0.001) as data show in Table 6. This finding agrees with results of study carried in Iraq (22).

Obesity has been recognized as a significant risk factor of breast cancer among postmenopausal women and is associated with poor prognosis. This result was in agreement with the results of another study that showed patients with high BMI are most clearly associated with hormone receptor–positive tumors and suggest that triple-negative tumors may have distinct etiology (23, 24).

This result disagrees with Lesley A. Stead study that triple negative tumors were equally common in black wo men diagnosed before and after age 50 (31% vs 29%), and who were obese and non-obese (29% vs 31%). Considering all patients, as BMI increased, the proportion of triple negative tumors decreased (p=0.08) (25). Body mass index (BMI) is widely used as a measure of obesity. Dignam et al. investigated the relationship between obesity (BMI ≥30.0 kg/m²) and outcomes in women with lymph node-negative, ER-positive early stage breast cancer. They found that obese women as compared with normal weight women had greater all-cause mortality (26). Obesity also has an adverse prognostic effect in women with lymph node-negative and ER-
negative breast cancer. However, this prognostic effect has not been consistent and may be influenced by several factors such as menopausal status, extent of disease, and receptor status (27, 28)

Conclusions

1. Most of Iraqi women with breast cancer were either obese or overweight at the time of diagnosis.
2. Women with high BMI presented with more aggressive stage at the time of diagnosis. Their tumor usually show positive hormonal status (ER/PR), HR+/Her2- being the most predominant molecular subtypes.
3. Increase awareness for not only breast cancer patients but also their physician about the importance of weight control during management of breast cancer patient and also breast cancer survivors.
4. Hence most of obese women have tumor hormonal status positive with favorable molecular subtype (ER+/Her2-), thus decreasing weight will mainly contribute to decrease tumor exposure to high endogenous estrogen especially in postmenopausal age, dramatically effect response to treatment in return.

Approaches of Removal Missed intrauterine Contraceptive Device (IUD)

Khalidah Mohammed Amin

Department of Gynecology & Obstetric, College of Medicine, Kirkuk University, Iraq

ABSTRACT

Background: Globally, more than one hundred million women choose intrauterine contraceptive device (IUD) for family planning. The complications related to IUDs are minor with low incidence and included pain, pelvic inflammatory disease, bleeding, ectopic pregnancy and missing or malposition of IUD. The missing IUD may be caused by displacement, perforation, embedding or expulsion of IUDs in uterine cavity or in peritoneal cavity. Current study was aimed to evaluate the pattern of diagnosis and management of missed or migrated intrauterine contraceptive device (IUD) by minimal access surgery, laparoscopy & hysteroscopy.

Method: The study was a prospective study in (54) patients referred to gynecological department in Azadi Teaching Hospital in Kirkuk between September 2009 and April 2018. The site of missed (IUD) was diagnosed by ultrasonography and x ray.

Results: Intrauterine contraceptive devices were removed after dilatation of cervix and exploration of uterine cavity in (28) patients, (7) cases by hysteroscopy, (15) cases by laparoscopic removal, in (3) cases by laparotomy and in one case IUD was taken out through cystoscopy.

Conclusion: It is recommended that approach for removal of missed IUDs should be planned according to the site. Laparoscopy is superior to laparotomy in perforated outside the uterus. Intrauterine device should be inserted by trained medical professionals.

Keywords: IUD, Laparoscopy, Hysteroscopy, Laparotomy, ultrasonography.

Introduction

Globally, more than one hundred million women choose intrauterine contraceptive device (IUD) for family planning [1]. The IUDs are regarded as common and effective contraceptive method [2]. The complications related to IUDs are minor with low incidence and included pain, pelvic inflammatory disease, bleeding, ectopic pregnancy and missing or malposition of IUD. The missing IUD may be caused by displacement, perforation, embedding or expulsion of IUDs in uterine cavity or in peritoneal cavity [3]. These missing complications had an incidence rate of less than 1%, but they are serious and accompanied by high risk of uterine perforation [4]. Prevalent risk factors accompanying the missing IUDs are inexperience of physicians, type or size of IUDs, lactating women and anomalies of uterus or cervix [5]. The removal of IUDs is commonly easy and safe procedure accomplished by detecting the IUD strings with grasping and pulling [6]. In Iraq, many complications were reported in relation to the intrauterine contraceptive devices like bleeding and migration or missing device [7, 8].

Diagnosis of missing IUD is dependable on regular evaluation of women after insertion of IUD every 6 months by history, physical examination, plain x-ray and trans-vaginal ultrasound examination. Two- or three-dimensional ultrasonography are routinely used for assessment of IUDs complication. However, in some cases with visceral perforation, computerized tomography is used [9]. Most of women with missing IUD were diagnosed in first 3 months after insertion of IUDs [10, 11].

Email: khalidagyn@gmail.com
Laparoscopy and laparotomy were also used for management of missing IUDs and associated with high effectiveness rates and less complications [12, 13]. These removal procedures could be implemented with or without anesthesia according to severity of complications as in some cases using only paracervical block, while in uterine perforation cases, general anesthesia is mandatory. For pregnant women, the IUD either left inside or removed if associated with high risk on pregnancy [11-13].

Unfortunately, Iraqi women had low knowledge and interest in family planning in addition to primitive weak national family planning program which is dependable on newly graduated low experienced physicians [14,15]. For that, this study was aimed to evaluate the pattern of diagnosis and management of missed or migrated intrauterine contraceptive device, by minimal access surgery, laparoscopy & hysteroscopy in a sample of Iraqi women.

Patients and Method

The design of current study was prospective clinical follow up study that was carried out in Gynecological Department of Azadi Teaching Hospital in Kirkuk governorate in Iraq through duration from 1st of September 2009 to 30th of April 2018. Study population was all women referred to Gynecology Department with missing intrauterine contraceptive device. Reproductive age group women with missing IUD were the inclusion criteria. The exclusion criteria were women with normal or ectopic pregnancy with IUD, and those women that refused to participate. A sample of 54 women with missing IUD was included in the study. The ethical considerations were in accordance with Helsinki Declaration and oral or written consent was taken from each woman before enrolling in the study. Approval of study was obtained from hospital authorities and the researcher was responsible for monitoring and managing the women with missed IUD.

The suspected women with IUD were referred from primary health care centers or from private clinics. After their admission, assessment of women was done by the researcher through taking history, clinical and gynecological examinations. The women were referred to x-ray unit in the hospital for Trans-vaginal or abdominal ultrasonography and some of them to abdominal, pelvic and hysterosalpingogram with uterine sound x-rays. The ultrasonography and x-ray were done for women with missing IUD by Radiologist in Azadi Teaching hospital or in private clinic (Figures 1 and 2). The diagnosis was confirmed by the researcher. Other principal pre-operative investigations, like blood film, blood sugar, HIV and hepatitis viral screen, were done in the laboratory of the hospital.

Planning for management and approaches implemented were done by the researcher depending on status of the women and availability of treatment facilities. Conventional approach was done by dilation of the cevix and exploration of uterine cavity searching for IUD strings and this approach was done for missing IUDs that appeared by ultrasonography, close and easily grasped. The conventional approach was done under local or general anesthesia. Regarding laparoscopic approach, it was done by the researcher in laparoscopy room in Azadi hospital for pregnant women and those unfit for general anesthesia or cannot tolerate pain. Laparoscopy equipment was not always available during study period. Laparatomy was done for women with perforated uterus or migrated IUD to adjacent viscera. This surgical operation was implemented in Surgical Theater of Azadi Teaching Hospital by the researcher.
under general anesthesia. Hysteroscopy and cystoscopy were done for special cases of women who failed in removing missing IUD by conventional approaches and cystoscopy was done for one case diagnosed as vesicle stone and missed IUD. All the women with missing IUD were followed up for 1 month after removal of IUDs by three visits to hospital and checking by researcher in addition to phone calling to assess the post-procedure complications of each procedure like pain, fever, bleeding, suturing infection, etc. The anesthetic complications were assessed intra- and post-operatively by the researcher which might be nausea and vomiting, anaphylaxis, respiratory depressions, etc. Duration of each procedure and hospital stay of women were also recorded by the researcher.

The data collected were analyzed statistically by SPSS software version 22. Chi-squared test and Fischer’s exact test were applied for analyzing data as suitable. Level of significance (p value) was regarded statistically significant if it was ≤0.05.

**Results**

This study included 54 women with missing IUD. Mean age of studied women was 32.4 years; 13% of them were less than 20 years age, 31.5% of them were in age group 20-29 years, 51.8% of them were in age group 30-39 years and 3.7% of them were ≥40 years. Mean parity of women with missing IUD was 3 children; 14.8% of them had 1-3 children, 66.7% of them had 4-6 children and 18.5% of them had more than 6 children (Table 1).

There was significant association between conventional approach for removing missing IUD and higher rate of post-procedure complications (p=0.02); women with laparoscopic removal of IUDs had no complications. No significant differences were observed between different approaches of IUDs removal regarding anesthesia complications (p=0.6). A significant association was observed between shorter procedure duration and laparoscopic removal of missing IUDs.
IUDs (p=0.006). Longer hospital stay was significantly prevalent for women with laparotomy while shorter hospital stay was significantly observed for women with laparoscopic removal of IUDs (p=0.002) (Table 4).

Discussion

The intrauterine contraceptive device is public family planning method used worldwide [16]. Despite its importance and safety, it has a low rate of complications such as bleeding, pain, displacement, infection and pregnancy [13]. Present study revealed that during 9 years period, 54 women were collected with missing IUD. In Nigeria, 10 years follow up study by [17] found that among 44,975 women with IUD, 168 women of them had missing IUD. These data confirming facts that complications of IUD are characterized by low rate (less than 1%) [18]. Mean age of women with missing IUD was 32.4 years. This finding was similar to results of [2] in Iran who found that age of woman with missing IUD was within age group 30-39 years. The mean parity of women with missing IUD was 3 children. Similarly, [19] reported para 3 for woman with missing IUD. Pregnancy was observed in 11.1% of women with missing IUD. A recent Turkish study reported that retaining IUD in uterine cavity of a pregnant woman results in high risk of premature rupture of membranes [20].

Current study showed that mean duration of missing IUD was 3.6 months. This finding was consistent with results of previous studies [21,22] who reported that high proportions of women with missed IUD were within first six months after insertion and mostly in mean of 3 months. In our study, Cooper IUDs represented prevalent type for missing IUDs. Similar findings were reported by [23] who found high prevalence of Cooper IUD type for missing IUD among studied women, however, this higher prevalence was attributed to long life of Cooper IUD type that may reach 10 years which was experienced to have high rate of missing.

In present study, 51.9% of women with missing IUD were managed with conventional approach, while 27.8% of them were managed by laparoscopy. This finding was similar to results of [24] who documented that most of women with missing IUD were managed by dilation of cervix and exploration of uterine cavity. This conventional method is common in hospitals of developing countries as the facilities for other approaches are limited [25]. The post-procedure complications were significantly higher for women with missing IUD managed by conventional approach. This finding coincides with results of [1] who reported high complications rate for conventional approach of removing missing IUD in comparison to other approaches. Our study showed that laparoscopic removal of missing IUD was associated significantly
with shorter procedure and hospital stay durations. These findings were in agreement with results of [26] who found that laparoscopic removal of missing IUD is accompanied with high success rate and safety in addition to shorter hospital stay.

**Conclusion**

The laparoscopic removal of missing intrauterine contraceptive device is a safe approach. It is recommended that removal approach should be planned according to the site, as laparoscopy is superior to laparotomy in perforated outside the uterus. Also, intrauterine device should be inserted by trained medical professionals.

The Study of Photothermal Effects of Radiation Laser on Human Skin Tissue

Sahib Neamah Abdul Wahid1, Ahmed Jumaah Mhawes2, Abeer Khudhair Atya1

1Department of Physics, Faculty of Education for Girls, 2College of Medicine, University of Kufa, Najaf, Iraq

ABSTRACT

Background: The physical principle of laser is the mutual effect between light and material. The energy produced by this effect can be precisely guided. This makes its use in biological materials results in tissue changes that can have therapeutic advantages. However, it should be noted that inappropriate use of radiation intensity invalidates and destroys the skills of surgeons. The aim of current study to study thermal and optical properties of human skin layers.

Results: Thermal penetration depth (of human skin layers (Epidermis, Dermis and Fatty tissue) increased with increasing the time(t seconds). Also, optical penetration depth (L/mm) of human skin layers (Epidermis, Dermis and Fatty tissue) was increasing with decreasing absorption coefficient(α/m). Moreover, increasing heating relaxation time () with decreasing the absorption coefficient (α/m).

Conclusion: As it was observed that the thermal penetration depth value of human skin layers was increased with increasing the time. Therefore; increasing optical penetration depth values with decreasing absorption coefficient of the human skin layers (Epidermis, Dermis and Fatty tissue). Also, increasing the heating relaxation time with decreasing absorption coefficient of human skin layers.

Keywords: Optical Penetration depth, time, Ztherm, heating relaxation time, absorption coefficient.

Introduction

The physical principle of laser is the mutual effect between light and material. The energy produced by this effect can be precisely guided. This makes its use in biological materials results in tissue changes that can have therapeutic advantages. However, it should be noted that inappropriate use of radiation intensity invalidates and destroys the skills of surgeons. The optics properties of skin depend on the shape, thickness and amount of melanin in skin tissues. The surgeon must know the characteristics of the tissue he is dealing with. It is necessary to know the type of laser (whether it is pulse or continuous), the intensity of the pumping and the wavelength of the laser[1,2].

In addition, it is necessary to know laser reaction with tissues as the biologic effects of different radiations differ in the different tissues. These effects can depend on the reflection of.

Thus, there is a specific use for each type of laser and depends on the therapeutic effects of laser on the spread of heat produced by radiation of the tissue. If it is carried out or reflected, there is no effect in it. In the case of dispersion of radiation, it means absorption of a larger area of the tissue and the spread of its effects and weakness. The degree of energy absorption by the tissue is determined by the wavelength of the laser and the length of exposure of tissue to the radiation.

Other factors include the size and speed of blood flow in the blood vessels as well as the intensity of the cutting area when the laser is used to cut the tissue[3-6].

The type of laser absorbed by the tissue may cause symptoms like clicking, cut the bleeding, fumigation and cracking of tissues[7].
Distribution and quantity of highly absorbing chromophores, for example haemoglobin and melanin, also scattering structures, for example filamentons proteins may affect light transport inside the skin \[8\]. Through the equation, which is called spectrum intensity-weighted average, we can calculate the effective optical absorption coefficient of human skin tissues (hair, epidermis and dermis)\[9\].

\[
\mu_x = \mu_y \cdot v_{f_y} \cdot S_{f_y} + \mu_{water} \cdot v_{f_{water,x}} \cdot S_{f_{water,x}} \quad \ldots(1)
\]

\(\mu\) = optical absorption coefficient, \(v_f\) = volume fraction of chromophore (collagen and blood) to the melanin and dermis for hair and epidermis, \(S_f\) = the spectrum percentage absorbed via chromophore and water, \(x\) = hair, dermis and epidermis, \(y\) = chromophore and water, \(X\) = the water inside tissue \(x\).

**Theory of Study**: This study depends on the laser interaction with human skin, The cell contains water and other chemical components, Two types of interactions are there; thermal and chemical.

The thermal effects on the tissue can result in:
1. Changes in cell membrane,
2. Changes in the nature of cells.
3. Composition of molecules.
4. Cut in the continuity of the tissue.

These effects lead to changes in viscosity, density and water content. Photothermal effects are affected by vaporization of water in the human skin layer. Moreover, the thermal properties are different in dermis, fatty tissue and epidermis \[3,10-12\] as shown in Figure (1).

**Beer’s Law showed\[13\]**:

\[
I_Z = I_0 \exp(-\mu_a Z) \quad \ldots(2)
\]

\(Z\): thickness

\(I_Z\): Absorbed intensity measured in W/cm\(^2\)

\(I_0\): Incident intensity measured in W/cm\(^2\)

\(\mu_a\): absorption coefficient measured in cm\(^{-1}\)

In addition, Wien’s displacement law showed\[5\]:

\[
\lambda_{max} = \frac{2898}{T} \quad \ldots(3)
\]

\(\lambda_{max}\) = the maximum wave length, \(T\) = temperature

where \[14\]:

\[
\lambda_{max} \propto \frac{1}{T} \quad \ldots(4)
\]

**Results and Discussion**

**The relation between absorption Coefficient and Optical Penetration depth in human skin layer**

Optical Penetration depth of the layer of the human skin was measured according to the following equations\[13\]:

\[
L = \frac{1}{\mu_a} \quad \ldots(5)
\]

\(L\) = Optical penetration depth

\(\mu_a\) = Absorption Coefficient

Absorption Coefficient of the layer can be found by using Laser Diode at wave length 1552nm which was showed in the Table (1)\[10\].

**Table 1: The relative amid thickness and absorption Coefficient**

Double Lumen Subclavian Catheter Complications among Patients with End Stage Renal Disease on Continuous Hemodialysis

Mohammed Hakim Shamran Al-Hchaim¹, Bashar R. Mohammed Ali¹, Abeer Miri Abdullah¹

¹Adults Nursing, Faculty of Nursing, University of Kufa, Iraq

ABSTRACT

This study aims to assess the double lumen subclavian catheter complications among patients with end stage renal disease and to find out the relationship between the patient double lumen subclavian catheter complications and their demographic characteristics.

A descriptive study was carried out through the present study in order to achieve the early stated objectives. The study was begun from February, 1st, 2017 to April, 10th, 2017. The study is conducted in Al-Najaf City in Iraq in dialysis centers of Al-Sadder Medical City and Al-Hakeem General Hospital. A non-probability (Convenience) sample of (29) patients with ESRD who are admitted to the dialysis centers. The data was collected on structured questionnaire designed specifically for this study, and it is consist of two parts: Part 1 Included Socio-demographic characteristics, and Part 2 Include (13) items concerned with the complications of double lumen subclavian catheter.

Double lumen subclavian catheter for hemodialysis is preferred by many because catheters can be left in longer than femoral or jugular catheters in mobile patients, but the subclavian vein catheterization is associated with a variety of complications.

The researcher can conclude that the infection of the catheter’s orifice is high percentage among double lumen subclavian catheters complications and the result shows that there is no significant relationship between socio-demographic data and complications.

The study recommends that the catheter should be performed only by trained personnel and should enhance the methods of sterile techniques in hemodialysis unit to decrease infection by improving the nursing practice through training course.

Keywords: Double Lumen, Subclavian, Catheter, End Stage Renal Disease, Hemodialysis.

Introduction

Renal failure (RF) is global health problem, which strikes millions of people worldwide, and causing either a lifetime severe disability or death. About (110,000) patients in the United States started treatment for RF in 2007 (1). A hemodialysis machine has a special filter called a dialyzer, or artificial kidney, to clean your blood. To get blood into the dialyzer, the doctor needs to make an access, or entrance, into blood vessels. This is done with minor surgery, usually to the arm. Three different types of access can be made—a fistula, a graft or a catheter (2).

The third type of access, called a catheter, is inserted into a large vein in the neck or chest. This type of access is generally used when you need dialysis for a short period of time. Catheters may be used as a permanent access but only when a fistula or a graft cannot be placed. The patient will be referred to a special surgeon for placement of the access (3-7).

The major risks are the complication associated with insertion (8). With expert techniques these complications

Corresponding Author:
Mohammed Hakim Shamran Al-Hchaim
Adults Nursing, Faculty of Nursing,
University of Kufa, Iraq
Email: muhammedh.alhjem@uokufa.edu.iq
are extremely uncommon. Chronic complications include catheter related sepsis, thrombosis of the catheter which will cause neck swelling and venous hypertension in the extremity \(^9\). Venous access under ultrasonographic and fluoroscopic guidance has the added advantage of significantly reducing the rate of immediate complications \(^5\). Inadvertent arterial puncture, ateriovenous fistula, thoracic duct injury, brachial plexus injury, laceration of the subclavian vein, and air embolism are the well described complication of the central line insertion \(^6\).

Materials and Method

**Design of the Study:** A descriptive study was carried out through the present study in order to achieve the early stated objectives. The study was began from February, 1st, 2017 to April, 10th, 2017 in Al-Najaf City in Iraq in dialysis centers of Al-Sadder Medical City and Al-Hakeem General Hospital.

**The Sample of the Study:** A non-probability (Convenience) sample of (29) patients with ESRD who are admitted to the dialysis centers.

**The Study Instrument:** A questionnaire was constructed by the researcher to assess the double lumen subcalvian catheter complication among patients with end stage renal disease. The questionnaires was constructed and composed of two parts Part 1: Scio-Demographic characteristics consisted of (8) items, including (age, gender, residency, socio-economic status, educational level, marital status, duration of disease and duration of dialysis). Part II. Complications of double lumen subclavian catheter consisted of (13) items.

**Data Collection:** The data was collected individually by interview technique in the hemodialysis center. They were interviewed in a similar way, in the same place, for all the sample who were included in the study.

**Data Analyses:** The data of the study were analyzed through the use of statistical package of social sciences (SPSS) version 19 through descriptive and inferential statistical analyses. The statistical data was analyzed by using descriptive statistics and inferential statistics.

**Results**

The majority of the study sample is within the first category of age groups and accounted for (31.0%). also shows the majority of the study sample (55.2%) are males and the remaining are females (44.8%). Relative to subject, residency, the results indicate that the majority of study sample (58.6%) were from rural area. In addition, the study results indicate that (62.1%) of patients were exhibit satisfied to some extent in related to socio-economic status. Also the study results indicate that the high percentage (34.5%) of study sample are illiterate in related to the level of education. Regarding to the subjects marital status, the majority of them are married and they accounted for (62.1%) of the whole sample.

Furthermore, with hemodialysis period, the study result shows that the majority of the study subjects (79.31%) were under hemodialysis for (one) year. Finally, with duration of renal failure, the study result shows that the majority of the study subjects (51.72%) were under renal failure for (one) year.

The frequencies of complication in patient with double lumen subclavian catheter: about 13 (44.8%) of patients have failure to insert catheter puncture, 7 (24.1%) of patients have puncture of subclavian artery, 6 (20.7%) of patients have inadvertent entry of the catheter into internal jugular vein, 16 (55.2%) of patients have bleeding, 18 (62.1%) of patients have the infection of the catheter’s orifice, 17 (24.1%) of patients have infectious endocarditis, 17 (58.6%) of patients have thrombosis of subclavian vein, 8 (27.6%) of patients have delayed pneumothorax, 16 (55.2%) of patients have insufficiency flow, 17 (58.6%) of patients have bacteremia related with the catheter. Finally, 7 (24.1%) of patients have the accidental extrusion of the catheter (Table 1, Figure 1).

### Discussion

The results of the present study show that the higher percentage of the study sample with in age group (41 – 52) years old. (10) pointed in their study that the highest percent “84 (42.0%) were in 40-59 age group”. (11) find that the majority of study sample were between 41-50 age years.

Regarding to the study subjects gender, the results indicate, that the majority of the study sample are males. Which is in consistency with (12), they mentioned that “the characteristics of the studied patients was 80: 47 (58%) men and 33 (42%) women”.

Regarding to marital status, the majority of study sample are married. This result is agreed with (13), he found that the highest percentage is for married patients. In addition, it’s clear that the patients in the same age are often married when compared with those with early age groups. Also those patients are part of the east population; those population often marry early, as compared with other people from other cultures.

In regarding to the duration of disease, the majority is for those who are suffering from the disease for more one year, which is in consistency with (14) in his dissertation “Internal Jugular Vein Cannulation with Two Silicone

**Fig. 1: The complication of double lumen subclavian catheter**

P-value < 0.05: significant relationship
Rubber Catheters: A New and Safe Temporary Vascular Access for Hemodialysis” who mentioned that the majority of study subjects suffer from disease < 1 year.

In addition to the duration of dialysis, the majority of study subjects are dialyzed for period one year and less than. (15), in agreement with this result they found that the majority of study subjects were use dialysis for (>6 months).

Double lumen subclavian catheter for hemodialysis is preferred by many because catheters can be left in longer than femoral or jugular catheters in mobile patients. However, subclavian vein catheterization is associated with a variety of complications including failure to insert catheter puncture, puncture of subclavian artery, inadvertent entry of the catheter into internal jugular vein, bleeding, the infection of the catheter’s orifice, infectious endocarditis, thrombosis of subclavian vein, delayed pneumothorax, hemothorax, hematoma, insufficiency flow, bacteremia related with the catheter and the accidental extrusion of the catheter.

This result is supported by many previous study (10,12,16), they mentioned that many complication occur with insertion of subclavian catheter. Also all them mentioned that “the most common complication were failure to cannulate (4%) and inadvertent arterial puncture (4%). In adventent arterial puncture in our study was similar to a study by (6) in which it was found that Arterial puncture occurred in 9.7% among on which 13 had resultant subcutaneous hematoma. This might be due to less prominent anatomical landmarks for subcutaneous insertion and deeply located veins requiring steeper angle for catheterization. The second commonest complication was mal-positioning/kinking in 2% cases. Some of the insertion related complications can be reduced with the aid of image guidance during catheter placement. However the use of ultrasound guidance during subclavian venous catheterization had mixed results in clinical trials, probably for anatomical reasons”.

Some of the above mentioned complications are comparatively low in number probably because of the small size and majority of the insertions were carried out by the well-trained personnel. Also stated the patients that had catheter at the initiation of the dialysis presented a higher morbidity and mortality than those who have had a fistula – the survival at 12 months was 60% vs. 83%.

Concerning the result related to associations between duration of disease and clinical data for patients with ESRD: The present study reveals that there is no significant association between study subject duration of disease and their clinical data. These finding agrees with a study of (10), in their study “Complications of Insertion of Double Lumen Catheter in Subclavian Vein in Patients of Renal Failure” they stated that there is no significant association between patients’ duration of disease and complication of cannulation.

**Conclusions**

According to the result of present study, the researcher concluded that: double lumen subclavian catheter for hemodialysis is preferred by many because catheters can be left in longer than femoral or jugular catheters in mobile patients but this access associated with many sever complications like (bleeding, infection of the catheter’s orifice, thrombosis of subclavian vein, insufficiency flow and bacteremia related with the catheter), also the result shows that there is no significant relationship between socio-demographic data and double lumen subcalvian catheter complications.

Nutritional Status Assessment among Children with Autistic Spectrum Disorder

Arafat Hussein Aldujaili¹, Sura Hassan Al-Hares², Aliaa Makki Alsafi³
¹Medical college, University of Kufa, Iraq; ²Community Medicine, Najaf Health Directorate, Iraq; ³Community Medicine, University of Baghdad, Iraq

ABSTRACT

The childhood Autism was a neurodevelopment disorders that symptoms are appear throughout the patient’s life which is characterized by lack of social & communication interactions in addition to repetitive, restricted interests and behavior. Recent studies revealed that the commonness of Autism Spectrum Disorders is rising, which could be because of diagnostic classification of ASD been updated. An essential step in the autism treatment is earlier detection to convalesce the quality of life of subjects.

The aim is to conclude the nutritional status of ASD children in Al-Najaf province 2015

A descriptive cross–sectional study conducted to evaluate state of nutrition in children with autism. Convenient model of autistic children in (Al Imam Al Husain Institute of Autism) and autistic patients in psychiatric department in AL-Hakeem hospital from 30th of April 30th of August 2015. The data were collected by questionnaire developed and filled by investigator through direct interview with autistic patient parents that visit psychiatric department in Al-Hakeem hospital and from case study sheet that present in AL-Imam Al Husain Institute of Autism which include ID, gender, residency, age of child (or date of birth??), the age level of education of parents, their occupation, and by measuring weight and height of children and compare with wt./age, wt/ht, ht/age & BMI/age growth charts. Epi-info software and Excel sheet for entry and analysis of data.

The sample size was 98 child, 86 boys and 12 girls & males to females ratio was 8:1, age groups were (28%) ≤ 5yr,72 % more than 5 year in which (52%) of them were normal, (33.9%) were overweight and (14%) were underweight, (28%) of the ≤5yr. were (45%) of them were overweight (37%) of them had underweight,& (16%) were normal, no significant association between the nutritional state with gender, residency, father’s oldness, mother’s oldness, father’s vocation, mother’s vocation, father’s scholastic achievement and but there were significant association between level of education of mother and age group. p value 0.03. and between age group of children and NS p value less than 0.0000.

Most cases below and equal 5 yrs. were overweight& obese 45% and large percent of above 5years 33% were overweight & obese, there is significant associations between nutritional status and level of education on of mothers for children >5 years and NS.

Keywards: Autism Spectrum Disorders (ASD), Pervasive Developmental Disorders group (PDD).

Introduction

The Autism Spectrum Disorders (ASD) is characterized of sober Neuro-developmental disorders, categorized as symptoms of the Pervasive Developmental Disorders group (PDD). The disorder often develops in the first three years of lifespan [1]. Its described by a distinct weakening in social interaction, suspended employment of linguistic and constrained configurations of behavioral; labelled as a triad

Corresponding Author:
Arafat Hussein Aldujaili
Medical college, University of Kufa, Iraq
Email: arafat.aldujaili@uokufa.edu.iq
of behavioral impairments. In add-on, autistic kids commonly exhibit serious behavioral instabilities, such as hostility, irritabilities and self-mutilating conduct [2, 3]. The occurrence of ASD is growing global. It is anticipated that at tiniest 10-20 per 10 thousand babies are born yearly with autism [4].

Whilst autism is exceedingly inheritable, investigators questionable both ecological and genomic dynamics as triggers [5]. In erratic suitcases, autism is strappingly concomitant with proxies that because birth absconds[6]. Arguments mount other projected ecoterrorist origins [7], for instance, the vaccine postulations have been refuted. Autism touches information managing in the brain by modifying in what way nerve cells and their synapses associate and unify; in what way this ensues is not satisfactory comprehended [8]. It remains lone of three predictable illnesses in the autism spectrum disorders (ASDs), the other two actuality Asperger syndrome, which absences postponements in cognitive elaboration and speech, and pervasive developmental disorder, not else specified which is spotted when the packed traditional of standards for autism or Asperger syndrome are not encountered [9].

Prompt idiom or behavior intercessions can aid kids with autism advance self-care, societal, and communication proficiencies [2]. Though nearby is no notorious therapy [2], there have been recounted patients who improved [10]. Not countless autistic patients alive autonomously after accomplishment maturity, nevertheless fewer suited fruitful [11]. An autistic society has established, with some personages pursuing a treatment and others deeming autism must be acknowledged as a dissimilarity and not cured so an illness [12].

The aim is to conclude the nutritional status among ASD children in Al-Najaf province.

**Materials and Method**

**Data Collection Time:** From 30th of April 30th of August 2015.

**Study Population Sampling:** Convenient sample patients with autism in (Al Imam Al Husain Institute of Autism) and autistic patients in psychiatric department in AL-Hakeem hospital.

Inclusion criteria all patient from age 3—19 years old and diagnosed as ASD.

Exclusion criteria every patient that visit psychiatric department and present in Al Imam Al Husain Institute of Autism) to avoid duplication of patient, and all patient less than 3 years old because ASD not diagnosed before that age and not more 19 years old.

**Data Collection Tools:** By questionnaire developed and filled by investigator through direct interview with autistic patient parents and from case study sheet the questioner including ID, gender, residency, age of child, father’s oldness, mother’s oldness, father’s & mother’s scholastic achievement etc. and by measuring weight of children in kilogram using UNICEF SCALE which using in screening after standardization and measuring the height of children in centimeter by stadiometer after bearing of feet and standing in upright position and by using growth charts weight for age and sex (normal if the point of intersection between age and weight at normal line of Z score, above if point of intersection between age and weight above normal line of Z score, below if point of intersection between weight and age below normal line of Z score), length for age and sex (normal, above, below by consuming Z results), weightiness on behalf of length and gender for kids fewer than five years (Z scores) and BMI for age and either normal, hazard of weighty, fatness, wasting & greater wasting) and weight for age and sex, age for height sex, and BMI for age and sex charts for children above 5 years old. Epi-info software and Excel sheet for entry and analysis of data. Family writing consents approved before measuring height and weight.

**Limitations**

1. Some child with ASD hyperactive so too difficult to get uprights position to measure the weight of child.
2. Increase days’ number of holidays because of hot weather that limit sample size.

**Results**

The whole selected sample was 98 children with ASD, the reported age range from 3-11years (39 -129) months, the mean age was 72.7 months with (stander deviation = ± 18.8) month, 86 of them were males & 12 were females, The males to females’ ratio 8:1. (Figure 1).
The majority of the age group 72% more than 5 years, 28% was less than 5 years which is shown in Figure (2).

Most of the cases found in urban region (86%) and (13.9%) in rural area (Figure 3).

The father ages range from 20- 50years; most of them (53%) were within 30-39 years age group, (34%) in 40-49 years age group and (12%) within age group 20-29 years as shown in Figure (4).

While the age of the mothers was ranged between 15-45 years in 3 main age groups most of them (48%) within the age group 25-34 years, (41%) of them within 15-24 years and the minority (11%) within age group 35-44 years as in Figure (5).

The educational levels of the fathers ranging from literate to post graduate studies & most of them were colleges graduated (54%), (35%)were secondary level, (8.2%) were primary level while post graduates form only (2%) as in Figure (6).

The levels of education of the mothers were (47%) of them were colleges graduates,(35%)were secondary levels, 16% primary levels and (1%) were illiterate.

Regarding the occupation of the fathers (48%) of them were employed, while the remainder were police men, workers and others. While most of the mothers were housewives, employs, worker and the others (students).

It was found that 50% of the autistic children were high weight for age by using weight for age and sex growth chart, while 31% were wasting and just 19% is normal.

By using the height for age growth chart it was found that 51% of the autistic children were above normal, 36% were below normal while just 13% were normal.
The weight for height chart showing that 62% of children less than 5 years old were above normal, 29% of them were below normal while only 8.3% of them were normal.

About (23%) of all sample size were below or equal to 5 years old, who were distributed according to their BMI & by using the BMI for age chart & found that 11(45%) of them were overweight, 9 (37%) of them had wasting, & 4 (16%) were normal. While in children over 5 years with ASD 74 (72%) out of the total sample it was found that 38 (52%) of them were normal, 25 (33%) were overweight and 11 (14%) were underweight.

By testing the association between the nutritional status with gender, residency, father’s oldness, mother’s oldness, father’s employment, mother’s employment, scholastic achievement of fathers and mothers it was discovered that there were not at all significant association, but there was a significant association between nutritional grade and level of schooling of mother and nutritional state and age groups.

**Discussion**

The total no. of sample size is 98, males to females’ ratio 8:1 higher than the study done in [13] in which it was four times among boys (4:1) than girls, this may be due to small sample size or may be the family concentrate attention toward male than female.

The majority were found in urban area which may reflect that the people in rural remote sites lack of autism signs awareness by parents and even by doctors, in addition to limited psychiatric health services in Al-Najaf where there is only one psychiatric department in one hospital (Al-Hakeem general hospital) which is located in center of Al-Najaf which is responsible to diagnose ASD and there is no psychiatric department in rural area.

Regarding the educational levels of the fathers & mothers of the ASD cases; most of them (47% of mother cases & 53% of father cases) were college levels because they were alert to their abnormal child’s behaviors than those in the other levels, and could be also due to their high socioeconomic status.

Regarding the occupation of the fathers most of them were employee (48%) like physician, engineer, teache etc., which reflect their educational levels and their awareness toward their children [13]. The same is true for the occupation of the mothers where 46% of total sample size were college levels, but most of them were housewives 60% which may be due to special care needed for their children.

The weight for age nutritional status assessment 50% of cases were obese & overweight which can stay accredited to that the offspring per autism were further often over heaviness competed to those with Attention Deficit Hyperactivity Disorder (ADHD) and to an age accorded allusion populace [2]. Others reveal that over-eating remains unique of furthermost corporate adverse consequence of medicine secondhand for tension linked behaviors in autism disorders [3].

The height for age assessment 51% of them were tall for their age, this is may be related to their good nutritional status & overweight.

The BMI chart for age. For children 5 years old & less, there is frank percent (45%) of overweight or obese, and for children larger than 5 years old the overweight and obesity were (33%) of sample size, this is due to patients with ASD consumed be stated to have unfamiliar eating traditions, which well-known that patients with ASD have distastes to particular surfaces, insignia, aromas, heats, and trademark labels of nutrients, with some partialities for lenient and sweetened foodstuffs [4-7].

High percentage of overweight & obesity is similar to national study conducted in Karbala [14] were obese and overweight forms 54% of total sample size. In, Scheck et al. [8] who conveyed that broods with autism validated added diet discrimination than characteristically emerging kids and they favored vigor condensed nourishments within diet clusters for instance chicken nugget, peanut lard, cake, sausage etc.). In totaling, persons may have nonconforming bodily commotion and consumption designs that are exclusively linked with the progress of fatness, & they are acknowledged to have motor deficiencies that may unfavorably disturb their capability partakes in sporting or corporeal accomplishments magnificently. Such motor deficiencies incorporate deprived motor proficiencies, unfairness of child-development milestone attainment, little muscular tone, mouth motor complications, & postural unsteadiness [9-12]. In toting, kids plus ASDs
may knowledge little intensities of physical commotion owing to their deficiencies in community proficiencies which might edge contribution in systematized behaviors with colleagues. Indeed, a modern report discovered that praxis/motor scheduling in kids with autism was powerfully connected among the societal, communicative, & behavior deficiencies that demarcate the illness [15].

Other study done in USA 2004 exploiting body mass index pro oldness & gender [16] which amount the occurrence of obesity in offspring amid long-lasting illness, this study unearthed that the commonness of obesity amongst kids thru autism was 23.4%. In toting to the report completed by Carol Curtin [17] wherever the occurrence of obesity in Autistic’s children was 30.4% which proximate the outcome in existing study?

In this study by testing the association between the nutritional status with gender, residency, age of the fathers, & mothers, occupation of the fathers, & mothers, educational level of the fathers and mothers it was found that there were no significant association, but nearby existed a significant relationship amongst nutritional state & scholastic accomplishment of moms were most of the normal weight children more than 5 years old in non-college level may be due to those mothers spent more time with their children and care about them than those with college level most time are busy and the children receive the attention from other person. Other significant association between nutritional status and age groups could be due to most of the sample size 62% of children from 6-8 years were normal weight.

Conclusion

Most cases below and equal 5 yrs. were overweight & obese 45% and large percent of above 5 years 33% were overweight & obese, there is significant associations between nutritional status and level of education on of mothers for children >5 years and NS.

Recommendations

1. Nutritional education of the mothers of ASD children about dietary pattern and avoid high caloric meals and encourage healthy foods

2. Training courses to parent, teacher in kindergarten and schools GP doctors about early detection of ASD in early childhood.

3. Media coverage in considering the predisposing factors stated in development the constellation of sign and symptom of ASD

In vitro Experimental Research for Using the Silver Nanoparticles as Plasmid Curing Agent in Some Types of Multi-Antibiotic Resistant Pathogenic Bacteria

Ahmed A. Mhawesh¹, Hasan A. Aal Owaif², Sura A. Abdulateef²

¹Dept. of Med. and Mol. Biotech., College of Biotech, Al-Nahrain University, Iraq; ²Dept. of Applied Sciences, Division of Biotech., University of Technology, Iraq

ABSTRACT

Background: Nanomaterials, between the present scenarios, bear born new avenues in medicine, diagnosis, or therapeutics. In try concerning this, the present-day discipline goals in imitation of deciding the working efficiency concerning silver nanoparticles in accordance with treatment plasmids of bacteria.

Method: A total of sixteen multi-antibiotic resistant isolates made up of 4 (25%) Escherichia coli, 4 (25%) Pseudomonas aeruginosa, 4 (25%) Staphylococcus aureus and 4 (25%) Streptococcus pyogenes were collected from different samples of burn and wound infections from patients attended to Al-kadhemyiah Teaching Hospital/Baghdad/Iraq. These strains were diagnosed molecularly by PCR on 16S rRNA using primers named 27F and 1492R; which yielding of 1,500bp or extra as shown with sequencing data.

Results: Strains showed multi antibiotic resistance to Gentamycin, Ciprofloxacin, Ofloxacin, Ampicillin, Nitrofurantoin and Erythromycin respectively. Resistance plasmid DNA of multi-antibiotic resistant strains used to be cured with three different concentrations of 0.75, 1.5, and 3 ppm of silver nanoparticles were confirmed by PCR technique for plasmids curing assay where, at 0.75 ppm of silver nanoparticles the plasmid curing percentage relatively were 50%, 75%, 100% and 100% respectively while at 1.5 ppm plasmid curing percentage were 75%, 50%, 100% and 100% and at 3.0 ppm plasmid curing percentage were 100%, 100%, 100%, 100% for (Escherichia coli, Pseudomonas aeruginosa, Staphylococcus aureus and Streptococcus pyogenes respectively) and cured traces have been again subjected to in vitro antibiotic sensitivity trying out to confirm curing actions.

Keywords: antimicrobial resistance, multi-antibiotic resistance, nanoparticles, silver.

Introduction

Infectious illnesses stay certain regarding the lead motives of vice and mortality worldwide. The WHO and CDC have expressed giant hassle involving the continued extend into the improvement of multidrug drawback amongst bacteria (1). This has caused initiatives world after enhance fresh yet more positive antimicrobial compounds as properly namely in accordance with enhance new delivery then targeting strategies (2). The antimicrobial property concerning silver nanoparticle is the fundamental purpose because its wide-scale usage, which consists of software program inside antibacterial fabrics, cosmetics, cloud filters and medicinal or meals packaging products (3). The bactericidal impact concerning silver among its more than a few chemical varieties has been exploited for the reason that historical civilizations, in the course of the 18th century, silver used to be typically back in accordance with deal with contaminated ulcers, yet greater recently, within the quickly 1920s, Ag-NPs were blanketed because anger treatment by using the US Food and Drug Administration due in accordance with their intensive toxicity in opposition to a huge spread regarding microorganisms (4,5). In this review, we pleasure reduce the contemporary lookup over nanoparticles yet what it is then may be applied in the after fight multidrug strong bacteria.
Also, its animadversion consists of the latest procedures among the development over modern nano biotechnology methods so may additionally project the scientific action after battle bacteria or particularly MDR bacteria.

Materials and Method

Sampling: Nanoparticles form silver were imported from NANO pars SPADANA Technology. The concentration was 4000 mg/l for silver Nanoparticles and six antibiotics were used as follows: gentamycin (GEN), ciprofloxacin (CPR), nitrofurantoin (NIT), ampicillin (AMP), chloramphenicol (CHL) and erythromycin (ERY) were commercially purchased from laboratory achievements; from Sigma Company (St. Louis, MO). In addition, more than 170 wound and burn swabs about sufferer’s reception therapy at the scientific wards of the Al-Kadhemyiah Teaching Hospital/Baghdad, Iraq have been randomly selected. Collection over samples used to be made barring attention because of age, sex, occupation or household background.

Processing over Samples: The silver nanoparticles have been stored in sealed glass bottles kept in a dark area at apartment heat (~25°C) then different concentrations (0.75, 1.5 and 3.0ppm) of silver nanoparticles were prepared from the stock solution of silver nanoparticles that hold the concentration of 4000ppm. Obtained swabs had been made to the laboratory right away for processing. Two swabs were taken from each patient. Swabs were collected in duplicates per a patient. While one was used for Gram staining, the other was used for culture.

Antibiotic Sensitivity Testing: This is used to be once celebrated between pursuance among consequence concerning the modified (6); Disc diffusion technique. Sterile Mueller Hinton agar plates and peptone water were prepared and dispensed into plane tubes in accordance with manufacturer’s instructions.

Phenotypic and genotypic characterization regarding the bacterial strains: Phenotypic characterization was carried out by mounting part of the viable culture and observed under the microscope to determine the morphological characteristics (7). Genotypic characterization of bacteria was carried out using wizard genomic DNA extraction kit, Agarose, Ethidium Bromide Solution (10mg/ml), GoTag Green Master Mix, nuclease free water, absolute ethanol, isopropanol, TAE 40X, Quantifior dsDNA system from Promega, USA (https://worldwide.promega.com/resources/) according to the manufacturer’s instruction.

MIC and MBC undertaking concerning silver nanoparticles: Minimal Inhibitory Concentration (MIC) was determined by broth micro-dilution technique based on the protocol described by (8). Cultural growth indicator was used to check the efficacy of nanoparticles against the test organisms. Gentamicin was used as a positive control and bacterial growth in the plate was inspected visually.

Plasmid Extraction: Extraction of bacterial plasmids was done by the following of PureYield™Plasmid Miniprep System protocol. This kit was purchased online and accomplished as provided instructions. (www.promega.com • Phone 608-274-4330 or 800-356-9526 • Fax 608-277-2601)

Plasmid Curing: Plasmid curing of Staphylococcus aureus, Streptococcus pyogenes, Escherichia coli and Pseudomonas aeruginosa strains that were antibiotics-resistant (did not show any zone of inhibition after incubation on Muller Hinton agar plates) where done by, to 10ml of overnight nutrient culture broth of it with different concentrations (0.75, 1.5 and 3.0ppm) of silver nanoparticles were added. The resulting of serial suspensions were then used as stock solutions and then incubated for up to 2 days then tested for presence of plasmid(s) or not by PCR technique.

In vitro Antibiotic Sensitivity Testing concerning Cured Strains: Plasmid cured traces have been once more subjected according to antibiotic sensitivity testing in accordance in imitation of the approach about Kirby-Bauer meanwhile described above.

Statistical Analysis: Statistical evaluation was performed using SPSS version 21.0.0 software program (SPSS Inc, Chicago, USA).

Results

Out of the 170 samples processed, only 120(71.0%) strains were isolated, made up of 41(35.0%) Staphylococcus aureus, 22(19.0%) Streptococcus pyogenes, 19(16.0%) Escherichia coli and 36(30.0%) Pseudomonas aeruginosa strains were obtained. In addition, results of current study showed that 8(19.5%) Staph. aureus, 4(18.1%) Streptococcus pyogenes, 5(26.3%) Escherichia coli and 12(33.3%) Pseudomonas aeruginosa strains showed multi-antibiotics resistance (Table 1).

From all the isolates mention above, a total of sixteen isolates made up of 4 (25%) Staphylococcus aureus, 4 (25%) Streptococcus pyogenes, 4 (25%) Escherichia coli and 4 (25%) Pseudomonas aeruginosa which were diagnosed as multi-antibiotic resistant strains where chosen to check their antibiotics sensitivity before and after curing by treatment with different concentrations of 0.75, 1.5, and 3 ppm of silver nanoparticles as a curing agent.

**Bacterial Strains Diagnosis:** *In vitro* genotypically, the chosen strains were diagnosed by PCR amplification, agarose gel electrophoresis was adopted to confirm the presence of amplification. All processes including Bacteria gDNA extraction, PCR amplification, sequencing and assembly. For these Bacteria, PCR on 16S rRNA using 27F and 1492R primers and yielding 1,300 bp or more sequencing data. The presence of 16s RNA genes of unknown bacterial species were fractionated on 1% agarose gel electrophoresis stained with Eth.Br. Lane 1: 100 bp DNA marker (Figure 1)).

**Standard Sequencing:** PCR product was sent for Sanger sequencing using ABI3730XL, automated DNA sequencer, by Macrogen Corporation – Korea. The results were received by email then analyzed using genious software.

**Figure 1:** PCR amplification of 16s RNA gene of bacterial species was fractionated on 1% agarose gel electrophoresis stained with Eth.Br. Lane 1: 100 bp DNA marker.
Minimum Inhibitory Concentration and Minimum Bactericidal Concentration: The MIC and MBC of silver nanoparticles against all chosen multi-antibiotic resistant bacterial strains in this study were found to be 0.75 and 3ppm, respectively.

Curing Activity of Silver Nanoparticles: The results of using silver nanoparticles at different concentrations (0.75, 1.5, and 3ppm) against chosen multi-antibiotic resistant bacterial strains to check their plasmid curing activity was cleared by their actions in comparison with six antibiotics sensitivity tests % (gentamycin, ciprofloxacin, ofloxacin, ampicillin, nitrofurantoin and erythromycin) before and after treatments (Tables 2, 3 and 4).

After curing, *Staphylococcus aureus* didn’t show any sensitivity change to ciprofloxacin (CPR) as all strains remained sensitive before and after treatment with different concentrations (0.75, 1.5, and 3ppm) of silver nanoparticles. There were (50, 50, 50 and 50%) reduction in resistance to gentamycin, ampicillin, nitrofurantoin and erythromycin, respectively, after treatment or curing with concentration 0.75ppm of silver nanoparticles. Also there were (75, 75, 75 and 75%) reduction in resistance to gentamycin, ampicillin, nitrofurantoin and erythromycin, respectively, after treatment or curing with concentration 1.5ppm of silver nanoparticles.

After curing, *Streptococcus pyogenes* didn’t show some sensitivity trade to ciprofloxacin (CPR) so all traces remained sensitive before yet below treatment along special concentrations (0.75, 1.5, and 3ppm) of silver nanoparticles. There were (50, 50, 50 and 55%) reduction within resistance in conformity with gentamycin, ampicillin, nitrofurantoin and stability erythromycin, respectively, afterwards cure yet curing with awareness 0.75ppm concerning silver nanoparticles. However, every line remained preventive after ofloxacin before then below curing (Tables 3). On average, at that place have been (45.8, 66.6, and 75 %) reduction between obstruction to the antibiotics since curing at concentrations (0.75, 1.5, and 3ppm) of silver nanoparticles, respectively.

In concerning to *Pseudomonas aeruginosa* strains after curing, they gave (25,25, 25, 25 and 25%) reduction in resistance to gentamycin, ciprofloxacin, Ofloxacin, ampicillin and erythromycin, respectively, after treatment or curing with concentration 0.75ppm of silver nanoparticles. Also there were (50, 50, 75, 50 and 50%) reduction in resistance to gentamycin, ciprofloxacin, Ofloxacin, ampicillin and erythromycin, respectively, after treatment or curing with concentration 1.5ppm of silver nanoparticles as well as there were (75, 75, 75, 100 and 75%) reduction in resistance to gentamycin, ciprofloxacin, Ofloxacin, ampicillin and erythromycin, respectively, after treatment or curing with concentration 3.0ppm of silver nanoparticles.
Curing activity of silver nanoparticles: In vitro genotypically, the results of using silver nanoparticles at different concentrations (0.75, 1.5, and 3ppm) against chosen multi-antibiotic resistant bacterial strains to check their plasmid curing activity is cleared by their actions by applying PCR manifestation or agarose gel electrophoresis was adopted after ensuring the presence concerning manifestation earlier than yet then treatments (Figure 2).

These results clarify that the curing activity of different concentrations of silver nanoparticles (0.75, 1.5 and 3.0ppm) against these selected strains. The curing percentages were 50%, 75%, 100% and 100%, respectively, while at 1.5ppm plasmid curing percentages were 75%, 50%, 100% and 100%, however, at 3.0ppm plasmid curing percentage were 100%, 100%, 100% and 100% against Escherichia coli, Pseudomonas aeruginosa, Staphylococcus aureus and Streptococcus pyogenes, respectively. Each percentage recorded above evaluated as numbers of band missing or standing in each adding curing agent (silver nanoparticles).

**Discussion**

Over the preceding not many decades, even has been a developing pastime concerning exploring alternative techniques after format then develop present day antimicrobials appropriate between conformity including the excellent study concerning microbial resistance in the direction of oft ancient antibiotics (9). Silver nanoparticles (Ag-NPs) hold learnt significant activity due to imitation along their alluring physicochemical homes. Several reports have shown so nanoparticles committed above about extraordinary basic metals execute lie back to flail each stopping then nonresistant bacterial strains (10). Ultimately, within current manuscripts, a lot on researchers improve in their workshop so silver nanoparticles so focused on multidrug stopping bacteria as S. aureus, E. coli, P. aeruginosa along extraordinary mechanisms on antibacterial moves as like bacteriostatic and bactericidal agent (11), it attempts hold been widely explored due to the fact that they furnish environmentally friendly or reasonably-priced routes in conformity with the synthesis over metal nanostructures, within addition in imitation of being effortlessly scalable production processes.

**Conclusion**

Resistance plasmid DNA of multi-antibiotic resistant lines used to be cured with three different concentrations of 0.75, 1.5, and 3ppm of silver nanoparticles were confirmed by PCR technique for plasmids curing assay where at 0.75ppm of silver nanoparticles the plasmid curing percentage relatively were 50%, 75%, 100% and 100%, respectively, while at 1.5ppm plasmid curing percentage were 75%, 50%, 100% and 100% and at 3.0ppm plasmid curing percentage were 100%, 100%, 100% and 100% for Escherichia coli, Pseudomonas aeruginosa, Staphylococcus aureus and Streptococcus pyogenes, respectively, and cured traces have been again subjected to in vitro antibiotic sensitivity trying out to confirm curing actions.

ABSTRACT

**Background:** Fig moth *E. cautella* (Lepidoptera: Pyralidae) is an economically important pest in the world, because it infects the storage product of wide range of agricultural crops specially grains and their derivative foods. This has directed the need for development of alternative strategies which are safe, low cost and effective against pest and the more important strategy is the biocontrol which includes the use of pathogens, parasitoids and plant extract. This study was conducted to evaluate the activity of the neem oil of *Azadirachta indica* and *B. thuringiensis* alone and in combination in controlling fig moth *E. cautella*.

**Method:** the study evaluated the effect of *Bacillus thuringiensis kurstaki* on larvae of *E. cautella*, the effect of Neem oil in the larvae of *E. cautella* and the the combined effect of *B. thuringiensis kurstaki* and Neem oil on larvae of *E. cautella*. Statistical analysis was conducted using completely randomized design CRD and Duncan test. Probit analysis was used to obtain the median lethal concentrations (LC₅₀) in addition to the median lethal time (LT₅₀), within SPSS system version 20.

**Results:** The results showed that there was significant increase in the effect of *B. thuringiensis* with increasing the concentration on the larvae of fig moth and the percentages of death were 9.7% and 50% at the concentrations 0.01% and 0.1%, respectively, after one day of treatment with a median lethal concentration (LC₅₀) 0.1 and increased to 53% and 100%, respectively, after four days of treatment with LC₅₀ of 0.008%. The effect of neem oil on the larvae of *E. cautella* showed a marked variation with the concentrations. The effect of the combination of *B. thuringiensis* and neem oil showed an increase in the mortality rate of larvae treated with both of them compared with the treatment of each separately.

**Conclusion:** *B. thuringiensis* and neem oil induced significant insecticidal effects on larvae of *E. cautella*, higher mortality was observed when the larvae were treated with both *B. thuringiensis* and neem oil in comparison to larvae that were treated with only one of these bioinsecticides. There were no indications of any side effects on human, environment and natural enemies.

**Keywords:** *Ephestia cautella*, Biocontrol, *Bacillus thuringiensis*, Neem oil, LC₅₀

Introduction

Fig moth *E. cautella* (Lepidoptera : Pyralidae) is an economically important pest in the world, because it infects the storage product of wide range of agricultural crops specially grains and their derivative foods. This has directed the need for development of alternative strategies which are safe, low cost and effective against pest and the more important strategy is the biocontrol which includes the use of pathogens, parasitoids and plant extract[1].
**B. thuringiensis** are gram positive bacteria, spores producing bacteria and have good characters that make them good biocontrols. It produces certain protein called Cry- protein that has insecticidal activity and was used commercially as a biopesticide.\[2\] The neem plant *A. indica* (Meliaceae) distributed in tropical and subtropical regions throughout the world and has been given much attention due to its chemical components.\[3\] Another study showed that the azadirachtin may directly influence the growth and development of treated insects through the inhibition of growth, death of larvae and decrease of age and fertility.\[4\] The individual effects of biocontrol agents have been well studied on different pest insects, but there are relatively few studies on the combined effects of them; therefore, current study was aimed to study the effects of neem oil and *Bacillus thuringiensis* alone and in combination on the fig moth (*E. cautella*).

**Materials and Method**

**Effect of Bacillus thuringiensis kurstaki on larvae of E. cautella:** Toxicity of *B. thuringiensis kurstaki* for the larvae of *E. cautella* was tested by exposing the fifth larval stage to 0.01%, 0.03%, 0.05% and 0.1% of bacterial suspension, as follows: 1) Direct spraying of each concentration, and then transfer the larvae to petri dishes containing 5g of diet. 2) Feeding on mixture of diet and bacterial suspension (3ml/10g), 3) treat the larvae by contamination the pieces of filter paper with bacterial suspension in the Petri dishes containing 5g of diet. 4) Control treatment by use of distilled water as an alternative to bacterial suspension of all previous exposure conditions. All treatments (3 replicates, 10 larvae/replicate) incubated under the same conditions of rearing, the larvae were monitored and rate of daily mortality was calculated.

**Effect of Neem oil in the larvae of E. cautella:** The effect of neem oil on fig larvae was evaluated by exposing the fifth larval stage to 0.0, 0.5%, 1%, 2%, 3% and 5% of the neem oil with 0.01% Tween-80 to facilitate solubility and emulsification with all cases described in the previous paragraph. All treatments (3 replicates, 10 larvae/replicate) incubated under same conditions of rearing, the larvae were monitored and rate of daily mortality was calculated.

The combined effect of *B. thuringiensis kurstaki* and Neem oil on larvae of *E. cautella*: The synergy between neem oil and Bt was performed by treating the fifth larval stage with 1% neem, 2% neem, 0.01Bt, 0.03Bt, 1% neem+0.01Bt and 2% neem+0.03Bt. All treatments (3 replicates, 10 larvae/replicate) incubated under same conditions of rearing, the larvae were monitored and rate of daily mortality was calculated. The data corrected by using\[1\] equation. The expected mortality of the treatment with a combination of both agents was obtained using the formula: \(E = O_a + O_b \times (1-O_a/100)\); where E represents the expected mortality and \(O_a\) represents the observed mortality caused by the neem alone and \(O_b\) is observed mortality caused by of *B. thuringiensis* alone.\[5\] Chi-squared (\(X^2\)) test was performed by calculating the \(X^2\) value using the formula:

\[X^2 = (O_c - E)^2/E\]

Where \(O_c\) represents observed mortality for combination treatment, and then compared to the table value for df 1 (>3.84). If the calculated \(X^2\) value exceeds the tabulated value, it indicates a non-additive effect (either synergistic or antagonistic) of the two control agents. A significant interaction of neem oil- Bt combination was determined through the difference of \(O_c\) \(\leq\) E, where positive = synergistic and negative = antagonistic. If the tabulated value exceeds the calculated \(X^2\) value, it represents an additive effect at \(P\leq0.05\).

**Statistical Analysis:** Statistical analysis was conducted using completely randomized design CRD and Duncan test. Probit analysis was used to obtain the median lethal concentrations (\(LC_{50}\)) in addition to the median lethal time (\(LT_{50}\)), within SPSS system version 20.

**Results and Discussion**

The effect of *B. thuringiensis* on larvae of *E. cautella*: The results (Table 1) showed that the death of larvae increased significantly with increasing the concentration of bacterial suspension and the percentages of death were 9.7%, 50% at the concentrations 0.01%, 0.1%, respectively. After one day of treatment with a median lethal concentration (\(LC_{50}\)) of 0.1%, the death of larvae increased to 53% and 100%, respectively, after four days of treatment with \(LC_{50}\) of 0.008%.

The percentages of death of larvae were increased also with increasing time after treatment which was 9.75
days after one day of treatment and increased to 53% after four days of treatment at the concentration 0.01% and the LT$_{50}$ was 4.2 days, while the percentages of death of larvae at the concentration 0.1 were 50% and 100% after one and four days, respectively, and the LT$_{50}$ was 1.1 day.

Table 1: The effect of B. thuringiensis on the larvae of E. cautella

There were no significant differences between the exposure methods (Filter paper contamination, Diet or Spray) of larvae to bacterial suspension (Figure 1), but the saturated filter paper was the best one in which the percentage of death was 77%.

Figure 1: Effect of treatment methods of Bt suspension 0.03% on mortality of E.cautella larvae

The color of dead larvae had been changed from white to brown and then black and this may be due to the effect of the toxin of Bacillus thuringiensis. This result agreed with the result of [6] who referred to the dead larvae and pupae of Culex and their color changed to brown and they referred also to the stopped feeding after ingestion of toxin, because the Cry toxin binds to midgut receptor and then inserts into the membrane to form lytic pores and causes septicemia and changed the color to brown.

The effect of neem oil on larvae of E. cautella: The result of the effect of neem oil on larvae of E. cautella (Table 2) showed that the effect was corporate with the concentration and percentage of mortality after one day of treatment was 13.3% at the concentration 0.5% and increased to 37, 42, 47 and 64% at the concentrations 1, 2, 3, 5%, respectively, and the LC$_{50}$ was 2.78%. The percentages of mortality increased after four days of treatment which were 44%, 91% at the concentrations 0.5 and 5%, respectively, and the LT$_{50}$ was 4.99 days at the concentration 0.5% and decreased to 0.7 day at the concentration 5%.

The study of the effects of exposure methods of larvae to neem oil (Figure 2) showed that the saturated filter paper method more effective than other methods and the percentages of mortality of larvae was 43, 54 and 76% after 24, 48 and 72 hr. Lowest percentage of mortality was recorded with the diet method which was 50.4% after 72 hr.

Figure 2: Effect of treatment methods of neem oil 5% on mortality of *E. cautella* larvae

The result also showed that the neem oil elongates the diapause period of treated larvae and emergence of abnormal adults, longest diapause period was recorded at the concentration 5%. These alterations may be due to the effect of alkaloids extracts like phenols and terpenoid which affect the development process like the effect on juvenile hormone which is important in the development of diapause to adult [7].

In this study, the lowest amount of food consumed was observed in larvae, this reduction in feeding was at least partially attributed to a reduction in \( \alpha \)-amylase activity. The level of \( \alpha \)-amylase may be a key factor in the efficient propagation of this pest insect [8].

Moreover, [9] mentioned that the neem oil was more effective than the insecticide Hocklicombi in the inhibition of the emergence of adults through the development of the fig moth *E. cautella*. Also, [2] recorded that the LC<sub>50</sub> of neem oil against the pest *H. armigera* was 12.95 mg/ml and affects the age length, productivity of female and the diapause emergence, the LC<sub>50</sub> of *Bacillus thuringiensis* against the same pest was 96.8 mg/ml.
The results also were in agreement with the result of \[10\] who found that the neem extract caused concentration-dependent effects on the mortality of pupae and the pupae that failed to emerge in adults had multiple abnormalities.

**Integral effect of *B. thuringiensis* with neem oil against larvae of *E. cautella*:** The study of the effects of the combination between *B.thuringiensis* and neem oil against larvae of *E. cautella* (Table 3) showed that there was an increase in death of larvae that were treated with *B.thuringiensis* combined with neem oil compared with larvae that were treated with each one alone. The percentage of death in the case of combination between (1% neem +0.01% Bt) was 80% after four days of treatment, while in the case of *B.thuringiensis* (0.01% Bt) alone was 53.7% and neem oil (1% neem) alone was 73% with significant differences between them.

The median effective time to cause 50% mortality (\(LT_{50}\)) was decreased in all combination treatments compared with the individual treatments and the lowest \(LT_{50}\) was recorded at the combination between 2%Neem + 0.03% Bt which was 0.97 day.

</tbody>
</table>

A chi-squared comparison that exceeds 3.84 with df= 1 and \(\alpha= 0.05\) is considered synergistic.
The difference between *B. thuringiensis* and neem oil in their efficacy against *E. cautella* may have resulted from the nature and mode of action of these bioagents and the synergism that shown between *B. thuringiensis* and neem oil may be partially explained by their binding to different receptors on the same midgut cell and targeting same tissue, this cooperation had been reported previously [11].

The synergistic relation between *B. thuringiensis* and neem oil may depend on different factors like the dose that was combined, the mode of action, the type of target pest and the environment. A study [6] was conducted to evaluate the synergistic effect of *B. thuringiensis* and botanical insecticide containing azadirachtin in different sublethal combinations against *Spilarctia obliqua* revealed that there was no synergistic effect observed when treatment was given at level 0.021% of Btk + 0.06% of azadirachtin, but it was observed when treatment was given at level 0.003% of Btk + 0.004% of a zadirachtin and this result was in agreement with that of this study.

**Conclusion**

*B. thuringiensis* and neem oil induced significant insecticidal effects on larvae of *E. cautella*, higher mortality was observed when the larvae were treated with both *B. thuringiensis* and neem oil in comparison to larvae that were treated with only one of these bioinsecticides. There were no indications of any side effects on human, environment and natural enemies so this study indicated that both *B. thuringiensis* and neem oil, either individually or in combination, have significant potential for use in controlling programs of *E. cautella*.

ABSTRACT

Background: Lithotriptic technique by shock wave is a common medical method in management of calculi in the kidney. Stones are formed when salts and mineral substances were crystallized in the kidney as an outcome of disturbance in the metabolism. The study objective was to assess lithotripsy technique by shock wave in treatment of kidney stones.

Method: 234 patients were recruited randomly at the period from January to December 2018 at lithotripsy unit in Baquba Teaching Hospital. All patients had kidney stones. Their ages ranged from 18–75 years. Patients were treated by shock waves 1100-4000 impulse per minutes.

Results: This study showed that 33% were females (60% had stones in left kidney, while 40% had stones in right kidney) and 67% were males (69% had stones in left kidney versus 31% who had stones in right kidney), stones size ranged between (7–19) mm. The outcome of treatment by shock waves included: 164 patients had complete breakdown of stones at first session, 43 patients had successful fragmentation of stones at second session and 27 patients had best crushed of stones at third session.

Conclusion: From the obtained outcome in the present study, we concluded that the lithotripsy technique by shock wave was effective and vital procedure for management of kidney stones.

Keywords: Kidney stones, lithotripsy, shock waves, fragmentation.

Introduction

Lithotriptic technique by shock waves is a common medical method for management of calculi in the kidney [1]. In this technique used shock waves with high energy that were generated from lithotripter machine and then these shock waves were concentrated by focusing system and sent into the body, passes through tissues and hit the target (kidney stones) [2] by sequences of shock waves the stone will fragment into small particles which can be excreted out of the body during urination [3]. Calculi are formed when salts and mineral substances were crystallized in the kidney as an outcome of disturbance in the metabolism [4]. There are many factors that lead to form calculi in kidney such as [5]:

1. Dehydration: It is most common factor that contributes to calculi formation.
2. Some disease such as hyperparathyroid. 3- Medications intake.
4. Inflammation in urinary tract.
5. Diet with high protein (especially animal protein), salt, calcium oxalate[6].

Materials and Method

This study included 234 patients. They were included randomly from lithotriptic unit at Baquba Teaching Hospital during the period from January to December 2018, their ages were between (18–75) years. All patients had calculi in the kidney, they were examined by radiography (tacked X-ray picture) to detect location of stones and their size then all of them transmitted to lithotriptic unit for management by shock waves.

The patient was positioned in supine on the treatment table over apparatus (head therapy). Fluoroscopy was used as a guide for detecting location of stones and then
directed shock waves toward stones, sizes of stones ranged (7–19) mm. A sequence of shock waves were required to fragment stones in kidney (different numbers of shock wave impulses were used depending on fragmentation of stones), range of shock waves and energy were increased gradually until reached in some cases a maximum of 4000 shock waves and 9 joule of energy.

Table (1) showed that 157(67%) of patients were males, while 77(33%) were females and a higher percentage of patients who had stones in kidney at the age group (30–39) year, including 62(26.5%) males and 28(12%) females. Regarding site of stones, 109(69%) males and 46(60%) females had stones in the left kidney. **Moreover,** according to body mass index, we noted that a high percentage of patients had normal weight where 150(95.5%) of were males and 65(84.4%) were females and regarding types of stones, results from current study indicated that the majority of patients had solitary stones where 147(93.6%) of them were males and 62(80.5%) were females. Furthermore, related to size of stones, we found that common size of stones was between (7–9.9) mm.

Table (2) showed that successful fragmentation of stones in 164 patients (115 males and 49 females) at first session and in 43 patients (26 males and 17 females) at second session and indicated that complete fragmentation of stones in 27 patients (16 males and 11 females) at third session.

Discussion

Current study was done to assess lithotripsy technique by shock wave in treatment of stones in kidney. The results showed that the majority of patients had stones where 157(67%) were males and 77(33%) were females, so stones were more prevalent in males due to different factors that contributed to forming stones in kidney as males had larger mass of muscles than females and metabolic abnormalities “tissues were broken-down daily that leads to increase the waste produced from metabolism” [7,8]. Our results showed highly significant difference between both genders (P<0.000), the result conformed those of [9,10].

Regarding age, most of patients who had kidney stones were at age group (30–39) years, this result agreed with [11,12], another study [13] found that more occurrence of renal calculi in patients at age group (30–50) years. The present study demonstrated significant relationship between age and incidence of stones (P<0.001).

According to the site of stone, there was no relationship between localization of stones and their occurrences. We found that 109(69%) of males and 46(60%) of females had stones in left side, this result was in agreement with [14].

In the present work, we found that majority of patients who were with normal weight 150(95.5%) were males and 65(84.4%) were females. Our results were similar to the results of study done by [15].
Patients who had solitary stones were 147 males and 62 were females, whereas 10 males and 15 females had multiples stones. Present study accordant with [16]. A large number of patients, 164 males and 49 females, showed excellent fragmentation of stones at first session, while 43 patients (26 males and 17 females) were treated during second session and remaining 27 patients were managed from stones at the third session, fragmentation of stones were different depending on [17]:

1. The properties of materials that the stones were composed of.
2. Number and energy of shock waves that strike the stones.
3. Respiratory movement may lead to missed shots of shock waves [18].
4. Body mass index affected the results of management, if the patient is overweight, the physician can’t put the stones precisely at the target point [19].

Our results were in agreement with [20,21] as these studies showed successful treatment of stone in kidney by using lithotripsy technique by shock waves.

Conclusion

From the obtained outcomes in the present study, we concluded that the lithotripsy technique by shock wave was effective and vital procedure for management of kidney stones.

Urinary Tract Infection Caused by *Escherichia Coli* and its Resistance to Antibiotics in Pregnant Women

Akmam Ali Habeeb

*Department of Biological Sciences, College of Sciences, Wasit University, Kut, Iraq*

ABSTRACT

**Background:** The infections that affect urinary tracts and caused by pathogenic bacteria are called urinary tract infection (UTI). It has been mentioned that the infection rate of UTI is increased in women due to their sex-based changes and revealed that UTI rate increases in women with type 2 diabetes, because of hormonal alterations during pregnancy. In addition, having multiple-deliveries in women increases the rate of UTI in these women. Current study was aimed to diagnose urinary tract infections (UTI) in women in Al-Kut City, Iraq.

**Method:** From Al-Zahra’a General Teaching Hospital, 60 samples of urine were collected from 60 pregnant and 20 non-pregnant women with and without UTI symptoms, respectively. There were also 15 samples of urine that were collected from women which suffered type 2 diabetes. The investigational study was continued from April, 2016 to April, 2017. Microscopic, cultivation, and biochemical tools were used.

**Results:** the isolated bacteria were from 5 species; *Escherichia coli*, *Klebsiella pneumoniae*, *Staphylococcus aureus*, *Proteus mirabilis*, and *Streptococcus agalactiae*. Using biostatistics, there were no significant differences ($P>0.05$) between pregnant and non-pregnant women regarding the isolated bacterial species. To measure the effect of age on prevalence of the infection, the current study result didn’t show any significant effect of this factor on this rate. However, it showed significant influence of sex factor on the incidence of the infection. In fact, the present study infection rate, 47.5%, occurred mostly in ages of women between 26 to 35 years. The present study also detected that the anatomical specification and the many deliveries of some women played important roles in increasing the rate of UTI. The resulted isolates showed various rates of resistance against antibiotics that ranged from the highest (55.8%) in *Proteus mirabilis* to the lowest (13%) in *Streptococcus agalactiae*. For the antibiotics, the highest resistance rate was against tetracycline (62%), while the lowest rate was against gentamycin (10%).

**Conclusion:** there are many bacteria especially *E. coli* that cause UTI in pregnant women. Current study results suggested launching future studies and following scientific approaches on better control and use of antibiotics against UTI in women.

**Keywords:** UTI, pregnant, non-pregnant, diabetic women, antibiotics resistance.

Introduction

The infections that affect urinary tracts and caused by pathogenic bacteria are called urinary tract infection (UTI). The condition is considered as a common problem that affects women of 20 to 50 years old (1). The inflammation that happens in this condition causes a painful process and risky situation that could affect kidneys if the treatment is not taken into consideration. Pregnant women are most affected by this condition, so as the uterus gets bigger and bigger at 6 weeks of pregnancy, it increases the pressure on the urinary bladder which leaves it always filled with urine and is not completely emptied when urinate. This also increases dampness in these affected parts which leads to increase the growth of pathogenic bacteria (2). It has been mentioned that the infection rate of UTI is increased in women due to their
sex-based changes and revealed that UTI rate increases in women with type 2 diabetes, because of hormonal alterations during pregnancy. In addition, having multiple-deliveries in women increases the rate of UTI in these women (3). UTIs are wide-spread problems in women, so this study was initiated to understand the causative agents inducing these infections.

**Materials and Method**

**Sample Collection:** Current study was aimed to diagnose UTIs (UTI) in women in Al-Kut City, Iraq. From Al-Zahra’a General Teaching Hospital, 60 samples of urine were collected from 60 pregnant and 20 non-pregnant women with and without UTI symptoms, respectively. There were also 15 samples of urine that were collected from women which suffered type 2 diabetes. The investigational study was continued from April, 2016 to April, 2017. The samples were mid-urine samples.

**Microscopic examination of urine samples:** The samples were placed in tubes and centrifuged at 5000rpm for 15min. The supernatant was discarded, while the precipitant was homogenized. A drop from that precipitant was placed on a clean glass slide and covered with a cover slide to visualize pus cells under a microscope using 400x of zooming power (3).

**The bacteriological and the antibiotic sensitivity tests:** Bacteriological examination of the urine was performed as it was shown in Table (1).

Results and Discussion

Age effect and the UTI: Current study results showed no significant differences ($p>0.05$) between both groups. The results also revealed that there were no significant ($p>0.05$) effect of age on infection rate in the tested women. The results indicated that the infection rate (47.5%) increased in the ages between 26-35 years. Moreover, ages of 16-25 years showed an infection rate of 37.5%. These results agreed with most studies around the world when it has been found that UTI is a common infection in school girls in a rate of 4%. It has been also discovered that the rate of infection reached 5% in various ages especially in teenage girls. Diabetes and pregnancy increased the rate of UTI in women (4).

Relationship between UTI rate and number of deliveries: The infection rate was highest in women with 1 to 3 deliveries. This rate was shown in 20 (50%) of the collected samples. There was a rate of 45% in 18 samples for women that had (4-6) deliveries in their life before the sampling time. These results agreed with (4) who mentioned that the rate of UTI increased in women due to their sex-based changes and revealed that UTI rate increased in women with type 2 diabetes, because of the hormonal alterations during pregnancy. Having multiple deliveries in women increased the rate of UTI in these women (4).

Bacterial isolates and microscopic analysis of urine samples: For the first group, 40 species of bacteria were isolated that contained 20 (50%) isolates of E. coli, 8 (20%) Klebsiella, 5 (12.5%) Staphylococcus aureus, 4 (10%) Streptococcus and 3 (7.5%) Proteus mirabilis. There were no significant ($p>0.05$) differences between numbers of bacterial isolates from both groups. For the case of urine examination, pus cells were dominant in a range of 7-18 cell/HPF, crystals were 1-17 cell/HPF, different cells were (1-11) cell/HPF and red blood cells were (11-15) cell/HPF. The bacterial presence in the urine was tested under microscope and was measured according to the significant occurrence of 30000/ml (4). Cultivation of 15 urine samples showed insignificant bacterial growth in only 10 samples although most studies suggested bacterial presence in the urine of women who suffer from type 2 diabetes (3). It had been previously suggested that most of the UTIs were induced by bacteria that were present in the UTs of the women with or without diabetes (5).

There was one bacterium that was isolated in the second group which was Proteus mirabilis (10%). For the case of urine general examination, the test showed normal values of crystals, red blood cells, epithelial cells and pus cells (6). The current study revealed that E.coli was the frequent bacterium that was isolated from diabetic pregnant women that had UTI and this agreed with (7) who had found that this bacterium was the most bacterium that caused UTI in women. Klebsiella pneumoniae and Proteus mirabilis have also shown the second highest presence in the affected diabetic-pregnant women with UTIs. The normal location of E. coli is the intestine as this bacterium is a member of normal flora. This bacterium when leaves the intestine, it is transferred to the external urinary tract parts in women and causes UTI. The infection is considered higher in females than males, but the reasons behind this phenomenon are not well known. The occurrence of infection in females is higher than that in males and the reasons behind that could be shorter (3cm) urethra in females than that (15cm) in males. The close urethral opening in females to the vagina entrance might also play a role in increasing UTI rate in females. The personal hygiene after mating, injuries after deliveries, injuries to the hymen membrane, proper way of cleaning after defeation and imprisonment of urine after mating might also place impact on getting UTI in females. Pregnancy encourages the occurrence of UTIs as a result of the presence of hormonal changes, changes in the urine pH and increased glucose in urine of diabetic pregnant women (8).

E. coli secrets hemolysin and this is considered cytotoxic substance which destroys the red blood cells and releases hemoglobin to be used by the bacterium to proliferate. In addition, hemolysin inhibits phagocytosis and chemotaxis processes of white blood cells (9). Moreover, some of the enterobacteriaceae family members have a capsule, characteristic feature that leads to formation of mucoid membranes and prevents phagocytosis. They also have pili that enhance bacterial attachment to epithelial cells (10). Some of these members don’t have pili, but also could attach to these epithelial cells without those pili. This ability of attachment to the epithelial cells helps bacteria evade clearance by urination process. Streptococcus agalactiae (Group B Streptococcus; GBS) was among isolated bacteria in both groups and it is considered as a normal-flora bacterium that is present in the genital tract of females (11). Klebsiella and E.coli caused UTI in diabetic patients (8), but Streptococcus Group B and Enterococci induced UTI in pregnant women at (10-30%). These bacteria...
may lead to premature labor or abortion in women (9). *Staphylococcus aureus* was the second frequent bacterial isolate from infected women and increasing numbers of studies indicated that *Staphylococcus aureus* caused UTI in women. This bacterium has various virulent factors such as capsule forming and hemolysin and protease secretions. These make the bacterium strong enough to induce UTI in people and more specifically women (12). *Proteus mirabilis* and *E. coli* were found to be the most bacterial species that had been isolated in previous studies. The results also revealed that tetracycline gave the highest resistance (67%), while gentamicin was the lowest (10%) in all isolates. Many studies revealed that bacteria that cause UTI infections usually resist many antibiotics. This might be related to the fact that most of the recognized genera carry resistance factors on their DNA and they transfer this ability to the next generations. In addition, excessive intake of antibiotics led to initiation of what is known as superbacteria that can resist most antibiotics. Ampicillin is one of the antibiotics that were used safely for mothers and newborns till recently when it started to give resistance. Piperacillin and tetracycline were the highest antibiotics that gave resistance in this study compared to erythromycin and amikacin. In addition, *proteus mirabilis* bacteria gave the highest resistance to all antibiotics in this study comparing to the others.

In conclusion, there are many bacteria especially *E. coli* that cause UTI in pregnant women. Current study results suggested launching future studies and following scientific approaches on better control and use of antibiotics against UTI in women.

Hallucinations in Chronic Mental Illness–A Clinical Study of Iraqi Patients

Kareem Nasir Hussein
Hummrabi Medical College, University of Babylon, Iraq

ABSTRACT

Background: Hallucination as a sensory perception without external stimulation of the relevant sensory organ. Hallucinations in schizophrenia are neither mental image nor true perception. Chronic mental illness is residual symptoms beyond 2 years of initial recognition. The aim of current study was to study the frequency of hallucinations of all modalities and to compare Schneider’s first rank hallucinations with other hallucinatory modalities in same group of patients and to compare the results of present work with result from studies done in other cultures.

Method: This is cohort study, each patient was clinically interviewed. The diagnosis was made according to the criteria of DSM-IV-TR through the use of the national institute of mental health diagnosis interview schedule (NIMH-DIS).

Results: The results of this study were compared to others and found to be relatively comparable. The types of Hallucinations experienced by patients were 72(86.15%) of patients had auditory type, 30(43.07%) had visual, the Schneider’s first rank hallucinations were found in 14(21.04%) patients. The other types of hallucination as tactile and olfactory were rare.

Keywords: hallucination, sensory perception, external stimulation, schizophrenia, chronic mental illness, residual symptoms.

Introduction

Chronic severe mental illness is characterized by persistent disabling psychiatric symptoms or by severely impaired function (1). Several events in the 1950s, including the development of antipsychotic medications and new commitment laws, led to dramatic changes (i.e. deinstitutionalization) in the treatment of the severely and persistently mentally ill. The 1960s brought the Community Mental Health Center Program as an alternative to state hospitalization, as well as new federal programs (Supplementary Security Income [SSI], Social Security Disability Insurance [SSDI], Medicaid and Medicare health benefits) (2). The prevalence of mental illness is higher in cities and in lower-class neighborhoods. This is largely due to the drift of chronically ill patients towards urban environments. Roughly, one-third to one-half of homeless persons in the United States suffer from schizophrenia although such estimates remain controversial (3).

Hamilton suggested a definition, it is a false perception that spring into begin in a primary way and are not transpositions or distortions of any genuine perception, and occur simultaneously with and a long-side real perception. He also distinguished hallucination from true perception in that they come from within although the subject reacts to them as if they were true perceptions (4).

Psychopathology of hallucinations: Although the exact cause and pathogenesis of hallucinations are not known, there is a substantial body of knowledge that points toward multiple etiological factors for hallucinatory phenomena.

Psychophysiological approach: The dissociation–disinhibition theory in which the CNS is seen as having three evolutionary levels; cortex, basal ganglia and spinal cord, and when the usual inhibitory influences of the upper most level are impeded, thus leading to the release of middle level activity in the form of hallucinations (5). The perceptual release theory suggested that the brain continually receives sensory stimuli of all sorts from the external and internal environments, then selectively excludes from consciousness the majority of impulses.
that are irrelevant to attentiveness or otherwise not needed for environmental adaptation. If the sensory input is disturbed or absent, as in the case of excessive.

The proposed a sensory-motor ratio theory focusing on disequilibrium between the internal and the external sensory inputs to the CNS leading to increased sensory awareness and decreased motor responsiveness. They proposed a theory of abnormal brain excitability as a mechanism for the production of hallucinations, they demonstrated that electrical stimulation of certain cortical and subcortical structures may induce different types of hallucinations. They supported the theory of hyper excitation of the CNS indicated that abnormal excitation of brain tissue and abnormal regulation of cognitive activity in left frontal lobe may contribute to hallucinations. By using a C.T. scan technique they found that a lateralization phenomenon of complex auditory hallucinations could be considered a significant clinical sign indicating the existence of a in the superior temporal gurus opposite the hallucination side.

By using a PET scan with fluorodeoxyglucose in chronic schizophrenic patients, it was found that metabolism in Boc's region and its right hemisphere homologue correlated positively and significantly with hallucinations, as it did in anterior cingulate and left superior temporal areas. The traced skin conductance in schizophrenic patients during periods of auditory hallucinations and found a substantial rise in the spontaneous fluctuation rate of skin conductance.

Psychobiochemical approach: Dopamine was believed to play a major role in those phenomena. It is also known that drugs which block central dopamine activity (antipsychotics) may alleviate the hallucinations. Further evidence was that D amphetamine, an indirect dopamine agonist, induces psychosis and hallucinations. Serotonin has also been considered in the biochemistry of hallucinations-it was believed that low central levels (brain stem) of serotonin might be an important factor that a number of hallucinogenic drugs such as lysergide (LSD), mescaline and amphetamine appear to act at least in part by blocking central serotonergic receptors. Furthermore, LSD causes a decrease in the rate of brain serotonin turnover and it is itself structurally similar to serotonin.

Psychodynamic approach: The interpretation of dreams felt that hallucinations are very similar to dreams and that both conditions represent psychotic states in which there is a complete lack of time sense, with the transformation of thoughts into images, mainly of a visual sort. Hallucinations may also be experienced in response to wish fulfillment. Modern psychodynamic views presented by object relations theorists offer another understanding suggested that hallucinations are the results of projective identification, with the violent expulsion and projection of what he termed bizzare objects.

Hallucination in chronic mental illness: Auditory hallucinations are the most frequent type usually formed and complex the voices may be heard as from outside or inside the head and schizophrenic patients of both sexes can hear both male and female voices. The auditory hallucinations in a clear sensorium are characteristic of schizophrenia - even pathognomonic stated that three types of hallucinations are diagnostic of schizophrenia; audible thoughts, voices conversing about the patient in the third person and voices in the form of running commentary.

Visual hallucinations: Have been described in many ways, either as common phenomena in schizophrenia or less frequent or even rare but not entirely unknown. Visual hallucinations in psychotic disorders appear suddenly, do not change if the eyes are closed or open. In schizophrenia are continuous except when asleep accompanied by other sensory disturbances, frightening, three dimensional, normal in size, bright in color and appear to be moving. The visual hallucinations in schizophrenia were less colored, complex and moving.

Tactile hallucinations: They occur principally in toxic states. It took place either in the form of abnormal perception under the skin (formication) - or in the form of electrical and sexual feeling in the body which occur more in schizophrenia. Bodily senses as touch or heat have been described as simple hallucination - while feelings of pain, electricity or sexual excitement which are attributed to external agency have been described as passivity experiences.

Coenaesthetic hallucinations: are peculiar visceral sensations not perceived under appropriate physiological conditions as burning sensation in the brain, blood flowing inside the blood vessels.

Kinesthetic hallucinations: are perceptions of body movement or part of it that are not actually moving. The African schizophrenics with somatic hallucination ascribed their experiences to witches, poisonous objects and insects that are being thrown at them.
Olfactory hallucinations: usually infrequent in schizophrenia or described as not uncommon in schizophrenia with lesion of temporal lobe and of bad character.

Gustatory hallucination: an uncommon type- of unpleasant nature - and usually accompanied by olfactory hallucination. It appeared to predict outcome in schizophrenia (more in the acute type) \(^{(21)}\).

Aim of the study

The purpose of this research was to study the frequency and types of hallucinations of all modalities in a group of Iraqi patients with chronic mental illness and compare Schneider’s first rank hallucinations with others in the same group of patients. Also, to compare the present results with those from studies done in other cultures.

Patients and Method

A Cohort composed of (300) patients suffering from chronic schizophrenia diagnosed by more than one consultant psychiatrist throughout their entire admissions. The study was carried out during the period from 1\(^{st}\), January 2014 to 1\(^{st}\), January 2016. Forty one patients (33 males and 8 females) were excluded from the study because of severe speech retardation - severe formal thought disorder impaired cognitive functions and language barrier. The rest 193 patients, 128 patients had only negative symptoms (85 males and 43 females) and 65 patients (33.6 %) had positive symptoms of hallucinations and delusions. It was composed of 33 males (50.76 %) and 32 females (49.23 %). The diagnosis was made according to the criteria of DSM- IV-TR through the use of national institute of mental health diagnostic interview schedule (NIMH-DIS) questions specific for the diagnosis of schizophrenia \(^{(21)}\).

Descriptive Statistics were used in the analysis of data which included frequency, mean, range and standard deviation, z-test and chi-squared test. Level of significance was tested at \(P\leq 0.05\).

Results

The point prevalence of hallucinations in the whole sample (65 patients) was 33.6%. Table (1) showed types of hallucinations experienced by the patients. Forty eight patients (86.15%) had auditory type, 11(43.07%) visual, 4(9.23%) had tactile and 2(3.07%) had olfactory type. Table (2) explained that the frequency of both pure auditory hallucinations and mixed ones was nearly equal in the sample (Table 2). In the present study visual, tactile and olfactory hallucinations were associated with auditory type. On the other hand, Table (3) clarified the content of both types of auditory hallucinations. Table (4) presented visual hallucinations experienced by 11 patient (43.07%) and their contents are demonstrated. Table (5) showed the frequency of tactile hallucinations and their contents, pain was the most prominent one. Moreover, Table (6) revealed that out of 65 patients with hallucinations, 34 patients (50.76%) had expressed delusional experiences.

Discussion

The male: female ratio in this study was almost equal (33: 32). This is probably due to the influence of strict criteria used in patients selection (chronic schizophrenics, with active symptoms of hallucination and delusions). In the original sample of 300 patients, males were found to be more than females (151: 83).

The mean age of males was 45.6 years, while that for females was 37.7 years. In this sample, 48(86.15 %) patients had auditory hallucinations, 11(43.07 %) patients had visual type, 4(9.23 %) patients had tactile type and 2(3.07 %) patients had olfactory type (Table 1).

Data from current study showed that auditory hallucinations were the most frequent types in the present, whereas visual and other types were relatively high.

The frequency of both pure auditory hallucinations and mixed ones was nearly equal in current sample (Table 2). In the present study, visual, tactile and olfactory hallucinations were associated with auditory type.

Olfactory hallucinations were too few (4 patients) in the present study probably due to a relatively small sample size. The point prevalence of associated delusions in the present study was 50.76% with a male: female ratio (10: 23; Tables 3-6).

Conclusion

Several types of hallucinations were found to occur in chronic mental illness. They may involve more than one sensory modality. The Schneider’s first rank hallucinations and delusions seemed to occur less
frequently in chronic schizophrenia and probably of little diagnostic significance. Visual hallucinations seemed to occur in sufficient numbers and are considered relatively specific to the syndrome of schizophrenia.

ABSTRACT

Background: Determination of mesio-distal width of human teeth is very important due to its relation to many dental fields like aesthetic dentistry, orthodontics, anthropometrics, prosthodontics, studying the differences between ethnic groups and in gender determination in forensic dentistry. So that Bolton developed an analysis to assist in establishing the discrepancy between the mesio-distal widths of the maxillary and mandibular teeth. This study was aimed to determine and compare the anterior and overall Bolton’s ratios in normal, crowded and spaced dentitions.

Method: One hundred fifty pair of dental casts belonged to 150 Iraqi individuals having class I dental relationship with normal, crowded and spaced dentition after analyzing the space in both dental arches. The mesio-distal crown widths of the maxillary and mandibular permanent teeth anterior to the second molars were measured using electronic digital vernier with 0.01mm accuracy to calculate Bolton’s ratios. Unpaired t-test, one-way ANOVA and post hoc Tukey’s test were used to compare the measured parameters.

Results: The combined mesio-distal crown widths were significantly higher in crowded dentition followed by normal then spaced dentition. Bolton’s ratios neither showed significant gender and group differences nor followed the same pattern of the combined mesio-distal crown widths.

Conclusions: The difference in Bolton’s ratios was related to the difference in the mesio-distal widths and dental arch discrepancy that must be addressed in details.

Keywords: Bolton’s ratio, crowding, spacing, tooth size discrepancy, mesio-distal crown width.

Introduction

Determination of mesio-distal width of human teeth is very important due to its relation to many dental fields like aesthetic dentistry, orthodontics, anthropometrics, prosthodontics, studying the differences between ethnic groups and in gender determination in forensic dentistry.(1)

The decision of removing enamel (dental stripping) or teeth (dental extraction) from the dental arches must not be done in an arbitrary manner, because the final results of successful orthodontic therapy comprised of achieving ideal interdigitation, overjet, overbite and alignment of teeth. In order to get such an optimum interarch dental relationship, the maxillary tooth materials should have a reasonable ratio with the mandibular tooth materials. So that, Bolton (2,3) developed an analysis to assist in establishing the discrepancy between the mesio-distal widths of the maxillary and mandibular teeth. This analysis consisted of two ratios; the anterior ratio obtained from dividing the collective mesio-distal widths of mandibular anterior teeth from canine to canine by their opposing and the overall ratio gained by dividing the collective mesio-distal widths of mandibular teeth from first molar to its antimere by their antagonists.

Teeth erupted in the oral cavity either in well-aligned state, crowded or spaced. The causes of the two latter problems were related to the discrepancy in the size of the jaw and teeth or may be related to different local factors (4).
A number of previous studies (5-8) concluded that a difference in the mesio-distal widths among normal, spaced and crowded dental arches did exist.

In Iraq, several studies had been conducted to establish the Bolton’s ratio in crowded dental arches with class I dental relation (9), class II division 1 with crowding and spacing (10), spaced dental arches with class I dental relation (11), in Down’s syndrome patients (12), in different malocclusion cases (13) and in different ethnic groups (14,15). On the other hand, (16) determined the real site of anterior tooth size discrepancy in different anterior Bolton’s ratio.

To the best of authors’ knowledge, there was no study compared the anterior and overall Bolton’s ratios among normal, crowded and spaced dentitions; therefore, the aim of current study as to determine and compare the anterior and overall Bolton’s ratios in normal, crowded and spaced dentitions.

**Materials and Method**

**Sample:** The sample of current study comprised of 150 pairs of dental casts belonged to patients attended the Department of Orthodontics at the College of Dentistry/University of Baghdad and students from the same college. They were selected according to the following criteria:

1. All individuals were Iraqi Arabs in origin within an age range of (18-25) years.
2. All had sound, fully erupted permanent dentition with Angle’s class I dental relationship.
3. No one had undergone orthodontic treatment.
4. Bimaxillary protrusion cases were excluded.
5. No periodontal problems like gingivitis or periodontitis.
6. No history of bad oral habits or congenital deformities like cleft lip and palate.

**Method**

Following clinical examination to check the fulfillment of the inclusion criteria, maxillary and mandibular dental impressions were taken using Alginate hydrocolloid impression material (Tropicalgin, Chromatic alginate, Zhermack, Italy), rinsed with running water, disinfected with sodium hypochlorite (1:10) and stored in closed plastic bag for ten minutes (17). Then after, the impressions were rinsed again and poured with dental stone (Elite Rock, Sandy brown, Zhermack, Italy) and just before the final setting of the dental stone, a base was prepared using plastic mold and plaster (Plaster of Paris, Al-Ahleea Co., Iraq). The base was labeled for participant’s name and number to be ready for the measuring procedure.

To classify the sample in current study, the arch length was measured by dividing the dental arch into four segments. The posterior segments were measured mesial to the first molars to the contact between the canines and the first premolars from the right and left sides. The anterior segments were measured from the distal contact point of the canines to the mesial contact point of the central incisors from the right and left sides (18). The mesio-distal width of all teeth anterior to the first molars was measured using electronic digital caliper (S.H®, China) with 0.01mm accuracy. Space was then analyzed using the following equation: Space analysis = (Arch length - Teeth width)

Any arch with negative three millimeters or more was assigned as crowded arch, whereas any arch whose space analysis revealed positive three millimeters or more was allocated as spaced arch, on the other hand, 0 ± 3mm regarded as normal.

As a final point, the samples were divided into three groups (5):

1. **1st group:** normal (well-aligned) dentition comprised of fifty pairs of study models belonged to 23 males and 27 females with equal and less than 3mm crowding or spacing per arch.
2. **2nd group:** crowded dentition composed of fifty pairs of study models belonged to 23 males and 27 females with more than 3mm crowding per arch.
3. **3rd group:** spaced dentition consisted of fifty pairs of study models belonged to 21 males and 29 females with more than 3mm spacing per arch.

The anterior and overall Bolton’s ratios were calculated according to the following equations (2,3):

Anterior ratio = (sum of mandibular 6 anterior teeth/ sum of maxillary 6 anterior teeth) × 100.
Overall ratio = (sum of mandibular 12 teeth/sum of maxillary 12 teeth) × 100.

The posterior teeth including both premolars and first molars were summed and posterior ratio was calculated according to the following equation:

Posterior ratio = (sum of mandibular 6 posterior teeth/sum of maxillary 6 posterior teeth) × 100.

Statistical Analyses: Data were analyzed using SPSS version 24 (IBM Co., New York, USA). The statistical analyses included means and standard deviations as descriptive statistics and independent sample t-test, one-way ANOVA test followed by Tukey’s test as inferential statistics. P-value was set at 0.05.

Results

Descriptive statistics and groups’ differences of the combined mesio-distal widths of teeth from canine to canine, first molar to first molar and from first premolar to first molars in the other side in both arches and different groups were demonstrated in Table (1). Generally, crowded arches possessed wider teeth followed by normal then spaced dentition with statistically significant differences among the groups as indicated by ANOVA and Tukey’s test.

Descriptive statistics and gender differences of Bolton’s ratios were demonstrated in Table (2) and results indicated non-significant gender differences.

| Table 2: Descriptive statistics and gender differences of Bolton’s ratios in different dentitions |
|-----------------------------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| Dentition | Ratios | Descriptive statistics | Comparison | | |
| | | Males | Females | | |
| | Mean | S.D. | Mean | S.D. | t-test | p-value |
| Normal | Anterior ratio | 77.399 | 2.324 | 78.473 | 3.368 | -1.289 | 0.204 |
| | Overall ratio | 92.132 | 2.380 | 91.814 | 2.710 | 0.437 | 0.664 |
| | Posterior ratio | 106.903 | 4.145 | 104.924 | 4.095 | 1.694 | 0.097 |
| Crowded | Anterior ratio | 78.180 | 4.830 | 78.517 | 3.736 | -0.278 | 0.782 |
| | Overall ratio | 91.681 | 4.134 | 92.340 | 3.717 | -0.594 | 0.556 |
| | Posterior ratio | 104.937 | 4.534 | 105.959 | 5.261 | -0.729 | 0.470 |
| Spaced | Anterior ratio | 79.310 | 2.652 | 80.482 | 3.977 | -1.173 | 0.247 |
| | Overall ratio | 92.227 | 2.559 | 92.772 | 2.434 | -0.765 | 0.448 |
| | Posterior ratio | 104.357 | 3.995 | 104.306 | 3.457 | 0.049 | 0.961 |

Group differences of Bolton’s ratios were summarized in Table (3). As it is clear in Table (2), there was no significant gender differences in all ratios and in all groups, so both genders were summed as one sample in each group for statistical purposes. The results showed that the anterior Bolton’s ratio differed significantly among the groups
being higher in spaced dentition followed by the crowded then normal dentitions. Furthermore, post hoc Tukey’s test revealed a significant difference between the normal and spaced dentition and non-significant differences between normal and crowded and between spaced and crowded dentitions. On the other hand, the overall and posterior ratios showed non-significant groups’ differences. Overall ratio was higher in spaced dentition followed by crowded then normal ones and just the reverse for the posterior ratio.

**Discussion**

In the present study, the sample was selected with an age ranged from 18 to 25 years. This range was considered the best age range for assessing teeth size discrepancy and measurement, because by the age of 16-17 years the majority of facial growth is nearly completed and above 25 years old the effect of aging like attrition may act as a factor that may affect teeth size discrepancy and measurement.

Current study revealed significantly smaller sum mesio-distal crown widths from canine to canine, first molar to first molar and from first premolar to first molars confirming findings from previous studies (6,8).

Bolton’s ratios, in addition to posterior ratio, did not show any significant gender differences in all groups (Table 2). Othman and Harradine (21) reported, in their review about Bolton’s ratios, that most studies found no significant gender difference and if found in some studies, it was small with males having slightly larger ratio.

The mean value of anterior Bolton’s ratio was higher in spaced dentition followed by crowded then normal ones with significant group differences. The overall Bolton’s ratio followed the same pattern, but with non-significant group differences. In comparison with other Iraqi studies, both ratios were less than those reported by (13) and near to that of (13) for normal occlusion only.

This is the first study that dealt with the Bolton’s ratios in normal, crowded and spaced dentitions and there was no study that discussed this issue as a whole. The findings of the Bolton’s ratios in current study may not follow the same order of that obtained for the combined mesio-distal crown widths, that’s to say, the ratios were not high in crowded dentition and small in spaced dentition with the normal dentition in between. This difference can be explained from many aspects. First; the cause of spacing or crowding was not determined; Is it due to small teeth with normal jaws or normal teeth with large jaws? or small teeth with large jaws? (The opposite is for the crowding). Second; a difference in mesio-distal widths between the upper and lower teeth might exist (22). Third; the difference in the inclination of incisors to get class I relation among the studied groups had not been studied because it needs lateral cephalometric X-ray (23). Fourth; the degree of crowding and spacing itself is not limited, because the cut-point of sample selection for the present study was more than 3mm for spacing and more than -3mm for crowding without determining the limit except for the normal dentition (0 ± 3mm).

In the literature, there was only one study compared Bolton’s ratios between the crowding and spacing class II division 1 dentition and the results indicated that the overall ratio was higher in crowded dentition, while the anterior ratio was slightly higher in spaced group with non-significant group differences (10). The latter study lacked a control group (normal dentition). On the other hand, (24) found that Bolton’s ratios and the collective mesio-distal widths of anterior teeth and overall teeth were higher in crowded dentition in comparison with non-crowded one. This supported the findings of the present study.

The posterior ratio was used to detect its effect on the overall Bolton’s ratio. Its mean value was near to that
reported by (19), but it did not differ among the studied groups although the collective mesio-distal widths of posterior teeth were significantly differed, being higher in crowded dentition followed by normal and spaced dentitions.

**Conclusion**

The findings of the present study revealed that there were non-significant gender differences in Bolton’s ratios. For the total sample in each group, the combined mesio-distal crown widths of maxillary and mandibular permanent teeth anterior to second molars were significantly wider in crowded dentition followed by normal and the least in spaced dentition. On the other hand, anterior, posterior and overall ratios did not follow the same order.

Further study is suggested to establish the normal range of Bolton’s ratios in crowding and spacing according to their severity.

ABSTRACT

Background: Self-care is probably decisive factor to control blood glucose level to establish euglycemia in diabetes. 3.7 million deaths in 2016 were due to diabetes and hyperglycemia.

Objectives: To assess correlation between diabetes self-care reflected by Diabetes Self-Management Questionnaire (DSMQ) scores and glycemic control by Hemoglobin A1c (HbA1c) in patients with type 1 diabetes and to stratify them according to the prescribed insulin regimen (basal-bolus vs. twice-daily premixed regimen) for further comparison.

Method: 100 patients with type 1 diabetes were cross-sectionally assessed using DSMQ in interview-sessions at Kerbala Educational Children Hospital-Endocrinopathy outpatient clinic and at a private clinic. Demographic data, recent records of HbA1c and Self-Monitored Blood glucose (SMBG), and other self-care variables were obtained. SPSS was used to assess correlations and to compare group characteristics.

Results: Correlations between HbA1c and DSMQ-subcales revealed non-significant correlations for Sum scale (SS), Glucose management (GM), Physical activity (PA), and Health-care use (HU) [Spearman’s ρ=.017; .080; .095 and -.054 respectively], however there was a significant correlation with Dietary control (DC) subscale [Pearson’s r=-.209; p-value=.037]. Premixed versus basal-bolus comparisons showed significant differences in mean HbA1c (± SD) 10.82% ± 2.33 vs. 9.28% ± 2.19; p-value=.002 and mean DSMQ-subcales scores except DC-subscale. There were non-significant differences regarding random SMBG, BMI, and score of DSMQ-DC subscale.

Conclusion: Non-significant relation between glycemic control and self-care except dietary control which was negative. Basal-bolus regimen was superior in long-term glycemic control despite lower self-care compared with premixed regimen.

Keywords: Diabetes self-care, Diabetes Self-Management Questionnaire, Glycemic control, HbA1c, Insulin regimens

Introduction

Diabetes is a metabolic group of diseases in which hyperglycemia occurs due to defective insulin secretion and/or insulin action¹.

About 425 million people, worldwide, were estimated to have diabetes. Some more than 96,000 children and adolescents under 15 years were estimated to have type 1 diabetes annually².

Type 1 diabetes is thought to be precipitated by immune-mediated destruction of pancreatic β cells³. A hallmark of type 1 diabetes is the need for exogenous insulin replacement. To enable patients to achieve near-euglycemia, insulin analogues have been developed. Short-acting preparations (to improve post-prandial control) and long-acting preparations (to reproduce
physiological basal profile), or premixed products (to cover both basal and prandial needs) are offered in a multiple daily injection (4)(5)(6).

HbA1c is a hemoglobin formed by a non-enzymatic glycation reactions between glucose and hemoglobin β-chain. HbA1c has been endorsed by American Diabetes Association, National Institute for Health and Care Excellence and World Health Organization for confirming the diagnosis of diabetes mellitus and also used as an indicator of glycemic control (6)(7)(8).

Schmitt et al. developed a psychometric tool in a “Diabetes Self-Management Questionnaire” to target diabetes self-care behaviors associated with metabolic control within common treatment regimens (9). The questionnaire has shown a reliable instrument that maybe useful for research associations between self-management and glycemic control (10)(11)(12). The purpose of this study is to assess correlation of glycemic control with diabetes self-care in patients with type 1 diabetes on basal-bolus insulin regimen compared with twice-daily premixed regimen.

Method

Study Design and Participants: A cross-sectional study was conducted at Kerbala Educational Children Hospital®-Endocrinopathies outpatient clinic and at private clinic at Kerbala from 24th of July 2017 to 26th of March 2018.

Inclusion criteria were type 1 diabetes patients at childhood to late adulthood age groups who were receiving insulin by a basal-bolus regimen (group 1) or a twice-daily premixed regimen (group 2). Whereas exclusion criteria involved any patient with other type of diabetes (i.e.: gestational, type 2, or adults on insulin pumps).

Additionally, demographic data were gained from patient interview or hospital records including gender, age, Body Mass Index, diabetes duration, complications status, recent SMBG, and recent HbA1c. The interview consumed 15-30 minutes. Furthermore, variables of self-management including diabetes history, glucose monitoring, diet, physical activity, and prescribed medications; were assessed in patients ascertain of their responses for further re-evaluation.

Diabetes Self-Management Questionnaire (DSMQ):
The DSMQ was developed at the Research Institute of the Diabetes Academy (9). The approved form consisted of 16 items identified after analysis of responses. A four-point Likert scale (to avoid a neutral response option and force specific responses), with the response options: ‘applies to me very much’ (3 points), ‘applies to me to a considerable degree’ (2 points), ‘applies to me to some degree’ (1 point), and ‘does not apply to me’ (0 points), was used.

The questionnaire provides a ‘Sum Scale’ (SS) score beside estimation of four subscale scores labelled:

- ‘Glucose Management (GM)’
- ‘Dietary Control (DC)’
- ‘Physical Activity (PA)’
- ‘Health-Care Use (HU)’
- And one item (16) requests an overall rating of self-care to be included in the SS only.

Scale scores were formulated as sums of item scores and then transformed to a scale ranging from 0 to 10.

Glycemic Control: HbA1c values were used as an indicator of glycemic control for the preceding 2-3 months (8). Most recent values were obtained from interview or from hospital records measured according to a laboratory using high-performance liquid chromatography performed with the Bio-Rad D-10™ Turbo analyzer. Recent SMBG readings were also recorded. For those lacking the records, an estimated Mean Plasma Glucose (MPG) was calculated using the DCCT study validated formula based on the linear regression equation (13)(14).

Statistical Analyses: The analyses were performed using SPSS 25.0.0 (IBM SPSS Inc., New York). Group comparisons involved Student’s t-test, Pearson’s chi-squared test and One-way analysis of variance (ANOVA) as well as non-parametric tests. A P-value of < 0.05 (two-tailed test) was considered as criterion of statistical significance. Cronbach’s α was used to assess internal consistency reliability.

Pearson product-moment and Spearman’s rank correlations were used to assess correlations between HbA1c and DSMQ-subscases. Additionally, known groups validity was assessed by assorting the patients
into 3 groups according to the HbA1c value, which were then examined regarding self-care activities of DSMQ-subcales. Patients with HbA1c values up to 7.5% (58 mmol/mol) were classified as ‘good glycemic control’, patients with values between 7.6 and 8.9% (60 and 74 mmol/mol) as ‘medium glycemic control’, and patients with values from 9.0% (75 mmol/mol) as ‘poor glycemic control’. Between-groups differences were analyzed using ANOVA.

### Results

**Samples Characteristics:** The total sample comprised 100 patients with type 1 diabetes of which 53% were females. Mean participant age (±SD) was 12.27 ± 6.78 years and mean duration of diabetes was 5.59 ± 4.54 years.

The characteristics of study sample are detailed in (Table 1).

Data are n(%) or M ± SD. HbA1c, glycated hemoglobin; DSMQ, Diabetes Self-Management Questionnaire; M, mean; SD, standard deviation. * regards differences between insulin regimens; Student’s t-Test or Pearson’s χ²-Test (two-tailed test). Mann-Whitney U test p-values are presented in square brackets. † Retinopathy, neuropathy, nephropathy, diabetic foot, and/or arterial occlusive disease.

**Distribution Characteristics and Reliability in DSMQ Subscales:** A Shapiro-Wilk test (p < .05) and a visual inspection of their histograms, Q-Q plots and box plots showed that DSMQ subscales: SS, GM, PA and HU were non-normal distributed with skewness of -.611, -.758, .087, and -.813 (SE=.241) respectively; and kurtoses of .113, .202, -1.222, and 1.496 (SE=.478) respectively. DC-subscale was slightly skewed (-.018) and kurtotic (-.620) but it does not differ significantly from normal as Shapiro-Wilk test p-value was > 0.05 (15) (16).

Internal consistency reliability (Cronbach’s α) showed an overall acceptable consistency (.684) and reliabilities within DSMQ-subscals ranged: GM=.672, acceptable; DC=.500, questionable; PA=.917, excellent; and HU=.240, poor.

**DSMQ Subscales with HbA1c Associations:** Correlation of HbA1c and DSMQ-subscals GM, PA, SS, and HU was non-significant. Table 2 displays coefficients of correlations regarding and regardless of insulin regimen been used.

Discussion and Conclusions

This study suggests non-significant correlation of HbA1c with overall self-care and health-care use in patients with type 1 diabetes. There is negatively significant correlation of HbA1c with dietary control albeit to a weak strength ($r=-.209; p-value=.037$). A finding similar to studies used diet in self-management questionnaires (9)(17).

Correlations with glucose management and physical activity were positive though non-significant. It is likely that knowledge affects glycemic control by frequency of monitoring blood glucose (18). Agha et al. study suggested that glycemic control is still poor in children despite of home monitoring of glucose and introduction of new insulin (19). Physical activity was shown to reduce the burden of disease in adolescents by a multicenter cross-sectional study (20).

Comparison of insulin regimens shows a superior HbA1c level with lesser overall self-care, GM, PA, and HU were achieved in basal-bolus group. Nonetheless, there are non-significant differences in DC and SMBG. Testa et al. study proved that satisfaction was impacted more positively by improved quality of life, reduced glucose variability, and better glycemic control with basal-bolus regimen compared with premixed regimen(21).

Limitations of this study may include: an obvious lack of information on the exact magnitude of diabetes in Iraq which affects estimating sample size, lower ages and/or educational level for the questionnaire to be self-administered; and recall bias of caregivers regarding most data which were not recorded in hospital profiles.

In conclusion, this study suggests a slight correlation between glycemic control and self-care activities in patients with type 1 diabetes although non-significant in sum score. The research also points that the basal-bolus regimen was better in long-term glycemic control despite the fact that patients had lower self-care as compared with the premixed group. Further research is hence needed to provide more evidence on diabetes self-care.

Ethical Considerations: A verbal consent was taken from patients and written approval for access to patient hospital records to be used in a scientific paper was certified by legal sectors.

Antibiotics Susceptibility and Bacterial Profiles of Urinary Tract Infected Patients in Ramadi City Hospital, Iraq

Zainab Khamees Abbas
College of Medicine, University of Anbar, Iraq

ABSTRACT

Background: Urinary tract infections (UTIs) are considered one of the few diseases which cannot be treated by antibiotics. These infections stand second place among the populations who are infected by bacteria. It is also estimated that in a year, among 1000 person nearly 18 individuals are affected by such infections. Additionally, UTIs are mainly caused in hospitalized patients. The aim of current study was to define urinary tract infections (UTIs) analysed in Iraq with specific importance on the bacterial profile, antimicrobial susceptibility pattern.

Method: This study was done at Ramadi Teaching Hospital, Iraq during the period from October 2017 to May 2018. A total 142 midstream urine samples were collected, cultured and examined under microscope and suitable biochemical tests were conducted to identify properly. Antimicrobial susceptible tests were performed by means of an automatic system Vitek MS, a highly stable and accuracy equipment for specific isolation and the detection of bacterial sensitivity technique as recommended by Clinical Laboratory Standard Institute guidelines.

Results: In total (75) samples were considered for analysis and nearly 52.81% were pointed as positive samples without contaminants. Among the available isolated bacteria, E. coli was found to be more effective in causing infections and the antibiotics that fight against the bacteria was found to be Amikacin, Gentamicine and Ciproflaxacin, respectively.

Conclusion: It can be concluded that E. coli covered a wider range in causing urinary tract infection conducted in Ramadi Teaching Hospital, In addition, Amikacin, Gentamicine and Ciproflaxacin were the most effective antibiotics against this infection. Antimicrobial drug resistance should be monitored regularly to expand the therapeutic guidelines and principles.

Keywords: UTI, culture and sensitivity test, E. coli, Amikacin.

Introduction

Urinary tract infections (UTIs) are considered one of the few diseases which cannot be treated by antibiotics. These infections stand second place among the populations who are infected by bacteria. It is also estimated that in a year, among 1000 person nearly 18 individuals are affected by such infections. Additionally, UTIs are mainly caused in hospitalized patients [1]. Bacterial growth in the urinary tract results in infections and is found to be available commonly over a wide range [2,3]. UTIs affect males and females of all age groups. Basically, women possess short urethra than men which is responsible for affecting women in larger proportions in comparison to men [4-6]. Bacteria present in rectum propagate to urethra thereby causing tract infection [7].

Normally, Staphylococci, Proteus, Enterococci bacteria insulates from internally admitted patients, while considering external patients, E. coli is said to be the most predominant factor. UTI is infrequently caused by an anaerobic organism, whereas the active young-aged women are affected by coagulase-negative Staphylococci [8-11]. A rise of antibiotic resistant concerns the health of patients especially in developing countries [12]. UTI is classified into different types such as lower and upper UTI. Commonly, infection occurs mainly on the urethra (urethritis) or bladder (cystitis).

Infections that occur in kidneys (pyelonephritis), ureters (ureteritis), or both are considered as the upper UTI. Due to the problem of lower UTI, all individuals face upper UTIs. Complications in urinary tract result
The present study was Nearly 142 urine samples were obtained. Further, selected colonies were identified is examined. Crystal, epithelial cells, color, reaction and appearance were investigated. cut-off for leukocyturia: 10-15 leukocytes/field, RBCs, and processing of 142 samples were performed for ICU patients.

Appropriate treatment for managing urinary tract infection is remarkably found to be a tedious task. Because of the rapid developments in isolating bacterial species, bacterial profile and etiology of the pathogens changes significantly in the past decades considering community and nosocomial infections. In spite of containing plenty of antibiotics in hand, restrictions on such antibiotics are enhanced considerably because of the inappropriate utilisation that restricts therapeutic options. Information about the pathogen type that causes infection in urinary tract and their resistive immunities helps the clinician to select an appropriate empirical treatment. Thus, the aim of the current study was to determine bacterial profile and antibiotics susceptibility pattern of infected urinary tract insulated from admitted patients in Ramadi Teaching Hospital.

Materials and Method

**Designed area of study:** The present study was performed in Microbiology department, Ramadi Teaching Hospital in Iraq from October 2017 to May 2018 and involved the admitted patients with inserted urinary catheter for greater than 48 hours in ICU. The patients who had any UTI symptoms before inserting the catheter, were excluded from the study.

**Sample Collection:** Nearly 142 urine samples were collected using clean midstream urine samples and were placed in sterile containers with broader mouth from infected patients who did not consumed antibiotics for fifteen days. The containers were taken suitable aseptic precautions using sterile disposable syringe after the catheter tubes were cleaned and clamped. To perform culture and sensitivity analysis, the collected samples were provided and stored in the department of microbiology. The 2-ml samples of urine were initially centrifuged at 3000×g for a duration of 10 min and tested at 400× magnification in which is the significant cut-off for leukocyturia: 10-151 leukocytes/field, RBCs, crystal, epithelial cells, color, reaction and appearance is examined.

Isolation of uropathogens is performed by inoculating μL of samples using a surface streak procedure. The inoculated samples were then subjected to blood agar, Pepton water, Simmon citrate agar, EMB, TSI, Semi-solid nutrient agar and a MacConkey agar plates, respectively. The above said treatments were autoclaved at a temperature of 121°C for a duration of 15 min and then finally incubation for 24 to 48 hours at 37°C temperature.

Identification of bacterial species: The urine culture with colony forming units (CFU)/mL >105 exists for not more than two microorganism is said to be positive UTI, whereas the occurrence of such culture units for more than two bacterial species were found to be contaminated. The observed positive culture subjects to certain biochemical reaction. Bacterial identification relies mainly on characteristics of colony culture, Gram staining and standard biochemical tests.

**Biochemical test:** Selected colonies were identified and differentiated according to culture characteristics; microscopic examination and microbiological analysis were tested biochemically for further confirmation of isolated bacteria. The identification of bacteria was performed using several biochemical tests such as indole, catalase, H2S production etc.

**Testing of antibiotic susceptibility pattern:** Further identification of isolated bacteria and their susceptibility to antimicrobial agents were achieved by means of an automatic system ASM ViteK (BioMerieux, Madrid) based on the guidelines followed by Clinical and Laboratory Standards Institute. Controllable requirements of the manufacturer were carried out in a precise manner.

**Results and Discussion**

Frequently, UTI is said to be a main reasonable source of microbial infection. Treatment of UTI patients depends mainly on organism type identification and appropriate choice of antibiotics. Resistance towards the causative bacteria changes depending on the areas and conditions. Observing the susceptibility patterns of antimicrobial agents assists the physician to select suitable beneficial antibiotics thus preventing the development of drug resistance. Initially, collecting and processing of 142 samples were performed for ICU patients.
Out of one 142 patients with catheterized urinary tract infection, 75 (52.81%) patients (21 males and 54 females) were considered positive culture regarding sex and age distribution. The percentage of infected females was larger than that of males. Similar prevalence was reported by [20], the percentages of males and females affected by urinary tract infection that was graphically represented in Figure (1). Moreover, Table (1) presented the significant P values of different age groups.

The yielded Gram negative bacterial species were isolated from 75 samples positive cultures showed significant growth of pathogens. Table (2) showed the distribution of the positive cultured samples on the basis of age and sex.

Table (3) showed the percentages of males and females affected by different bacterial species in urinary tract infections, P values were presented in Table (4). This study showed that the bacterial species E. coli (44) was considered as the most commonly isolated species that caused severe urinary infections among Gram-negative bacteria. The findings of this study were supported by findings from other studies [21-23].

Table (4) represented the different bacterial isolates according to Antibiotics based on Vitek 2 reports. The output results shows higher rate values of UTI is affected by E. coli (44) followed by Kleb. Pneumonia (10) and the minimum affected rate are caused due to Sphingomonaspaucimobilis (2). Inaddition to this, E. coli is registered as the commonly insulated bacterial species from females (32 out of 44). The antibiotic sensitivity pattern reveals that extreme sensitivity values is offered by the antibiotics Amikacin, Gentamicine and Ciprofloxacin respectively, in which the maximum value of resistant towards the urinary infections are possessed by Gentamicine followed by Ciprofloxacin antibiotics.

** The differences are significant at 0.01 level

The best ever efficient antibiotics that fight against E. coli bacterial species were Amikacin, Gentamicine and Ciproflaxacin. The consistency and higher levels of susceptibility pattern of E. coli against nitrofurantoin is influenced by its narrow spectrum, restricted indications, its limited tissue distribution and imperfect bacterial contacts in outer region of urinary tract \[24\]. These results coincide with previous studies \[20\].

Current study does not relate the maternal age, occupation, address, parity, marital status, education etc. with the isolated bacterial species. On the other hand, in other literature studies, certain risk factors were considered as UTI was related to maternal age and parity. However, previous studies did not characterize these effects in a detailed manner. Certain studies indicated that the existence of UTI usually depends on age, indicating that older people are commonly affected by such infections, whereas other studies pointed that it affects young age groups in high percentages \[25\].

The detection of phenotypes in resistant mechanism operates fast with effective costs, necessitate low labour appliance and avoids the requirement of higher technical expertise. These advantages make this detection to accomplish daily even in poor countries. The output of such detection produces better and effective results.

Figure 2: Distribution of Gram-negative isolates based on antibiotics obtained by Vitek 2 reports

Bacterial profiles indicated higher infection rate although it exists within a stated range. While inserting a catheter requires certain aseptic standards to be followed including the antibiotics policy formulation by adopting surveillance strategies etc., higher levels of resistant bacteria restrict the utilization of antimicrobial agents in therapy. Most challenging and aim of ICU that covers a wide range is said to be the antimicrobial resistance. Multidrug resistant strains are continuously surveyed to assist the selection of suitable efficient treatment and also to access the usefulness in adopting the controllable strategies of infection \[26\].
Conclusion

The necessity of effective and enhanced UTI diagnosis is significant. Treatment based on bacterial profile and antimicrobial susceptibility pattern improves the health of patients as well as paves the way to enhance the utilization of antibiotics against multidrug-resistant pathogens. Vitek MS showed better and higher accuracy regarding the analysis of Gram-negative bacteria in urine samples with CFU ≥105. Hence, it offers a reliable and perfect method in diagnosing urinary tract infection caused by Gram-negative bacteria. This method does not work suitably in case of Gram-positive bacteria. E.coli causes more effect on urinary tract when compared to other bacteria. The appropriate antibiotics that fight against the isolated bacterial species particularly E. coli were Amikacin, Gentamicine and Ciproflaxacin.

ABSTRACT

The oral cavity is considered as a complex microbial community. *Streptococcus mutans* has been the major bacteria that cause dental caries. This species of bacteria have many factors to facilitate colonized the tooth surfaces causing caries and lesions.

In this study, (150) samples include buccal swabs, which were randomly collection from 150 patient’s oral cavities (75 female and 75 male) during the period from November 2017 to April 2018 from non-government dental clinical in Baghdad, Karkh and Rusafa. The age of patients ranged from 25 to 50 years. The samples were cultured on selective and enriched culture media. Then, *Streptococcus mutans* isolates were identified by using Polymerase Chain Reaction (PCR) technique and sequencing of gtfD gene.

The results of the sequencing showed congruence with isolation *Streptococcus mutans* of amplified product of gtfD gene appeared 93% compatibility. (540 to 807) number of nucleotide from the gene of a gene bank, and have number score (403) bits, expect (1e-108), and corresponds to the global number ID: JX073019.1.

PCR method was used to detect gtfD gene in buccal swabs which is more sensitive than API 20 strepts and culture media to identify *Streptococcus mutans*. The study showed that oral *Strept. mutans* isolates had gtfD gene encoding glucosyltranferase which responsible for *Streptococcus mutans* pathogenicity and causing dental cavies in different age groups.

**Keywords:** Dental caries, Oral *Streptococcus mutans*, PCR technique, gtf gene

Introduction

*Streptococcus mutans* is Gram-positive streptococcus bacterium, grow in facultative anaerobes conditions. They are present in the human oral cavity causing teeth necrosis [¹]. It is a major pathogen of dental caries as a result of its ability to adhere and grow on the teeth surfaces [¹,²]. It is a cariogenic bacterium that hydrolyses the sugar to get energy and gives an acidic environment, which demineralizes the structure of the infected teeth and then dissolves the calcium causing holes [³].

PCR techniques are useful for the diagnosis and analysis of oral pathogenic streptococci using species specific primers (gtfD) which conceded the target of analyzed gene were done to identify *Streptococcus mutans* [⁴]. Identification and detection of Strep. mutans in clinical samples by using selective and enriched culture media, like Mitis salivarius bacitracin agar is not sufficient alone. However, polymerase chain reaction techniques are needed to identify and differentiate between the species of *Streptococcus*, and it also gives accurate results [⁵]. The aims of this study are to detect gtfD gene and determine the phylogenetic tree in *S. mutans* isolates from dental caries from Iraq patients.

**Materials and Method**

**Sample Collection:** The current study includes (150) samples (buccal swabs), which was randomly collection
from 150 patient’s oral cavities (75 female and 75 male) during the period from November 2017 to April 2018 at non-government dental clinical in Baghdad, Karkh and Rusafa. The age of patients ranged from 25 to 50 years. The samples transported in closed icebox to the medical laboratory.

**Isolation and detection of Streptococcus mutans:** All buccal swabs were cultured on MSBA (Mitis salivarius bacitracin 10% sacarose) (Oxoid) to inhibit the growth of most types of bacteria except Streptococcus mutans. The isolated colonies were subcultured on MSBA agar plates and incubated at 37°C for 24 h and 48 h in anaerobic jar with 5% CO₂ enriched atmosphere[6].

**DNA extraction from Streptococcus mutans:** Buccal swabs were transported to the medical laboratory to culture them on selective and enriched culture media and for extraction the total streptococcal genomic DNA using DNA extraction kit. G- spin DNA extraction kit, intron biotechnology, cat.no. 17045 was used to extract the DNA from Streptococcus mutans: It consists from 25 mL Buffer CL; 25 mL Buffer BL; 40 mL Buffer WA; 10 mL Buffer WB; 20 mL Buffer CE; 50 ea Spin Column/ Collection Tube; 3 mg x 1 vial containing RNase A and 22 g x 1 vial Proteinase K.

**Agarose gel electrophoresis of DNA**

**Agarose gel Preparation:** The procedure of Sambrook et al.,1989 [7] was used to prepare the gel. The agarose gel was prepared in 1.5% condensation by melting 1.5 g of agarose in 100mL of Tris Buffer - EDTA (TBE) buffer. Then, Agarose exposed to heat source to boil; after that, it was left to cool at (45-50°C). The cooled gel poured into the plates in which the plate of agarose support prepared after fixing the comb to make holes that could hold the samples. The gel was poured without making any air bubbles and left for 30 minutes. Then the comb was removed from the solidified agarose. The plate was fixed for the Electrophoresis and the tank was filled with Tris buffer - EDTA (TBE) to cover the gel surface.

**Preparation of Sample:** Three microliters of the processor loading buffer (Intron/Korea) was mixed with five microliters of the supposed DNA to be electrophoresis (loading dye), and electrical current of 7 v/cm was used for (1-2) hrs. Then, the gel was tested using UV light after putting the gel in pool contain on 30µL Red safe Nucleic acid staining solution and 500 mL from distilled water.

**KAPA Universal DNA Ladder:** DNA ladder (1000-10000bp) was used for determining the approximate size and quantity of double stranded DNA on agarose gel.

**Primers are used in the interaction:** The lyophilized primers were dissolved in the ddH₂O to get a final concentration of 100pmol/µL as a stock solution. It was kept at -20°C to prepare 10pmol/µL concentration as work primer suspended; 10µL of the stock solution mixed with 90µL of the free ddH₂O to reach a final volume (100µL), which investigated by using IDT (Integrated DNA Technologies company, Canada).

**Maxime PCR PreMix kit (i-Taq) 20µlrxn:** The kit has consisted of i-Taq DNA polymerase 5U/µL; DNTPs 2.5mM; Reaction buffer (10X) 1X; Gel loading buffer 1X. PCR program: Taq PCR PreMix 5µL was used. Each Forward and Reverse primer (10picomols/µL) were put in an Eppendorf tubes, then 1.5µL of template DNA was added, and the volume was completed to 25µL by adding 16.5µL distilled water. The PCR amplification reaction was performed in a thermocycler with the following cycling parameters (Table 2). The PCR products were analyzed by electrophoresis in 2% Agarose gel–TBE buffer. The gel was stained with Red safe concentration (20,000X) and photographed under UV light. The size of bands was compared with DNA ladder which conceder as size standard.

The PCR gave Streptococcus mutans which in Baghdad governorate in proportion 54.6%. Streptococcus mutans selective media. In contrast, Hadi disease had 100% were taken from patients with the dental and periodontal Xigheer and Sahib in Karbala was 39.39% from patients with teeth plaque. Whereas, positive culture for Mudallal isolates gave Gram positive cocci, arranged in pairs and examination appeared that the and oxidase. The results of light microscopic results for Voges Proskauer test, and negative for catalase and maltose fermentation. Also, they gave positive glucose and cellobiose fermentation, esculin hydrolysis and genotyping of Streptococcus mutans in patients with dental caries were almost identical with some substitutions.

The results of a current study were compatible with Flayyih et al., [15]. The researchers found that 29 of Streptococcus mutans isolates isolated from saliva and dental plaques samples in patients aged from 4 to 65 years old. Also, they revealed that all Streptococcus mutans isolates by using PCR technique had bands with 324bp which represent gtfD gene encoding a glucosyltransferase gtfD that play important role in dental plaque and caries. Also, the results of a current study are similar to the results of Hoshino et al., 2004 [16]. They were found that Streptococcus mutans had gtf gene codes for glucosyltransferase that synthesize glucan which plays an important role in dental plaque, and the PCR methods is useful for the gtfD gene detection there for oral Streptococcus mutans can be successfully used in clinical applications.

The results of a current study are compatible with AL-Mudallal et al. [6]. They found that the percentage of the positive culture for Streptococcus mutans on MSA medium was 39.39% from patients with teeth plaque. Whereas, Xigheer and Sahib in Karbala [11] found that all 100 samples were taken from patients with the dental and periodontal disease had 100% Streptococcus mutans which isolated on selective media. In contrast, Hadi et al., 2012 [12] isolated Streptococcus mutans from patients suffered from gingivitis in Baghdad governorate in proportion 54.6%. gtfD gene gave 350bp band for all isolates under study (Fig.2). Our result is compatible with study in Japan. Nomura et al., 2006 [17] revealed that the PCR for gtfD gene gave an approximately 4.5kb band for two isolates and 5.8kb band for other isolate isolated from the patient with endocarditis. Multiple alignments of the nucleotide sequences of the gtf genes were studied by Fujiwara et al., 1998 [14]. They found that gtfB, gtfC and gtfD genes isolated from Streptococcus mutans in patients with dental caries were almost identical with some substitutions.

The results of a current study were compatible with Flayyih et al., [15]. The researchers found that 29 of Streptococcus mutans isolates isolated from saliva and dental plaques samples in patients aged from 4 to 65 years old. Also, they revealed that all Streptococcus mutans isolates by using PCR technique had bands with 324bp which represent gtfD gene encoding a glucosyltransferase gtfD that play important role in dental plaque and caries. Also, the results of a current study are similar to the results of Hoshino et al., 2004 [16]. They were found that Streptococcus mutans had gtf gene codes for glucosyltransferase that synthesize glucan which plays an important role in dental plaque, and the PCR methods is useful for the gtfD gene detection there for oral Streptococcus mutans can be successfully used in clinical applications.

gtfD gene was used to study horizontal transmission of glycosyl-hydrolase through the family [17]. The current study describes the good identification of phenotyping and genotyping of gtfD gene in Streptococcus mutans isolated from patients with dental caries and the results are compatible to the results which done by [18]. They were used 1.2% agarose gel electrophoresis to depict the presence of gtfD gene and confirmed the Streptococcus mutans presence in the samples. Also, they were extracted genomic DNA from Streptococcus mutans which analyzed with 1% agarose gel electrophoresis. Positive PCR amplification by using primer pair specific to 16S rDNA was at 1,485bp that compared with standard 1KPb.

**Figure 1: Gel electrophoresis of genomic DNA extraction from bacteria, 1% agarose gel at 7v/cm2 for 1:15 hours**
Figure 2: PCR product the band size 350 bp. The product was electrophoresis on 1% agarose at 7v/cm². 1x TBE buffer for 1:30 hours. N: DNA ladder (100).

**Sequencing:** The sequencing and BLAST analysis of partial *gtfD* (figure 1, 2). The results of the sequencing showed congruence with isolation *Streptococcus mutans* of amplified product of *gtfD* gene appeared 93% compatibility. (540to807) number of nucleotide from gene of gene bank, and have number score (403) bits, expect (1e-108), and corresponds to the global number ID: JX073019.1 The results as shown (Figure 3), after alignment of product amplification of *gtfD* gene for first group having seven Transition (A>G, A>G, A>G, A>G, T>C, A>G and G>A, and having eleven Transversion (A>T, T>A, G>T, A>T, A>T, T>G, A>T, C>A, G>T, T>A and C>A) from the Gene Bank. *gtfD* gene was successfully amplified using specific PCR primers for the gene.

Figure 3: BLAST alignment
Phylogenetic tree construction: This study takes care for phylogenetic analysis for geographic genetic distances determination. The analyzes phylogeny occurred for specific genes-of-interest, partial-length of gtfD gene. The genetic dimension between Iraq and the isolates of the world is detailed according to the Phylogenetic tree and the comparison table. Hierarchical cluster analysis determine the following clusters: large Cluster divided into several neck: first root USA: Rochester NY, Papua New Guinea and IRAQ the genetic dimension was by 1.132, second root Japan and Japan Osaka the genetic dimension was by 1.113, third root Texas the genetic dimension was by 1.598, fourth root USA and Korea the genetic dimension was by 1.318 (Figure 4).

Figure 4: The clustering tree of the sequencing of Streptococcus mutans of gtfD gene

Conclusion

PCR method was used to detect gtfD gene in buccal swabs which is more sensitive than API 20 streps and culture media to identify Streptococcus mutans. The study showed that oral Strept. mutans isolates had gtfD gene encoding glucosyltranferase which responsible for Streptococcus mutans pathogenicity and causing dental cavies in different age groups.

Peripheral Neuropathy Types of Diabetic Patients in Babylon Province

Sarah Ali Alkindy¹, Farah Nabil Abbass², Ali Riyad Alanbari³

¹M.B.Ch.B. Graduated Student, ²Prof. Dr., Physiology Department, College of Medicine, Babylon University, Iraq; ³M.B.Ch.B., F.I.B.M.S., Specialist Doctor at Health Ministry of Iraq

ABSTRACT

Background: Diabetes Mellitus is a clinical syndrome characterized by hyperglycemia due to absolute or relative insulin deficiency. The prevalence of diabetic peripheral neuropathy (DPN) is 13.4% in Iraqi patients. In Saudi Arabia the prevalence of diabetic peripheral neuropathy is 66.3%. Distal symmetric sensorimotor peripheral neuropathy is the most common type of diabetic neuropathy. Therefore, the aim of current study was to determine the most frequent peripheral neuropathy type in diabetic peripheral neuropathy patients who visit the diabetic center in Babylon Province.

Method: Three hundred individuals were considered in the study. They were divided into two groups labeled as A and B. Group A involved 150 diabetic-free individuals and considered as a control group. Group B involved 150 diabetic diagnosed individuals. All participants are underwent neurological examination and nerve conduction study (NCS). The study was carried out at Mirjan and Al-Sadeq Teaching Hospitals in Babylon province during the period from Oct.2017 to Sep.2018.

Results: The electrophysiological changes assessed by NCS showed that there was a significant decrease in amplitude, conduction velocity for motor and sensory nerves in patients with peripheral neuropathy in comparison with that of control group (P<0.05). Also, there was prolongation in the F wave and distal latencies in patients with peripheral neuropathy in comparison with that of the control group, P value <0.05.

Conclusions: From those findings we can conclude that Polyneuropathy is the most frequent type of neuropathy (62%) followed by mononeuropathy (16.7%) and mononeuropathy multiplex (14%). In addition, the sensorimotor fibers are most frequent ones among other nerve fiber types (71.2%), but the early fibers affect are sensory fibers.

Keywords: Iraq; Diabetic Patients ; Neuropathy Types.

Introduction

Diabetes Mellitus (DM) is a clinical syndrome characterized by hyperglycemia due to absolute or relative insulin deficiency (¹). The prevalence of diabetic peripheral neuropathy (DPN) is 13.4% in Iraqi patients. In Saudi Arabia the prevalence of diabetic peripheral neuropathy is 66.3% (²). Distal symmetric sensorimotor peripheral neuropathy is the most common type of diabetic neuropathy. It is typically presented as a slowly progressive primarily sensory deficit in a length-dependent fashion. The symptoms are usually starting in the feet and spreading upwards, evoking the classic stocking glove distribution (³). These symptoms of DPN vary depending on fiber type involved. It is noteworthy that large fiber involved proprioception and light touch would be impaired. Small fiber involved pain and temperature perception would be impaired leading to paresthesias, dysesthesias, and/or neuropathic pain. Distal weakness occurs only in the most severe cases. Diabetic peripheral neuropathy may be presented early with diminished or absent deep-tendon reflexes, particularly the Achilles tendon reflex (⁴ and ⁵). Diabetic peripheral neuropathy can be diagnosed by variety of ways including full history, neurological examination and electrophysiological study (NCS). The
Electrophysiological changes include prolongation of latency (sensory and motor), decreased in amplitude & decreased in conduction velocity.

These changes are elicited first in the sensory nerves of lower limbs. The parameters abnormalities of NCS can reflect the pathological pattern of DPN.

Patients and Method

Three hundred individuals were considered in the study. They were divided into two groups labeled as A and B. Group A involved 150 diabetic free individuals and considered as control group. The other group, group B, involved 150 diabetic diagnosed individuals. The study was carried out at Mirjan teaching hospital and Al-Sadeq Teaching Hospital in Babylon province during the period from Oct.2017 to Sep.2018. All participants underwent neurological examination and nerve conduction study (NCS). The NCS can be assessed by motor and sensory nerves examination. Motor NCS can be done by applying surface electrode as recording electrode on the belly of muscle and reference electrode on the tendon of muscle. The motor nerves examined in this study were median and ulnar nerves, in upper limbs, and peroneal and posterior tibial nerves in lower limbs.

The sensory NCS can be assessed by applying ring electrode on the way of examined nerve where the nerve is more superficial. The sensory nerves examined in this study were median and ulnar nerves, in the upper limbs, and sural nerve in the lower limbs.

The amplitude, latency and conduction velocity of sensory and motor nerves were recorded by special machine for all participants. The F wave latencies of the motor nerves were recorded, too. These parameters are known as NCS parameters.

Results

The results of study groups were analyzed. The mean and standard error (SE) for sociodemographic data were summarized in Table (1).

**Discussion**

Most of participants were females (54.6%) and DM type II (70%). Males (45.4%) and DM type I (30%) were less frequent in our study as shown in Table (1) and Figures (1) and (2). The cause of these results may be due to females having improper glycemic control than males due to hormonal disturbances.

Regarding the NCS parameters changing (amplitude, conduction velocity, latency and F wave) there was prolongation in F wave latency and increment in latency for sensory and motor nerves of DM patients in comparison with controls. Also, there was a decrease in amplitude and conduction velocity of
motor and sensory nerves of DM patients in comparison with controls as shown in Tables (2). The reason for prolongation in F wave latency in DM patients may be due to demyelinating process of motor nerve fibers which means that the antidromically excited nerve needs more time to transmit the travelling signal so cause an increment in F wave latency (7). The cause of prolongation in latency and reduction in conduction velocity of motor and sensory nerve of DM patients may be due to demyelinating process in DM. Also, DM patients showed a decrease in amplitude of motor and sensory nerves. This may be due to a decrease in number of nerve fibers excited. By changing the abovementioned NCS parameters, we could record two types of results labeled as 1-type of peripheral neuropathy in DM patients. 2- type of nerve fiber affected in DPN patients. The most frequent type of peripheral neuropathy is poly neuropathy (62.7%) followed by mononeuropathy (16.7%). The mononeuropathy multiplex and normal NCS were less frequent (14% and 6.7%, respectively) as shown in Table (4). These results may be due to that DM patients were late in their visits to the specialist center and a poor control for their blood sugar level with longer duration of DM. These results were in agreement with those reported by (8-10).

The most common type of nerve fibers affected was sensorimotor fibers (45.7%) as shown in Table (5). This result agreed well with (11-15) who showed that the sensory nerves involvement were more frequent than F wave latencies prolongation. These results may be due to that DM patients had poor control for their blood sugar level and delayed their visits to specialist center. This can give more time to affect both sensory and motor nerve fibers. The motor fiber are less frequently affected than sensory fibers. Also, the sensory fibers were earlier affected. This may be due to the fact that the diameter of a sensory nerve is smaller than motor nerve and travelled longer than motor fiber. This reason made them more susceptible for developing neuropathy and may be the early sign of DPN.

Conclusion
From the results mentioned we can conclude the followings:

1. NCS with neurological examination give important information about DPN in diabetic patients, so this should be performed as a routine schedule in diabetic out-patient.

2. Sensory and motor polyneuropathy can be considered as the most frequent type of DPN in diabetic patients.

3. The mononeuropathy can give us early information about the DPN and the instruction should be given to patients to control the risk factors of DM to improve the outcome.

4. The DPN can be appeared as sensory nerve affected alone as an early stage of DPN when other tests values are normal.

5. The F wave latencies prolongation can be taken as an early sign of motor neuropathy before any changes in motor NCS parameters.

ABSTRACT

To identify the prevalence of rickets in preterm and term babies, and studying the risk factor associated with this disease in preterm babies as age, sex, residence, type of feeding, and changes in some biochemical tests. Total 200 cases with different ages from one month to two years were included, 100 cases of them were preterm babies and 100 were term babies. Patients who diagnosed as rickets radiologically among preterm babies were studied by history (sex, age, type of feeding, residence and clinical feature) and investigated serologically (serum calcium, phosphorus, alkaline phosphatase and vitamin D).

About 35% of preterm babies were diagnosed as rickets of prematurity and 9% were rickets in term babies. among risk factors, breast milk feeding was significant risk factors while residence and gender variation were found to be not significant risk factors. most common age reported with rickets was between 2 and 12 months. alkaline phosphatase elevated in 91% of cases diagnosed as rickets.

The rickets of preterm babies is an important disease to be studied in Iraq. Breast feeding is an important risk factor of the disease.alkaline phosphatase activity and radiological feature are important for screening.

Keywords: Preterm babies, Rickets, Risk factors

Introduction

Rickets is a disease of growing bone, occurs in children only before fusion of the epiphyses, and is due to unmineralized matrix at the growth plates. Rickets may be seen in young children 6 to 24 months old. Rickets may be caused by vitamin D disorder, calcium deficiency, phosphorus deficiency, renal loss or distal renal tubular acidosis¹.

Prematurity is a live born infants delivered before 37 completed weeks from first day of the last menstrual period².

Rickets in preterm babies has become a significant problem, as the survival rate for this group has increased.

About 80% of transfer for calcium and phosphorus from mother to fetus occurs during the 3rd trimester. Thus, premature birth interrupts this process, especially when breast milk and standard formula do not contain enough calcium and phosphorus to supply the needs of the developing premature infant ²,³ another reason is the high degree of skeletal growth that occur rapidly following birth ⁴.

Rickets of prematurity occurs as early as 1-4 months after birth. Most infants have no clinical manifestations, and the diagnosis is based on radiographic and laboratory findings, although some can have non-traumatic fractures, but most are not suspected clinically ⁵.

Biochemical changes that occur in rickets of prematurity, the serum phosphorus level is low or low-normal, Serum levels of calcium are low, normal, or high. Most patients have normal levels of 25-D. The hypophosphatemia stimulates renal 1α-hydroxylase, so levels of 1, 25-D are high or high-normal. Alkaline phosphatase levels are often elevated, but some affected
infants have normal levels. The diagnosis is confirmed by radiologic evidence of rickets, which is best seen on films of the wrists.\(^5\) Wrist X-ray show thickening of growth plate, fraying, cupping and widening of distal end of metaphysis.\(^6\)

This study aim To describe the prevalence of rickets in premature babies, identify age and sex distribution of rickets and some associated risk factors such us residence and types of feeding and identify the relation between clinical, radiological, and biochemical findings in positive cases in a trial to decrease morbidity among premature infant by early detection of rickets.

**Materials and Method**

Data was collected by direct interview to the parents in the outpatient clinic and in pediatrics ward of Al-Ramadi Teaching Hospital for maternity and children. The parents were given a full explanation about the purpose of the study and assurance about the confidentiality of the information and that the participation was completely optional.

Hospital based cross sectional case control was done on 200 children less 2 years of age, whom attending hospital during the period from the first of October 2017 to the first of April 2018 over a period of 6 months selected randomly.100 cases were preterm and 100 cases were term babies. A specially designed interview sheet was used to collect the information from the family. The sheet includes data on; name, age which categorized into 3 groups under 2 months, from 2-12 months and from 1-2 years, sex, residence whether rural or urban areas, and socioeconomic state, duration of pregnancy to know whether the child is term or preterm, type of feeding; breast, bottle or mixed feeding

Physical examination were performed including all signs of rickets such as; protruding abdomen, weak muscles, craniotabes, frontal bossing, wide fontanel, delayed dentation, rachitic rosary, Harrison groove, wide wrists and leg bowing.

All cases investigated with serum calcium, serum phosphorus, serum alkaline phosphatase and serum vitamin D level. Biochemical investigations were measured by specific method for estimation of their level by experiment laboratory staff.

Wrist X-ray was done by experiment technician and reports of X-rays was done by experiment radiologist, In this study the diagnosis depend on radiological findings.

All cases investigated with X-ray of wrist, looking for signs of rickets which include; fraying, cupping, widening of wrist, decrease bone density. Patient were divided according to maturity into full term(>=37 completed weeks of gestation) and preterm(<37 completed weeks of gestation), 200 cases were studied, of them 100 case full term and 100 case preterm, 35 cases were diagnosed as rickets in preterm and 9 cases in term children, rachitic preterm babies were studied fully and that of terms babies used to compare for the incidence only.

Exclusion criteria: All children more than two years old and Children on tonics and vitamin D supplements.

Statistical analysis was done by using SPSS program and Microsoft Excel 2007 system.

**Results**

The total cases were 200, half of them were term and other half were preterm babies, 9 out of 100 cases from term babies were diagnosed as rickets while 35 case from preterm sample were diagnosed as rickets.

The prevalence of rickets among term children 9%, as shown in figure (1).

Discussion

Rickets of prematurity and neonatal metabolic bone disease are terms used to describe the reduced skeletal mineralization seen in preterm babies, this makes the preterm newborn more susceptible to fractures during minimally invasive procedures and even with routine handling while in the Neonatal Intensive Care Unit. 6, 7

In this study, the prevalence of rickets was (35%) of preterm babies, other study in Iran 8 showed (23%) of premature babies develop rickets, in Nairobi 9 (58.8 %) and in Korea 10 was (44%). The reported incidence of rickets in prematurity varies widely from center to another 11, 12, since there is no general agreement on diagnostic criteria, it is impossible to certain how common the problem is. Reduced bone mineralization is almost universal in infants less than 1500gram, since they have poor calcium retention for several weeks after birth 13. It is found that risk of rickets in prematurity is inversely related to the infant’s birth weight and gestational age, and results obtained that osteopenia of prematurity occurs in 20-30% of preterm infants with birth weight below 1500 g and in 50-60% of preterm infants with birth weight below 1000 g. 2, 14.

Regarding gender variation, in this study male slightly more than female with no significant statistically, other studies showed the same results 2, 6, but no another study showed a significant variation in sex in rickets of prematurity.
Regarding type of feeding, in this study breast feeding babies are more frequently to develop rickets of prematurity than of that with bottle feeding. Another studies in UK and India showed the same results. studies showed that high-risk group of rickets of prematurity is made up of receiving unsupplemented breast milk. Despite the many documented benefits of breast milk for preterm, it just doesn’t have enough phosphate and calcium to support rapid bone growth. This is an important reason to use breast milk supplements.

In this study, the most age onset of presentation of rickets in prematurity was between 2 to 12 months. similar results was obtained in Nigeria, other researches demonstrate that the age of presentation of rickets in prematurity occur between 6 and 16 weeks age but may remain asymptomatic for weeks until overt rickets or fractures develop. Researches showed that in premature infants with gestational age under 32 week, bone mineral content was found to be 25% to 70% lower than term infants.

Regarding biochemical results, serum level of calcium was low in (11%) of cases, serum phosphate was low in (60%) of cases, serum alkaline phosphatase was high in (91%) of cases and serum vitamin D (25(OH) D ) was low in (31%) of cases.Nearly similar results were obtained in Hong Kong and Italy. Infants with rickets will demonstrate a normal serum calcium and a low or low normal serum phosphorus level. Infants with severe, prolonged osteopenia may demonstrate a low serum calcium level. In the majority of cases of rickets in preterm babies, 25 (OH)D levels are normal, but in opposite another study in Saudi Arabia demonstrate (75%) low level of vitamin D with rickets. Alkaline phosphatase levels are usually elevated in cases of active rickets, and some authors have suggested that serial measurements may be useful in predicting disease.

All the patients included in our study had some degree of radiological changes suggestion of rickets such as metaphysical Splaying, cupping, fraying, widening of epiphysial growth plate and poor mineralization of trabecular bone. The X-Rays is a very useful for early diagnosis as radiological abnormalities can be found before physical signs, however, screening test require both radiological and alkaline phpsphatase activity measurement to enable neonatologists minimize risk factors and optimize nutrition and mineral supplementation.

Conclusions

High number of cases of rickets occurs in prematurity, and mostly in ages between 2 and 12 months. Breast feeding is an important risk factor for the disease. Increase serum alkaline activity is an important test in diagnosis of rickets. Gender variation and residency was found to be statistically not a significant factors for this disease.

ABSTRACT

It may be assessed that indeed up with 30% for edifices overall might be those subject from claiming objections associated with the personal satisfaction about indoor air. Possibility sources about air contamination camwood be both natural What’s more inorganic particles. Microorganisms enters under the edifices throughout those airing about rooms alternately through those distinctive slots Also might create on the surfaces about Different materials. Intensively develops over poorly ventilated, moist and dusty situations. To this motivation behind the introduction of the indoor air contamination might make stranger for occupants over the uncover of the impurities of the open air. This article keeps tabs for living air pollutants from existing What’s more dead living sources, particularly the individuals associated for growths. Growth’s discovered in the indoor air of Domesticated dwellings clinched alongside an expansive degree need aid comparable clinched alongside their species arrangement on the individuals found on the outside of the building.

Keywords: Microorganisms, contamination, Home, pollutants.

Introduction

Increasingly, there need aid reports about respiratory manifestations connected with staying. Previously, homes for stickiness issues and the vicinity about microorganisms around Different building materials [1]. Here we Additionally focuses crazy that poor indoor air caliber might cause word related sicknesses [2,3]. Individuals use give or take 90% about their available time inside their dwellings. In spite of it is hard should have confidence those purposes of presentation of the indoor air contamination could make stranger over those uncover of the impurities of the open air air [4,5]. The amount Also sort of pollutants suspended buzzing around determine the nature of this air. Possibility wellsprings from claiming air contamination might make both natural and inorganic particles. This article keeps tabs on living air pollutants Concerning illustration common pollutants from living and dead living wellsprings. The point when Intuition around living factors, microbes would meriting of consideration. Microorganisms enter of the inner part of the building from those outside, Yet what’s worth accentuating will be that inside there need aid real sources for advancement [6,7]. Again as far back as quite some time this issue need not diminished or Actually intensified, Likewise might a chance to be inferred from the most recent WHO report-WHO rules for indoor air quality: soddenness and shape. It is evaluated that indoor suddenness influence 10-50% about indoor situations over Europe, Furthermore in the different Exceptionally created nations [8]. To this reason, it may be justifiable that those species about parasite separated from the indoor air would in any event clinched alongside half indistinguishable twin with disengaged from diverse materials, dust, alternately starting with those surface of the dividers from claiming these rooms [9,10]. Spores alternately conidia Furthermore other structures for growths enter those human body to Different routes for every os, for every nasal alternately for every cutaneum [6,11,12]. Indoor microorganisms are display buzzing around Likewise In this way known as bioaerosol, they settle on different surfaces, might create to layers for condensed steam on the dividers Furthermore windows,
for sustenance remains, under carpets Furthermore with respect to whatever available clammy material. Especially useful earth to those improvemen about a number microorganisms is home tidy [13,14].

Growths Furthermore hypersensitive responses: Unfavorable susceptibility with growths might make showed by: bronchial asthma, rhinitis, conjunctivitis, urticaria, or atopic dermatitis. Fungi, contingent upon the species, would fit with actuate every last one of four sorts from claiming excessive touchiness responses [15,16]. Vicinity of growths done household dwellings frequently may be connected with hypersensitive reactions [6,17]. Around every last one of portrayed sorts about hypersensitive responses created Eventually Tom’s perusing growths of the the vast majority basic belongs excessive touchiness of the sort. I - quick reaction, IgE-dependent. This sort from claiming safe reaction may be likewise called anaphylactic Also clinically is showed Concerning illustration asthma, rhinitis, sinusitis, urticarial, swollen vascular alternately obscuration from claiming bronchi. In this body of evidence contagious allergens actuate igg creation which opsonized massorete units What’s more basophiles [15,18]. Clinically, kind iv for excessive touchiness responses might a chance to be showed by contact dermatitis alternately urticarial. Additionally portrayed would granulomatous instances with trademark in lamasery in filtrates [19]. Contagious spores over a few little amounts would characteristic Furthermore ordinarily found On both indoor and open air air. For powerless individuals, however, they might produce Different hypersensitive responses [20]. Contagious antigen skilled will actuate this sort for response will be practically usually mannan, basically discovered done Mobile dividers of the class aspergillus Also open Polaroid. These need aid cytotoxic responses -dependent principally from igigi and ignite jan paderewski antibodies alternately units such cytotoxic lymphocytes, characteristic slayer (NK) cells, alternately actuated macrophages controlled to antigen which is inserted with respect to platelets or constitutes a part from cell layer [21]. Molds would those mossycup oak as a relatable point over summer, Also starting with september to november those issue bit by bit declines. Those reason for overwhelming exacerbations from claiming bronchial asthma in the late midyear would see clinched alongside secondary focuses for spores of the class Alternaria and Cladosporium toward this time. It will be accepted that growths from the request of mucorales Also starting with Penicillium, aspergillus alternately Trichoderma class might assume a comparative part [22]. Normally side effects show up after10-30 minutes then afterward contact for allergen. Sort ii responses are lesquerella incessant. This kind of hypersensitive response may be as a rule connected with safe complexes comprising from claiming contagious antigens Also antibodies. Such complexes would framed Toward the vicinity of little sums from claiming parasite in the form (in the body of evidence about APBA) or repeater introduction on little conidia such these framed by aspergillus fumigatus which attained best 2-3. 5 microns [23,24].

This parasite postures An risk not best due to the plausibility for making hypersensitive reactions, as well as due to the a lot of Different unstable natural mixes (VOCs) discharged Throughout the animated development and also In the period from claiming passing for its fruiting figures. On the other hand, because of its solid cellulosic Also lignolytic properties, this parasite is hazardous for building materials [25]. Mold-induced hypersensitive responses are regularly comparative will the individuals connected with in lumens. It doesn’t is concerned that some molds would classified Concerning illustration pathogenic and the others as non-pathogenic. Both aggregations need aid hazardous with human wellbeing [26]. The A large portion normal protests connected with exposures to mold allergens are: runny nose, conjunctivitis, cough, upper respiratory tract congestion, midsection torment alternately urticaria. Allergenic growths might also improve the indications Previously, patients with atopic dermatitis, in patients with hypersensitive alveolar alveoli alternately for bronchial pneumonin [26,27].

Growths Similarly as makers about unstable mixes: It is great referred to that growths camwood emit a considerable measure from claiming unstable natural exacerbates (VOCs),which are a standout amongst a significant number items about their elementary alternately optional digestion system [28,29]. Those indications connected with discharged by growths VOC those the vast majority often would showed Eventually Tom’s perusing absence of comfort, headaches, eye torment pharyngitis, dry cough, dizziness, smeared vision, difficulty to concentration, affectability will smell, fatigue, apathy, or much An more terrific inclination with colds. These mostly neurotoxic indications need aid
improved for a higher centralization about bio aerosol On indoor air [36]. It is trademark that following taking off such An building alternately An room, these indications Typically vanish rapidly [38,39]. Those emission for these compound mixes may be also specifically related with a ailing unit which will be called ailing fabricating syndrome (SBS). Emission from claiming unstable substances and also handling of a colossal sums about extracellular polysaccharides (EPS) happens particularly At the molds grows over shut rooms, poorly ventilated with a secondary relative moistness [31]. It may be great known that growths show more terrific metabolic action under higher relative moistness [21]. Such unsafe states could exist best On one room, in the entire artment alternately Indeed going in the entirety building, particularly In the last need been based for insufficient materials of the commonplace atmosphere in this locale. Around alcohol the The majority frequently all the need aid found 1-octanol, 2-octanol, methylbutanol or ethyllhexanol. Separated from alcohol, terpenes Also ketones are also frequently produced, for example, such that 2-pentanone 2-hexanone, 2-heptanone, 3-octanone, α-pinene, β-pinene, camphene, limonene, alternately methylfuranes. “around those fragrant hydrocarbons prepared Eventually Tom’s perusing growths those The greater part regularly need aid discovered cyclohexane and benzene. Those development from claiming growths inside these spaces may be constantly went with Eventually Tom’s perusing the discharge for carbon dioxide What’s more unstable natural mixes. Exacerbates discharged by growths have a place with such aggregations Similarly as fragrant and chlorinated hydrocarbons, alcohol, ketones, aldehydes or esters [12]. Not just growths bring the capacity to prepare MVOC. Such mixes might Additionally make prepared Toward microscopic organisms What’s more actinobacteria. A percentage compounds, for example, such that monoterpene, might Additionally originate from sure fabricating materials furniture, carpets Also other wellsprings [33]. It need also been indicated that generated Toward a lot of people species about growths formaldehyde and β-glucans demonstrates strongirritation impact to mucosal membranes [14].

Mycotoxins Similarly as items for auxiliary digestion system: Demonstrating to the antagonistic impacts from claiming growths exhibit in the regulate mankind’s environment, it may be unthinkable with disregard their poisonous impacts on the human body. For respect to human and creature health, those ordinarily known issue pose mycotoxins [35]. It may be irritating that Around those contagious number there need aid watched virulent strains that bring the possibility to expanded handling from claiming mycotoxins. This wonder might make related for those expanding utilization of plant security results (pesticides, fungicides), of which the mutagenic impact will be great known [36]. Mycotoxins need aid poisonous results from claiming auxiliary digestion system for molds. It may be accepted that these mixes need aid necessary Toward growths in their regular environment, Likewise A large portion for these substances need aid generated against different microorganisms (counting other species of fungi) Likewise a show fate of rival to biological corners [37,38]. Thus far, more than 400 separate mycotoxins have been depicted [39]. Mycotoxins might reason both intense What’s more Ceaseless issue Previously, people. With actuate intense inebriation which frequently all the winds with death, it is necessary with get a milligram dosage for every kilogram from claiming body weight [39,40]. On toxin Toward mycotoxins A large portion often hails through ingestion from claiming sustenance defiled for these mixes. However, taking under record the way that mycotoxins camwood amass in distinctive structures about mycelium and camwood diffuse under the society medium those grade mycotoxicosis camwood happen Indeed going Toward inward breath for spores conidia alternately pieces about mycelium. For example, Stachybotrys, chartarum produces mycotoxins which concentrated to conidia, phialides Furthermore conidiophores. An specific measure of these harmful exacerbates are Additionally discharged under the medium, particularly Throughout those sporulation time. An additional species, aspergillus flavus Furthermore aspergillus parasiticus produces mycotoxins which amass Previously, conidia and sclerotia [41].

Those significantly expanded frequency for tumor done people possess mildew covered rooms By and large may be undoubtedly related for long haul presentation with mycotoxins [40,42]. It will be accepted that tumor changes, particularly malignancy from claiming liver or kidney, might be Postponed impacts of long -term composition should low doses from claiming mycotoxins of the human body [37,41]. Around those The majority imperative and the A large portion usually encountered in the nature’s domain mycotoxins need aid included aflatoxins, ochratoxin A, zearalenone, trichothecenes
What’s more fumonisins [39]. Those first of the said shows up especially hazardous with people What’s more animals due to their cancer-causing properties because of those benzofuran ring [41]. The practically broadly conveyed in the earth makers of hazardous mycotoxins need aid various species of the class aspergillus. Large portions species starting with this genus, Furthermore specifically An. Fumigatus, a. flavus, a. Terreus, An. Niger, An. Clavatus Furthermore An. Chevalierii were separated starting with cellulose acetic acid derivation or collagen held materials [38,39]. Those mycotoxin creation itself and the force about this procedure rely on upon the contagious strain, Furthermore its genotype. It Additionally relies from its developmental stage, starting with those relative moistness What’s more temperature, Also starting with the concoction creation of the substrate, On which states that parasite grows. In the respect to those latter, the nature of the nitrogen wellspring assumes a especially paramount part for the lethal intensify processing [39]. Mycotoxins would transformed intensively toward higher temperatures Furthermore under those higher relative moistness and especially inside the dwellings with poor ventilation [42]. For example, the ideal temperature for the creation about aflatoxin may be 33°C. It need Additionally been found that under those a portion levels from claiming inorganic nitrogen, phosphates Also under the states about oxygen exhaustion What’s more raised carbon dioxide the preparation about this poison may be inhibited [40].

Mobile Phones Contaminated with Bacteria among Workers in Dental Clinics

Luma Jasim Witwit¹, Hasan M. Al-Rammahi², Israa Abass Ubaid¹, Zainab Khudhur Ahmad AL-Mahdi¹, Ahmed Alhelal²

¹Department of Microbiology, ²Department of Operative, College of Dentistry, Babylon University, Iraq

ABSTRACT

Unfortunately, cross infection in dental field is a critical issue that most commonly occurs via different ways. The possible transmitters are (dentists, students, workers, mobile phone and other dental instruments). thus, the aim of this study is to investigate the level of contamination by measuring the percentages and type of bacteria isolated by swabbing from different surface sites of (30) mobile phones devices of (dentists, students, and workers) in a hospital of Dentistry Faculty - Babylon university. Collection of swaps samples from (30) mobile phones of dental workers was conducted at University clinics and then transmitted to the laboratory of microbiology to evaluate their bacterial contamination levels. Both McFarland standard tubes and optical density methods were used for performing of bacterial quantification and the standard microbiological techniques were used for identification of the isolated bacterial agent. All of the investigated dental workers mobile devices have some degree of bacterial contamination (100%) either with single or mixed microbial agents. *S. epidermidis* having the higher chance of contamination (23.3%), (16.6%) *E. coli* and *Enterococcus fecalis* (20%) *Bacillus* spp., (10%) for *S. aureas*, (6.67%) *Pseudomonas* spp., (10%) *Streptococcus* spp., (3.33%) for each of *Salmonella* spp, *Klebsiella* spp., *Shigella* spp. and *Proteus* spp. respectively. The mean bacterial count was (1.5×10⁹) method. By using the surface spread method, the corresponding figures were an organisms/phone. Hand hygiene is very important in prevention mobiles contamination and suggestion of prevent using mobiles phones in side dental clinics units.

Keywords: Mobile phone, Bacterial contamination, hand hygiene

Introduction

The mobiles make life easier, but they pose a number of new hazards also (1). A vast number of microbes presents on the surfaces of the mobiles making them as a risk for human health (2). Our Mobiles can be considered as one of the necessities in our social and professional life today. As they are small and very useful during emergencies, they are the much preferred and most used routes of communication (3). Dental profession is no exception to cellphone use. Workers in dental field may exposed to many microorganisms exist in saliva and blood. Their cellular phones are rarely cleaned and they usually touch their phones without hand washing especially during and after finishing of the patient examination (3, 4). Infection control is one of the biggest challenges that facing the dental professionals, it is important risk factor for both the patient and dentist (5). However, microbial transmission in the dental field can occurs either directly from one person to another or indirectly, by contaminated tools and environmental surfaces that are not sterilized and disinfected regularly (6). Therefore, one of the most important ways of preventing the cross infection and dangerous diseases in dentistry is to increase awareness of dental workers about the scientific methods of disinfection and sterilization of dental equipment and devices dental offices (7).

Materials and Method

Sample Collection and Laboratory Diagnosis: The present study was done at the hospital of dentistry faculty of Babylon University. Random sampling of (30)
mobile phones from subject persons (students, workers and dentists) by swabbing determined five different sites in a measure (1 cm²) using a dry sterile cotton swabs and were put in (5ml) (BHIB) tube and incubated over-night at (37°C). The positive growth tubes were compared with the turbidity of different concentration of McFarland tube and were subjected to optical density measurement by spectrophotometer. The samples were analyzed in the laboratory of microbiology for culturing each sample on blood and macConkey agar and incubated under aerobic and an-aerobic condition for bacterial identification. For bacterial identification, purely isolated colonies were gram differentiated and after that biochemically distinguished by (urease, oxidase, coagulase, catalase, indol, TSI and MRVP) (8).

**Estimation Bacterial Counts:** Bacterial counts in area of (1cm²) of mobiles phones estimated using McFarland standard tubes (9, 10).

**Results**

From (30) different cellular mobile devices samples were collected in this study (students, workers and dentists) and were subjected to laboratory diagnosis the result revealed different percentages of bacteria (figure 1) show (23.3%) S. epidermidis, (16.6%) E. coli and Enterococcus fecalis (20%) Bacillus spp., (10%) for S. aureas, (6.67%) Pseudomonas spp., (10%) Strepococcus spp., (3.33%) for each of Salmonella spp., Klebsiella spp., Proteus spp., and Shigella spp.

The Quantity of bacterial contamination was estimated using McFarland standard tubes, the mean of bacteria was (1.5×10⁹).

**Discussion**

Mobile phones may be considered a source of infections because of their own temperament and nearness to touchy piece of our bodies, for example, faces, ears, lips and hands. Using of mobiles is highly prevalent among medical and dental workers, playing a significant role and positively affect their communication abilities. However; this referred only to technical point of view and have no consideration of their possible role in infection transmission. Preventing of infection transmission in is a critical issue in dental profession, because of the infectious diseases can be easily transmitted in dental environment (11).

The mobiles are usually carried by their owners in all places, and considering that the human’s hand and environments like kitchen, hospital, and toilet have a large number of microbes such as potentially pathogenic bacteria, so the mobiles can be also considered as a major device of transmitting disease in the community (12).
Cellular phones due to their high temperature and moisture content of the operatory becomes suitable surface for microbial growth. The results of this study revealed that different contamination ratio of the mobiles of (students, dentists, and workers) in a hospital of dentistry faculty of Babylon University, but the highest level were showed in Staphylococcus epidermidis (23.3%) (Figure 1) The high isolation percent of Staphylococcus epidermidis clarified that the source of most mobile phones contaminated bacteria are the skin\(^{(13)}\).

Another isolates of bacteria obtained from the samples of the present study are *E. coli*, *Enterococcus fæcalis* (16.6%) for each one, *proteus* spp.(3.33%), *Salmonella* spp.(3.33%) and *Shigella* spp.(3.33%) this is due to fecal contamination of these mobiles, which can result in community-acquired infection and disease outbreak \(^{(14)}\).

The spread of *Bacillus* spp. suggests the ubiquitous nature of *Bacillus* spp. giving it greater contamination of (students', workers, and dentists) mobile phones with different microbial isolates.

The results of our study showed (*Bacillus* spp. (20%), *S. aureas* (10%), *Klebsiella* spp., (3.33%) and *Pseudomonas* spp., (6.67%). This is due to the isolated bacteria are a subset of the normal skin microbiota as advanced by earlier researchers \(^{(15)}\).

The percentage of streptococcus spp. in our study was (10%). It was well known that Streptococcus species can cause illnesses such as meningitis, pneumonia, pharyngitis \(^{(16)}\).

The high level of bacterial agents that was isolated from mobiles was attributed to the poor hygienic and sanitary practices. However, the discrepancies showed among different studies might be due to the influence of sampling method, sample size and different laboratory processes \(^{(1)}\).

Result recorded high number of bacterial isolates found on the surface of mobiles \(1.5 \times 10^9\), these bacteria may cause infections if the conditions permit for finding its routs to the human body.

**Conclusion**

The mobile users are found in the market, hospitals, home, and schools. therefore, they can be considered as a major cause for spreading of infection in our community. According to bacterial isolates were obtained from mobile phones in the present study by culturing, staining, biochemical test and comparing the isolates with Macferland tubes and measure the optical density of its. Our study showed that mobiles would serve as vector for bacteria transmission among individuals. This proposes the capability of the mobile phones as a fomite, which can lead to community-acquired infections with possible public health implications. Periodic use of disinfectants or hand cleaning cleansers for cleaning of the mobiles and regular hand-washing ought to be supported as a method for shortening any potential disease transmission.

Molecular Detection of \textit{M. Pneumoniae} in Pneumonia Patients in Al-Hilla City, Iraq

Ahmed Adil Ali\textsuperscript{1}, Huda H. Al-Hasnawy\textsuperscript{1}, Noor Nabeel\textsuperscript{1}

\textsuperscript{1}Department of Microbiology, College of Medicine, University of Babylon, Iraq

\textbf{ABSTRACT}

A total of 71 patients with pneumonia (49 males and 22 females) from various age amass from short of what one to fifteen years old (<1-15) were engaged with this examination and subjected for inspecting by throat swabs collected from outpatients and inpatient admitted to Babylon Maternity and Pediatrics Healing facility, amid the period from November to walk 2018. The period of patients ran from 1 to 15 years. The most influenced age gather was (6-15) years with 35:71 (49.29\%) patients. While in age gathering (1-5) year 20:71 out of a rate (23.16\%) and 11:71 as (15.49\%) trailed by 5:71 (7.04\%) in > 15 years of age. As to the conveyance of \textit{M. pneumoniae} as indicated by the sexual orientation, high contaminated individual with pneumonia (49) was identified in females in comparision with the male (22). Each example was submitted to intensification with PCR procedure. The consequences of gel electrophoresis for DNA groups in view of particular adhesin qualities (myco and MP-P1) for \textit{M. pneumoniae}, demonstrated that \textit{M. pneumoniae} was certain with sub-atomic length (144bp, 399bp) individually, The two qualities (myco and MP-P1) give indistinguishable recuperation rate for determination of \textit{M. pneumoniae} in 12:71 with a rate (16.9\%) and 59:71 indicated negative outcomes in a rate (83.09\%). In end \textit{M. pneumoniae} diseases in offspring of Al-Hilla area has a part in pneumonia contamination. Additionally PCR can be utilized as an affirmed test for fast distinguishing proof of Mycoplasma pneumoniae pneumonia in children. On the other hand Throat swabs could be supplanted by different examples like nasopharyngeal lavage for coordinate identification of \textit{M. pneumoniae} in respiratory emissions.

\textit{Keywords:} \textit{M. pneumoniae, pneumonia , PCR}

\textbf{Introduction}

The conclusion of \textit{M. pneumoniae} pneumonia still depends on established strategies for culture and serology, both of which neglect to meet the criteria of a suitable analytic test. \textit{Mycoplasma pneumoniae} isn’t a piece of the ordinary greenery of the respiratory tract. Disengagement in the throat, nasopharynx, and pleural liquid can is viewed as characteristic of disease. The way of life strategies are moderately uncaring, tedious, costly, work serious and restricting its value for routine purposes \textsuperscript{(1)}. Fast research center determination of \textit{M. pneumoniae} contamination would encourage the decision of suitable antimicrobial operators for treatment of intense respiratory tract diseases, prominently pneumonia. Albeit much consideration has been engaged to enhance the finding of community acquired pneumonia, the identification and conclusion of contaminations caused by \textit{M. pneumoniae} remains a significant problem \textsuperscript{(2)}. Polymerase chain response (PCR), a generally late method, has been connected for the touchy and particular identification of an assortment of irresistible operators including the Mycoplasma spp. \textsuperscript{(3)}. The identification of \textit{M. pneumoniae} DNA in throat swab examples by PCR has been observed to be an exceptionally delicate and particular demonstrative method for the finding of intense \textit{M. pneumoniae} contamination \textsuperscript{(4)}. Atomic systems connected straightforwardly to respiratory tract examples are these days broadly utilized for the quick finding of respiratory tract diseases; in this manner, getting an agent example from the patient from the genuine site of contamination is generally imperative.
Throat swabs and nasopharyngeal suction (NPAs) are the example composes regularly utilized for \textit{M. pneumoniae} PCR (5), therefore, the recognition of \textit{M. pneumoniae} DNA in throat swab examples by PCR may give an enhanced standard to the determination of intense \textit{M. pneumoniae} contamination (6). Affectability is hypothetically high; it can recognize a solitary life form when sanitized DNA is utilized and it doesn’t require suitable creatures. As indicated by (7), intensification based strategies can build affectability up to 95%. Quality targets utilized in different sorts of PCR tests for \textit{M. pneumoniae} incorporate 16S rRNA, P1 adhesin, ATPase operon quality and tuf quality, and redundant component repMp1 (6).

Materials and Method

Clinical samples were collected from outpatients and inpatient admitted to Babylon Maternity and Pediatrics Healing center, for the period from November 2017 to 2018. The investigation included 71 patients and subjected for testing. The age of patients extended from 1 to 15 years, throat swabs was put in 2ml P.B.S and put in an ice pack until be taken to the research facility for extraction of bacterial DNA.

Genomic DNA Extraction: In this examination, the gathered examples; throat swabs from patients were subjected to DNA extraction method as indicated by conventions suggested by producer (Geneaid/UK). The accomplished DNA was put away at 2-8°C for assist applications and handling. Preliminaries for myc quality and p1 quality were utilized for distinguishing proof of \textit{Mycoplasma pneumoniae} microscopic organisms, item size and enhancement condition were recorded in Table (1), intensification was done by Polymerase Chain Response, that was performed in an aggregate volume of 20μl as specified in Table (2).

Results and Discussion

Conveyance of Pneumonia Patients: This investigation was performed on 71 patients with pneumonia (49 guys and 22 females) from various age aggregate from short of what one to fifteen years old (1-15) (Figure 1). The most influenced age amass was (6-15) years with 35:71 (49.29 %) patients. While in age gathering (1-5) year 20:71 of every a rate (23.16%) and 11:71 as (15.49%) trailed by 5:71 (7.04%) in > 15 years of age.

Intense respiratory diseases (ARI) are a main source of bleakness and mortality in youngsters (9). Be that as it may, the exact the study of disease transmission about etiological specialists of ARI in creating nations remains inadequately characterized (10). The pervasiveness rate of youth ARI because of these pathogens is exceptionally factor starting with one nation then onto the next because of contrasts in seasons and geographic regions. This finding was as per investigation of (11), who detailed that, an expansion of atypical pneumonia in kids between multi month to 14 years of age. The commonness rate of youth ARI because of these pathogens is exceptionally factor starting with one nation then onto the next because of contrasts in seasons and geographic zones (12).

Molecular Detection in Patients with Pneumonia:

Each example was submitted to enhancement with, The aftereffects of gel electrophoresis for DNA groups in light of qualities particular (myco and MP-P1) adhesin qualities for \textit{M. pneumoniae}, demonstrated that \textit{M. pneumoniae} was certain with atomic length (144bp, 399bp) separately. The two qualities (myco and MP-P1) give indistinguishable recuperation rate for finding of \textit{M. pneumoniae} (figure 2, figure 3) in 12:71 with a rate (16.9%) and 59:71 demonstrated negative outcomes in a rate (83.09%) as appeared in table (3-1). Each one of those patients were clinically analyzed as pneumonia by pediatricians as indicated by chest-x-ray and clinical signs. These outcomes were more than the outcomes gotten by (13) who found that the inspiration rate of \textit{M. pneumoniae} was (10%) among 100 researched patients with bring down respiratory tract infections. In any case, the present outcomes were can’t help contradicting the past examinations directed by (14) whose found that (45.5%), (33%) of patients with pneumonia were conveying \textit{M. Pneumoniae}, had \textit{M. Pneumoniae} in throat swabs. On the other hand, In Perua, an investigation uncovered that \textit{M. Pneumoniae} was found in a rate of (25.19%) in nasopharyngeal examples. A study of disease transmission division revealed an expansion of C. Pneumoniae cases, perceiving this pathogen as the most incessant reason atypical pneumonia taken after by \textit{Mycoplasma pneumoniae}, it is known to be atypical pathogen in charge of pneumonia (15). In the most recent years, there is an expanding enthusiasm to comprehend this pathogen, since it has been distinguished as vital reason for grimness and mortality in youngsters. \textit{M. pneumoniae} pneumonia (MPP) happens around the world, and records for 10 ± 40% of all instances of
network procured pneumonia. Notwithstanding, The emotional drop in its location saw amid this examination proposes that the discovery of M. pneumoniae saw in earlier years was straightforwardly connected with its epidemiological example and the recurrence of location of respiratory pathogens differed from year to year (16).

Bacterial and viral coinfection in children with M. Pneumoniae pneumonia are a major issue that ought to be additionally considered; since co diseases are more typical in disjoin MPP and they likewise have a tendency to be more genuine expanding bleakness and hospitalization (17).

Late presentation of PCR has fortified extraordinary investigation of its utility in analysis of irresistible maladies. We report here the use of PCR in identification of M. pneumoniae in clinical examples. Some problems must be understood. These incorporate a meaning of the most appropriate groundworks and the degree to which they cause enhancement of successions from related and irrelevant life form. Distributed DNA groupings of the ATPase (myco) and P1 adhesin qualities were utilized in this investigation. The adhesins are probably fundamental for the pathogenicity of these creatures and particular for the living being to be identified (17).

Concerning the age gathering, table (4) demonstrated that the most influenced age was (6-15) years as 8:71 (11.26%), while 4:71 (5.63%) in age gathering (1-5) years in correlation with age bunches that no energy rates (0.0%) were found. These discoveries were not as much as the outcomes performed by (13), who found that the most influenced age assemble was 8-14 years with a rate (23.3%). M. pneumoniae needs cell divider, and it is exceptionally touchy to natural conditions. Subsequently, exchange of disease requires close contact, which is generally more incessant in more established kids, who gain the contamination in school or amid playing with other kids (18) found that the predominance of M. pneumoniae contamination in kids tends to increment as per age. M. pneumoniae can be found in all age gatherings, with higher pervasiveness in youngsters matured 5 ± 15 years of age (19,20). Studies led in different nations have demonstrated that Community acquired M. pneumoniae contamination influence principally preschool, school-matured kids and youthful grown-ups. Albeit, few investigations have revealed the recurrence of M. Pneumoniae and diseases in infants (21). A particular conclusion is imperative, since b-lactam anti-toxin treatment of contaminations because of these atypical pathogens is inadequate, while the utilization of anti-infection agents, for example, macrolides can uniquely decrease the span of the ailments (21).

Conclusion

In end M. pneumoniae diseases in Al-Hilla area has a part in pneumonia contamination. Additionally PCR can be utilized as an affirmed test for fast distinguishing proof of Mycoplasma pneumoniae pneumonia in children. On the other hand, throat swabs could be supplanted by different examples like nasopharyngeal lavage for coordinate identification of M. pneumoniae in respiratory emissions

ABSTRACT

Worldwide, skin cancer is a major public health burden as its incidence has been increasing over the past decades. Basal cell carcinoma (BCC) is the most common form of human cancer which is highly curative when diagnosed early.

One hundred eighty five lesions on the head and neck belonging to 140 patients who were suspected to have BCC by clinical examination in a dermatological consultation clinic of Al-Yarmook teaching hospital were compared to 170 lesions on the head and neck of 140 patients attending Erbil dermatology teaching center who were suspected to have BCC by dermatoscopic examination. More than one lesion was found in some patients. The excisional biopsies of these lesions were sent for histopathological study to confirm the diagnosis of BCC. The corresponding biopsy results were compared with the socio-demographic and clinical features of the two study settings.

No significant differences between the two study settings were noted concerning sex or smoking history. On the other hand, statistical differences were observed regarding residency, previous work and family history of skin cancer with p* value equivalent to (0.000), (0.003) and (0.000) respectively.

In both study settings patients had skin photo type III, displaying significant differences concerning clinical types. Nodular type was more common in Baghdad while ulcerative type was more evident in Erbil with P*= (0.005) and (0.000) respectively.

Sun exposure is an important risk factor for developing skin cancer specially in those resident in rural areas. Dermatoscopical examination of the skin proved to be a useful real time noninvasive visual aid in the diagnosis of BCC yielding a higher sensitivity for the diagnosis of BCC than that of clinical diagnosis.

Keywords: Basal cell carcinoma, Dermatoscopy, Histopathology

Introduction

Worldwide, skin cancer is a major public health burden as its incidence has been increasing over the past decades (1). According to the latest published Cancer Registry in Iraq, skin cancer is the ninth most commonly diagnosed malignancy among the Iraqi population (2). Basal cell carcinoma (BCC) is the most common form of human cancer which is highly curative when diagnosed early and can be readily treated with office-based therapy (3), Ultraviolet radiation from sun exposure intermittently plays as an important etiological factor in its pathogenesis (4). Other known risk factors for BCC are fair skin, sun burn, smoking and subjection to ionizing radiation (5). It usually does not metastasize, but sometimes if neglected by the patient it can distract the skin and invade underlying structures like bone, its growth in size can make the lesion inoperable especially on the face (5,6).
BCC is defined by World Health Organization Committee of the skin tumors as “a locally invasive, slowly spreading rarely metastasizing tumor, arising in the epidermis” \(^{(6,7)}\), it is also known as Rodent Ulcer. It rarely metastasizes when diagnosed and treated early \(^{(7,8)}\), however it could present late or even devastating if further neglected thus necessitating aggressive surgical approaches \(^{(9)}\).

Skin type is another important factor which could influence signal intensity \(^{(10)}\). In general, skin types are classified into six categories according to the Fitzpatrick scale as follows:

- Type I: always burns, never tans (palest; freckles).
- Type II: usually burns, tans minimally.
- Type III: sometimes mild burn, tans uniformly.
- Type IV: burns minimally, always tans well (moderate brown).
- Type V: very rarely burns, tans very easily (dark brown).
- Type VI: never burns (deeply pigmented dark brown to darkest brown) \(^{(10,11)}\).

Clinical variants of BCC include: Nodular, Ulcerated, Superficial Spreading, Infiltrative and Morphea form with pigmented and non pigmented sub classification for each one \(^{(12)}\).

The aim is to detect the association between socio-demographical picture, clinical and pathological characteristics of patients with BCC attending Al-Yarmook teaching hospital and those attending Erbil Dermatology Teaching Center and to compare the accuracy of diagnosis between the two study settings by comparing the methods of diagnosis and the reported biopsy results.

**Materials and Method**

A cross sectional study conducted among patients attending a dermatological consultation clinic in Al-Yarmook teaching hospital and Erbil dermatology teaching center from August 2017 to June 2018.

A hundred eighty five lesions on the head and neck belonging to 140 patients who were suspected to have BCC by clinical examination in a dermatological consultation clinic of Al-Yarmook teaching hospital were compared to 170 lesions on the head and neck of 140 patients attending Erbil dermatology teaching center who were suspected to have BCC by dermatoscopic examination. More than one lesion was found in some patients. The excisional biopsies of these lesions were sent for histopathological study to confirm the diagnosis of BCC. The corresponding biopsy results were compared with the socio-demographic and clinical features of the two study settings.

Chi square test was used, *P* values less or equivalent to 0.05 were considered significant.

**Results**

Concerning the socio-demographic characteristics in Al-Yarmook teaching hospital patients, 68 (69.3%) of them were males and 30 (30.7%) were females, their ages ranged between 37 to 72 years, with a mean of 66.5 ± 1.5 years. Seventy eight (79.6%) patients were rural areas resident while 20 (20.4%) patients were city residents and 59 (60.2%) of them previously worked as farmers. Smoking was predominant habit among them in 68 (69.3%) patients. Family history of skin cancers was positive in 35 (35.7%) patients.

Regarding Erbil dermatology teaching center patients, 83 (61.9%) of them were males and 51 (38.1%) were females, their ages ranged between 35 to 87 years, with a mean of 68.3 ± 1.5 years. Sixty three (47%) patients were rural areas resident while 71 (53%) patients were city residents and 83 (61.9%) of them previously worked as farmers, smoking was predominant habit among them in 93 (69.4%) patients. Family history of skin cancers was positive only in 14 (10.4%) patients.

A significant differences were noted concerning the residency, previous work and positive family history of skin cancer among patients in the two study settings with *p* values (0.000,0.00,0.000) respectively (Table 1).

* Chi square test was used.

The patients’ skin photo type of Al-Yarmook teaching hospital according to Fitzpatrick’s classification was mainly type III 68 (69.3%) patients. Skin photo type II was observed in 23 (23.4%) patients, photo type IV in five (5.1%) patients and only two (2.2%) patients were of skin photo type I. On the other hand, in Erbil dermatology teaching center the patients’ skin photo type III was observed in 101 (75.3%) patients, photo type II in 19 (14.3%) patients, photo type IV in 12 (8.9%) patients and only two (1.5%) patients were of skin photo type I (Figure 1).

**Figure 1: Comparison between the two study settings concerning patients’ skin photo type according to Fitzpatrick’s classification**

The BCC tumors were classified according to their clinical types, in Al-Yarmook teaching hospital, the most frequent type was the nodular variant which found in 68 (52.7%) lesions. Morphea form was the least common one as it found only in 3 (2.3%) lesions. The BCC were generally and for each type clinically subdivided in to pigmented BCC (pBCC) and non-pigmented BCC (npBCC) which their proportions were (68.2%) and (31.7%) respectively, while in Erbil dermatology teaching center, the most frequent type was the ulcerated variant which found in 74 (45.4%) lesions. Morphea form also was the least common one as it found only in 7 (4.3%) lesions, pigmented BCC (pBCC) and non-pigmented BCC (npBCC) proportions were (65.5%) and (34.4%) respectively.
A significant difference between two study settings was noted in nodular and ulcerative types with P values of (0.005) and (0.000) respectively (Table 2).

* Chi square test was used, ** Fisher Exact test was used.

Concerning AI-Yarmook teaching hospital, 140 patients were examined with 185 skin lesions on the head and neck (more than one lesion in one patient). The diagnosis of BCC was suspected clinically, excisional biopsies done and the specimens were sent for histopathological study. Among those the diagnosis of BCC was confirmed in 129 (69.7%) lesions (Figure 2).

**Figure 2: Percentage of positive biopsies in clinically diagnosed patients at AI-Yarmook teaching hospital**

Comparing to the result of Erbil dermatology teaching center, 140 patients were examined with 170 skin lesions on the head and neck (more than one lesion in one patient). The diagnosis was suspected dermatoscopically to have BCC, excisional biopsies done and the specimens were sent for the histopathological study. The diagnosis of BCC was confirmed in 163 (95.8%) lesions.

**Discussion**

In the present work, a cross sectional study design was performed which has the advantages of being easily conducted and requiring less time (13). In both study settings males were more than females (69.3% and 61.9% in Baghdad and Erbil respectively). This can be due to more outdoor working and sun exposure or more smoking habits among males which can cause repeated trauma and burns to lips. That is consistent with the results of Abbas et al who found that 62.6% of their sample were males (14) with no significant differences noted between the two study settings.

In our study, the mean age of the study sample in Baghdad and Erbil was 66.5 ± 1.5 years and 68.3 ± 1.5 years respectively. Those were rather close to the findings reported by Janjua1 et al (17) where the mean age group of their sample was (61.3 ± 13.07 years), probably attributing that to the fact of the buildup of sun exposure over time.

The percentage of living in rural areas among patients with BCC in our two study settings, was 79.6% in Baghdad compared to only 47.1% in Erbil with highly significant differences (0.000). That might be explained by the differences in temperatures of rural areas between the North and centers of Iraq as a cumulative exposure to sunlight over years is necessary for tumor development (16) and this can probably highlight the significant differences between the two study settings concerning the history of previous work of the patients (0.003).

The lower frequency of BCC among Erbil rural inhabitants may be explained on the basis that rural patients regard initial lesions of BCC as a minor cosmetic
problem with insignificant impact on health and seek medical advice only when lesions become symptomatic or disfiguring. However, this comes in contrast to the result of Maia et al. (17).

A positive family history of skin cancer was demonstrated in 35 (35.7%) patients and 14 (10.4%) patients in Baghdad and Erbil centers respectively with very high significant differences between the two study settings (p value =0.000) (18, 19). Ahluwalia et al found that (40%) of their patients had a positive family history (20), while Abbas et al. (14) registered only (29.4%). Both could be attributed to genetic and environmental factors.

In both study settings, skin type III represented higher percentages (69.3%) and (75.3%) in Baghdad and Erbil respectively, while type I was the least common (2.2%) and (1.5%) in Baghdad and Erbil respectively, pigmentation of skin is considered a protective factor for skin cancer (5).

In our study, the following clinical types of the BCC were found: ulcerative, nodular, superficial spreading, infiltrative and morphea form. In Baghdad, the commonest type was nodular type which was seen in 68 (52.7%) of the lesions and this agree with the result of Lyubomir et al. who found that nodular basal cell carcinoma comprises about (80%) of the cases, while in Erbil the commonest type was ulcerative type which was seen in 74 (45.4%) of the lesions. This high proportion of ulcerative type could be due to the fear from ulcers that make the patient seek for medical help. Significant differences between nodular and ulcerative type among the two study settings was found with p value =0.005 and (0.000) respectively.

In Baghdad center, they adopted a clinical examination as a provisional diagnosis for BCC with sensitivity of 70% compared to 95.7% sensitivity of dermatoscopy provisional diagnosis that was adopted in Erbil center. Both centers depend on the result of biopsies as gold standard. Chi-square was significant at p* value =<0.05.

Conclusion

Sun exposure is an important risk factor for developing skin cancer specially in those resident in rural areas. Dermatoscopic examination of the skin proved to be a useful real time noninvasive visual aid in the diagnosis of BCC yielding a higher sensitivity for the diagnosis of BCC than that of clinical diagnosis. In the future, histopathological investigation of BCC lesions could be provided only to the control of the treatment.

Molecular Study of Toxoplasmosis in Spontaneous Aborted Women in Thi-Qar Province, Iraq

Abeer T. Ali¹, Dawood S. Mahdi¹, A. H. Awad²

¹Dept. of Medical Lab.Tech, College of Health & Medical Technology, Southern Technical University, Iraq; ²Dept. Biology, College of Pure Science, University of Basrah, Iraq

ABSTRACT

*Toxoplasma gondii* infection can be diagnosed with different methods. The most important one is a Polymerase Chain Reaction (PCR), which is used for the detection of *T. gondii* DNA. This method is simple, sensitive, reproducible, cost-effective, and used in a variety of clinical samples from animals or humans.

In this study a blood sample of 305 abortive women were collected from Bent AL-Huda and Al-Hussian Hospitals in Thi-Qar province from October 2017 till October 2018. Sample, which gave positive results (133) with ELISA test were used in PCR technique. DNA extraction of parasite was evaluated by using specific primers for *Toxoplasma gondii*, (193 bp, 580 bp, 399 bp).

The PCR results of aborted women showed that the Positive IgG was found in (34) sample 25.6%, IgM+ in (14) sample 10.53%, both IgM; IgG in (6) sample 4.51%. The high infection rate was found at age group (25-29), and the lowest at age group (30-34) years and according to residency rural (29%), and urban (47.6%). The positive PCR in first trimester was (39.62%), in second trimester was (47.36%), and the multiple abortion was 39%, while the single abortion 42%.

**Keyword:** *T. gondii*, PCR, Prevalence, aborted women, Thi-Qar

Introduction

Toxoplasmosis is a zoonotic disease, which has relevance to both veterinary and human medicine. The infection with *Toxoplasma gondii* is transmitted through the ingestion of row or under cooked meat or unwashed fruits or vegetable and can be transmitted congenitally from mother to fetus through placenta [1, 2].

The disease is transmitted from cat which is the definitive host to human by eating the under cooked meat or row meat [3]. It is consider as the important disease that infected the pregnant women [4]. If the pregnant acquired infection, the Tachyzoit will colonize in the tissue of placenta and then cross to fetus, which lead to miscarriages or sever damage to fetus [3].

The infected women before the pregnancy is still asymptomatic, it becomes active if the immunity of the pregnant women is impaired [6]. The risk of infection with toxoplasmosis depends on the period of pregnancy, if the women infected with toxoplasmosis during the first trimester of pregnant, it`s cause spontaneous miscarriage of fetus [5, 8] with severe damage. In second and third trimester of pregnancy, the transmission of infection to fetus is more than first trimester with low effect on fetus [9].

*Toxoplasma gondii* infection can be diagnosed with different methods. The molecular methods includes the PCR which is used for the detection of *T. gondii* DNA, this method is simple, sensitive, reproducible and cost-effective and used a variety of clinical samples from animals or humans.

Materials and Method

The blood samples were collected from 305 abortive women in Bent AL-Huda and Al-Habboby Hospital in Thi-Qar province during the period from October 2017-October 2018.
Five ml of blood were collected from each aborted women. Three ml were used in serological tests and the 2ml of blood was put in EDTA tube for DNA extraction.

The DNA was extracted from the whole blood samples by using (DNA extraction kit, Genaid - USA). The extraction was performed according to the manufacturer’s instructions. The extracted DNA was amplify with Polymerase Chain Reaction (PCR) using specific primers (Table 1) and following the program mentioned in Table (2).

Results

Prevalence infection of toxoplasmosis in abortive women using PCR technique.

1. According to the age and antibodies: The total percentage positive PCR in aborted women was 40.6% while the negative PCR was 59.4%. No positive PCR result was detected in normal control samples of women, while the negative PCR of control samples was 100%.

The high percentage of positive PCR 53.13% was found at age group 25-29 year, while the lowest 33.3% was found at age 30-34 year. The high percentage of negative PCR 66.7% was found at age group 30-34 while the lowest 46.87% at age group 25-29 years.

The high total percentage 53.13% of positive antibodies of *Toxoplasma* at age group 25-29 year. The lowest 33.3 % at age group (30-34). The high percentage of positive IgM+, IgG+ and (IgM+; IgG+) were 18.75%, 37.5% and 7.7% at age (25-29, >40,15-19) respectively (Table 3).

Statistics

No positive PCR result was detected in normal control samples of women, while the negative PCR of control samples was 100%.
Figures (1,2,3) show the PCR amplification of *T. gondii* 193bp, 399bp fragments gene in 1.5% agarose gel of aborted women samples.

**Figure 1:** PCR amplification of *T. gondii*, 193 bp fragment gene in 1.5% agarose gel, of aborted women samples. M = ladder. Lane 1 = Positive IgM. Lane 2, 3 = Aborted women negative PCR. Lane 4, 5, 6, 7 = Normal women without abortion negative PCR.

**Figure 2:** PCR amplification of *T. gondii*, 193 bp fragment gene in 1.5% agarose gel, of aborted women samples. M = ladder. NC = negative control. Lane 1, 2-5, 10-13 = positive PCR. Lane 6, 7, 8, 9 = negative PCR.

**Figure 3:** PCR amplification of *T. gondii*, 399 bp, fragment gene in 1.5% agarose gel, of aborted women samples. M = ladder. NC = negative control. Lane 1-14 = positive PCR.
Discussion

The study shows a significant difference between negative and positive PCR according to age groups. The high ratio of infection 53.13% in age group (25-29), and low ratio 33.3% that was recorded in (30-34) years, agree with Shahab study in Babylon province who showed the high rate of infection in age group (22-29) [10], but it is not agree with Al-Adlaan study in Thi-Qar province who mentioned the higher ratio of PCR 29.41% in age group (21-25) [11]. The reason for this high ratio may be due to the high concentration of IgM during the first infection (1-2) weeks and may be due to the rapidly transformed the T. gondii from tachyzito to bardyzoit stage in tissue, which decreased it concentration in blood and raised up the IgG concentration.

Testing 133 samples of aborted women with Polymerase Chain Reaction (PCR) technique in this study gave 54% positive samples (40.6%).

Positive IgG samples gave percentage (25.6%), the IgM (10.53%), while the (IgG and IgM) (4.51%). The IgG shows high ratio 37.5% in age group 40 years, while the IgM, and both (IgG and IgM) show the higher ratio (18.75%, 7.7%) in age group (25-29, 15-19) years respectively. This result is in consist with Al-Gazy study in Thi-Qar province [12] which showed that the high IgG ratio was found in (40 years) which referred to past infection. The result of study also agree with Souhiella study who showed the ratio of IgG is more than IgM (31.57%, 26.31%) [13], and also agree with Laila study in Jordan who found the IgG in 76 sample of aborted women (51.3%), and the IgM in 4 sample was (2.7%) [14] and agree with Odile study who showed the result of IgG (89%), while IgM (10.2%) [15]. But not agree with Behzad in Iran who tested 109 aborted women and show the same result between IgG and IgM [16].

The highest rate of infection found in single aborted women (42%). This result is not agree with Al-Gazy study in The-Qar province who found the women with multiple abortion was more than single aborted women while Shahab shows the high ratio was found in a single abortion [10], but without significant difference between the toxoplasmosis and the number of abortion [11]. This result agree with [15] who showed the single abortion is higher than multiple abortion (50%, 6.3%)

The recurrent abortion may be due to the past infection which is not recovery or the abortion women don’t take the specific medication or due to the immune compromise of pregnant women.

The high prevalence of toxoplasmosis at second trimester and third trimester is not agree with Hadi study in Al-Qadisia province who showed the high ratio of first trimester period is more than other periods (63.6%, 55.6%) respectively [17], and also not consistent with the study in Diyala by Al-Ghurairy who showed that the women in second trimester is more than first [18]. This corresponding with fact that the injury in pregnancy depend on the degree of fetus resistant, the fetus more vulnerable to infection during first trimester due to immune system is not complete.

The total percentage of positive PCR in rural and urban area was (29%, 47.6%) respectively. Al-Jumali in Babylon found the ratio of infection of urban and rural was (37.5, 14.3) respectively [19], Al-Mammamuri found 80.9% in urban and 66.7% in rural [20]. The present result was disagree with Shahab study who showed the higher result in urban area more than rural area (67.8%, 66.1%) respectively [10]. Al-Dory in Salah Al-Din city showed that the aborted women in rural area is more than urban [21], while Hassan in Karbala city showed there’s no relationship between resident location of patient and percent of infection [22].

Conclusion

There is a significant difference between negative and positive PCR according to age groups. High IgG ratio was found in (40 years) which referred to past infection. The recurrent abortion may be due to the past infection which is not recovery or the abortion women don’t take the specific medication or due to the immune compromise of pregnant women. Urban areas showed higher PCR positive resuls.

Serum Interleukin-4 Level Correlation with Age and Fasting Blood Sugar in Iraqi Major Depressed Patients

Ahmed Jasim Twayej¹, Muntadher Abdulabbas H¹

¹Pathological Analysis Department, College of Health and Medical, Al-Kafeel University, Najaf, Iraq

ABSTRACT

MDD is a common condition that affects the general population across a broad spectrum of ages and social backgrounds. It has been associated with inflammatory processes, including increased cytokine levels. High co-morbidity exists between MDD and chronic diseases like IR and Type 2 diabetes. Nevertheless, the correlation between among cytokines especially IL-4 and IR parameters have not been concentrated widely in MDD. In the present study, we measured IL-4 as anti-inflammatory marker, insulin and glucose as FBS, HOMA2%IR, HOMA2%S, HOMA2%B parameters in 60 MDD patients and 40 healthy controls. Associations between cytokine levels and IR were examined. IL-4, insulin, HOMA2%B, HOMA2%S and insulin resistance (HOMA2IR) increased significantly (p<0.05) in serum of MDD patients, in comareson with healthy controls. There is a significant correlation between FBS with IL-4 (p<0.05).

The current study introduce more confirms that major depressive patients is accompanied by activation of the immune system with significant elevations in the levels of IL-4 cytokine. These results indicate stimulation of the immune system and increased IR and modulation of IR by increased cytokine levels in MDD. The homeostatic model assessment beta-cell function (HOMA2%B) and (HOMA2%S) is strongly correlated with insulin resistance level (HOMA IR) in MDD patients.

Keywords: Major depressive disorder, Interlukin-4, Insulin resistance, Homeostasis model assessment.

Introduction

On of the main diseases with high lifetime prevalence rates is the major depressive disorder (MDD) which is a heterogeneous disease [1,2]. Clinical examination is the main method for MDD diagnosis with no biomarker available for any psychiatric disorder [3-5].

In the last decade, there is a growing interest in the role of cytokines in the pathogenesis of various psychiatric disorders, such as MDD. In case of systemic infections, cancer or autoimmune diseases, these cytokines can act on the brain to induce sickness behavior, leading to depressive symptoms development [6]. Cytokines affect brain function including behavior and play an important role in MDD and immune system dysregulation connection [7-11].

IL-4 is directly induce naive T cells differentiation to Th2 cells [12,13]. As MDD is associated with Th1 immune response and low IL4 expression, it receives more interest [14].

Insulin resistance (IR), Type 2 diabetes and cardiovascular diseases are believed to be positively correlated with depression [15,16].

Depression is inversely associated with insulin resistance, but positively associated with diabetes. However, the relation between insulin resistance and depression is poorly studied with conflicted results [17,18].

We have postulated that IR is part of the pathophysiology of affective disorders, and its improvement (via pharmacological or non-
pharmacological treatments) may reduce the severity of depression significantly \cite{19-22}.

The present work aims to explore the possible immunological changes that accompany MDD. To accomplish this goal, Interlukine-4 were measured in MDD patients and controls, Male-Female MDD patients and Smoking-Nonsmoking MDD patients. The second aim is to investigate whether glucose metabolism and insulin sensitivity were impaired in the MDD patients and estimate the correlations between this immune markers of MDD and IR.

**Materials and Method**

**Participants:** A total of sixty MDD patients (32 male and 28 female) and forty normal controls (24 male and 16 female) participated in the present study. Patients were recruited at the Psychiatry Unit, Al-Hakeem General Hospital, Najaf Governorate, Iraq and at a private psychiatric clinic during the period from April-November 2018. The patients were diagnosed for MDD by a psychiatrist based on (ICD-10 codes: F30-33). All patients were on a steady-state citalopram treatment (20mg daily) during the last few weeks.

Patients and controls were evaluated through a complete medical history to exclude any systemic diseases that may affect the biomarkers, including diabetes mellitus, liver and kidney diseases, (auto) immune disorders and neurological disorders, including multiple sclerosis, stroke and Parkinson’s disorder. Exclusion criteria for participants were any systemic or inflammatory disease. C-reactive protein (CRP) was not higher than 6mg/L, excluding subjects with overt inflammation.

About 5ml of venous blood were collected and left to clot and serum was collected by centrifugation at 3000rpm for 5 minutes. Serum was distributed into three Eppindroff tubes until assay. Venous blood samples were taken from the participants in the morning after at least 12 hours of fasting. Serum cytokines and insulin concentrations were measured using ELISA (BioAssay Systems®, USA).

**Statistical Analysis:** SPSS software was used for all data analysis. Pooled t-test used to compare between the groups. Statistical significance was considered when p<0.05.

**Result and Discussion**

**Comparison of the baseline biomarkers between MDD patients and controls:** Table 1 shows the socio-demographic, clinical and biomarker data of the participants in this study. In this table we examine differences in these variables between major depressed patients at baseline and healthy controls, were no significant differences in sex, age, BMI, smoking habit and FBS between the study groups. IL-4, Insulin, HOMA 2%B, HOMA2% S and HOMA 2%IR are significantly higher (P=0.000, P=0.028, P=0.043, P=0.038 and P=0.035 respectively) in the major depression group as compared with healthy controls.

</table>
Serum IL-4 found significantly high in MDD patients. This result agree with Pavon et al. [23] while it has been found with no significant change by [24,25] or significantly in lower level [26]. This might be due to many factors like patient diagnosis criteria. IL-4 is strongly expressed during brain infection or injury and anti-inflammatory cytokines suppress the expression of IL-1, TNF, and other cytokines [27,28].

IL-4 may be a player in the regulation of depressive-like behaviors in untreated baseline conditions [29]. This is important as IL-4 has compensatory immune regulatory effects attenuating the immune-inflammatory response [30]. Moreover, IL-4 has wakefulness-promoting effects [31] and is increased in men with insomnia as compared with those without insomnia [32].

Hyperglycemia and hyperinsulinemia may alter hypothalamic-pituitary-adrenal (HPA) axis function and as a result it might cause depression [33].

The significant increase in HOMA2IR index in MDD patients as compared with controls indicates a state of IR. [34] IR has a close association to the metabolic syndrome component [35]. Glucose transport is inhibited because high cortisol increase the fat cells quantity and lipid breakdown which release free fatty acids into the bloodstream and constricts blood vessels [36] leading to obesity, IR, cardiovascular diseases and depression [37].

No significant differences in the biomarkers between male and female subjects with the exception of BMI and smoking habit (p=0.018 and p=0.016 respectively) (Table 2).

Gender differences in depression is getting much concern lately because of lack of data and women exclusion from clinical trials [38]. Anxiety and eating are the most common comorbid disorders in women [39]. While men have higher rates of alcohol and drug abuse comorbid [40]. Smoking-induced oxidative stress that generates free radicals causing tissue damage [41]. Depression has been characterized by elevated oxidative stress that is in positive correlation with depression severity which can be corrected with treatment [42-44].

Table 3 shows that IL-4 in smoking MDD patients is higher significantly than in those of nonsmoking, while the other parameter are non-significantly indicating that the increased levels in these biomarkers in MDD are not attributable to smoking.

Numerous studies have confirmed that smokers do have a lower body mass index (BMI) than non-smokers\(^{45-46}\).

Smoking has been found associated with pro-inflammatory cytokines increased levels similar to depressed patients with high level of CRP, IL-6 and TNF–α and even higher with depressed smokers\(^{47-49}\).

**Correlations between Biomarkers:** Table 4 illustrate the correlation between study biomarker were found a significant correlation between immune marker IL-4 and age, also significant correlation between insulin and FBS with IR.

Where * is significance (p<0.05).

Based on HOMA, a good correlation was observed between b-cell function using hyperglycemic clamps and continuous glucose infusion\(^{50}\). IR individuals usually suffer from many abnormalities, including glucose intolerance and increased concentrations of inflammatory markers in addition to increased risk for cardiovascular diseases and cancer. Therefore, Diabetic patients with IR are at a higher risk for these complications.

**Conclusion**

There is a stimulation of the immune system and increased IR and modulation of IR by increased cytokine levels in MDD. Homeostatic model assessment beta-cell function (HOMA2%B) and (HOMA2%S) is strongly correlated with insulin resistance level (HOMA IR) in MDD patients.

Clients’ Satisfaction with Breast Cancer Early Detection Clinics in Iraq

Marwah Imad Al Ameen¹, Khalid Kareem Rajab², Jawad K. Al Diwan³

¹Al Karamah Teaching Hospital, Baghdad, Iraq; ²College of Medicine, Mustansiriya University, Iraq; ³College of Medicine, University of Baghdad, Iraq

ABSTRACT

Client satisfaction is vital in health services evaluation; given the absence of screening program, it’s important to deliver breast cancer early-detection services that appeals for women to use and ensure appropriate follow-up and care.

A cross-sectional study conducted in two breast early-detection clinics on 500 attendants. Satisfaction questions included 38 items covering eight domains (access, building readiness, cost, time, organization, education and general satisfaction). Data were analyzed by one-way ANOVA, t-test and post hoc Tukey’s test.

Mean score of satisfaction was 22.39 ± 6.1. The result showed a low satisfaction level, yet lowest in time and education domains. Type of clinic, age, education, employment, socioeconomic status, residency, waiting and counseling time showed significant differences.

Regular monitoring of clients’ satisfaction is necessary to improve and increase service uptake. Care should be directed to clients’ feedbacks together with awareness campaigns that market the availability of clinics and motivate its use.

**Keywords:** Clients’ satisfaction; early detection clinic; breast cancer; satisfaction

Introduction

Cancer is a public health problem. Following cerebrovascular diseases; it is the second cause of death in Iraq with breast cancer as the leading cancer among women (4720 new cases) [¹]. Early detection of breast cancer can improve survival and reduces cost of care, [²] for these benefits to be obtained, a high-quality service is crucial. Client satisfaction is vital in health services evaluation; it was identified as a quality outcome indicator to measure success of breast cancer services delivery system [³]. So unless the service is satisfactory from the standpoint of the clients, it’s unlikely that early-detection program will achieve its functional development results, which after all, depend on clients’ involvement and use of the service [⁴,⁵]. Thus, feedback from client satisfaction surveys is a recognized benchmark for healthcare quality improvement plans.

Clients’ satisfaction plays an increasingly significant role in quality of care reforms and healthcare delivery [⁶,⁷]. Despite the fact that breast cancer is one of the most-studied areas, yet measurement of clients’ satisfaction and the quality of breast cancer services are in its infancy.

The late diagnosis among Arab and Iraqi women had been related to low participation rates in breast early-detection activities [⁷]. Aiming to provide a high quality care, the current study would help practitioners focus their efforts when planning initiatives targeting client experience and enhancing quality.

Materials and Method

This cross sectional study was conducted from Sept.2018-end of Dec.2018. Sample size was calculated using the following equation [⁸]: \[n = \left(\frac{z^2 \cdot p \cdot (1-p)}{E^2}\right)\] where
Z equals 1.96, E equals 5%, P considered 0.50. The sample size; after adding 20% for unresponsiveness and sampling bias, reached 500. Multistage sampling was adopted starting from the two health districts of Baghdad city, from each district one hospital was chosen randomly after excluding hospitals with damaged or unavailable mammography unit. Lastly 250 women were selected from each clinic using systematic random sampling by choosing every fifth client according to their exit order.

**Tool of the study:** A questionnaire contained two sections: **Demography and socioeconomic status (SES)** [9] and **satisfaction:** the questions were developed through extensive literature review [5,6,10], revised by a committee of experts in community and family medicine and was piloted on 50 clients; changes were made accordingly to ensure relevance of items as well as clarity in language. Reliability coefficient Cronbach’s Alpha was 0.863. It included 38 items covering eight domains. The items were assembled in two-point likert scale. Each question received a score of “1” for ‘satisfied/Yes’ and “0” for ‘dissatisfied/No’. Scores were summed so that higher scores reflect higher satisfaction.

**Statistical analysis:** Data presented in mean, standard deviation. Mean percentages were calculated for each domain via dividing mean satisfaction score of the domain by its highest score. Data analyzed by one-Way ANOVA, t-test and post hoc Tukey’s test, P ≤0.05 considered significant.

**Results**

The response rate was 97.8%, the mean age of the sample was 42.4 ± 12.3 years ranging from (14-74) years. Clients were asked about their experience and satisfaction. The average time required to reach breast clinics was 1.14 ± 0.6 hours. The average waiting time was 57.7 ± 51.3 minutes while mean counseling time was 5.72 ± 3.5 minutes. Less than half (45.8%) didn’t receive axillary examination and higher percent were not asked or examined for nipple discharges. Majority of providers didn’t explain their examination findings nor answered questions.

Those who were dissatisfied about the constellation of service (214; 42.8%) were asked to provide a suggestion for service provision. Increasing the number of ultrasound-specialists was the main suggestion (112; 52.3%), sixty-four (29.9%) conveyed the need for better ticket management and registration while 17.8% requested that all units of service placed in one vicinity and asked for elevators. Regarding education, 239(47.8%) knew about BSE, of them 22 (9.2%) described regular BSE monthly during the past year, while 213(89.1%) reported practicing BSE but not regularly and four (1.7%) did not practice although knowing the procedure. Majority of women would recommend the breast clinic to their relatives and friends, yet 219 (43.8%) were dissatisfied about the overall service. Figure (1) demonstrates reasons for dissatisfaction with service. The average satisfaction score was 22.39 ± 6.19 ranged from (6-38) scores. Table (1) displays satisfaction score for each domain. The result showed a low satisfaction level, yet lowest regarding time and education.

Results show satisfaction was higher among clients of Al-Yarmook clinic (p = 0.000), older (p = 0.003), illiterate (p=0.002), housewives (p=0.009), from rural areas (p=0.045) of higher SES (p=0.001), who waited ≤15 minutes for examination (p=0.000) and whom counseling duration lasted ≥10 minutes (p=0.000).

Discussion

To our knowledge this is the first study that tackled clients’ satisfaction with breast cancer early-detection services in Iraq. Given the absence of screening program [1,7] the main task is to provide an early-detection services that are appealing for women to use with proper follow-up care.

Satisfaction: Satisfaction in all probability depends on experiences that client faces before entering the health facility and goes to beyond counseling. In the current study, domains of satisfaction were analyzed to identify parts that can be targeted for provision.

Access, Facility readiness and Cost: Two thirds of women could reach the clinic easily and reported no access difficulty, majority of clients were satisfied about cost and to some extent about building readiness agreeing with previous literature [11-14].

Clients-Service providers’ relationship: Satisfaction is significantly altered by exchanges with healthcare providers [3]; the privacy, courtesy, explanations given before and after examination plus technical skills, all play in determining clients’ satisfaction. Previous studies described physicians’ gender as a barrier for seeking breast cancer early-detection services [15,16]; in this survey 28.4% reported dissatisfaction with service-provider’s gender. Though the results from client satisfaction surveys might be distressing for providers because it subjects them to criticism and comparison, yet it helps to provide a feedback for staff and health planners, repeated measurements serve to monitor change in clients’ satisfaction especially if coupled with service improvements [6].

Organization: Less than half were dissatisfied with service constellation, the main demands mostly poured in the frame of time management; i.e. providing human resources and organizing tickets and registration, both suggestions aim to decrease waiting time and stagnation of clients in clinics. Results of client surveys should be used to improve service. Satisfied clients are more likely to come back and deliver positive comments to others [3].

Time: The waiting time not only affects the pursuit of health services but also the judgement on health workers practice, even more than their information and technical abilities [17]. Waiting time was comparable to that reported in Vietnam (50.3 ± 55.1) but higher than results from India (12.16 ± 2.3) and China (18.00 ± 22.6) [17-19]. Introducing an invitation system maybe needed.

Education: Increasing awareness is the first step to fight breast cancer, BSE is recommended as a common method to increase breast awareness hence contribute to earlier identification and reporting. [15,20] nearly half of women knew BSE yet 9.2% described monthly practice, similar to Saudi Arabia where 7.8% practiced regularly [21]. Breast examination is a delicate subject, there is apprehension and fear from being diagnosed with breast diseases [16], thus education is mandatory to encourage commitment to early-detection services.

General Satisfaction: Majority of women reported that they would recommend the clinic to their friends.
and families which is consistent with literature. \cite{13,22} yet 43.8% gave a dissatisfied response regarding the overall service and half of them stated that care and attentiveness are much better in private clinics. Evidence shows that interaction with providers had the ability to amend client’s impression on facility and services it provides, thus improving client-providers’ relationship will eventually draw more women and increase loyalty to early-detection program \cite{3,22}.

Clients of Al-Yarmook clinic showed better satisfaction which maybe inherent to organizational and structural differences between clinics agreeing with results from Iran. \cite{23} Al-Yarmook clinic is installed in a general teaching hospital that clients could access all branches of medical specialties per their visit, while Al-Eliwiya hospital is specialized in women health: obstetrics and gynecology mainly.

Older clients had better satisfaction probably because older women have more free time and can tolerate clinic routine. Women with higher education expect more and demand more thus the inverse relationship between education and satisfaction which had been reported in literature. \cite{24} In the same context of meeting clients’ expectations, those who came from rural areas had better satisfaction, probably due to a previous experience with nearby health facilities of limited resources. Working ladies are less satisfied perhaps due to their tight schedules and dual responsibilities, this is supported by results from Basrah and Iran \cite{24}.

Being of higher socio-economic status showed better satisfaction in contrast to results from Iran \cite{23}, possibly because those of higher status constituted only 25% of the sample and the fact they are financially capable and probably have a conscious knowledge of how things work in public clinics, so most likely they have an assisting person whether it’s a relative working in the hospital or a paid staff that facilities their entry and registration without needing to wait. Longer waiting time may cause a disagreeable effect on patient’s experience. \cite{6,17,19} Similarly current results showed with longer waiting times and shorter counseling duration, satisfaction tends to worse.

**Conclusion**

The current study illustrated the less satisfactory parts of service with understanding of demographic variables that influence satisfaction. Regular monitoring of clients’ satisfactions is needed for provision and increase service uptake, with care directed to clients’ comments together with awareness campaigns that not only market the availability of breast early-detection clinics but also motivates women to use the service.

The Prevalence of Polycystic Ovarian Syndrome and It’s Associated Symptoms in Selected Samples of Women in Al-Hilla City, Iraq

Suha J. Witwit
College of Medicine, University of Babylon, Iraq

ABSTRACT

This study aims to investigate the prevalence of Polycystic Ovarian Syndrome (PCOS) and its associated symptoms in selected samples of women in Al-Hilla City, Iraq. The study was conducted from Sep 21, 2017 to Sep 21, 2018 at infertility and outpatient clinics in Babylon Teaching Hospital at Al-Hilla City. A total of 2152 women aged between 15-45 years old were evaluated through full history and examination including: age, parity, BMI, history of menstrual dysfunction (amenorrhea, oligomenorrhea, menorrhagia), history of acne, hirsutism, galactorrhea, history of primary or secondary infertility, any family history of PCOS, hormonal assay, and ultrasound for assessment of ovarian morphology. The Rotterdam 2003 criteria adopted by the European Society were used for the diagnosis of PCOS which is based on presence of 2 out of the 3 following criteria: 1. Oligo &/or anovulation 2. Hyperandrogenism whether clinical or biochemical 3. Polycystic ovarian morphology by ultrasound.

All groups were comparable in their demographic criteria. The prevalence of PCOS in the current study at Al-Hilla City was 28.9%. About 19.9% of them were adolescent while the majority of them were young age group (76.9%) with less prevalence over 40 years about 3.2%. Menstrual dysfunction present in (89.1%) of patients in form of oligomenorrhea 77.7% while menorrhagia & amenorrhea present in 13.7% & 8.6% respectively and only 10.9% had regular cycle. This study show that 45.2% had history of infertility in which about half of them is primary infertility. About 19.1% of patients were overweight while 21.5% were obese but the majority of them (53.7%) were of normal body weight. Also the majority of patients were nullipara 43.5% & 10.2% were unmarried.

About 11.9% had positive family history of PCOS while acne, hirsutism & galactorrhea present in 15.1%, 25%, 11.2% respectively. Women with PCOS at urban area form about 57.7% while about 42.3% were from rural area. The number of patients who show full-blown criteria of this syndrome i.e. all 3 clinical features present was about 19.4% while those with possible PCOS form about 80.9%.

PCOS is a common endocrine disorder that affects about one-third of women and need to pay attention and search for the causes to treat and prevent long-term sequels.

Keywords: prevalence, amenorrhea, oligomenorrhea, hirsutism, polycystic ovarian syndrome.

Introduction

One of the commonest heterogeneous endocrine disorders is polycystic ovarian syndrome which lead to several health problems such as menstrual dysfunction, hirsutism, acne, infertility, obesity and metabolic syndrome (1). Also it affects about 7% of reproductive age women (2).

PCOS seems to be associated with an increased hazard of metabolic aberration including hyperinsulinism, insulin resistance, type 2 DM, cardiovascular disease, dyslipidemia, and endometrial carcinoma (3). PCOS has a major public health attention in society, so therefore it’s necessary to identify the proportion of women affected (4).

Corresponding Author:
Suha J. Witwit

Email: su_sa_2006@yahoo.com
It is commonly present in young females with oligomenorrhea, anovulatory infertility, or hyperandrogenic manifestation such as hirsutism, acne & obesity however this syndrome is commonly seen in a woman of normal body weight (5). Pcos is a genetically complex disease of undetermined etiology (6). Many believed that Pcos seems to be familial with a several aspect differentially inherited from one generation to the next (7).

Evaluation of the prevalence of pcos depend on the community being assessed as there are ethnic variation in the biochemical and clinical characteristics of pcos (8). The stated prevalence of pcos varies between 2.2-26% (9).

The purpose of the current study is to provide a population-based estimates for the prevalence of pcos in al-hilla city depending on clinical records of pcos diagnosis and signs constant with pcos. This study is considered the first to be carried out in our city to evaluate the prevalence of pcos using ESHRE/ASRM Rotterdam consensus.

Many factors implicate in the development of pcos, possibly the disorder present as genetic predisposition in the individual & it’s symptoms may aggravated by life style & environmental factors (10).

Most women with pcos may show only one or two clinical manifestations & the commonest is menstrual dysfunction which is mostly begin from menarche or sooner after it & may present in form of amenorrhea, polymenorrhea or oligomenorrhea & even might being normal cycle (11,12). It appears that the prevalence of pcos is commoner among females younger than 35 years (13).

**Definitions**

**Overweight & Obesity:** According to WHO criteria, normal BMI (body mass index) is between 18.5-24.9kg/m2 while BMI between 25-29.9kg/m2 is overweight & >30 kg/m2 regarded obese one (14).

- oligomenorrhea means delay in menses of more than 35 days (15).
- Hyperandrogenism whether clinical diagnosed by depending modified Ferrman & Gallway scoring system for evaluating & quantify hirsutism using 9 body areas (16) or biochemical which is mean elevated level of androgen.
- Ultrasonography: pcos can diagnosed when more than 12 follicles of 2-9mm present in one or both ovaries & increase in ovarian volume of 10 ml in at least one ovary (17).

**Study Protocol:** A particularly designed data formula was applied for recording information including full history, history of menstrual irregularity, acne, hirsutism, medications & family history, physical examination, hormonal assay & ultrasound finding.

**Hormonal analysis** including FSH, LH serum prolactin, serum testosterone & midluteal serum progesterone. The normal cutoff of FSH&LH was taken as 1-10mlu/ml, prolactin level of <35ng/ml was regarded as normal & total testosterone of < 70 ng/dl was regarded as normal (18).

Confirmed pcos was established when the patient had full-blown criteria of all oligo &/or anovulation, clinical &/or biochemical hyperandrogenism & polycystic ovaries by ultrasound while possible pcos when the evaluation is incomplete or was unavailable but the clinical phenotype was otherwise suggestive of this disorder.

**Data Analysis:** Statistical study was carried out using SPSS version 20. Categorical variables were presented as frequencies and percentages. Continuous variables were presented as (Means ± SD). Independent samples t-test was used to compare means between two groups. Paired t-test was used to compare means for paired readings. A p-value of ≤ 0.05 was considered as significant.

The majority (77.7%) of patients presented with oligomenorrhea. (n = 556)

Full Blown Criteria present in only (19.4%) of study patients.

Discussion

In this study, the overall prevalence of pcos in alhilla city/middle of Iraq was 28.9% which is comparable to the prevalence of pcos in another clinical study done at Hawler city/north of Iraq which was 32% (19).

Another Iranian study show the prevalence of pcos was 19.5% based on Rotterdam criteria (20).

As there are national & racial variation in the manifestation of pcos ie: it varies either in its presentation or prevalence around the world or in different racial groups within a country (8).

In current study about 19.9% of those with pcos were in adolescent age group & this disagree with two Iranian studies carried at Hashemipour in Isfahan & Rahmanpour in Zanjan was 3% (21,22).

While about 76.9% of patients their age was between 20-39 years old & this results were consistent with Alnakash & Al-Taee study as they noticed that 87.8% of the women with pcos included in their study were less than 35 years of age (23).

About 19.1% of patient were overweight (BMI>25kg/m²) & 21.5% were obese (BMI >30kg/m²) which is opposite to that founded in 12 studies show that the prevalence of overweight & obesity was 21% & 19% respectively (20) while another study show that the
prevalence of overweight & obesity was 32% & 24% respectively & this might be suggest that obesity per se is not a universal criteria of this syndrome (9).

Also another study done on 400 patient show that 24% were overweight & 32% were obese (24).

About 11.9% of patient in this study had positive family history which disagreed with Kahrar et al study who found the ratio of pcos in mothers & sisters was 24% & 32% respectively (25).

In total of 5 Iranian studies, the incidance of infertility was natural as 8% while in current study, those with primary infertility was 50.3 % & secondary infertility was 34.1% respectively with total incidence of %45.2 (26) (Table 1).

The total number of patient that manifest the phenotype of pcos (full blown criteria of pcos was 19.4% & this agree with Azziz study & Dewielly which present in 18.2%. as shown in table 2 (26,27), but this disagree with another study which carried between July 1998-Oct1999 as it demonstrate that confirmed pcos was 6.6 (24).

The prevalence of menstrual dysfunction in this study was 89.1% which higher than the rate of 22.9% reported by Soloman GC in his study (28) (Table 2). As well as the most menstrual disorder was oligomenorrhea which present in about 77.7% as shown in figure 1.

About 10.9% of patients was eumenorrhic in current study & this is higher than 3.7% of eumenorrhic women in Molcolm study (29) as shown in table 2.

The prevalence of hirsutism in current study was 25% which higher than the rate of 2.4% of physician –diagnosed hirsutism stated by participating in the Nurses’ Health Study II (27) (Table 2).

The prevalence of acne in current study was 15.1% while the Iranian study show that acne present in 26% (20).

In 5 studies, ultrasound morphology of polycystic ovaries estimated to be 52% (20) while in our study about 99% had ultrasound show morphology of polycystic ovaries.

**Conclusion**

pcos is common endocrine disorder that affect about one-third of women & need to pay attention and search for the causes to treat and prevent long term sequels.

ABSTRACT

The husband’s support is an important interpersonal factor in the prevention of cervical cancer performed by women but there are also women who have received support from their husbands who are still reluctant to make an effort related to the early detection of cervical cancer. This study aims to analyse the factors related to the husband’s support behaviour in cervical cancer prevention based on the Theory of Planned Behavior. This study used a cross-sectional design. The sample consisted of 102 husbands within childbearing couples taken using a cluster sampling technique. The variables of the research included the husband’s attitude, the subjective norm, perceived behavioural control, intention and support behaviour in relation to cervical cancer prevention. Data analysis was performed using Spearman Rho with α ≤0.05. The results showed there to be a significant relationship between attitude and intention (p=0.000; r=0.377), perceived behavioral control and intention (p=0.003; r=0.289) and the intention with the husband’s support behaviour in terms of cervical cancer prevention (p =0.000; r=0.431). The subjective norms within the intention indicate a significant relationship (p=0.059; r=0.188). To improve the prevention of cervical cancer, health care providers and health institutions should involve the husband to reduce female morbidity and mortality from cervical cancer.

Keywords: women, cancer, prevention, support, husband

Introduction

The early prevention of cervical cancer is possible to do since the beginning of cervical cancer caused by infection with the Human Papilloma Virus (HPV) which, if not dealt with, can be severe.¹ Cervical cancer prevention efforts are varied as improving public education activities on how to behave and how to live a healthy life, thus avoiding the risk factors for cervical cancer and offering early detection tests such as VIA and Pap tests, can reduce the incidence rate of cervical cancer.²

According to the WHO in 2012, new cases of cervical cancer total as many as 530,000 cases and deaths from cervical cancer reach as much as 270,000 cases, 90% of which occur in developing countries. Cervical cancer had the highest position in Indonesia in 2013, amounting to 0.8% and the estimated number of cervical cancer victims was 98,692 women. The East Java province ranks the third highest in Indonesia with the number of cervical cancer cases amounting to 21,313 inhabitants.³

In Indonesia, the government implements prevention efforts through early detection via pap smear tests. Health workers have made efforts to reach married woman by providing counseling about cervical cancer and facilitating the inspection of facilities for the early detection of cervical cancer. There are various factors that hinder the examination and early detection of cervical cancer in women such as shame and fear, the cost factor, especially in the economically weak, experience and motivation, as well as social support, especially from the husband as the decision makers in the family.⁴,⁵

Healthy behaviors arise when a woman gets support from the people nearby, one of which is the support from

DOI Number: 10.5958/0976-5506.2019.02251.4
her husband. A supportive husband is decisive because it will reinforce the motivation for the prevention, including early detection, of cervical cancer. The researcher, J Community Health, found the husband’s support to be the dominant factor in the prevention of cervical cancer, but some of the mothers who had the support of a husband did not undertake these efforts. It showed no clear point of view on part of the husband and the factors that play a role in the business of the husband and wife when it came to supporting and strengthening their motivation to take steps to prevent cervical cancer.

Research was conducted by Madhivanan about the family support related to encouraging the participation of couples of reproductive age (EFA) in the prevention of cervical cancer. This included support measures from the viewpoint of the wife. Research on the behavior of the husband’s support in the prevention of cervical cancer has not been done focused on male subjects. The factors related to the behavior of a man’s support is important to consider.

The Theory of Planned Behavior (TPB) explains that the behavior displayed by the individual arises because of the intention to behave. The emergence of an intention to behave deals with three factors: the attitude towards the behavioral, the subjective norms and perceived behavioral control. The aim of the study was to analyze factors related to husband’s support behavior in the prevention of cervical cancer based on the Theory of Planned Behavior.

**Method**

This study used a cross-sectional design. The population consisted of husbands who were of fertile age, as part of a couple in the Kauman sub-district, Nganjuk. The sample size in this study was 102 respondents. The technique of the sampling used was cluster sampling. The independent variables in this study consisted of attitude, subjective norms, perceived behavioral control and intention. The dependent variable was the behavior of the husband’s support for cervical cancer prevention. This study uses a demographic questionnaire. The instruments used to measure the TPB component variables including attitudes, subjective norms, behavioral control perceptions and the husband’s intention was in the form of a questionnaire developed based on each parameter. The instruments of the husband’s support in preventing cervical cancer were developed based on the emotional, instrumental, informational and reward support parameters. They used a positive and negative scale in the form of Likert statements. The data classification of all of the variables was done using T score referring to the data mean. The instrument carried out both validity and reliability tests.

**Data Analysis:** The descriptive statistics method was employed to analyze the data to generate the study results in forms of frequencies and percentages. This method allowed to summarize the characteristics of the study subjects based on the variables selected. Inferential analyzed using Spearman’s Rho test.

**Results**

The respondents were aged between 26-35 years by as many as 42 people (41.2%). The majority of the respondents had completed high school education by as many as 61 people (59.8%). The dominant job was self-employment by as many as 48 people (47.1%). The average income of the respondents was more than Nganjuk’s minimum wage, by as many as 48 people (47.1%).

There is a significant relationship between attitude \((r=0.377)\), perceived behavioural control \((r=0.289)\) and intention related to the behaviour of the husbands’ support in the prevention of cervical cancer. The more positive the attitude and the better the perception of control in the behaviour of the respondent, the higher the intention to support cancer prevention.

There is no significant relationship between subjective norms and intention in reference to the behaviour of the husbands’ support in the prevention of cervical cancer. The absence of a significant relationship arises when someone has a belief that is less due to people who are considered to be less important showing expectations that need to be met by such a person.

There is a significant relationship between the intention to conduct support from the husband in the prevention of cervical cancer. Spearman’s correlation value of 0.431 indicates that the intention to provide support has a strong enough relationship and that it is in line with the behaviour of the husbands’ support in the prevention of cervical cancer.

Discussion

The majority of the respondents have a positive attitude. The supportive attitude was found in relation to the prevention of cervical cancer. They consider that the attitude of support is essential to bringing up the intention to provide support for the prevention of cervical cancer. The attitude of a significant predictor of the intention of women in terms of screening for HPV is involved in the early detection of cervical cancer. Someone is going to have a positive attitude about the behaviour of the support in the prevention of cervical cancer because they have a feeling that is focused on siding with the statement that it is crucial to assist in the study. Belief is proportional to the right attitude towards vaccination. A positive attitude has a significant relationship with predicting the intentions of eating a healthy diet in pregnant women. The Theory of Planned Behaviour states that attitudes toward a particular
behaviour are a determining factor for the formation of an intention.12

A positive attitude tends to elicit high intention, but some of the respondents have a positive intention but they are lacking otherwise. There are also respondents who act negatively but who have good intentions. Based on the Theory of Planned Behavior, intention is not only influenced by attitude but also by subjective norms and perceived behavioural control. Each has their strengths regarding which factor affects the intentions of the individual, so there are always people who have a high intention and a positive attitude.13 The existence of other factors that affect the intention and attitude includes the demographic data such as age, education, occupation, income, knowledge, experience and media exposure as generated by the respondent.

Good subjective norms do not necessarily produce a high intention. The husband’s intention to provide support for the prevention of cervical cancer was influenced by the individual. According to the research, the global burden of women’s cancers is a grand challenge in global health. Some of the influential persons out of the respondents included parents, spouses, neighbours, friends and health workers. Generally, people tend to have confidence in the direction of other people. Someone special to us will significantly influence the formation of our beliefs.14

Most of the respondents have less subjective norms that showed that her husband was less influenced by those closest to them confidence. There were also respondents who had proper subjective norms and high intentions. The subjective norms and intentions were less steep, as well as the subjective norms and intentions being lesser as well.

The perception of the control behaviour of the husband in the prevention of cervical cancer is more directed at the husband and their confidence in the factors that influence the behaviour of their support and the votes that possessed the power of perception. The researchers categorised the viewpoint of behavioural control into two categories: the behavioural control perception of good and the perception of behavioural control being lacking. The control perception of good behaviour indicates that the husbands tend to be able to control their perceptions of the factors that influence the behaviour of the support in the prevention of cervical cancer.15 The husband’s perception can efficiently perform the reaction in favour of cervical cancer prevention. The perception of less behavioural control shows the tendency of the husband to be less able to control the perceptions of the factors that influence the behaviour of the support in the prevention of cervical cancer. The husbands perceived that it was difficult to support their wives in the prevention of cervical cancer.

The majority of respondents have the high intention of demonstrating a strong desire and urge in themselves to provide support in reference to the prevention of cervical cancer, even if the intention associated with the behaviour of the husbands’ aid in the prevention of cervical cancer mostly shows a low intention and where actions are lacking. The intensity is generally comparable with the behaviour performed but some of the respondents have high intentions but demonstrate less supportive behaviour in the husbands. This is similar to the respondents who had low intentions but good behaviour. Other factors influence attitude - behaviour, subjective norms, the perceptions of behaviour control and specific intentions.14 A lack of facilities and infrastructure owned by the husband can be a factor that also supports the implementation of a behaviour. Facilities and infrastructure can involve time, energy, materials and facilities. It could require the husband to be able to guarantee the facilities to support cervical cancer prevention behaviour with their wife.17,18

In addition to the above factors, the demographic data of the respondents can also affect the intention and practices of the support from the husband. The respondents who had heard of cervical cancer tended to have high intentions and good behaviour. As demonstrated by the high intentions, good behaviour refers to the respondents whose knowledge of cervical cancer is limited. The high intention of the prevention can arise when exposed to sufficient information and the experience gained by the respondents who most often obtained said information from their community leaders. The knowledge gained by the respondents was indirect. The respondents sought to understand the dangers of cervical cancer, and so their intention seems to be high.

**Conclusion**

A positive attitude about the prevention of cervical cancer means that the intention that appears in the husband will also be high. If the husband has the
perception of good behaviour related to the control of cervical cancer then this can increase the husband’s intention to support the prevention of cervical cancer. The husband’s subjective norm has no relationship with the husband’s desire to promote the prevention of cervical cancer, which is indicated by the presence of respondents who have less subjective norms obtained from community leaders. They can increase the intention of high respondents in support of cervical cancer prevention. High intention can encourage the creation of supportive behavior from the husbands in the prevention of cervical cancer.

The national program for the prevention and early detection of cervical cancer needs a policy involving the husbands. The recommendations for further research to increase the awareness of the husbands are directly involved in the efforts to prevent cervical cancer in their partners.

**Ethical Clearance:** Considering the data collection and ethical practices, the research passed the ethical review of the health research ethics committee of Faculty of Nursing, Airlangga University with certificate number 426-KEPK.

**REFERENCES**

15. Fallahi A, Shahrbabaki BN, Hashemian M, Kahanali AA. The needs of women referring to health care centers for doing pap smear test. Mashhad University of Medical Sciences; 2016 Mar;19(6).

Dysmenorrhea is one of the problems among female adolescents. The dysmenorrhea incident rate in East Java reached 64.25% consisting of 54.89% primary dysmenorrhea and 9.36% secondary dysmenorrhea. The aim of this study was to explain the correlation between physical activity as how it related to primary dysmenorrhea in female adolescents. This study used a cross-sectional research approach. The study was conducted in a Senior High School in Rengel, Tuban. This study used the purposive sampling technique. A total of 77 respondents (mean age 16.4 years), who were involved in the study. The data collection used a Physical Activity Questionnaire for Adolescents (PAQ-A) to measure physical activity and the measurement within the pain scale questionnaire used the Numeric Rating Scale (NRS). The data was collected using the questionnaires and the results were analyzed using the Spearman rho test with a significance level $\alpha \leq 0.05$. The results of this study showed there to be a correlation between physical activity ($p = 0.033$) and dysmenorrhea in female adolescents. The present study therefore has indicated a correlation between physical activity and dysmenorrhea. Physical activity is beneficial in reducing primary dysmenorrhea. For future implementation, it is suggested to conduct an appropriate intervention such as physical activity and stress management in order to reduce emotional symptoms associated with primary dysmenorrhea.

**Keywords:** physical activity, dysmenorrhea, female adolescents

**Introduction**

Primary dysmenorrhea is one of the most common gynecological disorders in women characterized by pain cramps in the lower abdomen during menstruation without pelvic pathology. This case often occurs in the first and second years after the onset of menstruation during ovulation. The overall prevalence of primary dysmenorrhea is 60% to 90% in female adolescents with a decrease in age. The psychological factors could involve primary dysmenorrhea, and a rise in prostaglandin, vasopressin concentrations and leukotriene levels. Prostaglandin causes pain by increasing the uterine tone and contractions. Pelvic cramping pain that starts just before or during menstruation and that lasts 1-3 days is a sign of dysmenorrhea. $2-4$ days before menstruation begins, the prostaglandin concentration increases to the uterine muscle during menstruation and it regulates the contractions of the abdominal muscles to help expel endometrial expulsion.

The dysmenorrhea incident rate in East Java reached 64.25%, consisting of 54.89% primary dysmenorrhea and 9.36% secondary dysmenorrhea. In addition, dysmenorrhea is a common cause of absence. The previous study showed that primary dysmenorrhea occurs less in women who exercise than women who do not exercise. Treating dysmenorrhea using abdominal and pelvic stretching exercises can be very effective at reducing pain in primary dysmenorrhea. Some studies have researched factors such as aerobic exercise as an effective treatment of dysmenorrhea but one study found there to be no relationship between exercise and dysmenorrhea. The variance of the findings on this disorder has led to present study focused on physical activity and the correlation to primary dysmenorrhea in female adolescents. It is expected to increase the knowledge on female adolescents as related to primary dysmenorrhea and it will hopefully motivate them to do more activities.
Method

Study Design, Setting, and Sampling: This study used a descriptive analytic design with a cross-sectional research approach. The population was obtained from a total of 331 female students from a senior high school in Rengel, Tuban. The study was performed on a total of 77 female adolescents who agreed to participate. The instrument used was a modification of the Physical Activity Questionnaire for Adolescents (PAQ-A) by Kowalski that had been adapted. It consisted of 7 questions about the summary of a person’s physical activity. Each question item consisted of 5 answer choices that described the intensity of the physical activity carried out. The measurement of primary dysmenorrhea used a questionnaire with a pain scale measurement using the Numeric Rating Scale (NRS) method.

Study Variables: The independent variable of this study was the physical activity. The dependent variable was primary dysmenorrhea.

Data Analysis: The descriptive statistics method was employed to analyze the data in order to generate the study results in forms of frequencies, percentages, mean, range and standard deviation. The data obtained was analyzed using the Spearman rho statistical test with a significance level of $p \leq \alpha \leq 0.05$.

Results

The menstrual information, i.e. age of menarche, length of menstrual cycle and length of menstrual flow, was recorded and has been shown in Table 1.

Besides, the statistical results reflect that the length of the menstrual cycle was from 7 to 80 days, where nearly 90% of them had their cycle within 25 to 35 days. For the length of menstrual flow, all of the respondents reported that their menstruation would finish within 3 to 7 days.

This research was conducted to find out the relationship between physical activity participation and the intensity of lower abdominal pain as shown in Tables 2 and 3. For physical activity participation, the researcher defined it using two levels: if they participated in the school sports team in primary or secondary school and an average of their physical activity participation for a number of hours per week over the past three months. When we considered the average sport’s participation in hours per week over the past three months, 50 of out of 77 respondents had participated in sports activities less than or equal to 2 hours per week and 27 out of 77 of them had participated in physical activities for more than 2 hours per week.

$p = 0.033, r = 0.243$

Based on Table 4, it was found that most teenage girls who had heavy physical activity had mild dysmenorrhea (22.1%), totaling 17 respondents. However, the teenage girls with mild physical activity mostly experienced moderate dysmenorrhea (23.4%), totaling 18 respondents.

The results showed that the proportion coefficient (p) was 0.033. Therefore $p = 0.033$ was smaller than the level of $\alpha = 0.05$. This means that the hypothesis (H1) accepted that there was a relationship between physical activity and dysmenorrhea in female adolescents. The correlation coefficient (r) obtained the value $r = 0.243$. According to the table r-value, there was a correlation between physical activity with dysmenorrhea, although the correlation was weak or low.

Discussion

The result shows that there was a correlation between physical activity and the primary dysmenorrhea experienced by teenage girls. This is supported by the majority of respondents with a heavy physical activity pattern having experienced mild dysmenorrhea (17 respondents). However, the respondents who have a mild physical activity pattern mostly experienced moderate dysmenorrhea (18 respondents). The dysmenorrhea incident will increase the awareness rate of women who do less physical activity, thus when getting dysmenorrhea, the oxygen cannot be distributed into the blood vessels in the reproductive organs as effectively which leads to vasoconstriction. The menstrual pain may result from the increased contractions of the uterine muscle which is innervated by the sympathetic nervous system. Stress is supposed to increase the sympathetic activity which may lead to the increase in menstrual pain by enhancing the intensity of the uterine contractions. Due to the fact that exercise could reduce and moderate stress, the sympathetic activity may be decreased. Thereby, the intensity of the menstrual pain and other related symptoms may be reduced as well. Another possible dilemma in this respect is that since performing physical activity leads to the release of endorphins which are produced by the brain, the pain threshold can be enhanced.

Effective exercise seems to be perceived as superior and reliable among health institutions, doctors, and women; exercise is beneficial. However, a combination of organic, psychological, and sociocultural factors may also be responsible. A common problem in women of reproductive age, is a very serious problem that can often directly affect the quality of life and cause periodic college absenteeism. Exercise is commonly cited as a probable remedy for menstrual symptoms with limited research available. The purpose of this study was to observe the effect of aerobic exercises on Primary dysmenorrhea.

Methods: Study was a randomized clinical trial. Participants were 100 female college students who were divided in “exercise“ and “control“ groups. The “exercise group“ was given Aerobic exercises and results of three cycles were registered. Outcome measures were VAS for Pain and SF36 for Quality of life. Data was analyzed using paired t test, chi square test and z test for statistical significance. Results: The results showed that pain (VAS scores It refers to regularly participating in any kinds of sport’s team during primary and/or secondary school. This involves actively participating in physical activities. For substantial health benefits, adults need to do at least 150 moderate – intense activities per week. Therefore in this study, the researcher uses actively
participating in physical activities to refer to the females who participated in physical activities for more than 2 hours per week. Inactive or no participation in physical activities refers to females who participated in physical activities for less than or equals to 2 hours per week.

The data showed that the majority of respondents who did not experience primary dysmenorrhea did intense physical activity and only a small proportion of respondents did mild physical activity. The respondents who did mild physical activity mostly experienced moderate dysmenorrhea and some of the respondents did not get dysmenorrhea at all. From this data, the physical activity of the respondents can be related to the primary dysmenorrhea. Exercise improves cardiovascular status, increases bone mineral content and reduces dysmenorrhea and the symptoms of premenstrual syndrome.\textsuperscript{11,12} It also helps to reduce pain, relieve stress and improve mood and health. Women who exercise have less severe dysmenorrhea and greater positive effects than women who do not exercise.

Physical activity can increase the release of several neurotransmitters including natural endorphins (brain natural painkillers), estrogen, dopamine, endogenous opiate peptides and it can also change the reproduction of hormone secretion, suppress prostaglandin from being released and increase the ratio of estrone-estradiol. This works to reduce endometrial proliferation and injects blood flow away from the uterus.\textsuperscript{12,13} Exercise can increase concentration and improve mood and behavior. However, there were 3 respondents in this study who did mild physical activity but who did not experience primary dysmenorrhea. There were also 4 respondents who experienced severe primary dysmenorrhea despite doing heavy physical activity.

This could occur because each individual’s perception of pain is subjective, thus it results in a varied pain response. The pain felt by each individual is different because it is influenced by the factors that cause pain. A lot of respondents who experience primary dysmenorrhea found that it is also based on other influential factors such as adolescence, menarche age and family history.\textsuperscript{14} Menstrual pain often occurs in teenage girls because the reproductive organs are imperfect in terms of endometrium growth. They are psychologically unstable. The frequency of pain will decrease according to age. Another factor that can trigger dysmenorrhea is menarche. Menarche is occurring at an earlier age than normal, where the reproductive organs have not developed optimally and there is still a narrowing of the cervix. This results in pain when menstruating because the female reproductive organs are not functioning optimally. Family history factors also play a significant role in the occurrence of dysmenorrhea in adolescents.\textsuperscript{14}

The respondents who did mild physical activity were female students who took dance and other extracurricular activities. Many of the respondents who did heavy physical activity took on Red Cross duties as their extracurricular activities. Based on the results and the theory explained, the analysis showed that the teenage girls who did physical activity routinely stimulated the production of endorphine hormones. These hormones can control the blood vessels, returning them to normal and thus, the blood flow will go more smoothly and reduce the pain.

**Conclusion**

The results of this study confirmed that physical activity such as extracurricular programs in school may be the preferred intervention for dysmenorrhea. Physical activity can increase the release of several neurotransmitters which work to reduce endometrial proliferation and it can also inject blood flow away from the uterus. We concluded that physical activity has a positive correlation with primary dysmenorrhea, even though the statistic-based tests showed there to be a weak correlation. The findings of this study showed there are other factors that can affect primary dysmenorrhea, such as age, menarche age and family history. It is recommended to improve and develop any other aspects associated with dysmenorrhea because it seems to be a significant problem for female adolescents that can cause further damage.

‘It was Hard but it is Satisfying’: The Lived Experience of Older Adults Moving to a Residential Home (Griya Werdha) in Surabaya

Setho Hadisuyatmana1, Hermansyah2, Elida Ulfiana1
1Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia; 2Puskesmas Loksado, Department of Health of South Kalimantan, Indonesia

ABSTRACT

Relocation stress could occur in relocated older adults. The signs and symptoms often manifest as non-specific complaints. This study aimed to elicit the lived experience of relocated older adults in a residential home in Surabaya. Individual interviews were conducted following consent being given, in addition to MMSE, GDS and Family APGAR score tests. Seven residents aged between 60 to 80 years old voluntarily participated in this study. A phenomenological approach was used to develop the narrative findings following verbatim transcription and the work by Colaizzi (1976). Five themes emerged from the study: moving was a hard decision, feeling lonely in the first months, trying to accept changes and the feeling of being health-supported. These themes reflected that moving to a residential home was hard despite the voluntary decision. Eventually, they adapt by virtue of support from the other residents, their visiting families and the health staff. Their final stories reflected satisfaction focused on their well-maintained daily and health needs.

Keywords: Relocation stress, older adults, residential home, experience

Introduction

Older adults who decide to or who are forced to live in residential homes are prone to psychological symptoms, such as relocation stress syndrome. The North American Nursing Diagnosis Association identifies relocation stress syndrome as a condition in which a person suffers from physiological and psychological disorders as a result of relocation from their home to a foreign environment. This can lead to stresses either physically, psychologically or socially. Health-professional support is significant when it comes to assisting older adults who are moving to a new environment, such as to a residential home.

Statistically, it is estimated that around 11,914 older adults are residents in both public and private nursing homes spread across Indonesia. Our preliminary study conducted in October 2017 at Griya Werdha, a residential home in Surabaya, identified that 19% of the residents were moving in less than 4 months. Four of them suffered from moderate to severe depression. Presumably, this is due to the adjustment process and it is an indication of the relocation stress. Relocation-stressed adults could experience changes in their self-control, identity and self-esteem due to the new environment whereby they might lose some degree of privacy while trying to establish a new relationship with the other residents.

Psychological support is significant when it comes to assisting the residents to adapt to the new homely environment. Nonetheless, there is an area of silence in the literature to explain this assumption in the context of Indonesia. Thus, this study was designed to elicit the lived experiences of older adults as new residents in Griya Werdha. It is expected that the results would illuminate the expectations toward a better service in residential homes. We used the theory of life crises and transitions by Moos & Schaefer as the lens in terms of gaining an understanding of the studied phenomenon.
Method

Study Design, Setting, and Sampling: This study used a phenomenological approach to understand the lived experiences of older adults who were recently moving from their home to a residential home in Surabaya. The setting was purposively selected as it represented the most accessible facility for most older adults living in Surabaya and the cities nearby. The informants were recruited purposively through the snowballing technique. The criteria determined in this study was to include only residents aged 60 - 80 years old, moving in to the Griya Werdha in four months or less at the time of data collection, with a good cognitive status and who were able to communicate well.

Data Collection: All potential informants were first screened for cognitive function using Mini Mental State Examination (MMSE). Their level of stress was measured using the Geriatric Depression Scale (GDS-SF) short form and APGAR (adaptability, partnership, growth, affection, resolve) following individual consent being given. The informants who met the inclusion criteria were then invited to an individual guided-interview using a list of open-ended questions. A hermeneutical process and probing questions were employed to engage with the informants’ worldview. Each interview was audio recorded and transcribed verbatim.

Data Analysis: The collected data was then analyzed following the seven steps provided by Colaizzi (1976). These steps were as follows:

- **Step 1, active reading:** The authors actively read the entire transcript, which involved repeated readings with the aim of understanding the general picture of the informant’s perspective on the experienced phenomenon.

- **Step 2, color coding:** This step was conducted to identify the color-coding significant statements. The color-coded statements were then copied for the next step.

- **Step 3, giving meanings:** This process inquired the authors to carry out an internal process to interpret the meaning of each statement using the participant’s point of view. This process involved back and forth discussions between all authors to formulate the meanings that emerged from each informant.

- **Step 4, developing themes:** This step included categorizing each unit of meaning into potential themes by collecting the coded statements that shared similar information into sub-themes or themes.

- **Step 5, integrating themes into a complete description:** This step was carried out through a deeper discussion in order to obtain a clear and justified description on the generated themes and sub-themes.

- **Step 6, validation to informants:** The generated description was then given to the informants for a final reading and compliance check. This step was significant to ensure that the stories developed through the different informants reflected their personal experience in the past. For the informants who were unable to read, the chief investigator of this study read the results on behalf of the informant.

- **Step 7, refining results:** The results were refined if there any complain occurred during the validation process.

Results

Three female and 4 male older adults as new residents voluntarily shared their lived experience when they decided to move in to the Griya Werdha. Their ages ranged from 61 years to 78 years. Their last education obtained was as follows 1 person never went to school, another person did not finish primary school, 1 person graduated from elementary school, one person graduated from junior high school, two graduated from high school or the equivalent and one person graduated from college. They were mostly Javanese; 4 of them were Moslems and the others were Christian by religion (see Table 1).

Table 1: The demographic characteristics of the new residents who were participating in the study (n = 7)
Four themes emerged in this study and these can be understood as structures that shape their experience. They were: moving was a hard decision, feeling lonely in the first few months, accepting changes and the feeling of being health supported.

**Moving was a hard decision:** Making the firm step to live at Griya Werdha was difficult, even though it was their decision. The informants recalled that they never had an idea of what it would be like to live in a nursing home, as informant 1 recalled:

> “I was shocked because I felt alienated. Previously, I would never know, oh...here we are now, oh now we have rules. So, we were shocked and we can’t get out. I used to be free to go anywhere and I can’t do it anymore” (Informant 1)

It was a mixed feeling when discussing about the residents’ life in the past. Many of them were reminded of the job that they used to work for a living and some of them were reminded of their families at times, as Informants 3 and 7 stated:

> “…I kept thinking about my old job... I didn’t feel comfy to have left it that way...” (Informant 3)

> “Sometimes I feel fine and happy but I always remember my family...” (Informant 7)

**Feeling lonely in the first months:** The changes felt by the informants when starting to live in the residential home were expressed as them feeling lonely. They recalled that they used to have many types of old friends. They compared that they were now in an uneasy situation to make new friends, as Informant 1 replied:

> “…I felt lonely, yeah, lonely. I have many friends out there, many kinds of them and free. I had to make friends with those who stayed in this... around here” (Informant 1)

On the other hand, they also highlighted that they, many times, missed their family, as stated by Informants 5 and 6:

> “…yeah, that feeling keeps distracting me... I miss my family...” (Informant 5)

> “…But, to be honest, I miss my little grandson.” (Informant 6)

**Accepting changes:** Eventually, all residents have to accept change to adapt to the new environment provided in the residential home. They started to seek distractions through various activities, including watching TV and regularly exercising. For instance, Informant 1 and 4 replied:

> “…we watch TV and karaoke, for entertainment. To get rid of the feeling of being lonely, we watch TV and do karaoke. It feels a little better” (Informant 1)

> “We do sports and aerobics, every day. There are also dancing competitions sometimes” (Informant 4)

Slowly but surely, the new residents started to accept their new life. They distracted their thoughts and avoided negativity, such as recalled by Informants 5 and 7:

> “…I convinced myself that I had lost my life out there. I was starting a new life here” (Informant 5)

> “To overcome this problem, I try to be happy, think positively and what can I do? I must accept my fate as it is” (Informant 7).

The process of accepting changes in their life was also facilitated by their family and relatives who were regularly coming to see the informants to ensure that they were not alone. Informant 3 and 7 recalled:

> “I still have a nephew. They also often come here to see me” (Informant 3)

> “I have nephews and grandchildren, twice already, they have visited me twice” (Informant 7)

**Feeling of being health-supported:** Currently, the residents evaluated that living in the residential house was fully supported despite the restrictions put in place by the rules and regulations. The informants expressed their satisfaction of the support given by the nurses and social workers who worked in Griya Werdha, their residential home.
“Good, everything is fulfilled. For example, eating… all of my health needs are fulfilled” (Informant 3)

“All I know is that I am happy. I like it. First when I came here, I was sick. After I was cured, then they told me to stay. I don’t have to worry about eating and sleeping. They give me enough heat and sleep. And that’s true” (Informant 7)

Discussion

The study findings elicited the older adults when they decided to move into a residential home in Surabaya. They were unaware about living-in as new residents due to a lack of information regarding their life-changing decision. They expressed that it was not as expected and that there was a sense of regret during the first four months as new residents. In most cases, the informants were moving into residential homes due to loneliness, a decreased health condition and limited health support at home.\footnote{Hesitation, feeling shocked, rejection, or mixed feelings were apparent as they verbally expressed their experiences when moving to Griya Werdha.}

Feeling lonely was expressed when the informants were asked about their experience of living-in in the first months. They lacked information on what it was like to stay under unheard rules and regulations, which restricted them from going out of the facility even for a short amount of time. This situation could be a contributor to the drastic changes for the new residents and this explains their unheard expressions due to the transition.\footnote{However, this was not explored further in the current study. The change of feeling could also an effect from the meaningful difference between the person’s past life-experience and their current situation. Thus, relocation has an impact on psychological well-being.\footnote{We assume that restricted mobility and unfamiliar rules and regulations were responsible for the residents’ psychological well-being. This finding recommends that older adults should be well prepared before making the decision to live in a residential home and the health personnel thus need to support them during the transition period.}}

Light exercise, watching TV and aerobics were selected as how the new residents tried to overcome their blue feelings. They were distracted by different activities and pleasant thoughts as a means of transferring the feeling of loneliness. The theory of crisis and life transition simply defines this as a resolution phase, where a person consciously selects coping skills to resolve any problems and changes.\footnote{This study found that the coping mechanism of the new residents was adaptive and self-reliant despite their various levels of education background. This finding calls for a further study to investigate on how education can impact on older adults when selecting a coping mechanism.}

The new residents were supported through the provision of scheduled activities, including religious activities, physical exercise and periodic health checks, as well as supportive facilities such as an outdoor gazebo, playing cards, musical instruments and a Karaoke set. All of these have the aim of letting them make themselves feel at home. Koppitz et al\footnote{identified four phases of adaptation in relocated adults: being cut-off, being restricted, being cared for and moving on. The residents who were participating in this study were mostly in the phase of moving on, whereby they had adapted to the new homely setting and had accepted the scheduled activities. This phase was achieved as all of the informants had stayed in the residential home for more than 4 months by the time that the data was collected. However, this study was not designed to explore the length of their stay and the correlation with relocation stress.} -identified the need for well-maintained communication between the residents and their families.

Family support became an important element for a successful transition. Frequent visits were highlighted as an indication of the meaningful attention perceived by older adults who were moving to Griya Werdha. This suggests that family visits could help the new residents to cope with their loneliness and it could also maintain their psychological well-being.\footnote{Family support became an important element for a successful transition. Frequent visits were highlighted as an indication of the meaningful attention perceived by older adults who were moving to Griya Werdha. This suggests that family visits could help the new residents to cope with their loneliness and it could also maintain their psychological well-being. These findings highlight the need for well-maintained communication between the residents and their families.}

The informants in this study expressed meaningful feelings when asked about their recent experience of living in the Griya Werdha. They expressed happy feelings, which was in contrast with the first few months of moving-in. Moving in to Griya Werdha was an unpleasant experience. Nonetheless, their acceptance of the change eventually made them satisfied concerning living in the residential home. This finding is shared with an earlier research study by Chang et al\footnote{despite the feeling of being isolated remaining. The residents also expressed their gratitude for having a place to continue their life without worrying about needing support for their daily needs.} despite the feeling of being isolated remaining. The residents also expressed their gratitude for having a place to continue their life without worrying about needing support for their daily needs.
Conclusion

Hesitation, feeling shocked, rejection and mixed feelings were verbally expressed by the residents in this study when discussing their experience of first moving to Griya Werdha. The lack of information on what it was like to stay under unheard rules and regulations were reasons behind these psychological expressions. Thus, this highlights an urgency; older adults should be well prepared before making the decision to live in a residential home. This study found that the coping mechanism of the new residents was being adaptive and self-reliant despite their different education backgrounds. Family support emerged as an important element for a successful transition. The residential home thus needs to facilitate a well-maintained communication between the residents and their families.

Pre-Schoolers’ Eating Behavior in Urban Communities: An Overview

Eka Mishbahatul Marah Has¹, Nursalam¹, Ferry Efendi¹, Yuni Sufyanti Arief¹, Dwi Faqihasu Syarifah Ha³

¹Faculty of Nursing, Universitas Airlangga, Mulyorejo Street (Kampus C), Surabaya City, East Java, Indonesia; ²Faculty of Health, Universitas Muhammadiyah Gresik, Sumatera Street No.101, Gresik Regency, East Java, Indonesia

ABSTRACT

Introduction: Adequate nutrition is needed by preschool-aged children to allow for growth and development optimally. Eating behavior during the preschool years also shapes lifelong dietary preferences. This study aimed to describe the pre-schooler eating behavior in urban communities.

Method: The design used was descriptive with a cross-sectional approach. The population consisted of mothers and preschool-aged children (aged 3-5 years) in Gresik Regency (an urban area in East Java). The sample size was 90 respondents, taken using a simple random sampling technique. Preschool eating behavior is defined by energy adequacy level and dietary diversity. The data was collected using food recall over 24 hours and this was described using frequency and percentage distribution.

Results and Analysis: The results showed that most pre-schoolers had a good energy adequacy level (64.4%). The most significant contributors to energy were carbohydrates, protein and fat. Most pre-schoolers have good dietary diversity (75.6%). Most of their food composition consisted of rice, animal and plant protein and milk. Vegetables and fruits were rarely consumed.

Discussion: It can thus be concluded that the pre-schooler’s eating behavior in urban communities was good. Further research can use these findings to develop an intervention to enhance the healthy eating behavior of pre-school children in urban communities.

Keywords: eating behavior, preschool aged-children, urban communities

Introduction

The growth spurt and rapid development occurred at <5 years of age.¹ This represents a time of significant cognitive and behavioral growth, dominated by the dynamic and robust progressive process of brain development that will later be continued with maturation and experience.² with the initial expression of many psychological abilities that will continue to be refined into young adulthood. Likewise, brain development during this age is characterized by its “blossoming” nature, showing some of its most dynamic and elaborative anatomical and physiological changes. In this article, we review human brain development during the preschool years, sampling scientific evidence from a variety of sources. First, we cover neurobiological foundations of early postnatal development, explaining some of the primary mechanisms seen at a larger scale within neuroimaging studies. Next, we review evidence from both structural and functional imaging studies, which now accounts for a large portion of our current understanding of typical brain development. Within anatomical imaging, we focus on studies of developing brain morphology and tissue properties, including diffusivity of white matter fiber tracts. We also present new data on changes during the preschool years in cortical area, thickness, and volume. Physiological brain development is then reviewed, touching on influential

Adequate nutrition can be obtained through a variety of diets in recommended amounts, based on the body’s dietary needs. This refers to frequent eating, where preschoolers should eat every 3-4 hours or about 4-6 meals every day. In portions, their plates should consist of half vegetables and fruits, a quarter for healthy carbohydrates, and the rest being healthy proteins, including oils, milk and water. When it comes to choosing a diet, preschoolers still depend on their mother. On the other hand, as their sense of taste develops, preschool-aged children have their own food preferences and they become more selective in their choice of food. They also are easily attracted by unhealthy snacks in their environment. Once they have established unhealthy eating behaviors, it is hard to correct in later life. Poor eating behavior in children is a public health issue. Little is known about the preschoolers’ eating behavior in urban communities.

Unhealthy eating behavior in preschool children can lead to malnutrition. Longitudinal research using Indonesia Family Life Survey’s data found that the prevalence of stunting and underweight preschoolers decreased significantly in waves 1 to 4 (stunting from 50.8% to 36.7%; underweight: from 34.5% to 21.4%). The prevalence of ‘at-risk’, being overweight or being obese increased significantly from 10.3% to 16.5%. Stunting, and at risk of overweight/obesity or obesity in Indonesian children aged 2.0-4.9 years; and the National Health Survey (RISKESDAS) in 2013 noted that 37% of children aged under 5 years old were affected by moderate and severe stunting, 12% of children aged under 5 were affected by wasting (low weight-for-height) and 12% of children were overweight. The prevalence of malnutrition is decreasing compared with 2010, but it still cannot achieve the WHO target on Sustainable Development Goals (SDGs).

A child deprived of adequate nutrition may never reach his full physical or cognitive potential, which can limit his ability to learn and earn. They also have an increased risk of falling sick and experiencing a greater severity of disease.

In developing countries such as Indonesia, the double burden of malnutrition is more prevalent in urban areas. Urban malnutrition is caused by unhealthy eating behavior. Urban populations tend to consume more calories and more highly processed foods. They frequently rely on cheap and convenient street foods. However, they also have good access when it comes to accessing a greater diversity of fresh foods such as animal-sourced foods, legumes, vegetables and fruits.

Gresik Regency is categorized as an urban area that is in the northwest of East Java Province, along the coastline. By 2017, from the 84,696 under five year old children who came to Posyandu Balita (integrated health care center for under five-year-old children) in Gresik Regency, 0.6% were found to be underweight. The previous research found that most of the mothers in the area preferred to buy food from food stalls instead of cooking themselves. The composition of the food consumed was often a rice and protein made both from either animals or plants. This study aimed to describe the preschooler eating behavior in urban communities.

Method

Study design, setting, and sampling: This was descriptive research with a cross-sectional approach. The population consisted of mothers and preschool-aged children (aged 3-5 years) in Gresik Regency registered as members of a Posyandu Balita. The sample size was made up of 90 mothers and pre-schoolers in pairs, who became involved using a simple random sampling technique. Randomization was conducted by entering all pre-schooler names into a fishbowl, prior to their selection. In the case of non-consent, we re-did the selection process to achieve 90 respondents.

Study variables and data collection: The general demographic data that was collected included the mother’s age, the children’s age and the familial monthly income via a questionnaire completed by the mothers at the time of recruitment. It is important to describe the characteristics of a population. A 24-hour dietary recall (24HR) was used to evaluate the child’s eating behavior. The 24HR is a structured interview designed to capture detailed information about all foods and beverages taken in the past 24 hours. The mother was asked to report and complete the form on behalf of the children. In order to make it easier for the mother easier when reporting their pre-schoolers’ meals, a food model was provided during the interview. The energy adequacy level was evaluated by comparing the results of the 24HR with

results from several different functional imaging and recording modalities in the preschool and early school-age years, including positron emission tomography (PET). Thus, there is a need for adequate nutrition to achieve optimal growth and development.
the Recommended Dietary Allowance (RDA) for preschool-aged children in Indonesia, according to Widyakarya Nasional Pangan dan Gizi. The data was then categorized as 1) Good ≥100% RDA, 2) Fair >80-99% RDA, 3) Less 70-80% RDA and 4) Deficit <70% RDA. Dietary diversity was evaluated by assessing the variety of food consumed by the pre-schoolers which should consist of healthy carbohydrates, animal or plant protein, vegetables, fruits, healthy oil, dairy and water. The data then categorized as 1) Good (all food components were fulfilled) or 2) Not good. All prospective respondents were given information about the study. Written informed consent was obtained from all participating mothers. The respondents completed the informed consent form while waiting for service at Posyandu Balita.

**Data Analysis:** Descriptive statistics were used for all of the data represented. The collected data was described using frequency and percentage distribution.

**Results**

Table 1 presents the characteristics of the respondents. It shows that most of the mothers were classified as young adults (21-40 years old), by as many as 95.6% mothers. More than half of the pre-schoolers were three years old, as many as 55.6%. Most of the respondents were living in a family with a monthly income that was less than the regional minimum wage (IDR 3.867.874), as many as 75.6%. Table 2 presents the frequency and percentage distribution of the respondents based on the variables. It shows that most pre-schoolers have a good energy adequacy level, as many as 58 respondents (64.4%). Most pre-schoolers have good dietary diversity (68; 75.6%). Most of the food composition consisted of rice, animal and plant protein and milk. Vegetables and fruits were rarely consumed.

**Discussion**

Most pre-schoolers had a good energy adequacy level. It means that most of them had an adequate intake for energy. The RDA for Indonesia stated that an adequate energy intake for a child 1-3 years old is 1,350 kilocalories per day while for a 4-6 year old it is 1,400 kilocalories per day. The adequate energy intake for the pre-schoolers was determined by considering a healthy child’s daily need for energy to support their growth. For ≥4 year old children, correction for physical activities was added.

The research results showed that all of the respondents with a less energy adequacy level were five years old. As they grow older, preschool-aged children develop their food preferences. Furthermore, most children began to attend school at five years old. Previous research found that almost 75% of 5-year-old children did not meet their estimated energy requirements. The school environment sometimes exposes preschoolers to unhealthy food choice or street foods.

The energy is required for maintenance, growth and repairs of the body. Carbohydrates, protein and lipids are major sources of energy. Similar to this statement, the research results found that the most significant contributors to energy were carbohydrates, protein and fat. The typical Indonesian diet is high in carbohydrates and starchy foods, with cereals being the primary source. Previous research also found that urban communities tend to consume more calories and more highly processed foods. They frequently eat convenience street foods, which are cheaper and simpler.
than cooking at home. Affordability is still a barrier for low and middle-income groups. In this research, many of the respondents with a family monthly income of less than the local minimum wage had an inadequate energy intake. On the contrary, there was one preschooler with a family monthly income that was more than the local minimum wage who had a less adequate energy level.

Based on the demographic data, the mother was ≤20 years old. Mothers of a younger age usually have a low level of nutritional knowledge and experience. Dietary diversity is a qualitative method used to measure food consumption that reflects the household’s access to a variety of foods and it can be a proxy for the nutrient adequacy of the diet of individuals. Most respondents had good dietary diversity. This means that the food consumed by the preschoolers consisted of carbohydrates, animal or plant protein, vegetables, fruits, healthy oil, dairy and water. A diverse diet is needed to ensure optimum growth in preschoolers. Urban communities have good access to a greater diversity of fresh foods such as animal-sourced foods, legumes, vegetables and fruits compared to rural communities. This supports the availability of diverse foods.

Based on a 24HR analysis, most of the food composition consisted of rice, animal and plant protein and milk. Vegetables and fruits were rarely consumed. Many of the respondents still perceive that the most important thing is the adequate intake of energy, although the diet itself was not varying in nutrients. Rice is a staple food of Indonesians that supplies around 70% of the total energy. Because of its location, near to the coastline, Gresik Regency is abundant in seafood-based protein. People living there mostly have a good protein intake. Previous research found that more than half of the children in Indonesia have dietary intakes that are less than the RDA for vitamins, which can be obtained by consuming vegetables and fruits. Another research study found although the nutritional value of preschoolers fulfilled their RDA, the nutrient compositions often did not meet the necessary standards. Mothers were seen as the key moderator influencing their dietary intake of vegetables, fruits, and other healthy foods. However, mothers face numerous challenges in feeding their pre-schoolers vegetables and fruits, such as the child’s aversion to vegetables (because of their unpalatable taste), the family environment and the short shelf life of fresh vegetables and fruits.

**Conclusion**

The pre-schoolers’ eating behavior in urban communities was good. The mothers should gain more knowledge about nutrition and food composition which fits with the needs of pre-schooler to allow them to grow optimally. The mother also should shape the good eating skills of their pre-schoolers. These findings can be used to develop an intervention in order to enhance healthy eating behavior in pre-schoolers in urban communities.

Playing Cards Using the “Tepuk Nyamuk” Method Improves Cognitive Function and Social Interaction in the Elderly

Retno Indarwati1, Ika Nur Pratiwi1, Nurul Yuniarsih1

1Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Playing cards using the “tepuk nyamuk” system is a game using a standard 52-card deck to focus between the words spoken on the card that is to be issued while tapping the back of the hand between the players on the card. The study aimed to find out the effect of playing cards using the “tepuknyamuk” method on improving cognitive function and social interaction. This study was quasi-experimental with 30 respondents who were elderly individuals who experienced cognitive decline and social interactions. The independent variable was playing cards in the “tepuknyamuk” method and the dependent variables were cognitive function and social interaction. The results indicate that there was an influence from playing cards on cognitive improvement (p=0.000) and social interaction (p=0.000). Playing cards in the “tepuknyamuk” method has the positive effect of improving cognitive function and social interaction for older adults. Further studies are suggested to determine the effect playing cards on other cognitive components.

Keyword: playing cards in the “tepuknyamuk” method, cognitive, social interaction, elderly

Introduction

The elderly experience normal cognitive decline problems across all aspects including a decrease in memory, language, thoughts and considerations. In general, the prevalence of dementia and Alzheimer’s is 3-10% at 65 years of age and it ranges from 25-50% at the age of 85 years and above.

Based on a preliminary study, 40 out of 138 (28.29%) older adults experienced cognitive decline. The risk factors for decreased cognitive function include age, sex, education, area of residence, reduced physical and social activity and diseases such as those that are cardiovascular in nature, diabetes mellitus, hypertension and cerebrovascular issues. The decline in cognitive function needs to be overcome because it plays an important role in daily activities such as decision making, thinking and remembering things. The impact of cognitive decline is dementia and in the long term, this can cause Alzheimer’s disease.

The risk factors that affect the decline in social interactions include health, family problems and social support. The impact of a decrease in social interaction is cognitive impairment and this can also trigger social isolation. The research conducted by Zhu et al, found that recreational activities can improve cognitive function and social interaction because there are many activities such as walking, cycling, gymnastics and playing puzzles that facilitate cognitive enhancing hippocampal neurogenesis, synaptic plasticity and neurotropics. The problems can also be overcome using playing cards. Based on research studies conducted in Columbia and Sweden, playing cards can improve cognitive function and social interaction in the elderly. The positive effects of playing cards includes building social relationships, developing skills and cognitive thinking. The purpose of the research was finding out the effect of playing cards using the “tepuk nyamuk” method on improving cognitive function and social interaction in the elderly in a nursing home.

Method

Study Design, Setting and Sampling: The study was quasi-experimental. The samples consisted of 60 respondents (30 in the treatment group and 30 in the
control group) who were staying at UPTD Griya Werdha and Hargo Dedali nursing home in East Java, Indonesia. The inclusion criteria in this research was older adult who could sit. Those with hearing loss and older adults who were color blind were excluded. The research was conducted in the treatment group by providing cards played with the “tepuknyamuk” method 5 times over 2 weeks with a duration of 15 minutes taken for each meeting. The data was analyzed using the Wilcoxon signed and Mann Whitney tests.

Results

In the treatment group, the results for the cognitive function were higher than before (Table 1). The result of the statistics tests showed significant differences in the cognitive values pre- and post-test. These results indicate that the game can improve the cognitive function of the elderly, especially when based on the components of orientation, attention and language. The results of the Mann Whitney analysis showed significant differences in the cognitive values in the pre-test in both the treatment and the control group (Table 2). In the treatment group, there was a difference pre- and post-test in the components of social interaction concerning cooperation and conformity. Based on the results of the statistics test on the ability of social interaction, the treatment group showed a significant difference in relation to the cognitive values during the pre-post test. The results of the Mann Whitney analysis showed that there were significant differences between the social interaction skills pre-test in the treatment group and in the control group.

Discussion

The respondents liked the game because they understood the flow of the game and the respondents were scrambling to be guides for their group team. This causes the respondents to understand the game training quickly and they will also often invite other respondents to stay focused and to practice continuously. The elderly who practice using their brain more often can slow cognitive decline. The brain can be stimulated by playing cards using the “tepuknyamuk” method that have many types of shapes as well as strategy-based game rules. All of these elements will stimulate the limbic system which will be processed by the hippocampus and amygdale. This is passed on to the cortex’s prefrontal. The stimuli that enters the prefrontal will stimulate the prefrontal to work according to its functions such as planning, organizing and solving problems. The prefrontal responses to thinking will affect the increase in cognitive function. “Tepuknyamuk” cards are one of the games that can improve cognitive function because of the elements of the game.

This research shows the influence of the orientation ability of the elderly. Orientation includes short-term memory. Short-term memory includes verbal memory, namely by assessing new memories about orientation and assessing the ability of the individual strategies to learning new things. Playing cards with the “tepuknyamuk” method was a game that was still unknown to the elderly because it used different methods and strategies to what they were used to. This meant that they had to practice their orientation skills. The provision of memory stimulation affects the level of orientation ability in the elderly. Playing cards are a good method for improving the orientation of the elderly because the games can make the elderly focus on what they were told. In this study, there was no increase in memory components and registration. All of the respondents pre-test were in the good category, so for the post-test, the value of memory function and registration remained 3. The limbic system is part of the amygdale, which functions to control emotions and memory processes by stimulating the hippocampus.

The limbic system stimulates aspects of memory and registers it in the cognitive function component. Information storage is a part of the synapses. Synapse facilities affect the subconscious mind processes which gives rise to perception or memory. The hippocampus is long-term memory that can store relatively permanent information. During the game, the respondent will recognize the stimulus of the playing cards based on the patterns and colors. This stimulation will stimulate the limbic system, especially the hippocampus, and encourage the recall of past memories of playing cards, the card patterns and the used colors. These elements on the playing cards can stimulate the brain so then it can improve short-term memory. The hippocampus is also a learning center that will continue to be honed through the method of “tepuknyamuk”. This should be carried out continuously so then it can improve cognitive function. Playing cards is entertaining because it is done together with fellow older adults and this can lead to happy and pleasant feelings.

Older adults who previously felt alone because they have not adapted to the environment and who rarely interact can feel happy as a result of the positive interactions that occur during the game. Giving them attention means directing the mind to something that needs to be learned and remembered. For example, remembering numbers and counting down. In information processing, memory involves the process of
encoding, storing and recalling. The results of the study showed that memory training for attention/calculation in the elderly is influenced by the processing speed and effectiveness of the strategies used to improve the elderly in terms of learning to memorize numbers, sequence numbers and counting down. Processing speed is influenced by several factors including age, education and verbal ability. Playing cards are a good method to improve attention/calculation, because from the game, the elderly can practice numbers and letters from the cards that are issued.

The working memory increased when the elderly completed the task in terms of language using a collection of word lists, naming and following orders. This was influenced because the ability of the elderly in relation to re-evaluating tasks in terms of language uses and learning strategies related to ways of thinking and taking action in different situations. Playing the cards is a good method to improve the language component of the elderly. This is because the game trains the elderly to follow orders from the guide.

The results of the study have shown an increase in the components of cooperation, competition, contradiction and conformation. The respondents were very happy with playing cards using the “tepuknyamuk” method because the respondents scrambled to be guides on their team and they exchanged stories during the break. This caused the respondents to motivate the other respondents to stay focused and to practice continuously. Through social interaction, the elderly can think more positively and optimistically about life. The elderly who play games more often experience a positive effect; one of them was tolerance between the players, which can improve social interactions in the elderly.

The results of the study showed the effect on the ability of cooperation in the elderly, with the existence of the game requiring the elderly to work together in groups. According to smartphones and e-tablets in perioperative medicine, the existence of good cooperation allows the elderly to get a sense of belonging to a group. They can share stories, interests, concerns and they are able to engage in creative and innovative activities together. Playing cards are a good method to improve cooperation with the elderly because this game requires collaboration. Collaboration means staying in harmony with each other, cooperating to motivate each other and reprimanding if there is a loss of focus. The results of the study showed the effect on the component of competition. The results of the study ‘Adequacy of Sample Size in Health Studies’ said that social interaction decreases when it is supported by the attitude of the elderly, who tend to be selfish and unwilling to listen to the opinions of others. This causes the elderly to feel socially alienated which ultimately feels useless because there is no emotional distribution through socializing. Playing cards using the “tepuknyamuk” method was a good method to increase social interaction in relation to the component of competition, because the game trains speed and focus so as not to lose at playing. The results of the study showed an increase in the component of good contradiction or opposition. Good opposition can be interpreted where the respondent never scolded the elderly. The more frequent the interactions, the more likely that there will be conflict or problems. As the game progresses, the elderly do not experience opposition - this affects the ability of social interaction when it comes to trying to be better.

The results of the study showed that the majority of the treatment group experienced an increase in the component of conformity. Older adults who are active in social activities are more likely to adjust to aging well. If the elderly are active within a social involvement, then the elderly can reduce cognitive decline through the appreciation and good treatment of the environment. Playing cards using the “tepuknyamuk” method was good for increasing social interaction in the component of compatibility because the game has the effect of adjusting to one’s peers and the surrounding environment. The results showed that by playing “tepuknyamuk” for a short duration (2 weeks) and frequently (10 times a meeting), this can improve cognitive function and social interaction in the elderly. Based on the functional consequences theory, the elderly will experience age-related changes and have risk factors that make the health of the elderly decline. The results showed that playing cards using the “tepuknyamuk” method is effective at increasing cooperation and conformity. It improves the cognitive function that occurs because the elderly individuals are actively participating in the game.

**Conclusion**

Playing cards using the “tepuknyamuk” method proved that even short frequency games and durations for the meetings can improve cognitive function and social interaction. The results proved that playing cards are more effective at improving cognitive function in reference to the components of orientation, attention and language.
Social interactions are more effective at increasing cooperation and conformity. Playing cards can be done regularly to maintain the cognitive function of older adults. Further studies are strongly recommended to explore the relationship between recreational activities that may affect the cognitive functioning of the elderly.

**Ethical Clearance:** The study passed the ethical review and obtained an Ethical Approval certificate No. 1190-KEPK issued by the Health Research Ethics Committee of the Faculty of Nursing, Universitas Airlangga.

Motivational Interviewing as a Problem Solving Intervention to Improve Adherence: Review of the Related Literature

Erna Melastuti¹, Tintin Sukartini²

¹Doctoral Degree Programs, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia;
²Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Patient behavior changing through adherence therapy is very difficult. Identifying the most effective approach is very important regarding adherence. Motivational Interviewing (MI) is a clinical approach involving communication, collaboration, evocation, autonomy and increasing motivation alongside the final results of behavior change. The principles underlying MI include empathy, developing differences, avoiding debate and supporting self-efficacy. MI interventions allow for the changing of the relevant cognitions and self-regulation processes that leads to adherence to the treatment.

Method: A literature review was conducted focused on journals published between 2013 and 2018. Fifty relevant journals were obtained and data was extracted from 25 relevant selected journals. The search was carried out by entering the keywords ‘adherence’, ‘motivation’ and ‘MI’ into the SCOPUS, ScienceDirect, Sage, ProQuest, Elsevier, SpringerLink and Google Scholar databases.

Conclusion: MI studies show that MI-based interventions are effective in promoting health behavior changes. It is also associated with positive health outcomes such as low blood pressure, diet, decreased smoking, lower cholesterol, and better blood sugar control.

Keywords: adherence, motivation, MI

Introduction

It is very important for clients to change their behavior in order to undergo success within the therapy program. Adherence is defined as the client’s decision to receive and follow instructions related to the stated regulations. In the regulation of chronic medical conditions, bad adherence leads to worse results in the context of medical care, higher rates of hospitalization and increased health care costs. Adherence can be said to be “a key mediator between medical practices and client outcomes”. The strategies to improve medication adherence must involve clear and specific information. The average level of non-adherence is about 50% and this results in a large use of funds in the context of health care costs per year. Motivational Interviewing (MI) has proven to be more effective than other strategies, such as traditional informative strategies. It has been shown to be as effective as adherence cognitive therapy but with fewer time costs.¹

MI is a clinical approach used to increase the motivation of the clients to change by helping them in exploring and solving their ambivalence and resistance toward changes in a client-centered approach. MI is a goal-oriented communication method.² MI is a patient-centered care approach to maintaining the intrinsic motivation in all individuals formed between the clinician and the client. The clients are guided towards goal setting, identifying potential barriers, and increasing self-efficacy and commitment to achievement goals. Patients articulates their ideas and plans rather than communicating so to their health care providers. The role of health care providers is to facilitate, not dictate, and what may have felt like the struggle now is cooperation and egalitarian relationships. MI was originally developed as a model for treating substance abuse, but it has now been modified for other cases. MI uses open questions, reflection and understanding the personal nature of the clients. It also involves partnerships
with anyone in the medical setting. The MI technique is portable, low-tech and it can be integrated into the existing consultation model. MI-based interventions are short, consisting of three sessions which last for 20 to 30 minutes each, followed with another over the telephone. The interventions are managed by nurses in the client’s own home which is conducted when are doing home care visits.

Readiness for change is defined as a processor state of movement between no intention to make changes in behavior to committing and maintaining behavior change. MI follows positive results in other health care domains with respect to behavior change.

Method

Study Design, Setting and Inclusion criteria: The method used a search process by entering the keywords ‘MI’, ‘motivation’ and ‘adherence’ on databases such as SCOPUS, ScienceDirect, Sage, ProQuest, Elsevier, SpringerLink and Google Scholar. A screening of the articles was done. The purpose of this study was to see the extent to which MI interventions affect client adherence to therapy. The inclusion criteria used in this literature review was articles in the year range of 2013 - 2018. The articles used were articles that had been published internationally of a standard level 1 - 2 (including RCTs and R randomized). All of the articles were written in English.

Data Analysis: The data analysis was conducted by collecting the articles that used a quantitative design focusing on diabetes mellitus, cardiovascular disease, alcohol dependence, mental illness and schizophrenia, chronic disease, HIV disease and kidney failure.

Results

There were a total of 50 articles obtained from the search strategy, evaluation and methodological assessment. Of this total, 25 articles did not meet the study criteria and thus were dropped out of this study. The aggregation of the review of the quantitative design articles showed that the results were grouped through the MI in the areas of diabetes mellitus, cardiovascular disease, alcohol dependence, mental illness and schizophrenia, chronic diseases, HIV disease and kidney failure.

A. Clients with diabetes mellitus: The research conducted by Chlebowy et al examined MI as an intervention to improve the degree of health and adherence of therapy of the clients with cardiovascular problems. The study findings were that MI affected drug adherence and the diabetic markers. Other studies from Boved-Fontan et al found that MI conducted by health workers aimed at clients with dyslipidemia achieved significant reductions in all lipid parameters, cardiovascular risks, weight reduction and dietary adherence. The study’s MI was therefore a problem solving treatment that could reduce type 2 diabetes and cardiovascular disease risk in real life. The intention to treat and the following analysis showed there to be a significant difference in the outcomes between the two groups. The strengthening of the MI interventions in diabetes mellitus clients was examined by Moura et al, which states that the clients reported an increase in care over a 6-month period in the quality of the diabetes care received. It was reported that there was an increase in their level of physical activity, fruit and vegetable consumption and medication adherence. Another study found that MI is not a single intervention. It covers a variety of specific techniques to encourage behavior change and it requires training and time to come to fruition. The results of the study support the adoption of MI.

B. Clients with cardiovascular disease: A previous study conducted by Al-Ganmi et al was based on RCT studies. The client conducted a brief semi-structured interview to identify the level of adherence to treatment and to determine the predictive factors for non-adherence. The results showed that MI led by nurses had the potential to increase the adherence of therapy. Another study by Hardcastle et al reported there to be significant differences between the obese client group and hypercholesterolemia at baseline, thus showing a significant increase in BMI and cholesterol level between the intervention and control groups. From the results of the study, it can be concluded that low intensity MI counseling interventions are effective at bringing long term changes to some, but not all, health-related outcomes. Other studies took on the subject population of 1,704 participants and this total was randomized to
receive MI interventions delivered by healthy lifestyle facilitators trained in a group, in individual formats or ongoing their usual care. The primary results showed changes in weight and physical health. Secondary outcomes included changes in the low-density lipoprotein cholesterol and Cerebro Vascular Disease (CVD) risk scores.

C. Clients with HIV disease: The study by Ekwunife et al. was conducted in six hospitals offering HIV care. The participants were randomized for the population of the intervention and control groups. The structured adherence support scheme was called the ‘Incentive Scheme’. The findings prove that applying conditional economic incentives combined with MI can increase the retention and adherence of ARV consumption among HIV patients. Other studies have developed a project called IMPACT (Individuals Motivated to Participate in Adherence, Care and Care). It is a multi-component approach for newly incarcerated HIV-infected people that specifically targets treatment, retention and medication adherence by overcoming various obstacles in terms of treatment involvement. Research by Sued et al. showed that the doctor-based MI intervention was feasible and effective at improving and maintaining client adherence, viral suppression and client-doctor communication and attitudes about the treatment.

D. Clients with psychological disorder: A research study by Mallisham and Sherrod emphasized the enthusiasm and MI intentions in training programs used to produce translations of newly acquired knowledge into nursing practices. The results showed that MI can develop meaningful, client-centered communication skills and that this can lead to improved medication adherence. Another study by Barkhof et al. consisted of a randomized controlled study including 114 clients who experienced psychotic relapses due to medication non-adherence within the past year. The participants received an adapted MI form or an active control intervention in the form of health education (HE). The results showed that MI improved treatment adherence in previously non-adherent clients who experienced a psychotic relapse. The study focused on medication adherence in patients with schizophrenia and the researcher conducted a qualitative case study of several MI sessions to analyze the interaction processes that affects motivation in clients with schizophrenia. The results found there to be three success factors for MI-based interventions, which are the relationship of trust between the client and the therapist, the ability of the therapist to adapt his MI strategy to the client’s processes and linking client values with long-term treatment adherence. Another researcher conducted a study on sixty-four outpatient clients and conducted 2 MI sessions focused on cognitive function. The condition of MI is associated with a great improvement in task-specific motivation along with the presence of larger training sessions. The results of interview-based motivational interventions for people with schizophrenia can be effective at reducing symptom severity and hospitalization, and it can increase medication adherence, functions and insights into both diseases and treatment through the medium term (six months) follow-up period. In this study, n = 1,000 adolescents were screened and adolescents with results indicating anxiety or depressive symptoms (n = 162) were advised to seek psychological health care in the group. The result showed that the MI results need to be offered to adolescents to function as models to optimize their health care management in daily clinical practice.

E. For clients with alcohol disorders: A study by Crane et al. involved 60 offenders who were randomly asked to attend a brief motivational interview (BMI) session or control intervention before the start of their treatment. The findings showed that binge drinkers had a lower medication adherence than the participants who did not binge-drink. The BMI participants who binge-drank attended more treatment sessions and were proved to have lower dropout rates than the binge-drinker control participants. Other studies have quantified the extent of MI in terms of adherence to a reduction in alcohol consumption and drug use. Three contexts of general MI research evaluate the efficacy of MI, the effectiveness of MI and MI training. The results show that MI adherence is usually the lowest and most varied in the context of evaluating MI training and conversely, that adherence is usually the highest and lowest variable in the context of evaluating the efficacy and effectiveness of MI.
F. Research on clients with kidney disease: A research study by García-Llana et al was conducted to determine the effectiveness of individuals in the context of pre-dialysis intervention programs (90 minute monthly sessions over a 6-month period) in terms of adherence, their emotional state and quality of life as related to health (HRQL). The results showed that after the intervention, the clients reported significantly higher levels of adherence, lower levels of depression and anxiety and better HRQL.

F. Research on chronic diseases: The study was conducted by Mutschler et al. The purpose of the review is to understand how MI works to change the behavior of teenagers. Results: based on SDT (self-determination theory), three mechanisms were found in the studies that were reviewed, including competence, linkages and autonomy. Other researchers found there to be effectiveness in MI-based pre-treatment in the context of pain rehabilitation. Another study was conducted on 1000 adolescents with this single-center approach. Adolescents were screened if their results indicated anxious or depressive symptoms (n = 162). The results showed that MI for adolescents can serve as a model for optimizing health care management in daily clinical practice. Other studies obtained results indicating that MI techniques that can provide effective and essential costs in terms of functional activities, thus reducing the rate of decline in quality of life. Research by Pirlott et al addresses the counselor’s enthusiasm, empathy and global direction, as well as calculating the behavior that is consistent with MI which correlates significantly with an increased intake of fruits and vegetables.

Discussion

The main components of MI are RULE. MI has four guiding principles, represented by the aforementioned acronym. “R” stands for “resisting the righting reflex.” Reflecting righting occurs immediately when showing the risks or problems with the client’s current behavior. “U” is to “understand client motivation”. Clients have their own reasons for adhering to behavior changes. “L” stands for “listening.” Listening involves more than just using one’s ears to hear the words that the client says. Listening is not the same as asking. “E” stands for “empowering clients”, in order to explore the clients’ ideas about the changes that they can make to improve their health. Empathy is an important skill in MI. Empathy does not judge and it does not indicate that the counselor always agrees with the client. It demonstrates how the counselor can be patient. The approach to the MI’s skills is represented by the OARS acronym: open questions, affirmations, reflective listening and summaries. Open questions are unstructured and do not suggest a response. Affirmation is a statement that recognizes the strength of the client and this helps the counselor to create relationships with their clients. Listening or reflecting reflectively is another important MI skill. Using reflection allows the counselor to convey the counselor’s understanding of the client’s situation and to make the client feel understood.

Conclusion

MI is an interview style designed to promote behavior change and it is defined as a set of targeted communication skills to motivate clients to change their own behavior in the interest of their health.

Parent’s Experience of the Grief-Loss Process with Children with Leukemia

Joko Suwito1, Adin Mu’afiro1, Kiaonarni OW1, Irine Christianty1

1Faculty of Nursing, Health Polytechnic of Ministry of Health Surabaya, Indonesia

ABSTRACT

Leukemia brings in changes in a child’s psychology that results in losses for the parents. The purpose of this research was to draw out and interpret the loss and grief process of parents whose children are suffering from leukemia. This research applied a phenomenological qualitative research design. The informants were parents whose children were suffering from leukemia. The instrument of this research was the researcher. The data gathering technique used consisted of in-depth interviews. This research was located in the Bona room of Dr. Soetomo General Hospital in Surabaya. We analyzed the data through triangulation and the sources used were reference materials. The result showed that the parents were shocked and in a state of disbelief at first, even going so far as to reject what had happened. The parents blamed themselves and were angry at everyone. Words cannot express their deep grief, and they tried to accompany their children every moment possible. The parents whose children were suffering from leukemia encountered loss and were going through a grieving process. The nurses were given the suggestion of giving the parents a chance to express their grief.

Keywords: experiences, parent, grief-loss, children with leukemia

Introduction

This research aimed to explore the coping mechanism of parents whose children were suffering from leukemia who experienced loss and the grief process in the children’s room of Dr. Soetomo General Hospital in Surabaya, Indonesia (RSDS). Among the 100 children there, it was confirmed that 4 of them were suffering from leukemia.1 The most common type of blood cancer was Acute Lymphoblastic Leukemia (LLA).2

The prevalence of cancer was 4.3 per 1,000 inhabitants in Indonesia. Cancer was ranked seventh among the causes of death (5.7%).3,4 Leukemia constituted one-third of all malignancies in both children and adolescents.4

The number of cancer incidences in children at the RSDS has increased year to year. In 2015, there were 106 new cases and in 2016, there were 108 new cases.2

Leukemia can be described as a blood cell malignancies originating from the bone marrow, marked by the proliferation of white blood cells and impaired leukocyte regulation with the manifestation of abnormal cells in the peripheral blood. Ugrasena stated that leukemia is probably caused by chemical and physical substances. Children are quite susceptible to consuming foods and drinks that are comprised heavily of preservatives.5

The psychological impact that was felt by children who suffered from leukemia was something complicated. The long process that children who suffer from leukemia go through certainly brought in drastic emotional changes for the children who experienced sadness, difficulties in losing a battle and the potential pathway to death.5

The parents whose children were suffering from leukemia generally felt guilty or anxious because they felt responsible for what had happened to their child. In sadness, some even hoped to take the place of their
child. They tried to reduce the suffering of their children and sought to prepare their kids for death. The parents need support from everyone.⁶

The results of the study found that the parents were not informed about this as an “important problem.” Even though doctors might not be able to predict the precise moment that their children die, any information about that from another parent’s first-hand experiences could help them prepare for it.⁶

Leukemic children who die experience many pathways of death. The parents accompanied them and then grieved after their child’s death, even to the point of ending their own lives. Understanding the similarities and differences in the pathways to child mortality and their parents’ experiences is an essential foundation given the various palliative, end-time and loss services needed to help both the children and parents.⁷

Besides, it is necessary to remember that for life-threatening illnesses that are not always fatal, we are not always able to distinguish between the children who died and the children who survived at the time of diagnosis, whether during the initial treatment or even after the first event if the treatment has failed. This uncertainty increased the challenge and importance of understanding how to integrate aspects of palliative treatment from the time of diagnosis.⁸

Wolfe and their colleagues (2000) reported that parents whose children were suffering from cancer stated that, in the last month of the children’s life, their children were quiet or they felt unpleasant (53 percent), more than a few of them were sad (61 percent), some of them not particularly calm and peaceful every time (63 percent) and they were scared more often (21 percent). Regardless of the suffering that their children experienced at the end of their life, 70 percent of the parents described the death of their child as “peaceful”.⁹

The nurses became essential to helping the clients through the period of grieving and they sought to restore their self-function to as they were before. The nurses had to be trustworthy guides for the client. The nurses had to examine their attitudes, maintain an attentive presence and provide a psychologically safe environment so then the clients could express their feelings. The effort of the nurses in maintaining an attentive presence could be made certain by using open body language such as standing or sitting with their arms down, facing the client and maintaining adequate eye contact, especially when the clients were talking. The next effort was to create a psychologically safe environment by ensuring that the client felt that they had confidentiality, where the nurse stopped giving individual advice and where they gave the clients the freedom to express their thoughts and feelings without the feeling of being afraid of being judged.⁸,¹¹

Method

Study Design, Setting and Sampling: This study was descriptive and qualitative with a phenomenological design. The participants of this research were the parents of children suffering from leukemia who were undergoing treatment at the children’s IRNA RSDS in August 2018.

The inclusion criteria for the participants in this study was that they were the parents of leukemic child patients who were undergoing treatment at the IRNA of the RSUD Dr. Soetomo Hospital, Surabaya with or without complications, leukemic pediatric patients who had been diagnosed with leukemia for more than or equal to 3 months, leukemic children who were more than 2 years old and parents who were 20 to 60 years old.

The number of participants in the phenomenology study totaled 11 people who agreed and signed an Informed Consent form after the purpose and focus of the study was explained. The sampling technique used was purposive sampling and the data collection techniques used were an observation and in-depth interviews. The research instrument used was the researcher as an individual. The research used their field notes and they additionally conducted audio-visual records that supported the participant’s information.

Study Variables: The parents experiencing the grief and loss process felt refusal, anger, bargaining, depression and acceptance.
The causes of grief and loss in the parents regarding their children who were suffering from leukemia allowed the researcher to obtain several sub-themes.

**Data Analysis:** The data was processed using a word processing application, making it easier to import the processed applications and data text analyzers to further classify the themes (variables), categories and sub-categories (coding) and to find keywords that directly pointed to the quotations of the participant’s statement (script). The processing and analysis of the transcript data in the form of text was done with the Free - General Public License (Free - GPL) QDA Miner 5.0 application.

The validity of the data carried out through triangulation was done using sources, data and multiple methods. The triangulation of the data sources used was from the nurses who were in charge of the Bona I IRNA Child Care room at Dr. Soetomo General Hospital, Surabaya.

The triangulation method was done using a voice recording, field recording and video recording. The recordings are listened to and then played back over and over before the transcripts were made. The data was re-matched with the participants’ expressions and gestures during the interview, and then the transcripts were printed and stored.

**Results**

All of the participants were parents who took care of their children with leukemia. We excluded a 10th participant who was a grandmother who treated leukemia patients. All of the participants were female in the age range of 28 to 48 years old. The level of education started from elementary school or madrasah ibtidaiyah and went up to junior high. The occupation of the participants consisted of 4 farmers, 3 traders, 3 private employees and 1 advocate.

The leukemia child patients were as many as 11 children; 8 males and 3 females. The age of the leukemic children was between 5 years and 19 years old. The duration of the illness varied from 4 months to 48 months (4 years). Three patients were single children, 4 patients were the second child out of 2 siblings and 4 other children had 2 to 3 siblings.

The presence of children was a complement to the happiness and integrity of the family. A child diagnosed with suffering from leukemia prompted an unfortunate process of sadness and loss in the family. Some expressions of grief and loss experienced by the parents were refusal, anger, bargaining, depression and acceptance.

**1. Shock, Disbelief and Refusal:** There were 9 participants out of the total of 11 participants who said they felt denial, disbelief and shock when they found out that their child had been diagnosed with leukemia by a doctor. The following was revealed by nine of the participants:

“... First, I was shocked and in a state of disbelief. I was not expecting it… it was anemia for a month and then suddenly, it was leukemia. I was sad but I was shocked (crying)” (P8)

“... At first, I did not know what the doctor told me about leukemia, I said to the doctor, “Don’t you dare to say it, doc ... why must it be my child that suffers?”... “ (P9)

**2. Anger:** Usually, after the rejection, there is the angry phase. The expression of the participant’s anger was not revealed to the officers or others but it did come out in the form of jealousy of others, such as the expressions of the five participants:

“... My first thought was, ‘How come it was my child?’ I want to express my wrath. Every day, the wellness of my child keeps dropping, even when my child took the potion and was undergoing chemotherapy. I was felt hollowed ...

“... I started crying every day and I feel like I do not deserve my child suffering. How come it is not someone else’s child? I could not stand this ...

**3. Bargaining:** Some participants, as many as seven people, experienced a stage of bargaining. The participants expressed acceptance and sincerity regarding the condition of their children but they were still hesitant and hoped for a miracle that could cure their children even though they realized that it was very difficult.

“... God is indeed fair, but why is it that I have this disaster? I believe there is wisdom behind this disaster even though it is not here but it will be later in heaven. I must be optimistic and be ready if there is something ahead. I cannot help but be prepared ...

“ (P9)
“... I do not feel that I deserved it, and then I had the effects of the chemotherapy explained --- that many have recovered and many have died. When I was told that it was by chemo, I postponed it for ten days, I was still trying to use herbal medicine, but there was no result. Finally, I signed for chemotherapy ...” (P11)

4. Depression: Depression can arise after the bargaining stage. Not all of the participants experienced this stage. Four participants experienced this stage, namely participants two, three, seven and eleven.

“...Even in this time, I still feel sad and anxious ... my child is not even an adult. Sometimes my child could fall ill and suddenly die ...” (P3)

“...I have been sincere about what will happen to my child. For five days, I was desperate; there was only a sense of heartache. It is hard to accept sincerity from the origin smoothly ...” (P7)

5. Acceptance: The parents whose children were suffering from leukemia totaled as many as 7 participants who were at the acceptance stage. This was as expressed by the following participants:

“...Now I just look on the bright side... as long as it is the best for my child to follow all of the procedures...” (P2)

“...I resigned myself; hopefully, my child is given strength and healing. Now I follow the procedures and surrender to God for giving me a test. What my doctor says, I follow. I am standing ready if there is anything...” (P11)

The causes of grief and loss in the parents whose children suffered from leukemia involved:

1. Uncertain child condition: The deteriorating condition of the child was the cause of participant grief, such as the following expression:

“... The condition of my child is increasingly dropping. Sometimes my child was unstable when taking medication or when going through chemotherapy. I do not have the heart for that...” (P5)

“... Now my child has relapsed. I hope that my child is strong. My child said, “how tired I was like this, how come my illness is not lifted?...” (P10)

2. Loss of child: Three of the participants stated that the cause of their grief and the loss that they expressed was that they were afraid of losing their child. This was as revealed by the following participants:

“... There was a fear of losing my child first ... (the sentence was interrupted, the sentence was not finished and they were holding back tears) because I have seen my child’s peers now, who have had the same treatment... many of them have died...” (P1)

“... there is an anxiety of losing my child, even though the medication is free...” (P4)

3. Could not go to school: Six participants revealed the cause of their grief. The loss felt was that their children wanted to go to school but they could not. This was stated as follows:

“...My child should go to school and play like others, but now he is far from his family...” (P5)

“...It has been three months in the hospital. My child said, “O mother, I cannot go to school anymore Bun, can I?” (P8)

4. Only child: There was a participant who revealed that the cause of his sadness was being a single child patient, namely:

“... My child was my only and favorite child, and now they have fallen sick...” (P7)

5. The family falling sick: There was also the presence of family members who are at home with the children who have also fallen sick, which caused grief and loss in the parents. The 7th and 11th participant’s statements were as follows:

“... Mother and Father at home are also sick, and it made me think. My physical presence here is to take care of the child but my mind is at home and it is also thinking about my parents, who are also sick...” (crying) (P7)

“...my mind was not calm. I felt sad because his grandfather also had had a stroke and no one took care of him. I have to take care of their grandchildren here...” (P11)

Discussion

The parents whose children were suffering from leukemia experienced grief and feelings within the loss...
process ranging from disbelief through to rejection, anger, bargaining, depression and acceptance. Uncertain health conditions cause the children to not play or attend school.

These following were suggested should be tried to express the feeling of grief and loss openly to nurses so that it could relieve the psychological burden, tried to keep providing play and school activities according to the patient’s abilities. The nursing services have to maintain excellent communication. They were expected to meet the psychological needs of the children when it came to playing and they also sought to encourage the children to attend school while in the hospital.

**Conclusion**

The parents of leukemic children in Dr. Soetomo Hospital experience grief and loss processes including rejection, anger, bargaining and depression.

The Relationship of Social Support with Older Adult Depression in Hargo Dedali Nursing Home, Surabaya

Sylvia Dwi Wahyuni1, Sultan Shahdana1, N K Armini1

1Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Older adults are vulnerable to health problems including depression caused by stress when facing changes in their life, such as retirement, illness, disability, placement in a nursing home, the death of a partner and the reduced availability of social support. This study aimed to explain the relationship of social support with the incidence rate of depression in older adults in Hargo Dedali Nursing Home, Surabaya. This research used a correlational design with a cross-sectional approach. The sample consisted of 20 older adults who lived in Panti Werdha Hargo Dedali Surabaya who were selected through purposive sampling. The independent variable was the social support of the older adults while the dependent variable was the incidence rate of depression. The data analysis used was Spearman rho with \( p = 0.037, r = -0.468 \) and a significance level of \( \alpha <0.05 \). There was a significant relationship between social support and the incidence of older adult depression in Hargo Dedali nursing home, Surabaya. The higher the level of social support, the lower the incidence of older adult depression. Health workers, especially nurses, can improve their competencies in order to provide health services to the older adults, especially when related to the provision of social support and the anticipated incidence of depression in the nursing home.

Keywords: social support, depression, older adult, nursing home

Introduction

Progress in the field of health and increasing socioeconomic welfare has an impact on the increasing life expectancy, which is one indicator of the success of development. Life expectancy has increased the population which causes the number of older adult people to continue to increase from year to year. For five decades, the percentage of older adult Indonesians has doubled (1971-2017) to 8.97 percent (23.4 million). This rapid increase means that Indonesia has entered an era of having an aging structured population. Increased life expectancy is related to the number of diseases and psychological disorders that manifest in the older adult, one of which is depression. The psychological mental disorders that are often found in the older adult are depressive disorders, cognitive impairments, phobias and alcohol use. In addition, an increase in the number of older adult people who are not followed by an increase in the efforts to provide adequate social support will have an impact on the increasing number of dependents towards the productive age population (old dependency ratio). The burden that must be borne by the population of a productive age will increase. Meanwhile, high stressors and unpleasant life events can lead to the possibility of the older adult experiencing anxiety, loneliness and depression. Depression symptoms in older adults are often ignored and not addressed because of the low level of social support. However, research related to social support and depression in the elderly living in nursing homes is still rare.

Data on the prevalence of depression in older adults in Indonesia is quite high. The incidence of acute geriatric space was 76.3%, with the proportion of geriatric patients who experienced mild depression being 44.1%, with 18% for moderate depression, 10.8% for major depression and 3.2% for very severe depression. Another study conducted by Wada et al focused on older adult in two cities on the island of Java. The data obtained...
showed that 33.8% had depression. Dedali Hargo Panti Surabaya cares for 40 older adult people. All of the older adult have a family. The results of the preliminary study conducted by the researchers on 5 older adults were that 3 said that they were rarely visited by their relatives. Two older adult people said that they felt sad if they were not visited by their family and 1 older adult person said that their fellow residents and caregivers were their family now.

Aging will cause physical and psychosocial changes. Physical deterioration is characterized by a decrease in the functioning of the five senses and a decrease in immunity, leading to various diseases. Psychological setbacks include feeling useless, being easily sad and feeling depressed. Social setbacks include the absence of relatives who can provide assistance, a lack of economic ability, feeling unproductive and no longer being able to play a role in society.

Depression is most common in older adults, although it is not part of the aging process. There are several factors that influence the occurrence of depression in older adults, namely demographic, biological, psychosocial, economic and religiosity factors. The demographic factors included being of the female sex, being single in terms of their marital status and feeling stress in their life. The biological factors in the older adults that can increase the risk of depression include suffering from a chronic disease, sensory disorders, impaired physical mobility, cognitive decline and other physiological changes that are a result of aging. Having a low income and being in a state of economic difficulty are some of the economic factors that contribute to increasing the risk of depression in older adults.

Syamsuddin said that an older adult person wants to live with their family, especially their nuclear family, and they want to get good care from them. However, due to several factors, the older adults do not get care from their family, such as having not had children, of having had children but their offspring died, the child went to their in-laws instead, the children did not want to be bothered by taking care of their parents or the children being too busy. For some older adult people, living in a nursing home is not the best choice. On the contrary, it becomes a better choice that is sometimes sad. Older adults who get long-term care have a higher incidence of depression than in regular society.

Increasing the social support for older adults will give the individuals a feeling of comfort, of feeling loved when experiencing depression and assistance in the form of enthusiasm, empathy, trust and attention so then the individuals who receive it feel valuable. Johnson and Johnson stated that social support is the existence of other people who can be relied upon to provide assistance, enthusiasm, acceptance and attention so as to improve the welfare of the individual. Positive social support can restore their physical and psychological condition. Familial and environmental social support is very important in the process of healing and in the recovery of patients. Therefore, this study aimed to explain the relationship of social support with the incidence of depression in the older adults at Hargo Dedali Nursing Home Surabaya.

Method

This study used a correlation design with a cross-sectional approach to determine whether or not there is a relationship of social support with the incidence of depression in the older adults in Surabaya Dedali Hargo Nursing Home. The number of samples in this study totaled 20 people. The selection of the samples was based on the following inclusion criteria: 1) can read and write, 2) can communicate verbally and 3) cooperative. Meanwhile, the exclusion criteria were 1) in special care, with a serious illness or on bedrest.

The independent variable in this study was social support and the dependent variable was the incidence of depression in older adults. The researcher used a short form of the Geriatric Depression Scale (GDS) questionnaire to measure the dependent variable. The independent variables were measured using a social support questionnaire that assessed the four types of support, namely emotional, instrumental, informational and reward. The results of the depression assessment using the Geriatric Depression Scale (GDS) questionnaire short form and the value of the Social Support questionnaire were analyzed using the Spearman rho test using a degree of significance (level of significance). The result was p < 0.05, which means that there was a significant/significant relationship between the independent variables and the dependent variable. The incidence of errors tolerated in this study was 5%.

Results

Hargo Dedali Nursing Home is a private nursing home. Every new older adult in the Nursing Home will go through a trial period for 3 months to maintain comfort. If there is a new older adult person who is perceived as disturbing the peace between the older
adult and influential over the other older adults, based on the institution’s policy, they would forcefully repatriate the older adult back to their family.

The demographic characteristics of the respondents showing their recent education history, age, marital status, the presence or absence of family outside the institution and if they had a long occupancy in the nursing home has been presented in Table 1.

</table>

Table 1.1 describes the characteristics of the respondents. Most had a history of tertiary education. The age of the respondents was mostly between 79 - 90 years old and the marriage status of the majority was that of widowhood, for 19 people (95%). All of the older adult people had family members who lived outside of the nursing home. Most of the older adults had lived in the home for more than 1 year.

1. Social support for older adults

Spearman Rho $r = -0.468, p = 0.037$

The table above shows that the older adults who feel that they get good social support within the normal category (not depressed) total as many as 8 people (40%). Older adults with enough social support totaled 5 people (25%) did not experience depression and 1 person (5%) experienced mild depression. Leading on from this, 2 people (10%) had moderate depression. For the older adults with less social support, 1 person (5%) was categorized as normal (not depressed), 2 people (10%) were categorized as experiencing mild depression and
3 people (15%) were categorized as having moderate depression. The analysis conducted using the Spearman rho statistical test obtained a significance value of $p = 0.037$ of $\alpha <0.05$. This shows that there is a significant relationship between social support and the incidence of depression. The Spearman rho correlation value of 0.468 shows that the direction of the negative correlation has an inverse relationship with sufficient correlation coefficients.

**Discussion**

Social support refers to the attitudes, actions and social acceptance of sick patients. Social support enables their social functioning to the fullest and this can improve their level of adaptation in terms of their social health. The social support felt by the older adults in Surabaya Hargo Dedali Nursing Home was mostly good for as many as 9 people (45%), although there were older adults who felt that they had less social support (as many as 3 people). The aging process requires support from the surrounding environment, both from the nursing home, fellow residents and from the families living outside the orphanage. The aging process in the older adults is a change that is related to time; it is universal, intrinsic, progressive and detrimental. This situation can lead to reduced adaptability to the environment. Most of them were aged 79 - 90 years old. Someone who is over 70 years old or older is a high risk older adult person.

Older adults need social support to go about their daily lives. The types of social support, according to Wills and Ainette (Baum et al., 2012), can be divided into 4, namely emotional support, appreciation, instrumental and information. The support needed by each individual is different depending on their needs. Social support is not merely about providing assistance; it is about what is important according to the perception of the recipient’s meaning of the aid. This allows the older adult to feel more emotional supported and appreciated because they feel the benefits of the assistance for themselves.

Most of the respondents did not experience depression (normal) (14 people, 70%). There were 3 people (15%) with moderate depression and 3 people (15%) experiencing mild depression. The incidence of depression varies so much that depression is known according to the symptoms, which are mild, moderate, severe and with or without psychotic characteristics. Older adults who did not experience depression (normal) were able to accept changes in their bodily condition according to the aging process experienced. Most of the respondents considered that life is something fun. There were 3 respondents who were experiencing moderate depression (respondents no. 6, 8, 10). The respondents felt dissatisfied with the life they were experiencing, lost interest in activities and felt bored.

There was a relationship between social support and the incidence of depression in the older adults at Surabaya Dedali Hargo Nursing Home ($p = 0.037$). The Spearman rho - 0.468 correlation value indicates an inverse relationship with sufficient correlation coefficients. The higher the social support of the older adult, the lower the incidence of depression in the older adult. Older adult people who feel that they get good social support within the normal category (not depressed) totaled as many as 8 people (40%). There was 1 person (5%) older adult with social support experiencing moderate depression. Older adults with enough social support totaled 5 people (25%), older adults who did not experience depression totaled 1 person (5%), older adults who experienced mild depression totaled 2 people (10%) and the rest of the older adults had moderate depression. Older adults with less social support totaled 1 person (5%), older adults categorized as normal (not depressed) totaled 2 people (10%), older adult categorized as experiencing mild depression totaled 3 people (15%) and the rest were categorized as having moderate depression. The social support received by the older adults gives the individuals a feeling of comfort, of feeling loved when experiencing a decrease in self-esteem, bolstering assistance in the form of enthusiasm and demonstrating empathy, trust and attention so then the individual who receives it feels valuable.

**Conclusion**

Social support affects the incidence of depression in the older adult who live in the nursing home. The better the social support felt by the older adults, the lower the incidence of depression that is experienced. Therefore the support of families, residents and the administrators of the orphanage is needed by the older adults to maintain their mental health condition and to prevent the occurrence of depression.

Knowledge and the “Magibung” Tradition Related to the Dietary Self-Management of Diabetes Mellitus

Kusnanto1, Yayuk Ratnasari Dewi Anggreni1, Lailatun Nimah1, Hidayat Arifin1

1Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Magibung is the tradition of eating together with one’s family and relatives to celebrate traditional events. This tradition is contrary to the dietary recommendations for diabetes mellitus (DM) patients. The purpose of this study was to identify the correlation between knowledge and the magibung tradition on the self-management diet of diabetes mellitus patients. This study used a cross-sectional design. The samples obtained consisted of 138 respondents through purposive sampling. The data was collected using the Summary of Diabetes Self-Care Activities (SDSCA) questionnaire and the data was analyzed using the Spearman rho analysis test. The results showed that there was a correlation of knowledge (p=0.000) with diet self-management and that there was no correlation between the magibung tradition (0.184) with diet self-management. Age was the dominant factor that influenced the level of knowledge about diet for the DM patients. Being on a diet does not prevent the patient from participating in the magibung tradition. This is because it is about respecting family tradition and the community. Health workers are expected to optimize the health education provided to DM patients by paying attention to the local culture, especially to the elderly groups, in order to better understand DM self-management through discussion activities such as home visits, counseling and holding special gatherings.

Keywords: knowledge; magibung tradition; diet self-management; diabetes mellitus

Introduction

Diabetes mellitus (DM) requires patient independence in terms of managing their lifestyle. However, the results obtained are often not optimal and many sufferers have not shown independence in managing their diabetes.1 The diet is the basis for managing DM in the form of eating arrangements by providing all essential food elements according to the patient’s energy needs. This aims to maintain the BB and to prevent fluctuations in blood glucose levels through adherence to a schedule covering the type and amount of food required.2,3 Research conducted in several regions in Indonesia showed that the level of adherence of DM patients to regulating their eating according to the recommendations was still lacking.4-7

Indonesia ranks sixth in the world with ± 10.3 million people having been diagnosed with DM. It is ranked fourth in the world with ± 7.6 million people living with DM without knowing about the disease.8 The data of the Riset Kesehatan Dasar/Health Basic Research (RISKESDAS) in 2018 showed that the prevalence of DM patients in Indonesia had increased to 8.5% compared to 6.9% in 2013 for ages above 15 years old.9,10

Bali is famous for its blend of religious and cultural traditions, one of which is the magibung tradition originating from the Karangasem Regency. It is a traditional activity where a group of people sit in a circle to eat together out of one container.11,12 Magibung is full of compulsory rules as a form of discipline, such as not being able to overtake and following the food instructions. Exclusion from the community can result as a form of social sanction due to not following the magibung.11 Interviews with the DM patients found that
most of the menus served at magibung were variations of processed pork and “lawar foods”. Some of these types of foods have a high fat content such as processed pork, pork rolls and sequences (processed offal). These are not in accordance with the principles of the accuracy of the schedule and the recommended type and amount of food.13,14

The understanding of the DM patients who lacked an obligation to participate in the partying tradition was the most frequently problematic factor in DM patients as they did not go on a diet according to the accuracy of their schedule and the type and amount of food recommended. Thus, their self-management became worse, besides the effect of the economic, cultural and belief systems, social and religious factors.4,15,16 Some of the studies describe the eating habits at the family gatherings to be one of the situations that causes DM sufferers to have difficulty maintaining their dietary principles due to family stress or the context of trust that signifies solidarity and kinship from the traditional value of eating together.16–19 The purpose of the study was to identify the correlation between knowledge and the magibung tradition on the self-management of a diet suited for diabetes mellitus.

Method

Research design, population, sample and variables: The design of this study was correlational with a cross-sectional approach. The population consisted of 155 people with type 2 diabetes mellitus and the number of samples involved in this study was 138. Selecting the respondents was done through the purposive sampling method according to the chosen inclusion and exclusion criteria. The inclusion criteria specified were Type 2 DM patients with a minimum elementary school background, 1 year of having been diagnosed with the disease and being able to engage in traditional activities within the local village. The exclusion criteria were respondents who were confined to a state of bedrest. The independent variable in the study was the level of knowledge and the magibung tradition. The dependent variable was the self-management of their diet.

Instruments: The instruments used were three types of questionnaires in the form of a dietary knowledge test questionnaire based on The Starr County Diabetes Education Study developed by Laili NR with a Cronbach’s alpha value of 0.890.20 The magibung tradition questionnaire had a Cronbach’s alpha value of 0.775. The dietary self-management questionnaire was based on The Summary of Diabetes Self Care Activities (SDSCA-selected) translated and modified by Putri LR with a Cronbach’s alpha value of 0.855.21

Research procedures and analysis: The procedure for retrieving the data was by filling out questionnaires after the respondents had given their informed consent. The study was conducted for 2 weeks in 5 health centers, namely the Manggis I Health Center, the Sidemen Health Center, Bebandem Health Center, Karangasem I Health Center and Karangasem II Health Center. The collected data was analyzed using the Spearman rho analysis test with a confidence interval that was 95% with alpha (α) = 0.05.

Results

The majority of the respondents were 56 - 65 years old. The majority of the respondents were women. The respondents had the ability to speak Balinese as a colloquial language. Most of the respondents had primary level education as their educational background. The majority of the respondents worked as farmers. Based on the income aspect, the majority of the respondents had a total income of 2 million rupiah and most of the respondents had suffered from DM for between 1 - 3 years (Table 1).

Knowledge is based on one’s capacity to receive and use information about health to make decisions and actions in relation to managing their illness. The results of this study are also supported by the research into the factors associated with self-care practices among adults with diabetes, a rising global health problem, requires continuous self-care practice to prevent acute and chronic complications. However, studies show that few diabetes patients practice the recommended self-care in Ethiopia. The aim of this study was to assess factors associated with self-care practice among adult diabetes patients in public hospitals of West Shoa Zone, Oromia Regional State, Ethiopia.

Methods: In this cross-sectional study, 257 diabetes patients (mean age 42.9 ± 14.6 years, 54.1% male, in that the level of knowledge of patients about DM disease and its management has an important correlation with the practice of self-care. The better the level of knowledge possessed by the sufferer, the better they can improve their dietary self-management and vice versa. Based on the theory of Culture Care, knowledge is everything that humans know about objects, traits, intuition, revelation and thinking according to logic and experiments that are empirical (based on trial and error). Knowledge can be obtained through formal education and the surrounding environment (family and community). Individuals will receive knowledge in the form of experience and belief.

Culture Care theory also mentions that health behavior is formed by various factors working together. Research by Bakr and Breen et al explained that a low level of knowledge and a low level of income could negatively affect a patient’s nutritional and health status due to the lack of nutritional information related to food selection and a lack of access to nutritious food. In addition, Putra argued that the educational background of the patient being low can also lead to a poor understanding of DM which has an impact on poor self-care behavior.

Culture can influence the daily diabetes self-management in several ways, one of which is the environment in the form of familial and social factors. The results of this study contradict the research by Chesla et al, who argued that various types of obligations to attend cultural celebrations with banquets can inhibit the self-management of diabetic diets due to the tendency for opportunities that promote a lack of self-control over

food restrictions during meals. It was also stated that it was different from this study, in that Culture Care theory shows that the family and social environment was a strong aspect in the lives of the patients, one of which was through the role of food culture. The social roles and the symbols or meanings of food that are usually seen at banquets such as weddings, where relatives and friends share the same food, are a part of the tradition that signifies solidarity and builds social bonds.

People with DM in Karangasem still carry out the magibung tradition in the negative category or they have eating behavior that can harms the sufferers of DM. The patients rarely control themselves by consuming food without paying attention to the amount. In terms of the dietary self-management of patients in relation to the negative tradition of magibung, they also display a lack of self-management in their diet. Based on the content of the questionnaire, it was found that the respondents, in the diet self-management category, answered on average that they still often consumed high-fat foods in the form of beef, mutton, fried foods and sugar-containing snacks at a frequency of 5 - 6 days a week. This result is in accordance with the study by Bakr E-SH, which stated that DM patients, both men and women, have never eaten vegetables and that they like to consume red meat (dark meat). The respondents who practiced dietary self-management did not think that although they rarely go on a diet and even though they still regularly consume their prescribed drugs, their blood sugar will remain under control.

The surrounding community environment in the form of the familial and social factors through the tradition of magibung does not affect the self-management of DM patients. The researcher assumed that despite the obligation to follow the tradition, the DM patients in the Karangasem community were still able to control themselves while following the magibung tradition. This is evidenced by the majority of respondents who took part in the magibung tradition who were able to exercise control over themselves and who were not behaving in a way that was detrimental. They were still accompanied by good self-management in terms of their diet. In addition, the respondents also argued that following the tradition is a part of respecting their family traditions and how it manifests in their community life. It is not a problem for DM patients to follow the magibung tradition but DM sufferers also have to choose the type of food that can be eaten (according to their diabetes diet), keep up with their schedule and stay in control when the tradition is taking place. It can be concluded that the magibung tradition of the Karangasem community does not affect the implementation of dietary self-management carried out by the DM patients.

Conclusion

The level of knowledge has a relationship with the self-management of diabetic patient diets. There is the tendency for sufferers with a low level of knowledge to lack dietary self-management practices. The magibung tradition of the Karangasem community is not related to the implementation of self-management diets for DM patients. The DM diet does not prevent the patients from participating in the magibung tradition. Health workers are expected to optimize the health education that they provide by paying attention to the local culture of the DM patients with more emphasis on the community, especially within the elderly age group to better understand DM self-management. This can be done through discussion activities in the form of home visits, counseling or holding special gatherings for DM patients. The next researcher is expected to examine the factors related to the implementation of a self-managed diet further so then it can be known more deeply about what factors are at play in the cultural dimension that can have an impact on the implementation of a DM self-managed diet.

Community Empowerment in the Madura Tribe with Exclusive Breastfeeding in the Working Area of Community Health Center Sreseh Sampang Madura

Esti Yunitasari, Arsyita Hanifa Umayro, Ika Nur Pratiwi

Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

The Madurese are a group of people who live on the island of Madura located in the province of East Java, Indonesia. They have a very strong culture, including when it comes to exclusive breastfeeding for newborns. The coverage of exclusive breastfeeding in this area is 40%. The aim of this study was to determine the relationship of community empowerment in the Madura tribe with exclusive breastfeeding using a cross-sectional design. The population consisted of mothers who had infants aged 6 - 8 months old. The samples totaled 132 respondents taken based on the inclusion criteria. The independent variable was community empowerment. The dependent variable was exclusive breastfeeding. The data was collected using a questionnaire and analyzed using the Spearman rank correlation with a level of significance of 0.05. The results were $p = 0.000$ ($p < 0.05$), which means that there is a relationship between community empowerment and exclusive breastfeeding, $r = 0.994$, which means that the relationship between community empowerment and exclusive breastfeeding is strong. The conclusion of this study is that the role of community empowerment, especially the involvement of religious figures and community leaders, is needed in an effort to improve the exclusive breastfeeding in the Madura tribe.

Keywords: exclusive breastfeeding, community empowerment, religious figure, community leader

Introduction

Exclusive breastfeeding is a feeding practice in infants during the first six months (0 - 6 months) which can improve the immune system of babies. The impact of infants who are not given exclusive breastfeeding is that they are particularly vulnerable to diseases such as inflammatory tract infections, respiratory infections, allergies, asthma attacks, decreased intelligence cognitive, increasing obesity, heart and blood vessel disorders, diabetes risk mellitus and the risk of chronic disease.

Exclusive breastfeeding in Indonesia is relatively low at only 80%, while in East Java, it reaches 73.8%. The coverage of exclusive breastfeeding in Sampang area is 40%. Various factors lead to lower exclusive breastfeeding, among others, when more and more mothers believe that breastfeeding alone is not sufficiently filling for their babies and that complementary feeding is an acceptable cultural thing to do when infant feeding. The recent research results in Indonesia showed that infants who get MP-ASI before they are 6 months old are more affected by diarrhea, constipation, colds and heat than babies who are only exclusively breastfeeding. In addition, accelerated feeding for infants can cause obesity.

The factors related to exclusive breastfeeding include the social support consisting of the support of the husbands, families, community leaders and health workers. Given the importance of exclusive breastfeeding for the optimal growth of both physical and mental health and intelligence, it needs attention from community empowerment which consists of: 1) the presence of community leaders and health cadres, 2) the existence of community organizations including community-based health efforts, (3) the availability of public funds, 4) the availability of facilities and materials.
from the community, 5) the level of public knowledge, 6) the technological willingness of the community and 7) for the decision making of the community to be carried out properly. However, the Madurese culture encourages the provision of complementary foods in addition to breast milk before the baby is 6 months old. This culture is still widely found in Sreseh Sampang District. This is certainly contrary to the concept of exclusive breastfeeding.

Community empowerment is needed for exclusive breastfeeding coverage with the help of community leaders and health cadres to encourage them to know and play an active role in mobilizing the target communities through communication, information and education. To realize the coverage of exclusive breastfeeding, one of its strategies is to improve community empowerment through exclusive breastfeeding support for pregnant women, in addition to postpartum and breastfeeding mothers.

The form of community empowerment in the Madurese community that is directly related to exclusive breastfeeding is social support consisting of support from the health workers. There is a relationship between community empowerment and exclusive breastfeeding for breastfeeding mothers. Some opinions from the results of the study explain this. In addition to these factors, there are several other factors associated with exclusive breastfeeding including socio-economic level, knowledge and culture. Based on the problems above, the authors was interested in analyzing and determining the relationship between community empowerment in the Madura tribe with exclusive breastfeeding.

Method

This research used a descriptive correlational research design with a cross-sectional approach. The sample size was 132 respondents in total. The sampling technique used in this research was purposive sampling. The independent variable in this research was the provision of community empowerment. The dependent variable in this study was exclusive breastfeeding. The instrument used in this study was a questionnaire. The first questionnaire was about the facilitators of women’s breastfeeding empowerment and ICRE (Individual Community Related Empowerment), consisting of 20 questions representing the facilitators of community empowerment and exclusive breastfeeding. The second questionnaire was about exclusive breastfeeding, which refers to the breastfeeding experience scale modified by the researchers. There were 6 questions using 2 choices for the answers. The answer “Yes” was given a score of 1 and the answer “No” scored 0.

This research was conducted in the working area of the Community Health Centre Sreseh, in the Sreseh District of Sampang Regency. This study started from March to June 2017. The data was measured using the Spearman Rank correlation statistic test if the significance value was \( \alpha \leq 0.05 \).

Results

The characteristics of the respondents showed that most of the respondents were aged 26 - 30 years old for as many as 56 respondents (42.2%) and most had 2 children (71.2%). The education level was still minimal with 79 people (59.8%). Most of the respondents did not work or they were a housewife, totaling 83 people (62.9%) (Table 1).

There were 10 respondents (7.5%) with a sufficient level of community empowerment who did not exclusively breastfeed. There were 49 (37%) who had a sufficient level of empowerment who exclusively breastfed. Breastfeeding was not exclusive to community empowerment for as many as 14 respondents (10.6%); 59 respondents (44.6%) had good empowerment and exclusive breastfeeding. The Spearman rank statistical test results obtained (p=0.000) with a significance level α (0.05). There was a relationship between community empowerment with exclusive breastfeeding in the working area of Sresheh Sampang Madura Community Health Centre. The value of the correlation coefficient (r) = 0.960 means that the level of the relationship is strong enough with the direction showing there to be a positive correlation between community empowerment and exclusive breastfeeding. This shows that if an empowered society is getting better, then exclusive breastfeeding is also getting better (Table 3).

Discussion

The distribution of educational demographic domain data shows half of the respondents have less education level. The higher the client’s education, the better the client’s conviction as it is usually supported by rational scientific evidence. Such individuals can learn to adapt to the appropriate culture according to their health condition. Formal maternal education affects the mother’s knowledge level; where the level of education is low, then the knowledge gained will be less and vice versa. Knowledge is an important domain for the formation of one’s actions. Mothers with a low level of education tend to be stronger in terms of maintaining food-related traditions and cultures, thus making it difficult to receive new information in terms of the proper feeding of infants.

The results showed that half of the respondents had a good level of education but that they still provided early breastfeeding. Different maternal education levels do not determine the breastfeeding behavior of infants aged 6 - 8 months. Knowledge is a domain that is important for attitude formation. Good knowledge was already possessed by the respondents which formed the basis for determining their attitude. The respondents with a good level of knowledge tend to be good in terms of exclusive breastfeeding.

Mothers aged 19 - 25 years old generally have a more adequate milk production than older mothers. This occurs because of breast enlargement with every ovulation cycle from the beginning of menstruation to age 30 years. However, degenerate breast and milk producing glands (alveoli) as a whole occurs after the age of 30 years. A person’s behavior both positive and negative will be influenced by age including in predisposing factors, where the more mature one’s age is, the more positive the behavior. Age is one component that comes from within that can affect behavior. Promotes immune system formation and supports organ development. Breastfeeding could
also protect from obesity, diabetes and cardiovascular disease. Furthermore, human colostrum (HC When viewed through the number of children, this indicates that a mother with the number of children 2 while the mother with the number of children 3-4 (multiparas) did not give exclusive breastfeeding to the baby at the age of 0-6 month.

The absence of any experience with a psychological object tends to form a negative attitude toward the object.⁴ According to the Analysis of the Implementation of Exclusive Breastfeeding Program, mothers with a multi-parity status are 3 times more likely to do exclusive breastfeeding compared with first time mothers.⁵ There is no significant relationship between the number of children with exclusive breastfeeding practices.⁶ This was assumed because mothers who have children <3 in the study area had more free time to come to the health care facility with the opportunity to obtain information related to exclusive breastfeeding practices.

The number of children does not affect the level of exclusive breastfeeding. The Madurese habit of breastfeeding depends on the culture and traditions of the people around them. Viewed from the economic factors, we can show that all of the respondents have a lower economic status with an under average income. Someone who has the material resources will use them to pay to treat his illness to get better sooner.⁸ In the case of supplementary feeding, income is important because the better the family economy, the better the purchasing power related to supplementary food becomes easier. Otherwise, the worse the family economy, the more difficult the purchasing power when it comes to additional food.⁹ in others they are given as complementary foods during weaning. Improper food selection at this stage is associated with a high prevalence of malnutrition in children under 5 years. Here we listed the traditional foods from four continents and compared them with human milk based on their dietary contents. Vitamins such as thiamine (~[2-10] folds Families of a high economic status will tend to choose to give formula milk, instant porridge or biscuits that are of good quality and with a better nutritional content, whereas families with a lower economic status will tend to choose to provide rice or bananas as an additional food to babies because they are economically cheaper and follow the local culture.⁹

Community empowerment can be done by health workers, cadres and religious leaders in relation to educating on exclusive breastfeeding. This means showing that the level of the relationship is strong enough with a positive correlation between empowering the community with exclusive breastfeeding. This means the better the community empowerment, the higher the level of exclusive breast feeding. For the coverage of exclusive breastfeeding, one of the strategies is improve community empowerment by providing exclusive breastfeeding support to pregnant women, in addition to postpartum and breastfeeding mothers.¹⁰,¹¹

The improvement of the coverage of exclusive breastfeeding requires knowledge of exclusive breastfeeding that can be provided by the health workers and local cadres through information. This is in order to identify the facilitating factor that can contribute to the development of effective policies and interventions.¹² This is in accordance with the theory of community empowerment in which the presence of community leaders and health cadres, the existence of community organizations, the availability of facilities and materials and an awareness of the level of knowledge of the community and of technology is very much needed in the process of exclusive breastfeeding.²² The domain of community empowerment that contains the social and cultural factors shows that most of the respondents have a negative value concerning culture. The negative culture of the respondents includes the habit of giving bananas, porridge and water to infants before the age of 6 months for the baby to sleep faster and stop crying.⁵

**Conclusion**

Good community empowerment will enable the mothers to exclusively breastfeed. It is usually a factor of culture that affects breastfeeding. The participation of health workers and cadres through community empowerment, especially the involvement of religious figures and community leaders, is needed in an effort to improve the exclusive breastfeeding within the Madura tribe in order to reduce the behavior provision of early breastfeeding and the increased coverage of exclusive breastfeeding.

**Ethical Clearance:** The ethical approval for this study was granted by the IRB committee of the Faculty of Nursing of Airlangga University in 2017.

**Source of Funding:** There was no funding source for this research and for the writing of this report. There was no source of funding involved in the decision to submit the article for publication.

Health-Related Quality of Life for Patients with Cardiovascular Disease after a Coronary Artery Bypass Graft: A Systematic Review

Tintin Sukartini¹, Hidayat Arifin¹, Ulfa Nur Rohmah¹, Dian Rizki Ramadhani¹
¹Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT
CABG can affect health-related quality of life (HRQoL) and it can take a long time to improve. The following question was raised: ‘How long does it take for the HRQoL of patients with a Coronary Artery Bypass Graft (CBAG) to increase?’ The aim was to analyze the recent scientific production of HRQoL in cardiovascular patients with CABG. The PRISMA approach was used and we examined articles from Scopus, EBSCO and ProQuest that were published between 2014 - 2018. We used “health related quality of life”, restricted our search to “coronary artery bypass graft” and used “after” in the title, keywords and abstract connected by the Boolean operator “AND”. SF-36 was used to assess the HRQoL and it increased within six months after CABG. This was influenced by self-control, obesity, age, gender, emotions and personality. Improving the patient’s quality of life is key for the nurses to control so then the heart surgery patients become prosperous and thus reduce their morbidity and mortality.

Keywords: health related quality of life; coronary artery bypass graft; cardiovascular disease

Introduction
The number of individuals suffering from cardiovascular disease in the world continues to increase every year. Cardiovascular disease is the foremost most disease in Indonesia, ischemic heart disease specifically.¹ The most common medical treatment for heart disease is Coronary Artery Bypass Grafting (CABG) for coronary heart disease. Medical management can affect the quality of life of patients with cardiovascular disease.² The act of limiting activities, restricting eating and making changes in their lifestyle in post-CABG patients is an effort that is required to maintain the quality of life in patients after medical management. Only a few patients experience depression and this interferes with HRQoL.³ Attention must be directed to the more important aspects, namely quality of life, because individuals not only want a long life but they also want to improve their quality of life.⁴ Improving the quality of life is also one indicator of the success of CABG operations. This includes symptom prevention and management behaviour post-CABG recovery. The patients also believe and have hope about controlling their illness and treatment in the new approach and they seek to clarify the various symptoms and adaptations that are useful in terms of quality of life.⁵ The importance of measuring the impact of medical interventions on quality of life related to patient health (HRQoL) is emphasized. HRQoL is also seen as how the results of the treatment can successfully provide potential changes to the lives of the patients.⁶ Some studies also suggest important results in terms of increasing HRQoL, such as several factors being involved namely comorbid diseases, depression, anxiety and the incidence rate of cardiovascular invasive procedures.⁷ But up until now, although some studies say that there is a decrease in quality of life after CABG, it is but not yet known in detail the factors that contribute to quality of life in patients who have had CABG. The purpose of the study was to analyze recent scientific production about HRQoL in cardiovascular patients with CABG.
**Method**

**Research design and search strategy:** The systematic review research design resulted from and focused on the latest research over the last 5 years. This study used the Preferred Reporting Items for Systematic Reviews and Meta-Analyzes (PRISMA) approach. The process of searching the articles was electronic. The data was obtained from Scopus, ProQuest, and EBSCO. The literature review used the keywords ‘Health related Quality of Life’, ‘After’ and ‘Coronary Artery Bypass Graft’. In the article search, we used the Boolean operator “AND”. After a number of articles was obtained, the researcher then selected them again according to the specified inclusion and exclusion criteria. The article searching process was carried out from August to October 2018. The search for articles used keywords that had been determined by the researchers and they also provided limits as per the inclusion and exclusion criteria. The data obtained from Scopus, EBSCO and ProQuest were then selected one by one by the researchers to determine their suitability. After obtaining articles that were in accordance with the researchers’ intentions, the articles were analyzed one by one and grouped to get the results. The next step was to discuss what had been found based on the points obtained from the results.

**Inclusion and Exclusion Criteria:** The desired articles were articles published between 2014 – 2018 and articles written in English focusing on the keywords in the search for relevant articles. Articles with samples that did not focus on patients with PCI and CABG, the discussion of articles looking at outside life quality (HRQoL) as well as articles based on a systematic review, narrative review, thesis, books or chapters, abstracts and editorials were not used in this study.

**Results**

The initial literature search returned 123 abstracts (71 from SCOPUS, 39 from EBSCHOHOST and 20 from PROQUEST). After reviewing the abstracts for relevance and matching them with the inclusion criteria, 45 articles were selected for a full-text review (34 from SCOPUS, 15 from EBSCHOHOST and 6 from PROQUEST). There were 24 duplicate articles and 2 articles published in 2013 which were excluded. Finally, 19 articles were chosen to be reviewed. The studies were heterogeneous. There were 13 cohort prospective/observational studies, 4 randomized trial studies, 1 longitudinal study and 1 descriptive qualitative study [Figure 1].

The general instruments used were 13 studies analyzed with The Short-Form Health Survey (SF-36 and SF-12). The Short-Form Health Survey (SF-36) questionnaire has been proven to be the most widely used tool to evaluate quality of life among patients undergoing cardiac treatment and surgery.3

Most of the studies stated the majority of respondents’ HRQoL scores increased after undergoing CABG surgery, both in the physical and mental domains. Two years after CABG, the clients became more confident in themselves and their health, with 81% of patients having a good quality of life.5 Post-CABG HRQoL is influenced by a variety of factors, including the type of CABG (on-pump or off-pump), self-control related to health, obesity, age, gender, type-D personality and the role of emotional physical roles, vitality and social functions.

**Figure 1:** Flowchart of articles selected in the systematic review; the selection process using PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyzes). The articles were obtained from SCOPUS, EBSCO and ProQuest totaling 123 articles. The final studies included in the synthesis was 19 articles.

**Discussion**

There are several stages related to behaving healthily. The stages include precontemplation (in 6 months, not yet interested in making changes), contemplation (considering changes in the next 6 months), preparation (trying to make changes but not and wanting to do it again the following month), action (actively developing
strategies to make changes, sometimes after almost 6 months with time and effort to commitment) and maintenance (changes continue, starting 6 months after the action phase begins). The health-related quality of life increased in patients 6 months after CABG was performed. However, 12 months after CABG was done and even for years after, there was an increase in the quality of life as well. The most common occurred after 6 months. This may occur because patients who have long been hospitalized may have begun to experience boredom or they may be in the action stage. In addition, depression before surgery causes a high level of hospitalization. Prolonged surgical pain can last for up to 6 months and they may have difficulty returning to their previous activities. One needs to consider the effect post-CABG cardiac rehabilitation on older elderly people, as this has an adverse impact on CABG. Psychological morbidity includes depression, anxiety, personality and emotional roles reinforcing a decrease in the quality of life of the patients. This improvement does not seem to be realized in all patients who had undergone CABG surgery.

Objective: The aim of this study was to test the direct and indirect influence of personality trait Type D on no change-deterioration trajectories HRQoL and the mediating influence of increased symptoms of anxiety and depression. Methods: The hypothesized influence of personality trait Type D on the relationship between increased anxiety and depression and no change-deterioration trajectories in HRQoL was tested with path analysis using structural equation modeling. Results: The results of the current study show that Type D personality comprised a vulnerability factor for poor patient-reported outcomes (i.e., HRQoL and distress) over the years, CABG measures have reduced the significant mortality rates but strangely, there are still patients who have a psychological condition even 5 years post-CABG. The lack of resolution for the psychological problems of patients after rejection can cause recurrent heart attacks. For that, the nurse should facilitate by helping and relaxing the patients by providing sedatives.

The female gender is reported as slowing the increase in HRQoL due to low coping mechanisms and changing role perspectives. Women often suffer from chest pain in the arterial area in an epicardial coronary. There was a gender difference in the biological process that transmits and modulates pain signals; the nervous system of men and women is different when it comes to detecting and responding to pain (pain sensitivity) and the emotional cognatic response to pain differs between men and women. The female gender therefore correlates with a quality of life related to low health. Pain is also associated with the quality of life of patients who have carried out CABG. It is known that the standard blood vessels used for CABG are the safnia magna vein and the left internal mammary artery of the chest. Although the prevalence of severe pain decreases yearly by year and modern analgesic methods are used, chronic pain after CABG remains a concern because the incidence rate of chronic pain has reached 30-50%. Chronic pain after CABG also relates to the subsequent cost estimates for the health care and social support systems. This post-operative CABG pain may also be associated with the somatic, visceral and neuropathic conditions. The lack of resolution for the psychological problems of patients after rejection can cause recurrent heart attacks. For that, the nurse should facilitate by helping and relaxing the patients by providing sedatives. The perception of post-CABG training has an impact on HRQoL. Bad perceptions becomes a barrier within cardiac rehabilitation training. It is known that poor diet and poor exercise are the independent risk factors in developing worsening CAD post-CABG surgery. Exercise, lifestyle modification and diet after CABG surgery is important to pay attention to in order to avoid future risks to one’s health. The differences in age do not really show as having a specific impact on HRQOL. The patients who are <60 year old age undergoing CABG have worse outcomes than those of an older age. Age is related to cognitive processes. Cognitive differences are usually higher in older people compared to middle-aged adults. Clinical performance included pulmonary function, which is a physical component related to a decrease in lung function that is also related to an increase in CRP and post-operative blood cortisol concentrations and a greater preoperative IVC.
they know the effects of the disease (treatment, follow-up, limitations). Functional capacity and quality of life in patients dependents on any comorbidities, and this can greatly increase the health care costs of the comorbidity itself. This makes the patients feel that their health function has deteriorated, thereby reducing their quality of life.

**Conclusion**

Health-related quality of life after CABG has proven to be significantly improved. The peak time shows that the patient feels that their quality of life is good after 6 months of action. This needs to be observed again later on. The link of having many supporters involved in the improvement of their quality of life is key for the nurses to control. This is so then the heart patients reduce their risk of morbidity and mortality.

Factors Contributing to Leprosy Stigma among Madurese People

Laily Hidayati, Harmayetty, Mahsus Ridwan
1Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Leprosy is a disease that still has a stigma in society. Leprosy patients are considered have a curse from God, so they must be shunned, are incurable and are disinherited. This study aimed to identify the factors contributing to the leprosy stigma among the Madurese people in Indonesia. This was a descriptive analytical study with a cross-sectional approach that involved 107 adult people living around leprosy patients obtained through simple random sampling with other certain criteria. The variables measured were education, economic status, regulations and policies, cultural values and lifestyle, the family and social factor, the religious and philosophical factor, technology and leprosy stigma. The data was collected using a questionnaire and analyzed using the Spearman Rho test (α=0.05). The study revealed that education, economic level, regulations and policies, cultural values and lifestyle, the family and social factor, the religious and philosophical factor and also technology had a significant correlation with leprosy stigma (p=0.011; p=0.02; p=0.008; p=0.011; p=0.015; p=0.000; p=0.0037). It is expected for the government and health workers to conduct socialization and counseling focused on leprosy, therefore allowing people to be able to understand the disease, thus lowering the leprosy stigma.

Keywords: leprosy stigma, madurese people, education, economic factor, cultural values.

Introduction

Leprosy is a disease that still has a stigma within the community. The stigma arises because of the false perception of leprosy. Many people still think that leprosy is caused by a curse or witchcraft, that it is a punishment from God, sin, eating certain types of food or inherited. Wrong beliefs in the community have continued to expand until now, thus affecting the self-confidence and social function of leprosy patients. This study aimed to determine the factors associated with the emergence of stigma in the Madurese people based on their beliefs and culture.

The World Health Organization (WHO) reported in 2015 that there were 210,758 new lepers and that Indonesia ranks the third largest focus of leprosy cases in the world after India and Brazil. Throughout 2013, the Indonesian Ministry of Health recorded 16,825 new leprosy cases with a disability rate of 6.82 per 1,000,000 people. In addition, the East Java Health Office reported that in 2015, there were 3,835 cases consisting of 3,506 adult patients and 329 cases where the patients were children. The distribution of leprosy cases in East Java based on leprosy type was 498 PausiBasiler (PB) and 3,337 Multi Basiler (MB). Based on the Bangkalan Regency Health Profile in 2015, the number of new leprosy cases was 310. This number has increased from the previous year. One of the biggest leprosy case contributors is the Burneh Health Center work area. Based on the data from the Burneh Health Center, the number of new case findings in 2014 was 12 lepers, increasing in 2015 to as many as 22 lepers and more in 2016, up to 38 lepers.

Bangkalan Regency is an area that still has many leprosy sufferers. This is influenced by the condition of Bangkalan regency, which is mostly made up of slum areas. The spread of leprosy in the Bangkalan area not only affects the ongoing health conditions but it also affects the social and economic conditions. The results
of the preliminary study focused on 8 randomly selected respondents on April 2017 showed that there is still a negative perception (stigma) felt by the leprosy patients from the community. Some unpleasant events related to the stigma can occur, such as 1) when a man with leprosy attended the congregational prayer, other people stayed away from him; 2) a woman with leprosy is not married -although she wanted to- because she is ostracized by the community and confined herself to her home until she was finally able to escape to Kalimantan Island; 3) a teenager with leprosy refuses to go to school because he is bullied and thought of as strange by his friends and 4) two patients dropped out of a treatment regime because they were embarrassed and felt the stigma even from the health workers. Therefore, it is necessary to identify why the stigma is still high in the community, so then in the future, an appropriate intervention can be formulated to overcome this problem.

Method

Study Design, Setting, and Sampling: This study was descriptive using a cross-sectional approach. The population in this study consisted of the community living around people with leprosy in the same area (1-2 km in distance) in Bangkalan Regency, as many as 146 people; 107 respondents were selected through simple random sampling.

Study Variables: The variables measured included education, economic status, regulations and policies, cultural values and lifestyle, the family and social factor, religion and philosophy, technology and the leprosy stigma.

The education and economic factors were measured using a questionnaire. The questionnaire focused on regulations and policies, cultural values and lifestyle, social life and family, religion and philosophy and technology was modified from transcultural theory. The stigma questionnaire is a modification of the questionnaire on community stigma used in studies focused on HIV/AIDS sufferers.

Data Analysis: A descriptive statistics method was employed to analyze the data in order to generate the study results in the form of frequencies, percentages, mean, ranges and standard deviation. This method allowed us to summarize the characteristics of the study subjects based on the variables selected. The data was analyzed using the Spearman Rho correlation test with a significance level of ≤ 0.05.

Results

To begin with, 107 respondents were residents obtained from the community around known lepers. Table 1 presents the characteristics of the respondents included in this study. All of the respondents were adults with an age range of 26 - 35 years old for the majority (55.1%). Most of them (64.4%) were female. In addition, most of respondents were farmers (42%) and unemployed (25.2%).

Table 2 displays the distribution of each of the variables measured in this study and the statistical results. It was found most of the respondents had graduated from elementary school and that 21 respondents had a negative stigma. In addition, the statistical test results showed $p = 0.011$ ($p <0.05$), so there was found to be a significant relationship between the level of education and the leprosy stigma in the community. In line with the previous results, other factors (economic, regulatory and policy, cultural and life value, social and family, religious and philosophy and technology) also showed a significant relationship with the emergence of leprosy stigma in the community with a value of $p <0.05$ respectively (see table 2). In fact, all of the variables also showed a weak to strong correlation.

**Discussion**

Based on the data that has been conveyed above, the following will be discussed about the relationship of each of the factors studied according to the purpose of the study, which is to explain the factor analysis related to the emergence of leprosy stigma in the community based on the theory of transcultural transmission at Burneh health center in Bangkalan Regency.

The respondent’s distribution data based on the economic factors showed that the majority of the respondents had an less economic status with an income below the Bangkalan minimum wage, which was < Rp. 1,530,655.00 for as many as 38 (35.5%) respondents. The economic relationship with leprosy stigma showed there to be a correlation coefficient of 0.220, thus indicating there to be a weaker correlation strength. The lower the economic income of the community, the higher the stigma that the community has. Economic factors are one of the important things related to someone providing good support. Friedman and Leininger stated that the higher the level of economic status, the more support and decision-making can be provided in the treatment of lepers. A person will utilize the material resources that are owned by them to finance his illness so then he can get well soon. The factors that influence a person’s economic status include education, employment, income, economic conditions and cultural background. 7,8

In relation to the regulatory and policy factors, the results of the statistical test showed the factors as having a significant correlation with the leprosy stigma in the community. The regulatory and policy factors yielded that almost half of the respondents had negative rules and policies, namely that 46 (42.9%) of the respondents had a negative stigma. The relationship between regulations and policies with the leprosy stigma showed a correlation coefficient of 0.257, which indicates a weak correlation strength. The more negative values that the regulations and policies that people have, the lower the stigma of the community. According to the theory of transcultural nursing by Leininger (2002), it explains that the hospital policies and regulations that are applied and that everything that affects individual activities in cross-cultural nursing care. 8 In this study, there were no government regulations and policies relating to leprosy.

Based on the results of the research that has been conducted on the cultural and life values factor, the majority of the respondents have a negative value for cultural values and lifestyle in relation to the emergence of the leprosy stigma in the community for as many as 40 (37.3%) respondents. The negative cultural values and lifestyle of the respondents stated that, from the beginning, they thought that leprosy had to be shunned, that it was a hereditary disease and that it could spread throughout the community. They assumed that leprosy is a frightening disease. According to transcultural theory, culture is the norm of the actions of the group members.
who are being studied, who can then be divided and provided instructions for thinking, acting and making decisions. In this study, there was a relationship between cultural values and the emergence of leprosy stigma in society. The results of this study are in line with the theory of transcultural nursing, where culture and lifestyle factors are very influential concerning a person’s actions. The respondents who have the stigma of leprosy are influenced by their habits, as well as the beliefs that have become the rules of life of a region, where most of the cultural and lifestyle factors have a tendency towards displaying negative behavior towards leprosy. According to the researchers, cultural values and lifestyles are closely related to the emergence of leprosy stigma in society. If the culture adopted by the individuals or related groups in daily life is not good, then this will affect the behavior of the individuals or groups in viewing and treating lepers. This can be seen from societal habits or culture, where many people still think that leprosy is a disgusting disease; a disease that must be shunned, even to the point where leprosy is considered to be a hereditary disease. The higher the cultural values and lifestyle that the community has, the lower the stigma.

The respondent distribution data based on the social and family factors showed that most of the respondents had negative values regarding the social and family factor in terms of the occurrence of the leprosy stigma for as many as 37 (34.5%) respondents. The social and family factors that are inherent in the community to date, so if they are suffering from leprosy then it is kept a secret because of a fear of their neighbors or people who they know. People who suffer from leprosy are exiled or confined to a room and there are still many people who stay away from lepers because they are afraid of contracting the disease. Pierce defined social support as a source of emotional, informational or mentoring support provided by people around individuals both in the neighborhood and in the community to deal with every problem and the crises that occur in everyday life. Based on the results of the study, the results indicate that there is a relationship between the social and family factors towards the emergence of the leprosy stigma in the community. Familial social support is still bound by the habits, customs, and beliefs of the family or community, thus causing a negative perception of leprosy. The higher the social and family factor owned by the community, the lower the stigma that they have.

The results of the data on the religious and philosophical research that has been conducted by the researchers indicated that most of the respondents have a negative value regarding their religious and philosophical factors, as many as 43 (40.1%) respondents. People still think that leprosy is caused by a curse from God, from eating wrong and also by rarely worshiping. According to the transcultural theory of nursing, religiosity provides a very strong motivation to place the truth above all else, even above a person’s own life. This causes a person to have a humble nature and open sense of self. Religiosity and philosophy includes the existence of a religion that is embraced, as a way of looking at the disease and as a method of treatment involving religious habits that have a positive effect on health. It is known that there are three dimensions involved in the religiosity of the Madurese. The experience dimension is about feeling calm when doing religious actions. The dimensions of religious knowledge is focused on beliefs that are described by tradition. The frequency dimension is about what the impact will be after doing a religious action, between the bad and good effects.

The research results showed that there is a relationship between religion and philosophy with the emergence of the leprosy stigma in society. The respondents thought that leprosy could be caused by a curse from God because of the sins of the individual, because of a curse or because he rarely worshiped. Some thought that leprosy could only be cured by a shaman or a traditional medicaster, or by religious leader referred to as a “kyai”. The higher the strength of the religious philosophy that the community has, the lower the stigma it has.

The respondent’s distribution data based on technological factors showed that most of the respondents had less technology, with as many as 40 (37.3%) respondents answering negatively. This was due to the lack of knowledge of the respondents in terms of utilizing or obtaining health and/or electronic technology. Therefore how the respondents get their information about leprosy is lacking. Even today, there has never been any form of offered counseling about leprosy either from the government or from the puskesmas.

According to the theory of transcultural nursing, technological factors are one of the factors that influence individual behavior based on culture. Health technology is an infrastructure that allows individuals to choose or get offers to solve problems within the health services.
The utilization of health technology is influenced by the attitudes of the health workers, paired with the needs and interests of the community. Technology refers to all forms of technology used to create, store, change and use information in all its forms.\textsuperscript{8,12}

**Conclusion**

The variables that significantly correlate with the emergence of leprosy stigma in the community in the Burneh health center in Bangkalan Regency are educational factors, economic factors, regulatory and policy factors, cultural values and lifestyle factors, social and family factors, religious and philosophical factors and also technological factors. It is expected that the Burneh Community Health Center in Bangkalan Regency will conduct socialization and counseling on the causes and transmission of leprosy in each hamlet or village. This is so then people can better understand what leprosy is and how it is transmitted.

How Diabetic Men Perceive Sex and Sexual Dysfunction

Hafnailmy Muhalla
Doctoral Degree Programs, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Sex is an adult human need, including for diabetic men. Irregular changes in the blood sugar level causes complex sexual disorders with a high incidence rate, but this has never been explored in-depth regarding the fundamental view of sex and their disorders. This study explored the subject of focus by conducting a qualitative research study using a phenomenology approach that aimed to explore diabetic men and how they perceived sex and sexual dysfunction at a General Hospital in Jakarta. In-depth interviews were conducted with 7 participants. The findings provide detailed information on two main themes; sexual perceptions and how the men perceive the associated dysfunction. It was concluded that sex is a primer and a secondary need. Dysfunction becomes a disturbance of the primer need and this affects the patient psychologically.

Keywords: diabetic men, sex, sexual dysfunction

Introduction

Diabetes is a huge and growing global problem; close to 350 million people in the world have a diabetes. In 2013, the number of diabetes cases in the world numbered 382 million and this is set to increase by more than 55% (592 million) in 2035. In 2012, diabetes was the direct cause of 1.5 million deaths, with more than 80% of them occurring in low-and middle-income countries. The WHO projects that diabetes will be the leading cause of death by 2030.

People with diabetes have an increased risk of developing a number of serious health problems, including people in Indonesia. The International Diabetes Federation (2014) said that Indonesia is the fifth largest diabetes population in the world. This number is as a consequence of a large problem.

Uncontrolled blood sugar results in several complications within the vascular and neural system, including relating to sexual health. Diabetes is the main biological organic cause of sexual dysfunction.

Sex is a part of human life. As an important human need, sex has never been explored clearly. People have no idea how to explore it or where to find the help needed to solve their sexual problems. This results in a sexual pattern problem between the patient and their partners.

Sexual dysfunction may occur for more than 50% of men; this can include sexual desire disorder, erectile dysfunction (ED), early ejaculation and orgasm disorder. Sexual dysfunction is higher in diabetic men with complications than sexual desire disorder (19% vs. 4%), ED (31% vs. 6%), orgasm problems (31% vs. 2%) and all other dysfunctions (40.5% vs. 6%). The two main sexual problems for diabetic men are erectile dysfunction (35.8%-82%) and early ejaculation (30%-70%).

The sexual changes cause complex problems that are both physical and psychological. Diabetic men feel insecure, guilty, warrant a decrease in intimacy, have low self-esteem and they feel like it is a doomsday and a change in their welfare patterns. In a partnered relationship, they feel like a failure in the marriage, and they are embarrassed to discuss or solve it. All of the psychological responses are influenced by their health beliefs, namely that sexual functioning has an important meaning within the overall health condition, including what they perceive about sexual health.

In Indonesia, sexual problems are never or rarely discussed. This is because of several factors concerning...
the patients, their family and the health staff. Sexual complexity, sexual identity and sexual dysfunction are some of the knowledge areas in nursing practices. Considering sexual well-being and its effect on a diabetic man’s life, it is important to have a holistic approach to the care of diabetic men. This study has explored, in depth, the fundamental views of how patients perceive sex and sexual dysfunction.

Method

Using the phenomenology approach, this research was conducted in a general hospital of Jakarta following the granting of ethical clearance. A total of 7 participants was selected to reach the saturation point of the data. The criteria of the participants were that they were diabetic men with sexual dysfunction between 30 and 60 years old, who were married, who had a good standard of good communication, who were cooperative, who had never been a participant before and who had given their informed consent.

The first screening was decided using the International Index of Erectile Function (IIEF). Using the in-depth interview method, field notes, recordings and memory note, the interview was conducted 1 - 3 times in a private room. The data was digitally recorded and transcribed verbatim by the researcher, re-read, transcribed, identified, defined and the themes and sub-themes were named. The researcher used credibility, dependability, conformability and transferability to ensure that the methods were valid.

Results

The narrative was used to interpret the themes and sub-themes. This research found there to be 2 major themes; 1) the perception of sex in a man’s life and 2) the perception of sexual dysfunction in a man’s life.

The perceive of sexual: The diabetic men were asked “What do you perceive of sex for men?”

Primary needs (major): The diabetic men had a view that sex is a primary need or a major thing in a man’s life.

Important: They mentioned that sex is very important aspect of their life. For example:

“Wooowwww, that is an important thing, it makes me exited… it is a major thing” (P1-)

Primary needs: The diabetic men explained clearly that sex is an important need for them. They can differentiate this sexual view with the view of a woman. According to his wife’s opinion, he said:

“According to me, as a man, sex is yeaaaah it is a life need, primarily, that… as a primary need. Sex is a second primary needs, according to me yeah, to me. Well, the first primary needs are eating, drinking, and sex is the second. This is a very primary and major need. For women, I think that it is not too necessary” (P 2-)
Requirement: The diabetic men appreciated that sex is a requirement in their lives. They were convinced:

“Yeah that is a requirement…” (P 7-)

Secondary needs (un-necessary/not important): For some of the participants, it is a secondary need only. For the same question, “What do you perceive of sex for men?”, some of the participants gave the following opinions:

Not dependent on sex: One of the participants said that in marriage, they are not dependent on it being sexual, as there are other things that are more important. For example:

“Yaaach, marriage is not dependent on it… isn’t it?” (P 3-)

Sex is not everything: The same participant continued with the explanation that sex is not everything in life. He said:

“… sex is not everything” (P 3-)

Un-Necessary: In case, another participant said briefly that sex is not an important thing anymore because his wife is sick and they have a child already. They said that:

“… my wife is sick now. My physician sad that he have a myo (mean myoma), massive bleeding, and now she is on obstetric ward, sex is not necessary anymore Nurse” (P 4-)

“… that not important anymore, we had an offspring” (P 6-)

The perception of sexual dysfunction: The participants were asked “How do you perceive sexual disturbance or the sexual dysfunction that is hurting you now?” and “What is your opinion about this disturbance in your life?”

Interfering with one’s primary needs (major): Sex is a primary need for men. When dysfunction occurs, the participant felt interfered with. This phrase was expressed in some of the following categories:

Dangerous for life: One diabetic man assumed that sexual dysfunction is very dangerous. He said:

“Wow wowwow… it sooooo dangerous, very dangerous… “(P 1-)

Disturbing in life: Two of the 7 participants said that sexual dysfunction was disturbing in their lives. Both said:

“Soooooo this problem, diabetes… these sexual problems are very disturbing, exactly…” (P 3-)

“I felt disturbed previously, ya” (P 6-)

Does not interfere life: One of the 7 participants thought that sexual dysfunction is normal and an ordinary thing. This was proven by:

“It is normal, I still have passion and I am excited” (P 7-)

Psychological impact: Sexual dysfunction is considered to be a cause of psychological changes. Those are a decrease in the spirit (demoralizing), a decrease in self-esteem and it being a very important problem.

Demoralizing (decreasing their spirit): One of them said that sexual dysfunction is a decreasing of the spirit.

“… when it disappears, there is no spirit in me to take make it work” (P 2-)

Decreasing their self-esteem: One of the participants explained that sexual dysfunction will change his self-esteem. They feel useless and feel shame with their partner.

“I feel ashamed regarding my wife” (P 2-)

Being very important: Regarding the participants, sexual dysfunction is an influential problem in life. The second participant said that:

“… it is a problem for me, a big problem…” (P 2-)

Age as a cause of sexual dysfunction: In the interview, a few of the participants said that sexual dysfunction occurs as a part of getting older. The answers for the question “Is there any influence from age?” are as follows:

“So, this is a dysfunction…yeah all of this depends on age…” (P 1-)

 “… decreases along with age…” “(P 3-)

“I think it is because of age, I am nearly 50” (P 4-)

Discussion

The aim of this article was to identify the perceptions of diabetic men on sex and sexual dysfunction.

Sex in life is a process, and the perception of sexual dysfunction is about sexuality, sexual functioning and
healthy sex. The participants considered that sex is an important part of life, as a primary need after eating and drinking and as a requirement for staying in shape regarding sexual function.

The participants assume that sex is restricted to coitus. Rowland and Incrocci (2008) said that a man is sexual and that they focus on different women. A man focuses on the genital area, as a means for having coitus (having sex).15

The healthy sexual views become a point of man. Mccarthy & Metz (2008) said that sexual health is based on both the physical and psychological dimensions in men. The sexually healthy man is a man who has self-esteem, who is proud of their sexuality, and who believes in themselves and their power. They have a wide imaging sexual, which is good for the body it will be good for sexual life, and vice versa.11

Generally, sexual health in a man is sexual satisfaction, including making love, and having a good level of sexual knowledge and health. These are seen of as a power and as part of an ongoing developing process. The result of sex is intimacy and satisfaction.11

Men are proud of their sexual virility and masculinity. The principle of sexual health is being proud of one’s sexual functioning, having self-esteem focused on sexual desire and having good sexual functioning.11 According to them, a normal sex life is about having a normal penis, normal sexual functioning (an erection and ejaculation), normal sexual fantasies (aggressive and attractive sex) and how to make love well.

In fact, when the dysfunction occurred, the men felt disturbed, with a low sense of self-esteem and with a low spirit. They perceive sexual dysfunction as a primary need disturbance and this has a psychological effect. Dysfunction makes their life dangerous and this can change their wife’s response by 180 degrees. Finally, it hurts their integrity and self-esteem as a man and as a husband.

As a primary need, a healthy sexual life is a condition that increases one’s spirit and sense of life. However, when dysfunction occurs, it is like doomsday. According to the participants, they feel worthless, they have no spirit, they feel hopeless and they feel unhappiness after work because they have no functioning when it comes to giving satisfaction.

In other fact, there was one participant who was not bothered because they only experienced middle or light dysfunction. They only experienced early ejaculation and thus they can have a healthy sexual relationship.

Another participant perceived that sexual dysfunction is caused by age and getting older. It is a normal condition of the degenerative process. In theory, the peak age is around 30 years old. After that, the degenerative stage will occur. Physiological changes in the elderly regarding their sexual activity is gradual and shows vascular, hormonal and neurological aspects. There is still the assumption that chronic disease will weaken the sexual condition directly, impacting on the reproduction system and allows for the spurring on of psychogenic sexual dysfunction.

In fact, some of the participants explained that sex is not everything. Marriage is not just dependent on sex and being sexual is not a primary need. Three participants noted clearly they have sexual problems because of erectile dysfunction, early ejaculation and because they cannot give their partner satisfaction. However, marriage is not about sex and having sex. There are a lot of ways to give a love and attention (P3). Two other participants (P6 and P5) said that a good and high commitment within marriage is more important. They have made a promise to God, to give one another love, attention and by understanding each other as is necessary in life (P3, P6, P5).

Conclusion

Sex in a man’s life is perceived as both a primary and secondary need. Sexual dysfunction is perceived as an interference of a primary need, as having a psychological impact, decreasing the spirit and causing low self-esteem. Age is a cause of sexual dysfunction.

Ethical Clearance: The ethical approval for this study was granted by the IRB of the Nursing Faculty of Indonesia University, permit letter 1556/H2.F12.D/PDP.04.02/2011

Short Education Movies and Demonstration Methods Related to Elementary Student Wound Care Behavior

Erna Dwi Wahyuni, Vinda Kuswana Murti, Candra Panji Asmoro

Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

School-age children are susceptible to injuries that can cause cuts and potentially infection, but children’s knowledge of wound care is still lacking. The study aims were to analyze the influence of Short Education Movies (SEMs) and demonstration methods on the wound care of elementary students. The study was quasi-experimental with a control group pre- post-test design. A total of 40 out of 181 elementary students in Peneket and Sidorejo were taken as respondents through simple random sampling. The independent variable was Short Education Movies (SEMs) and demonstration methods. The dependent variables were knowledge, attitude and practical wound care. The data was collected using questionnaires and observations. The data was analyzed using the Wilcoxon signed rank test and the Mann Whitney U Test. The results showed that health education using the SEM and demonstration method can increase the knowledge (p=0.000), attitude (p=0.001) and practices (p=0.000) of the intervention group. The Mann Whitney test in the intervention group and the control group obtained the following results: knowledge (p=0.002), attitude (p=0.000) and practice (p=0.000). The application of SEM and the demonstration method is effective when applied to elementary students because it is easily understood.

Keywords: Short Education Movie, demonstration, injury, wound care

Introduction

A wound is a disruption of normal tissue continuity that is both structural and functional. Wounds can cause infection if not handled properly, so they need the best management from the start. School-age children don’t have good knowledge of wound care. The role of school-age children in providing first aid for their wounds greatly determines the continuation of wound healing.

The incidence rate of school-age child injury in northern Sweden is 2.4 per 100 children, with an annual incidence rate of 2.9 per 100 students in Norway. The incidence rate of injuries in Indonesia was 7.5% in 2007 and this has since increased to 8.2%. The Central Java province’s data about the prevalence of injuries and their causes shows that they are due to accidents by 40.1%, falling by 42.1%, being exposed to sharp objects by 6.7% and burning by 0.6%. The victims of minor injuries in 2015 ranged about 500 and in 2016, this ranged about 450. The prevalence of the usual causes of injury in school is falling to about 40.9%. According to Pertolongan Pertama untuk Anak Cara-Cara Praktis Menangani Kecelakaan dan Mengatasi Keadaan Darurat, injuries can cause infection in children of a low socioeconomic status. The incidence of infection can be prevented by the proper handling and intervention of the injuries. Health education about wound care can be done so then the children can treat any injuries that are experienced independently.

Health education is a form of intervention designed to help individuals and communities to improve their health by increasing their knowledge or by influencing their attitudes and practices. Learning through different demonstration methods can increase the student’s learning motivation. The learning method conducted using short films can increase creative thinking, strengthen visual understanding, provide an active role for the students and be effective in the wider context.
According to Piaget, children are at the stage of concrete operational development. They need a real learning situation where the method is used in demonstrations after getting the material using a short movie. However, research on learning using short films or Short Education Movies combined with demonstrations about the care of minor wounds has never existed until now.

The purpose of this study was to determine the effect of Short Education Movies and the demonstration method on the wound care behavior in school-age children.

Method

Study Design, Sampling and Variables: The study was a quasi-experimental pre-test post-test with a control group design. The research was conducted at an elementary school in Peneket and Sidorejo, Center Java. There were 40 out of 181 elementary students in Peneket and Sidorejo taken as the respondents through simple random sampling. The total sample used amounted to 40 respondents, consisting of 20 respondents in the intervention group and 20 respondents in the control group. There were 2 respondents from the control group who dropped out because they did not attend the post-test. The sample criteria consisted of the inclusion criteria, exclusion criteria and drop outs. The inclusion criteria in this study were children who were in the concrete operational stage at the age of 9-11 years. The exclusion criteria were students who did not attend the scheduled meeting, while the drop out criteria consisted of the respondents who did not complete the research activity and who thus resigned as respondents. The independent variable was the Short Education Movie (SEM) and demonstration method. The dependent variables were knowledge, attitude and practice wound care.

Instruments: The knowledge and attitude questionnaire guide was a modification of the Yuliana questionnaire. Observation sheets were used for the practice. The tools used were a Short Education Movie in the form of a video; it also included the tools and materials needed for wound care demonstration and the appropriate leaflets. The Short Education Movie provided contained the steps to treating minor injuries such as abrasions, burns, bruises and the 6 steps of hand washing.

Data Collection: In this study, the researcher used simple random sampling, which is where the researcher chooses the sample by giving an equal opportunity to all members of the population to be determined as a member of the sample. The selection of the respondents was done randomly using a lottery. The choice of the individuals to become members of the sample was really based on chance, in the sense of them all having the same opportunity. The selected students were then given an explanation of the research and they were given an informed consent sheet to ask for approval from their parents.

The study was conducted pre-test and post-test. In all of the groups, the pre-test was carried out by filling out a questionnaire on their knowledge and attitude before then practicing first aid on bruises, abrasions and burns. The intervention group was given health education by looking at the video and then the demonstration was accompanied by the facilitator. The interventions in the intervention group were carried out 2 times. The control group was given a placebo leaflet without any information about wound care or hand washing. Then the post-test was done in both groups in the same way as the pre-test. The study was conducted in December 2018.

Data Analysis: The data was analyzed using the Wilcoxon signed rank test and the Mann Whitney test with the level of significance $\alpha \leq 0.05$.

Results

Wilcoxon Signed Ranks Test $p = 0.000$ $p = 0.237$

Mann-Whitney U Test $p = 0.002$
Table 1 showed that there were differences in the knowledge between the intervention and control groups. The results of the Wilcoxon signed rank test in the intervention group showed p-value = 0.000, which means there was a difference in knowledge before and after the intervention. The results of the statistical tests done using the Wilcoxon signed rank test in the control group showed p-value = 0.237, which means there was no difference in the knowledge before and after giving the placebo leaflet. The Mann Whitney U Test result statistically showed that there was a significant difference between the post-test result in the intervention group and the control group.

Table 2: Statistical Results for Attitude

</table>

Table 3 showed that there were differences in practice between the intervention and control groups. The results of the Wilcoxon Signed Rank Test in the intervention group showed p-value = 0.000, which means that there was a difference between practice before and after the intervention. The results of the Wilcoxon Signed Rank Test in the control group showed p-value = 0.18, which means that there is no difference between the practice before and after the intervention. The Mann Whitney U Test result statistically showed that there was a significant difference between the practice in the post-test result in the intervention group compared to the control group.

Discussions

The influence of SEM and the Demonstration Method on Knowledge of Wound Care: The level of knowledge of the intervention group respondents in the pre-test was mostly in the sufficient category, and there were still those in the lower category. The results of the post-test focused on knowledge showed that more than half were in the good category and that none were in the lesser category. According to Metode Brainces terhadap Peningkatan Pengetahuan,Sikap, dan Praktik Perawatan Anak Usia Sekolah, the level of knowledge
of the students after being given health education was better than before being they had been given health education. Starting from giving the stimulus through vision, hearing, the child knows about the information and it is then processed in the brain so then they are able to recall the material. Based on this study, the majority of the respondents experienced an increase in knowledge but 2 of the respondents were found to have a steady level of knowledge. This is because of the ability to process information and because each child remembers the material differently. The two respondents who remained at the same level of knowledge were caused by them not focusing when the health education activities were given.

The control group in the pre-test for knowledge obtained the most data, which was in the sufficient category. After the post-test, it was still the same, namely in the sufficient category. There were 2 respondents from the control group who were declared as having dropped out because they did not attend the post-test. The control group had no increase in knowledge even though they had been given a leaflet. According to the study by Elvina, health education and leaflet administration could increase the knowledge of preventing asthma suffering in asthmatics. The results of this study were not in accordance with the previous studies. There was no difference in knowledge between the pre-test and post-test in the control group because the researcher gave the leaflet to the respondents without there being any information on injuries and wound care. The control group was not given any health education, and they were only given leaflets without any information about injuries. The content of the leaflet was only a question about whether there has ever been counseling provided about injuries, how to program the School Health Unit, and questions about the doctor.

The influence of SEM and the Demonstration Method on the Attitude to Wound Care: The results showed that not all of the respondents in the intervention group had a positive attitude in the pre-test. The intervention showed the results of an increase in the attitude of the respondents in the intervention group. The results of this study support the theory of Lawrence Green (1991) in which he states that health education can influence the predisposing factors involved, namely attitude, where the predisposing factor can lead to changes in a person’s behavior. Education is a system that has an influence on the formation of attitude because it can lay the foundation of understanding and moral concepts in individuals. The results of the control group showed that more than half of the respondents had a positive attitude in the pretest stage. The results of the post-test attitude in the control group showed that the respondents still had a negative attitude. The results in the control group were almost the same as those of the intervention group. The research by Maulana, stated that attitude is not innate and that it can be formed through experience. Health education using Short Education Movies can be given twice to provide effectiveness to the students in remembering the material provided. This study is in accordance with the previous studies regarding the effect of health education on attitude. However, when the intervention and control groups were compared, there was no difference. This is because attitudes are difficult to change in a short time. Changing an attitude takes a long time and repetitive intervention.

The factors that can affect the outcome of the data is the factor of the facilitator in stating that the communication was not adequate enough to deliver the information to the respondents. This is a weakness in this study.

The influence of SEM and the Demonstration Method on the Practice of Wound Care: The practical for the intervention group respondents, when the pretest time was obtained, showed that all of the intervention groups had fewer practice categories. The results of the intervention group’s post-test were mostly in the good category, as there was a good increase in the scores. The results of this study supported the theory of Lawrence Green (1991) which states that health education can influence predisposing factors, namely the practice where such predisposing factors can lead to changes in a person’s behavior. This study is consistent with research Sauerberger and Kawuriansari, who conveyed about health education that has a positive relationship with knowledge and practice (actions), where if knowledge and practice can be maintained it will lead to consistent behavior.

The control group showed there to be no difference in the pre-test and post-test values because the leaflets provided did not contain information about injuries. There were differences in the behavior of the intervention and control groups. According to Media Leaflet dalam Pembelajaran, they stated that the weaknesses of the leaflet media is that the media cannot stimulate sound effects and motion effects, and that they are easily
Leaflets are less attractive than movies. The researcher only provided leaflets without any information about injuries, so the leaflets contained only the effects of the placebo.

Conclusion

SEM and the demonstration method influences the increase in knowledge, attitude and practices of minor wound care in school-age children. The respondents, after being given the intervention, will get better care information so as to increase their knowledge. Although difficult attitudes can be changed in a short time, the results of the data showed that the intervention can improve the attitude of the respondents for the better. Practice can bring the respondents ‘real’ situations so then the respondents can see, hear and increase their skill at treating minor first aid injuries. Further researchers are advised to compare the effectiveness of the demonstration method combined with Short Education Movie media with more methods and media in order to obtain better health education methods for school-age children.

ABSTRACT

Differences in cooking techniques can affect the glycemic level of rice. The aim of this study was to identify the differences in the blood glucose levels of people with DM after consuming rice cooked using either the steamed method or magicom. This study used a pre-experimental design with one group pre-post test with a repeated measure, which was then compared with the difference in fasting glucose levels with a 2-hour post-prandial glucose level. The sample consisted of 24 type 2 DM patients. The independent variable was the cooking method and the dependent variable was the blood glucose level. The data collection was conducted using an observation and a questionnaire. The data analysis was done using a paired t test with a significance level of 0.05. The results of the independent sample t-test analysis obtained a value of \( t = -1.583 \) and \( p = 0.128 \), so there was found to be no significant difference between the fasting blood glucose levels and 2 hours post-prandial. The results of the descriptive comparison analysis showed that there were differences in the glucose levels between consuming rice cooked using either the steamed or magicom method of 18.304 gr / dl with \( p = 0.128 \). Rice cooked with the steamed method is more likely not to increase the blood glucose levels than rice cooked with mMagicom. DM patients should consume rice that has not been heated for a long time.

Keywords: Blood Glucose Level, Steam Method, mMagicom, Diabetes Mellitus Tipe 2

Introduction

The cultural change related to cooking rice is going from steamed rice to using a rice cooker. There has also been a shift in the culture of eating between those who previously consumed cold rice from wakul to those who are now consuming hot rice from rice cookers. This causes a problem because hot rice has a higher glycemic index (GI) than cold rice. The consumption of food with a high GI can continuously increase th insulin resistance to glucose, causing diabetes mellitus. So far there have been no studies explaining the differences between the effects of the different rice cooking methods on the increasing blood glucose levels.

The International Diabetes Federation (IDF) estimates that 415 million adults worldwide are suffering from type 2 Diabetes Mellitus (DM). This figure is expected to continue to increase to 640 million in 2040. In Indonesia, the proportion of DM is 6.9 percent among the non-communicable diseases. The prevalence of DM is 1.5 percent, whereas East Java has a higher prevalence than the national average of 2.1 percent.

Technological advances in food cooking not only provide convenience but they also cause various other impacts on human health. One technology that is currently widely used by the public is the method of cooking rice with a rice cooker. The shift in culture to cooking rice from steamed rice is a rice cooker, and there has also been a shift in the culture of eating from those who previously consumed cold rice from a wakul to those eating hot (warm) rice from rice cookers. This causes a problem because hot rice has a higher glycemic index (GI) than cold rice. The continuous consumption of high glycemic index foods can increase the insulin resistance to glucose and cause DM. So far there have been no
studies explaining the differences in the effect of rice cooking methods on an increase in blood glucose levels.

One of the important goals of medical nutrition therapy in people with DM is to achieve and maintain blood glucose levels in the normal or near normal range. Effective nutrition interventions are very important to achieve better glycemic control and thus reduce the risk of diabetes complications while improving quality of life.\textsuperscript{8,9} Carbohydrate diets are the most important determinant of postprandial glucose levels and they are the main nutritional component of foods consumed by diabetics. Therefore, knowing the pattern of glucose response after consuming carbohydrate foods can help to identify the best foods that can be consumed daily.\textsuperscript{8-10}

The glycemic index of a food is influenced by several factors, one of which is the method of food processing, such as heating (steaming, boiling, frying) and milling (shoveling) to reduce the particle size. The processing method can change the physicochemical properties of food. Heating starch with excessive water results in starch undergoing gelatinization and structural changes. Reheating and cooling the starch that has undergone gelatinization also changes the structure of the starch further, which leads to the formation of new insoluble crystals in the form of terrogrograsi starch, which causes changes in the IG values.\textsuperscript{11-14} The purpose of this study was to identify differences in the blood glucose levels of people with DM after consuming rice cooked with the steamed and magicom methods.

Method\textsuperscript{15,16}

This study used a pre-experiment design with the pre-post-test group repeated measure. The population consisted of 95 people with type 2 diabetes mellitus and the samples involved in this study totaled 24 people. The selection of the respondents was done using the purposive sampling method according to the inclusion and exclusion criteria. The inclusion criteria specified were Type 2 DM patients with a minimum elementary school background, who had had the disease for 6 months and who were actively engaged in diabetes mellitus club activities. The independent variable in the study was rice cooking with both the steamed and rice magicom methods. The dependent variables were fasting blood glucose levels and 2 prandial post-hours.

The observation of the blood glucose levels was done with an On Call device. The characteristic data of the respondents was collected through a questionnaire developed from the patient’s medical report data. The respondents, prior to this, had provided informed consent. Before the measurement was done, the patient was asked to fast for 6 - 8 hours beforehand, and then the measurement as done before and 2 hours after eating rice post-prandial (PP)

The collected data was analyzed using descriptive and inferential statistics and a paired t test at a significance level of 0.05.

Result

This study showed the respondent’s characteristics in terms of gender, the number of complications related to the disease, how long they had been suffering with DM, their education level, working experience, hospitalization history and if they were regularly taking their medicine.

Based on the results of the t-test for the Equality of Means analysis, it was found that there were only differences in the glucose levels between the respondents who consumed rice cooked with the steamed and magicom methods respectively. There were differences in the glucose levels of 18,3014 gr/dl with p = 0.128, meaning that for the blood glucose levels for these 2 groups, it was stated as not being significantly different.

Discussion

There were no differences in the fasting blood glucose levels and 2 hours pp in the type 2 DM patients in the Diabetes Mellitus Club of Dr. Soegiri Hospital Lamongan. They consumed good rice wraps, used the method of cooking steamed rice and they also used a rice cooker. However, from the t-test results for the Equality of Means analysis, the steamed method and the magicom method were not significantly different. This result can be influenced by the broad cross-sectional area being wider than the cross section area. The heating is faster and more evenly distributed, so the time needed is shorter than the rice cooker method.

The prevention of DM can be done in three ways, primary, secondary and tertiary. Primary prevention is aimed at preventing diabetes. Primary prevention can be done by having a balanced diet, regular exercise, maintaining a normal weight, getting enough sleep, avoiding stress and avoiding drugs that cause diabetes. Secondary prevention aims at making sure that the existing DM does not cause complications related to other diseases and that it eliminates any symptoms and complaints of disease. Prevention Secondary diabetes is carried out with a balanced and healthy diet, maintaining a normal body weight, monitoring blood sugar, and exercising regularly. Prevention of tertiary diabetes aims to prevent the occurrence of defects such as blindness, kidney failure, and stroke.\cite{14,17,19}

Based on the opinion of Rimbawa and Siagian (2004), long heating can increase the size of starch granules. Where the expanding granule has been increased, the free starch molecule is very easily digested. This is because the digestive enzymes of starch in the small intestine have a wider surface to connect with to the enzyme, eventually resulting in a rapid increase in blood sugar levels.\cite{20,21}
In terms of the rice cooking method, the steamed method, when compared with the magicom method, showed there be no difference when analyzed using the Equality of Means t test even though descriptively there were differences in the glucose levels of 21.791 gr/dl. The pairwise comparison test stated that it was not significantly different. This is because one of the times used to cook the rice between the steamed and magicom methods was only 2 minutes different. Besides that, all of the liquid was entirely absorbed in the rice seeds when compared with the steamed method where there was liquid starch which is shed from the water in the cage. It is possible that this result distinguishes the rice glycemic index between the various methods.

In accordance with the research of Daradakumbura, Wejesinghe and Prassantha (2013) upon examining the rice cooked using the rice cooker, steamed and cider methods, it was found that there was no significant difference in the glycemic index level, although descriptively in the rice cooker method, the difference in the glucose levels was higher. This is possibly because it is based on the fact that the process of putting it in takes about 2 minutes. Another result was that the rice cooked with a rice cooker is consumed immediately, so if the rice is left to heat in a few hours, this will increase the glycemic index of the rice.

In type 2 DM, the patients obtained 37.5% glucose levels that were still above normal, where their fasting glucose levels were still > 140 mg/dl. This also relates to a decrease in pancreatic organ function because 33.3% are retired, so their pancreatic function experiences a decrease due to the aging process. With these conditions, DM education needs to be carried out to support behavior change and to improve the understanding of the disease.

The DM education material covers the course of DM, the need for DM control, the complications of DM and the risks, pharmacological and non-pharmacological therapy, the interaction of food, activities and drugs, ways of independent blood glucose monitoring, the importance of physical exercise, foot care and how to deal with hypoglycemia. The limitations of this study were the low participation rate of DM patients and social support in health promotion activities and the difficulty of controlling confounding variables including stress factors.

**Conclusion**

Rice cooked using the steamed method is more likely not to increase the blood glucose levels than rice cooked with magicom. It is recommended for diabetic patients to lessen their consumption of rice that has been heated for a long time, by releasing the electricity flow of magicom. Steamed rice is better than the rice cooker method at maintaining blood glucose stability. The research implications are that patients need to know the method of cooking rice that is good for DM patients. There needs to be a new method of health education and family support to control blood glucose levels.

Factors Affecting the Nurse’s Caring Behaviors in Surabaya Jemursari Islamic Hospital

Yanis Kartini¹, Ayu Alfa Lavia Putri², Nursalam³

¹Doctoral Degree Programs, Faculty of Nursing, Universitas Airlangga & Lecturer of Faculty of Nursing and midwifery–Universitas Nahdatul Ulama Surabaya Indonesia; ²Student, Faculty of Nursing and Midwifery–Universitas Nahdlatul Ulama Surabaya, Indonesia; ³Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Caring is a central nursing practice. However, many nurses are still found to have less care for their patients’ condition. Some of them are still inhospitable, harsh and less sensitive to the patient’s condition. This study aimed to analyze the factors affecting the nurse’s caring behavior in hospital. The design of this study was descriptive and observational, done using the cross-sectional approach. This study involved the population of all nurses working in the medical and surgical rooms of Surabaya Jemursari Islamic Hospital, totaling 44 nurses. The sample of 40 respondents was chosen using the simple random sampling technique. The independent variable was the nurse’s individual characteristics: age, sex, level of education and emotional intelligence. The dependent variable was the nurse’s caring behavior. A questionnaire was used to collect the data which was analyzed using the Chi-square Test. The nurse’s individual characteristics, namely age, sex, and level of education, did not affect the nurse’s caring behaviors (ρ ≥ α: 0.05), whereas emotional intelligence affected the nurse’s caring behaviors (ρ = 0.00 ≤ α). The factor affecting the nurse’s caring behavior was emotional intelligence. Therefore, hospitals need to provide nurses with training for better self-management and caring behavior.

Keywords: caring, emotional intelligence, empathy, self-management, self-control

Introduction

Caring is the trend in this era because the current wave of healthcare marketing has shifted from excellent service based on standard operating procedures or minimum service standard to care with character, which sets the values of caring as the principles of healthcare.¹,² Caring is a basic concept of nursing.³ High quality nursing care supported with good caring can affect the quality of healthcare because the caring performed by nurses may influence patient satisfaction.¹,⁴ In fact, many nurses are still found to have a lack of caring for the patient’s condition while showing their inhospitality, anger, unfriendliness, unresponsiveness to the client’s complaints and poor communication with their clients. Among the 10 people obtained through the interviews in the preliminary data stage, it showed that 7 people complained about the nurse’s behavior. They stated that some of the nurses showed inhospitality, that they ignored the complaints from the patient’s family and that they gave less of an explanation and information when performing nursing care. This condition may affect the healing process and patient satisfaction.⁵

The research conducted by Koll et al claimed that the nurse’s skills and care about the patient’s privacy were the satisfying factors for the patients.⁵ The research conducted by Abdulrouf et al stated that there was an effect of perceived disconfirmation consisting of reliability, assurance, tangibility, empathy and responsiveness on patient satisfaction in RSI Sultan Agung Semarang.⁶ The patients need nurses who listen to their complaints willingly, who share their feelings and who give suggestions with care. In addition, they need nurses who make frequent visits voluntarily, who

Faculty of Nursing, Universitas Airlangga
Email: yanis.kartini-2018@fkp.unair.ac.id
ask about the patient’s condition and feelings, and who give clear and complete information about all actions done to the patients.

Caring behaviors are actions that are concerned with the well-being of a patient, such as sensitivity, comforting, attentive listening, honesty and nonjudgmental acceptance. Caring behaviors are affected by several factors, such as the nurse’s and patient’s perception, age, sex and so forth.

Based on these problems, the researchers are interested in investigating the factors affecting the caring behavior of the nurses working in Surabaya Jemursari Islamic Hospital. The factors being investigated were the individual characteristics comprising age, sex, level of education and emotional intelligence.

**Method**

The design of this study was analytical and observational done using a cross-sectional approach. The population involved in this study was all of the nurses and clients hospitalized in the medical and surgical room of Surabaya Jemursari Islamic Hospital. The population comprised of all nurses working in the medical and surgical room of the above stated hospital, totaling 44 people in which 40 respondents were chosen as the samples using simple random sampling technique. The independent variables comprised of the age, sex, level of education, and emotional intelligence of the nurses, whereas the dependent variable was the nurses’ caring behavior.

The independent variables comprised of age, sex, level of education and the emotional intelligence of the nurses, whereas the dependent variable was the nurses’ caring behavior.

This study used a questionnaire as the instrument to collect the data. The data of the independent variables, such as age, sex, level of education and emotional intelligence, was filled in by the nurses. Emotional intelligence refers to the dimensions of emotional intelligence developed by Goleman. The questionnaire consisted of 40 statements, comprising of 8 statements about emotion recognition, 8 statements about emotion management, 8 statements about self-motivation, 8 statements about empathy, and 8 statements about building a relationship with others. Moreover, a Likert scale 1-4 was used to score the answers. The scoring criteria for the positive statements was as follows: score 1 was very inappropriate, score 2 was inappropriate, score 3 was appropriate and score 4 was very appropriate. For the negative statements, scoring was done the other way around. This questionnaire has been tested resulting in the value of validity item (rit) being 0.332-0.665 and the value of Cronbach’s alpha was 0.893.

The data about the nurse’s caring behavior was measured based on the patient’s perception after the patients received nursing care 2 x 24 hours at minimum. Each nurse was judged based on his/her caring behavior by three former patients. The score for caring behavior was the average score accumulated from the three patients. The questionnaire used to score caring was based on Watson’s ten carative factors. The questionnaire about caring was adopted from the Caring Behaviors Inventory (CBI). This questionnaire contained 42 items and it had been tested resulting in the value of validity item (rit) of 0.155-0.696. The value of Cronbach’s alpha was 0.934. This questionnaire was based on Watson’s ten carative factors. This instrument had 5 dimensions, namely 12 statements about respectful deference through to the other 12 statements about the assurance of a human presence, 9 statements about positive connectedness, 5 statements about professional knowledge and skill and 4 statements about attentiveness to the other’s experience. All statements have been made in the positive form. The questionnaire used in this study was a Likert scale of 1 - 4. Score 1 is very inappropriate, score 2 is inappropriate, score 3 is appropriate and score 4 is very appropriate.

The preliminary data was analyzed using univariate analysis using percentages. Further, they were analyzed using the Chi-square test with a significance level of α = 0.05.

**Results**

**Nurse’s Characteristics:** The nurse’s characteristics comprised of age, sex, level of education and emotional intelligence have been shown in Table 1. Based on Table 1, most of the respondents (75%) were females, nearly all were (80%) > 25 years old, most (67.5%) had graduated with a Diploma 3 and most (60%) had high emotional intelligence.

Factors of the Nurse’s Characteristics Affecting their Caring Behaviors: The correlation between sex, age, level of education, emotional intelligence and the nurse’s caring behavior was presented in Table 3. Based on Table 3 for the sex factor, for the 10 male nurses, most of them (70%) had good caring behaviors. Among the female nurses, half of them (50%) showed good caring behavior, whereas the other half had poor caring behavior. Furthermore, the Chi-square test obtained the result that $p = 0.464 > \alpha (0.05)$, which meant that $H_0$ was accepted. There was no difference between the caring behaviors possessed by either the male or female nurses.

Based on Table 3 for the age factor, it was illustrated that among the 8 nurses <= 25 years old, most of them (75%) had good caring behavior. Of the nurses >25 years old, half of them (50%) also possessed good caring behavior, whereas the other half had poor caring behavior. Moreover, the Chi-square test obtained the result that $p = 0.258 > \alpha (0.05)$, which meant that $H_0$ was accepted. There was no difference found between the caring behaviors possessed by nurses in late adolescence (<=25 years old) and those aged >25 years (in early adulthood).

Based on Table 3, the level of education factor showed that among the 13 nurses who graduated from a Diploma 3 Nursing Program, most of them (54%) had poor caring behavior. For the nurses who graduated from the Ners Profession Program, most of them (59.3%) had good caring behaviors. The Chi-square test resulted in $p = 0.435 > \alpha (0.05)$, which meant that $H_0$ was accepted. There was found to be no difference between the caring behaviors possessed by the nurses who had graduated from D3 Nursing and those who had graduated from the Ners Profession Program.

The results related to the emotional intelligence factor illustrated that among the 16 nurses with lotional intelligence, nearly all of them (87.5) had poor caring behavior, whereas among the 24 nurses with high emotional intelligence, nearly all showed good caring behavior. The Chi-square test obtained a result of $p = 0.00 < \alpha (0.05)$, which meant that $H_0$ was rejected. There was a difference in the caring behaviors possessed by the nurses with both high and low emotional intelligence. The nurses with high emotional intelligence had a chance of showing good caring behavior 35 times more when compared to those with low emotional intelligence (OR = 35.00).

Discussion

Sex has no correlation with caring behavior. The result of the Chi-square test showed that p = 0.464 describes that there is no difference in the caring behaviors possessed by male and female nurses, despite the tendency of the male nurses having better caring behaviors than the females. This opposes the theory claiming that women have a maternal instinct, a soul for love and a mother’s affection for her family.12

Age also has no correlation with caring behavior (p = 0.258). In fact, the nurses aged 25 years or under and those aged above 25 years showed no difference in performing caring behaviors, even though those in late adolescence (<= 25 years) had a bigger opportunity to possess better caring behaviors than those aged above 25 (in early adulthood). The average age of the nurses working in Surabaya Jemursari Islamic Hospital was 30 years, in which the lowest age was 20 and the highest age was 35 years. All of the respondents were classified as being of a high productive age. BPS (Statistics Indonesia) differentiates people in Indonesia into 2 categories. The first group was for people of a high productive age (15 – 49 years), whereas the second refers to those of a productive age (50 – 64 years). At a high productive age, a person has the ability to make both products and services. To a nurse, the services will be better if they are balanced with good caring behavior. This is because it gives the patients satisfaction.8

Similarly, level of education does not affect caring behavior. No difference in the caring behaviors was found between the nurses holding a Diploma level 3 for Nursing and those who had graduated from the Ners program (p = 0.435). It is not in line with the results of the research conducted by Sunardi (2014), who stated that a higher level of education provides better caring behavior. Nurses possessing high education have careful considerations because of their wider knowledge and perception compared to those with a lower level of education. Higher education will correlate positively with the nurse’s caring behaviors.12

Emotional intelligence has a correlation with the nurse’s caring behavior (p = 0.000). Table 65.10 shows that among the 24 nurses who have high emotional intelligence, nearly all of them (83.3%) had good caring behaviors. High emotional intelligence covers the abilities of knowing one’s own emotions, controlling their
emotions, self-motivating, supporting and understanding other people’s emotions as well as maintaining a relationship with others. These are important abilities which must be possessed by each individual, especially nurses.\(^9\) An individual who has the ability to know his/her emotions will have more of an ability to know and anticipate how his/her actions influence others. A nurse with good sensitivity will be more sensitive to the needs of other people in turn. A nurse who has the ability to understand his/her own feelings will have more of an ability to control his/her own emotions so then he/she can perform actions and communications correctly and full of care. The nurse’s unawareness of being frustrated, disgusted, annoyed, angry or depressed resulting from a patient’s condition emerges from the inability to control their emotions. It may give negative impacts to patient. Good understanding and self-emotion acceptance will enable a nurse to understand the differences and uniqueness of their patients.\(^6\)

The nurse’s ability to understand and support other people’s emotion will create a nurse-patient relationship with an open atmosphere, where they trust and understand each other and share experiences between the nurse and his/her patient. Emotional intelligence is highly needed by a nurse for good interactions. During an interaction, a nurse must have empathy, control their emotions and know his/her and other people’s emotions to trust and help each other. By offering empathy to their patients, a nurse has the ability to give them affection in every decision and action that is taken, which is an important aspect of nursing care. Developing a relationship of trusting and helping each other is very important in transpersonal caring. Nursing care requires the figure of a nurse who has high emotional intelligence. From the patient’s perception, nursing care performed with perfect skills without good emotions is inadequate; it causes dissatisfaction. Caring behaviors that are supported by good emotional intelligence will create the healthcare expected by the patients.\(^9\)

**Conclusion**

The factor affecting the nurse’s caring behaviors was emotional intelligence. The nurse’s characteristics such as age, sex, and level of education did not affect the nurse’s caring behaviors. The nurses need self-training for better emotion control by recognizing and managing their emotions, by having the motivation to do their best, by developing empathy, by maintaining a relationship with others, and by learning from others who have succeeded in controlling their emotions.

The management of the hospital needs to carry out training programs in order for the nurses to manage their self-control and to provide their services with sincerity. **Ethical Clearance:** This research proposal was ethically reviewed by the research ethics committee of Surabaya Jemursari Islamic Hospital (ref: Certificate No. 00010/KEPK-RSI JS/II/2018) and it was certified as being ethically eligible. This research was beneficial. Each candidate received a sheet of information explaining the nature, reasons behind and volunteerism aspects of this research, as well as an informed consent and complaint form to provide the respondents’ confidentiality and code number.

**Source of Funding:** No funding support was provided for this research and the authors used self funding to conduct the research.

**Conflict of Interest:** The authors have declared there to be no conflict of interest within this publication.

ABSTRACT

The identification of behavioral and emotional disorders of children with special needs in inclusive classroom learning by using the important health belief model approach is carried out by shadow teachers before starting learning. This is used to regulate and place children into different learning systems by adjusting for their needs in relation to meeting the learning outcomes. This study aims to explore the meaning of the shadow teacher’s experience in identifying the behavioral and emotional problems that occur when accompanying children with special needs at following along with the learning in inclusive classes with the health belief model approach. This study was a phenomenology qualitative study that used a purposive sampling technique. The data analysis used the Interpretative Phenomenology Analysis approach. Through in-depth interviews, observations and assistance from the note file, the population involved 7 participants who produced five themes. Three sub-themes were identified for perceived susceptibility: (1) lack of adherence to orders, (2) aggressive behavior, (3) difficulty expressing desires. Two sub-themes identified on perceived severity: (1) independence, (3) stigma. This study encourages the improvement of competence, especially the implementation of assessments when dealing with children with special needs, concerning the provision of adequate facilities and arrangements for inclusive learning and to raise public awareness of the acceptance of children with special needs in the community.

Keywords: Health Belief Model, Behavior, Children Special Needs

Introduction

The right of children with special needs to get formal education is like that of other normal children, thus encouraging the government to design formal schools with inclusive classes. Entry into inclusive schools is an important moment and a transition process for the social development of children with special needs. This is because it can produce assertive behavior and the identification of intellectual abilities. Behavior becomes very important before starting the learning process.¹ The biggest challenge that must be faced by companion teachers is the demand of meeting the achievements of learning for children with special needs, even without learning guidelines.² Not only is it required to be able to create an atmosphere so then the children with special needs feel that they are not the only ones who need special attention, but they also must be able to increase their potential, feel like those who are normal, feel accepted and valued in a social environment and able to provide motivation in children with special needs to allow them to be able to get a picture of themselves and live independently.²,⁴

During their participation in inclusive classes, children with special needs often experience various obstacles. Various barriers for children with special needs have been identified, including decreased physical condition, intellectual abilities, communication skills and decreased social and emotional conditions. There is a tendency towards them being opposing and solitary, and appearing different from normal children.⁵ The emergence of predominantly female (internalized and depressed) behavioral problems and externalizing (aggressive and hyperactive) behaviors dominated by boys will have an impact on social adaptation problems and academic achievement.⁶,⁷
Time allocation is very important in the learning of children with special needs. The least the accompanying teacher must spend more time on individual learning, small group teaching and cooperative learning. Accompanying teachers often experience burnout due to the tasks that must be carried out. It is very complex; besides educating, they are also teaching, guiding, directing, training and evaluating their development. The purpose of the study was to explore the meaning within the shadow teacher’s experience in identifying the behavioral and emotional problems that occur when accompanying children with special needs to follow learning in inclusive classes with the health belief model approach.

Method

This study used the Phenomenology Interpretive Approach. This was chosen to explore the experience of companion teachers in identifying the behavior of children with special needs while participating in inclusive learning through the health belief model approach. The pattern follows a reflection of the important themes that describe the phenomenon that occurs in children with special needs through writing that connects between the categories and orientation in the event experienced. We paid attention to the balance of the research theme by looking at each part as a whole.9,10

This technique used purposive sampling that met the inclusion criteria, namely that the participants were still active and recorded as the accompanying teacher, that they had at least 1 year of experience of accompanying children with special needs, that they were aged 35 - 50 years with a family with the consideration that individuals have entered the responsibility stage and who were willing to participate and share experiences as they assist children with special needs. A total of 9 participants were willing to become respondents, and only 7 participants were interviewed because they also achieved data saturation. All of the participants were interviewed and observed in two rounds by the researcher directly, using a tool in the form of field notes and a data recorder with a duration of 30 - 40 minutes.

This study collected the data through semi-structured interviews individually in March 2017. The data collection and data verification stages were carried out for 5 months. The interviews were recorded using a tape recorder, transcribed word for word and any nonverbal responses were recorded using note files and validated again with the participants as well as listening to the recording again. The questions in the interview included behaviors that describe the problems that occur in children with special needs in terms of seriousness, risk, the benefits of the actions given and any obstacles when assisting the children with special needs in participating in inclusive classroom learning.

The data analysis used the Interpretative Phenomenology Analysis approach. Following the guidelines for the data analysis from the interviews and field notes, the data was read carefully and repeatedly. The themes were interpreted to gain a sense of understanding and involvement, especially after being confronted with the data in the field notes. The validity of this research was evaluated using the concept of reliability, dependability, dependability and transferability.

Results

Seven out of the 9 participants took part in this study. The age range of the respondents was 35 - 50 years old with 1 male respondent and 6 female respondents with the special needs children being between 2 - 9 years old. Descriptions of the behavior of children with special needs can be explained by using the approach of the health belief model consisting of three sub-themes identified for perceived susceptibility: (1) less obedient at following orders, (2) aggressive behavior and (3) difficulty expressing desire. Two sub-themes were identified for perceived severity: (1) independence, (3) stigma.

Four categories were found in the children with special needs who had difficulty following orders and needed firmness, namely “Difficulty understanding instructions”, “Need a short order, clear and repeated”, “Orders must be written” and “there is a system of reward and punishment”:

“...He did not comply with the rules… we tried putting an understanding into them but it is too difficult” (P3)

“Autistic child indeed obey commands so long as it is as short as possible and as clear as possible and repeats” (P4).

“I made a program to make a schedule by the hour as soon… such as when studying in class. I put the paper form on his desk ‘pee is not in the garden, pee in the bathroom’” (P6)
“...he played with it and so we must take the cellphone. We have a reward and punishment system. First we might reprimand them and after the punishment, we give them an explanation” (P2)

There were three categories for the children with special needs who experience aggressive behavior.

“...sitting straight “yes” This (holding hands) know that he was immediately hit on the chest” (P6)

“His son is getting bigger and I am also a woman whose strength is not strong, sir. What is holding, yes, I bounced automatically…” (P5)

“...they behave like it is right… tantrums that yes, the angry autistic child was very bad indeed” (P1)

There were three categories found when the child expresses their heart:

“If it’s time to go to the library ... it’s not good. He is sometimes angry, sir, angry until he bangs on the door until sometimes he is hitting himself.” (P5)

“He wants something but he doesn’t want to say, he just approaches it” (P1)

Three categories were found for children with special needs whose lives depend on others:

“I have a very good voice, I taught tutoring.” At that time, my mind was like that” (P1)

“Parents who are protective of their child means that they are not allowed to do it themselves. Everything is done by their parents” (P2)

“Their enthusiasm is extraordinary, finally they are able to perform it is truly extraordinary” (P7)

There were two categories found in children with special needs that experience discrimination:

“People who do not understand say that such children should be ostracized and said that crazy person” (P3)

“Children with intellectual disruption… his social factors will also be disrupted, sometimes his treatment is unfair” (P2)

**Discussion**

This study resulted in five main themes related to the risks experienced by children with special needs that can be identified by the teacher assisting the children with special needs. The first theme is the difficulty of obeying orders. The accompanying teacher of children with special needs feels that children with special needs have difficulty understanding the instructions given. They must repeat the sentences and make sure that the command sentences are very short and clear. Concerning the difficulties obeying orders, there is a tendency for children with special needs not to obey rules or orders, which means that children with special needs try to avoid assignments. Various strategies and efforts need to be made by the accompanying teacher so then the children with special needs are obedient to the command.

Children with special needs to obey orders. It is necessary to form clear, strict orders and avoid multiple interpretations and orders would might be obeyed by children with special needs when only one specific command was given without any interpretation. The order would be followed by the children with special needs as the orders do not contain multiple choices and are given repeatedly. Companion teachers should directly correct destructive behavior to make a list of daily activities and to involve their parents in giving instructions so then children with special needs can learn to be obedient.

The participants agreed that children with special needs often experience aggressive behavior especially when experiencing tantrums, and even up to the point of attacking people. This behavior arises as a result of a failure to fulfill their desires because the language that is often used is non-verbal, so it is difficult to understand. Some of the aggressive behaviors in mentally disabled children where this behavior is the most common is shouting at everyone, which often disturbs other students who are considered weak, speaking disrespectfully to everyone, disobeying the rules at school and at home, and often swearing at everyone. The accompanying teacher must work with their parents to prevent challenging behaviors in children with special needs through self-assessment programs.

Non-verbal language is always used to express the desires of children with special needs. However, because of the interference in focusing, children with
special needs have difficulty expressing what they want. The results showed that to express desire, children with special needs often beat themselves, bang on doors and approach the desired target without saying anything. Children who have difficulty expressing their desires have Nonverbal Learning Disorders (NLD) with the characteristic of being unable to develop in the fields of social competence, academic performance, visual spatial ability, motor coordination and emotional functions. The introduction of letters from an early age is an effective means of language recognition in children with special needs.

This problem becomes very serious. This is because children with special needs are very dependent on others so they have difficulties when it comes to living independently. Some accompanying teachers agree that children with special needs are very dependent on others because of the difficulties of living independently. The results of the study show that children with special needs are always a burden on others, that they have difficulty doing things themselves but that when they are able to do good, they are extraordinary. The factors that affect children when it comes to being less able to be independent are the lack of vocabulary until the teacher trains them to understand conversations in maintaining learning involvement, behavior and motivation when completing tasks. Their parents are very important; this is first and foremost for children with special needs because it becomes the foundation from which to fulfill their needs to allow them to practice independence.

Stigma is a serious threat for children with special needs. Stigma arises because of the existence of prejudice and because of the poor assessment of children with special needs. They lose their identity as human beings who have dignity and a position in society. Children with special needs are children who have mental disorders that are often treated unfairly. The initial response when finding out that their child was born with a disability condition was that the parents refused their presence as if there was an abundant disaster. But the family members are not the same in responding to the presence of siblings who have disabilities. There are those who accept and those who refuse. Some parents blame themselves and experience severe psychosocial problems. The seclusion of children with special needs by the community means that the children with special needs lack opportunities to socialize. The result of the stigmatization of society is that children with special needs experience social constraints that have an impact on the atmosphere of feeling marginalized by community groups.

**Conclusion**

Difficulty in understanding orders, behaving aggressively and expressing the desires experienced by the children with special needs are the risks that must be experienced as they accompany mental emotional disturbances that have a serious impact on independence and exclusion in the community. This finding can inspire companion teachers to prepare children with special needs when attending inclusion class learning through self-oriented teaching to allow them to be able to meet their own needs without the assistance of other people and for them to able to socialize in the community. Besides that, it is also necessary to prepare the community to be able to accept the existence of children with special needs in the surrounding environment so then they can socialize with their peers without discrimination.

Analysis of Factors Related to The Mother’s Behavior to Increase Breastmilk Production

Retnayu Pradanie¹, Aria Aulia Nastiti¹, Thaliah Jihan¹
¹Faculty of Nursing Universitas Airlangga Surabaya Indonesia

ABSTRACT

The coverage of exclusive breastfeeding in Indonesia has not reached the national target set by the government. Problems that may inhibit exclusive breastfeeding include insufficient breast milk production. The purpose of this study was to analyze the factors related to maternal behavior in facilitating the production of breast milk based on the precede-proceed model. This study used a descriptive analytical design with a cross-sectional approach. The respondents consisted of 143 mothers collected with cluster sampling. The dependent variable in this research was the mother’s behavior in facilitating breast milk production. The independent variables in this research were knowledge, attitude, culture, the availability of health facilities, family support and health worker support. The data was collected using questionnaires and analyzed using Spearman rho’ with a significance level of α≤ 0.05. The results showed that almost all of the factors had a significant correlation with the mother’s behavior in facilitating breast milk production (knowledge p=0.039, attitude p=0.013, culture p=0.024, health facilities availability p=0.023, family support p=0.000). The factor of health worker support showed as having no correlation with the mother’s behavior in facilitating breast milk production (p=0.177). It is expected that the health workers at public health centers should increase their supports to mothers and their families about exclusive breastfeeding.

Keywords: breastfeeding, breastmilk production, precede-proceed model.

Introduction

The mother’s awareness of the importance of exclusive breastfeeding is able to increase the coverage of exclusive breastfeeding in Indonesia. Many women stop breastfeeding their babies because they think that their breast milk amount is insufficient to meet their baby’s needs. This phenomenon is in line with the research that showed that 20% of breastfeeding mothers stop breastfed due to the perception of having less breastmilk production, periods of vulnerability for breastfeeding cessation, reasons for breastfeeding cessation, and the association between predelivery intentions and breastfeeding behaviors. STUDY DESIGN Using 2 years (2000 and 2001)

Based on the Surabaya City Health Profile, there is one area that showed a significant decline in exclusive breastfeeding coverage over the last 3 years. The exclusive breastfeeding coverage in this area only reached 43.53% in 2015. This is precisely inversely proportional to the coverage of exclusive breastfeeding in Indonesia, which reached 55.7%. The exclusive breastfeeding coverage in Surabaya also increased by 60.52% in 2012, by 64.33% in 2014 and in 2016 this increased to 65.10%. The coverage of exclusive breastfeeding in Indonesia has indeed increased but it is still very far from the target set by the government nationally, which is 80% of the number of babies in Indonesia. Based on preliminary studies conducted in the area, only 21 out of 78 infants aged 0 - 6 months who exclusively breastfed, and 9 out of 10 mothers stated that they only produce less breastmilk. It can thus be concluded that 90% of breastfeeding mothers experience problems with less breastmilk production.

Babies who do not breast feed tend to be easily at risk of infection or disease. The impact of not exclusive breastfeeding concerning infants includes indigestion,
impaired growth, an increased risk of morbidity in infants and nutritional disorders, including being at risk of aggravating ARI and diarrhea. Mothers who understand the importance of exclusive breastfeeding for their babies will try to improve and facilitate their breast milk production. Consuming traditional herbal medicines such as katuk leaves (*Sauropus androgynous*) or green vegetables and nuts are some common behaviors in the mothers in Indonesia when trying to increase breastmilk production.

The mother’s behavior is a kind of formed behavior that could be influenced by predisposing, supporting and driving factors. Based on the theory of Precede-Proceed by Lawrence Green, a person’s behavior can be concluded to be influenced by knowledge, attitudes, traditions or culture, family support, the availability of health facilities and the performance of health workers. This study is focused on analyzing the factors of knowledge, attitudes, culture, the availability of health facilities, family support and health worker support, which can influence the behavior of the mothers in facilitating the production of breast milk based on the theory of the Precede-Proceed Model.

### Method

This study used descriptive analysis with a cross-sectional approach. The research was conducted at one of the Health Centers in Surabaya, during June - July 2018. The population in this study consisted of 228 nursing mothers. The sample consisted of 143 mothers who had problems with breast milk production carried out by cluster sampling.

The dependent variable in this study was the behavior facilitating breast milk production. The independent variables in this study were knowledge, attitude, culture, the availability of health facilities, family support and health worker support. The instruments in this study used questionnaires which had already been tested for validity and reliability. The data was collected by doing visiting the respondent’s house. This was then analyzed using Spearman rho with a 95% confidence level.

### Results

The demographic data of breastfeeding mothers in this study has been shown in Table 1.

**Discussion**

Most of the breastfeeding mothers in this research had a good level of knowledge about the importance of breastfeeding for both the mother and baby, the things that can affect breast milk production and how to increase their own breastmilk production. Most respondents who have good knowledge have sufficient behavior when it comes to the effort to increase breastmilk. The statistical results obtained a significance correlation between knowledge and maternal behavior in increasing breastmilk production. The majority of breastfeeding mothers in this study were highly educated, having graduated from high school (62.2%) and college (21.7%). The level of education is very influential on knowledge, especially in the formation of behavior. The higher the level of education of a person, the higher the level of one’s consciousness and the more mature they are in terms of decision making. Mothers who have a high education level are predicted to show a more persistent effort to achieve breastfeeding success compared to someone with a low level of education. Mothers who have a higher level of education will find it easier to find information about breastfeeding which will increase their confidence in breastfeeding their babies. Mothers who have higher education tend to be stronger to deal with problems and difficulties, including dealing with less breastmilk production. There were under 6 month old babies already being given formula milk. The reasons were having a lower level of breastmilk production and being working mothers. This is in line with the research that stated that 24% of working mothers reported that they were not sure they could produce enough milk for their babies. This indicates that counseling and support about lactation are still very needed by working mothers to reach the exclusive breastfeeding target. The better the mother’s knowledge about how to increase their milk production, the better the behavior of mothers in increasing breastmilk production.
The majority of nursing mothers in this study had a positive attitude and behaved in sufficient categories. The statistical results obtained a significance correlation between attitude and maternal behavior in facilitating breast milk production. There are still a small number of mothers who gave additional food and formula milk while still breastfeeding their babies. This is consistent with the previous research that states that one of the reason mothers give up on exclusive breastfeeding is because of the mother’s perception of breastmilk production. A positive attitude will develop positive behavior and vice versa. Good mother’s knowledge will also affect the mother’s attitude when it comes to being positive. Attitude is a closed response to a stimulus or a particular object which involves the factors of opinion and the emotions concerned (happy-unhappy, agree-disagree, all right and so on). The factors that influence the formation of attitudes are personal experience, culture, other people who are considered to be important, mass media, educational institutions or institutions, religious institutions and individual emotional factors.

There is a significant correlation between cultural factors and maternal behavior in facilitating breast milk production. The culture that is trusted by the mothers and their family will greatly affect the behavior of the mothers in increasing their breastmilk production. Nursing mothers who have a positive culture facilitating breast milk production will behave in sufficient categories to facilitate breastfeeding; out of the respondents, this totaled 60.1%. Positive behavior to increase breastmilk production is affected by culture/beliefs, including by consuming herbal medicine both factory packaged or homemade (54.5%), doing gently breast massage care (66.4%) and consuming more green vegetables and fruits (74%). There also some mothers who believe that breastfeeding could change the beautiful shape of their breasts (10.4%) and that during breastfeeding, they should restrict themselves when it comes to spicy foods due to the prevention of diarrhea among their babies (66.4%).

The statistical test obtained a significant correlation between the availability of health facilities and the mother’s behavior in facilitating breast milk production. The health facilities can be easily reached, while health education and postpartum maternal visits were also obtained by most of the respondents in this study. The health facilities are support for the occurrence of a person’s behavior or society. Facilities can be in the form of time, money, energy, tools and skills. Health behavior will be influenced by the presence or absence of health facilities. The availability of supporting facilities will help the nursing mothers to reach the point of exclusive breastfeeding, especially for working mothers. Numbers of women living as a worker and a housewife have increased. This also increases the potential risk of breastfeeding discontinuation. Three months of maternal leave policy and inadequate lactation promotion support in workplace have been identified as factors that hinder lactating practices. The World Health Organization recommendation of 6 months of exclusive breastfeeding and joined regulation of three Indonesia ministers (Ministry of Health, Ministry of Labour, and Ministry of Women Empower

The majority of respondents get sufficient family support in the enough category. The statistical results also indicate there to be a significance correlation between family support and maternal behavior in facilitating breast milk production. The family in this study were the husband, biological mother, mother-in-law, brother and closest person who lived in one house with the respondent. One form of family support for nursing mothers is to provide assistance in the form of material, physical assistance and assistance when it comes to solving problems. Support and family presence is very important for nursing mothers to be able to increase self-confidence, stabilize emotions, and provide strong motivation. Support from husbands and biological mothers is more dominant in influencing mother’s behavior. Husbands who help with housework, take care for babies and give their wives praise will increase their happiness and create a comfortable atmosphere. Mothers who received support from their husbands were 10 times more likely to report confidence in their breastfeeding than those who did not.

The statistical results obtained that there was no significant relationship between health worker support and the mother’s behavior in facilitating breast milk production. This could be caused by less encouraging the mother’s spirit and less convincing her that her breastmilk production is sufficient enough to meet the baby’s needs. The role of health workers in improving public health is needed. Health workers, especially those working in first line services, will interact more often with the community because they are the first and closest
health provider to the community. Nurses can act as health care providers through the roles of nursing care, educators, health educators, case inventors, liaisons, coordinators, counselors and general role models. The role of health workers should be to provide strong support for exclusive breastfeeding success. The support that can be done by the health workers is by holding counseling about lactation management during antenatal, intra-natal and postnatal, hence being a good preparation stage for the mothers and their families to reach the point of exclusive breastfeeding.\(^{16}\)

### Conclusion

Knowledge, attitude culture, the availability of health facilities and family support are the factors that contribute to forming good behavior in breastfeeding mothers in terms of increased breastmilk production. The support of health workers had no significant correlation with the behavior of mothers in facilitating breast milk production because of the incomprehensive information and support about exclusive breastfeeding.

An Effect of Breath Dhikr on the Stress Level of Patients with Pulmonary Tuberculosis

Hanik Endang Nihayati¹, Haris Arganata¹, RR Dian T¹, Fildzah Cindra Yunita¹

¹Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Introduction: Pulmonary tuberculosis is an infectious chronic disease that can cause a stress condition on patients, such as the symptoms of tuberculosis disease, the long treatment process with a large amount of drugs, daily activity disruption, job loss and death threats. Unresolved stress can lead to irritability, anxiety, negative thinking, despair and helplessness. Some even blame God.

Objective: This study aimed to determine the effect of dhikr breath on the stress levels of patients with pulmonary tuberculosis in the public health centres of Tanah Kalokedinding Surabaya.

Method: A quasi-experimental design method with pre- and post-control groups was used. There was a treatment group and a control group; each group consisted of 16 respondents. The data analysis was performed using the Wilcoxon Signed Rank test and the Mann Whitney U test with a significance level of \( p < 0.05 \).

Results: The result of the Wilcoxon Signed Rank test showed that the stress level of the treatment group had significance with \( p = 0.000 \). The control group had no significance; \( p = 0.317 \). The Mann Whitney U test showed the differences in the stress levels post-intervention with \( p = 0.000 \).

Discussion: Dzikir breath was a positive stimulus that affected the cognator process according to Roy’s adaptation theory in the form of merging dhikr and breath, which is aimed at realizing God. Further research is expected to use cortisol measurements to obtain more accurate results. This should be performed at stress levels in other chronic disease patients.

Conclusion: Breath Dzikir is a spiritual therapy that can change stress into eustress (positive stress) and decrease the stress level of pulmonary tuberculosis patients overall.

Keywords: Breath Dhikir, Stress, Pulmonary Tuberculosis

Introduction

Pulmonary tuberculosis, in addition to having an impact on the physical body, can also result in psychosocial or psychological problems that can lead to mental disorders (severe depression).¹Psychosocial problems such as stigma in society, the fear of being incurable, feeling isolated, not being confident and economic problems, can cause stress for the sufferers.²Unresolved stress will stimulate the hypothalamus to secrete corticotropin releasing factor (CRF), thus causing the pituitary gland to secrete adrenocorticotropic hormone (ACTH) and stimulating the adrenal cortex to secrete cortisol.³An increase in excessive cortisol secretions causes complications, namely a decrease in the immune system and an excessive metabolism.⁴

The prevalence of stress in pulmonary TB patients is 90%, varying from moderate to severe.⁴Stress manifestations can be shown physically, psychologically and through behavior because of the conditions that they experience, such as symptoms of TB-related illnesses, long treatment processes with large amounts of medication, the disruption of daily activities, stigma in society and threats of death.⁴Stress that is not dealt with
properly can lead to anger, anxiety, negative thinking, despair and a sense of helplessness. Some even blame God. This condition can result in irregular pulmonary TB patients taking medication and even discontinuing medication, which will later affect their quality of life.7

One way of handling stress is through a spiritual approach or psychiatric therapy. This can form adaptive coping to help the pulmonary TB patients when dealing with the stress experienced.8 9The religious psychological therapy that the researchers use is breath dzikir. Breath remembrance is a combination of dzikir and deep breaths which can make an individual sincere, grateful and trigger a relaxed state so as to reduce stress. This can even help in controlling one’s emotions.10 The research used Roy’s adaptation theory framework. This is because spiritual therapy through psychology with the method of dhikr is a therapy that can improve individual positive coping mechanisms.8 Previous studies have proven the benefits of reducing stress and anxiety through psychological therapy, especially the method of dhikr. Dhikr relaxation can reduce the stress in patients with essential hypertension.11

Method

This study aimed to prove the influence of breath dzikir in reducing the stress levels in pulmonary tuberculosis patients. A quasi-experiment method with a pre- and post-test control group design was used. The period of research was February to May 2018.

Sample: The research samples consisted of pulmonary TB patients in the area of Tanah Kalikedinding Health Center in Surabaya taken using non-probability sampling (purposive sampling). The size needed for each group, both the intervention and control group respectively, was 16 people. The inclusion criteria were pulmonary TB patients who experienced moderate to very severe stress, Muslim and aged between 17 - 64 years. The exclusion criteria included pulmonary TB patients with severe psychiatric disorders or mental disorders, severe complications such as pleurisy, pleural effusion or carcinoma, who had MDR and who had severe comorbidities such as HIV or AIDS.

Research Instrument and Data Analysis: The instrument used to measure the dependent variable was the stress level questionnaire sheet Depression Anxiety Stress Scale 42 (DASS 42). It was been tested for validity and reliability12 with 10 respondents with the same characteristics; the results obtained r values of 0.64 - 0.76 (r> 0.63) and a Cronbach’s alpha result with a reliability of 0.938 (α> 0.6). The researcher used 14 stress scale items from DASS 42, which were later modified to make them easier to understand.

The data analysis was performed using the Wilcoxon Signed Rank test and Mann Whitney U test with a significance level of p <0.05. All of the statistical tests were measured using the Statistical Package for the Social Science (SPSS) version 16.0.

Results

The pulmonary TB patients who suffered from the disease and who experienced stress consisted of 18 female from the age >45 years; 18 people had a high school level of education, 26 people were married, 20 people were unemployed and 20 people were from the latent treatment phase (Table 1). The type of stress most experienced was psychological (emotional) stress in both groups (Table 2 and Figure 1).

Before being given the breath dzikir intervention, most of the respondents in the treatment group had moderate stress levels. The stress levels in the treatment group consisted of 15 respondents (93.75%) with moderate stress levels and 1 respondent (6.25%) with severe stress levels. In the control group, 16 respondents (100%) had moderate stress levels (Table 3). After being giving the breath dzikir intervention in the treatment group, the stress level of the group decreased, although there was a respondent, the sixth, whose stress level was still constant. The results of the Wilcoxon signed rank test between the pre- and post-test was $p=0.000$. This means that H1 was accepted and that there was a significant influence from dzikir breath on the decreased stress levels. In the control group, there was no significant difference found in the stress level of the respondents. The Wilcoxon signed rank test statistic had a value of $p=0.317$. This means that there was no change in the stress levels in the control group of respondents.

Wilcoxon $p = 0.000$  
Mann Whitney Before The Breath Dzikir $p=0.780$  
After The Breath Dzikir $p=0.000$

The stress level both of groups before the intervention was not significantly different. This was indicated by the results of the Mann Whitney U test with a value of $p=0.780$. This meant that there was no significant difference between the stress level of the treatment group and the control group before being
given the intervention in the form of breath dhikr. The results of the statistical test after being given the breath dhikir intervention showed a value of \( p=0.000 \). This is smaller than 0.05, meaning that there was a significant difference in the stress level of the treatment group and the control group after being given the intervention.

**Discussion**

Based on Roy’s adaptation theory which states that some people do not have an effective coping system, the stress experienced can cause maladaptive psychological processes and self-concepts. The cognator system in the psychological processes that experience stress are closely related to mood and the mind, giving rise to bad moods dominated by negative thoughts and anxious feelings. Stress conditions that are not properly addressed will interfere with one’s physiological conditions as well, which stimulates the hypothalamus to secrete corticotropin releasing factor (CRF). This causes the pituitary gland to secrete adrenocorticotropin releasing hormone (ACTH). This stimulates the adrenal cortex to secrete cortisol. An increase in excessive cortisol secretion in pulmonary TB patients can lead to complications, a decreased immune system and an excessive metabolism. According to Roy’s theory, a human is seen of as a system of adaptation. This theory aims to help the patients adapt to changes in their physiological needs, self-concept, role function and any interdependent relationships during health and illness. Therefore humans are actually able to adapt to the stressful conditions that they are experiencing if they have effective coping methods.

One effective method of coping and dealing with spiritual-based stress is psychoeligious dhikir breath therapy. Breath Dzikir is a method of combining dhikir and deep breaths, which can make individuals sincerely accept, give thanks, increase confidence and trigger a relaxed state, thereby reducing stress and even helping in controlling one’s emotions. Spiritual factors contribute to the healing process of clients. Even those who are religious are better able to cope with suffering and the healing process is faster. Increasing the spiritual factors is also intended to maximize the benefits of experience, treatment and a feeling of peace for the patients. Breathdhzikir can be used as one of the complementary therapies to overcome the emotional problems that are proven to reduce the stress level of respondents in this study.

Dhikr contains elements of spirituality or religion that can arouse self-confidence and faith in the person who is sick. As the immune system increases, this accelerates the healing process. A positive emotional response from the influence of the therapy of breath dhikr runs in the body and is received by the brain stem. After being formatted into the language of the brain, it is then transmitted to one part of the cerebrum, the hypothalamus. The hypothalamus then transmits impulses to the hippocampus (a vital memory center that coordinates everything that is absorbed by the senses) to secrete GABA (Gama Amino Batiric Acid). GABA acts as a controller of emotional responses. It also inhibits or reduces the activity of the neurons or nerve cells, CRH and other producing neurotransmitters cortisol and stress hormones. There will be a process of homeostasis and the repairing of the disrupted neurotransmitter system, giving rise to optimism, eliminating negative thoughts and generating positive thoughts. All protectors in the human body work with obedience to worship, such as getting closer to Allah SWT. There is the creation of an atmosphere of balance from the neurotransmitters in the brain. Hormone stability and reduced stress can cause eustress in pulmonary TB patients.

The results of this research are in accordance with several studies’ results, in which dhikir can reduce stress and increase the positive response of someone who has a problem. Previous research has focused on patients with kidney transplants who experience stress; it was found that the higher a person’s spirituality, the better they are coping and dealing with problems. Spirituality can also improve quality of life and reduce the anxiety and depression of patients who have cancer. Breath remembrance is a spiritual therapy, so it can therefore reduce stress levels in pulmonary TB patients as evidenced by the significant reduction in stress levels in the treatment group. In the control group, they did not experience a decrease in stress levels. The decrease in stress levels in the treatment group was because the respondents carried out breathing dhikir in earnest and according to the guidelines that the researcher gave 2 times a day for 7 days for ± 10 minutes each time. The more frequently that dhikir is done, the lower the anxiety that someone experiences.

**Conclusion**

Breath Dzikir is a spiritual therapy that can change stress into eustress (positive stress) and decrease the stress level of pulmonary tuberculosis patients.

Family Burden Effect on the Ability in Taking Care of Schizophrenia Patient

Winda Kusumawardani¹, Ah.Yusuf⁶, rizki Fitryasari⁷, Lailatun Ni’mah², rr. Dian Tristiana²

ABSTRACT

The existence of schizophrenia affects family systems and the ability to care. The study aimed to determine the relationship between family burden and the familial ability to treat schizophrenic patients. The design used was descriptive analysis with a cross-sectional approach. The population consisted of the family of schizophrenic patients in Menur Mental Hospital, Surabaya, Indonesia. In total, 21 respondents were obtained through consecutive sampling. The independent variable was the family burden and the dependent variable was the ability of the family to care for schizophrenic patients. The data was collected using a questionnaire and the results were analyzed using the Spearman Rho correlation test. The results showed that burden has a moderate relationship with the family ability (p = 0.008) (r = 0.656). The subjective burden was greater than the objective one. A lower burden felt by the family will improve their caring abilities. The families should be able to manage their existing and objective goals so then they can treat schizophrenia patients well.

Keywords: subjective burden, objective burden, schizophrenia, Indonesia

Introduction

Schizophrenia is one type of mental disorder that is causing a serious problem. The maladaptive behavior of schizophrenia patients has become a family burden that produces stressor. The burden faced by the family causes high family stress.¹⁻³ The perceived burden of the family can be either objective or subjective.⁴ Objective burdens can be limited social relations and work activities, financial difficulties and disturbing the physical health of the family members while the subjective burden can be a feeling of loss, sadness, anxiety, embarrassment and stress. The high burden felt by the family affects the willingness of the families to care for the patient and this often leads to recurrence in patients. Schizophrenia patient recurrence contributes to high schizophrenia rates both nationally and globally.

The prevalence of severe mental disorders including schizophrenia in Indonesia according to Riskesdas is 1.7 per 1000.⁵ The incidence of schizophrenia in East Java was 0.22% while in Surabaya, it was 0.2%. Data from the Menur Mental Hospital Surabaya from January until March 2016 showed that there were 5,819 patients; 90% were schizophrenic and 80% of them had relapsed. The incidence of schizophrenia is difficult to decrease due to high recurrence rates. The causes of recurrence were due to not taking their medication and contacting the doctor regularly, stopping the drug immediately, a lack of support from their family and the existence of severe problems that create a stress relapse in the client.⁶⁻¹⁰

People with schizophrenia will be abnormal in their functionality in their daily activities. The family should do the tasks such as recognizing family problems, making the decision to take appropriate actions, taking care of their family members, modifying a healthy family environment and utilizing health service facilities. This high burden is a factor that affects the intention of the family to carry out the task of caring for schizophrenic patients. The stronger the intention, then there is also an impact on how strong the family belief is when it comes to showing the ability to care for schizophrenic clients.⁷¹¹ This study wants to explain the relationship between family burden with family ability to care for patients with Schizophrenia.

DOI Number: 10.5958/0976-5506.2019.02269.1
Method

Study Design, Setting and Sampling: The research used a descriptive correlational research design with the cross-sectional approach. The population consisted of the family of schizophrenic patients who were treated at Menur Mental Hospital in Surabaya. The sample totaled 21 respondents obtained through the consecutive sampling technique.

Study Variables: The independent variable was a family burden and the dependent variable was family ability in taking care for Schizophrenia patient. The family burden was measured by a modification of the Caregiver Burden Index questionnaire. The family ability variable questionnaire was developed based on the concept of the family task which as modified for families with schizophrenia.

Data Analysis: The data obtained was then analyzed using the Spearman Rank test with a significance $\alpha \leq 0.05$.

Results

Based on Table 1, it can be explained that the majority of respondents (62%) were siblings; 29% were 20-30 years old, 48% were working as employees and earned 500.000-1.000.000 rupiahs every month.

Spearman’s Rho p = 0,008

The statistical test shows that there is a relationship between family burden with family ability with a medium relationship level (p = 0,008, r = 0.561). A high burden that is felt by the family will decrease the ability of the families to care for patients with schizophrenia.

Discussion

Family Burden in Caring for Schizophrenia Patients:
The families experience burden when treating patients with schizophrenia. The family burden is the impact of the illness on the family members affecting their emotional stress. The burden is felt when a
The family ability to modify the healthy environment is still felt as being less. Maintaining a comfortable home can be done by building good communication and providing support in various situations. The results show that both the patients and their families experience social stigma. The families do not always address the stigma well; the family can project shame and anger towards the patients with schizophrenia. The conducive environment referring more to emotional expression is an indicator of the quality of the emotional environment for schizophrenic patients. The families show a high emotional expression. The family difficulties in modifying the environment can be affected by the time spent treating patients with schizophrenia. The long duration of care makes some families feel saturated and tend toward high emotional expression. The family must create an acceptance for a patient’s condition, including

Family Ability in Taking Care of the Schizophrenia Patient: The family ability to provide care consists of five family health tasks. The family must be able to perform the patient’s Activity Daily Living, instrumental Activity Daily Living (iADL) and psychosocial needs. The family should be trying to keep the patients engaged with their regular medication and consultations with the health services, they can treat the patients in recurrence and when meeting all patient daily needs. The results showed that 81% of families were able to recognize the health problems. This means that the families understand the causes, symptoms, treatment and consequences of schizophrenia which strongly supports the families in caring for and meeting the needs of their patients every day.

The results showed that 66.7% of the family have less of an ability to make the decision to take appropriate action and to modify the healthy family environment. Appropriate decisions begin with the family foresight in terms of observing the signs and symptoms that occur in patients, including immediately seeking the right information and to decide what actions are to be taken by the family. The results show that most families bring the patient to a shaman before professional health services. They do not allow the patients to leave the home, separating the patients from society or placing them in a special room not far from home. The family is the most important in solving problems through the family decisions based on the shared rights and responsibilities that ultimately determine the service that is to be used. The family decision to bring the patients to a shaman is influenced by the family understanding of the causes of schizophrenia, and if they are related to the spiritual aspect of life, such as involving spirits and witches.

The subjective burden is described as the psychological reaction of the family members. The subjective burden felt by the family during the treatment of schizophrenia is expressed as a feeling of sadness, confusion, anxiety, suffering and embarrassment due to the unnatural behavior shown by the patient, such as being angry without a cause, and refusing to eat, drink and take a bath for a long time. Families tend to have protective feelings as well as feeling shame from their neighborhood and surroundings. The families are more likely to hide the patients. Psychological burden is also felt as a mind burden. This burden is caused by a family that is concerned about the future of their patient. Schizophrenia patient families are always thinking about the many problems caused by unusual patient behavior. The family should have sufficient resources to survive life with the patients. The mind burden felt by the family affects them psychologically, as the family is the primary caregiver of schizophrenia patients.

The family also experiences an objective burden. This can be explained as a burden associated with the care given by the family. Based on Table 4, the high objective burden of the family is in the form of physical burden, financial burden and social burden. The physical burden creates a negative impact on the physical health of the family. They feel physically exhausted because they have to stay up with the patient every night causing less rest, while in the daylight, they must keep working and move. The financial burden was also felt by almost 57% of families, includes the number of costs incurred to meet the needs of the patients such as medical expenses, day-to-day expenses, hospital transportation and hospitalization costs. The majority of families (48%) are employees who work, so they often have to leave a job that results in reduced revenue. The social burden felt by the family related to constraints of the number of activities and time means that the family cannot spend their time elsewhere because they must always take care of the schizophrenic patient. The community are also keeps a distance from the family and patient. They were refuse the existence of the patients and their families in the neighborhood.
respecting and cultivating an attitude of responsibility toward the patient so then they does not lose their role in the family.

**Relationship between Family Burden with the Family Ability to Care for Schizophrenic Patients:**
The research findings showed that the subjective burden is higher than the objective burden. Families who have a burden may not be able to treat the patients well. Subjective burden has an impact on the lack of family ability to make decisions to determine the appropriate actions, to make modifications to a healthy family environment and to support the patient’s recovery process. Families with a high subjective burden will find it difficult to modify the family environment. Psychologically, the family cannot control their emotions because of the unusual patient behavior; they become increasingly depressed and give continuous criticism to the patient with schizophrenia. Family with a high emotional expression will not solve the problem and this causes a recurrence in the patient. Families need help to lower the subjective burden, both psychologically and in their mind.

**Conclusion**
Families who treat patients with schizophrenia feel a higher subjective than objective burden. The subjective burden will decrease the ability of the family to care for the patient with schizophrenia, especially when it comes to making decisions and modifying their environment. Nurses need to develop a family psychoeducation approach to help the families break down their perceived burden. This is so then they are able to perform their family care tasks.

Family Support Improves Hypertensive Patient Drug Compliance

Ninuk Dian Kurniawati1, Erna Dwi Wahyuni1, Yani Arnoldus Toulasik2

1Faculty of Nursing Universitas Airlangga, Surabaya, Indonesia; 2Prof. DR. W.Z. Johannes Kupang
General Hospital, East Nusa Tenggara, Indonesia

ABSTRACT

Family support is one of the support types with the aim of achieving optimal blood pressure control for patients with high blood pressure. This study aimed to analyze the relationships between family support, adherence to taking medication and blood pressure control in patients with hypertension in the RSUD. Prof. Dr. W. Z. Johannes Kupang. The design of this study was descriptive correlational through a cross-sectional approach. The population was the hypertensive patients in the hospital of Prof. Dr. W. Z. Johannes Kupang. The sample consisted of 200 respondents recruited using simple random sampling. The independent variable was family support while the dependent variables were compliance with taking medication and blood pressure. The data was collected using a questionnaire and observation checklists. The data was analyzed using Spearman Rho with a significance level of α = 0.05. The results showed that there were relationships between family support and medication adherence (p = 0.000), adherence to taking medication and systolic blood pressure (p = 0.000) and medication compliance with diastolic blood pressure (p = 0.000). It can be concluded that family support correlates with the patients’ compliance when taking medication and blood pressure. Further research is recommended to examine the causes of poor medication adherence among patients with good family support.

Keywords: Family support, medication adherence, hypertensive patients, blood pressure

Introduction

Hypertension has a high prevalence rate in the population in general. Although there is extensive drug availability, only about 25% of hypertensive patients have controlled blood pressure.1 Hypertensive patients experience difficulties in adhering to antihypertensive treatment. Poor adherence to hypertension drugs not only results in uncontrolled blood pressure but it also becomes a major risk factor for other diseases, such as coronary heart disease, cerebral thrombosis, stroke and chronic kidney failure.2

The World Health Organization (WHO) records that 26.4% of people worldwide are suffering from hypertension. This is around 972 million people. This number is likely to increase to 29.2% in 2025.3 Of the 972 million people with hypertension, 333 million are in developed countries and 639 are in developing countries, including Indonesia.4 According to the National Health Indicator Survey (Circular) data, only 30% of hypertensive patients take antihypertensive medication. Hypertension ranks 5th in the most common diseases in NTT with 39,344 patients.5

Efforts have been made by RSUD.Prof.Dr.W.Z. Johannes Kupang-NTT through the doctors and nurses to enhance the patients’ compliance. However, this has yet to show optimal results. Adherence to treatment is very important in patient care because it can reduce recurrence and achieve controlled blood pressure.6 Non-adherence in taking hypertension medication can cause recurrence, resulting in an increase in the number of hypertensive patients who visit the hospital. Low adherence to antihypertensive drugs has also been observed among hypertensive patients, where more than half of them do not achieve controlled blood pressure, so giving in to

the disease where their quality of life decreases. These studies mainly focused on hypertensive patients in urban areas. More information regarding prevalence and the correlated factors for medication adherence for rural patients with hypertension is needed to better control blood pressure and prevent hypertension-related complications. Methods The study was carried out in three township hospitals in Shanxi Province (Northern China). Family support has been proven to align positively with the health outcomes for various medical conditions, including patients who are in inpatient care in hospitals. Family support can be defined as the assistance and protection given to the family members.

Based on the description above, in this study, the researchers tried to explain the relationship of family support with adherence to taking medication in patients with hypertension who had experienced a relapse in the work area of the RSUD Prof. DR. W. Z. Johannes Kupang-NTT.

**Method**

This study used a descriptive correlational design through a cross-sectional approach. This research was carried out in the RSUD Prof. DR. W. Z. Johannes Kupang-NTT hospital in December 2018. The population consisted of 403 hypertensive patients. The sample was 200 hypertensive respondents recruited through simple random sampling. The independent variable was family support. The dependent variables were adherence to taking the medication and blood pressure. The data collection was carried out by the researchers through the use of a questionnaire and observation check lists. The data was then analyzed using Spearman Rho with a significance level of $\alpha = 0.05$.

**Results**

Table 1 describes the participants’ characteristics. It can be seen from Table 1 that the respondents with hypertension were mostly female (60.5%). Nearly half of the respondents were aged more than 65 years (33.5%), were mostly married (99.5%) and almost half had a secondary level of education (grades 10-12). They worked as entrepreneurs (37%) with their income mostly being less than Rp. 1,660,000 (60.0%).

Table 2 resumes the family characteristics. It was found that the majority of the patient’s family were female (66.5%), had a secondary level of education (57.5%), were entrepreneurs (56%) and were mostly aged 26 - 35 years (54.5%). Nearly all of the families were married (93%) and more than half (56%) were the patients’ offspring.

Table 3 presents the relationship between family support and medication adherence among the patients with high blood pressure. As illustrated in Table 3, in general, the majority of the respondents (91%) received strong family support, strong emotional and appreciation support (94.5%), strong instrumental support (88%) and moderate information support (67%). As predicted, most individuals who received strong family support (53%) adhered to their hypertension medication regimens; adversely, individuals with weak family support showed poor adherence to taking the hypertension medication.

</table>

n = 200, Spearman Rho, p: 0.000, r: 0.295

The statistical analysis using the Spearman Rho showed a significance correlation (p = 0.000) with a coefficient correlation of r = 0.295; there was a relationship between family support and medication compliance in hypertensive patients with a sufficient correlation and positive direction. This implies that the higher the family support, the higher someone’s obedience to taking the medicine.

Table 4: Drug compliance in hypertensive respondents in RSUD. Prof.DR. W.Z. Johannes Kupang-NTT

<table>
<thead>
<tr>
<th>Adherence to taking medicine</th>
<th>Drug compliance (n = 200)</th>
<th>Stop/reduce medication with reasons (n = 200)</th>

<td>44.5%</td>
<td>41.5</td>
</tr>
<tr>
<td>Adherent</td>
<td>55.5%</td>
<td>58.5</td>
</tr>
</tbody>
</table>

Table 4 summarises the drug compliance among the respondents. It is revealed that the level of adherence of the respondents concerning taking their medication was mostly obedient (55.5%) and that more than half of the respondents never forgot to take their medication (58.5%), nor did they deliberately skip their medication either (71%). Nevertheless, some respondents said that they stopped/reduced their medication for varied reasons: felt worse (69.5%), disturbed by the obligation (65.5%) and experienced some difficulties when taking the medication (65.5%). The bigger proportion of respondents complied with taking the medication although when they were travelling (57.5%) and felt healthy (66%).

Table 5 shows the relationship between medication adherence and blood pressure. As can be seen from Table 5, most hypertensive patients obeyed when it came to taking their medication (55.5%). Additionally, among the patients who adhered to taking their medicine, most of them showed normal both systolic (47.5%) and diastolic (39%) blood pressure. Adversely, a small percentage of patients with poor adherence showed a mild increase in diastolic blood pressure (19.5%).
The Spearman Rho analysis showed there to be a significant relationship between medication adherence and systolic blood pressure (p= 0,000) with a coefficient correlation of r = -0.536. This shows a strong relationship between medication adherence and systolic blood pressure with the direction of the relationship being negative; the higher compliance with hypertensive medication, the lower the systolic blood pressure.

Spearman Rho, p : 0,000, r : - 0.536

Furthermore, the Spearman Rho statistical test showed there to be a significant correlation between adherence and diastolic blood pressure (p = 0,000) with a sufficient coefficient correlation (r = - 0.298). Thus it can be concluded that there was a sufficient relationship between medication adherence and diastolic blood pressure with a negative direction; the higher the patient’s compliance, the lower the diastolic blood pressure.

### Discussion

The study showed there to be a positive-direction-relationship between family support and the medication adherence of hypertensive patients; in other words, the higher the family support, the better the patient’s adherence to taking their medication. This supports the theory of the Health Belief Model by Rosenstock, which states that family support plays a role as an external factor that influences the respondents to taking treatment actions.13 Family supports includes emotional, appreciation and the instrumental and information support that will have an impact on compliance. Good family support provided by the family members to the patients can help with the healing process.10

This study revealed that in Kupang, Indonesia, almost all of the respondents received strong emotional and appreciation family support, where the family always accompanies, loves and cares for the family members during their treatment. This form of support makes the individuals feel comfortable, confident, felt accepted, loved, secure and content.14 These forms of support are very important because hypertensive patients need both emotional support and sufficient appreciation so then the patients feel loved and keep up the treatment.

Additionally, this study found that a small proportion of respondents received weak instrumental support such as finance and the facilities that they need. This lack of support was related to having a low income. This supports the previous research which concluded that a lack of instrumental support may cause non-compliance in treatment because the families are unable to provide for their treatment-related needs.15,16

This study found there to be a relationship between medication adherence in patients with hypertension and systolic blood pressure in a negative direction, where the better the adherence, the better the systolic blood pressure control achieved. This supports the existing literature which proves a relationship between adherence to taking antihypertensive drugs to blood pressure in hypertensive patients both systolic and diastolic blood pressure.7,17–19 these studies mainly focused on hypertensive patients in urban areas. More information regarding prevalence and the correlated factors for medication adherence for rural patients with hypertension is needed to better control blood pressure and prevent hypertension-related complications. Methods The study was carried out in three township hospitals in Shanxi Province (Northern China) The success of the patients in treating their hypertension greatly influences their controlled blood pressure. The success factors are related to the patient’s compliance in taking medication and family support.

In this study, most of the respondents continued to take their medication even when they felt healthy (no symptoms). The success of the treatment of hypertensive patients is influenced by the active role of the patient and his willingness to regularly see the doctor. There is also
their adherence to taking antihypertensive drugs. The respondents who did not stop taking their medication even when they felt healthy mostly had normal systolic blood pressure. This confirms the previous literature which found that adherence has a significant effect on decreasing systolic blood pressure.\textsuperscript{18,19}

Most respondents received good informational support. The family members provided the respondents with information, which in turn enhanced the respondents’ medication adherence. This finding supports another study that found the family support can strengthen each individual, increase self-respect, and that it has the potential to be the main prevention strategy for the whole family in facing the challenges of everyday life.\textsuperscript{11,17} Moreover, the research by Turan et al. concluded that the level of perceived support from the families was higher than the perceived level of support from friends or other individuals.\textsuperscript{17} These confirm the importance of enhancing family support for each hypertensive patient.

Moreover, the study showed there to be a relationship between medication compliance in patients with hypertension and diastolic blood pressure in a negative direction, where the higher the adherence to taking antihypertensive drugs, the lower the diastolic blood pressure. This confirms the findings of Ariyanto, which examined the relationship between compliance and blood pressure.\textsuperscript{20} These findings support the results of a study conducted by Márquez-Contreras et al., which concluded that adherence to treatment is very important in patient care. This is because it can reduce recurrence/recurrent hypertension and it is very necessary to achieve controlled blood pressure.\textsuperscript{19} Compliance in taking medicine is very important in achieving controlled systolic and diastolic blood pressure.

Almost all of the respondents with hypertension had never deliberately skipped their medication within the past 2 weeks. Compliance with medication is influenced by good family support. Family support is an effort given from the family members both morally and materially in the form of real motivation, advice, information and assistance.\textsuperscript{11} This affirms the research of Fajriyah et al. and Permatasari et al’s work, which found that adequate family support was associated with a decrease in mortality.\textsuperscript{11,12}

**Conclusion**

Family support has a relationship with compliance with the medication where the better the family support, the better the level of adherence of the patients with hypertension to taking hypertension medication. This will increase; the less the family support, the more that patient’s level of non-compliance will increase.

Compliance with taking medication has a relationship with systolic and diastolic blood pressure where the more obedient patients take antihypertensive drugs. Therefore the hypertensive patients will have more controlled systolic and diastolic blood pressure.

The Relationship between Family Support and Self-esteem among Cervical Cancer Patients Undergoing Chemotherapy

Supatmi1, Widya Irene Mayangsari2, Retno Sumara2, Esty Yunitasari3

1Doctoral Degree Programs, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia; 2Faculty of Health Sciences Universitas Muhammadiyah Surabaya, Indonesia; 3Faculty of Nursing, Universitas Airlangga Surabaya, Indonesia

ABSTRACT

The main management of advanced cervical cancer is chemotherapy. The side effects of chemotherapy include changes in the patient’s biology and the psychological impact on the patient through a decline in self-esteem. The factor that can affect the self-esteem of cervical cancer patients undergoing chemotherapy includes family support. This study aims to determine the relationship between family support and self-esteem in cervical cancer patients undergoing chemotherapy. The design was an analytical correlation with a cross-sectional approach. The population in this study was patients with stage IIB cervical cancer which consisted of 47 respondents recruited using the purposive sampling technique. The data was collected by a questionnaire. The results showed that 59.6% had good family support and 59.6% had high self-esteem. This was analyzed using the Spearman rank test with a significance level of 5 (0.05). We obtained a correlation coefficient (r) between family support and patient self-esteem that was 0.982 with a p-value of p=0.000. This means that there was a very strong relationship, namely the better family support given to the cervical cancer patients undergoing chemotherapy, the higher the self-esteem of the cervical cancer patients undergoing chemotherapy at Dr. Soetomo General Hospital Surabaya. Family support is very necessary to give to the cervical cancer patients undergoing chemotherapy to improve the patient’s self-esteem in terms of accepting their condition.

Keywords: Family Support, Self-esteem, Cervical Cancer, Chemotherapy

Introduction

Women diagnosed with cancer face many challenges, starting from the beginning of the disease and through the treatment measures, late diagnosis, side effects of the medication, financial problems, and the possibility of facing other consequences such as physical and psychosocial effects, and to explore women’s needs and experiences of psychosocial support following end-of-treatment. Methods: Data were collected from 337 gynaecological cancer survivors, 19–39 years at diagnosis, using a study-specific questionnaire and the Swedish Quality Register of Gynaecologic Cancer. Predictors of distress were investigated with multivariable logistic regression analysis. Open-ended questions were analysed with content analysis. Results: The prevalence of cancer-related distress was 85% (n = 286)Cervical cancer is the growth of malignant cells located in the cervix.2,3 One of the management methods of cervical cancer treatment is chemotherapy.4 Hypnosis has been used for pain relief in metastatic patients but rarely for induction of anesthesia. Material and method Between January 2010 and October 2015, 300 patients from our Breast Clinic (Cliniques universitaires Saint-Luc, Université catholique de Louvain)The side effects of chemotherapy include changes in biology that affect changes in the patient’s psychology in turn. The biological changes that occur in the patients undergoing chemotherapy include nausea vomiting, hair loss, wrinkled skin, blackened nails, bleeding, weight loss, decreased appetite, the patients feeling very weak and tired, being easily bruised or bleeding, canker sores, swollen feet and pain.5,6

Drastic biological changes mean that the sufferer experiences psychological changes such as expressing helplessness, feeling embarrassed, decreasing self-confidence, the fear of not being attractive anymore and the patient feeling like no one wants to accept his current condition, feeling grieving, being scared, confused, feeling that their families are not being fulfilled and feeling despair during the chemotherapy treatment.\(^7\) The biological and psychological changes that occur in the patients with cervical cancer who undergo chemotherapy have an impact on the sufferers’ self-esteem.\(^8\) The self-esteem referred to in patients with cervical cancer is an acceptance and rejection of himself against changes.\(^9\) According to the Family Support and Self-Esteem of Breast Cancer Patients study by H. Adam Malik Hospital Medan, individuals who have low self-esteem will show an attitude of rejection and they will always blame themselves. Conversely individuals who have high self-esteem will show acceptance and have a sense of trust self and enthusiasm when undergoing chemotherapy treatment.\(^11\)\(^,\)\(^12\)

The incidence rate of cervical cancer in Indonesia is 20,928 cases and the mortality rate is 9,928 people.\(^13\) The incidence rate of cervical cancer in Indonesia is \(< 19.92\%\) per 100,000 women per year. According to the study titled Cervical Cancer Screening and Prevention in Low-resource Settings, 64\% of patients with cervical cancer were at an advanced stage and 54\% of advanced cervical cancer patients underwent chemotherapy.\(^14\) 90\% of patients with cervical cancer who undergo chemotherapy will experience side effects such as nausea and vomiting, hair loss, wrinkled skin and decreased physical function. This can affect the patient’s psychology, so the changes that occur can affect the self-esteem of cervical cancer patients.\(^15\) Family support given at 93.4\% can increase the self-esteem of cervical cancer patients who undergo chemotherapy by 60\%.\(^10\)

Based on the preliminary study data from the Obsgyn Ward in Dr. Soetomo General Hospital, it was found that the number of patients with cervical cancer on January 1\(^{st}\), 2017 through to December 12\(^{th}\), 2017 was 1,185 people with cervical cancer. The number of cervical cancer patients who underwent chemotherapy treatment totaled 627 patients with cervical cancer. In the initial survey of 8 people with cervical cancer who underwent chemotherapy, it was found that 6 people with low self-esteem categories showed a response to feelings of shame, the fear of not being attractive anymore, feeling insignificant, not being confident and being unable to meet the needs of their child and her husband because of the side effects of chemotherapy treatment. There were 2 people with either high and moderate self-esteem categories who showed a feeling of enthusiasm and who were able to accept the self-changes that occurred due to the chemotherapy treatment.

The support provided by the family will help people with cervical cancer become enthusiastic about undergoing chemotherapy treatment. This can increase the patient’s confidence in the changes after chemotherapy. High self-esteem can affect the self-esteem of cervical cancer patients and this can help to accelerate their healing process.\(^5\)

**Method**

The methodology of this research was a correlation analytica study with a cross-sectional approach. The population in this study consisted of cervical cancer patients who had underwent chemotherapy in Dr. Soetomo General Hospital Surabaya from October to December 2017, amounting to 54 patients via a purposive sampling technique that gathered 47 respondents. In this study, the data analysis technique used the Spearman Rank Statistical Test with SPSS Version 16.0. The instruments in the study were a family support questionnaires including instrumental support, award support, instrumental support, emotional support and a Rosenberg questionnaire self-esteem scale that had been modified.\(^10\) The validity test of this questionnaire used SPSS version 16.0 with a large r table that was determined according to the number of respondents who tested with a significance level of 5\% (0.05), which was 0.4438. The instrument items were considered to be valid or relevant if the r count > r table was specified.

The results of the first validity test on the family support questionnaire obtained the value of the r count as 0.881. The minimum r count value in the questionnaire was 0.559. It can be concluded that there were no invalid questions. The results of the second validity test, namely on the questionnaire, obtained an r count value of r count of 0.857. The minimum r value calculated was 0.544. The reliability test of the questionnaire was carried out using Cronbach’s alpha method 0 to 1 with the results of the reliability test on the first questionnaire, namely about family support being 0.771. This means that the
questions within the questionnaire were declared to be reliable. The results of the second reliability test on the self-esteem questionnaire also showed that Cronbach’s alpha was 0.768. The questions in the questionnaire were therefore declared to be reliable. To ensure that this study was safe for all participants, the participants had the purpose of the study explained to them. Informed consent was obtained prior to the study beginning. Confidentiality and anonymity were maintained throughout the study. The participants were informed that they could stop at any time without discrimination during the study.

Results

Based on the results of the data analysis above, the relationship between family support and the dignity of the cervical cancer patients undergoing chemotherapy in Dr. Soetomo General Hospital Surabaya showed that good family support will increase the patient’s self-esteem. This was found in 28 respondents. Sufficient family support or less will moderate the patient’s self-esteem; this was found for 19 respondents. The results showed that the correlation coefficient (r) between family support and the self-esteem of cervical cancer patients undergoing chemotherapy was (r) 0.982 with a significance level (p) = 0.000 < 0.05 (Table 1).

Discussion

For the family support for the cervical cancer patients, most of the respondents received family assistance (28 respondents, 59.6%), as many as 16 respondents received sufficient family support (34.0%) and the remaining 3 respondents (6.4%) received less family support. The results of this study are supported by the factors associated with the behavior of the prevention of cervical cancer in women of childbearing age. The existence of high family support will make the patients feel more calm and comfortable when they are undergoing chemotherapy. Good family support is seen when families, like their relatives, children and loved ones, are seen accompanying the cervical cancer patients while they are undergoing chemotherapy at the hospital. This is supported by the research into cancer of the cervix uteri, in that the existence of positive support from the family will make the patients enthusiastic and committed to undergoing chemotherapy. In addition, good family support in assisting the patients will make patients stronger at fighting the disease and they will accept their physical condition as a result of the chemotherapy treatment that they are undergoing. Good family support given to the family members who are in the stage of adaptation to disease or recovery can affect the success of the healing process. This is supported by the role of the family in providing support related to the achievement of self-integrity post-radical mastectomy for breast cancer patients. Related to the experience of women after undergoing cervical cancer therapy, the good family support given to cervical cancer patients undergoing chemotherapy are: 1) meeting their basic needs including appropriate food and drink, and facilitating the patient’s head covering to cover the parts of their hair that fall out due to chemotherapy; 2) the family motivates and advises the patients not to despair when undergoing treatment and they pray for their recovery; 3) the families must always give their enthusiasm, love, empathy and attention to patients by assisting or waiting for the patients during chemotherapy treatment and 4) families provide information and remind the patients of their chemotherapy treatment schedule.

High self-esteem is influenced by the feelings of being accepted, loved, and respected by others. Individuals also have experience related to the success that has been achieved in their lives. Self-esteem comes from two sources, namely from the self and others. The first aspect of self-esteem is to be loved and to get respect from others. Their self-esteem will increase if someone gets love and motivation from others. High self-esteem is shown when the patients feel capable and confident in doing all of their daily activities, accepting their condition sincerely, not blaming themselves or others and feeling respected and valued despite suffering due to the side effects of the chemotherapy treatment.

The results showed that the correlation coefficient (r) between family support and the self-esteem of cervical cancer patients undergoing chemotherapy was (r) 0.982
with a significance level \( p = 0.000 \geq 0.05 \). The results of this study are supported by the results of Family Support and Self-Esteem of Breast Cancer Patients in H. Adam Malik Hospital Medan’s study, in that there is a significant relationship between family support and self-esteem. The higher the family support given to the cervical cancer patients undergoing chemotherapy, the higher the self-esteem of the cervical cancer patients will be because the family has a very important role in forming one’s self-esteem.\(^9\) The results of this study reinforce the previous research, in that there is a close relationship between the two variables. Cervical cancer patients undergoing chemotherapy in the Dr. Soetomo General Hospital mostly have high self-esteem. This means that cervical cancer patients have a high assessment and acceptance of themselves. This happens because most cervical cancer patients get good support from the family through the support of information, appreciation, emotional and instruments. This is vice versa in cervical cancer patients who have moderate self-esteem due to the support obtained from weak and moderate families.

Families have an important role, which is focused on being supportive during the healing and recovery process of their family members, so then they can achieve optimal health status.\(^20\,21\) and to explore women’s needs and experiences of psychosocial support following end-of-treatment. Methods: Data were collected from 337 gynaecological cancer survivors, 19–39 years at diagnosis, using a study-specific questionnaire and the Swedish Quality Register of Gynaecologic Cancer. Predictors of distress were investigated with multivariable logistic regression analysis. Open-ended questions were analysed with content analysis. Results: The prevalence of cancer-related distress was 85% \( n = 286 \)\(^3\) In addition, the family can help someone to accept their current environment or circumstances. They can help the patient with their care process where the family strives to provide support. They can increase the spirit of life and commitment of the patients who are to undergo chemotherapy treatment.\(^22\)

Self-esteem is influenced by two things, namely how the individuals value themselves in the various aspects of their lives and how much social support they get from others.\(^9\) Lack of support from their loved ones will affect a person’s self-esteem. Inadequate family support in cervical cancer patients can cause the pessimistic patients to not undergo the chemotherapy which comes with various side-effects that must be experienced. The patients will thus despair and not undergo chemotherapy according to the schedule determined by the doctor.\(^22\) Family support that is given well through instrumental, rewarding, emotional and information support for the cervical cancer patients who undergo chemotherapy can affect the patients’ self-esteem by fostering self-confidence, giving them a high self-assessment and increasing the patient’s motivation to recover.\(^23\)

**Conclusion**

The family support provided for cervical cancer patients who are undergoing chemotherapy in Dr. Soetomo General Hospital Surabaya was mostly good. The self-esteem in the cervical cancer patients undergoing chemotherapy in Dr. Soetomo General Hospital Surabaya was mostly high. The family support was related to the self-esteem of the cervical cancer patients undergoing chemotherapy treatment in Dr. Soetomo General Hospital Surabaya.

ABSTRACT

Dengue Hemorrhagic Fever (DHF) can result in shock complication which eventually lead to death. Family knowledge and attitudes are essential to prevent shock from dengue fever. The provision of education in the form of health education about dengue shock which is self-care strategies for optimizing metabolic control and prevent complications. The purpose of this study was to determine effect of health education toward knowledge and attitude parents for prevention of DHF shock. The research design used was Pre-experimental with one-group pre-post-test design. The population in this study were all parents who have children with DHF. A sample of 20 parents was recruited by a consecutive sampling technique. The variables were measured using a questionnaire and observation sheet. Data analysis was done by a Wilcoxon Signed Rank Test and McNemar Test. The results showed there were increased knowledge and attitudes. Statistical analysis obtained value ρ = 0.000 means there were the influence health education of dengue shock to the knowledge and attitude parents of children with dengue hemorrhagic fever. It can be concluded that counselling improves parental attitudes for prevention of DHF shock.

Keywords: Health Education; Parents; Knowledge; Attitude; Dengue Hemorrhagic Fever.

Introduction

Dengue Hemorrhagic Fever (DHF) is a disease caused by dengue virus that is transmitted from person to person through the bite of the Aedes Aegypti mosquito.¹ Signs and symptoms of DHF patients include high fever 4-7 days, headache, muscle pain, joint pain, and bleeding under the skin.² Management with rehydration, antipyretics, and bed rest for DHF patients is adequate because it is self-limited.³ Handling late DHF can lead to dangerous complications.

Dengue Hemorrhagic Fever to date is one of the public health problems in Indonesia that tends to increase the spread and the number of patients. In the last 25 years, hyperendemicity DHF globally has centered in urban tropical areas.⁴ In East Java in 2015 there were 19,942 cases of which 1.4% died.⁵ The death of Dengue Hemorrhagic Fever patients is possibly due to late handling and dengue shock.⁶ This situation can be seen in the report of the incidence of dengue shock in one of the hospitals in Gresik, within three years the average of 34.7% of all cases of DHF.⁷

Signs and symptom of dengue shock are: weak, cold skin, wet skin, restless patients, rapid and weak pulse, blood pressure decreases.⁸ Parents’ knowledge of Dengue Hemorrhagic shock is still lacking where parents do not know what measures should be taken in preventing dengue shock in children. A 2-week survey in the Children’s Room of Muhammadiyah Gresik Hospital found 88.2% of parents to be less knowledge about the meaning of DHF, and the signs and symptom of dengue shock.⁷ Knowledge and parental attitudes are very influential in the attainment of health education.⁹ Nurses as a health worker have a role and responsibility in providing health education, according to the duty of a nurse as educator in giving information.¹⁰ The Muhammadiyah Gresik Hospital Children’s Room only provides information about DHF, but is not specific about
DHF shock. The problem statement in this study was to study the explanation of the influence of counseling on DHF shock on the knowledge and attitude parents of children with dengue fever.

**Method**

**Study Design, Setting, and Sampling:** The research design used pre-experiment with one-group design pre-post-test design. This design was to analyze the knowledge and attitude of parents before and after getting counseling in the prevention of dengue hemorrhagic fever shock.

The population in this study was parents of children patient with DHF in Gresik hospital in tropical coastal areas. A sample of 20 parents of children with DHF was recruited by consecutive sampling technique. Data collection was adjusted to the criteria of the parents can read, write, and their children do not have complications. Data were collected for seven weeks from October to November 2016.

**Study Variables:** The independent variable of this research is health education about prevention of dengue shock. The dependent variable of this study is the knowledge and attitudes of parents in preventing dengue shock. In this study, samples were taken according to the inclusion criteria and exclusion criteria. Health education variables regarding prevention of dengue shock include:

1. Definition of shock
2. Signs and symptoms of shock
3. Complications of shock
4. DB shock prevention

Variable knowledge of parents in the prevention of dengue shock assessed is:

1. Knowing the definition of dengue shock
2. Signs and symptoms of dengue shock
3. Complications from dengue shock
4. How to prevent dengue shock

The variable attitude of parents in preventing dengue shock consists of:

1. Response about the definition of dengue shock
2. Signs and symptoms of dengue shock
3. Complications of dengue shock
4. Prevention of dengue shock

Instruments of knowledge and attitude were assessed with a standard questionnaire which tested as valid and reliable. Counseling instruments were carried out with extension units (SAP) and leaflets. Each subject was conducted pre-counseling data of knowledge and attitude, then counseling for 15-20 minutes every day for three days. Data of knowledge and attitude were obtained after getting counseling on day 4.

**Data Analysis:** Descriptive statistics method was employed to analyze the data to generate the study results in forms of frequencies, and percentages. Inferential data were analyzed with Wilcoxon Signed Ranks Test and McNemar Test with significance $\alpha \leq 0.005$.

**Results**

The results of data collection indicate the characteristics of research subjects as presented in Table 1. The subjects of the study showed that the patient’s gender was mostly female. Age of the subjects included in the productive age ranged from 26-45 years. The subject’s education was almost entirely at the senior high school level.

Table 2 shows the research results of respondents’ knowledge before being given counseling intervention on DHF shock, mostly sufficient knowledge (60%). After getting intervention, respondents’ knowledge was almost entirely classified as good knowledge (90%). The result of Wilcoxon Signed Rank Test statistics shows that $\rho = 0.000$, which means there is influence of counseling about the shock of DHF on the knowledge of the parents in Marwah Children’s Room Muhammadiyah Gresik Hospital. The respondents’ attitudes before being given counseling about DBD shock were mostly negative (70%). After obtaining counseling intervention, respondents’ attitudes were mostly positive (70%). A small element of respondents’ attitude was still found to be a negative attitude, 30%. Result of the McNemar Test showed $\rho = 0.000$, which means there is influence of counseling about shock of DHF to attitude of parents in Marwah Children’s Room Muhammadiyah Gresik Hospital.

Discussions

Knowledge of DHF Shock: The results showed that counseling about DHF shock had an effect on the increase of parents’ knowledge of the child. These results are in accordance with previous research that the increasing knowledge of parents will affect the incidence of DHF shock. The results are reinforced by the theory that counseling is an effective method to instill knowledge and motivation.

Another factor that can increase the knowledge of parents of children about DHF shock is possibly the characteristics of respondents. This result is consistent with the theory that knowledge is influenced by education, experience, age, occupation, income, and information. Characteristics of the subjects, including the age of patients, are included in the productive age which greatly affects the mindset and the process of acceptance. This situation is in accordance with the theory that the adult age of individuals can make self-adjustment independently of social life, being able to decide the problem rationally, and, thus, stable and mature emotionally. This condition shows a person can decide rationally about the importance of understanding DHF shock for himself.

The next characteristic is the level of subject education above the basic education. The published theories suggest that the more educated one becomes, the easier the person is to receive information. This condition shows that a person’s higher education will tend to get information, and the more information that goes in, the more knowledge gained.

Attitude to DHF Shock: Results of research on the counseling of DHF shock can improve the attitude of parents of children in preventing the occurrence of shock. This result is in accordance with previous research that health promotion improves parental attitudes in preventing dengue fever. This result is in line with previous theories which show that attitudes are a form of evaluation or reaction of feelings, whereby something that we have been experiencing is shaping and influencing our appreciation of the stimulus. This condition explains that the response will be one of the foundations of the formation of attitudes, to be able to have a response and appreciation one must have experience related to psychological objects.

Respondents who are waiting for and receiving DHF shock prevention counseling can increase awareness of the importance of holistic distraction prevention of dengue fever. Awareness is the attractiveness (Interest) of respondents in applying the intervention of DHF shock counseling through various considerations (Evaluation). Interest becomes the motivation to try (Trial) and implement (Adoption) prevention intervention of DHF shock as a whole. Increased knowledge of respondents makes the basis of increasing attitudes, because attitudes are the embodiment of knowledge received by respondents caused by infection of dengue virus transmitted by the female Aedes mosquito. This is the second leading cause of deaths in Champasack Province, where Pakse district has the highest number of this outbreak. This cross-sectional study was designed to assess the knowledge, attitude, and practice of people regarding dengue disease.
in 9 villages of the Pakse district from July to September 2006. Purposive sampling was done to collect data from 230 subjects. They had a fair knowledge about the vector (70.9% A good understanding of the handling of shock DHF makes respondents positive, because of the supporting, characteristics of respondents, such as age, and education.

The results also indicate that there are still respondents who have negative attitude after obtaining counseling. This result is possible because there are respondents who entered early adulthood, so like to make adjustments independently, and demand rationalization. This condition indicates that the emergence of attitude is based on the evaluation process in individuals who give conclusions on the stimulus in the form of positive or negative. This condition supports that parents who are given counseling should be given in-depth knowledge. The result of knowledge research is still found by respondents whose knowledge is sufficient, so there is a possibility that his attitude is still negative, and major outbreaks occurred in 2006 and 2010. However, no data on the local knowledge, attitude and practice (KAP) This knowledge will form the trust, so that it becomes the basis of one’s attitude toward a particular object.

**Conclusion**

Prevention of DHF shock can be achieved through health education interventions in the form of counseling. Counseling on the prevention of DHF shock can improve the cognition and affection aspects (knowledge and attitude) of parents of dengue fever in doing self-care and prevention.

The nurse as an educator should be active in providing counseling to patients and parents about the signs, symptoms, and impact of DHF Shock. Researchers are then expected to develop counseling by adding online media in counseling as a form of innovation in educational activities.

ABSTRACT

Family-centered empowerment (FACE) is a nursing intervention by increasing family filial values, which consist of responsibility, respect, and family care. The objective of the study applied a family-centered empowerment model (FACE) to the health status of children suffering from leukemia. The study used quasi-experiment design, with the sample being 30 families with children suffering from leukemia treated in Soetomo Hospital Surabaya. Independent variable is family-centered empowerment (FACE) model and the dependent variable is health status condition of children suffering from leukemia. There is influence of FACE model to health indicator of children suffering from leukemia, consisting of child weight p = 0.000 (<0.05), leukocyte p = 0.002 (<0.05), and bleeding incidence p = 0.041 (<0.05). The Family Centered Empowerment (FACE) model is applied to families with children suffering from leukemia by nurses as an intervention of family filial value enhancement in increasing responsibility, respect and care so that families can develop their family appraisal skills to provide the best care while facing the challenge of treating children with leukemia. The family-centered empowerment model can improve family ability in treating children with leukemia, which impacts on child health indicator.

Keyword: Family, Empowerment, leukemia, children

Introduction

Leukemia is a blood cell malignancy originating from the bone marrow, characterized by the proliferation of white blood cells, with manifestations of the addition of abnormal cells in peripheral blood. The rapid change in symptoms in patients with leukemia causes children to feel great pain.¹ Children who suffer from leukemia really need serious attention for a long time, commitment, and it is a hard struggle for family members who care for them.² Caregivers or families who have children with chronic conditions are faced with demands, challenges, emotional and cognitive problems, and changes in roles in family and society. This has an impact on family sustainability in providing care for children, especially in the maintenance phase of the treatment of acute lymphoblastic leukemia (ALL). One of them is family disobedience in following the treatment process set by the doctor. Families of children with chronic disease conditions often feel helpless in meeting their children’s healthcare needs and in sustaining their family life. The helplessness experienced by the family will affect their ability to support providing care for their children. This has an impact on the health status of children suffering from leukemia.

Therefore, an intervention is needed to empower families in caring for children suffering from chronic diseases.³ The family’s ability to care for children with leukemia is very necessary to improve their quality of life and, as such, nursing interventions in an effort to improve the family’s ability to care for sick children are very important. Cancer in children has become a global problem because its incidence continues to increase, especially in developing countries. In Pakistan, 60% of children die of cancer. The 2013 Basic Health Research (Riskesdas) showed the Special Region of Yogyakarta (DIY) was the region with the highest prevalence of cancer patients in Indonesia for all ages based on a doctor’s diagnosis of 4-5 per 1,000 residents.⁴

Based on the estimated number of cancer patients, Central Java and East Java Province are the provinces with the highest estimate of cancer patients, which is around 68,638 and 61,230 people, respectively. The average cancer prevalence in Indonesia is 1.4 per 1.00 population. Based on the register of the Division of Hematology & Oncology, SMF, Pediatric Dr. Soetomo Surabaya obtained data that, in 2016, there were 252 new cases of children diagnosed with cancer, the most number being Acute Lymphoblastic Leukemia (ALL) with 108 new cases.

Family empowerment is an intervention that nurses can use to help families. The expected results in families with such empowerment are the ability to cooperate with health professionals, minimize the effects of chronic conditions on children and siblings, restructure family roles and responsibilities, satisfy children’s healthcare needs, and reduce healthcare use and costs, so that, in the end it is expected to increase the health status of children with leukemia.

**Method**

**Study Design, Setting, and Sampling:** This study uses a quasi-experiment design. The sample used in this study was 30 mothers with children suffering from leukemia who were treated at the Children’s IRNA Dr. Soetomo Surabaya Indonesia, which was divided into two groups, namely 15 treatment group respondents and 15 control group respondents. The independent variable in this study is the Family Centered Empowerment (FACE) module and the dependent variable in this study is the family’s ability to treat leukemic children and the condition of the health status of children with leukemia. Indicators in family capacity measured were perceived health, personal growth, and existential wellbeing, while the children’s health indicators measured were nutritional status, secondary infection incidence, and bleeding events. Data were analyzed using parametric pair T-test and independent t-test.

**Result**

In the treatment group, the average value after treatment was higher than before treatment, even though the increase had not reached 10% of the average value before treatment (Table 1). The results of statistical tests showed a significant difference between family abilities before and after treatment. The highest difference is the personal growth indicator, which is the mother’s perception of her condition and which includes the development of positive life skills, and realistic and healthy self-development. These results indicate that the FACE module can improve the family’s ability to care for leukemic children, especially the ability of the family, in this case the mother’s ability to manage desired expectations, and planning actions to help achieve goals.
while caring for leukemic children. In the control group, it can be explained that the average value before and after also increases with the average increase smaller than the treatment group. Based on statistical tests, it was found that there were no differences in family abilities in treating leukemic children in the control group. Based on the results of statistical tests of differences between the treatment group and the control group, there was a difference in the average value of the family’s ability to treat leukemic children. The average value of the family’s ability to treat leukemic children in the treatment group was higher compared to the control group. This shows that the application of the FACE module can improve the family’s ability to care for leukemic children, which includes perceived family ability (personal health), personal growth and existence for prosperous conditions (Existential wellbeing).

The average value of health indicators of children suffering from leukemia, in this case BB, leukocyte value, and the occurrence of bleeding, in the treatment group shows an increase in health indicators, namely the average value of child BB increases, the average value of leukocytes in the normal range, and the frequency of bleeding; on average, there is a rare bleeding category (Table 2). Statistical tests show that there are significant differences between the indicators of children’s health before treatment and after treatment. This shows that the application of the FACE module to the family can improve the health indicators of children with leukemia.

In the control group, it can also be explained that there was a change in the average value of health indicators for children suffering from leukemia, but the change in the average value in the control group was lower than that of the treatment group. The results of statistical tests show that there are differences in the health indicators of children with leukemia on leukocyte values, and there is no difference in the indicators of body weight and the frequency of bleeding.

Based on the statistical analysis of the differences between the health indicators of children with leukemia in the treatment group and the control group, it was explained that there was no difference between the indicators of health of leukemic children in the treatment and control groups. It can be explained that the administration of the FACE module in the treatment group can improve the health indicators of children suffering from leukemia, especially in increasing body weight and decreasing the frequency of bleeding.

Discussion

The results of the study showed that family abilities significantly influence children’s indicators. The family capacity in this study includes the results of family care indicators in caring for leukemic children, which consist of perceptual indicators about managing health, personal and family growth, and the existence of prosperous conditions.

The results showed that the majority of respondents were in the medium category on each indicator of parenting results, with the highest category on the indicator of family ability, in this case how the mother manages her health while providing care for leukemic children. The highest low category is an indicator of family ability to maintain the condition of existence of wellbeing while caring for children with leukemia. This shows that the family’s ability to treat leukemic children still needs to be improved.

The existential condition of welfare conditions (existential wellbeing) can be influenced by several factors, one of which is age. In this study, the age of the mother was mostly in the category <35 years (early adult). The life cycle in the early adult category, according to Erikson, is in the phase of generativity vs. stagnation. One of the tasks that must be achieved is to be able to devote themselves to achieving a balance between the nature of giving birth to something (generativity) by doing nothing (stagnation). Failure to improve the ability to give birth to something will cause stagnation in the family in providing care to a sick child. This is what can reduce the ability of the family to maintain welfare conditions in them.

The indicators of children in this study were the nutritional status of children, the incidence of secondary infections, and the occurrence of bleeding. Cancer and its treatment can affect energy intake and its use. The results showed that most child health indicators were in the moderate category. Indicators that have the highest good category are in indicators of nutritional status. This shows that the family’s ability to treat leukemic children is more visible in how parents improve their ability to meet the nutritional needs of children suffering from leukemia. Increasing family capacity in caring for children with chronic conditions is influenced by family knowledge and experience. The results of this study indicate that the ability of mothers to meet children’s nutritional needs can be seen in the indicator of increasing body weight of children suffering from leukemia. There are several factors that cause malnutrition in children with cancer, including: a) specific factors for tumors; b) factors related to patients; and c) factors related to treatment. The results also showed that children’s indicators of secondary infection aspects seen from laboratory values of leukocytes in children showed differences before and after intervention to mothers in improving their ability to care for leukemic children, even though the difference was not significant for changes in leukocyte values, but still within the limits normal. The description of laboratory values in children suffering from leukemia varies from mild to severe. The laboratory results are influenced by the age of the child. Likewise, for child health indicators that are seen from the frequency of bleeding events, based on the results of the study, there are differences in the decrease in the frequency of bleeding events before and after the intervention. Decreasing the incidence of infection and bleeding events is supported by the fulfillment of optimal nutritional needs carried out by the mother and can also be caused by the treatment process undertaken by children suffering from leukemia.

The family’s ability to care for leukemic children requires an effort made by health workers so that the family’s ability to care for leukemic children increases and children’s health indicators can also be improved.

Conclusion

The Family Centered Empowerment (FACE) model that is applied to families improves the health indicators of children with leukemia, which includes increased child weight, decreased incidence of secondary infection with indicators of leukocyte value stability, and decreased incidence of bleeding frequency. It was found that the FACE model for improving the ability of families to care for leukemic children found can be applied in families as one of the nurses’ references in providing child nursing care in chronic disease conditions.

Social Support and its Correlation with “3M Plus” Behavior in the Prevention of Dengue Hemorrhagic Fever

Lintang Kusuma Ananta¹, Ferry Efendi¹, Makhfudli¹, Eka Mishbahatul Marah Has¹, Gading Ekapuja Aurizki¹

¹Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

The incidence of dengue hemorrhagic fever has increased slightly in recent years. One of the factors is the decrease of the “3M Plus” behavior—draining bathtub regularly, covering water containers, burying garbage in the ground, plus other prevention attempts. The aim of this study was to analyze the correlation between social support with the “3M Plus” behavior in the prevention of dengue hemorrhagic fever. The study used a correlational method with a cross-sectional approach. The sample was 51 housewives in Surabaya. The independent variable was social support, while the dependent variable was “3M Plus” behavior. The data were collected by using Social Provision Scale questionnaire and “3M Plus” behavior questionnaire and analyzed by using Spearman rank correlation with α<0.05. A close positive relationship was found between social support with the behavior as p=0.01 and the coefficient correlation r=0.517. The findings show that the support from figures in the community is strongly related to the people’s “3M Plus” behavior. The government should involve, empower, and encourage the community public figures to be active in the prevention of dengue hemorrhagic fever.

Keywords: behavior, dengue hemorrhagic fever, social support, prevention program

Introduction

The incidence of dengue hemorrhagic fever (DHF) in the world continues to increase every year and has become a major global health focus. Around 2.5 billion people who live in tropical and subtropical countries are at risk, including the Indonesian people.¹ The outbreaks of DHF can be avoided if the early awareness and vector control systems are implemented properly, integrated and sustainable.² The government of Indonesia has conveyed information about these activities to prevent outbreaks of dengue fever in the community through Act No. 4 of 1984 concerning infectious disease outbreaks and Minister of Health Regulation No. 1501/Menkes/Per/X/2010 concerning certain types of infectious diseases that can cause outbreaks and efforts to overcome them.³⁴ Vector control through vector survey is regulated in Minister of Health Decree No. 581 of 1992, requiring that mosquito nest eradication activities are carried out periodically by the community coordinated by neighborhood and citizens associations in the form of a “3M Plus” prevention behavior program consisting of draining bathtub regularly (menguras), covering water containers (menutup), burying garbage in the ground (mengubur), plus other prevention attempts.⁵ Since then, the government has been promoting the program massively as a priority action in grassroots.

The success rate of mosquito nest eradication activities through 3M Plus can be measured by larvaefree index (LFI). If the LFI is more or equal to 95%, the transmission of DHF can be prevented.² However, the LFI in Indonesia reached 76.3% in 2012, 79.3% in 2013, and 80.9% in 2014.⁶ This shows that there is still a lot of work to do to prevent the DHF cases in Indonesia.

Several factors associated with the dengue prevention behavior are age, gender, duration of stay in a regency, total family members, as well as the perception of prevention behavior.⁷ The prevention program is also associated with community participation, intersectoral coordination, and community empowerment, as well as economic cost.⁸ ⁹ However, no prior study has been
conducted to identify the relationship between social support and the implementation of prevention behavior, especially in the 3M Plus program of Indonesia.

Social support can have an implication in a health behavior. Also, social support and leadership can influence the organizational commitment. It enables the promotion of 3M Plus behavior to be given by community leaders, because social support from community leaders in health behavior shows a high percentage of 58.97%. The components of social support consist of attachments, social integration, reassurance of worth, reliable alliance, guidance, and opportunity for nurturance.

There are several factors that can influence a person’s behavior according to Green (1984), namely, enabling, predisposing, and reinforcing factors. These three factors support the social character of the community, including the reinforcing factors where community leaders provide innovation and behavioral encouragement so that the surrounding community will adopt this behavior and, in the end, there will be a change in the community behavior.

Thus, this research is aimed to identify the relationship between social support and 3M Plus behavior in the prevention of DHF in the community.

Method

This study used a correlational research design with a cross-sectional approach. The study involved 51 mothers in Benowo District, Surabaya. One respondent represented one household. The duration of the study was two months from May to June 2016. The inclusion criteria of the respondents were had obtained a senior high school degree, maximum age 50 years, healthy and had no mental disorder.

The variables were social support and 3M Plus behavior. The social support was measured using the Social Provision Scale (SPS) by Cutrona and Russel (1987). The SPS uses a 4-point Likert scale scoring with 1 stands for “very much disagree” and 4 for “very much agree”. The questionnaire had 24 items covering six domains, including attachment, social integration, reassurance of worth, reliable alliance, guidance, and opportunity for nurturance. Meanwhile, the 3M Plus behavior was assessed using the instrument developed by Wuryaningsih (2008). The instrument consisted of 15 questions with two answers, “Yes” (Score: 1) and “No” (Score: 0). The interpretation of the total score was good for more than 10, enough for 5-10, and less for less than 5.

Data analysis used rank test correlation Spearmen test with significance level α <0.05. The data analysis used a quantitative method and was carried out for quantitative data covering the stages of descriptive and analytic analysis. This research will perform a descriptive analysis of all research variables by calculating the mean and standard deviation.

Results

Table 1 shows that the age of respondents was mostly in the range of 18-35 years, as many as 27 people (52.9%). Most respondents were unemployed or becoming housewives, as many as 34 people (66.7%). The majority of respondents’ income was still below the minimum regional wage (UMR), as many as 36 people (70.6%). There were only 18 people (33.5%) who had a family history of suffering DHF.

The respondents who obtained good social support were 30 persons (58.8%) and only one person (2%) had lack of social support. In addition, the majority of 3M plus behavior level was good (34 people; 66.7%) and enough (17 people; 33.3%). There was none who practiced less 3M behavior (Table 2).

Table 3 shows that respondents who received good social support and had good 3M plus behavior were 26 people (51%) while respondents who received less social support and had enough 3M plus behavior were one person (2%).

The statistical analysis of the Spearman Rho correlation test shows that the p = 0.01 (<0.05) and the correlation coefficient (r) = 0.517. The results indicate that the H₀ is rejected. There are a significant relationship and a fairly strong level of relationship in a positive direction between social support and 3M Plus behavior in the prevention of DHF. It shows that, if the social support is increasing, the 3M Plus behavior will be also getting better.

Discussion

The study results show a strong positive relationship between social support and 3M plus behavior in the prevention of DHF, which means that the better the social support provided, the more the 3M Plus behavior is implemented. Social support is categorized as a reinforcing factor which can affect human behavior, in this case 3M Plus. In the DHF prevention strategy, a collaboration between the community, health workers and community leaders is needed. Community leaders themselves are one form of social support in society. A study also reveals that intersectoral coordination, community empowerment programs and routine control, which involve leadership of public figures, can change the behavior in dengue prevention. However, the respondents who have less behavior can be influenced by a lack of interaction with community leaders, even if the social support was good.

Further, social support is the result of the interaction of the situational context (certain influential life events), intrapersonal context (how someone sees themselves and the existence of important people around them and also the expectations in relationships with these people), and interpersonal contexts (subject relations with social support providers). The leaders also can provide counseling, which is also effective to change the prevention behavior in community. The results show as many as 12 people obtained enough social support, but had enough 3M plus behavior, while eight people got enough social support and had good 3M plus behavior, and one person got less social support but had enough 3M plus behavior. Such results also can be influenced by a personal factor, such as age, gender, duration of stay, perception and total family members.

The social support is the result of the interaction, one of which is intrapersonal interaction, namely, how someone sees themselves, the nature of the surroundings, public figures, and also the relationship expectation of these people. The good results can be the effect of the good relationship between respondents and community leaders, so that good collaboration is formed in the prevention of DHF through 3M Plus programs. The results are also strongly influenced by the willingness of the respondents to establish intense relationships with the community leaders. For respondents with less social support, but having sufficient 3M plus behavior, it is likely because the respondent did not want to establish a good relationship with community leaders because they were only 20 years old (too young) and did not have more emotional maturity like respondents aged 36-50 years. However, such respondents had an awareness of 3M Plus behavior in the prevention of dengue, because of having past experience that family members had been affected by dengue.
Conclusion

It can be concluded that the majority of respondents obtained positive social support and had good 3M Plus behavior. There is a meaningful relationship between social support and 3M Plus behavior in preventing DHF. Social support from public figures in the community is strongly related to the people’s 3M Plus behavior. The study recommends the government to involve, empower, and encourage the community public figures to be active in the prevention of dengue hemorrhagic fever.

Factors Associated with Pulmonary Tuberculosis of Positive Acid Fast Bacilli in Surabaya

Lailatun Nimah¹, Tintin Sukartini¹, Syarif Hidayatullah¹
¹Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

The study aimed to explain the most important factors in the incidence of positive acid-resistant pulmonary tuberculosis. This study used a cross-sectional approach. The sample was 68, consisting of 34 AFB (Acid Fast Bacilli) positive and 34 AFB negative, determined by initial examination. Data was collected via questionnaires and analysed by univariate (frequency distribution) and bivariate using Chi Square test with significance number <0.05. The most influential BCG immunization status, education, smoking, occupation, knowledge, nutritional status, occupancy density, income and gender, indicate the relationship but the risk is neutral, while age and comorbidities have no significant associated risk. The risk factors contributing to positive AFB in Perak Timur and Tanah Kali Kedinding areas were BCG immunization status, education, smoking habit, occupation, knowledge, nutrition status and occupancy density.

Keywords: pulmonary tuberculosis, Acid Fast Bacilli positive, immunization status

Introduction

Pulmonary tuberculosis is a contagious chronic infectious disease, caused by the bacterium Bacillus resistant Mycobacterium tuberculosis which attacks lung parenchymal tissue. Mycobacterium tuberculosis species include: Mycobacterium tuberculosis, Mycobacterium africanum, Mycobacterium bovis.¹Pulmonary – prevention and control. 3.Tuberculosis – economics. 4.Tuberculosis, Multidrug-Resistant. 5.Annual Reports. 1.World Health Organization. ISBN 978 92 4 156505 9 (NLM classification: WF 300 Global Tuberculosis report 2015, found 9.6 million new cases of pulmonary tuberculosis in 2014 with the number of cases occurs in Southeast Asia (58%), the Western Pacific (58%) and Africa (28%).² Prevalence and incidence of pulmonary tuberculosis in 2014 increased to 647/100.000 and 399/100.000 population from the previous year of 272/100.000 and 183/100.000 population, as well as the mortality rate from tuberculosis in 2014 had increased to 41/100.000 population from the previous year, namely 25/100.000 from population.³

The Directly Observed Treatment-Short course (DOTS) strategy of tuberculosis is the World Health Organizations (WHO) recommended approach, which involves passive detection of Pulmonary Tuberculosis cases, primarily using sputum smear microscopy. The global target using the DOTS program was to detect 70% of new sputum-smear positive Pulmonary Tuberculosis cases.³ However, only 32% of new sputum-smear positive Pulmonary Tuberculosis cases estimated were detected throughout the globe.⁵

The prevalence of chronic cough and sputum positivity were significantly higher among males compared to females. The higher prevalence of persistent cough and AFB positive sputum among males need further exploration. High population density, malnutrition create a substantial risk for infection with Mycobacterium tuberculosis in Bangladesh.⁶ Factors AFB significantly associated with: age > 35 years, past history of TB treatment, BMI < 18.5Kgs/m², and being a male currently consuming alcohol in India.⁷and also studied geographical distribution and the presence of different M. tuberculosis strains in the survey area. A community-based cross sectional survey was carried out from July 2010 to October 2012 in

DOI Number: 10.5958/0976-5506.2019.02275.7
Chennai city. Prevalence of bacteriologically positive PTB was estimated by direct standardization method. Univariate and multivariate analyses were carried out to identify significant risk factors. Drug susceptibility testing and spoligotyping was performed on isolated M. tuberculosis strains. Mapping of PTB cases was done using geographic positioning systems.

RESULTS:

Of 59,957 eligible people, 55,617 were screened by X-ray and/or TB symptoms and the prevalence of smear, culture, and bacteriologically positive PTB was estimated to be 228 (95% CI 189-265) History of contact with active tuberculosis patient and increased family size were significantly associated with smear positive pulmonary TB. This study aims to explain the factors associated with the incidence of acid bacilli positive pulmonary tuberculosis in Indonesia.

Method

Study Design, Setting, and Sampling: This cross-sectional study uses a survey conducted in two health centres there are Perak Timur and Tanah Kali Kedinding Located in Surabaya Indonesia. Two region health centres are the highest lung tuberculosis cases in Surabaya. The sample size 68 lungs tuberculosis patients. This consisted of 34 AFB (Acid Fast Bacilli) positive and 34 AFB negative. This study was conducted from 4-30 June 2018. After obtaining informed consent from each patient, a face to face interview was conducted using questionnaires requiring 10-20 min to be completed. Inclusion criteria: Age > 14 years. The results of the initial examination were positive in category I positive and negative smear, mentally healthy when doing the research, able to communicate well, able to write and read. Exclusion criteria is an incomplete answer.

Dependent variable in this study is incidence acid fast bacilli:

Data Analysis: Univariate and multivariate analysis was performed to look for any association between TB and risk factors such as age, gender, education level, occupation, income level, comorbidities, knowledge level, smoking habit, BCG immunization status, nutrition status, occupancy density.

Results

The results of univariate analysis found 68 respondents with pulmonary TB patients with positive smear (34) and negative smear (34). Among the 11 variables showed that there were 2 homogeneous variables (same), namely non-productive age (7.4%) and high income level (10.3%) because they were below 15% while the other variables were heterogeneous.

Table 2 showed statistical results of age factors obtained at \( p = 0.642 \) means \( p > 0.005 \), no significant relationship was found between age and the incidence of positive smear pulmonary TB. The results of the gender variable statistical test obtained a value of \( p = 0.049 \), so there was a relationship. CI value = 0.994-7.3331 showed that the CI value is not significant so it is neutral. Education factors were obtained at \( p = 0.003 \) means \( p <0.05 \), concluding that there is a significant relationship. The risk of incidence of positive pulmonary TB in smear is 4.9 times greater at the lower education level compared to the level of higher education to experience pulmonary smear positive AFB and is based on the value of CI = 1.672-14.273 which indicates a significant relationship.

Occupation test obtained a value of \( p = 0.007 \), indicating there was a significant relationship. The risk of incidence of pulmonary TB positive smear is 4 times greater in people not working rather than those in work. CI value = 1.426-11.04 which indicates a significant relationship. Income level test results obtained the value of \( p = 0.046 \) concluding that there is a relationship. CI value = 0.803-62,311 which indicates that the CI value is not significant because it includes number 1, so that it is neutral. There was no difference in the risk of positive smear pulmonary TB occurring between high and low income levels.

Comorbidities factor test obtained \( p = 0.128 \) it concluded that there was no significant relationship. The results of the statistical knowledge level test results obtained a value of \( p = 0.021 \), concluding that there is a significant relationship. The risk of positive AFB pulmonary TB incidence is 3.4 times greater in people with a sufficient level of knowledge than people with a good level of knowledge to experience positive smear pulmonary TB and CI value = 1.176-9,994 showed a significant relationship.

Smoking habit obtained \( p = 0.031 \) concluding that there is a relationship and positive smear lung is 4.3 times greater in people smoking than those who do not smoke. CI value = 1.066-17.389 showed a significant relationship. BCG immunization status were obtained \( p = 0.000 \), concluding that there is a questionable relationship between BCG immunization status and the incidence of positive smear pulmonary TB. The risk of occurrence of pulmonary TB positive smear is 47 times greater in people who are not immunized than people who are immunized. CI value = 5.753-386,291 showing that there is a significant relationship.

The nutrition status test results obtained \( p = 0.038 \) showing a significant relationship. The risk of positive pulmonary TB incidence is three times greater in people with underweight nutritional status than normal nutrition status for positive pulmonary TB and can be seen from the CI value = 1.042-8.8896 which showed a significant relationship. Occupancy density statistical test obtained a value of \( p = 0.028 \) it can be concluded that there is a significant relationship. The risk of occurrence of positive pulmonary TB incidence is 3 times greater in people who live in dense settlements than those who do not to experience the incidence of positive smear pulmonary TB and seen from the CI value = 1.108-8.049 which indicates a significant relationship.

Discussion

The results showed no significant association between age and the incidence of smear positive pulmonary TB. The two age categories were respondents in this study, namely productive age (15-64 years) and non-productive age of more than 64 years. Univariate test results showed homogeneity in this factor so that it becomes that in one of the causes there is no significant relationship between age and the incidence of positive smear pulmonary TB. The results of this study are in accordance with the statement that ages 15-50 years have a high risk of experiencing pulmonary TB incidence three times greater than non-productive age. The majority of patients in the two health centres were mostly productive age. Most of the population of Indonesia is a productive age. Infectious diseases occur a lot in this age group.

Gender status was no difference in risk of occurrence of positive smear pulmonary TB between men and women. The results of this study are not in accordance with the statement prevalence of smear, culture, and bacteriologically positive TB was highest amongst men aged 55-64 years. and also studied geographical distribution and the presence of different M. tuberculosis strains in the survey area.

METHODS: A community-based cross sectional survey was carried out from July 2010 to October 2012 in Chennai city. Prevalence of bacteriologically positive PTB was estimated by direct standardization method. Univariate and multivariate analyses were carried out to identify significant risk factors. Drug susceptibility testing and spoligotyping was performed on isolated M. tuberculosis strains. Mapping of PTB cases was done using geographic positioning systems.

RESULTS: Of 59,957 eligible people, 55,617 were screened by X-ray and/or TB symptoms and the prevalence of smear, culture, and bacteriologically positive PTB was estimated to be 228 (95% CI 189-265 The activity between men and women going out to work, socializing can be a factor in this. The risk of transmission to infectious diseases is equally likely between men and women.

Education level is a factor significantly associated with smear-positive TB were education levels of primary, secondary education, occupation of merchant and urban residence. The majority are positive pulmonary TB patients with low education. Their education is at elementary and junior high school level. Education which has a low impact on health.

The majority of positive pulmonary smear patients do not work. Employment status can determine socioeconomic status. Low economic status affects mortality rates caused by disease. Pulmonary TB often occurs in low economic status, this is related to someone who does not work or unemployment. Work can determine the socioeconomic class of the community. The number of pulmonary smear positive TB patients who do not work causes them to be unable to healthy food, adequate shelter so that the risk of transmission of pulmonary TB is higher.

Low and high income levels both have the same effect on the incidence of positive (neutral) pulmonary TB. Socioeconomic and behavioural factors are also showed to increase the susceptibility to infection. the lower the economic status, the higher the risk of suffering from pulmonary TB. The majority of patients with positive pulmonary TB have low income. A person’s income level is very influential on a person’s behaviour in maintaining one’s own and family’s health. Revenue will affect the purchasing power of adequate nutritional and residential needs.

There was no significant association between comorbidities and the incidence of smear positive pulmonary TB. Along with-established risk factors (such as human immunodeficiency virus (HIV), malnutrition, and young age. No patients were suffering from HIV at the study site. This allows the absence of a relationship. The majority of smear positive pulmonary TB sufferers are accompanied by hypertension, vertigo and some people have insulin-controlled diabetes mellitus. The relationship between the level of knowledge and the incidence of pulmonary TB positive smear has a significant relationship. Good level of knowledge will be very stressed on increasing the regularity of care for pulmonary TB that takes a long time (6 months).

Tobacco smoking and alcohol use is highly prevalent in India, particularly among men. Active smokers have a greater risk of developing pulmonary tuberculosis. Biological explanations including impaired clearance of mucosal secretion, reduced phagocytic ability of alveolar macrophages and decrease in the immune response and or CD4 lymphopenia due to the nicotine in the cigarettes have been given as reasons for increased susceptibility to pulmonary tuberculosis.

Patients with pulmonary TB with no BCG scar and high initial AFB sputum intensity are at risk of remaining
sputum culture positive at the end of the second month of anti-TB treatment. These findings reflect a beneficial role for BCG vaccination on sputum conversion which should also be examined in large studies in other areas. The finding of a beneficial role for BCG vaccination on the treatment of pulmonary TB is important for TB control and vaccination programmes. Most respondents were never vaccinated with BCG, this is the factor that causes respondents to get pulmonary TB easily.

Respondents in this study were normal and underweight. Studies have showed that malnutrition (both micro- and macro-deficiency) increases the risk of TB because of an impaired immune response. Occupancy density has a significant relationship with the incidence of smear positive pulmonary TB.

**Conclusion**

Education level, smoking habit, occupation, knowledge, nutritional status, occupancy density, income and gender, indicate relationship but the risk is neutral, while age and comorbidities have no significant associated risk. The most dominant risk factors in the incidence of pulmonary tuberculosis acid fast bacilli in Indonesia is BCG immunization status.

ABSTRACT

The family is the entry point in providing nursing services in the community, the involvement of all family members is needed in carrying out health tasks as an effort to prevent and treat DM. This aim of the study was to analyse personal and family factors towards family health tasks that have family members with DM patients. The study design used an analytic observational design with a cross sectional approach, a population of 184 DM families, a sample of 67 respondents using cluster random sampling. Analysis was conducted using the Spearman rho test. The results of the research of the patient factors influencing family tasks are age (p = 0.003), gender (p = 0.837), education (p = 0.013), work (p = 0.936), duration of suffering (p = 0.538). Family factors that affect family health tasks are family type (p = 0.137), family development (p = 0.097), income (p = 0.001), knowledge (p = 0.001). The average health assignment is 56.7% less. DM patients and families need to increase their knowledge about DM, complications, prevention, treatment therapy and be able to maximize health facilities in providing continuous care.

Keywords: Family, DM, personal, family health tasks

Introduction

Family behaviour plays an important role in efforts to improve health and prevent disease. The family is the entry point in providing nursing services in the community, the involvement of all family members is needed in carrying out health tasks as an effort to prevent and treat DM. The family functions as a support system for members suffering from DM who demand greater economic, social, and psychological sacrifice from the family.¹ The inability of the family to carry out five family health tasks for people with DM can be caused by several factors, one of which is family knowledge and family social economy. Knowledge gained will also influence families to make the right decisions in choosing treatment measures for DM patients in accordance with the family economy. The task of family health in caring for DM patients is also needed such as routinely controlling blood sugar, regulating diet, handling patients when blood sugar drops and controlling the taking of some medicines have been carried out by the family partly because they do not care about patients and have often been warned but ignored by sufferers.²

World Health Organization (WHO) data in 2017 shows that the prevalence of people with DM with neuropathy reaches 50% and those with foot injuries is 15-25%. The results of the study in Arabic state that 70% of lower extremity amputations are DM patients with foot injuries.³ Indonesia ranks 7th in the world with the highest number of DM patients and estimates reaching 6.7-11.1 million sufferers (IDF, 2017). The results of the 2018 Riskesdas study indicates that the prevalence of DM in the population of Indonesia aged > 15 years increased to 8.5%. East Java ranks 5th in the number of people with DM in Indonesia, namely 7.4% (Ministry of Health, Republic of Indonesia & Ministry of Health, 2018). Surabaya itself has a higher incidence of diabetes than the national rate of around 7.6%.⁴ Data in one of the health centres in southern Surabaya shows that the number of new patient visits was between 200-350 patients per month (Kebonsari Health Center).

Seeing the high prevalence of people who have DM disease, it can be said that there is a high risk of diabetes
foot injury. The trigger factors for foot injuries are vascular damage and nerve damage. Decreased blood flow in the leg area can result in injury, the condition of neuropathy also causes sufferers not to feel the sensation of the foot area. Increased blood sugar levels that occur continuously can cause an imbalance of the material used by the intercell matrix, accumulation of sorbitol in the basement membrane of cells can cause disruption of microcirculation and thickening of cell membranes, so that inadequate cells receive oxygen and nutrients required. As a consequence of the occurrence of gangrene wounds.

The practice of family nursing as a centre of nursing is based on the idea that the family is the basic unit for carrying out nursing care for individuals and family members. Families are part of a community that has different cultural, social and economic differences, structure, functions and coping. The family carries out 5 health tasks, namely: 1) recognizing health problems, 2) being able to decide on appropriate health measures for the family, 3) being able to care for family members who experience health problems, 4) being able to maintain a healthy home atmosphere or modify the environment to ensure health family members; 5) able to utilize nearby health care facilities for families. Handling DM really requires the active role of individuals and families as a supportive system to optimize their health status. Families who cannot complete family health assignments are given an education towards the sufferers themselves, especially to families for initial treatment in the event of hypoglycaemia in patients, treatment to prevent diabetes injuries, prevention of relapse from diet and activity, and routine control of blood sugar until taking routine medication. The purpose of this study was to analyse patient and family factors in carrying out family health tasks in DM patients.

Method

The design uses the observational analytic method, where observations were made to identify the independent variables, which included patients and families affecting the dependent variable, that is five health tasks of families. Data retrieval is done by a cross sectional approach. The population in this study was a family with one family member suffering from DM in Surabaya, amounting to 184 families. The sampling technique in this study used probability sampling with cluster sampling with a total sample of 67 families in Surabaya. Independent variables are patient and family factors while the dependent variable is family health tasks, the data scale is ordinal.

The research instrument used questionnaire sheets and observations. The results of the validity and reliability test stated that the questionnaire that the researcher submitted was stated to be reliable or valid, the results of the reliability test value “Cronbach’s Alpha” (0.971). The bivariate data analysis used the Spearman rho statistical test with a significance level of p <0.05.

Results

This study showed the characteristics of patients with DM. In table 1, which includes the factors of age, sex, education, work, and duration of suffering from DM. Some of these factors are associated with family health tasks. From the results of data analysis, it was found that there were only 2 factors from patients related to family health tasks, namely age (p=0.003) and educational factor (p=0.013).

The characteristic family factor in this study found that characteristic family factors were associated with the implementation of family health tasks, which were seen from family type, family development, income, and knowledge factor. Table 2 is an analysis of family factors and health tasks.

In general, 59 families (88.1%) were able to recognize health problems well, 34 respondents (52.3%) were unable to decide the right actions for the family, 52 respondents (77.6%) were unable to provide care for their family members who had DM disease, 38 respondents (56.7%) were less able to modify the environment that could support health, and 43 respondents (64.2%) were less able to use health facilities.

The research data shows that many families of DM sufferers are lacking in carrying out family health tasks. The task of good family health is 9 people (13.4%), 20 people (29.9%) carried out sufficient health tasks and 38 people (56.7%) are lacking in carrying out family health tasks.
Discussion

The research data shows that many families of DM sufferers are lacking in carrying out family health tasks. Getting to know family health problems, namely the extent of the family, recognizes the facts of health problems that include understanding, signs and symptoms, causes and influences and family perceptions of the problem. Family recognition of the problem of DM includes knowledge about the understanding of DM, knowledge of the causes of DM and the role of the family in finding and collecting information and notifying family members about the problem of DM. The family is familiar with healthy conditions and changes experienced by family members from the observation of many families who say that DM disease is a hereditary disease, this disease can cause sores on the feet, this disease can be caused by lifestyle and eating patterns.

One of the family health tasks, namely that the family is able to make decisions regarding appropriate health actions, can be seen from: the extent to which families understand the nature and extent of the problem, whether the family’s health problems are felt, whether the family feels surrendered to the problem, whether the family feels fear of the consequences of the action of the disease, whether the family has a negative nature of health problems, whether the family can reach existing health services, whether the family lacks trust in health workers, whether the family is misinformed in dealing with problems. All factors that influence a family’s ability to make decisions are the effects of positive knowledge obtained by the family. Families provide the necessary actions for family members who experience DM such as choosing good health facilities with BPJS services, choosing the right treatment and knowing the consequences and benefits of each action that will be taken. The family immediately brings patients to the nearest health service if they experience DM complaints such as symptoms of dizziness, dizzy eyes and tingling.

Families are able to care of family members who are sick, especially those with DM, must be able to make complex behavioural changes, for example by making meal planning, physical exercise, hypoglycaemic efficacy drugs and counselling. Family-owned experience and knowledge can help families take appropriate care to reduce health problems experienced by families. The family in providing care is shown by carrying out simple treatments for prevention to a minimum in accordance with the abilities that the family has. There are still many family tasks regarding care that have not been carried out properly, especially regarding the regulation of eating in DM patients, routine blood sugar control every month and minimal family economic conditions.

The family response when there are sick family members varies greatly from not doing anything with unobtrusive reasons, taking certain actions such as self-medication, looking for traditional health facilities, seeking treatment at drug stalls, seeking treatment to modern health facilities organized by the government or private institutions such as medical centres, health centres, hospitals to find modern treatment organized by practicing doctors. Based on the data of respondents characteristics that the respondents work varied and the majority of the respondents jobs were entrepreneurs and some traders were also just housewives. According to Fautino (2008) the higher the quality of one’s work, the higher the income earned, and vice versa. So this makes it easier for people to reach existing health services. Health services that are quite far from their homes make families reluctant to bring sick family members to health services. Someone who has been diagnosed with diabetes for years can receive a diagnosis of his illness and treatment regimen, and have a better adaptation to his illness by integrating new lifestyles in their daily lives. Someone explained that the duration of DM at the time of diagnosis was confirmed by the fact that it did not provide a description of the duration of DM, even though diabetes may have occurred beforehand but the patient did not know because there were no significant symptoms from DM. In fact, people with shorter duration of suffering from more DM cannot perform health tasks properly.

The income category shows the value of \( p = 0.001 \) (\( p \) value <0.05) so it is concluded that there is a relationship between family income and family health tasks. According to Friedman’s theory (2010), it is known that the level of socio-economic status influences a person’s health. Families with high income levels and utilization of health services and prevention of disease also increase compared to low income will have an impact on the lack of utilization of health services in terms of health care due to drug purchasing power and costs incurred in visiting health care centres, this economic situation or income holding important role in improving family
health status and one’s development. The knowledge category shows the value of $p = 0.001$ (p value <0.05), it is concluded that there is a relationship between family knowledge and family health tasks. People with high knowledge find it easier to understand health behaviours compared to people with low levels of knowledge. Knowledge held by respondents regarding diabetes and management will create awareness for them and eventually will cause them to behave according to what they know. Knowledge is one of the drivers for someone to change behaviour or adopt a new behaviour. Family members who have knowledge of DM are expected to carry out the task of caring for DM patients well.12

**Conclusions**

Family independence in carrying out family health tasks that have family members who suffer from DM needs more attention. Age, education, income and family knowledge factors influence the family’s ability to carry out family tasks. So it is necessary to modify these factors through several efforts to empower families, education, health promotion, and cross-sectoral efforts related to national health insurance.

ABSTRACT

Caring is a hospital strategy by which to achieve patient satisfaction. The aim of this study was to assess patient satisfaction with nursing care and to identify the predictors based on Swanson’s theory of caring, including compassion, competence, and upholding trust. Cross-sectional studies were conducted in patients at a hospital in Kediri District (n = 390 by simple random sampling) from May to October 2018. The instrument in this study was developed in accordance with the standard guidelines of Swanson’s theory, and patient satisfaction was measured using PSQ (Patient Satisfaction Questionnaire). Multiple linear regression was used to identify predictors. The mean score of client satisfaction was 6.09 (SD = 0.936) (range of possible score = 1-10). Upholding trust (0.02), Compassion (0.03), and competence (0.03) significantly predicted client satisfaction (R Square = 0.895). The constructs of Swanson’s Theory significantly predicted patient satisfaction. This study supports an investigation about the factors underlying client satisfaction on a larger scale, as well as the identification of targets in designing future interventions.

Keywords: Caring, Patient Satisfaction, Swanson’s Theory of Caring

Introduction

Caring is the main thing used by hospitals or other health services to achieve patient satisfaction. Some experts agreed that patient satisfaction is the key of existing hospitals or other health services.¹ Patients could feel satisfied when caring was as expected.² That statement makes nurse caring behaviour the main part of patient satisfaction used as the evaluation of health services.³ Caring as the evaluation of health service becomes a trend in this era.⁴ The wave of health service marketing has changed from an excellence service era to care with character era, with caring values as the principle in health services.⁵ The correlation between caring and hospital services and patient satisfaction was proven by research.⁶ Health service researchers, health service centres, and the regulators of health services also admitted that patient satisfaction is a part of a constituent’s clinic report.⁷

Based on the data of one of hospital in Kediri city, it shows that the number of patient satisfaction to nursing service is less than 80%. In 2017, the number of patient satisfaction decreased, from 79% in 2016 to 77% in 2017. That number is still under Indonesia government standard which determines that satisfaction must be over 85%. This case is often correlated to low nurse skills in caring for patients. Based on research about caring, it showed that up to now, caring is understood as empathy.⁸

As an effort of increasing patient satisfaction, a nurse must have standard caring skills to provide medical services to patients. Therefore, the goal of this research is to measure patient satisfaction and to observe factors affecting satisfaction itself.

This research uses Swanson’s Theory of Caring as a framework. Swanson argued that caring is correlated to both nurse philosophical behaviour and nurse performance, namely always giving information, understanding, delivering messages, conducting therapy, and wishing the best final result.⁹ All nurse caring skills are classified into three main constructs from Swanson’s Theory of Caring such as; Upholding Trust, Compassion, and Competence.¹⁰ Qualitative research from Belgium
shows that the main construct from Swanson’s Theory of Caring can measure nurse caring skills. While nurse caring skill itself is really correlated to patient satisfaction.

Therefore, we argue that Swanson’s Theory of Caring can explain directly the level of patient satisfaction. In this research, we explore some factors associated to the level of patient satisfaction based on the construct of Swanson’s Theory of Caring. The hypothesis we offered, Upholding Trust, is associated with the level of patient satisfaction. Comparison is associated to the level of patient satisfaction, and competence is associated to the level of patient satisfaction.

Method

Study Design, Setting, and Sampling: Cross-sectional studies were conducted in patients at a hospital in Kediri District. The recruitment of respondents used simple random sampling. Respondents consisted of patients hospitalized for more than two-day care. Patient having co-morbidity (insanity and neoplasia), and patients not finishing the questionnaire was beyond the research. This research was conducted on 390 hospitalized patients agreeing to join in this research.

Study Variables: The independent variables were upholding trust, compassion, and competence while the dependent variable was the level of patient satisfaction.

Instrument: The data collection method used a questionnaire. The test of patient satisfaction level used PSQ (Patient Satisfaction Questionnaire), while to test Upholding Trust, Compassion, and Competence used an instrument developed from the instrument standard of Swanson’s Theory of Caring.

1. Swanson’s Theory of Caring Questionnaire: This instrument’s purpose is to test nurse caring skills. We got permission from Swanson via e-mail to use and translate this instrument. The translation process was conducted to suit the conditions in the research area. This instrument has questions related to upholding trust, compassion, and competence, with 5 questions each of them.

2. PSQ (Patient Satisfaction Questionnaire): This instrument aims to test the level of patient satisfaction to health service. PSQ has 18 points, and it is divided into 9 favourable points and 9 unfavourable points. The point distribution in PSQ as follows: the aspect of satisfaction (2 points), technique quality (4 points), interpersonal attitude (2 points), communication (2 points), financial aspect (2 points), time with doctor (2 points), and access and comfort (4 points).

Data Analysis: The data was analysed by SPSS version 22. Multiple linear regression was used to identify the contribution of upholding trust, compassion, and competence variable to patient satisfaction. The redundancy variable in this research are socio-demographic factors such as; sex, education, job, and age. Pearson correlation analyses were used to view the correlation between socio-factors and patient satisfaction. The significant level applied was p < 0.05.

Results

Socio-demographic characteristics of the respondents: 390 respondents in this research responded 100%. They are on average 36.6 years old. More than 55.4% of respondents are male. 58.3% of respondents’ educational background are elementary school, 39.8% are high school, and 1.9% are college. Most respondents (71.2%) are staff, 3.8% are civil servant, 1.9% are policemen/military, and 23.1% are jobless. Age, education, and occupation are statistically correlated to satisfaction level, while sex does not determine patient satisfaction.

Patient satisfaction: The mean score of patient satisfaction in this research is 13.09 (SD = 1.36) range of possible score = 0-18). Based on the result of questionnaire analyses, more than 60.2% respondents
stated, “The medical care I have been receiving is just about perfect”, but more than 60.2% also stated, “Nurses sometimes ignore what I tell them”, and 45.8% respondents stated, "I find it hard to get an appointment for medical right away”. The result of data collection from PSQ-18 can be viewed in table 2.

</tbody>
</table>

The correlation between socio-demographic factor to patient satisfaction: The analyses of Pearson correlation showed that there was no significant correlation between sex and patient satisfaction (p=0.926) while age, education, and occupation are correlated to patient satisfaction: age (p=0.021), education (p=0.03), occupation (p=0.004). The detailed results can be viewed on table 1.

The effect of upholding trust, compassion, and competence to patient satisfaction: The mean of every variable is 10.42 (SD = 1.72) for upholding trust variable (range of possible score = 5–15), 12.53 (SD = 2.74) is for compassion variable (range of possible score = 5–15), and 13.42 (SD = 2.8) is for competence variable. Regression linear multiple analyses show that upholding trust, compassion, and competence are significant at once in predicting patient satisfaction (p = 0.00) (R Square = 0.895), if it was viewed from significance level differently, it will show that (p = 0.02) is for upholding trust, (p = 0.03) is for compassion, and (p = 0.03) is for competence.

Discussion

This research found that patient satisfaction in hospitals where this research was conducted had a mean score 13.09 (range of possible score = 0-18). It was not a good research finding yet, because the experts agreed that patient satisfaction is the key of hospitals, or other health service exist. We found that most respondents were satisfied enough for caring from nurses, but some respondents stated that nurses used to ignore what they wanted, and more than half respondents stated that it was hard to make a medical appointment soon. It may be caused by the abundance of nurse responsibility in research location, and low nurse motivation, so it makes their performance in caring patient decrease. It was supported by some experts’ opinions that nurse responsibility abundance is correlated to nurse caring behaviour. In this research, socio-demographic factors (like sex, education, and occupation) is correlated to patient satisfaction, but it is not correlated to sex. It was also reported in a research that every social situation of individual could affect their perception to health service satisfaction. In the effort of increasing patient satisfaction, hospital or other health service management must fix the standard of caring based on the social situation around them.

This research tries to observe the factors effecting patient satisfaction based on Swanson’s Theory of Caring. The research result shows that the main construct of Swanson’s Theory of Caring (upholding trust, compassion, and competence) can explain more than 85% kinds of patient satisfaction. In this research, we found that the construct of Swanson’s Theory of Caring could explain the patient satisfaction in a hospital (research location) as documented on previous study. It was known that upholding trust, compassion, and competence can predict nurse skill caring, while nurse skill caring itself is correlated to patient satisfaction. Other research explained that Swanson’s Theory of Caring can be used as a approach in nursing models to develop more holistic nursing science. That statement makes nursing caring attitude the main part of patient satisfaction used as evaluation system of health services. Caring as a health service is a trend in this era. The wave of health service marketing has changed from an excellence service era to a care with character era becoming caring value as a principle of health service. Information, motivation, and behaviour skill are the main factors to influence performance behaviour called nurse caring behaviour in this research. This study only investigates the description of patient satisfaction and caring factors that influence it, we do not investigate how good caring and bad caring are.

Figure 1: Extended Swanson’s Theory construct to predict patient satisfaction. Notes: Statistics reported next to arrows are standardized regression coefficients. *p < 0.001 ; ** p < 0.05

Conclusion

We found patient satisfaction in less good condition in this population, because as we know patient satisfaction is the key to hospitals and other health services’ existence. Socio-demographic factors (age, education, and occupation) is correlated to patient satisfaction, but not to sex. We also found that the construct of Swanson’s Theory of Caring can explain patient satisfaction in hospital research. This study helps professional health officials and researchers to understand patient satisfaction. Further research must apply Swanson’s Theory of Caring as an intervention and measure the success in increasing patient satisfaction, because evidence-based nursing practice needs a nursing guidance model to develop the holistic nursing practice and application. This study supports both researchers and professional nurses to observe the based-factors of patient satisfaction on a wider scale, and to identify the target in arranging intervention in the future.

The Correlation between Family Support and Quality of Life in Mothers with Positive HIV in Surabaya

Ika Nur Pratiwi,1 Purwaningsih1, Sevina Ramahwati1
1Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

The quality of life of mothers with positive Human Immunodeficiency Virus (HIV) is a concern due to a lack of family support. The aim of this study was to determine the relationship between family support and the quality of life of mothers living with positive HIV in Surabaya. This was a descriptive correlational study with a cross sectional approach. The subjects were 30 mothers with positive HIV from two public health care facilities in Surabaya who were already confirmed to have positive HIV by healthcare professionals without manifestation of Acquired Immune Deficiency Syndrome (AIDS). Family Support Questionnaires used were family support and World Health Organization Quality of Life (WHOQOL) HIV for quality of life. The data was analysed using Spearman’s Rho correlation test with P value < 0.05. The result showed that the majority of respondents are in early adulthood (26-35 years). Some respondents had HIV for less than 4 years and used anti retro viral (ARV) for 2 years. There was a moderate positive correlation between family support and quality of life of mothers with positive HIV (P = 0.026, Spearman’s rho = 0.48). The better the family support, the higher the quality of life which may be achieved by the clients.

Keywords: family support, quality of life, mother, HIV

Introduction

HIV cases cause various effects on sufferers, in addition to reducing the body’s resistance and the emergence of opportunistic infections (OIs), patients can also experience psychological and social problems.1 The HIV epidemic is a global crisis and a serious challenge to developmental and social progress. Since its start in 1981, AIDS has become a major health problem worldwide. There have been more than 78 million people infected with HIV by the end of 2013 with people living with HIV/AIDS amounting to 35 million.2 In Indonesia, the number of new HIV infection cases is known to be 8,908 people, these cases have increased twice compared to 2013 where 6,528 (42.0%) cases were women. According to the type of work, the housewife group ranks highest.3 The highest percentage of the age of HIV infection was reported in the age group 25-49 years (68%), followed by the age group of 20-24 years (18.1 %). East Java entered second province (19,249 cases) after DKI Jakarta (32,782 cases).4 The city of Surabaya has the largest number of cases of HIV in East Java.5 HIV cases in Surabaya have the potential to cause problems because until 2016, the age group affected by HIV was highest in the age range of young adults, the productive phase. Young adulthood begins at the age of 25 years and ends at age 40.5

HIV cases caused various effects on sufferers in addition to reducing the body’s resistance and the emergence of opportunistic infections (OIs), patients can also experience psychological and social problems.1 Family support can have a positive impact on improving the quality of life for people with HIV.6 Quality of life in people with HIV is very important to understand because this infectious disease is chronic and progressive so that it has a broad impact on all aspects of life. Quality of life is an important component in evaluating the well-being and life of people with HIV.7 Family support has an important role to improve coping with one’s adaptation to situations that are full of pressure, reduce morbidity and discipline treatment for clients and indirectly support family support to improve one’s physical health.8

DOI Number: 10.5958/0976-5506.2019.02278.2
In Surabaya, there are four public health care facilities which provide HIV/AIDS treatment services; public health care Sememi, public health care Perak Timur, public health care Putat Jaya and public health care Dupak. Some mothers of HIV who were met at the Public health care Dupak said that they came to the Public health care Dupak rarely accompanied by family, and still fulfilled their daily needs without assistance from the family. They often feel that they are excommunicated by their families even though they live in one house after their husbands die, they worry that their neighbours will move away with the disease so they choose to keep it a secret. They also revealed disturbances in appetite, sleep disturbances, disruption of relationships with family and the environment and physical discomfort due to taking ARVs. The purpose of this study was to determine the relationship of family support and quality of life of mothers with HIV positive in Surabaya.

Method

Study Design, Setting, and Sampling: A cross-sectional data collection on mothers with HIV positive was conducted. The population in this study were 16 HIV positive women in public health care Dupak and 20 HIV positive women at public health care Sememi so that the population was 36 HIV positive women. Inclusion criteria to enter the study were; HIV positive mother whose status is known to the family, able to read and write, doesn’t stay nomadic and which is not accompanied by AIDS. This study used purposive sampling which obtained 30 samples at public health care Dupak and public health care Sememi.

Study Variables: The independent variable in this study was family support which was measured using a family support questionnaire based on the theory of family support from house which had been tested for validity and reliability. This consisted of 18 question items representing 5 sub-variables, namely informational support (11-13), award support (14-16), instrumental support (6-10), emotional support (1-5) and social network support. The questionnaire is presented in 4-grade Likert scale.10

The dependent variable in this study is the quality of life (QOL) of mothers who were HIV positive who were measured using the life quality from WHOQOL-HIV BREF. This questionnaire consists of 31 questions with 29 items included in the calculation of scores and two items of questions that measured the quality of life and general health conditions. The questionnaire is presented in a 5-grade Likert scale.11 The WHOQOL-BREF has been recommended as the most suitable instrument for assessing the QOL of various people.12 This questionnaire have been tested for validity and reliability with the Cronbach Alpha test.

Data Analysis: The results were analysed using Spearman’s correlation test due to the skewed distribution of data with a significance level of α<0,05.

Results

There were 30 mothers with HIV who were respondents to the study. The majority are 26-35 years old (50%), as many as 60% of respondents are still married, have used ARVs for 2 years (50%) and have children ≥1 - ≤2 (57%) (table 1).

Description: p = significance value (<0.05) r = correlation coefficient (> 0.3494).

Discussion

This study shows that there is a significant correlation between family support with the quality of life of mothers who are HIV positive in Surabaya. Contingency (r) it obtained 0.405 which means that the relationship of family support with the quality of life of mothers who are HIV positive has a moderate strength correlation. Family support is one factor that is significantly related to quality of life in HIV clients where clients with good family support are more likely to have a good quality of life. Families who support people in China who are living with HIV/AIDS (PLWHA) have a 61% chance, 1% more to get a good quality of life compared to those who do not support.  

The majority of respondents received good family support while the rest received less family support and sufficient family support. The role of the family is very important in client health care. Family support is needed by HIV sufferers as a support system or main support system so that they can develop effective responses or are coping to adapt well in dealing with the stressors they face in relation to their physical, psychological, and social illness. Family support can have a positive impact on the quality of life for people with HIV. Furthermore, among HIV-infected adults whose relationships between social support and psychological adjustment were examined, greater support, including financial and spiritual support, was found to reduce psychological distress, such as symptoms of depression.

The existence of family support will make families able to function with various intelligence and reason, so that it will improve their health and adaptation in life. In concept, the existence of chronic diseases such as HIV/AIDS will reduce the quality of life of patients. This disease can develop even worse if the client experiences pressures from both family and society. This will affect the physical and psychological conditions of the client. The long and prolonged pressure will have an impact on the immune system and accelerate the progression of the disease. If the pressure from the client can be controlled, the modulation of the immune system is to be better so that the quality of life becomes good.
The results showed that the majority of respondents had a quality of life in sufficient condition. Quality of life is an individual’s ability to enjoy satisfaction during life. Clients with HIV who have sufficient quality of life categories up to very good categories can also be affected by regular consumption of ARVs. ARV therapy will stop HIV activity, restore the immune system and reduce the occurrence of OIs, improve quality of life and reduce disability. Quality of life itself is influenced by various factors, namely the presence of sex, age, education, occupation, marital status, income, religion, how long the client has HIV, how long the client has consumed ARVs and so on. A good environment around HIV clients can improve the quality of life of clients.

About 50% have used ARVs for 2 years with the healthy condition during data collection. Zhang reported that approximately 81% of HIV-infected patients in China had symptoms when they began ART. Another study indicated that the QOL of patients with symptoms would see more pronounced improvements than those without symptoms after ART. Generally, with the increase of therapy time, the QOL of people infected with HIV showed a rising trend from baseline to 24 months. However, more in-depth research is needed to better understand the underlying causes for the plateau and, in some cases, decrease. In particular, greater attention should be paid to patients after 6 months in order to continuously improve patient quality of life.

Educational factors influence the quality of HIV positive mothers. Individual education factors will relate to the level of insight and knowledge. The level of education is one of the factors that influences the quality of life of clients of HIV and AIDS. Based on the results of the study, it was found that the average duration of suffering was approximately 4 years. Long suffering from the disease is a significant factor affecting quality of life.

In this aspect of limitation explained the obstacles or limitations of researchers during conducting research, among others: filling out questionnaires takes longer. The thing that is feared is influencing the respondent’s answer because this filling in of the form can disrupt the respondent’s daily activities and the respondents’ collection techniques that are different between public health care Dupak and Sememi, are feared to influence respondents’ answers in filling out the questionnaire. The public health care Dupak collection technique meets the respondent directly (door to door) while at the public health care Sememi they are collected by respondents at one time.

Conclusion

Family support is related to the quality of life of HIV-positive mothers in Surabaya. The better the family support, the higher the quality of life of the client. The majority of HIV positive mothers have good family support. Further development in information has other factors (health worker support, community behaviour, the effect of ARV therapy etc.) that can affect the quality of life of patients with HIV/AIDS.

Ethical Clearance: This study did not use animals and does not mention the identity or medical record of the respondents. The ethical approval for this study was granted by the IRB committee of the Faculty of Nursing at the Airlangga University no. No. 186-KEPK June 2016.

The Effect of Balance Exercise on Postural Balance of Elderly as Fall Prevention in Institutionalized Elderly

Elida Ulfiana1, Triyana Puspita Dewi1, Ah Yusuf6
1Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

The common problem of elderly physical changes is a postural balance which can increase the incidence of fall. Balance exercise is an exercise program to increase the postural balance of elderly. This study aims to analyze the effect of a balance exercise that increases elderly postural balance. This study was a quasi-experimental design. The samples were 28 respondents from Wana Seraya Denpasar Nursing home based on inclusion criteria and divided into treatment group and control group containing 14 respondents in each group. The variable was elderly postural balance with balance exercise as the intervention. The participants were evaluated using the Berg Balance Scale. This study used the Wilcoxon Signed-Rank Test and Mann Whitney Test. The results showed that there was an increase in the postural balance in the treatment group (p=0.014), but, in the control group, there was no change (p = 1.00). There was a significant effect of balance exercise in increasing elderly postural balance with the value of p=0.001. A positive effect of the balancing exercise in the postural balance in institutionalized elderly subjects was found. This study recommends balance exercise for providing elderly postural balance that helps to decrease fall incidence among the elderly.

Keywords: balance exercise, postural balance, elderly

Introduction

The age-related change of the elderly will affect the ability to carry out daily activities. The physical problems that most often occur in the elderly are balance disorders so that they easily fall. Falls in the elderly are an increasing problem, causing a high degree of morbidity, mortality, and use of healthcare services. Falling in the elderly is associated with complications that cause prolonged hospitalization, isolation, dependency, immobility, decreased function, increased mortality rate and increased healthcare costs. Various risk factors that can increase falls in the elderly include disorders of the sensory system, central nervous system, cognitive and musculoskeletal. Degenerative processes in the sensory system, motor, and muscle strength will have an impact on the ability to maintain body balance. Falls is an incident reported by a patient or eyewitness who sees an event that causes the elderly to be suddenly lying on the floor or lower ground, with or without loss of consciousness or injury. Falls can have a serious impact in the form of a groin fracture and soft tissue injury, but the fear of falling in the elderly can also affect the limitation of activity so that there is a decrease in their postural balance.

Postural balance is a motor skill carried out by the neuromuscular system that integrates with the sensory, cerebellar and brain systems. Information about the body’s position in regard to the environment or gravity is introduced by the visual, vestibular and proprioceptive systems. The central nervous system is useful for modifying motor and sensory components so that stability can be maintained through changing conditions. Balance can be assessed using the Berg (Berg Balance Scale) balance scale, which is a scale with specificity of the challenge of the elderly in maintaining balance. This test is quite easy to use and effective for predicting falls and disturbances in the postural balance of the elderly.
Optimizing the physical abilities of the elderly in activities can be honed by providing an exercise that emphasizes increasing postural stability. Some physical exercises that have been applied to provide changes to balance from various studies include tai chi, qi gong, Wii balance and other forms of occupational therapy. Physical exercise in the elderly must be individual and includes specifications in the form of frequency, intensity, duration, exercise mode based on the results of exercise testing and various limitations mainly related to the musculoskeletal system. Recommendations from the American Heart Association are at least three times a week with duration of 30 minutes. The purpose of this study was to evaluate the effect of balance exercise on postural balance in the elderly for falls prevention.

Method

The type of research was quasi-experimental with a pre-/post-test design research involving treatment groups and control groups. The population in this study was all elderly people who resided at the Wana Seraya Tresna Werdha Social Institution (PSTW) Denpasar, namely 47 elderly who have a history of falls more than once a year. This study uses a simple random sampling technique that involves 28 elderly people. The independent variable in this study was balanced exercise. Balance exercise is taught three times a week for two weeks with a duration of 30 minutes only for the treatment group. The dependent variable in this study was postural balance in the elderly. This study uses the Berg Balance Scale as a measurement tool to evaluate the development of the ability of the elderly to maintain postural balance. Berg Balance Scale will show changes in postural balance in the elderly between before and after intervention through 14 items of balance assessment. Scores 41-56 are included in the independent category, the score of 21-40 includes the walking with assistance category, and the score 0-20 is included in the wheelchair category. Statistical tests were performed using the Wilcoxon Signed-Rank Test and Mann Whitney Test with a significance level of $\alpha \leq 0.05$.

Result

Characteristics: Respondents in this study were 28 elderly in the age range between 60 - 89 years, most of them were female. All respondents had a history of falls in the last one year.

The medical history of the respondents was found to be mostly experienced by osteoarthritis. Only one respondent had a history of stroke. Medication history of the elderly found use of multivitamins, analgesics, and anti-allergic drugs.

Postural Balance: Table 2 shows that all treatment group respondents experienced an increase in the balance after the balance exercise intervention. The Berg Balance Scale score of the treatment group increased to a minimum score of 43 and a maximum score of 48. The respondents in the walking with assistance category had a score range between 31-39 while the independent category had a score range of 41-48.

Wilcoxon Signed-Rank Test | 0.014 | 1.000
Mann Whitney | 0.001

Control group respondents were measured using the results of respondents experiencing a slight increase in scores, from a minimum score to 34 and a maximum score of 42. Only one respondent in the control group was independent. The respondents in the walking with assistance category control group had a score range of 34-40 and independent had a score of 42. As regard the increase in the treatment group category, as many as six respondents showed a significant change while the control group had no respondents who experienced a change in category. Based on the results of the analysis of the treatment group using the Wilcoxon Signed-Rank Test, the value of p = 0.014, less than α (≤0.05), showed that there was a significant effect on the treatment group from before to after the balancing exercise was given. The same analysis was also conducted on the control group with the results of p = 1.000 over α (≤0.05) indicating no influence between before and after the study. The Mann Whitney Test results compared the Berg Balance Scale score between the treatment and control groups after the intervention and found a p = 0.001 less than α (≤0.05). This value indicates that there are significant differences between the two groups so that it can be concluded that the hypothesis (H1) is accepted, namely balance exercise can improve postural balance in the elderly at Wana Seraya Tresna Wredha (PSTW) Denpasar.

Discussion

Before the intervention of balance exercise, a total of 10 respondents of the treatment group walking with assistance category found it difficult to do some movement in the valuation, among others, stand on one leg, placing foot alternately on the bench and taking the goods from the floor. The minimum score of the treatment group is 25 and the maximum score is 43. After the same measurement of the control group, a total of 13 respondents walking with assistance had difficulty doing standing movements on one leg, placing their feet alternately on the bench and taking items from the floor. The minimum score of the control group is 33 and the maximum score is 42.

After looking at demographic data and medical history, a number of supporting factors were found for these conditions: respondents have female gender, over the age of 80 years, have a history of repeated falls, a history of osteoarthritis with recurring pain, a history of very minimal physical activity, medication history pain and vitamin relievers and low index bark. Some of these conditions greatly affect the ability of the elderly to get a good postural balance. This statement is supported by previous research conducted by Dunn (2009) that changes in various body systems due to increasing age will greatly influence the ability of postural control as an ‘age effect’. Postural balance and control are influenced by previous life history and the effect of overall aging. The elderly with balance disorders have a risk of falling by 2.2 times compared to the elderly without balance disorders.

The measurement results of balance in the treatment groups showed as many as six categories of respondents increased the balance of walking with assistance or became independent and eight other respondents did not experience an increase in the category and no respondents experienced a decrease in the category. Some movements that are difficult to do, such as standing on one leg, placing the legs alternately on the floor and taking items from the floor were able to be done well by the respondents of the treatment group so that there was an increase in the scores of the assessment items.

Some of the initial movements which had been difficult for the treatment group respondents to do, such as placing their legs alternately on their backs, after the intervention the movement was able to be done well because the intervention was carried out optimally. This statement is supported by Jones and Barker (2005) who found that the balance exercise movement in the form of knee flexion and hip flexion can make respondents maintain that position because it can train the ventral and medial thighs, dorsal hip muscles, and inner and surface dorsal pedis muscles because, when lifting one leg, it requires coordination of these muscles.

The elderly have postural balance and control are influenced by previous life history and the effect of overall aging. The elderly with balance disorders have a risk of falling by 2.2 times compared to the elderly without balance disorders.
Standing on one leg movement, in general, was still difficult for the control and treatment groups. Respondents who were not able to do the movement well had the minimal ability when making modifications without holding onto the chair during knee flexion, hip flexion, hip extension, and single leg side movements. Balance exercise was able to improve the postural control ability of the elderly as evidenced by the increase in scores in other movements, such as sitting to stand, standing without support, sitting without support and looking back.

A good postural balance can improve the ability of the elderly to prevent falls. Exercises given to improve postural balance must pay attention to the readiness of the elderly in the exercise. Balance exercise will help the elderly to gradually increase physical alertness so that they remain active by providing wider physiological contact so as not to be isolated from stimuli and prevent injuries. Balance exercise involves good integration between the central nervous system, peripheral nervous system, and musculoskeletal system, especially the lower extremities, and can increase the ability of the elderly to control changes in body position that can occur at any time. The stages of balance exercise movements such as plantar flexion, knee flexion, hip flexion, hip extension and single leg side involving a group of lower limb muscles, have an impact on increasing muscle strength so that falls in the elderly can be prevented. This shows that the elderly need continuous stimulation in order to remain active despite increasing age.

**Conclusion**

Based on the discussion above, the conclusion of this study is that balance exercise can improve postural balance in the elderly through plantar flexion, knee flexion, hip flexion, hip extension and single leg side movements, which can stimulate the ability of the elderly to maintain postural balance.

Contributing Factors of the Mother’s Behavior in Filling Nutritional Needs for Under-Five Children with Overweight and Obesity

Elida Ulfiana¹, Praba Diyan Rachmawati¹, Dyah Khusnul Fadhilah²
¹Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia; ²Aura Syifa Hospital, Kediri, East Java, Indonesia

ABSTRACT

Overweight and obesity in children are still a global problem. The problem of overweight and obesity in under-five children can have a bad impact on growth and development. Nutritional problems in children are influenced by mothers’ feeding behavior. This study aims to analyze the factors that influence the behavior of mothers in fulfilling nutrition for under-five children with overweight and obesity. The design used was a cross-sectional approach. The population was mothers who have under-five children with overweight and obesity. The sample was determined using purposive sampling and found 40 respondents. The independent variables in this study were previous behavior, perceived benefits, perceived barriers, self-confidence, attitudes and commitment, while the dependent variable was the behavior of mothers in fulfilling the nutrition of under-five children. The data were collected by using questionnaire and analyzed by using Spearman’s Rho. The results of this study indicate that the behavior of fulfilling the nutritional needs of overweight and obesity children was influenced by the perceived benefits (r = 0.701, p = 0.000), perceived barriers (r=0.488, p=0.001), attitudes (r=0.640, p=0.000) and commitment (r=0.637, p=0.000). Further research is recommended to provide effective health education to prevent overweight and obesity in under-five children.

Keywords: maternal, midwife, nurse, referral hospital

Introduction

Overweight and obesity are health problems needed to be aware of at the world level, including Indonesia.¹ Globally, over 40 million of under-five children are estimated as overweight and obese, of whom about 30 million live in developing countries.² Under-five children who are overweight have high risk of obesity in adulthood and have the potential to experience metabolic diseases and degenerative diseases in old age.³,⁴

The nutritional status of children under five is influenced by food intake which is indirectly influenced by several factors, including the characteristics or behavior of the children’s mother. Mothers as the closest people to under-five children who have a role in the process of child development through the selection of nutritious food ingredients and can arrange a balanced food menu according to the needs.⁵ Balanced food arrangements can guarantee the fulfillment of nutritional needs for toddlers appropriately.⁵

Obesity that occurs in under-five children can be caused due to unhealthy eating patterns, because toddlers generally have a large amount of food, various types of food consumed, do not have a regular eating schedule, parents’ socioeconomic status can have a tendency to lead to wrong eating patterns, and lack of attention from parents can have an impact on uncontrolled toddler nutrition.⁷,⁸ The government is focused on the problem of malnutrition compared to the problem of excess nutrition, although both of these are problems that are occurring in Indonesia. Double Nutrition Load (BGG) is a phenomenon that has occurred in several developing countries, including Indonesia. In Indonesia there is an overweight prevalence of 11.9%, whereas in East Java in 2012, 10.6% of children under five were overweight.⁹,¹⁰
Pender’s Health Promotion Model is a theoretical perspective that explores factors related to health promotion behavior that aim to improve health and quality of life. Setting a diet, includes ensuring the adequacy of balanced nutrition, has been recommended by experts to avoid the risk of obesity in children under five. In addition to regulating diet, getting children to stay physically active through various sports or playing activities can also reduce the risk of obesity. This study aims to analyze factors related to mothers’ behavior in fulfilling nutrition for under-five children with overweight status and obesity.

Method

Study Design, Setting, and Sampling: Design used in this study was observational analytic with a cross-sectional approach. The population was mothers who have under-five children with overweight and obesity in Kediri districts. The sampling technique used was purposive sampling and found a sample size of 40 mothers from public health centre (PUSKESMAS). The questionnaire used to measure mother’s behavior and independent variables consisting of previous maternal behavior, perceived benefits, perceived barriers, self-confidence and attitude was compiled by researchers based on a modification of the parameters of nutritional fulfillment behavior and the health promotion model theory, while the questionnaire used to measure mothers commitment was modified based on parameters of maternal behavior in preventing nutritional problems in under-five children and the health promotion model. Before collecting the data using this questionnaire, the researcher tested the validity and reliability, which shows that the entire questionnaire are valid and reliable.

Study Variables: The dependent variable in this study is the behavior of mothers in fulfilling the nutritional needs of under-five children with overweight status and obesity. The independent variables in this study include:

1. Previous maternal behavior
2. Perceived benefits
3. Perceived barriers
4. Self-confidence
5. Attitudes related to maternal actions
6. Commitment in fulfilling nutrition for under-five children

Data Analysis: The data obtained were analyzed by researchers using Spearmans Rho with α=0.05 to find out variables related to nutritional fulfillment behavior.

Results

The characteristics of the respondents indicated that the highest maternal age was in the age range of 26-30 years, 17 (42.5%) respondents. More than half of the respondents did not work, 24 (60%). Respondents in this study had the level of education in senior high school as many as 23 (57.5%) respondents. More than half of the respondents, namely 25 (62.5%), had a high income economy level. As regard characteristics of respondents seen from the age of the child, most children were aged between 3-5 years, as many as 32 (80%) (Table 1).

Based on Table 2, the results of the statistical test, Spearman rank correlation coefficient, show the value of r = 0.186 and the significance value of p = 0.251, which means there is no relationship between behavior and previous experience. The results of statistical tests using Spearman Rho showed a significant relationship...
between the benefits felt by the behavior of fulfilling nutritional needs with the value of \( p = 0.000 \) and the perceived benefits were strong and in line with nutritional fulfillment behavior in children with \( r = 0.701 \).

The results of the statistical tests showed a significant relationship between the perceived barriers to the behavior of fulfilling nutritional needs in infants with overnutrition and obesity with a value of \( p = 0.001 \) and a value of \( r = 0.488 \). The results of the statistical test of the relationship between self-confidence and the behavior of fulfilling nutritional needs for children with overweight and obesity showed no significant correlation, with the value of \( p = 0.350 \) and \( r = -0.152 \)

### Discussion

No significant relationship was found between previous experience and behavioral fulfillment. Behavior and prior experience are the frequency of the same health behavior in the past.\(^{12}\) This is not in line with the findings previous study which states that one of the factors influencing the fulfillment of nutritional needs is previous experience.\(^{17}\) The results show that there were some respondents who did not have experience because their children were the first child so that the respondent had no experience in meeting the nutritional needs of the family. Family income can also influence the choice of food types to meet under-five children’s nutrition.\(^{18}\) Under-five children who are overweight and obese tend to have high income parents who can allow children to consume foods that are favored by the child, so they can increase high nutritional intake. Some respondents with poor behavior in fulfilling nutrition were respondents having a low family income.

There was a strong relationship between perceived benefit and the nutritional fulfillment behavior of infants. Perceived benefits are perceptions of benefits or benefits that can strengthen individuals to perform a health behavior.\(^{12}\) The benefits can directly motivate a behavior; a good parent’s knowledge of the benefits can be a motivation for them to provide food with the right quality.\(^{19}\) Knowledge of parents related to the level of education, mothers having a positive perception of the benefits in meeting nutritional needs and good behavior were respondents with high education.\(^{20}\)
This study shows that perceived barriers also have a strong influence. If someone does not have barriers from the action taken, then that person will have good health behavior.\textsuperscript{12} Parents with children with overweight and obesity have good knowledge about the benefits of fulfilling the right nutritional needs, but there are perceived barriers of behavior with appropriate nutrition; parents are preoccupied with daily activities so tend to provide food to children only with the aim to eliminate hunger by serving it quickly and easily without regard to the nutritional content.\textsuperscript{21} This is also related to parents’ self-confidence, which, in this study, does not have an influence on the behavior of fulfilling the nutritional needs of children with overweight and obesity. This result is not in line with research that states that, with strong self-confidence, a person will feel able to perform certain health behaviors so that the desire to behave will be stronger.\textsuperscript{16} According to the theory, self-confidence is a belief from within a person to be able to do good health behavior, related to how parents believe that they are able to have a good influence on fulfilling their children’s nutritional needs.\textsuperscript{21,22} Parents who have positive self-confidence do not necessarily have good behavior to fulfill children’s nutritional needs, according to the results of previous studies. This tends to be caused by a time when parents cannot control the food consumed by children, for example, the influence of advertising on television and factors sourced from children who tend to prefer foods that are interesting and tasty compared to the nutritional value contained in the food consumed.\textsuperscript{23} According to the answers given by respondents, mothers believe they are able to choose nutritious foods to be consumed by children every day; however, mothers also stated that they often allow children to consume snacks that children like, such as fast food.

There is a strong relationship between attitudes in fulfilling nutrition with nutrition fulfillment behaviors in under-five children and the majority of respondents had a positive attitude. The more positive the attitude, the better the behavior.\textsuperscript{12} Respondents having a positive attitude and good behavior are respondents who had a higher education, because the individual’s attitudes are related to knowledge and education possessed. A positive attitude will shape the behavior of fulfilling nutritional needs in a good category. Parents with children who are obese have the attitude or intention to provide good quality nutrition, this is manifested by the behavior of giving healthy food too, but, in reality, there are many barriers that also influence the behavior of healthy feeding, causing children to be obese or overweight.\textsuperscript{19,24} There is a strong relationship between commitment in fulfilling nutrition and nutritional fulfillment behavior in infants. Commitment is the desire to carry out certain health behaviors, including the identification of strategies to do it well.\textsuperscript{12} The intention to behave (commitment) is a desire or plan that will be carried out.\textsuperscript{25} Mothers who had weak commitments had bad behavior. The results of the research that have been carried out are in line with the results of study stating that commitment is related to the behavior of fulfilling nutritional needs.\textsuperscript{16}

**Conclusion**

Mother’s behavior in fulfilling nutritional needs of under-five children with overweight and obesity is influenced by several factors, namely perceived benefits, perceived barriers, self-confidence, attitudes and commitment to meet nutritional needs, while previous experience and self-belief of mothers have no influence on mother’s behavior in fulfilling children’s nutritional needs. The most powerful factor in influencing this is the perceived benefit.

Commitment for Anaemia Prevention is Associated with Adherence to Iron Supplementation and Iron Intake Among Pregnant Women

Mira Triharini¹, Ni Ketut Alit Armini¹

¹Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT
Anaemia during pregnancy is still a major problem in the world which can affect the health of the mother and foetus. The commitment of pregnant women to improve adherence to iron supplementation and eating iron-rich foods can prevent iron deficiency anaemia. This study aimed to identify the correlation between of commitment for anaemia prevention with adherence to iron supplementation and iron intake. Design: The study was a cross-sectional study with a population sample of 125 pregnant women who attended antenatal care at five community health centres in Surabaya. The study was conducted from August to October 2017. The statistical test results showed the commitment statements, “I maintain personal hygiene by frequently washing hands” had the highest score (4.38 ± 0.67) and “I take iron supplements regularly even if it causes nausea” had the lowest score (4.05 ± 0.84). Of the four statements about adherence to iron supplementation, “I take iron supplements regularly every day” had the highest score (4.35 ± 0.86) while ‘I take iron supplements along with orange juice or vitamin C drinks’ had the lowest score of 1.52 ± 0.87. There was a significant association between commitment for anaemia prevention and adherence to iron supplementation during pregnancy (r = 0.227; p = 0.011) and between commitment for anaemia prevention and iron intake (r = 0.432; p <0.001). Health workers need to conduct health education about the prevention of anaemia in every pregnant woman who attends antenatal care.

Keywords: Commitment, Anaemia prevention, Adherence Iron Supplementation, Iron Intake

Introduction
Iron deficiency, or as commonly known as anaemia, in pregnant women is still a major nutritional issue, mostly in low and middle income countries. According to world health organization, anaemia is considered to be a huge public health challenge as population studies find that anaemia prevalence is at 5.0% or higher. Prevalence of anaemia ≥40% in a population is classified as a severe public health problem by the World Health Organization.¹ The prevalence of anaemia was 18.0% in Northern Tanzania.² According to Indonesia basic health research in 2018, 48.9% of pregnant women were anaemic.³

Anaemia, during pregnancy can adversely affect the mother and foetus, resulting to especially premature birth and low birth weight.⁴ Anaemia can be prevented through giving iron supplements, education about possible dangers of anaemia, taking foods that have high contents of iron, increased consumption of dairy foods, and eating a wide variety of foods that have vitamins that can increase iron level, such as vitamin C, and prevention of infectious diseases such as tuberculosis.⁵

During pregnancy, the mother will experience a physiological process in which there is an increased need for iron supply. To meet the need for this component, it is necessary to increase intake of food high in iron to boost the iron reserve in the body. The iron requirement for pregnant women is not sufficiently met by only taking iron-rich food, rather it requires iron supplementing to meet the required level.⁶ Previous research shows that using iron supplements will increase haemoglobin levels and prevent anaemia in pregnant women.⁷–⁹
Nutritious foods that can be taken to prevent anaemia include energy-rich foods such as carbohydrates, proteins and vitamin C. A study showed that there is a significant correlation between nutrients and haemoglobin levels. Women with anaemia show a low-energy diet deficiency, protein, folate, vitamin B12, iron-rich diet, vitamin C and red meat.10

The regular intake of iron supplement is an important effort in the prevention of anaemia. The composition of each iron supplement for women of childbearing age and pregnant women, should contain at least 60 mg of iron, in the form of Ferro Sulphate, Ferro Fumarate or Ferro Gluconate, and 0.400 mg of folic acid.11 According to Indonesia Basic Health Research in 2018, only 61.9% of pregnant women consume at least 90 iron supplements during pregnancy.3 Non-adherence to consumption of iron supplements is caused by the perceived side effects.12

According to the Health Promotion Model, commitment is defined as an intention to perform certain health practices, such as identification of strategies to conduct health promotion behaviour.13 Health workers need to provide health education and identify patient strategies in dealing with problems in performing health behaviours. Study supports the importance of commitment to compliance with health behaviours. There is a relationship between commitment and compliance in diabetic patients.14

The commitment to take iron supplements and dietary iron intake needs to be researched further because of many obstacles and side effects, such as boredom and forgetfulness. Currently, there is still limited research about the commitment for anaemia prevention during pregnancy. The aim of this research is to identify the correlation between commitment for anaemia prevention with adherence to iron supplementation and iron intake.

Method

Study Design, Setting, and Sampling: This study used a cross-sectional design conducted in August-October 2017 on 130 pregnant women. The population of this study was the pregnant women who attended antenatal care at five community health centres in the Surabaya, namely, Jagir, Medokan Ayu, Sidotopo Wetan, Asemrowo and Gundih. The size of the sample meeting the criteria was 125 pregnant women. The inclusion criterion was pregnant women having obtained iron tablets from the Community Health Centre. Exclusion criterion was pregnant women having complications that require medical action.15

Data Analysis: Spearman’s Rho was used to determine the correlation between commitment for anaemia prevention with adherence to iron supplementation and dietary iron intake. In all statistical analyses, a p-value <0.05 was considered significant.

Results

More than half of the participants were aged 25-35 years (n=80, 64.0%). Most of them (n = 89, 71.2%) with parity 1-3. More than half of the participants (n = 98, 78.4%) had secondary education. In addition two-thirds of the participants (n = 87, 69.2%) had incomes below 3 million rupiahs per month. The greatest iron intake was in age < 25 years (76.68 ± 31.12), nullipara (72.29 ± 18.79), university education (71.34 ± 15.47), and income was ≥ 3 million rupiah (63.92 ± 26.77) (Table 1).

The mean score of commitment was 25.80 (95% CI 25.36-26.24). The mean score of adherence to iron supplementation was 17.38 (95% CI 16.99-17.78). There was a significant association of commitment with adherence to iron supplementation (r = 0.227; p = 0.011). The mean score of iron intake was 63.45mg/day (95% CI 58.03-68.86). There was a significant association of commitment with iron intake (r = 0.432; p < 0.001) (Table 4).
Discussion

This study shows that there was a significant association of commitment for anaemia prevention with adherence to iron supplementation. Commitment is the intention to carry out certain health behaviours, such as the identification of strategies to promote health promotion behaviour. A commitment will encourage individuals to engage in health behaviours despite the obstacles encountered. A study showed that there is a correlation between commitment and physical activity behaviour in mothers and young children with low-income. Commitment is required for healthy eating behaviour in male and female students in Nigeria. Of the five commitment statements, “My family needs to know that I have a commitment to prevent anaemia during pregnancy” had the highest score. Support from the family is very important because, during pregnancy, the mother will experience physical and psychological changes. This condition can be a burden that requires the support of others. Study shows that physical problems experienced due to nausea and vomiting cause weaknesses and helplessness in pregnant women, necessitating the husband’s support. Health education about iron supplement provided by health workers has not involved family members and, therefore, families do not understand the importance of iron supplements properly. This is supported by related research that established the knowledge of pregnant women needs to be improved through the provision of health education during antenatal care accompanied by husbands to improve their understanding of anaemia and compliance by taking iron tablets.

The statement “I put iron supplementation in a place easily visible to avoid forgetting” had the lowest score. Many pregnant women do not take iron supplementation regularly because they forget. Most of the pregnant women understand the importance of taking iron supplements regularly, but require more information about drinking properly. There are many obstacles that pregnant women will experience in taking iron supplements, such as side effects, forgetfulness and boredom. This is supported by research that the two main causes of maternal disobedience are side effects and forgetfulness. A study has shown several factors affect the consumption of iron tablets. Adherence to iron supplementation among pregnant women in Surabaya is influenced by perceived benefits, barriers and family support.

The adequacy of iron during pregnancy is influenced by adherence to iron supplementation. Iron requirements increase during pregnancy and cannot be fulfilled only through iron-rich foods, so the mother needs to take iron tablets regularly. Each iron supplement for pregnant women should contain iron at least equivalent to 60mg of iron elements. Adequacy of iron needs to be fulfilled through iron-rich foods and adherence to iron supplementation. The obstacle perceived by pregnant women to fulfil food is the lack of information about iron-rich foods and food prices. Adherence to iron supplementation can decrease because of side effects, and forgetting to take it regularly.

Commitment is the intention to carry out certain health behaviours, including the identification of strategies to be able to conduct good health promotion behaviour. Commitment will encourage individuals to carry out health behaviours despite obstacles encountered. Pregnant women who are committed to prevention of anaemia will make efforts to increase consumption of iron-rich foods and adhere to iron supplements despite various obstacles.

Conclusion

There is a significant correlation between commitment, adherence to iron supplementation and iron intake. Health workers need to conduct health education on adherence to iron supplementation in pregnant women and the problems encountered by pregnant women. Understanding the problems to face will make pregnant women strategise appropriately in improving adherence to iron supplementation and improving iron adequacy.

Ethical Clearance: Sampling was conducted after ethical approval from the health research ethics committee of the Faculty of Public Health, Airlangga University in Surabaya (No 123-KEPK).

How Do I Fulfill My Nutrition: The Experience of Older Adults Who Live Alone

Elida Ulfiana¹, Oktaviana Ristya Anggraini¹, Rista Fauziningtyas¹

¹Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

The barriers to living alone get bigger when older adults get older. One of them is being unable to fulfill their nutritional needs. Older adults who live alone must be able to fulfill nutritional needs, personal hygiene and health independently. This research was conducted to describe experience of older adults who live alone to fulfill their nutritional needs in Magetan, East Java. The methodology employed was a phenomenological qualitative design. We conducted in-depth interviews with seven older adults who live alone. The data were analyzed using thematic content analysis. Six themes emerged as the strategy to get ingredient and food were cooked by self, bought from the seller, collected from farm; the barriers to fulfilling nutritional needs were getting old, disease and financial insufficiency. To fulfill the nutritional needs is a challenge for older adults, especially when they get sick. So, they need support from family, neighbors, and government to overcome the barrier. It is expected to be a consideration in policies regarding monitoring programs of the condition of older adults who live alone.

Keywords: nutritional need, food, barriers, live alone, older adults

Introduction

The older adults enjoy their old days with their family, but, in certain circumstances and for certain reasons, they decide to live alone.¹ An older adult who lives alone must fulfill their nutritional needs independently. Based on a study in Indonesia, intake of malnutrition was more common in older adult aged 70 years who lived alone. In addition, the incidence of malnutrition is quite high in older adults in rural areas because the diet is unsuitable to the needs.²

The decision of older adults to live alone can come from themselves or because the family does not want to take care of them. Factors that affect older adults in living alone are cultural factors, family background, and personality. Indonesian cultures adheres to a social system that is collective in nature and most still adhere to the extended family system, which is one house consists of several nuclear families including grandparents. So, it is common for an older adult to live with their family.³ Conflict in the family can also be a reason for older adults to live alone. In addition, there are older adults who want to be independent, actively establish communication with their neighbors, be free to do activities, and do not want to burden their families. However, there are consequences of problems that can affect older adults who choose to live alone, such as the problem of meeting adequate nutritional needs.⁴

Research on older adults who living alone has been done, but there has been no in-depth research on the experience of older adults who live alone in fulfilling nutritional needs. As such, the researchers are interested in using qualitative research methods with phenomenological designs to explore the barrier to fulfill nutrition for the elderly who live alone in Magetan, Indonesia.

Method

Study Design, Participants and Sampling: This study employed a qualitative design with a phenomenological approach. This approach allowed the researcher to probe the barriers experienced by the older adults when fulfilling their nutritional needs. The researcher selected

DOI Number: 10.5958/0976-5506.2019.02282.4
the participants through purposive sampling among the older adults who live alone in Magetan, East Java, Indonesia. Snowball sampling was used in this research. Older adults who were known by the researcher were approached. Then, they recommended others older adults as potential participants. The inclusion criteria were: 1) lived alone without family or partners, 2) had good cognitive function (Short Portable Mental Status Questionnaire score within 0-2), 3) able to read and write and 4) agree to share and speak about their experiences. The recruitment was discontinued when the data saturation was determined by the seventh participant.

Procedure: The interviews were scheduled at the participants’ homes at a convenient date and time, involving both the older adults and the researcher. After an explanation about the research process and giving signed consent, the participants were asked demographic questions and screened for nutritional status with Mini Nutritional Assessment (MNA). Then, an in-depth interview with older adults using four open-ended questions (with additional questions if necessary) was conducted to explore the experience of older adults to fulfill their nutritional needs. The interview process was 15 – 45 minutes and recorded.

Measures: A series of open-ended questions for the older adults was developed to let the participants tell their experience when fulfilling their nutritional needs. The interview questions were designed based on previous research on fulfilling nutritional needs for older adults. In addition, the empirical knowledge of the writer about the older adults and their nutritional needs was used when created the questions. A demographic questionnaire (created by the author) was used to obtain basic demographic information (e.g. gender, occupation, income, age, education, etc.). The following questions were conducted during interviews: “What do you think about fulfilling nutritional needs?” “Please tell me how was your experience when fulfilling nutritional needs while living alone?” “What were the barriers that you encountered when fulfilling nutritional needs while living alone?”

Data Analysis: The data were analyzed and interpreted using the Colaizzi method. This method allow data to be clarified with participants, as well as possible changes in the results. A summary of the process of data analysis is as follows. Step 1: describe the phenomenon of study. The researchers increased the knowledge of “the older adults who lived alone and how they fulfill nutritional needs” through reading research articles and books. Step 2: collect the phenomenon through the participants’ opinions verbatim. Step 3: read the whole phenomenon collected from the participants. The verbatim script was synchronized between the sound recording and field notes. Step 4: sort the significant statements. The researcher coded the participant statements that had a significant meaning as listed verbatim. Step 5: formulate the meaning of each significant statement. The researchers fully used the participants’ point of view and put aside all assumptions of the researcher. Step 6: categorize each unit of meaning into a theme. Step 7: integrate each theme into a complete description. Step 8: validate the results of the analysis with the participants. We allowed the participant to read the verbatim transcript and validate the meaning. Step 9: refine the analysis results with the data obtained during the validation process.

The author involved two colleagues for an external finding validation, discussed the different perspectives, and clarified any “bias of researchers” that may have influenced the process of data interpretation. In addition, to minimize the researcher bias, the researchers wrote a reflective diary. The reflective diary was used to write down the author’s thoughts, feelings, and perceptions about “fulfilling nutritional need for older adult” when conducting the research. This allowed the researchers to re-examine their position when problems arose.

Results

A summary table of the characteristic of participants is included in Table 1. All participants were older adult females who lived alone.

The third subtheme “collect from farm” was described by participants:

“... the sweet potatoes are my own, I take them from the backyard garden. I usually collect pumpkins in the fields ...” (P4)

“I take the vegetables and fruit from the garden, for example papaya leaves or young papaya, there is also spinach, long bean leaves, I take all of the vegetables from the garden. In my backyard garden, there is also papaya, mango, banana, the banana on the table is also from the garden. I planted it myself, Miss.” (P6)

The barriers to fulfilling the nutritional needs: We conclude three subthemes as barriers in fulfilling the nutritional needs, such as getting older, disease and financial insufficiency. The first subtheme, “getting older”, was described by participants:

“Becoming older like me, it means health starts to decline. I have difficulty to fall sleep, even eating is hard for me. Doing everything is difficult.” (P3)

“I can’t eat, most of the food is hard to chew. I do not have teeth anymore, only two teeth (pointing to the teeth. So I mean I have to choose soft ones like tofu or vegetable like chayote” (P5)

The second barrier to fulfilling the nutritional needs is “disease” as described by participants:

“The difficulty is that, if uric acid is recurring, my left and right knee is rheumatic, the fingers also get sore. I can’t take water from the well. It is difficult for me. Moreover, if I have to cook or go to market, I can’t handle it. So I just buy food in the food stall in near my house.” (P2)

The third barrier to fulfilling the nutritional needs is “financial insufficiency” as described by participants:

“.. I eat whatever that is available, Miss, if I don’t have money, I eat two times per day or I fast on Monday and Thursday. Not bad, I can save my money. Understandably, I don’t have money, usually my child gives me money, not too much is given. Or income from selling vegetables in the garden.”(P6)

**The strategy to get ingredients and food:** We deduced that there were three subthemes to get ingredients and food, such as bought from the seller, collected from farm and cooked by self. The “bought from the seller” subtheme was described by participants:

“Sometimes I buy chicken or vegetables at the market, then ask someone to cook, a half kg of chicken can be two days, really. If I’m not feeling well, I buy food at a warung (food stand) near my house. “(Participant 2/P2)

“..Everything what I want to eat, I just buy, such as meatballs, tepo pecel (a kind of food), nasi campur (a kind of food).” (P3)

The second subthemes “cooked food by self” was describe by participants:

“I buy the seasonings, tofu, tempe (a kind of food made from fermented soybean) and vegetables in a shop near my house, Miss. I rarely buy food. I cook by myself, the taste is more suitable.”(P5)

“I cook every day, Miss, I never bought it. I save more money if I cook by myself.” (P1)
Discussion

Cooking is an activity to convert raw food ingredients into foods that are ready to eat, have quality, and are safe for consumption. The purpose of processing food ingredients is to reduce the risk of losing nutrients in food ingredients, increase digestibility, and maintain color, taste, tenderness, appearance of food, and being free from organisms or harmful substances to the body. This is supported by other study maintaining the cleanliness of food or drinks in the daily processes food by cooking it yourself and maintaining food quality more. The process of providing food starts with attention to the food ingredients to be chosen. Food ingredients need to be considered and selected as well as possible in terms of cleanliness, appearance, and health. Choosing materials that will be processed must involve knowing good food sources and paying attention to the characteristics of good food ingredients. The results of interview were obtained by processing food by other people. The older someone is can cause various disorders in fulfilling their daily needs, so can increase dependence on others. Declining physical abilities can affect older adults in cooking and preparing food.

The influence of the aging process can cause various problems, both physically, biologically, mentally, and socioeconomically. Older people will experience setbacks, especially in the field of physical ability. In addition, Maryam et al. (2011) explained tooth decay (toothlessness) will reduce the ability to digest food. In old age, permanent teeth become dry, more brittle, darker in color, and even some teeth have been dated.

The challenge to live alone is greater as people grow older. There are barriers to fulfilling daily needs, such as eating, bathing, etc. According to Maslow, older adults who live alone may be malnourished and lose weight because they cannot afford enough food, also they are too weak to prepare three meals per day. Some older people have no appetite because they are sick or lonely, and unable to get food regularly. In addition, there is a decrease in digestive function, depression, changes in economic condition, lack of knowledge about nutrition, physical inability, such as difficulty shopping and cooking, all of which may become a problem in fulfilling nutrition in older adults.

According to Miller (2012), depression and other cognitive decline can affect diet and ability to prepare food. There is a strong relationship between nutrition and low income. The decline of physical condition of older adults would cause a decline in the economic field. Economically, people who are more than 60 years old are no longer productive. Declining work ability means amount of income also decreases or even disappears altogether. This condition causes older adults to be often seen as a burden rather than as a resource.

Limitation of this study is that this research could not be generalized to a larger population because a different phenomenon might occur. However, this study is very important for the development of knowledge in fulfilling nutritional needs in older adults. This research can be used as a platform for policy makers, especially in Indonesia, to improve health services for older adults in the community.

Conclusion

The obstacles of older adults who live alone in fulfilling their dietary needs are old age, illness, and economic inadequacy. These obstacles must be overcome by involving cooperation from government, health workers and community. Community involvement in fulfilling nutritional needs of older adults is needed in the form of special attention and supervision by cadres in the older adult who lives alone. Health workers at the Puskesmas (Health Center Service) need to make home visits for older adults living alone. This activity will help to find out the nutritional status of the older adult, in addition to the regular program from the Posyandu (Self Health Service) for older adults. There needs to be real support from family members in the form of material and non-material assistance to support the needs of the older adult who lives alone.

Relationship between Personality Type and Family Support with Genital Hygiene Behavior in Adolescent Girl

Iqlima Dwi Kurnia¹, Ilya Krisnana¹, Arfa Zikriani¹
¹Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

There are several factors that affect the genital hygiene behavior of adolescents, including personal and family support. The purpose of this study to explain whether there is a relationship between personality type and family support in the genital hygiene behavior of adolescent. This research used correlation research method with cross-sectional approach. The samples of the study were 116 respondents using random sampling technique. The data analysis used descriptive analysis of chi-square correlation test. This study found that most respondents had good family support and extrovert personality types with the same score of 60.2%, and most of the respondents had clean behavior in genital hygiene, as much as 71.2%. The chi-square correlation test results obtained p value = 0.076, which means there is no relation between personality type and genital hygiene behavior in adolescent girls, while the correlation test of family support with genital hygiene behavior on adolescent girls obtained p value = 0.036 which means there is relationship in both personality type and family support. There is no relationship between personality type and genital hygiene behavior. Good family support can improve hygiene behavior of young women. The existence of good family support will affect adolescents in behaving.

Keywords: personality type, family support, genital hygiene behavior, adolescent girl

Introduction

Adolescence is a transition from childhood to the next level. Adolescence is where there is a change in physical and psychological characteristics in a person. Adolescence women begin to experience puberty with menstruation. Maintaining the cleanliness of the genital area at this time is very important as an effort to improve reproductive health. Microorganisms can easily enter the reproductive organs due to poor genital hygiene. Poor or even bad hygiene habits, if done repeatedly, will have a serious impact in the future. High prevalence of poor MHM (menstrual hygiene management) and considerable school absenteeism due to menstruation among Indonesian girls highlight the need for improved interventions that reach girls at a young age. The management of menstruation presents significant challenges for women, and it is plausible that MHM can affect the reproductive tract.

The previous research of impact of toilet hygiene training programs found (58%) of respondents cleaned their genital area in the right way, i.e. from front to back, but there were still (25%) who did it from back to front, and (17%) did it randomly. Research conducted on female students in Bekasi Middle School said that, out of 102 respondents it was found (62.7%) of children washed their genitals from the front to the back, the rest did it the wrong direction, and (80.2%) students changed their underwear less than twice a day. There are several factors that cause genital hygiene not to be done well. Previous research said that the factor of a person’s character plays an important role in acting and behaving in everyday life. Jung divided individual attitudes into extrovert and introvert personality types, distinguishing individuals who are either more caring or indifferent about what is happening. According to Jung, personality is defined as the overall feeling, mindset, and behavior that is often used in carrying out adaptations that take place continuously during one’s life.
Based on previous research, it is stated that personality types affect students in the perception of prevention of vaginal discharge. Individuals with an introverted personality tend to have negative perceptions, as much as (65.6%), while those with extroverted personality find it easier to consult with others, because they have a positive perception, as much (64.8%), in handling it. There are other factors that influence genital hygiene behavior, such as family support. Fulfillment of family support can improve the health status of family members, because the family is the closest party to remind its members about each other. A good family support will produce good family member behavior. The existence of support from the family can also influence individual coping, handling stress, and increasing interpersonal skills.

Based on research in Surakarta, it is stated that students who have family support have the potential to be 1.50 times more likely to have good genital hygiene behavior than students who do not get family support. This has resulted in much inappropriate behavior of adolescents or even wrong genital hygiene. Poor behavior in genital hygiene in adolescents will cause signs and symptoms in the form of hives, redness, irritation, vaginal discharge and infections, or even more severe problems, if ignored. The family support instrument uses a family support questionnaire developed by previous research by Febriyanti. The choice of answers consists of TP (never), KK (sometimes), SR (often), and SL (Always). The total score of respondent’s family support is poor when the accumulation of scores is in the range of 25-48, the accumulated score of 49-72 is categorized in moderate family support and good family support if the respondent gets a score of 73-96. The dependent variable in this study is the behavior of genital hygiene. The genital hygiene behavior instrument uses a measuring instrument developed by Amelia et al. consisting of 15 items entailing three parameters, namely general hygiene, genital hygiene and genital hygiene during menstruation. Choice of answers used the checklist (√) in the column provided. The choice of answers consists of TP (never), KK (sometimes), and S (always). The calculation results have a maximum score of 30. Scores of 0-10 are categorized as poor genital hygiene behavior, scores of 11-20 means that respondents have moderate behavior hygiene, and, if the respondent scores 21-20, it is categorized as good genital hygiene behavior.

**Method**

**Study Design, Setting, and Sampling:** This research uses non-experimental studies included in the correlational study with cross-sectional methods. The sample in this study were female adolescents students in Senior High School (SMPN) 29 Surabaya, involving 116 respondents using random sampling technique.

**Study Variables:** The independent variables in this study are personality type and family support. Instruments to determine the personality type in this study used the MBTI questionnaire (Myers-Briggs type indicator). The choice of answers does not determine right or wrong, the respondent simply chooses one answer from the answer choices, “a” or “b”. A person’s personality type can be known through the accumulation of the respondent’s answers, if the accumulated answer scores ≥13 then it indicates that the respondents are more likely to extrovert personality type, but if the answer score accumulated ≥13 then the respondent’s personality type tends to introvert.

**Results**

This research was conducted at SMP Negeri 29 Surabaya, located on the road Prof. Moestopo No. 4, RT 01/RW 01, Kel. Pacarkeling Kec. Tambaksari Surabaya, East Java.

Based on Table 1, related to demographic characteristics, it can be seen that most respondents sit in class VII with a total of 65 (56.0%) female students. The number of the 13-year-old majority respondents was seen from the data as 52 (44.8%).

**Table 1: Demographic characteristics of respondents n: 116**
Based on the data in Table 2 below, it shows that the personality type of respondents as mostly extroverted, as many as 60 (59.5%). Family support received by respondents shows all respondents have a good family support, as many as 70 (60.3%).

|                  | Total    | 116 | 100% |

Based on Table 3 below, it shows that respondents who have genital hygiene behavior in the net category found in extroverted personality types, as many as 44 (37.9%), did not get less support from their families, and the support obtained by respondents was dominated by good family support, as many as 71 (60.2%). Similar to family support, there were no respondents who had bad behavior or were not clean; respondents mostly had clean genital hygiene behaviors, as many as 84 (71.2%) and respondents with an introvert type as many as 38 (32.8%). The results of statistical tests using chi-square correlation test showed that p > α (0.076 > 0.05), which means that there is no relationship between personality type and genital hygiene behavior in adolescent girls.

p = 0.076
Based on Table 4, it shows that there were no respondents who behaved unclean in maintaining genital hygiene. Respondents who have cleanliness in the net category majority have good family support, as many as 55 (47.4%).

Based on the chi-square correlation statistical test results, it obtained $p = 0.036$ with a significance level of $p < \alpha$ or $p < 0.05$ ($0.036 < 0.05$), so that there is a correlation between family support and genital hygiene behavior in adolescents.

### Discussion

There is no correlation of personality types with genital hygiene behavior in adolescent girls. Based on previous research, there is a relationship between personality types and adolescent health behavior.16 Family relationships were available at baseline and information on behavioral and mental health outcomes (self- and parent-reports) were available at follow-up ages of 18 and 25 years.17 This contrasts with the results of the research that have been obtained. The differences causing the opposing results to is the age of the respondent. Previous research examined adolescents aged 16-17 years, and these differences can affect a person’s personality type because, at that age, they already know information, and more experience is obtained than teenagers in junior high school, so that it can affect respondents in behaving. This is corroborated based on adolescent growth, which states that the age of junior high school students is the category of early adolescents, and the age of high school students is the category of middle adolescents, where psychological and cognitive maturity is more dominant in middle adolescents.18

The differences in this study may be due to differences in background that shape the personality of the respondents. This is reinforced by previous research that there are environmental factors that support the formation of one’s personality. Environmental factors include family, culture and school.19

There was a relationship between family support and genital hygiene behavior in adolescent girls, which meant answering and proving the second hypothesis by obtaining a 0.036 correlation value so that it can reduce the risk of the child having problems in their genital area, such as infection, vaginal discharge, itching, and others. Previous research shows that, even though most of the respondents have heard of RTI’s (reproductive tract infections) and sought treatment when symptomatic, they demonstrated poor overall understanding of the subject.20 This is consistent with previous research, that the increased family support or parental strategies in increasing their relationship with children can help children in preventing bad and unhealthy habits.21 External support from family members and friends has been indicated as being important for maintaining oral health for the vulnerable group of care home residents.22

Other studies also say that children who do not get good support from their families are more likely to be negligent in maintaining the perineal hygiene than children who get family support.23

Most of the family support obtained by the respondents received good support. This indicates that the four functions of the family occur well, such as the family’s function in providing information, motivation, rewards, and provision. For example, in filling out a family support questionnaire on item No. 15.17 instrumental support, and 19 respondents obtaining high scores. The existence of good communication between parents and children is the initial foundation of a good relationship, and this will support the quality of family support provided.
Conclusion

Most respondents have extroverted personality types and good family support. There was no correlation between personality type and genital hygiene behavior in adolescent girls, but there is correlation between family support and genital hygiene behavior in adolescent girls. The researchers recommend that families pay more attention and provide information about genital hygiene in adolescent girls.

The ST-36 Acupressure Increased Gut Motility To Sectio Caesarea Patients with Subarachnoid Block Anesthesia

Abu Bakar¹, Achmad Safaat¹, Sriyono¹, Siti Nur Qomariah²
¹Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia; ²Faculty of Health Science, Universitas Gresik, Gresik, Indonesia

ABSTRACT

Postoperative patients with Subarachnoid Block anesthesia will experience paralytic ileus. Various efforts to overcome this have been carried out, including early mobilization, chewing gum, warm compresses, and acupuncture. The actions taken have not yet shown maximum results. This study aimed to analyze the effect of ST-36 acupressure on gut motility and flatus time in postoperative patients with Subarachnoid Block anesthesia. This research used Quasi-Experiment with pretest-posttest group design. Population in this research was post operation patient with Subarachnoid Block anesthesia in Sidoarjo Hospital. A sample of 14 respondents in control group and 14 respondents in experimental group were obtained using purposive sampling technique. Data retrieval was done by criteria using lidodex 100mg/2ml anesthetic or 5% lidocain + adrenaline. Data were analyzed using independent t test. The result showed that there was difference average frequency of gut motility between control group and experimental group after given intervention ST-36 acupressure (p=0.013). The time of flatus showed that there were no significant differences in the two groups (p = 0.262). It can be concluded that ST-36 acupressure can increase gut motility, whereas it did not affect flatus time.

Keywords: Gut Motility; ST-36 Acupressure; Subarachnoid Block; Sectio Caesarea.

Introduction

Subarachnoid Block (SAB) anesthesia is usually used in lower abdominal surgery, inguinal areas, perineum, and lower extremities.¹ Spinal anesthesia slows gastrointestinal motility and causes nausea. Decreased gastrointestinal motility can lead to paralytic ileus, which results in gas accumulation and abdominal distension.² Intestinal manipulation during surgery, reduced immobilization and oral intake can all affect bowel function. Normal intestinal peristalsis will disappear within a few days, depending on the type and duration of surgery.³ The intestine will return to normal activity and function after the effects of the anesthetic are gone.⁴

Flatus is an important indicator in restoring postoperative bowel function. Recovery of intestinal motility is the initial stage in post-surgery; bowel motility returns within 24-48 hours and the motility of the colon recovers within 3-5 days.⁵ randomized, controlled trial design. An urban medical center in Taiwan. 60 patients with colorectal cancer who had undergone abdominal surgery.

METHODS: Patients were randomly assigned to two groups, the ST-36 acupressure group (n = 30 Patients who have not recovered their intestinal peristalsis after anesthesia can suffer from obstructive ileus or intestinal obstruction if, at that time, they are given food intake.⁶ Therefore, patients often complain because they have to wait a long time to be able to eat and drink, so that the patient as to endure lengthy hunger and thirst.

Based on a preliminary study in Rahman Rahim Sidoarjo Hospital from medical records, it was found that data on patients who were operated on using Subarachnoid Block anesthesia during 2014 obtained from medical records showed 706 patients with ages ranging from 13 to 76 years. The average patients numbers

in January to March 2015 obtained 40 patients who were operated on using Subarachnoid Block anesthesia. In 50% of patients, the return of flatus time was <24 hours, 37.5% of patients at flatus return within 24-48 hours and 12.5% of patients with flatus within >48 hours. When the patient’s hemodynamic status is stable, the patient will be encouraged to mobilize to stimulate his intestinal peristalsis. Based on existing data, there were about 88 patients experiencing prolonged recovery of intestinal peristalsis in one year.

Various efforts have been developed to overcome this, including early mobilization, chewing gum, warm compresses, and electroacupuncture use.7,8 The results of previous studies indicate that acupressure in ST-36 (Zusanli) was able to accelerate first flatus time, oral fluid intake, and improve postoperative gastrointestinal function.5 An urban medical center in Taiwan. 60 patients with colorectal cancer who had undergone abdominal surgery. Patients were randomly assigned to two groups, the ST-36 acupressure group (n = 30) Other supporting research proved that there were differences in the acceleration of recovery time of gastrointestinal motility in patients post-colorectal surgery performed by electro-acupunture (EA) on ST-36. Point ST-36 is a body acupuncture point that has a strong effect; this point is able to improve the immunological response and endurance.9

Various studies have been conducted to accelerate intestinal motility repair due to the action of anesthesia, for example by acupuncture and electro-acupuncture. However, this therapy is not a convenient therapeutic procedure, because it uses invasive techniques and must be carried out by trained experts. However, there are other alternative techniques, such as therapy that is more easily applied, namely acupressure. Acupressure is a Chinese medicine therapy and has the same basic principles as acupuncture treatment. Acupressure is a non-invasive, safe therapy, and one of the therapeutic techniques that is easy to do using only fingers, elbows or blunt tools, such as wooden sticks, so that patients will feel more comfortable when given therapy.10

Based on the above phenomenon, the researchers were interested in conducting a study of the effect of ST-36 acupressure to improve intestinal motility and flatus time postoperative patients with Subarachnoid Block anesthesia.

Method

Study Design, Setting, and Sampling: The research design used was Quasi-Experiment with the design of the pretest posttest group in postoperative patients under Subarachnoid Block anesthesia. The population in this study was all postoperative patients with Subarachnoid Block anesthesia in Hospital Sidoarjo. The sample of 28 postoperative patients with Sectio Caesarea under Subarachnoid Block anesthesia consisted of 14 treatment group respondents and 14 control group respondents who were recruited by purposive sampling technique. The sample was recruited using the criteria between 18 years and 55 years old, using lidodex 100mg/2ml anesthetic or 5% lidocain + adrenaline, surgery in the abdominal area, and the body area to be stimulated (akupresure ST-36) does not experience injury, swelling or fracture. The treatment group received ST-36 mobilization and acupressure intervention, while the control group received hospital standard intervention, namely mobilization. The study was conducted May 17 to June 11, 2015.

Study Variables: The independent variable is ST-36 acupressure given by the researcher to patients with reference to the module. The parameters of the ST-36 acupressure module are massage performed at the ST-36 meridian point, which is four fingers under the patella and one thumb wide outward from the shin. Massage time three minutes with 1-1.5cm on both feet. Massage twice, first after the patient’s hemodynamic status is stable and eight hours later. The dependent variable was intestinal motility and flatus time, which was assessed by observation before the action (pretest) and after the action (posttest). Gut motility observation by researchers was done using a stethoscope. Observation of flatus time was carried out by the researcher by asking the patient what time was flatus. Observation of the pretest was carried out after the patient was transferred to the inpatient room, that is, after completion of the recovery room or when the patient’s condition was stable (about one hour in the recovery room). Observation of posttest was carried out after eight hours of pretest and given ST-36 acupressure.

Data Analysis: This study uses descriptive analysis carried out using the number of frequencies and percentages for categorical data and the mean, median, and standard deviation used for numerical data. Analysis of the main data used the independent t test with a significance level of p <0.05.
Results

The results of the research in Table 1 show that, out of 28 respondents, there are six early adult respondents (26-35 years) in the treatment group and eight respondents in early adulthood in the control group. Regarding the proportion of respondents’ weight in the treatment group and the control group, the majority of weight was between 51-60 kilograms (78.6 % and 92.9%, respectively). In addition, most of the respondents in the treatment and control groups were housewives (57.1 % and 50%, respectively).

The mean frequency of intestinal motility pretest in the treatment group was no better than the control group (Table 2). Standard deviation of intestinal motility pretest in the treatment group was more homogeneous than in the control group. The independent t test results obtained p value = 0.803, which means there was no significant difference in the value of intestinal motility pretest respondents in both groups (same condition). The first test in the treatment group had a slightly less good intestinal motility (4.79 x/minute) compared to the control group, which was 3.29 x/minute. Specifically to answer the purpose of research, statistical results obtained independent t test with p = 0.013, which means there is a significant difference test value of post-intestinal motility of respondents in both groups. In addition, the average flatus time in the treatment group was better (22.86 hours), while, in the control group, it was 26.64 hours. Independent t test results obtained p value = 0.262; it can be interpreted that there is no significant difference between flatus time in the treatment group and the control group.

Discussion

The results showed that the intestinal motility of respondents in the treatment group experienced a significant increase after ST-36 acupressure was given compared to the control group respondents. The results of this study are in line with previous studies which stated that ST-36 acupressure can improve gastrointestinal function in postoperative patients with colorectal cancer. An urban medical center in Taiwan. SAMPLE: 60 patients with colorectal cancer who had undergone abdominal surgery.METHODS: Patients were randomly assigned to two groups, the ST-36 acupressure group (n = 30) This condition occurs because the digestive tract in postoperative patients will move slowly due to side effects of anesthesia, where, when anesthesia occurs paralysis, the digestive muscles need time to adapt again. Physiologically, P increased frequency of bowel...
motility is meaningful because the drug’s effectiveness has been declining over time. When the work of the drug ends, the inhibition of spinal stimulation begins to decrease and the lower digestive muscles begin to work, which is characterized by an increase in the frequency of bowel sounds, reduced nausea, flatus and bloating does not exist.12 The results of this study indicate that physiological processes can be traversed rapidly because ST-36 acupressure can stimulate the hypothalamus for acetylcholine mesecretion and substance P. These substances play a role in the muscle movements of the gastrointestinal system so that it stimulates intestinal motility.10

Return of the function of intestinal motility in postoperative patients can be influenced by several factors, including age, gender, type of surgery, weight and work or activity. The results showed that the factors that influence the return of patients’ intestinal motility function are homogeneous. Regarding age of respondents in both groups, including young adults, where age indicates good development of the gastrointestinal system, movement of intestinal motility decreases with increasing age and slows down esophageal emptying.13 Meanwhile, the sex and type of surgery are each only one criterion, namely, all female sex and surgery performed by sectio caesarea. The type of operation equation does not show differences in the dosage of anesthesia given, so that the length of recovery time of the gastrointestinal system is generally the same.11

Another factor is weight, where b is closely related to the effectiveness of acupressure. Acupressure ST-36 is performed by the therapist’s hand so that the thicker the fat layer of the patient, the depth and strength of the emphasis will be different.14 In addition to body weight, in this study the activity of respondents was associated with the type of work. Aktivitas will influence the physiological function of organs, whereby a person who often moves his organs will function better than the rare mover.15 Other physiologists also show that blood circulation in the gastrointestinal tract and the lining of the intestinal wall is directly related to the level of activity. Motor, secretory and absorptive functions will increase after activity, as well as gastrointestinal circulation.15

Other research results are that there was no effect of ST-36 acupressure on flatus time between the treatment group and the control group. This situation is possible because, in both group, there were several respondents who had intestinal motility at the time of post-surgery. This situation is in accordance with Home Visits which states that the factors affecting the occurrence of flatus include intestinal peristalsis, the contraction of the muscles of the abdomen and eating.16 The results also showed that almost all patients had normal amount of intestinal motility, between 5-35 x/minute; this was directly proportional to the increase in intra-abdominal pressure. Intestinal peristaltic movements also make the space become pressurized, thus, forcing the contents of the intestine, including the gas inside, to move toward a lower pressure, which is to around the anus.16 Flatus occurs when there is a peristalsis where gas is pushed into the rectum, resulting in increased pressure in the rectum and causing the sphincter to relax and occur flatus.15 After surgery, patients can first drink a little water, then can eat porridge and, if they can dispose of the wind the next day, then they can eat rice.17 The contents of the intestine are the main stimulus for the occurrence of product contractions and flue gas puts pressure on the walls of the colon.13

**Conclusion**

ST-36 acupressure can accelerate the increase in the amount of intestinal motility in postoperative patients under Subarachnoid Block anesthesia. The first flatus time in postoperative patients with Subarachnoid Block anesthesia was not proven to be accelerated by ST-36 acupressure. This therapy is expected to be collaborated with mobilization to get more optimal results, namely, accelerating the return of intestinal motility and flatus time. The main implications for nursing practice from this study were improving services and alternative therapies for returning intestinal motility and flatus time. Subsequent research related to the effect of ST-36 acupressure on intestinal motility and flatus time is expected to be carried out in postoperative patients with general anesthesia.

ABSTRACT

Depression is a common comorbid condition among patients with heart failure (HF). Depression in HF is associated with poor health outcomes, increased risk of mortality, readmission, and decrease in functional status. The aim of this study was to explore the experience of HF patients related to symptoms of depression. The study was conducted at a government hospital in East Java, Indonesia and used a phenomenological approach. The population of this study was inpatients with HF who were obtained through a purposive sampling technique. Eighteen HF patients were recruited as participants. Data collection took place from February to May 2016 by interview and field notes. Collected data was analyzed through thematic analysis. There were three main themes that emerged from the data: cognitive function, emotional, and somatic responses to disease. HF patients reported impaired cognitive functions, especially in decision making and perception of disease. They also had several emotional responses including sadness, guilt, hopelessness, suicide, crying, and anger. There were also somatic responses including energy loss, fatigue, disruption of sleep patterns, decreased appetite and sexual interest. Understanding the description of depressive symptoms in HF patients can help nurses and other health professionals provide appropriate interventions to reduce depression.

Keywords: heart failure, depression, symptom, qualitative, patient’s experience

Introduction

Depression is a common comorbid condition among patients with HF. The prevalence of depression ranged from 23.8% to 67% in hospitalized patients and around 16.7% to 70% in outpatients with HF.¹ In another study, the general prevalence rate of depression in HF patients ranged from 9% to 96.1%.² Compared with the general population, the prevalence of depression in patients with HF is higher.³ In conditions of advanced HF, worsening signs and symptoms of the disease also intersect with depressive symptoms, making it difficult to distinguish whether the symptoms are purely due to depression or progression of HF.²³

The presence of depression in HF is associated with deterioration of disease prognosis, increased risk of hospital readmission, as well as decreased in functional status.⁴⁵ HF patients with depression are at the highest risk of experiencing medication nonadherence, which causes a decrease in health status.⁶ In the majority of studies the relationship between depression and HF shows that an increase in depressive symptoms is significantly associated with a higher mortality rate.⁷ In addition, several studies show that depression is the main predictor of poor quality of life in patients with HF.⁷⁸

Several studies have examined the relationship between depression and some somatic symptoms in HF, i.e. fatigue, sleep disturbance, daytime symptoms, and functional status. The number of HF patients with symptoms of fatigue and depression is greater than those who do not have both symptoms.⁹ Fatigue and depression become mediating factors between insomnia symptoms and self-reported functional performance.¹⁰ Daytime symptoms (fatigue, excessive daytime sleepiness, and depressive symptoms Patients who continue to
experience sleep disturbance over time are at risk of doubling the incidence of hospital readmission.11

Most of the previous studies examined the symptoms of depression quantitatively and made a connection with other variables.1,4–10,12,13 The recent qualitative studies have also explained the experiences of patients living with HF, which one of them explains the detail experiences related to symptoms of breathless.14–19 However, there is a lack of information describing how depression symptoms are experienced by patients and what are the most common symptoms of depression among patients with HF. Therefore, the aim of this study was to explore the experience of HF patients related to symptoms of depression.

Method

This study used a phenomenological approach to gain an understanding of the experience of HF patients related to symptoms of depression. The population of the study was inpatients with HF at a government hospital in East Java, Indonesia. Participants were selected using a purposive sampling technique. The inclusion criteria were: had been diagnosed with HF at New York Heart Association (NYHA) class III to IV, had a stable hemodynamic state, could communicate verbally using Javanese or Indonesian, and were willing to participate in this study. The advanced stage of HF was selected because, theoretically, most of patients in this stage suffer from depression. Participants were excluded if they were not cooperative in interviews and needed critical treatment in ICU/ICCU.

Data collection took place from February to May 2016 by twenty-one semi-structured interviews. All interviews were conducted by the lead author and took between 45 and 60 minutes. Data obtained were processed and analyzed using thematic analysis of Colaizzi methods. All interviews and field notes were transcribed as a whole and extracted to formulate meanings from the phrases and statements. Meanings were organized into categories, sub-themes, and themes.

Results

Eighteen patients with HF were enrolled into the study. Table 1 presents the characteristics of the study participants. The participants were mostly male (55.6%) with a mean age of 53.6 (SD 10.7) and an age range of 36-71 years. Most participants were less educated (61.1%), were married (77.8%), and were unemployed (61.1%). More than half of the participants were in NYHA class III (55.6%) and were admitted to the hospital for the first time (61.1%).

</table>
Three main themes emerged from the phenomenological analysis: the cognitive functions of HF patients, emotional responses due to HF, and somatic responses to disease.

1. Cognitive Function: Patients with HF reported impaired cognitive functions, especially in decision making and perception of disease. Almost all participants expressed an inability to make decisions for themselves. They were very dependent on their family and other support systems in making decisions about treatment, financing, and care.

“I can’t think of anything else, mam. I leave it to my daughter. Everything depends on how my daughter is. She is the one who takes care of everything.” (P5)

“I’m confused, mam. I don’t know how to deal with this pain.” (P10)

Patients also showed different perceptions of their illness. Some patients positively perceived the condition of their illness. However, other patients negatively revealed that the illness suffered was a form of God’s anger due to their actions in the past.

“I am sure God loves me, so He trial me like this. Maybe because I used to sin a lot, so I was reminded of this illness.” (P13, P15)

“I am sick, because God is angry with me. He want to punish me because I rarely worship.” (P10)

“I wondered why God gave me this illness. What did I do wrong?” (P6)

2. Emotional Responses: The most emotional responses that emerged in this study were sadness, feelings of guilt, hopelessness, suicide, crying, and anger. Various expressions of sadness arose from patients due to their illness. They were sad because their role was disturbed and burdened with medical expenses.

“I have been hospitalized for months. I am sad that I cannot gather with my children.” (P12)

“Because of this illness, I can’t work. Though a lot of costs have to be spent… It’s sad. How is paying for the hospital?” (P10)

The patients showed feelings of guilt for the illness they suffered. Most patients felt a lot of sinning towards God and that they had performed wrong life patterns in the past.

“My sins are many, maybe, so God give me this.” (P10)

“I used to eat a lot, Mam. A day can be up to five times. I don’t like the vegetables. Maybe because of that I became sick like this.” (P12)

The patients also displayed crying and anger as expressions of sadness. Expressions of anger are usually revealed to the family via verbal and non-verbal expressions.

“…I’ve been crying a lot lately. I don’t know why. Just come out like that.” (P16)

“It feels like this chest is heavy. So, I want to keep crying.” (P5)

“I often get upset and perform it to my wife…” (P12, P13)

Patients who entered the hospital for the third time or more showed feelings of despair. They were tired of going into the hospital and wanted to end the hardships of their lives by suicide.

“I am already tired of frequently readmission to the hospital. I have been treated everywhere but there is no result. Tired of taking medicine too. I want to end it soon. It’s better that I am going to die, so I don’t bother my wife…” (P11, P12, P18)

3. Somatic Responses: Almost all participants showed a somatic response in the form of energy loss, fatigue, disruption of sleep patterns, decreased appetite, and decreased sexual interest. Response to loss of energy was indicated by the inability of patients to carry out activities as usual. Most patients just laid in bed and needed more effort to do something.

“I lay more on my bed. It’s hard to do anything. I’m afraid of getting worst. Just take a break, sometimes it’s suddenly tight.” (P2, P12)
This state of energy loss causes patients to get tired easily while on the move, even when performing minimal activities.

“I am tired. So usually just sit for a while, after that lay down again. If it is forced to sit for a long time, it is even more congested. “ (P12)

In advanced patients, tightness complaints appeared often. This causes patients to frequently wake up due to tightness, especially at night. Patients revealed irregularities in their sleep patterns that had an effect on sleep deprivation.

“I often wakes up at night because of tightness. Sometimes during the day, but often at night. So it’s difficult to sleep, I often disturbed. “ (P6, P5)

In addition, patients also showed a decrease in appetite and sexual interest. Decrease in sexual interest is more due to the physical condition of the patient.

“I have no appetite at all...” (P4)

“I have no interest in sexual activity. My husband also knows my condition. So, he doesn’t force it.” (P4, P18)

**Discussion**

The findings show that participants in this study experienced impaired cognitive functions, including the inability to make decisions and comprehend their disease. The inability to make decisions occurred both in older and younger patients. Patients showed dependence on their family or health workers in the treatment of illness. They expressed confusion and helplessness due to a lack of information regarding their illness and treatment. They also showed that they need support from the people around them. This finding is consistent with symptoms of depression in the general population, where depression affects a person’s ability to think. Depression can impair attention, memory, the processing of information, and decision making skills. It can cause a decline in cognitive flexibility. Patients with depression reveal biased utility judgments that can lead to the selection of sub-optimal alternatives and failure to maximize experienced utilities.

The second theme generated from this study is emotional responses due to disease. Participants in this study showed expressions of sadness, guilt, hopelessness, suicide, crying, and anger. These expressions become a sequence response due to the illness, began with feelings of sadness and guilt, then patients displayed crying and anger as negative emotional focused-coping. This is consistent with previous studies regarding emotional response in depression patients. Impairment in emotional responses is theoretically a main issue of depression. In several studies, depression was related to a deficit in positive affect. They report experiencing pleasant stimuli as less pleasant than healthy controls.

Somatic responses were the last theme of this study. These responses include energy loss, fatigue, disruption of sleep patterns, decreased appetite and sexual interest. All of these symptoms appear as natural trajectories of the disease, making it difficult to distinguish whether they were caused by depression or not. However, several previous studies had confirmed the link between depression and symptoms of HF, giving a clear explanation regarding the relationship. Some arguments suggest that pathophysiological mechanisms and worsening of physical conditions as a result of disease progression are the main causes of depression in heart failure patients. The main HPA axis activation plays an important role in neurohormonal regulation. In addition, the HPA axis also mediates the sympathetic nervous system hyperactivity as indicated by an increase in plasma levels of norepinephrine, epinephrine, and catecholamines. For example, cardiovascular, stroke, diabetes and obesity morbidity. These somatic consequences could partly be due to metabolic, immunoinflammatory, autonomic and hypothalamic-pituitary-adrenal (HPA Both of them compile to produce effects, not only on somatic symptoms of depression but also on HF physical symptoms.

**Limitations:** Our study has several limitations. First, as is the nature of qualitative studies, our findings cannot be generalized to the general HF population. However, our study has provided a comprehensive description of experience regarding symptoms of depression. Second, all interviews were conducted only in one region of Indonesia in East Java, which could not yet represent the cultural and ethnic differences of the HF population in Indonesia.

**Conclusion**

The findings of this study provide a deep understanding of HF patients’ experiences related to
symptoms of depression. There were three main themes that emerged from the phenomenological analysis, including cognitive function, emotions, and somatic responses to disease. Understanding the description of depressive symptoms in HF patients can help nurses and other health professionals provide appropriate interventions to reduce depression and subsequently improve quality of life.

Spiritual Intervention and Thermal Stimulation in Pregnant Women with Back Pain

Sri Wahyuni¹, Tutik Rahayu¹, Hernandia Distinarista¹, Apriliyani Yulianti Wuriningsih¹, Siti Diah Nofitasari¹

¹Faculty of Nursing, Sultan Agung Islamic University, Semarang, Indonesia

ABSTRACT

Back pain is one complaint that is often experienced by pregnant women. This complaint increases with increasing maternal age. The purpose of this study is to determine the effectiveness of spiritual intervention and thermal stimulation of back pain in pregnant women. The method uses a quantitative with quasi-experiment pre-post test design with control on 40 people; subjects were taken by purposive sampling. Interventions in group 1 listened to Qur’anic murottal Ar Rahman surah and were given warm compresses, while in group 2, Qur’anic murottal was the subject’s favourite surah and were given warm compresses for 20 minutes. The data was analysed using the Wilcoxon and Man Whitney tests. The Wilcoxon test in group 1 showed that there was an effect of listening to murottal Alqur’an Ar-Rahman surah and warm compresses to decrease back pain, with p value 0.000. In group 2, there was an influence of listening to murottal Alqur’an favourite surah and warm compresses to decrease back pain, with p value 0.000. The Mann Whitney test from both groups showed no significant difference in decreasing back pain in groups 1 and 2 with p value 1.000.

Conclusion: There is a significant reduction in pain before and after intervention.

Keywords: Spiritual Intervention, Thermal Stimulation, Pregnant Women, Back Pain.

Introduction

Pregnancy is a physiological process that couples always expect in a family. During the pregnancy process the mother will experience changes in her body which often cause complaints. Complaints are common and are felt by almost every pregnant woman, including the back.¹

Complaints of back pain in pregnant women occur because it is influenced by several factors, including physical changes that occur during pregnancy. During pregnancy, women generally experience changes in body size and weight gain, the growing of the foetus in the uterus causes the abdominal wall to become stretched. Posture resulting from the stretching of the abdominal muscles can cause pregnant women to experience lordosis.²

Lordosis posture in pregnant women affects the shoulder, causing it to be attracted to the back due to prominent abdominal enlargement and for maintaining body balance, curvature of the vertebrae inward also becomes excessive. Sacroiliac joint relaxation that accompanies changes in body shape stimulates an increase in back pain. Complaints of back pain like this usually begin to be felt when entering the second trimester, and increases when gestational age increases. Pregnant women with complaints of back pain have a lower quality of life and more often complain of pain.³

Complaints felt by pregnant women who experience back pain have an impact on daily activities, so that the mother experiences a disruption in carrying out activities such as moving or changing positions, difficulty walking, sleep disturbances and emotional disturbances.⁴ Pregnant women with back pain must be careful in carrying out activities. It is very important to be given an understanding of ergonomic positions, and avoid maladaptive movements, improper pelvic movements and unbalanced weight.⁵ Treatment that is routinely carried out in the antenatal period can reduce pain in malposition due to back pain experienced by pregnant women.⁶
Complaints felt by pregnant women should not be ignored and must be treated so that the mother feels comfortable during her pregnancy. Back pain in pregnant women can be given pharmacologically or non-pharmacologically. Efforts to treat pharmacology can be done by administering analgesic drugs, while non-pharmacological management can be done by providing acupuncture, relaxation, massage, distraction and exercise therapy. Efforts to treat pain with pharmacology must be careful and it is necessary to monitor drug side effects that may occur, while handling pain with non-pharmacological is safer and does not cause side effects.

Many studies suggest that pregnant women often complain of back pain with mother experiencing disruption in carrying out daily activities. Research conducted on women’s experiences of low back pain during pregnancy finds that multipara pregnant women with back pain have a significant sleep disorder compared to primiparous mothers. From all pregnant women who experience back pain, the data obtained shows that 57.7% experience disruption of activity and 77.5% of mothers feel bored. Pregnancies in older women with back pain complain of pain in the legs, neurological disorders and disorders of elimination in both urination and defecation.

Management of warm compresses is part of non-pharmacological therapy that can be given in obstetric cases to women in the antenatal, intranatal and postnatal areas. In giving warm compresses the study subjects showed a significant reduction in pain before and after the intervention. Giving warm compresses in addition to reducing the level of pain can also increase blood flow to the local tissue. In addition to warm compresses, music therapy can also be done to reduce the level of pain and anxiety. Research conducted on the effects of music on labour pain relief, anxiety level and postpartum analgesic requirement, states that giving stimulation of auditory music therapy can reduce pain.

Research on efforts to overcome complaints of pain with the provision of warm compresses and music therapy is most often performed on mothers who face labour, while for mothers who experience back pain has not been done much. The average researcher gives treatment with warm compresses or just music therapy which then measures the pain level to be able to assess the level of reduction in pain that occurs. In this study a combination of warm compressing and murottal Alquran was part of auditory stimulation for distraction therapy.

Method

This research is a quantitative study that uses quasi-experimental design studies with two groups pre-test – post-test design with control in 40 research subjects taken through purposive sampling technique in Semarang City, Central Java Province, Indonesia. The treatment given to the research subjects was spiritual intervention and thermal stimulation. Subjects in group I were given interventions to listen to Qur’anic murottal Ar Rahman surah and warm compresses, while the research subjects in group II were given Qur’anic murottal interventions of favourite subject’s surah and warm compresses with a duration of 20 minutes.

Results

Table 2 shows that in group I the results of the p value was 0.000 which means that there is a significant difference in the level of back pain in group I before and after the intervention. So it can be concluded that there is an effect of murottal Qur’anic given from Surat Ar-Rahman and warm compresses to reduce back pain in pregnant women.

The table also shows that in group II the processing results obtained a p value of 0.000 so that H0 was accepted, there were differences in back pain before and after intervention in the study group II subjects and it could be concluded that there was an effect of preferred use of murotal surrah listening and giving warm compresses to reduce back pain.

Table 3 shows that the results of processing data are p value 1.000, which means H0 is rejected, meaning that there is no significant difference in decreasing back pain in giving Qur’anic murottal Ar-Rahman surah as spiritual intervention and thermal stimulation by giving Qur’anic murottal to the favourite subject’s surah as spiritual interventions and thermal stimulation. These results have the meaning of Qur’anic murottal spiritual intervention listening to Ar-Rahman surah and thermal stimulation by giving spiritual intervention listening to the subject’s favourite surah and thermal stimulation with warm compresses having the same impact on decreasing back pain in pregnant women.

Discussion

Research shows that murotal spiritual interventions listen to Qur’anic murottal Ar-Rahman surah and thermal stimulation by giving spiritual interventions to listen to the subject’s favourite surah and thermal stimulation with warm compresses have the same impact on decreasing back pain in pregnant women. The intervention given to both groups equally significantly affected the reduction of pain in pregnant women.

Spiritual intervention in the form of listening to Qur’anic murottal is part of distraction therapy. Distraction therapy is a form of therapy that is done to divert attention to other things that can make patients forget about the pain that is felt.13 Auditory stimulation can affect emotions, activities of the brain and also the nervous system and cardiac output.14 The auditory interventions provided by one of them can be Qur’anic murottal listening. Qur’anic murottal interventions are received by the auditory system, are transmitted to the brain which in turn affects the limbic system. Hearing stimulation is accepted by the brain in the midbrain region which stimulates the midbrain to secrete Gama Amino Butyric Acid (GABA), enkephalin and beta
endorphin, which act as electric conductive inhibitors, have an analgesic effect and function as a softener. Increases in hormone endorphins are able to reduce stress levels and control the pain felt by individuals. The use of the Qur’anic murottal stimulation is a simple action to be carried out and optimizes the religious side of the research subject. Qur’anic murottal administration when compared with other auditory therapies such as music has more influence on pain reduction. Patients who experience long-term pain conditions need a spiritual touch to increase their enthusiasm and strength in dealing with their pain.

Providing warm compresses of thermal stimulation has the benefit of increasing the temperature of local skin, promoting blood circulation, stimulating blood vessels, reducing muscle spasm, relieving pain sensations, and providing calm and comfort. Warm water is a means of slowly pumping the heat to the body, which has a positive effect. Warm water can also affect the outer body, inner body and blood circulation. Warm temperatures can make a positive value for the body’s energy because it has a good influence on cell components which consist of various electrons, ions and others. Warm water with a temperature of 35-40 °C has a physiological impact on the body which can prevent muscle spasm and smooth blood flow so as to reduce pain. The water temperature at the time of giving compresses for thermal stimulation must be maintained. Giving compresses can be carried out in between 15 and 20 minutes.

The physiological effects of heat therapy can relieve pain, increase blood flow and metabolism and increase the elasticity of connective tissue. Thermal therapy in the form of a warm compress is passed on by the TRPV1 TRP nerve transduction receptor (TRPV1), which is a heat receptor. This TRPV1 receptor is in the primary afferent neurons, spinal cord, and throughout the brain. Activation of TRPV1 receptors in the brain can reduce antinociceptive effects. Heat stimulation in tissues stimulates vasodilation and blood flow to the tissues so that the supply of nutrients and oxygen to the location of pain becomes smooth. This condition increases peripheral metabolism, provides warmth, and makes the muscles of the body become more relaxed and reduce pain.

Warm compress therapy is one of the non-pharmacological methods for relieving pain that can be done easily, with various variations of giving and using available equipment at any time without the need for complicated skills. But if done correctly, it will have a significant impact on reducing pain.

Conclusions

The study concluded that spiritual intervention and thermal stimulation were effective for reducing back pain in pregnant women in Semarang City. The provision of spiritual interventions by listening murolatal and thermal stimulation by providing warm compresses can make pregnant women experience relaxation of their back pain. The two interventions support and enhance the mother’s comfort so that back pain is significantly reduced.

Clinical Supervision Training to Increase Nurses’ Work Performance in Hospitals

Sirajudin Noor¹, Agianto², Nursalam³, Herry Setiawan⁴

¹Doctoral Degree Programs, Faculty of Nursing, Universitas Airlangga, Indonesia; ²School of Nursing, Universitas Lambung Mangkurat, Indonesia; ³Faculty of Nursing Universitas Airlangga, Indonesia; ⁴School of Nursing, Universitas Lambung Mangkurat, Indonesia

ABSTRACT

A common problem often faced by healthcare service management is the difficulty in finding qualified nurses. Training is one of the characteristics of an organization that has a positive impact on increasing professionalism and the work performance of nurses at the hospital. Improving supervision is a method to monitor the quality of services by hospital supervisors. This study attempts to determine the effect of clinical supervision training as one of the organizational characteristics on increasing the work performance of nurses at the hospital. The quasi-experimental study design was used in this study with 68 nurses who were working in a hospital in Banjarmasin. The observation was carried out before and after training. The dependent variable in this study is clinical supervision training, and the independent variable is work performance. Univariate, and bivariate were used in data analysis. There was an effect of clinical supervision training as one of the organizational characteristics on increasing the work performance of nurses at the hospital (p=0.00). Clinical supervision training increased work performance on clinical supervision abilities. Nurse training improved the quality of healthcare services, especially nursing care.

Keywords: clinical supervision, nurse, work performance

Introduction

The difficulty of finding health workers, including qualified nurses, is a common problem often faced by hospitals or health services.¹ This has an impact on the low quality of performance.² Hospitals have limited resources. They see performance improvement activities centred only on increasing cost requirements, not adding value to building the organizational commitment.³ Based on the pilot study, the patient’s perception of the quality of nursing services is still lacking (25.85%). Nursing services are not a good enough category (> 20%) including the aspects of providing nursing services according to a nursing appointment. A hospital as an organization depends on how to utilize human resources who have optimal work productivity.⁴ The low performance of nurses is related to an overload of work, long shifts, the complexity of work relations, and lack of opportunities for career development.⁵ One of the characteristics of career development for nurses in hospitals is training. Career training and development can impact organizational commitment and nurses’ belief in work so that they can improve nursing performance and provide satisfaction to patients while they are hospitalized.⁶,⁷

Nurses need moral support, personal quality development, integrity, knowledge, and self-awareness.⁸ The previous study explained that clinical supervision affects the quality of services so that they can be considered as activities and improve the quality of nursing practice.⁸ Practical nursing is always associated with supervision. Nursing and supervision care training is proven to increase nurse motivation and performance.⁹ Supervision is one form of supervision carried out in the inpatient ward. The implementation of supervision has a positive impact on staff professionalism and accountability. Clinical supervision is effective for improving the quality of patient care.¹⁰

Nowadays, clinical supervision in the hospital is carried out unscheduled, unstructured, is not recorded, and is not given good feedback. In the end, clinical supervision activities cannot give objective results in improving the quality of nursing performance. This happens because supervisors do not properly understand the concept of clinical supervision. There are some supervisors who are aware of the concept of clinical supervision. They are willing to argue that their work does not only involve supervising clinical supervision activities. The head of the nursing department said that, so far, supervisors had not received specific clinical supervision training. Most of the training that they have is in general training such as ward management or head nurse management.

Activities which are carried out by supervisors are expected to guarantee nursing interventions in standards. Supervisors have responsibility for care management, but they were not fully properly and correctly implemented in clinical supervision activities. The hypothesis in this study is that there was an increase in clinical supervision abilities after supervisors received clinical supervision training. The aim of this study was to determine the effect of clinical supervision training to increase the work performance of nurses at the hospital.

Method

This study was a quasi-experimental pre-post test control group design with the intervention group in the form of clinical supervision training and the control group not given training. There were 68 nurses with each group consisting of 34 nurses. A simple random sampling technique was used in this study. The inclusion criteria were associate nurses who worked in an inpatient room and who had more than three years for work experience.

The study was conducted at Ulin General Hospital Banjarmasin from April to June 2016. Data collection used a checklist observation sheet that contained the supervision activities. The supervision activities were how the supervisor performed as a role model in giving nursing intervention, how to evaluate the nursing intervention, how to encourage nurses, how to make scheduling the nursing shifts, and giving the reinforcement for the nurses who successfully implement the nursing process. The instrument was developed from the evaluation of supervision activities by Keliat and Akemat by adjusting the clinical supervision model developed by Brigid Proctor.11

The preliminary data was carried out by observing the room supervisor who carried out the clinical supervision to the nurses who implement nursing care. Room supervision was assessed by the guidelines of the observation sheet that had been prepared. Observations were carried out in 34 clinical supervision activities in each group. Supervised implementing nurses were recorded, then on different days observed at the time of treatment (without supervision) as preliminary data on the ability of care during the nursing procedure before treatment. The intervention phase was conducted in clinical supervision training to supervisors who were in the intervention group on April 15, 2016, while in the control group there was no clinical supervision training. The participants of training (intervention group) got the training module which contains topics on the implementation of clinical supervision in care. The training is carried out in several stages, including the provision of cognitive and affective knowledge for ten hours and implementation assistance to increase psychomotor abilities for two weeks.

Univariate analysis was used to determine the distribution of age, gender, education level, and work period. A paired sample t-test and independent sample t-test were used to analyse the variables with a significance level of 0.05.

Results

The characteristic respondents are shown in the table below:

The table above showed that the value of clinical supervision ability before treatment in the intervention group was 55.38 and after treatment was 89.85. In the control group the average score of clinical supervision ability before treatment was 56.03 and after treatment 57.06. The results of analysis showed that there were significant differences related to implementation of clinical supervision before and after treatment in the intervention group (0.000). Whereas in the control group there was no significant difference regarding the ability of clinical supervision before and after treatment (0.153).

Table 4: The influence of clinical supervision among intervention and control group before and after clinical supervision training

</tbody>
</table>

The table above described that the differences in mean in the intervention group was 34.47 and the control group was 1.03. The results of the analysis concluded that there was an influence of clinical supervision training on the clinical supervision abilities of supervisors at Ulin General Hospital Banjarmasin (p=0.00).

Discussion

The results of the analysis of clinical supervision abilities before being given training in the intervention group and the control group showed poor results. The range of values of 50-60 with an average value of 55.38 before being given treatment in the intervention group was low. It still needed an increasing value of 44.62 to achieve the maximum value of clinical supervision capabilities by the supervisor.

The observation result before being given treatment showed that most supervisors did not comply with the guidelines in carrying out clinical supervision implementation, such as the clinical supervision that they did: 1) unscheduled, 2) unclear targets, 3) no bait behind, 4) which was undocumented 5) was not sustainable. It cannot provide objective information related to the implementation of activities based on a predetermined standard.

There was a significant difference regarding the ability of clinical supervision before and after clinical supervision training (0.000) in the intervention group. This was in contrast with the control group where there
was no significant difference between before and after the intervention (0.153). This proved that the training about effective clinical supervision improved the clinical supervision capabilities of the supervisor. Another research also stated that there were differences between groups that got training and the control group that did not get clinical supervision training (0.001) and found the influence of supervision on the ability of wound care performed by nurses. There was the influence of supervision training on the supervisor’s ability to supervise the implementation of patient safety. The intervention group and the control group gave different responses based on the presence or absence of stimulus in the form of clinical supervision training. This showed that through clinical supervision training, it was proven effective to improve the ability of supervisors to carry out clinical supervision.

Supervisors need cognitive, affective and psychomotor skills. This can be achieved by attending education and training. Supervisors also need to get special education or training to effectively carry out clinical supervision activities. They need good knowledge, including communication, motivation, guidance, direction, leadership, and experience. Moreover, they can carry out the clinical supervision well and according to a purpose. Head nurses and supervisors who have received clinical supervision training have been shown to improve their ability in clinical supervision activities.

The training plays an important role in an organization to improve the ability of managers. They are able to carry out their duties and functions well. Clinical supervision ability for supervisors needs to be developed through supervision training that will improve cognitive, affective and psychomotor abilities. It impacts productivity and or outcomes as expected. Clinical supervision training provides a good change, indicated by changes in knowledge of supervisors after training with almost perfect scores on post-test and passed for evaluating the results of supervision practices. The clinical supervision training is an important part in improving the ability of the supervisor to carry out the clinical supervision properly. The factors that influence the application of patient safety are directional functions, and primarily supervision activities by the manager. The ability of nursing managers is required to be able to carry out the function of direction for a manager through supervision activities to ensure the ability of nursing services.

The results of the analysis showed that in the intervention group there was an increase in the average value of 34.47, while in the control group the average value increased by only 1.03. This proved that there was an influence of clinical supervision training among supervisors on clinical supervision abilities at Ulin General Hospital Banjarmasin (0.000). The aim of the training was to improve the ability of supervisors to implement their main tasks. It should implement the clinical supervision of nurses in the ward to create a conducive work climate, support and motivate, and be effective on patient safety application.

Training is an effort to improve technical, theoretical and conceptual capabilities and employee morale in accordance with the needs of work or position through education and training. Education and training are the same as development, namely the process of improving both technical and managerial work skills. One of the indicators of the success of training can be seen from the initiative of employees who are trained. After participating in the training, employees can independently do what they have been taught and try to develop their creativity. To get reliable organizational performance, the process of human resource management needs to be properly implemented. There are three activities in the process of human resource management, namely: 1) Ensuring that competent employees can be identified and selected; 2) Providing up to date knowledge and expertise; 3) Ensuring that the organization maintains competent and well-performing employees who are able to continuously produce high performance.

The training in this study was conducted over 7 weeks. It was too early to accept behavioural change to be optimal. Someone who gains knowledge has it impact upon their behavioural change in providing services to patients. In its implementation, the supervisor has not explored all of his abilities in carrying out clinical supervision. It is limited by the grace period of the study.

This is in accordance with Lewin’s theory of change which suggests that a person needs to move into a new state. Supervisors who have information need to find out the changing stages. This is, namely, by providing good information, assisting in the implementation, assisting in solving problems and conducting feedback and continuous coaching efforts to supervise nurses. Therefore, it should be noted by policymakers to always meet the needs of the supervisor and education of the room supervisor in an effort to improve the ability of clinical supervision.
Conclusion

There were differences in clinical supervision abilities before and after training in the intervention group (0.000) and the control group (0.153). Hospitals need to improve the implementation of clinical supervision by programming education and training activities. It can be carried out continuously by all supervisors to improve the quality of care and work performance of nurses at the hospital.

Ethical Clearance: This study was approved by the Ulin General Hospital International Review Board (IRB) with number 004/III-RegRiset/ RSUDU/16.

Feeding Patterns of Children with Stunting Based on WHO (World Health Organization) Determinant Factors of Behaviours Approach

Ilya Krisnana¹, Rafidah Azizah¹, Tiyas Kusumaningrum¹, Eka Mishbahatul Marah Has¹

ABSTRACT

The stunting of children is a problem that is happening in Indonesia. Stunting can be caused by several factors, one of which is the feeding pattern of the child applied by the mother. The purpose of this study was to analyse the factors related to feeding patterns on children with stunting. This research design used a cross sectional study. There were 136 respondents (mother and toddlers) in this study who were chosen by simple random sampling. The independent variables were knowledge, attitude, personal reference, and income, while the dependent variable was feeding patterns. The data were collected by Infant and Young Child Feeding (IYCF) questionnaire then analysed by using ordinal regression. The result showed that there were relationships between health workers and posyandu cadres (p=0.001), and income (p=0.00) with feeding patterns. It can be concluded that the feeding patterns in children with stunting could be influenced by health workers, posyandu cadres and parent’s income. Income was the most influential factor with the pattern of feeding (estimated 15.4). This was because the higher the income, the greater the variety of food items that could be purchased by the mother. Personal references were used to enhance preventive and promotive efforts to provide health education to the mother.

Keywords: stunting, feeding pattern, behaviour, children

Introduction

Child stunting is a problem in Indonesia. Children with stunting describe poor linear growth, because the golden and critical period happens between the ages of 6-24 months. Based on one of the expected outcomes of the second purpose of Sustainable Development Goals (SDGs), which is to end every form of malnutrition by 2030, including a 2025 international target to reduce the number of stunting and wasting on children. However, to date the reduction in target has yet to be achieved. Stunting children in developing countries can be caused by an improper feeding pattern. Infants to three year olds are passive consumers. It means that they consume the meals that are provided by their mothers or nannies. Mothers should pay attention to the intake of nutrients consumed by their children, so their growth and developments are in accordance with their age.

The short-term effect on stunting children is increasing morbidity. The long-term effects that may occur in individuals and society are cognitive ability deficit, poor health and a decrease in productivity, and the increasing risk of degenerative diseases such as diabetes, it can also cause psychomotor, soft motor skills, and neurosensory integration problems. The effects caused by lack of nutritional intake are thin children, slow body growth, decreased level of intelligence, mental disturbance, and even death.

Child stunting prevention measures by the government by making policies to reduce the number of child stunting are in accordance with Health Constitution Number 36 of 2009 that is by improving food consumption patterns that correspond with balanced nutrition and nutrition conscious behaviour. The treatments are to reduce the number of child stunting by providing micronutrient supplements to balance protein in pregnant women, educating mothers to breastfeed...
their children for six months exclusively. Additionally, administering vitamin A to children who are above six months old. However, the government measures that have been done by now have not yet decreased the numbers of child stunting.9

The parents’ behaviour in feeding their children can affect the children’s nutritional status.10 The parents’ behaviour will develop when there is stimulus, either from within (internal), or from outside (external). WHO behavioural theory explains that there are lot of reasons for someone to behave. Therefore, the same behaviour among some people is caused by different backgrounds.11 The theory can be used to analyse both internal and external factors related to the mothers’ behaviour to feed stunting children, and the theory is easy to understand for analysing health behaviour.

Method

Study Design, Setting, and Sampling: This study was a descriptive analytic with cross-sectional study. The population of this study was mothers of children aged 6-24 months in the sub-district of Papar. There were 136 samples picked by using probability and cluster random sampling.

Study Variables: The independent variables were knowledge, attitude, references from people who are considered important (health workers and posyandu cadres), and family income. The data was collected using questionnaires, such as knowledge questionnaire, attitude questionnaire, and Infant and Young Child Feeding (IYCF) questionnaire, that have been tested for validity and reliability with the Cronbach Alpha test.

Data Analysis: The data was analysed by using ordinal logistic regression with significance level α=0.05.

Results

The majority of respondents were at the productive age between 20-35 years old, a total of 106 respondents (77.9 %). In terms of occupation, mostly they were housewives, a total of 100 respondents (80.9%), while their husbands worked day labour, a total of 48 respondents (35.3%). In terms of education 72 respondents (52.9%) were high school graduates. In terms of income, the majority of them have low income, a total of 94 respondents (69.1%) (table 1).

Table 2 shows that the majority of respondents had sufficient knowledge with low feeding patterns, a total of 33 respondents (24.2%). Statistical analysis with α < 0.05 was reported that knowledge (p=0.516) have no relation in feeding pattern to stunting children. The attitudes of the respondents were balanced between positive and negative, a total of 34 and 30 respondents. But most of them had positive attitude with low feeding patterns, a total 34 respondents (25%). Statistical analysis with α < 0.05 was reported that attitude (p=0.555) has no relation with feeding pattern to stunting children.

The majority of the respondents had references from health workers or public figures (posyandu cadres) which were negative with a low feeding pattern, a total of 38 respondents (27.9%), statistical analysis with α 0.05 was reported where health workers and posyandu cadres (p=0.0001) had a relationship with feeding patterns to stunting children.

The majority of respondents had a low income as well as low feeding patterns, a total of 45 respondents (33%). Statistical analysis with α < 0.05 reported that the parents income is related to feeding patterns in stunting children. The dominant factors were related to feeding patterns in stunting children, where the value (p=0.000) compared to the other variable with magnitude of influence indicated by value (estimated: 15.4) shows that it is 15.4 times riskier at influencing feeding patterns to stunting children than knowledge, attitude, and personal references (table 3).

Discussion

The respondents have good knowledge about the benefits of feeding pattern to children. The results of this
study are supported by the research by S Notoatmodjo and F Isnantri et al., which showed that there is no relationship between knowledge and feeding patterns.\textsuperscript{12,13} Mothers have good knowledge about child feeding, but not many of them have applied their knowledge, such as giving various kind of food to their children and introducing foods to their children from an early age.\textsuperscript{14} The family’s economic condition is the main reason why mothers serve the meal, therefore their children get less various food or smaller portioned meals.\textsuperscript{15,16} Food consumption rate is influenced by the income and food product price. High income will determine the quality and quantity of food purchased.\textsuperscript{17} The family’s economic condition is the main reason why mothers serve their family’s meal.\textsuperscript{16}

One of the factors that affecting knowledge is the level of education.\textsuperscript{18} A small portion of respondents are elementary school graduates. The elementary school graduate respondents have less knowledge - 10 out of 21 respondents. Less knowledge is influenced by the level of education.\textsuperscript{19} The level of education will help mothers in acquiring knowledge, understanding, and helping them to think more rationally in absorbing information. Knowledge is influenced by a person’s age.\textsuperscript{11} The majority of respondents are at a productive age between 20-35 years old, a total of 106 respondents (77.9%), at that age a person can absorb information well. People with the ages between 20-35 years old can understand information well.\textsuperscript{12}

The majority of the respondents have a positive attitude in feeding patterns, as evidenced by agreeing to wash their hands before feeding their children, so that the highest score is obtained, while the lowest score was obtained from the respondents that will not force their children if they did not want to eat. Contrasted with a study by NZ Rakhmawati et al. and P Hearty et al., stated that there are positive relationships between attitude and consumption behaviour.\textsuperscript{14,20} Attitude has three components that can shape behaviour and which are influenced by knowledge, thinking, beliefs, and emotions. Attitudes do not always materialise to an action, supporting factors such as family are needed so that actions can be materialised.\textsuperscript{3}

Attitude is a person’s closed response to a stimulus or certain object, which involves the factors of opinion and emotion of the concerned person (correct-incorrect, agree-disagree, pleased-unpleased, etc). Based on this study the majority of respondents have a positive attitude with low feeding patterns which means that the attitude in inversely proportional. Less attitude will achieve a good feeding behaviour. The mothers’ positive attitude does not necessarily lead to a better feeding pattern. It is because the attitude is a closed response and not an action or activity.\textsuperscript{14}

Personal references (health workers and posyandu cadres) are related to children’s feeding patterns. Human behaviours are deeply influenced by the people that are considered important around them, and what they say or do tends to be emulated.\textsuperscript{21} Supporting factors are needed to realize attitudes into real behavior.\textsuperscript{22} Those factors include facility and support from other parties, which is a personal reference in a living environment. The success of the mothers in carrying out the right feeding pattern requires the role of health workers.

The majority of respondents have low incomes as well as low feeding patterns. Income is the most influential factor in feeding patterns to stunting children. The increase of household income give mothers chances to improve the quality and variety of food purchased.\textsuperscript{23} There is significant relationship between income and feeding. The less the income then the less variable the food options.\textsuperscript{24} Variations in consumption of fish are related to economic status, and can cause stunting in children.\textsuperscript{25} Diets low in dairy and meat can cause children to have growth problems.\textsuperscript{26} The family’s income will affect mothers’ attitude in serving meals for their family, especially their children.\textsuperscript{27}

The job characteristics of someone can reflect income, social status, and socio-economic status.\textsuperscript{28} The working status of someone also influences someone’s ability to maintain their health by doing medical check-ups regularly. It is concluded that the income obtained by the respondents are motivated by someone’s work.

**Conclusion**

Based on this study, knowledge are not always influenced by proper feeding patterns. Increased knowledge is not only obtained from formal education but also from informal education. Attitude may not immediately be materialised into an action. There are influencing and supporting factors needed, such as personal experience, cultures, other people that are considered important, mass media, educational and religious institution, also
emotional factors of individuals and family. Therefore, income significantly impacts on feeding pattern because it affects an improper feeding pattern.

**Ethical Clearance:** This study did not use animals and does not mention the identity or medical record of the respondents. The ethical approval for this study was granted by the IRB committee of the Faculty of Nursing at the Airlangga University no.1221-KEPK.

**Source of Funding:** This study and publication was self-funded by the authors.

**Conflict of Interest:** There is no potential conflict of interest over the publication of this article.

ABSTRACT

The students are the group most vulnerable to disasters, especially children with disability. Teachers should have the skills to handle disasters when they occur. The low preparedness of School-Based Disaster Preparedness/Sekolah Siaga Bencana (SSB) teachers in disaster risk reduction can lead to increased vulnerability of teachers in dealing with disaster threats. This study was conducted to analyse the relationship of the role of the teachers in the implemented curriculum SSB in Vulnerability of school teachers with disability in Malang City. This research is a quantitative study, using correlative analytic observational design and cross sectional approach with a sample of 30 teachers taken from elementary schools and junior high schools with disability. The results of bivariate analysis using gamma correlation test obtained the results of knowledge factors (p = 0.005; r = 0.47) attitude (p = 0.000; r = 0.75), means of infrastructure (p = 0.000; r = 0.98), and disaster information (p = 0.000; r = 0.59) for SSB teachers’ preparedness.

Keywords: Knowledge, attitude, curriculum, teachers, School-Based Disaster Preparedness, Vulnerability

Introduction

Preparedness is an important element and part of disaster management.¹ Building such a culture requires innovative, economic, logical, human-oriented, and needs-oriented interventions.² School is one of the main stakeholders responsible for building preparedness. According to Takahashi, besides being the source of knowledge, schools have several strategic roles in building preparedness, such as being the source of knowledge, dissemination of disasters, being participatory educational centres for communities, providing practical guidance on what to prepare before disasters, and actions which should be done during and after the disaster.³ So, school readiness becomes crucial in improving public preparedness.⁴

In the World Conference on Disaster Risk (United Nations International Strategy for Disaster Reduction [UNISDR]; Geneva, Switzerland), it was proposed that comprehensive school safety consists of three pillars: (1) safe school facilities, (2) effective school disaster management and disaster risk reduction (DRR), and (3) endurance education.⁵

The establishment of Sekolah Siaga Bencana/SSB (School-Based Disaster Preparedness) is a preparedness effort for facing disasters in schools, which is the implementation of the Hyogo Framework 2005-2015. School-based disaster preparedness is a school that has the capability of managing disaster risks. These capabilities are measured by having disaster management planning (before, during, and after a disaster); availability of logistics; security and comfort in education; infrastructure and emergency systems supported by knowledge and skills of preparedness; standard operational procedures; and early warning systems.⁶ A study by Lesmana and Purborini indicated that the level of SSB preparedness is still low, in terms of knowledge, attitude, and actions undertaken by SSB in DRR.⁷
Method

Participants and Procedure: The recruitment of participants used simple random sampling. Participants consisted of the teachers who teach students with disabilities. This research was conducted on (n=30) teachers agreeing to join in this research. The independent variables were upholding knowledge, skill and competence while the dependent variable was the level of disaster preparedness.

Instrument: This research is quantitative, conducted by using observational analysis with a cross-sectional approach. The setting of the study were SDLN and SMP LB of which the location was Malang City, Indonesia. This study was carried out from August to November, 2018. The population was 30 teachers from two school SSB in Malang, and the sample size in the study was 30 teachers in SSB taken from grades five and six with a purposive sampling technique. The uni-variate was conducted to identify characteristics of the respondent, bi-variate analysis was conducted to describe the relationship between knowledge and attitude with SSB teachers’ preparedness to deal with the disaster, using gamma correlation test with significance level ($\alpha$) = 0.005; and multi-variate logistic regression was used to see how much influence knowledge and attitude had towards teachers preparedness SSB.

Statistical Analysis: The data was analysed by SPSS version 21. Multiple linear regression was used to identify how far the contribution of upholding trust, compassion, and competence variable was to patient satisfaction. The redundancy variable in this research is socio-demographic factors such as: sex, education, job, and age. Pearson correlation analyses were used to view the correlation between socio-factor and patient satisfaction. The significant level applied was $p < 0.05$.

Result

Socio-demographic characteristics of the respondents: Based on the data obtained from the results of the study, the general characteristics of respondents based on age, gender, training experience, knowledge, attitude, and preparedness were as follows.

Table 1: Distribution of Respondents by Age in SDNLB Kota Malang and SMP LB Malang City

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Table 2 illustrates that the number of male teachers was almost equal to that of the female teachers; the number of male teachers was 10 (40%) and the number of female teachers was 20 (60%). Meanwhile, based on training experience, more than one-half of the teachers never had disaster training (73.4%). This was due to the absence of training programmes related to disaster preparedness for teachers from the government, schools, and private parties.

Source: Primary Data (2018).

Data from each variable are presented in Table 3. The result of the uni-variate analysis showed that from 16 respondents, more than one-half of the teachers had good knowledge (53.2%) with a positive attitude (53.2%). Overall, the SSB teachers preparedness in Malang City was still low (59.6%).
Table 4: Results of Bi-variate Analysis Gamma Correlation Knowledge Relation to SSB Teachers Preparedness in Earthquake Disaster Risk Reduction

<td>0.000</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Based on Table 6, it can be seen that attitude was the variable that had the greatest influence on preparedness, that is OR = 4.308; meaning, the attitude of “poor” teachers of SSB would cause the low preparedness of SSB teachers in DRR for disaster our times compared to SSB teachers who have a “good” attitude respondents in this research responded 100% after controlled knowledge variables. Knowledge became the second-factor affecting preparedness, with value OR = 159.

Discussion

Based on the results of the analysis of the knowledge variable, it was found that there is a significant relationship between knowledge and the preparedness of SSB teachers in DRR, with the significance of 0.007 less than alpha (5%) with correlation value of 0.47, showing a positive correlation with enough correlation strength. The results of the analysis show that more than one-half (53.2%) of SSB teachers have good knowledge of DRR. Most of the teachers are able to answer all questions correctly in the knowledge questionnaire.

According to the researchers’ assumption, the above-average knowledge of SSB teachers is because education about disasters is given to SSB teachers. The teachers are taught about the types of disasters, signs of disasters, the need to save themselves the right way, the place of evacuation in the event of an earthquake, early warning systems in schools, and emergency equipment brought in anticipating risk reduction of earthquake disasters. The results of this study are in line with the results of research conducted by Thomas which suggests that knowledge of respondents will be related to the level of preparedness of individuals in facing disasters. Meanwhile, the research of Pathirage, et al. also indicates that preparedness is influenced by one’s knowledge of disasters and the obtained training experience.

This is because knowledge is an intellectual aspect that is closely related to all that is known by the man himself. Knowledge gained is an accumulation of education given to a person, both formally and informally, which will support someone in solving a problem. This is because of knowledge-oriented intelligence, thinking power, and knowledge, as well as the understanding of someone.

Efforts to disseminate information that can be useful for the community in building preparedness should be based on sound knowledge. In this case, the school becomes a source of information for SSB teachers in increasing knowledge, so that the knowledge given must
be innovative, economical, logical, human-oriented, and needs-oriented.\textsuperscript{14} It appears that most of the rehabilitation is driven by multi-lateral international organizations and nongovernmental organizations (NGOs) that dedicate resources in the education sector (i.e., the fifth in the overall sectoral allocation of post-disaster recovery funds), including school reconstruction and DRR education, in the hope of creating long-term impacts and providing an efficient prevention scheme.\textsuperscript{15} One form of DRR is an effort to increase knowledge; a lack of knowledge can factor into interactions that can lead to increased casualties and material losses. This is due to a lack of understanding of hazards, resulting in unpreparedness and powerlessness in facing these threats.\textsuperscript{14}

Based on the result of the analysis on the attitude variable, it was found that there is a significant correlation between knowledge and the preparedness of SSB teachers in DRR, with the significance of .000 less than alpha (5%), with correlation value of 0.75, showing a positive correlation with correlation strength. However, it should be acknowledged that the positive or negative attitudes have confounding factors that can influence a person to behave, such as previous experience, education level, region, and disaster knowledge. The study of Codreanu, et al. also indicates that someone who has a positive attitude tends to be calmer in facing disaster threats.\textsuperscript{15}

Although most SSB teachers have a positive attitude, there are SSB teachers who have negative attitudes toward preparedness, who are mostly less prepared for DRR. According to Azwar, many factors can influence a person to behave towards the object of attitude, such as personal experience, which is the basic factor in the formation of attitudes.\textsuperscript{16} Therefore, personal experience must leave a strong impression. Attitude will be easily formed if it involves emotional factors. The personal experience that SSB teachers have in coping with the disaster in Malang city is a solid foundation for teachers to have a positive attitude in DRR. However, the experience of teachers in dealing with disasters is not a major factor in shaping awareness of preparedness, but must be supported by good disaster education.\textsuperscript{17}

However, there is also a Java culture called Lindu assuming that the coming disaster is a form of soil fertility and fruits. This way of viewing can certainly hinder the attitude of the community to be prepared for DRR. This culture is slowly eliminated by the increased knowledge of teachers and communities related to disasters. The success or failure of disaster management depends on the involvement of culture, traditions, and customs. It is important to consider the cultural context of the affected regions, such as customs, traditions, local practices, and ethnic composition of a region for effective and easy implementation.\textsuperscript{18}

It is very important for the achievement of preparedness to be improved, especially in areas that are at a high risk of disasters. The Malang area is one of the more potentially earthquake-prone areas.\textsuperscript{19} Learning activities are interactive, inspiring, and challenging, motivating learners to participate actively and providing sufficient space for an initiative, creativity, and independence according to the talents, interests, and physical and psychological development of learners. These activities are carried out systematically through exploration, elaboration, and confirmation processes to form a positive attitude.\textsuperscript{20}

In addition, there are no vehicles and special lanes to mobilize teachers quickly in the event of an earthquake, considering that one of the schools, SDLB, displays vulnerability. So, the potential for disaster impact is a very high. Therefore, the functions and responsibilities of schools and teachers in emergency situations become an important point in DRR at schools, so that competent human resources are needed.\textsuperscript{21}

While comprehensive DRR initiatives should not be confined to infrastructure alone, they should cover a wide range of issues, such as representing the schools of thought in science, engineering, structural, and physical organization, since infrastructure plays an important role in reducing vulnerability of risky communities, such as schools.\textsuperscript{22}

**Conclusion**

There is a significant relationship between knowledge and attitude with SSB teachers’ preparedness in DRR in Malang city. The results of this study can be used as feedback to solve the problem of SSB teachers’ lack of preparedness in school-based DRR. Prevention and preparedness efforts cannot stand alone. The government should be cautious in utilizing the concept of SSB as a DRR by innovating and improving teachers’ knowledge of disasters and encouraging a positive attitude for preparedness.

The Effect of the Health-Trace Map Game towards Motivation on a Clean and Healthy Life Style among Street Children in Surabaya

Pipit Festy W, Sanda Marta Ari Firmansyah, Yuanita Wulandari, Fathiya Luthfil Yumni

1Faculty of Health Sciences, Muhammadiyah University of Surabaya

ABSTRACT

Street children generally live in a less supportive environment, with inadequate facilities and infrastructure, and a lack of health information. These make street children vulnerable to health problems. Increasing motivation for a clean and healthy lifestyle in street children is a good solution to maintain their health. The Heath-Trace Map game is a learning media that can be used as motivation. The aim of this study was to analyse the effect of the Health-Trace Map game as health education media towards motivation on clean and healthy lifestyles among street children. The One Group Pre-Post Test design was used in this study. 30 street children had joined this study. The Wilcoxon Sign Rank Test with a significant level of \( \alpha < 0.05 \) was performed to analyse the data. The results showed the \( p \) value = 0.000 ( \( p \) value < \( \alpha = 0.05 \)), from which it can be concluded that the Media Health Trace Map Game had an effect on increasing the Motivation of Clean and Healthy Life Behaviour among Street Children in Surabaya.

Keywords: Children, health, media, motivation

Introduction

The economic crisis situation triggered the emergence of one of the social population problems in Indonesia’s big cities, namely the emergence of the phenomenon of the existence of street children. Street children come from poor families, most of whom have experienced a lack of attention and affection from parents and family. The impact of street children can lead to the emergence of thuggery, various diseases, disruption of traffic and comfort of road users, disruption of the beauty and order of the city, crime vulnerability, a neglected education, and even dropping out of school. Problems with street children can cause health problems, one of which is that the health of street children living outside the home has not been fulfilled, namely the lack of healthy behaviour because of the physical and psychological needs of street children with limited facilities and infrastructure, such as living in a far from clean concept (without environmental support), inadequate infrastructure, incomplete facilities. A lack of information makes street children vulnerable to disease.

Based on data from the Ministry of Social Affairs, it is noted that the number of street children in Indonesia reached 16,290 street children. Surabaya, as one of the metropolitan cities in Indonesia, also has not escaped a population of street children. In Surabaya it is shown that there was a significant increase in the number of street children in 2010, with 80 people, in 2011 there were 45 people, in 2012 there were 114 people, in 2013 there were 94 people and in 2014 there were 76 people, in 2015 there were 85 souls of street children. Whereas, in 2014, the number of street children decreased but it was not significant but, in 2015 it experienced an increase again. This shows that the volume of street children from year to year is not stable and the problem needs serious handling from various parties.

The needs of all children are increased, such as educational needs. One effort that can be done to educate street children is to increase PHBS by doing health promotion, since street children need knowledge and motivation about PHBS. By knowing about PHBS, street children will care more about their health.

DOI Number: 10.5958/0976-5506.2019.02290.3
Schools or communities, as one of the targets of PHBS in educational institutions, need to get attention given to the large number of school age children, which is 30% of the total population of Indonesia. The period of elementary and junior high school is a period that needs to be instilled in PHBS values and has the potential as an agent of change to promote PHBS both in the school, family and community environments so as to later create quality human resources (MenKes RI, 2011). The impact if there are less PHBS on street children is that most of them are exposed to contract various diseases (such as diarrhoea, tooth decay, skin disease, ear disorders, helminthiasis), learning environments that are not supportive and which reduce enthusiasm and learning achievement in school.¹

The researcher invited street children to understand the counselling material provided by the Health-Trace Map game method that was different from previous research. That previous research suggested that the application of the Course Review Horay Method had an effect in increasing the average value of knowledge, attitudes, and practices on Clean and Healthy Behaviour (PHBS) in Saptorenggo Elementary School 05, Pakis District, Malang Regency.²⁻⁷ Whereas research that suggests that health education through the Kasugi Card game 3 times affects the increase in knowledge of clean and healthy behaviours, which are the same as students getting 3 times the amount of health education through the lecture method carried out in grade 5 elementary school students in West Bandung Regency.⁸

The Health-Trace Map is a rectangular adventure game played in groups (3-5 people). This game, which aims to train physical skills and cognitive abilities and motivation of children in this game, is very easy and also fun. Therefore, the learning model of the Health-Trace Map game is one of the learning models that can create an exciting and fun atmosphere. Fun learning must consider children as subjects. These comforts include children who are not depressed, accept learning in a relaxed manner but remain focused, have the freedom to ask questions and opinions, get gifts (rewards) that motivate them to be able to change PHBS.

Method

Study Design, Setting and Sampling: The type of research used is the Pre-Experimental design method using the One Group Pre Test-Post Test design approach with samples taken using Non-Probability Sampling, namely Total Sampling. The population in this study were all street children of elementary school and junior high school in Cahaya Bunda Jembatan Merah Community, Pabean Cantikan-Surabaya, which numbered 30 children, while the sample was all street children from elementary schools in Cahaya Bunda Jembatan Merah Cantikan-Surabaya, which numbered 30 children starting April 22 - May 27, 2018.

The procedure of this study uses an instrument that is the game of the Health-Trace Map and question questionnaire sheets made by the researchers themselves who have tested validation and reliability with Cronbach’s Alpha = 0.759 with 13 questions that have been modified by researchers using the Likert Scale (Strongly Agree, Agree, Disagree, Strongly Disagree). There are 6 components of PHBS in schools that adjust to conditions in the field to measure motivation according to Herzberg’s theory which consists of intrinsic and extrinsic factors. A sheet about their motivation for PHBS was filled with scores 1-4 on positive and negative statements through health education with the Health-Track Map game. The data includes the motivation of street children to PHBS in schools that are adapted to environmental conditions such as washing hands with clean water and soap, eating healthy snacks, using clean and healthy toilets, not inhaling, weighing and measuring altitude every 6 months, and discarding garbage in its place. There are also SOP, SAK and leaflets in this study.

Results

This research was conducted at the Cahaya Bunda Pabean Cantikan-Surabaya Community from April 22 to May 27, 2018. From the total population determined the same as the sample number because the total sampling did not have inclusion and exclusion criteria, namely as many as 30 street children. Based on Table 7 above shows the results of research on respondents’ motivation before and after being given Health Education intervention on PHBS with Health-Trace Map media from 30 respondents getting motivation towards PHBS, street children before being given low category motivation assistance, 18 children (60%) and eliminating the decline to 2 children (6.7%) after being given an intervention. Street children before being given intervention were in the medium category, 10 children (33.3%) and decreased changes to 3 children (10%) were given intervention. Street children before being given a high motivation category intervention of 2 children (6.7%) and an increase in increase to 25 children (83.3%) after being given an intervention.

Discussion

A. Motivation about Clean and Healthy Life Behaviour (PHBS) Before Health Education was given with the Media Game Health-Trace Map on Street Children: Students who are often truant and have low learning motivation generally have parents with a level of poor and inconsistent involvement. The low level of involvement of parents can lead to not fulfilling the need for social support needed by children (vanBreda, 2015). With motivation to learn students will have energy that encourages consistency of learning. Students will also have clear learning goals and can choose activities that are not useful. These three functions simultaneously encourage student performance in learning and support achievement. The use of media is very appropriate to changing family behaviour for health attitude.
someone wants to work hard if there is hope to be realized into reality.

B. Motivation about Clean and Healthy Life Behaviour (PHBS) after being given Health Education with the Media Game Health-Trace Map on Street Children: The Health-Trace Map game has benefits that include: (1) providing knowledge and adding insight to children through the learning process of playing while learning about PHBS in schools, (2) stimulating the development of thinking power, creativity and language in order to be able to cultivate attitudes, mental, and good morals, (3) creating an attractive playing environment, providing security, and fun, (4) learning sportsmanship to recognize defeats and wins, (5) learning to work together and waiting for their turn, (6) honing social skills and closeness.

This is due to the implementation of a good Map Health-Trace game. Whereas in the Health-Trace Map game this is done 6 times in 1.5 months. To achieve success in conducting Health-Trace Map interventions by paying attention to several things, namely: (1) Each group consists of 3-5 children, because this game requires compactness to solve common problems, (2) Consists of various ages and mixed sexes in 1 group, in order to be able to discuss each other and resolve challenges that exist until the finish, (3) compactness and togetherness, to not fight each other and solve together.

Based on the results of research after being given Health Education with Media Games Health-Trace Map the desire for street children mostly increases because this game is a good medium to increase the motivation of street children because in this process street children can exchange ideas and practice to study fellow friends who become their problems so that street children expressed their desire to change to do Clean and Healthy Life Behaviour (PHBS) which at first they were lazy to do.

C. Effect of Health Education on Motivation about Clean and Healthy Life Behaviour (PHBS) Before and After the Intervention with the Media Game Health-Trace Map on Street Children: The Health Education process increases understanding to achieve the desired goals, without high motivation it will enable a good Clean and Healthy Life (PHBS) to arise. According to (Atikah & Eni, 2012) PHBS at school is a set of behaviours practiced by students, teachers, and the community in the school environment on the basis of awareness as a result of learning, so that they are able to prevent disease, improve their health, and play an active role in creating a healthy environment. Motivation is a person’s desires from within a person so that the person carries out certain activities to achieve a goal, the motive cannot be observed, which can be observed is the activity or perhaps the reasons for the action.

One of the benefits of learning media is to make children more attractive when receiving material so that it can foster learning motivation. The use of Health-Trace Map media used in the delivery of information will be more innovative, creative, effective, and interesting because there is interest from respondents towards the media used. The use of media that is different from usual which will arouse the interests or desires of respondents towards media and after that information will be easier to be absorbed, understood, and applied by children.

The results of street children motivation on Clean and Healthy Life Behaviour (PHBS) before being given Health Education intervention with Media Health-Trace Map Games showed that most street children still have low and moderate motivation and high motivation in only a few children but, after being given Health intervention Education with Media Games Health-Trace Map motivation of street children about Clean and Healthy Life Behaviour (PHBS) there is an increase in motivation of street children, mostly high and moderate motivation and low motivation for only a few children.

Conclusion

Based on the results of the study, there is an influence between Health Education and Media Health-Trace Map Game on Motivation about Clean and Healthy Life Behaviour (PHBS) in Street Children in Cahaya Bunda Komunitas Jembatan Merah Pabean Cantikan-Surabaya.

Promoting Spiritual Nursing Care in an Intensive Care Unit: A Systematic Review

Nadia Rohmatul Laili¹, Hakim Zulkarnain², Deni Yasmara¹, Sriyono¹
¹Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia; ²School of Health and Social Care, Edinburgh Napier University, Edinburgh, Scotland

ABSTRACT

Most of the patients in intensive care units (ICU) are intubated. These conditions can affect the psychological, social and spirituality condition of the patients. The nurse’s role in terms of providing spiritual care is still not optimal. Many feel the urge to reach out to their patients and offer spiritual support, but they do not know how to do it. However, the procedure or intervention needed for providing spiritual care is still little known about. This study aimed to explain the nursing interventions that could be applied for promoting spiritual care based on the existing literature. The systematic review was guided by the PRISMA protocol. A comprehensive search was carried out on a selection of databases; PubMed (Medline), CINAHL, Scopus, Springerlink, ProQuest, EBSCOHost, Web of Science Clarivate Analytic and Science Direct. The searching of published studies was done comprehensively using several keywords: “spiritual nursing care” OR “spiritual care in ICU” OR “spiritual intervention” OR “spiritual AND nurse” OR “spiritual AND critically ill patients” OR “implement spiritual intervention”. The searches were limited to publications in English with the year of publication being from 2009 up to February 2019. Ten studies were included in the review. This review confirmed some of the ways to promote spiritual nursing care in the ICU. Nurses, in promoting spiritual nursing, need the ability to communicate effectively and also to collaborate with the patient’s family and/or chaplain. It is hoped that this review could be a reference for nurses to allow them to provide spiritual nursing care in the ICU.

Keywords: nursing, spiritual care, intensive care unit

Introduction

Patients who are in the Intensive Care Unit (ICU) are patients who have serious illnesses. Most of the patients in the ICU are intubated. These conditions can affect the psychological, social, and spirituality conditions of the patients. Patients who have these conditions become vulnerable to spiritual distress. The healing process and their coping mechanisms may be delayed if the patient is in spiritual distress and the nurse must utilize this to provide for the spiritual needs of the patient.

Despite evidence of the benefits from spiritual care, physicians and other health-care providers commonly fail to assess and address their patients’ spiritual care needs in the ICU. In some of the studies mentioned so far, the nursing role in providing spiritual care is still not optimal. Nurses in the ICU often emphasize physiological needs such as stabilizing the patient’s vital signs, and relieving the physiological symptoms. They rarely pay attention to the psychological and spiritual needs of the patients or their spiritual needs are often ignored.

A study revealed the differences in the nurses’ perception level regarding spiritual care and, consequently, in clinical practice. Although the results demonstrated positive perceptions of spiritual care, the participants rarely incorporated this care into their daily activities. Research has revealed that nurses rarely provide spiritual care needs for their patients. Most of the studies on spiritual care needs were focused on general wards. The studies on the spiritual needs of patients with critical illnesses were scarce and not well prepared. A survey focused on 123 ICU nurses from 4

Turkey hospitals identified that the nursing perceptions and practices in relation to providing spiritual care were still inappropriate.⁹

The barriers for nurses providing such care have also been identified. Many feel the urge to reach out to patients and offer spiritual support but they do not know how to do so.¹⁰ The absence of spiritual care in patients may also be caused by the feelings of the nurses who lack the individual skills to carry out spiritual care.¹⁰ They were thus unable to meet the spiritual needs of their patients.¹¹

Spiritual care can improve the patient’s condition and also make the patients comfortable with their critical illness and it can even facilitate the patient’s death process.³ However, despite all of the attention given to the spiritual dimension, the majority of nurses still feel that they require more guidance and support from governing bodies to enable them to support and effectively meet their patients’ spiritual needs.⁷ Protocols or guidelines in clinical practice must be tailored to specific needs and beliefs.¹² This study aimed to explain nursing interventions that could be applied in promoting spiritual care based on the literature.

Method

The systematic review was guided by the PRISMA protocol (preferred reporting items for systematic review and meta-analysis).¹³

Identification of Studies: The search was carried out using the following databases: PubMed (Medline), CINAHL, Scopus, Springerlink, ProQuest, EBSCOHost, Web of Science Clarivate Analytic and Science Direct. The search of the published studies was done comprehensively using several keywords: “spiritual nursing care” OR “spiritual care in ICU” OR “spiritual intervention” OR “spiritual AND nurse” OR “spiritual AND critically ill patients” OR “implement spiritual intervention”. The searches were limited to having been published in English and where the year of publication was from 2009 up to February 2019.

Study Selection

1. Inclusion and exclusion criteria: Inclusion criteria were imposed as a part of the study selection: 1) intervention given by the nurse, 2) adult patients and 3) in the ICU setting. Studies falling under the following criteria were excluded from the review: 1) reviews and 2) epidemiology studies.

2. Quality assessment: The critical appraisal and study quality assessment were carried out by the authors independently and any discrepancies between the authors’ decision were resolved with consensus.

Results

From Figure 1, we can see that 112 studies were found from the electronic search. The first screening eliminated 62 articles because they were identified as duplicates. We continued to conduct the screening process based on language and the availability of the full text and 28 articles were excluded. The remaining 38 studies were screened based on the inclusion and exclusion criteria and 10 studies were included in the review. The ten studies that were included in the review can be seen in Table 1.

Figure 1: Study selection based on the PRISMA protocol
We can see that there are a wide variety of interventions given to the patients related to spiritual care. The majority of the interventions providing spiritual nursing care in the ICU were interactions between the nurse and patients, communication and collaboration with the family and/or chaplain.

Some of the kinds of intervention mentioned in the study revealed that spiritual care is integral care, and that it is not limited to spiritual rituals. Furthermore, it is interrelated with physical and psychosocial care. Communication is also an aspect in part of spiritual nursing care. Simple interventions like being with the patient, listening to them, asking open-ended questions related to their spirituality and beliefs, active spiritual practices and starting and maintaining a dialogue with the patient and families play an important role in providing spiritual nursing care. In providing spiritual care for critically ill patients in the ICU, nurses have to collaborate with the chaplain or with their family. Nurses also have to facilitate patients when conducting their prayers by helping the patients to pray or by reading holy scriptures. It was difficult to find a specific nursing intervention for providing spiritual nursing care in an intensive care unit, especially with critically ill patients. This review confirmed the findings that to provide spiritual nursing care in an intensive care unit, the nurses can follow roles such as (a) assessing the spiritual needs of the patients, (b) collaborating with the family or chaplains, (c) communication and (d) facilitating the patients when praying.

**Discussion**

The results of this systematic review have showed that to implement spiritual nursing care, nurses should not be limited to religious ritual activities. The forms of spiritual care that were found in this review can be initiated when assessing the patients spiritual needs. In the assessment phase the nurse listens to the patient and explores the patient’s spiritual problems. Together with the patients, they can allow them to express their experiences of pain, suffering or need, and listen to the patients express their emotions and anxieties as well such as depression, sadness, fear or loneliness, which can hinder their health physically, emotionally and spiritually. These actions can improve the nurses’ understanding of the patient’s spiritual needs. An accurate assessment is very important in order to determine the intervention that is to be used. The assessment of spiritual needs should be carried out with a systematic approach in which the nurses conduct assessment approaches in all aspects. Effective assessment depends on creating a relationship of mutual trust and respect for the values and beliefs that exist in the client.

In conducting spiritual nursing care, nurses also need to take collaborative steps with the patient’s family and chaplains. The patient’s family plays a major role in directing their patients’ spiritual care. Effective nurse-advisor collaboration is needed (especially given the current changes in the health care system) to provide adequate spiritual care. In addition, increasing the involvement of nurses and chaplains in the context of ethical issues tends to make nurse-chaplain collaboration even more important. The family has an important role to play in supporting and improving the patient’s health status. The nurses also have to collaborate and connect with religious leaders to provide spiritual care for the patients and their families. Knowledge of the differences in assessment between the nurses and religious leaders, any differing terminology and the role of the pastors will enhance this collaboration.

Spiritual care also includes respecting the religious beliefs and culture of the patients, and listening and talking with the clients and with the patients by caring for, supporting, showing empathy, facilitating participation in religious rituals, promoting a sense of well-being and referring them to chaplains. Praying is the main method by which the patients’ spiritual needs can be met. Prayer remains a safety net in both health and sickness. Prayer has a positive effect on psychological and physical well-being. Patients identify kindness and respect, talking and listening, and prayer as the most important aspects of their spiritual care. Praying with or for patients, spending time supporting and convincing the patients, listening to the patients verbalizing their fears and anxieties, showing respect for the dignity and spiritual beliefs of their religion, showing kindness and caring, arranging visits of spiritual/religious leaders and offering hope are all important.

Based on the results of the review, communication can be one form of spiritual care that the nurses can do in the ICU. Nurses who are able to communicate well with patients will have a positive impact. Spiritual communication is described as an important nursing role at the end of a patient’s life, and nonverbal
Communication, listening and discussing the patient’s emotions are emphasized as being important and effective nurse communication skills during spiritual care conversations.\(^2\) Spiritual communication is important to apply in the ICU. Nurses can assess and integrate the spiritual needs of the patients and their families into clinical care by engaging in spiritual care communication strategies.

**Limitation**

The systematic review was unable to conclude a specific spiritual nursing intervention available for conscious or unconscious patients.

**Conclusion**

Spiritual nursing care is not only limited to spiritual rituals. Simple interventions like open communication, helping the patients to pray and collaborating with the family and chaplain can be implemented in terms of promoting spiritual care in the ICU.

Factors that Affect the Mother in the Control of Their Child’s Fever

R. Probowati H Wibowo
Nursing Study Program, STIKES Pemkab Jombang Indonesia

ABSTRACT

A fever is one of the signs and symptoms of disease that often occurs in childhood. Fever in children makes the mother frightened when facing her child’s health problems. The mothers assume that every child will develop a seizure fever. The purpose of this study was to find out the factors that influence the mothers when handling fever in the one of First Level Health Facilities in Jogoloyo, Sumobito and Jombang.

The research design was cross-sectional. The population of mothers with toddlers totaled 420 respondents. The sample of 210 respondents was gathered using a simple random sampling technique. The independent variables were factors that influenced the mothers in managing fever in toddlers and the dependent variable was the frequency of fever.

The results of the research show that 67% of the mother’s had good knowledge, the frequency of children with a fever was 45% and the mother’s who received advice from health workers was 87.3%. Good experiences from their family/friends made up 37.5%. Significant bivariate analysis was conducted on knowledge, the frequency of pain, advice from the health workers and their family/other people’s experiences with a p value < 0.05.

Advice from health workers consisted of health education about how to handle fever in children. This can increase the mother’s handling of feverish children, therefore structured education is very beneficial for the mother.

Keywords: maternal factors, fever management, toddler

Introduction

Children are in a phase where the body grows and develops physically, mentally, spiritually, in addition to their immune system. A child’s immune system can be obtained from internal and external factors. A child’s immune system with frequent illnesses, on the one hand, will be changed and the child will learn to adapt to the disease cycle.

A fever is an increase in temperature above the normal temperature limit caused by abnormalities or toxic substances in the central setting of the body temperature, the hypothalamus. A fever can be used as a sign of a change in a child’s health, such as it improving or worsening. Fevers are the most common in groups of children and it causes their parents to bring the children to the health services.1

Indonesia is a tropical country and almost all tropical diseases symptoms involve a fever. A fever is not an external and internal disease in its own right; a fever is a sign or symptom of an illness. Toddlers that are less than 5 years old are children who do not have a good immune system and so they will be more susceptible to disease. If the children often experience a fever, then this will impact on the quality of the children’s health as it can impair their growth and development. If the fever is not handled properly, then the child will experience febrile seizures because high temperatures will cause the release of an excessive electrical charge in the neuron cells of the brain.

DOI Number: 10.5958/0976-5506.2019.02292.7
Fever involves different seizure thresholds for each child. Fever affects the ion and cell metabolism and ATP production. Every 1 degree increased will also increase their carbohydrate metabolism by 10-15%. The presence of fever will cause an increase in their glucose and oxygen requirements. A fever can cause tissue hypoxia including the brain tissue, which will have an impact on their lack of energy.

Some of the diseases that children often suffer from are fever, coughs, diarrhea, vomiting, chicken pox, measles and skin infections. Data from the National Health Survey in 2011 about the morbidity of infants and toddlers showed that 49.1% of infants were 1 year old, and 54.8% of infants were 1-4 years old. If a fever continues to increase, it will cause febrile seizures. At present, a fever is considered a common pain condition. A fever is also a condition that is often suffered by children. Almost every child has had a fever.

The incidence of fever often occurs in children (Jayanti, 2011). According to the World Health Organization (WHO), the number of cases of fever in the world are 18-34 million cases (Jayanti, 2011).

In Asia, around 10-15% of children have fever-associated symptoms or signs of illness (Grace, 2010). The results of the 2013 RISKESDAS showed that the incident rate of fever reached 37.2%. Prosil Jombang’s 2018 health study was ranked second in the outpatient cases at the puskesmas. In the first health facility of Dr. Heri Wibowo Sumobito Jombang, the majority were in cases of anemia where the child also came in with a fever. The statement from Lubis (2011) found that 31% of patient visits were caused by fever. Fever is a major complaint of the children being brought to the first-level health services or ED where nearly 70% of visits are ED. Fever generally makes all parents and caregivers suffer from phobias or fears.

Fever is considered to be a sickness that makes the children not want to eat or drink, and it gives them insomnia which will result in drastic weight loss. The most important thing is that the fever is a symptom of disease and that it is very serious (Rain et al. 2014).

Handling fever in children depends on the role of the parents, especially the mothers. Mothers are integrals part of the organization of households, in which their tendencies are to care for their children skillfully so then they can grow healthy. Mothers tend to have a good knowledge of fever and have a good attitude in relation to providing care for the best fever treatment for their children.

Method

Types of quantitative research: The cross-sectional design used a population of 420 mothers with febrile toddlers in 2018. The sample of 210 respondents was gathered using the simple random sampling technique. The independent variables were the factors that influenced the mothers with toddlers with a fever, dependent variable, maternal knowledge, the frequency of the fevers, getting advice from the health workers and the good experiences of the family/neighbors. Bivariate analysis was done using the Chi square test and the multivariate analysis used logistic regression. The place of research was a first level health care facility, Heri Wibowo Sumobito Jombang.

The research design was cross-sectional. The population of all mothers with toddlers was 420 respondents. The sample of 210 respondents used a simple random sampling technique. The independent variables were the factors that influenced the mothers in managing their toddlers with a fever and the dependent variable was the frequency of the fever. The bivariate analysis was conducted using a Chi square and the multivariate analysis used logistic regression.

P value < 0.05. Multivariate logistic regression analysis of the most influential advice from health workers. Knowledge, frequency of illness and family or other people’s experiences were found to be influential.
Discussion

Based on Table 1, it can be concluded that the factors that affect the mothers in handling fever in toddlers are as follows: the lower the mother’s education level, the more that the mothers are less able to handle their children with fever. Low education affects one’s thinking patterns. The lower a person’s education is, the slower they will be at getting information, especially information about handling fever in children.

Younger mothers will be better at handling children with a fever. Younger mothers can easily access a wider range of information through electronic media, which is now growing rapidly. At a young age, someone will easily follow any technological developments including health information, which in the present decade is easy to access through various media outlets.

Mothers who do not work handle children with a fever better. This is because the mother does not work and thus she has a lot of time to care for her child. The mother can use her full time to care for her child. When working, the mother’s time available to care for children is reduced because some of the time is used for work. In line with the results of Felfe Christina’s research, Amy Hsin., 2012 that when mothers work to care for their sick children less than mothers who do not work.

The older the child, the better the mother handles the fever. The child’s immune system will also develop as they age, in which case the children will not easily experience pain, especially the pain manifested by the symptoms of a fever.

The age of young people will make it more likely for parents to seek treatment from the health services. Parents who have children who are still young certainly have fears or anxieties when their children are sick. This anxiety can be due to the fear that unwanted things can happen and the fear that the child will experience seizures. It may also be due to them being an only child.

The sex of the boys makes the mothers better at handling children. Boys are highly expected in the family because they are the next generation. Boys often get more attention from their parents.

The position of having more than one child makes the mother better at handling children with fever. The mother will have experience of caring for a child before.

The advice given by the health workers has a good influence on how children are treated with fever. In handling sick children, the family is the first responsible for caring for the child. Handling a fever requires a partnership between the health workers and families (Notvitgon, 2010). One of the health workers’ tasks is to be educators, namely to provide information about health problems, especially on ways to treat fever whose sources can be trusted. Health workers can be met at the health center in the form of basic health services or at independent practices that have a role in providing health promotion/education to the community.

Other people’s experience about fever can also influence the way that the mother treats her children. A person’s experience of nervousness and success in managing fever can be copied by the mothers. Notoatmodjo (2007) stated that a person health behavior is determined by one of them being a reference.

The experience of success will be a good experience to imitate. Examples of failure/unsuccesfullness in a person will be a good lesson. Failures are not to be used as an example but to avoid so as not to experience the same failure with someone else.

The mother’s knowledge has a very good influence on the handling of children with fever. A good mother’s knowledge will mean that the mothers know how to handle a fever well. Good knowledge will affect someone when it comes to taking action. Knowledge is the main factor involved in someone taking action. The higher the knowledge level, the better someone will take action. The knowledge of the mother about fever will be a guideline for the mother in handling the fever. This was in line with the results of the research by Riandita (2012). This is about the level of knowledge of the mothers about fever and the management of fever in their children. In the line with Handanu (2017), the level of knowledge of the mothers about fever affected the management of fever in their children.

Based on Table 2, the advice from the health personnel, knowledge, the frequency of illness and the experiences of others influenced the handling of the mothers with children with fever. The information came from the most influential health officer.
Conclusion

Conclusion: The factors of knowledge, the frequency of illness and the experiences of their family/other people affected the mother when handling a fever. Advice from the health workers was the most influential on the mothers. Age, gender and the child's position did not affect the mother when handling the fever.

Suggestions:

1. For the health workers, increasing their role in health promotion aims to increase their maternal knowledge when handling sick children.

2. For the mothers, increasing their knowledge about handling sick children can be done through various media channels.

Correlation Self-Efficacy and Nurse Motivation in the Implementation of Nursing Care in a Private Hospital

Mundakir1, Ika Nur Ramadhani1, Yuanita Wulandari1, Siti Aisyah1
1Faculty of Health Sciences, University of Muhammadiyah Surabaya, Surabaya, Indonesia

ABSTRACT
The implementation standard of nursing care, according to the MOH RI (2005), is 75% of the average implementation of nursing care component. However, the implementation of nursing care as the provision of services at the hospital has not been optimal. This study aims to analyze the relationship between self-efficacy and nurse motivation as related to the implementation of nursing care. A correlational cross-section approach was used. This research was conducted at one of private hospital in Sepanjang. Thirty nurses who served as Team Leader Nurses participated. Purposive sampling was conducted. A Self-development Questionnaire was used to collect the data. The Spearman rank (rho) statistics test was used to analyze the data. The results showed there was a correlation between self efficacy and the implementation of nursing care (p = 0.00 <0.05 ; r= 0.997). There was a relation between nurse motivation and nursing care implementation where the value of the Spearman rank statistical test was (p = 0.000 <0.05 ; r = 0.964). Increasing the self-efficacy and motivation of nurses is very important in supporting the performance of the nurses, especially when implementing nursing care.

Keywords: self efficacy, nurse motivation, implementation of nursing care.

Introduction
Nursing services are a part of the health services in hospitals that support the healing process and the health recovery of patients who are treated. The quality of nursing services will reflect the quality of the service that is provided to the patients. The implementation of health services is carried out in a responsible, quality manner touching all levels of society without exception. Studies that have identified the provision of services in the hospitals referring to the implementation of nursing care have not been optimal, starting from the assessment stage through to the evaluation. However, in reality, up until now there are still many complaints and criticisms from the public regarding the services provided by nurses. This proves that the nursing care services are not optimal. If the provision of nursing care is still not in accordance with the standards of nursing care, then many clients will feel dissatisfied with the services provided because they do not meet the needs, expectations or desires of the patients receiving the health services.

The implementation of quality nursing care is needed. The standard of implementation of nursing care, according to the Ministry of Health of the Republic of Indonesia (2005), is 75% of the average implementation of the nursing care component. The results of Wahida et al’s study (2007) showed that the level of nurse involvement in the implementation of nursing care at the H. Damanhuri Barabai Regional General Hospital was good by 37.5%, quite at 25% and less at 37.5%. This shows that the implementation of comprehensive nursing care has not been carried out optimally. Nurlaila et al. (2013) also reported that the data from Labuang Baji Makassar General Hospital in 2010 showed that the overall standard of nursing care was 61.65%, which was carried out in the internal, surgical, midwifery and perinatal disease departments. The results of Mundakir’s (2016) study at Siti Khadijah Sepanjang Hospital show that the process of bio-psycho-socio-spiritual nursing care by the nurses was made up of assessments (46.7%), nursing diagnoses (26.7%), interventions (23%, 3%), implementation (23.3%) and documentation (3%).

Facing such conditions, hospital nurses need to understand and realize that the services provided to the patients must be carried out professionally with a sense of responsibility and accountability. Performance can be influenced by several factors, including individual factors, psychological factors and organizational factors. Individual factors include ability, expertise, background and demography. Psychological factors include self-efficacy, attitude, personality, learning and motivation. Organizational factors include resources, leadership, structural rewards and job design. Self efficacy has an influence on overcoming pressures in the workplace.

In the research of Sri Rahayuningsih (2004), the independent variable of self efficacy had a positive and significant effect on performance. Nurses who have self efficacy have the feeling of being able to do work, better abilities, so the self efficacy variable can be explained by the feeling of being able to do work, better abilities, happy job challenges and satisfaction with their work. Besides self efficacy, which has an influence on performance, motivation also has an influence. The results of the study conducted obtained that there is a relationship between motivation on the nursing performance (p-value: 0.004).

Based on the above problems, to find out the causes of the successful implementation of nursing care, it is necessary to carry out more in-depth observations of all nursing care implementation processes ranging from assessment through to evaluation in order to obtain information on the quality services provided to the community. According to Manajemen dan kepemimpinan dalam keperawatan, there are several forms of staff development that can be carried out, including in-service education, orientation, job training, continuing nursing education, leadership training, career development, comparative studies, performance assessment, education and training, internships in more advanced hospitals, nursing work groups and the development of teamwork in the room. To be able to improve the self-efficacy and motivation of the nurses in the implementation of nursing care, there is a need for job security, an appropriate salary, benefits and fostering good relations with the supervisors, colleagues and subordinates. This is done to create optimal nursing staff performance. The final goal is to provide quality services to the customers. By describing the problem above, the researchers are interested in conducting research in order to analyze the relationship between the self-efficacy and motivation of nurses within the context of the implementation of nursing care.

**Method**

The research design used was cross-sectional, which is a type of research that emphasizes the time of the measurement/observation of both the independent and dependent variable data one at a time. The research was conducted for 3 days at one of the private hospital on the 19th, 20th and 21st July 2017. The sample in the study consisted of 30 nurses who were team leader. The method of sampling in this study was total sampling.

The instrument used in this study was a Nurse Motivation Questionnaire adopted from the Nurses Motivation Questionnaire developed by Nursalam. For the stage of knowing the details of the implementation of nursing care, in addition to using questionnaires, observations and interviews were conducted to obtain more accurate data. The data was analyzed using the Spearman rank statistical test (rho) with α below 0.05.

**Results**

The majority of the respondents were women (87%) who were 39 - 41 years olds (33%) who had been working for 20 - 21 years. Their education background was that of a Nursing Diploma (97%).

<td>0</td>
</tr>
</tbody>
</table>

*Spearman Rank Test* $\rho = 0.000 < \alpha = 0.05$ contingency coefficient $= 0.990$

Based on the analysis of the data using the Spearman Rank (Rho) statistical test, the value of $\alpha = 0.000$ was obtained. This value is less than $\alpha (0.05)$. It can thus be concluded that $H_0$ is rejected, which means that there is a relationship between self-efficacy and the implementation of nursing care.

**Discussion**

The self-efficacy of the nurses at one of the private hospitals in Sepanjang showed that 17% of respondents had good criteria and that 73% of respondents had sufficient criteria. This is caused by the self-confidence to overcome problems, to carry out their intentions and goals, being calm when facing difficulties and the belief that there is always a solution for every problem. This belief can be derived from age and work experience. The respondents in this study had an average age of over 30 years old with an average work experience of more than 12 years. The respondents who had high self-efficacy were in the age range of 39 - 41 years. This is because the number of respondents in the age range of 39 - 41 years old was more than the other age ranges. The respondents who were over 39 years old also had a long working experience of more than 16 years, so the ability to overcome problems was not difficult for them. As many as 10% of respondents with fewer criteria was because the respondents did not always have many ideas in the context of dealing with the difficulties that exist.

The respondents who had less self-efficacy were the respondents who were younger than 34 years old with less than 16 years work experience.

Based on the results and theories presented above, it can be explained that the self-efficacy of the nurses was quite good for those aged above 39 years old who had been working for more than 16 years. This is due to their self-confidence and ability to overcome problems. Age and experience have thus been proven to have an influence on the decision making ability.

The motivation of the nurses and the related results showed that 20% of respondents obtained good criteria and that 57% of respondents had enough criteria. This is caused by the level of supervision from the leaders, the provision of education and training and satisfying working conditions. As many as 23% of respondents had lower criteria, caused by them not being satisfied with the salary earned and the close teamwork.

The above results illustrate that the motivation of the nurses plays a pretty good role relating to salary acquisition, supervision from their leadership, education and training and comfortable working conditions. Many of the nurses were motivated to work better.

The implementation of nursing care resulted in 7% of the respondents having a good criteria and 70% of respondents as having a sufficient criteria. This can be...
caused by strong abilities and motivation. Besides that, it could also be due to the supervision function carried out by the head of the room. Only 23% of the respondents had a lower criteria. This is because the nurses were still not satisfied with the rewards received concerning their performance.\(^{13}\)

Based on the results and concepts described, it can be said that there is a relationship between self-efficacy and the implementation of nursing care. The higher the self-efficacy that is owned by someone, the better that the person will be able to do their work and overcome all problems easily. Moreover, the respondents who were more than 39 years old and who had a longer working experience of more than 16 years tended to have high self-efficacy values. High self-efficacy values will affect a person’s ability to make decisions when facing problems. To remain calm when facing problems, it is important to know that there is always a solution for each problem and that should be goal-oriented.\(^{14}\)

In the meantime, based on the results, it has been shown that there is a relationship between the nurses’ motivation and the implementation of nursing care at one of the private hospitals in Sepanjang. The greater the motivation possessed by someone, the more that the person will work well because of the encouragement or reasons behind it.\(^{15}\) The encouragement of the nurses in one of the private hospitals in Sepanjang was through the supervision carried out by the head of the room, through their training and education and through the comfortable working environment. As evidenced from the results, the implementation of nursing care carried out by the nurses was categorized as quite well.

**Conclusion**

Increasing the self-efficacy and motivation of nurses is very important in terms of supporting the performance of the nurses, especially when implementing nursing care.

**Acknowledgments**

We would like to thank the respondents who participated in this study. Many thanks go to the Head of the Hospital and every nurse who welcomed us during the data collection.

Medication Adherence and Quality of Life among People Living with HIV/AIDS (PLWHA) Who Joined and Did Not Join a Peer Support Group

Purwaningsih1, Aria Aulia Nastiti1, Elsa Yunita Mujarwati1
1Faculty of Nursing, Universitas Airlangga, Indonesia

ABSTRACT

ARV medication adherence and the quality of life in PLWHA are still low and most PLWHA have not joined a peer support group. This study aims to provide a comparative study of medication adherence and quality of life among people with HIV/AIDS (PLWHA) who joined and did not join a peer support group. The data of 39 PLWHA were collected from hospital in Madura, Indonesia. The independent variables measured include PLWHA who joined and did not join a peer support group, and the dependent variables included adherence to taking ARV drugs and quality of life for PLWHA. The medication adherence level and quality of life PLWA who joined a peer support group were better than who didn’t. Further studies are recommended to understand expected about other factors such as differences in medication adherence and quality of life in PLWHA with Drug Drinking Companions (PMO) or with family support.

Keywords: PLWH, Quality of Life, Medication adherence, Peer support group

Introduction

The number of people living with HIV who stopped ARV therapy increased from 23.25% in 2016 to 24.39% in 2017. Factors that cause PLHIV to stop ARV therapy are their own desire and failure of follow-up by health workers.1 The impact of stopping ARV therapy can increase the number of viruses, so that viral load will increase and CD4 cell count decrease. Therefore, there is a possibility of opportunistic infection. If PLWHA have ever received ARV therapy then stop it, CD4 decline becomes faster than PLWHA who have never received ARV therapy.2

The number of PLWHAs who don’t continue ARV therapy leads the death rate of PLWHA to increase. Treatment and self-care of PLWHA can be affected by psychological problems that have an impact on the quality of life.3 Psychological problems experienced by PLWHA are more severe, but the treatment is still more focused on social problems, such as stigma.4

According to WHO and UNAIDS estimates until the end of 2016, 36.7 million people were living with HIV, 1.8 million people had just been infected with HIV and the number of people who died of HIV reached 1 million people. PLWHA who received ART in mid-2016 were more than 18 million people (WHO, 2017). Based on reports of HIV-AIDS in Indonesia, the number of people living with HIV who had started ARV therapy increased to 158,224 PLWHA, but only 50.46% of PLWHA were still continuing ARV therapy.5

Some of the factors that are the main obstacles to non-adherence with ARV therapy a stigma, ARV side effects and forgetfulness, and facilitators that also influence include caregiver support, peer support groups and knowledge about HIV. Irregularity in taking medication or a bad adherence in ARV therapy can cause treatment failure.5

Social support is needed to increase PLWHA’s life expectancy. In addition, emotional support from families, health workers, and other fellow PLWHA is also needed.6 Their social support needs may increase. Five focus groups were conducted in Washington, DC with 23 HIV-positive African American women aged 52-65 to explore women’s perceptions about how
aging and HIV chronicity affects their social support needs. Participants were recruited from the longitudinal Women’s Interagency HIV Study (WIHS).

Seeing the phenomena and supported by existing data and based on Green’s theory of health behaviors where there are peer motivating factors that are badly needed by PLWHA, the researchers wanted to compare the level of adherence to taking Antiretroviral (ARV) drugs and the quality of life of PLWHA who joined and did not join the PSG. Therefore, this research will be very useful to increase the level of adherence to taking antiretroviral drugs and the quality of life of PLWHA.

Method

Study Design, Setting, and Sampling: The research design used is quantitative research with comparative descriptive methods. The population used in the study was all PLWHA who were receiving ARV therapy at the VCT Polyclinic at RSUD Dr. H. Slamet Martodirdjo Pamekasan. Samples were obtained using total sampling technique with the following inclusion criteria: 1) PLWHA who were more than 20 years old, and 2) PLWHA who can read and write, while the exclusion criteria set by the researchers are 1) PLWHA who have mental disorders, and 2) PLWHA with decreased awareness. The number of samples in this study were 39 respondents, consisting of 23 PLWHA who participated in the Malatèh Setaman peer support group and 16 PLHIV who did not join the PSG. The data collection process was carried out from June to July 2018.

Study Variables: Data for the independent variables are PLWHA who joined a peer group and those who did not, while the data dependent variable was obtained from filling out a questionnaire about adherence to taking ARV drugs using MMAS-8 and the quality of PLHIV using the WHOQOL-HIV BREF.

Data Analysis: Descriptive statistics method was employed to analyze the demographic data to generate the study results. The difference of quality of life and medication from the two groups were analyzed using Mann-Whitney U Test with a significance level α≤0.05.

Result

Demographics characteristics data of these 39 respondents describe the types of respondents in VCT Polyclinic Dr. H. Slamet Martodirdjo Pamekasan, which includes age, gender, last education, employment, income, marital status, and number of children.

Discussion

Most respondents often forget to take medication on time, feel disturbed because they have to take medication every day and often feel the side effects from drugs taken. The results of this study are in line with the research of Ammon et al. (2018) which shows that the main obstacle of non-adherence to ARV treatment is the side effects of ARV drugs, forgetfulness and lack of support from other parties, such as peer support.5

PLWHA who did not join KDS had stopped taking medication when their condition worsened. When they feel healthy, PLWHA think they do not need the medicine anymore. Basically, to undergo ARV therapy, the support of various parties is greatly needed, including the health professional team, family and peer support teams, so that when things happen that can make PLWHA want to stop taking ARV drugs, they motivate them to continue taking medication according to dosage.7

For PLWHA who still cannot accept the condition of their illness, peer support groups and case managers are supporting factors because, generally, PLWHA who join peer support groups get a lot of knowledge from the group and have the opportunity to share knowledge and remind each other, including in terms of taking medicine.8

Accidentally not taking medicine is often carried out by PLWHA who do not join PSG. Feeling bored and desperate about their illness is the reason for PLWHA to do this. Even though they routinely take medicine every month, they do not always drink all of the medicines. The motivating factor in improving the health behavior of PLWHA in adherence to taking ARV drugs can be obtained from peers with PLWHA and people who care about HIV.9 So, if the role of peers here operates properly, then PLWHA may not do things that harm themselves, like deliberately not taking the medicine.

The low information that mothers have of HIV and the lack of sufficient support from peer support groups to comply with taking antiretroviral drugs causes low compliance with taking ARV drugs.10 Social support is recognized as important in treatment because it always provides support to PLWHA so that they do not feel ashamed to bring their medication while doing activities with their friends.11

The results of this study were also supported by the results of Xu’s research, which found that social and emotional support and counselling from peer groups were strong compliance factors.12 Judging from the existing peer support groups, such as regular meetings, studying together, supervision of taking medication and capacity building for PSG, members can improve the obedience of PLWHA in taking ARV drugs because, besides getting knowledge, PLWHA can also understand the importance of taking the drugs.

Having to take medicine every day is uncomfortable because there will be demands and they will feel burdened. So, often there will be a feeling of boredom
with the routine. When this boredom arises, the role of the closest people who can strengthen PLWHA is needed. Motivation, support and even just the presence of others will be very meaningful. Therefore, the presence of peers in the PLWHA’s lives will greatly influence each of them to motivate fellow PLWHAs to continue taking ARV drugs.

Most of the respondents who joined peer support groups received more support from their environment because the health of PLWHA and the environment in which PLWHAs live also directly affected the quality of life of PLWHA. The results of this study are in line with the research of Novrianda et al., which showed that PLWHA must feel safe while in their neighborhood, so that there will be an increase in quality of life by the way the families receive PLWHA, as in do not avoid, do not reject and do not isolate them. In addition to the family environment, the external environment can also be influential because humans are social beings who need other people in their lives.

Financial resources are also an important factor in the environmental domain. Research conducted by Hultman and Hemlin in 2006 showed that respondents who do not have a job have worse quality of life than those who do. Likewise, the lack of economic needs and insufficient influences greatly on the quality of life. Misunderstanding in the community about HIV makes people tend to isolate PLWHA, so that they make PLWHA increasingly withdrawn from social life.

The majority of the two comparison groups both have enough energy in carrying out their daily activities and are satisfied with their sleep, but also many PLWHA who do not join PSG have less energy in carrying out activities. The results of this study are in accordance with Carter’s (2012) study (cited in Novrianda et al.,2015) who suggested that peer support influences the quality of life of PLWHA, such as energy/fatigue, sleep, cognitive function, physical activity, and their daily activities.

The majority of the two comparison groups alike rarely have negative feelings, such as loneliness, despair, anxiety and depression. The psychological problems experienced by PLWHA are actually more severe, but the treatments that have existed so far are still more focused on social problems, such as stigma.

Most PLWHA who did not join the PSG were not satisfied with their ability/capacity to work, while PLWHA who joined the PSG were very satisfied with their ability/capacity to work. This result is in line with the research by Van Tam who found that improved quality of life was related to the level of freedom of PLWHA. Most people living with HIV/AIDS who do not join a peer support group feel very afraid of the future and are very worried about death, while PLWHA who join a peer support group are not. Increased quality of life is related to the spiritual level, such as perceptions about the future and worrying about death. Higher spiritual needs are found in PLWHA with stage IV HIV.

This research results related to this quality of life are supported by Sesaria’s research which showed that the role of peer support groups is very good for the quality of life of PLWHA.

Quality of life is an important factor and needs to be considered, especially for the mental health of PLWHA, and can contribute to the happiness and self-satisfaction of PLWHA and provide benefits to the family and community. Activities commonly carried out by peer support groups, such as meetings, studying together, peer assistance, supervision of taking medication, Community Counseling, Information and Education and fundraising, can also be done to improve the quality of life of PLWHA directly.

Conclusions

PLWHA who joined a peer support group had a higher level of adherence to taking antiretroviral (ARV) drugs and better quality of life than PLWHA who did not join. It is recommended for VCT Polyclinic Nurse of Dr. H Slamet Martodirdjo Pamekasan hospital to involve PLWHA who have joined a PSG to meet and invite new PLWHA or who have not joined to do so. For Malatèh Setaman peer support groups, it is recommended to make online discussion at least twice a week, especially inviting PLWHA who have not joined a PSG to join in the online discussion. Further research is expected about other factors, such as differences in medication adherence and quality of life in PLWHA with Drug Drinking Companions (PMO) or with family support.

Ethical Clearance: The research was approved by the Health Research Ethics Committee of the Faculty of Nursing, Universitas Airlangga, in 2018.

The Influence of Bibliocare on Depression Level of Cancer Client with Chemotherapy

Ah Yusuf, Elida Ulfiana, Rr. Dian Tristiana, Puteri Hirika Reptes

1Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Cancer clients undergoing chemotherapy require stimulation from cognitive aspects to turn negative perceptions into positive ones. Utilization of a book as a media therapy is called bibliocare. This study is aimed to analyze the effect of bibliocare to change depression level in cancer client with chemotherapy. This study was Quasi-Experiment, population in chemotherapy center of Dr. Mohammad Hoesin Hospital, Palembang, sample size 36 patient, taken by simple random sampling. The independent variable was the implementation of bibliocare. The dependent variable was depression level. Data were taken by using Hamilton Depression Rating Scale (HDRS) questionnaire then analyzed by Wilcoxon Signed Rank Test and Mann-Whitney U test. The result showed a significant effect of bibliocare implementation on depression in the treatment group with Mann-Whitney U test, p=0.000. Sixteen respondents experienced a decrease in the level of depression, two people remained the same and no one experienced an increase in depression. It showed a significant difference between pretest and posttest bibliocare implementation. It could be concluded that the implementation of bibliocare could change depression level in cancer client with chemotherapy.

Keywords: Bibliocare, Depression, Cancer, Chemotherapy

Introduction

Chemotherapy in cancer affects physical and psychological problems. Physical problems due to chemotherapy are manifested with hair loss, body weakness, blackened skin and other effects. Psychological problems include worry, anxiety, and depression. Depression in cancer clients is contributed from various aspects. The client feels fear of pain, having a short life, losing independence, and feeling helpless. Some aspects that adequately affected the client’s emotional condition were therapeutic side effects, length of treatment, repetitive treatment, high cost, and lack of communication and information from the medical team. Medical treatment for cancer can affect the body’s metabolic system, which affects the psychological aspects.

Cases of cancer clients have increased from 1.4 million people to 12.7 million people. The World Health Organization (WHO) stated that there are always new cases related to cancer and, currently, there are 28 types of cancer in 184 countries around the world. According to Basic Health Research in 2013, the prevalence of cancer clients in all age populations in Indonesia was 1.4%. The highest prevalence of cancer was found in D.I Yogyakarta province, with 2.4%, while East Java is 0.5%. Cancer client data at Central General Hospital (RSUP) Dr. Mohammad Hoesin Palembang in 2015 showed there were 2,838 patients, and increased up to 5,758 patients in 2016.

According to research in 2016, cancer clients experience psychological distress, anxiety and depression as much as 45%. Cancer clients that undergo some chemotherapy often have anxiety. This anxiety is influenced by internal factors (adaptability) and external (physical threat and self-esteem), as explained in Roy’s nursing theory about adaptation. The process before the onset of depression starts from the feeling of a threat then the clients will continue to think about their condition, which can lead to stress phase and eventually
raises anxiety (input). This process leads to an angry reaction both to themselves and to others (the process). This self-indignation is what often leads to maladaptive conditions causing depression (output).  

Some studies have stated that book-reading therapy can reduce stress and anxiety levels in cancer clients. Utilization of a book as a media therapy is called bibliocare. Bibliocare is a therapeutic activity of treatment using a book followed by a discussion according to the topic of life problems at that time. Bibliocare can be used in people with depression problems, who are asked to read self-help and motivational books to speed up the healing process. Bibliocare helps the clients to process painful personal experiences by normalizing feelings and enhancing coping support through stories. Based on the above exposure, this study aims to determine the influence of bibliocare on decreased levels of depression in cancer clients who underwent chemotherapy at the Central General Hospital (RSUP) Dr. Mohammad Hoesin Palembang.

**Method**

This research was Quasi-Experiment using pre-/posttest control group design. The sample was 36 cancer client respondents, selected by simple random sampling. Independent variable is bibliocare, dependent variable is depression. The data were analyzed by Wilcoxon Signed Rank Test and Mann-Whitney Test, with significance level p ≤0.05. This study has obtained the approval of ethical clearance from the field of education and research Hospital Dr. Mohammad Hoesin Palembang, number TU.05.01/11/9516/2016.

**Result**

Demographic descriptions stated more than half of respondents were from women’s treatment and control groups, most of whom only went to senior high school/senior high school, the majority were 31-50 years old and almost all treatment and control group respondents were married. Many respondents worked as entrepreneurs, the majority of respondents were Muslim, many respondents had chemotherapy series 3, more than half of the respondents’ treatment and control group.

**Effect of Bibliocare toward Depression Levels:**

Wilcoxon Signed Rank Test results showed that there was a difference of depression level in the treatment group before and after bibliocare, p = 0.000, while, in the control group, there was not found any changes in depression level, p=0.399 (Table 1).

The treatment group obtained 16 respondents who experienced decreased depression level (negative ranks); none experienced an increase in depression and two respondents had the same value between before and after bibliocare. In the control group, six respondents experienced decreased depression level, three respondents increased and nine respondents had the same value between before and after the intervention. Mann-Whitney test results showed that there was a difference of depression level between treatment group and control group after giving intervention.

**Discussion**

The rate of depression before being given bibliocare in the treatment group and the control group was
100%, meaning that, of 36 respondents, all experienced depression. The majority of respondents considered the diagnosis of cancer as an incurable disease diagnosis and ended with death, but they did not lose their life expectancy; only a small percentage (22.2%) felt that they had no life expectancy since diagnosis of the disease. The majority of respondents aged 31-50 years amounted to 80.6%. Factors causing depression are age, lifestyle, environmental, and biological factors. Risk factors for the occurrence of depression in cancer patients include negative thoughts about cancer, stage of cancer and treatment measures undertaken. The cause of depression is the presence of cognitive factors, in which a person with low cognitive distortion will cause depression. One’s mechanism is influenced by the cognator aspect. Occupation and educational level greatly affect the occurrence of depression.

More than half of respondents, or 55.5%, were female with married percentage 91.7%. Other causes of depression are psychosocial factors, which include life events and environmental stress, that affect a person’s mood. Biological factors, such as gender also affect a person’s depression level. Regarding biological factors, the disease process in a woman can lead to hormonal changes, resulting in emotional symptoms such as anger and depression. One of the factors causing depression is a psychosocial factor in the form of environmental stress. Undergoing long chemotherapy is one of the adaptations of a person to a contextual stimulus. In respondents undergoing chemotherapy series until the sixth (6th) series, it takes a long time to affect the emotional level during the session because it takes a long time to reach the end of the chemotherapy session. Chemotherapy makes the majority of cancer clients experience worry, fear of death, and pain during therapy.

This phenomenon shows that, knowing the diagnosis of disease, the severity of the disease and the prognosis of cancer is an aspect that affects one’s emotional level. Taking chemotherapy treatment also affects a person’s psychological aspects. Before giving bibliocare, there are many things that cause cancer clients who undergo chemotherapy to experience depression. Chemotherapy as one of the main choices of treatment for cancer and has side effects that can cause anxiety, stress, and depression.

The rate of depression after being given bibliocare in the treatment group was 61.1% to normal. Almost all respondents still felt sad knowing the diagnosis of the disease, but some respondents experienced a better change. Respondents also still felt scared about the side effects that will be felt due to undergoing chemotherapy, but some respondents also changed to a better direction. The majority of respondents after being given bibliocare already considered that the diagnosis of cancer was a diagnosis of a curable disease and most of the respondents did not lose their life expectancy (91.7%). Respondents stated that the books provided had similar stories to their circumstances, this being the motivation for respondents to do the same. Most of the respondents liked to read, and a small proportion didn’t. Bibliocare or reading therapy can solve one’s personal problems.

The respondents of the treatment group and the control group underwent a third chemotherapy treatment with the percentage of 30.6%. The majority still felt bored undergoing chemotherapy treatment because they had to undergo chemotherapy to reach the sixth session, and one session can take 15 days depending on the condition of the respondent. The findings are consistent with other studies that stated chemotherapy makes most cancer clients fearful, afraid of death, and feel pain during therapy.

This phenomenon shows that undergoing chemotherapy treatment also affects a person’s psychological aspects. The findings are consistent with other research that stated chemotherapy is one of the most important treatment options for cancer and has side effects that can cause anxiety, stress, and depression. Having an interest in reading also affects emotional level. Research states that reading allows a person to express their feelings so they can lower the anxiety levels that can lead to depression.

The result of statistical test of comparison of pre-post-depression rate of bibliocare in the treatment group showed that there was a change of depression level, meaning there was influence of bibliocare on depression level in the treatment group. The results of this study are in accordance with other studies that found bibliocare is useful to express yourself, your thoughts and feelings. Bibliocare is also applied as a way to solve problems that can significantly lower the level of depression. Respondents in the treatment group experienced a change in depression rates for the better (normal) based on the Hamilton Depression Rating Scale (HDRS) questionnaire. In the posttest results in the posttest group of bibliocare giving, the change of
the respondents’ perceptions became positive as they revealed that the stories were similar to their story and respondents who experienced a change in depression levels. This happened because not all control group respondents were given bibliocare. This phenomenon is possible because the patient may have experienced additional stressors during chemotherapy treatment. Based on the data, it also showed nine respondents having the same value or who did not experience changes in depression levels before and after the HDRS questionnaire given to the control group. This happened because not all control group respondents were given bibliocare.

After reading the bibliocare book, the majority of respondents who experienced a change in depression revealed that the stories were similar to their story and the respondents’ perceptions became positive as they realized that many people had experienced a worse case than theirs. Therefore, respondents were able to rise and did not feel sad again.

In the second question, some respondents felt no hope of life after being diagnosed with cancer, but some of them didn’t feel the same way. The respondents who were young and newly diagnosed with cancer still believed they could be cured. Respondents’ coping mechanisms were disrupted due to stressors they experienced after being diagnosed with cancer. The process of decreasing the life expectancy of the respondents was influenced by the catharsis stage. At this stage, the respondents were asked to read the words of motivation listed in the book repeatedly. This affected their psychological and cognitive aspects. A person’s adaptation of the stimulus received will affect their coping mechanism. Coping mechanisms that are affected in this case were the effectors, as they relate to self-concept and self-function. Stimulus given in the form of words of motivation provides a spirit of life for respondents who felt they had a short life expectancy.

In the third, fourth, fifth, and tenth questions, many respondents felt sad at having to undergo chemotherapy, feared the side effects, and felt bored undergoing the long series of the therapy. The process of decreasing the respondents’ sadness was influenced by the deep insight stage of bibliocare. At this stage, the respondents and researchers discussed together the contents of the reading that had been given. The contents of these readings talked about the success of other cancer patients who underwent chemotherapy. The purpose of this stage is to encourage respondents in undergoing chemotherapy. This also affects the psychological aspects of respondents. Respondents who adapt to chemotherapy affect their self-concept of mood disorders (sad, hopeless, helpless). Adaptation will affect the concept of themselves and the role of someone else. This is the mechanism of effector and cognator. The external stimulus a person receives is a stimulatory stimulus.

### Conclusion

This study showed that there was a change in depression levels before and after being given bibliocare in the treatment group. Depression rates between the treatment group and the control group experienced a difference. Sixteen respondents experienced a decrease in the level of depression after being given the bibliocare among the cancer clients undergoing chemotherapy.

Parental Self-Efficacy on Temper Tantrum Frequency in Children

Yunita Fauziah1, Ferry Efendi1, Ika Nur Pratiwi1, Gading Ekapuja Aurizki1
1Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Although typical in children between the ages of 18 months and 4 years, temper tantrums can be predictive of maladaptive outcomes, particularly if they continue into later ages. Parental self-efficacy (PSE) has emerged as a powerful mediator of children temperament and a predictor of specific positive parenting practices. This study aimed to determine the correlation between PSE and temper tantrum frequency in children aged 2-5 years. This study was a correlational research. Ninety-six parents of children aged 2-5 years participated in this study. The Self-efficacy for Parenting Task Index-Toddler Scale and Multidimensional Assessment of Preschool Behaviour Problem were used to assess the study variables. The data was analysed using Spearman’s rank correlation test. The statistical test results showed a significant correlation between parental self-efficacy and temper tantrum frequency (p-value = 0.000; r = -0.669). The majority of respondents had a moderate level of PSE, and most of the children had low temper tantrum frequency that was mostly expressed with screaming, stamping feet and holding breath. It can be concluded that there was a correlation between PSE and temper tantrum frequency in children aged 2-5 years in a negative direction, which means the higher the PSE, the lower the temper tantrum frequency.

Keywords: Temper Tantrum, Self Efficacy, Children Health

Introduction

Temper tantrums are the most common behavioural problems in children from 16 months to 6 years in the form of explosive anger indicated by behavioural variations ranging from crying and shouting, to rough and aggressive actions such as throwing things, rolling on the floor, banging the head and kicking or hitting the parent or guardian. Temper tantrums are common in pre-school children, but it is abnormal if it occurs every day. Abnormal temper tantrums are manifested by tantrums that occur daily or not daily but with prolonged duration of more than 5 minutes with aggressive behaviour. Abnormal temper tantrums contribute many negative effects onto children. The short-term effects may include children’s anger by hurting themselves and others or destroying objects around them, as well as uncontrolled emotions and aggressiveness. In the long term, the children could not deal with their surroundings, could not adapt to a new environment and found difficulties in solving a problem. Children who suffer temper tantrums with abnormal frequency are also associated with delinquency in their teenage years.

A study in Finland found that 87% of 132 parents reported that their child had experienced temper tantrums. The average tantrum begins between the ages of 2 and 3 and stops before the age of 5 years. The duration of tantrums in 46.5% of children ranged from 5 to 10 minutes. Temper tantrums are experienced once a week in 37.3% of children and once a month in 30.7% of children. A study conducted in Indonesia shows that high-frequency temper tantrums in pre-school children reached 26% of 88 respondents. A study of Syam added that 34.2% of the 38 parents reported could not control the tantrums of their children.

Parents are often unaware that they can allow the occurrence of the tantrum in their children. Parents with low parental self-efficacy (PSE) are usually unsure of their own abilities as parents so that when the child...
throws a tantrum, they cannot show a proper response.\textsuperscript{12} The parents often give in to the wishes of the children, provoked by the show of emotions or could not show persistence in parenting.\textsuperscript{1} Parents who always follow the request of their children will lead to the occurrence of tantrum behaviour when the request is rejected. The children with strict protection and domination by their parents will also react against their parent’s wish by acting out a tantrum behaviour.\textsuperscript{10}

Parents with high levels of PSE will display positive parenting behaviours by building a healthy and fun nurturing environment.\textsuperscript{13} The high self-efficacy level makes the mother fully involved in performing her role as a parent.\textsuperscript{14} Parents with a high PSE level also have higher interest, commitment, and persistence in facing challenges during the parenting activities.\textsuperscript{15} This makes the parents consider difficult child behaviour as a challenge that requires more effort and creative ways to overcome the behaviour.\textsuperscript{12,16}

Parental behaviour in nurturing and educating children is one of the main predictors of a temper tantrum in children besides environmental factors and characteristics of the children.\textsuperscript{17} PSE is the main determinant that will influence the strategy chosen by parents in facing a temper tantrum which then influences the behaviour of the tantrum.\textsuperscript{18} Parents with high PSE will be more responsive to all the needs of children during tantrums, so parents can deal with and prevent tantrums well. The level of PSE also affects the parenting style chosen by parents. Parents with a democratic parenting style tend to have children with normal temper tantrums and parents who apply an authoritarian parenting style tend to have children with abnormal tantrums.\textsuperscript{10}

However, there is no previous study of the PSE regarding the frequency of temper tantrum. Therefore, the purpose of this study was to identify the correlation between PSE and the temper tantrum frequency in children aged 2-5 years.

**Method**

This study used a cross-sectional approach. The study involved 96 parents of students of three preschool programs of Mawar, Melati 3 and Flamboyan in Mulyorejo District, Surabaya, Indonesia. The data were collected using Self-efficacy for Parenting Task Index-Toddler Scale (SEPTI-TS) questionnaire to measure the PSE level and the Multidimensional Assessment of Preschool Behaviour Problem (MAP-DB) questionnaire to measure the children’s temper tantrums.

SEPTI-TS has 53 questions divided in seven subscales encompassing emotional availability, nurturance/valuing/empathetic responsiveness, protection, discipline/limit setting, play, teaching and instrumental care/structure/routines. The scoring system was a 6 point Likert scale where a score of 1 meant very disagree and 6 meant very agree.\textsuperscript{19}

MAP-DB was a questionnaire with 22 questions. The questionnaire was developed with 14 items which captures behavioural expressions, interactional context and triggering events, plus 8 items of anger regulations. The scoring system used a 6-point Likert scale where score 0 meant never and 5 meant many times each day.\textsuperscript{20} The data was analysed using Spearman’s rank correlation test with $\alpha \leq 0.05$.

**Results**

Table 1 shows the demographic data of the respondents. All respondents were female and the majority aged between 26-30 years (40.6%). The respondents were mostly high school graduates (55.2%). The majority were housewives (69.8%). Forty-two respondents (43.8%) had 2 children, 33.3% had only 1 child, and 22.9% had more than 2 children.

Based on Table 2, 62.5% of the children were female, and 37.5% were male. Half of those (50%) was 3 years old, and 49% of those were the first children.

Table 3 shows cross-tabulation between two variables. The parents with high PSE level were 14 respondents (14.6%) with 12 of those having children with low category temper tantrums and 2 respondents having children with temper tantrums in moderate category. In addition, 82 parents (85.4%) had moderate PSE level where 44 of those had children with low temper tantrums, meanwhile the other 38 had children with moderate tantrums.

Spearman’s rho test result on PSE with temper tantrums in children aged 2-5 years obtained degree of significance $(p) = 0.000$, which means there is a correlation between parental self-efficacy with the frequency of tantrums in children aged 2-5 years. The value of correlation coefficient $(r)$ of -0.669 shows a
fairly strong level of relationship between two variables. The correlation coefficient is negative, which means there is an inverse correlation between the two variables. So it can be inferred that the higher the parental self-efficacy means the temper tantrums experienced by the children will be lower.

Spearman’s rho coefficient = -0.669 p = 0.000

Discussion

All respondents were mothers of the children. A study revealed that mothers have higher self-efficacy than fathers.21 In addition, most of the respondents reached senior high school education. The level of education is important as it affects the health literacy of the parents. The parents with lower health literacy will also have lower PSE.22 The mothers self-efficacy also can be raised by providing proper education for the mothers.23 Most of the respondents work as housewives. Career women tend to have limited time to interact with their children and this affects their ability to always accompany their child as well as their self-efficacy.24

The findings are in accordance with a study which mentioned that there is a significant relationship between the level of PSE with the child’s developmental status and behaviour, where the higher the level of PSE will lead to the better the status of development and behaviours shown by the child.16,19 Also, maternal self-efficacy had a negative correlation with dysregulation in child behavior.25 Other studies have also identified PSE as a factor mediating components that affect parenting qualities such as maternal depression, child temperament and social support.26–28

The subscale of discipline in children is closely related to the parenting pattern that parents follow in
dealing with their children, one of which influences authoritarian attitudes and disciplines. In authoritarian parenting, parents have a tendency to take care of the children according to what is best regarded by them, such as with punishment and indifference. This attitude can cause tension and discomfort that allows the occurrence of chaos in the house. It is supported by a study which mentions that parenting patterns are related to the incidence of temper tantrums. Parents with authoritarian parenting have children with uncontrolled temper tantrums more than parents with democratic parenting.

**Conclusion**

The study concludes that the PSE level for most parents is in the medium category. The frequency of temper tantrums of most children is in a low category. There is a strong correlation between the PSE and temper tantrum frequency in a negative direction, which means the inverse correlation between the two variables.

Preschool programs are expected to establish and run a parenting class program to increase parenting knowledge and abilities on parenting to enhance the PSE. In addition, the preschool programs are also recommended to increase the quantity of character building programs that shape the characteristics of children to prevent temper tantrums.

Motivation Affects Self-Efficacy Greater than Age, Sex, and Education in Diabetic Patients in West Coast Area of Java Island

I Wulandari¹, Kusnanto², S. H. Nufus³

¹Doctoral Degree Programs, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia; ²Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia; ³School of Nursing, STIKes Faletehan Serang, Banten, Indonesia

ABSTRACT

Self-efficacy and motivation are required for patients with type 2 diabetes in managing their diabetes. This study used observational analytic design with a cross-sectional approach. Samples recruited were 115 respondents selected by using purposive sampling method. The data analysis used logistic regression with significance level of α < 0.05. This study results showed that motivation more affects patient’s self-efficacy (p < 0.001) after being controlled by age, sex, and education. Conclusion of this study was that the highest patient motivation is influenced by the patient’s desire to recover from his illness and support from the family. The recommendation of this study is how to develop self-efficacy and motivation to establish the adherence of diabetic patients to carry out their self-care management.

Keywords: characteristics, motivation, self-efficacy, diabetes mellitus

Introduction

Diabetes mellitus (DM) is a chronic disease that requires adherence in carrying out self-care in order to achieve glycemic control and slow the emergence of complications.¹ Patient adherence to do self-care management for current DM is not yet entirely good and optimal. Adherence of DM patients is influenced by internal factors (individual characteristics, knowledge, self-awareness, and motivation) and external factors such as physician’s ability and health system support.² The results showed that motivation, self-efficacy, perception, treatment process, and degree of illness can inhibit the implementation of self-care in addition to individual factors such as age and gender.²-⁴ These barriers can affect adherence of DM patients running self-care, causing poor glycemic control, increasing the risk of hypertension, occurrence of complications, and maintenance costs.⁴

DM patients are expected to increase globally by 204 million, from 425 million in 2017 to 629 million in 2045 or an increase of around 48%.³ Indonesia ranks 6th out of ten countries with the highest number of patients diagnosed globally with DM, namely 10 million. The highest number of patients diagnosed with DM was at the age of 20-64 years, amounting to 327 million people compared to ages 65-99 years at 123 million people.⁵

Adherence to self-care management among DM patients requires the confidence of the patient that he can deal with and undergo treatment after being diagnosed. The results of the current research showed that one of the causes of the failure of DM patients to carry out self-care management is lack of motivation. This motivation is the driver of the patient’s self-awareness because of the belief in healing the illness.³⁶⁷ Other factors related to adherence to the implementation of DM self-care are patient characteristics, such as age, gender, occupation, education, and also local culture.³⁴⁸⁻¹²

The previous research showed, among other factors, that intrinsic motivation and self-efficacy are often found to be major factors in influencing patients to manage their diabetes.³⁹⁻¹⁴ Motivation makes someone have a strong desire to make efforts so that the goal is achieved.
Motivation can affect self-efficacy.\textsuperscript{2,15} Self-efficacy of diabetes patients refers to an individual’s belief in one’s competence in successfully performing a given action on diabetes management. Higher self-efficacy is associated with more prudent self-care behaviors and better glycemic control, indicating that individuals who perceive themselves more confident in managing their disease are also more likely to do so.\textsuperscript{1,8,15}

The aim of this study was to determine the self-efficacy determinants of the characteristics and motivation of patients with type 2 diabetes mellitus.

Method

Study Design, Setting, and Sampling: The study design used observational analytic with cross-sectional design which was held from May to September 2018. The population in this study was diabetes mellitus outpatients. The sampling technique used a nonprobability sampling with purposive sampling approach as many as 115 subjects.

Study Variables: The questionnaires for motivation measurement were validated and the reliability tested with Cronbach’s alpha value of 0.92. Motivational instruments were adopted from previous studies and validity and reliability were tested by researchers, consisting of 13 closed-ended questions.

The self-efficacy questionnaire used the Diabetes Management Self-Efficacy Scale (DMSES) in which the language had been modified; the validity and the reliability were tested with Cronbach’s alpha 0.919, consisting of 16 questions.

The process of data collection was carried out in an outpatient room. Patients who met the inclusion criteria and were willing to be involved as research subjects were determined as respondents. Respondents involved were given instruments in a certain room so that the confidentiality of the data was guaranteed.

Data Analysis: The data were analyzed using SPSS software version 16. The data analysis was performed by using Chi square in bivariate and logistic regression for multivariate analysis. The research results are displayed in the form of percentages, p values and OR values

Results

The results of the analysis in Table 1, show occupation variable has P value 0.442, so that it is excluded from the model. However, sex and education variables remain included in the model because previous studies show that age and education are related to self-efficacy.

Table 2 shows the results of the first multivariate analysis of the four dependent variables; the education variable has the highest p value. Table 3 shows that, after occupation variable is excluded, there is no change in OR value > 10% in other variables. So the occupation is put back into the model. Then, because the education variable has P value greater than 0.005, it is excluded from the model.

The final results of multivariate analysis are shown in Table 6. It shows a significant correlation between motivation and self-efficacy, while the variables of age, education, and gender become the control variables. The results of the analysis showed that the Odd Ratio (OR) of the motivation variable was 4.3 (95% CI: 1,838 - 10,120), meaning that patients with high diabetes motivation would increase their chances of showing positive self-efficacy by four times compared to those with low motivation after being controlled by age, gender, and education.

Discussion

The results of this study indicated that motivation plays an important role in the self-efficacy of diabetic patients to carry out self-care. Motivation provides a more meaningful correlation than age, sex, and education. This study revealed that internal motivation is important in shaping the beliefs and confidence in carrying out self-care. Patients with strong motivation have strong fighting strength, so that they are not burdened to undergo diabetes management and this can affect patient self-efficacy.15 Self-efficacy is part of the most important mechanism of human self-reflection and is one part of human agents. Human beliefs about self-efficacy affect the form of the action that they will choose to do, what effort they will give to this activity, how long as they will survive in the face of obstacles and failures, as well as their toughness following a setback.15 Self-efficacy has a very strong quality influence in human actions. Self-efficacy combines with the environment, previous behavior, and other personal variables, especially expectations, for results to produce behavior. People who believe that
they can do something that has the potential to be able to change events in their environment will be more likely to act and be successful than people who have low self-efficacy.\textsuperscript{1,15}

The results of this study were supported by several previous studies. Internal motivation and self-efficacy play the biggest role in diabetes management. Therapy, advice from a professional health worker, or existing health facility is not sufficiently helpful if the patient does not have the desire within himself to be willing to comply with the recommended treatment.\textsuperscript{2,3,9} Motivation constraints that are commonly encountered and based on the results of previous research are the boredom of adherence on diet, continuity in exercising, and fear of complications due to prolonged medication.\textsuperscript{2,6,8,9} The concept and assumption of a diet, for example, is a factor that is often found as an obstacle to the implementation of diabetes diet management when there is no motivation to run it.\textsuperscript{1,9,12}

Motivation can also affect other diabetes self-care adherence, such as medication failure. Recent study found that 50% of medication failure was caused by physician factors, 30% of patient factors, and 20% healthcare-related factors.\textsuperscript{17} Patient factors that contribute to the failure of treatment for diabetes are denial of the disease, denial of the seriousness of the disease, low health literacy, high cost of medication, too many medications, side effects of the medication, poor communication between physician and patient, lack of trust in physician, depression, lifestyle and absence of symptoms.\textsuperscript{17,18}

Motivation is not the only factor that influences self-efficacy. Patient characteristics can also affect the efficacy of his treatment of the disease and the care that must be taken.\textsuperscript{13,19,20} The study also showed that patients over 56 years had more positive self-efficacy than those under the age of 56. The reason obtained from in-depth interviews was that they were more receptive to their illness than those aged less than 56 years. Especially for elderly patients (over 60 years), they lived their lives and diseases by surrendering to God and had no difficulty in carrying out therapy according to the advice of a doctor or nurse, while younger patients said it was more difficult to accept the disease and didn’t expect to have diabetes therapy and management every day of their lives.\textsuperscript{3,8,13} Psychologically, acceptance of the disease and surrender to the ultimate God helped the patients sincerely set the therapeutic program.\textsuperscript{1,7,21}

The limitation of this study is not analyzing external factors that can affect self-efficacy, such as family factors or health workers. Limitations in sampling also became one of the weaknesses in this study. Samples should be taken randomly so that the results are better and cover a wider area.

**Conclusion**

The findings revealed that motivation had a great potential to achieve the self-efficacy needed to achieve glycemic compliance and control. The characteristics of age, education, and gender were confounding factors that can affect self-efficacy, but can be overcome if the internal factors, such as motivation, are more positive. The findings can explain why motivation and self-efficacy are very important for adequate glycemic control. This research can be developed to find internal self-efficacy factors, including internal motivation, to achieve self-care adherence and glycemic control.

The Correlation of Duration of Hormonal Contraception with the Case of Breast Cancer at RSUD Jombang

Sestu Retno Dwi Andayani¹, Rizki Aprillia², Mamik Ratnawati³
¹Lecturer, ²Student, Nursing Study Program, Stikes Pemkab Jombang, Jombang, Indonesia

ABSTRACT

Breast cancer is the most deadly case for women. One of the causes is duration of hormonal contraception use. The purpose is to determine correlation of duration hormonal contraception use with breast cancer cases. Study design used analytic correlation with a cross-sectional method. The population is all users of hormonal contraception at RSUD Jombang (396 people). The sample size used purposive sampling technique with 364 respondents. Independent variable is duration of hormonal contraception use and dependent variable is breast cancer cases. Furthermore, analysis test used chi-square with α = 0.05. The result indicated that 60 (48.1%) from 125 respondents using hormonal contraception >5 years had got breast cancer. However, all of 239 respondents (65.8%) using hormonal contraception <5 years did not get breast cancer. The result of chi-square is p = 0.000 <0.005, which means strong correlation of duration hormonal contraception use with breast cancer cases. The conclusion is hormonal contraceptive use >5 years will increase the risk of breast cancer cases.

Keywords: hormonal contraception, breast cancer.

Introduction

Breast cancer is a type of cancer which often occurs in women in Indonesia. The risk factors for breast cancer are, age > 50 years, alcohol consumption, obesity, giving birth at the age of more than 35 years, never giving birth, not breastfeeding, menopause at age > 50 years, early menarche, radiation exposure, and the long term use of hormonal contraception.¹ The hormone is exposure to sex hormones such as estrogen and progesterone in which excessive amount interferes with physiological processes in the body, including mammary tissue.²

Based on the Hospital Information System (SIRS) in 2014, the number of outpatients and inpatients (12.8%) had breast cancer as many as 12,014 people (28.7%) and cervical cancer with total 5,349 people.³ Breast cancer had a contribution of 30% and is the most dominant in Indonesia, outstripping cervical cancer or cervical cancer which contributes 24%.⁴ The mortality rate from breast cancer is high in developed countries and it is still low in developing countries, including Indonesia.³ Based on early detection of breast cancer in Indonesia as of 2016, the number of breast cancer patients was 4,030 people with those surviving cervical cancer numbering 1,739 people.³ Based on breast cancer data in Jombang Hospital in 2017 there were 31 people with breast cancer.

Many factors can cause breast cancer, one of them is the use of hormonal contraception. It is a part of a program known as family planning which is an attempt to delay pregnancy or determine the number of or time between pregnancy using contraception.⁶ According to the World Health Organization (WHO), nearly 380 million couples used family planning and 65-75 million of them used hormonal contraception such as oral contraceptives, injections and implants.⁷ Data of the National Population and Family Planning Board showed that the choice of contraception was the most interested or chosen by new and active family planning users, namely pills and injections.¹ Data from the national population and family planning body (BKKBN) in 2013 received 8,500,247 couples of reproductive age who
were new family planning participants, with details of injectable contraceptive use 4,128,115 participants (48.56%), pills as many as 2,261,480 participants (260%), implants were 784,215 participants (9.23%), condoms were 517,638 participants (6.09), intrauterine contraception 658,632 participants (7.75%), MOW (female surgery method) 128,793 participants (1.52%), MOP (male surgery method) 21,37 participants (0.25%). From the above data, we can see that the most widely used is hormonal contraceptive methods. In addition, data from the health profile of Jombang district, showed that the type of contraception used by acceptors is injection KB, as much as 61.9%, followed by pills and implants. Previous studies had shown that there was a correlation between the use of hormonal contraception and the incidence of breast cancer.

Some studies suggest that the use of hormonal contraception over a long period of time or ≥5 years can increase breast cancer risk. Women who use hormonal birth control have a risk of 2,990 times more likelihood of getting breast cancer. Other studies suggest that hormonal contraceptive use causes increased exposure to estrogen and progesterone hormones which can cause cell proliferation in the breast glands and inhibition of the apoptotic process. This, hormonal contrast was one of the risk factors for breast cancer.

Prevention efforts were a healthy lifestyle, counseling, and also early detection with the BSE system (check your own breasts) to see whether there were lumps or other changes that were a sign of breast cancer and required medical attention. Based on the above background, the researchers are interested in conducting research related to the use of hormonal contraception with the occurrence of breast cancer in Jombang General Hospital.

Method

Study Design, Setting, and Sampling: The design of this study was cross-sectional analytic. Population was all hormonal contraceptive participants who used injections, pills and implants in the Jombang Hospital, as many as 396 people. The sample size, as many as 364, used purposive sampling technique. The independent variable was duration of hormonal contraceptive use and the dependent variable was breast cancer cases. The place and time of the study were the Jombang District Hospital, 9-15 May, 2018.

The study used observations and used the chi-square statistical test

Results

Long usage of hormonal contraception

Source: primary data 2018
Based on Table 3, 12 of the 52 respondents who used <5 years of Hormonal KB all 100% had no breast cancer.

**Discussion**

**Long usage of hormonal contraception:** Table 1 shows that most (65.8%) of the older respondents use hormonal contraception <5 years, as many as 27 people. Previous theory mentioned that nearly 70% of acceptors used hormonal contraception methods. The duration of use of hormonal contraception depended on the type of contraception which was used every day for many years, but there were also many side effects complained about by family planning acceptors because they use hormonal contraception methods.

According to researchers, some respondents used hormonal contraception <5 years because the contraception which was chosen was inappropriate or unsuitable, so they replaced it with other hormonal contraceptives for a period of <5 years.

Based on the results of the study, it was shown that almost all (77.2%) of the respondents obtained information, as many as 66 people. The delivery of information or messages about family planning programs can use radio, TV, and promotion with the aim of problem solving within the community to improve or achieve family planning programs. Information on the selection of appropriate contraception types and good time periods can be obtained by consulting a doctor or health worker.

According to the researchers, the information obtained by respondents about KB programs and hormonal contraceptives was obtained from many various sources. Before starting a plan to use hormonal contraception, the acceptor candidates will be given information on the types of side effects and how to overcome them.

Based on the results of the study, it showed that the majority (53.2%) of respondents used injectable contraception type, as many as 42 people. This can be due to the benefits of using hormonal contraception, which can be used by breastfeeding mothers, do not need to be consumed every day or used before sexual intercourse, and help to overcome cramps during menstruation and reduce menstrual blood.

According to injectable contraceptive research, many respondents used these methods because most considered them suitable and effective as they did not require lengthy usage and were not as difficult as other contraception. The use was only 1-3 times a month, whereas contraception pills must be routinely taken every day and the user must understand how to take medication and people who do not know and use other contraceptives, might feel sick and be afraid of the risks of breast cancer incidence.

**Breast cancer incidence:** Table 2 shows that for almost all respondents, the incidence of breast cancer did not occur, as many as 304 people (83.5%). This supports previous research into causes of breast cancer not only from hormonal contraception, but also age, genetics, pregnancy, radiation, diet and being overweight.

According to research, the occurrence of breast cancer because of hormonal birth control alone cannot be generalized as a cause of breast cancer as breast cancer itself occurs due to factors such as age, occupation, offspring, and not having children as well as hormonal factors. One of the hormonal factors can be obtained by using a long-term hormonal birth control because of the frequent exposure to estrogen and progesterone, which can trigger the growth of breast cancer cells.

According to research, respondents aged >35 years were more susceptible to breast cancer because at that age a person experiences a decrease in the immune system, so that they are easily exposed to diseases, one of them being breast cancer. Especially if supported by factors that cause breast cancer.

Based on the results of the study, it showed that the majority of respondents were aged >35 years, as many as 50 people (63.3%). Women in their mid-30-40s were at risk of developing breast cancer at that age because this is the most common ages in which the first stages of breast cancer were detected.

According to research, respondents aged >35 years were more susceptible to breast cancer because at that age a person experiences a decrease in the immune system, so that they are easily exposed to diseases, one of them being breast cancer. Especially if supported by factors that cause breast cancer.

Based on the results of the study, it showed that the majority of respondents did not work, as many as 56 people (70.9). Women who work have a higher risk of breast cancer, especially in women who work at night, because the light at night can suppress the production of melatonin in the brain so that the hormone estrogen increases; melatonin is believed to increase breast cancer cell growth.
According to research, some jobs could be a risk factor for breast cancer, such as work that is directly exposed to chemicals, such as in factories. Women who were often exposed to light at night, such as watching the screen of a cellphone with high light intensity for a long time, could trigger the growth of breast cancer cells.

Based on the results of the study, it showed that all respondents did not experience a family history of cancer, as many as 79 people (100%). Women with offspring or who previously had a family member suffering from breast cancer had a high risk of developing breast cancer. About 5-10% of breast cancers were reduced, meaning the seeds of cancer were a direct result of gene abnormalities (gene mutations) that were lowered from their parents.3 those who have family members aged 65 years have twice the risk, and, among younger women with breast cancer, the more likely it is the disease is hereditary.15

According to the research no history of breast cancer in the family would reduce the risk of breast cancer. Breast cancer could also be avoided with a healthy lifestyle and not choosing jobs that trigger breast cancer. Women could also do an early check-up with a health service if there were one or two family members who had previously had breast cancer as this could help to prevent the spread of cancer and allow prevention as soon as possible.

Based on the results of the study, it showed that the majority of respondents did not experience a weight gain (43 people equal to 54.4%). Women who were overweight after entering menopause at the age of > 35 years had a higher risk of developing breast cancer.3 Women who are overweight have a higher level of estrogen than they should, because, before menopause, the ovaries and fat tissue both produce estrogen. After menopause, the ovaries stop producing estrogen so that estrogen comes from fat tissue. Having more fat tissue means increasing estrogen levels after menopause, thereby increasing the risk of breast cancer.

According to the research, there was no increase in body weight due to a match with the type of contraception used; those who used hormonal contraception were asked if they experienced weight gain or side effects.

The correlation duration of hormonal birth control with breast cancer: The results of the Contingency Coefficient statistical test obtained a significant number with a value of 0.524, which means there was a correlation between the two variables with medium strength and a positive direction.

Previous research stated that the risk factors affecting breast cancer incidence were the age of the respondent, age of menarche, age of menopause, length of breastfeeding, duration of oral contraceptive use, consumption patterns of fatty foods, fibrous food consumption patterns, obesity, dietary patterns, passive smoking and alcohol consumption.16 Women currently taking oral contraception had a one-fourth greater risk than women who have stopped using it 10 years ago, but the increase in risk is not statistically significant. This supports other studies which state that hormonal contraceptive use causes increased exposure to estrogen and progesterone hormones, which can cause cell proliferation in the breast glands and inhibition of the apoptotic process.11

According to the research, hormonal contraception used > 5 years could be trusted as the cause of breast cancer. The incidence of breast cancer itself was usually detected at the age of > 35 years, so that more women who had already been affected by the impact of breast cancer, with awareness for early examination would certainly be able to reduce the factors that cause breast cancer. The use of hormonal contraception could not be used as a reason for breast cancer. Hormones were not only obtained from contraception, but could be obtained from other drugs that contain the hormones estrogen and progesterone. The occurrence of breast cancer could be triggered from the use of hormonal contraception > 5 years and is supported by other factors, including unhealthy lifestyles, rarely exercise, working in places that were often exposed to chemicals, and tobacco. The results of the study showed that there was a correlation between the use of long-term hormonal birth control and the incidence of breast cancer, even though from 239 respondents and there were 364 respondents who used family planning < 5 years, which means they had a lower risk of breast cancer.

Conclusion

This study illustrates that there is a relationship between the duration of use of hormonal contraception and the incidence of breast cancer in Jombang Hospital with a probability value (0.000) and is supported by the results of contingency statistics with a value of 0.524,
which means there is a correlation between two variables with moderate strength and positive direction, where the duration hormonal contraceptive use is directly proportional to the minimum incidence of breast cancer. Further research is expected to develop nursing planning and increase knowledge and early detection of breast cancer.

Experiences of Recovery from Acute Coronary Syndrome: A Systematic Review

A Khoiriyati¹, Kusnanto², Ninuk Dian Kurniawati²

¹Doctoral Degree Programs, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia; ²Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Understanding how patients experience recovery from acute coronary syndrome is critical for improving continuity of care. Continuity of care from hospital to home can be particularly challenging. This review aims to provide an overview of patients’ experiences of recovery from ACS. Data sources used keyword search of Medline, CINAHL plus, Scopus, Science Direct and Proquest databases. The inclusion criteria were conducted with adult population, qualitative research and articles published in English language in 2008-2018. This review used Preferred Reporting Items for Systematic Reviews and Meta Analysis (PRISMA) guidelines. The samples of 21 qualitative articles were included. Discharge planning and systematic follow-up shortly after discharge are increasingly viewed as being important. Patients need adequate instruction and information on how to integrate health information. Further research is needed to improve intervention strategy among people suffering from ACS, especially in developing countries.

Keywords: Acute coronary syndrome, experience, recovery

Introduction

Acute coronary syndrome (ACS), especially ST elevation myocardial infarction (STEMI) and non-ST elevation myocardial infarction (NSTEMI), can cause significant morbidity and mortality.¹ The risk of recurrence of heart disease is also still high after ACS, especially in the first year.² Stroke, or cardiovascular death after acute coronary syndrome. We investigated these aspects and developed tools for predicting these events according to the time of their occurrence. Methods: A retrospective study was conducted of 4858 patients who survived an acute coronary event. We analyzed the incidence and predictors of acute myocardial infarction, stroke, or cardiovascular death during the first year (n = 4858) The transition period of recovery is a complex process requiring input, timely exchange of information and coordination between various disciplines, both with patients and families.³ Healthcare professionals need to pay attention to patient perspectives through a carefully performed dialog formulated in a personal care plan for each patient with ACS.⁴ There is a need to better understand patients’ perceptions of their illness. Objective: To explore patients’ experiences of ACS during their hospital stay. Design: A qualitative interpretative interview study was conducted among patients during their hospitalization for ACS. Setting: The study was performed in two designated coronary care units at a hospital in Sweden. Participants: Twelve participants (five women and seven men; age range, 45-72 years

Experience in adjusting and adopting lifestyle changes after ACS is influenced by subjective experience in an individual, sociocultural and environmental context. Other factors that influence the adjustment of post-ACS patients are misunderstanding, misconception and confusion about the process and management of the disease. Post-ACS patients need continuous input and support from professional health personnel during the rehabilitation and recovery process.⁵ The purpose of this review is to provide an overview of patients’ experience of recovery after ACS.

Method

Study Design, Setting, and Sampling: The researchers searched CINAHL plus, Medline, Scopus, Science Direct and Proquest databases for studies conducted with adult population, qualitative research and articles published in English language in 2008-2018. The keywords included recovery, rehabilitation, experience, acute coronary syndrome, and myocardial infarction. This review used Preferred Reporting Items for Systematic Reviews and Meta Analysis (PRISMA) guidelines. Studies were included if they were original articles assessing the patients’ experience of recovery from ACS. The researchers excluded reviews that did not explore patient experiences, e.g. the experiences of family, carers, nurses, and partner following the spouse’s coronary attack.

Results

There were 252 papers found from five databases: 43 papers from Scopus, 15 from CINAHL plus, 46 from MEDLINE, Science Direct 8 papers and Proquest 140 papers. There were 189 papers which were excluded because of irrelevant studies. There were 21 papers that met the inclusion criteria after a review based on abstract and full text.

Twenty-one qualitative studies published during 2008-2018 were identified exploring the experience of recovery after ACS or MI. Six studies were conducted in Australia,\textsuperscript{6-11} five in Sweden,\textsuperscript{4,12-15} three in USA,\textsuperscript{16-18} two in Norway,\textsuperscript{19,20} two in Denmark,\textsuperscript{21-22} one in Ireland,\textsuperscript{23} and one in the United Kingdom.\textsuperscript{24} These studies involved a total of 438 participants post-ACS/MI including (270 women, 168 men), and seven mentors. Sample size was ranging from eight to 130.

Data collection used a variety of interview techniques with age ranging from 40-90 years. Various qualitative designs were used, including phenomenology, grounded theory, and case study. The majority of interviews were conducted at the participant’s home and in hospitals, which lasted between 20 and 120 minutes.
Discussion

Women’s views of their MI were complex and diverse. The basic psychosocial problems were: changing patterns of fear (fear of living with heart disease, fear of death and fear of recurrence), anxiety, and uncertainty.

The basic psychosocial process to resolve the conflict is living a new normal: uncertainty in seeking help (indecisiveness; self-treatment; emerging perception), rapid changing, evolving patterns (confronting mortality; avoidance; readjustment, reminiscing the past) and spiritual solace. Patients were motivated to change their lifestyle and contemplated taking their life in new directions, adopting a change of life perspective, finding a meaning in what had happened and managing consequences of MI. Individual perceptions of patients’ lifestyle and support, one year after an AMI, with or without mentorship, had similarities and tendencies to variation in their perceptions, with both a positive and negative view of life.

The lived experience of individuals in cardiac rehabilitation who have positive outlooks on their cardiac recovery includes choosing life over death, learning to live a new self, and a life-transforming cardiac event. Choosing life over death describes an increased awareness of mortality that leads individuals to make improvement in their health a priority. Learning to live a new self was used to describe participants’ experience of changing their lifestyle and the usage of facilitators to overcome barriers. All of the participants described cardiac rehabilitation as one of the important first steps toward successful cardiac recovery. Some participants described their cardiac event as a life-transforming experience, despite the negative effect of cardiac event on the participant’s life.

Both men and women have recovery experiences after ACS. The women’s recovery process is a multidirectional process with a desire to develop and approach a new perspective on life, including engaging in activities (behavioral dimension), appreciating social life (social dimension: how women receive and give support in their social environment) and psychological (their way of thinking, reflecting, and appreciating life), and mobilizing own resources. The experiences of midlife women who survive MI and return home to recover included freedom/un-freedom, knowing/not knowing. Not only the women, the men also have awareness that life is lived forwards and understood backwards. The myocardial infarction causes limitations in their lives even five years after the MI. The women experience physical restrictions, fatigue and also other health complaints. Furthermore, the older women suffer from various co-morbidities.

Conclusions

Transition to recovery is a phased psychological process and where people gradually accept the details of the new situation and the changes that come with it. Further studies are strongly recommended to research to improve intervention strategy among people post-ACS, especially in developing countries.

ABSTRACT

HIV/AIDS is a disease that weakens the immune system, causes opportunistic diseases, and increased morbidity and mortality. Since the beginning of its discovery, the HIV/AIDS epidemic now has spread and infected all countries. There are still many people living with HIV/AIDS (PLWHA) neglecting to prevent transmission of HIV infection. Prevention of HIV transmission is a serious challenge and it is important to reduce new infections. Not many people with HIV positive status are willing to tell their partners, and this has the potential to infect others. This cross-sectional study is aimed to identify the relationship between factors of knowledge and spirituality with the prevention behavior of HIV/AIDS transmission by PLWHA, and recruited 100 PLWHA in Jakarta. The results of bivariate analysis through the chi-square test concluded that there was no relationship between knowledge and the prevention behavior of HIV/AIDS transmission, and there was a significant relationship between spirituality and prevention behavior of HIV/AIDS transmission. Therefore, the spirituality aspect of PLWHA needs to be considered by the health team to behave positively in the prevention of HIV/AIDS transmission.

Keywords: Knowledge, Spirituality, Prevention Behavior of HIV/AIDS Transmission

Introduction

HIV/AIDS is a disease that weakens the immune system, creates vulnerability to opportunistic infections, and threatens morbidity, and is main cause of death.\textsuperscript{1,2} UNAIDS stated that no country in the world is free from HIV/AIDS.\textsuperscript{3}

The first HIV case was reported more than 35 years ago has since caused 36.7 million of the world’s population to live with HIV and more than 35 million die from AIDS.\textsuperscript{4} The Indonesian Ministry of Health in 2017 reported that, as of March 2017 the highest number of HIV infections was in Jakarta (46,758), followed by East Java (33,043), Papua (25,586), West Java (24,650), and Central Java (18,038), with a cumulative number of 242,699 cases. Whereas most AIDS was in East Java (17,014), Papua (13,398), Jakarta (8,769), Bali (6,824), Central Java (6,531), West Java (5,289), North Sumatra (3,897), South Sulawesi (2,812), Kalimantan West (2,597), and East Nusa Tenggara (1,959), with a national cumulative number of 87,453 cases.\textsuperscript{5}

According to the Pelita Ilmu Foundation report in 2017, there were 3064 PLHIV living with HIV at the foundation, of whom 2658 were still alive, and 406 had died. The foundation develops four types of programs, including prevention programs, health services, and support for people with HIV. Prevention programs consist of reproductive health education and AIDS in schools; guiding teenagers in the community; guiding street children and adolescents; prevention of mother-to-child transmission (PMTCT); reproductive health education and AIDS for children in prison; community-based drug prevention; counseling for prospective workers; and AIDS campaigns in public places. Whereas VCT programs and health services include HIV testing and counseling (VCT) services for risk management; adolescent health clinic services; family clinic services (general, women and children); and VCT and CST for prisoners.\textsuperscript{6}
Support programs for PLWHA are carried out with a variety of activities, including Ramadhan studies for PLWHA Muslims, and night contemplation is carried out regularly. In the evening, service events are held by experts, such as theater of love and education about the latest information about HIV/AIDS. “Memorial Temple” is one of the activities attended by PLWHA and their families. In the “Memorial Temple”, the ODHA family draws on a canvas about the daily activities or ordinary work done by PLWHA. All programs are dedicated to the vision of the foundation, namely to create a society that behaves healthily independently and with broad insight so that it can lead a productive and quality life.6

PLWHA can be at high risk of transmitting HIV, both consciously and unconsciously. An investigative report has proven that. From 1997-2009, an ODHA man in Texas carried out “attacks with deadly instruments in the form of body fluids” to 13 women he dated, so that all of them were tested positive for HIV. Five of the 13 women reported to the police and testified in court, until finally the man was found guilty of crimes and the Texas court sentenced him to 45 years in prison.7

Other factors also play a role, namely the negative environmental response, including ODHA families, can provoke anger among PLWHA and encourage deliberate transmission of the virus. In addition, it can reduce the desire of individuals to take HIV tests, have safe sex, access to health services, and to adhere to ARV therapy.

Efforts to deal with the endemic of HIV/AIDS through increasing public knowledge are carried out by many parties, including HIV/AIDS activists, governments, and non-governmental organizations, including the involvement of religious leaders and religious organizations. The CDC, on its website, informs about prevention of HIV infection with five strategies, including abstinence, limiting sexual partners, not sharing needles, using condoms properly, using HIV prevention drugs and post-exposure prophylaxis. The most important thing is to take antiretroviral drugs, because you can stay healthy and, if you have an HIV-negative sex partner, it can be effective without the risk of transmitting it.8

Millions of information about HIV/AIDS can be accessed through the Google search engine. By using HIV/AIDS keywords, there were 261,000,000 information content, with 139,000,000 HIV/AIDS prevention keywords, and with HIV/AIDS transmission, there were 23,700,000 information content.7,9 HIV/AIDS prevention efforts also involve the Faith Based Organization (FBO), both related to prevention, transmission and care in a socio-cultural perspective.

In-depth interviews and observations of phenomena in Central and Bali found that the involvement of religious institutions and leaders in the prevention of HIV/AIDS has strategic values, both directly and indirectly. These different regions have shown changes in discourse and practice regarding the issue of HIV/AIDS, both among religious leaders and the wider community.10 Involvement of spiritual values as a foundation of faith that will fortify oneself from behaviors that are at risk of contracting and transmitting HIV to and from other people around them.10 The involvement of religious institutions and figures is expected to instill spiritual values as a foundation of faith that will fortify themselves from behaviors at risk of transmitting HIV to others.

Indonesia is known as a country with the fastest increasing HIV/AIDS prevalence. New infections are still high, between 20,000-25,000 cases per year. This means that the threat of HIV/AIDS is still serious and requires continuous action.10

The high addition of new infections requires an approach, not necessarily from the view of the medical field, but also social and cultural. Realizing the importance of this, wherein religion and its characters are important elements that influence society, the government has since involved the Ministry of Religion to integrate the issue of HIV/AIDS.

Public education and the involvement of religious institutions and figures have broadened the HIV/AIDS intervention effort not only in order to increase knowledge about HIV/AIDS, but also to build the spiritual quality of PLWHA and the community as a bastion against risky behavior. However, the factors of knowledge and, especially, spirituality in relation to the prevention behavior of HIV transmission are more regarded as opinions than evidence. This research found new findings (evidence) that show a positive relationship between the two factors mentioned above to prevent HIV transmission among the PLWHA. Therefore, this study is intended to explore the relationship between the factors of knowledge and spirituality of HIV/AIDS transmission among PLWHA.
Method

Study Design, Setting, and Sampling: This descriptive correlation study involves about 2,658 HIV/AIDS population in the Pelita Ilmu Foundation at Jakarta. The total sample of 100 clients was obtained through purposive sampling with the criteria of respondents as PLWHA, aged over 18 years, able to write and read, in a conscious state, and willing to participate in research. Data collection was done using a questionnaire that has been tested for validity, and includes three main aspects, namely: 1) knowledge of HIV/AIDS transmission (Cronbach’s alpha: 0.368), 2) instruments of spirituality level of PLWHA (Cronbach’s alpha: 0.692), and 3) behavioral instruments to prevent HIV/AIDS transmission (Cronbach’s alpha: 0.606).

Data Analysis: Descriptive statistics method was employed to analyze the data. Univariate analysis is intended to determine the frequency and percentage of each variable, while bivariate analysis uses the chi-square test to test the differences between the two groups of categorical data in order to see the significance of their associations.

Result

1.1 Demographic data of respondents

Table 1: Frequency distribution of respondents based on the demographic characteristics of respondents (n = 100)

<table>
<thead>
<tr>
<th>Variable</th>
<th>Categories</th>
<th>F</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age</td>
<td>20-30</td>
<td>25</td>

<td>31-40</td>
<td>47</td>
<td>47</td>
</tr>
<tr>
<td></td>
<td>41-50</td>
<td>25</td>
<td>25</td>
</tr>
<tr>
<td></td>
<td>51-60</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>

The results of the univariate analysis in Table 1 above show that, based on age, the majority of PLWHA are the age group 31-40 years (47%), generally men (59%), with senior high school education (58%), married (66%), with a background in the employment of private employees (36%), and, based on religion, the majority are Muslim (94%).

1.2. Relations between variables

Table 2: Relationship between knowledge level and prevention behavior of HIV/AIDS transmission (n = 100)

<table>
<thead>
<tr>
<th>Level of knowledge</th>
<th>Prevention behavior of HIV/AIDS transmission</th>
<th>Total</th>

<td>24</td>
<td>85.7</td>
<td>4</td>
</tr>
<tr>
<td>Total</td>
<td>94</td>
<td>85.4</td>
<td>9</td>
</tr>
</tbody>
</table>

The results of the analysis of the relationship between the level of knowledge and the behavior of prevention of HIV/AIDS transmission found that there were as many as five (6.9%) PLWHA who had a good level of
knowledge, and behaved positively in the prevention of HIV/AIDS transmission, while, among PLWHA with moderate levels of knowledge, there were four (14.3%) PLWHA, who behaved positively in preventing HIV/AIDS transmission. The results of the statistical test obtained a value of \( p = 0.262 \), thus, it can be concluded that there is no relationship between the level of knowledge and the behavior of prevention of HIV/AIDS transmission.

### Table 3: Relationship between spirituality level and prevention behavior of HIV/AIDS transmission (\( n = 100 \))

<table>
<thead>
<tr>
<th>Level of spirituality</th>
<th>Prevention behavior of HIV/AIDS transmission</th>
<th>Total</th>
<th>P Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Negative</td>
<td>Positive</td>
<td>n</td>
</tr>
<tr>
<td>High</td>
<td>7</td>
<td>29.2</td>
<td>17</td>
</tr>
<tr>
<td>Moderate</td>
<td>2</td>
<td>2.6</td>
<td>74</td>
</tr>
<tr>
<td>Total</td>
<td>9</td>
<td>91</td>
<td>100</td>
</tr>
</tbody>
</table>

The results of the analysis of the relationship between the level of spirituality and the preventive behavior of HIV/AIDS transmission were obtained. There were 17 (70.8%) PLWHA who had a high level of spirituality, behaving positively in preventing HIV/AIDS transmission, while, among PLWHA with moderate levels of spirituality, there were 74 (97.4%) PLWHA who behaved positively in preventing HIV/AIDS transmission. The results of the statistical test obtained a value of \( p = 0.001 \), thus, it can be concluded that there is a significant relationship between the level of spirituality and the behavior of prevention of HIV/AIDS transmission.

### Discussion

The statistic test results between the variable level of knowledge and the prevention behavior of HIV/AIDS transmission showed no relationship between the two variables. The results of this study are in line with study that argues that high levels of HIV knowledge, are not enough to reduce the risk of sexual behavior, and consuming alcohol may increase sexual relations at high risk in the female population. Likewise, other study suggests that there is no significant relationship between the level of knowledge of HIV/AIDS and adolescent attitudes toward premarital sexual behavior. The same thing was also concluded by Astuti, who stated that there was no relationship between knowledge of HIV/AIDS and attitudes toward prevention of HIV/AIDS transmission. There are still possible other factors that influence the prevention behavior of HIV/AIDS transmission among PLWHA, including the strong peer influence. Eighty-seven percent (24) of respondents with low knowledge had negative behaviors in the prevention of HIV/AIDS transmission, and are at risk of transmitting to others, as the results of a study suggest that people with low HIV knowledge have a 47% higher chance of having sex under the influence of alcohol and have a 40% chance of having unprotected sex with their last three sex partners.

The results of statistical tests between variables of spirituality level and prevention behavior of HIV/AIDS transmission concluded that there was a relationship between the two variables. The spiritual values contained in religious teachings are a span of daily behavior, including understanding of commands such as in the Holy Qur’an: “And cooperate in righteousness and piety, but do not cooperate in sin and aggression. And fear Allah; indeed, Allah is severe in penalty.” This value is believed by the people and is a guide for them to avoid behaviors such as unauthorized and risky sexual relations, as a sin and violation, which will bring consequences if violated.

Adultery or sexual intercourse outside of marriage by changing partners is very high risk of transmission of HIV/AIDS. The prohibition on adultery is very real and firm: “And come not near unto adultery. Lo! it is an abomination and an evil way.” Likewise, the warning as well as the threat that states: “And those who cry not unto any other god along with Allah, nor take the life which Allah hath forbidden save in (course of) justice, nor commit adultery – and whoso doeth this shall pay the penalty.”

The spiritual values above clearly explain that adultery is forbidden, if a Muslim who obeys with a
high level of spirituality can have a greater chance of behaving positively toward the prevention of HIV/AIDS transmission, this can also prove the need for spiritual support for PLWHA. This is in line with Stacy, who conducted a systematic review of 137 studies and concluded that the level of risk of sexual HIV was lower among Muslims.16

Conclusion

The results of bivariate analysis through the chi-square test concluded that there was no relationship between knowledge with the prevention behavior of HIV/AIDS transmission, and there was a significant relationship between spirituality and prevention behavior of HIV/AIDS transmission. This research suggests that the healthcare team can facilitate services to increase knowledge about HIV/AIDS and improve the spirituality of PLWHA, which can be done through working with religious/spiritual institutions and figures such as clerics, clergy and others.

Ethical Clearance: The ethical approval for this study was granted by the IRB committee of the Faculty of Nursing at the Airlangga University in 2018.

Call for Papers / Article Submission

The editor invites scholarly articles that contribute to the development and understanding of all aspects of Public Health and all medical specialities. All manuscripts are double blind peer reviewed. If there is a requirement, medical statistician review statistical content. Invitation to submit paper: A general invitation is extended to authors to submit papers papers for publication in IJPHRD.

The following guidelines should be noted:

• The article must be submitted by e-mail only. Hard copy not needed. Send article as attachment in e-mail.
• The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
• As a policy matter, journal encourages articles regarding new concepts and new information.
• Article should have a Title
• Names of authors
• Your Affiliation (designations with college address)
• Abstract
• Key words
• Introduction or background
• Material and Methods
• Findings
• Conclusion
• Acknowledgements
• Interest of conflict
• References in Vancouver style.
• Please quote references in text by superscripting
• Word limit 2500-3000 words, MSWORD Format, single file

All articles should be sent to: editor.ijphrd@gmail.com

About the Journal

Print-ISSN: 0976-0245  Electronic - ISSN: 0976-5506, Frequency:  Monthly

Indian Journal of Public Health Research & Development is a double blind peer reviewed international journal. The frequency is half yearly. It deals with all aspects of Public Health including Community Medicine, Public Health Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, Public Health Laws and covers all medical specialties concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and south east Asia.

The journal has been assigned international standards (ISSN) serial number and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases.
