</tr>
</tbody>
</table>
All of indicators of action category were low (Table 5). Most of reason why structural official of district health office in West Lombok District did not disseminate DHA document was they thought that it was not their obligation but it was obligation of program section in district health office.

The utilization of DHA document was low because the structural official in West Lombok and Central Lombok District Health Office stated that they had never seen DHA document. Another low indicator was archives of DHA document because they stated that DHA document was only archived at program sub-unit. Furthermore, the study also found that dissemination of DHA information to the structural official of District Health Office was ineffective and none of structural official followed the AIDA stage in chronological order.

Table 6 depicted that all of the structural official of District Development and Planning Agency were aware about the benefit of DHA. However, their interest to find out more information about DHA was lower than their awareness. There was 100% of structural official of development planning agency of West Lombok District and 50% of structural official of development planning agency of Central Lombok District that categorized into...
uninterested category. The structural official of West Lombok District stated that there was not coordination between District Development and Planning Agency and District Health Office about DHA program. Therefore, they did not have any interest on DHA document.

In addition, the desire to leverage DHA document in both districts was 100% for structural officials of District Development and Planning Agency because they were supported by their good perception about DHA. Result shows that there were 50% of structural officials of development planning agency of Central Lombok District which utilized DHA document. There was none of the structural officials of development planning agency of West Lombok district who utilized DHA data or document because they stated that they had never seen DHA data or document due to lack of coordination. The study found that there was only one structural official of Central Lombok District Development and Planning Agency who followed the AIDA model in chronological order. It showed that the information dissemination about DHA was ineffective in the structural official of District Development and Planning Agency.

Awareness was the stage when people aware with product or service. This stage also was known as knowledge level\(^7\). Awareness of respondents with DHA program was supported by their knowledge of DHA. Furthermore, it also supported by their education background which related to health sector or health account. As mentioned by Notoatmodjo\(^8\), education background was one of factor which influenced people awareness.

Interest was the stage when people response to the information, the product or the service through their emotion, specific feeling or mood\(^9\). The result of this study showed that not all of the respondents interested with DHA program. People were aware with the product or service but they did not have interest to find out more information about the product or the service\(^10\).

Desire stage was also in the affective stage. This stage when people had desired to use or to buy the product or the service. Action was the stage when people fulfill their desire. The result showed that desire of all respondents in DHA program was higher than their interest. This condition was supported by Notoatmodjo\(^8\) that attitude did not reflect people action and vice versa.

The study found that there was none of DHA team member in both districts who followed AIDA stage in chronological order. According to Rawal\(^11\) dissemination of information was effective if people followed AIDA stage in chronological order. This meant that dissemination information about DHA in DHA team was not effective.

**Conclusion**

Based on the study, it can be concluded that the low utilization of DHA document were caused by several factors in DHA Team, District Health Office, and District Development and Planning Agency. Result showed that the technical ability and knowledge of DHA Team still categorized as average. Research also showed that the structural official of District Health Office and District Development and Planning Agency mostly never attend DHA training, there were low district regulation which support utilization of DHA, most of DHA Team and the structural officer of DHO and District Development and Planning Agency was uninterested and inaction regarding DHA document, and lack of information dissemination of DHA document.

According to study result and discussion, this study suggested that it was needed to increase role of member of DHA team in both districts in order to increase their action to utilize DHA document. Besides, they should optimize the information dissemination about DHA to the structural official of district health office and the structural official of development planning agency in both districts in order to increase their interest on DHA. Last, coordination with District Development and Planning Agency was needed in order to increase stakeholder action to utilize DHA document.

The Analysis Distribution of Filariasis Vector in Sanggu Village, Southern Barito District

Luqman Nur Hakim¹, Globila Nurika¹
¹Magister Program of Environmental Health, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

One of filariasis endemic area is located in South Barito, Central Kalimantan, and Indonesia. Finger blood surveys were first conducted in 2004 in Sanggu with 1.34% f rate. The objective of this study is to analyze the spread of filariasis vector in Sanggu, South Barito. The sample of this study is all of the mosquitoes which caught inside and outside the houses which come from 3 point of research location that includes settlement like forest, swamp and lake. The results showed that there are number of species of mosquitoes. Culex sp were found outside and inside the house and 5 species of mosquitoes were; Mansonia sp, Culex sp, Anopheles sp, Aedes aegypti and Aedes albopictus found near in the swamp, lake and forest. The conclusion of the study showed that the most caught mosquito species were Culex Sp and Mosquito as filariasis vector that is inside the house of 12 heads / person / hour and outside of house is 27.2 tail / person / hour. These could be influenced by the temperature and humidity in the village ranging from 24 ℃ - 28 ℃ and 84% - 90%. The prevention could be done by socializing the discovery of chronic filariasis sufferer, spraying, collecting data of chronic filariasis patient, keeping the house always clean, cleaning environment; cutting shrub or tree and its branches so that sunlight could shine the entire house.

Keywords: Filariasis, vector, Culex sp

Introduction

Filariasis or elephantiasis disease is a chronic infectious disease due to parasitic infection of the nematode group that attacks the human lymphatic system directly. [1]. Filariasis disease which occurring in Indonesia is filariasis of lymph nodes. [2], the very complex factors are caused this disease which includes the worms as the agents, humans as the host, and adult mosquitoes as the vectors. More than 1.4 billion people in 73 countries are at risk of being infected with filari worms. Approximately 65% of the infected are in the Southeast Asian region, 30% in the African region, and remains are in the tropics. Lymphatic filariasis causes more than 25 million men with genital disorders and more than 15 million people with lymph oedema. [3].

There are three species of filariasis-causing worms: Wuchereria bancrofti, Brugia malayi, and Brugia timori. All of these species are existed in Indonesia, but more than 70% of filariasis cases in Indonesia are caused by Brugia malayi [4,5]. From the data reported in 2002-2014 cumulatively there are 14,932 chronic cases of filariasis cases spread in 418 districts / cities in 34 provinces in Indonesia. While the highest defect cases is in East Nusa Tenggara with 3,175 cases in 20 districts / cities [6].

In 2014, there are cases of chronic filariasis as 227 cases from 14 districts / cities in Central Kalimantan Province which classified as endemic filariasis and one of them is located in South Barito. [6]. The filariasis morbidity highest case of South Barito is located in Sanggu Village with the ratio 11 per 100,000 populations with Mf rate of 1.1%. B. Malayi microfilaria was found[7]. In 2016, 6 positive people were found as another new case of filariasis in Sanggu village which not as much as in 2014 [7]. Sanggu village has a total area of 5,800 ha / km2, 2,152 ha / km2 of forest, 300 ha / m2 of swamps, rivers / lakes with 30 hectares of land and a rice field of 800 ha / m2 [8,9] which resulting to be a place of mosquitoes habitat to live and cause filariasis disease.

The purpose of this research is to analyze the spread of filariasis vector in Sanggu Village, South Barito.
Material and Method

The study sample was all mosquitoes which caught inside and outside the home. Sampling was conducted at 3 points on settlements such as forests, swamps and rivers / lakes located in Sanggu Village, South Barito Regency. The Parameters used in this study to measure filariasis vector density are as follows: [10,11,12,13]:

- Man Biting Rate (MBR).
- Man Hour Density (MHD).
- Abundance Relative.
- Figures Frequency.
- The species domination number.

Finding

The results of mosquitoes caught is conducted on 3 houses in Sanggu Village with inside and outside the house using aspirator located in swamp, lake, and forest are as follows:

Number of mosquito species inside and outside the house

Swamp area, indicating that the mosquitoes caught outside the house amounted to 14 consisting of 3 species; Mansonia sp, Culex sp and Aedes sp. The highest number was Culex sp total with 8 (57.14%) and the lowest catch was Aedes sp with 2 (14.3%). While in the house amounted to 1 consists of 1 species, namely Aedes aegypti (100%).

Lake area showed that the mosquitoes caught outside the house numbered in 44 consisting of 5 species; Mansonia sp, Culex sp, Aedes aegypti, Aedes albopictus and Anopheles sp. The highest number of catches was Culex sp total with 18 (40.9%) and the lowest catch was Anopheles sp with 3 (6.8%). While in the house amounted to 15 consisting of 4 species; Mansonia sp, Culex sp, Aedes aegypti and Anopheles sp. The highest number of catches was Culex sp totaling 6 (40%) and the lowest catch was Mansonia sp with 1 (13.3%).

Forests area, indicating that the mosquitoes caught outside the house amounted to 10 tails consisting of 2 species; Culex sp and Aedes aegypti. The highest number of catches was Aedes aegypti (9%) and the lowest catch was Culex sp (1%). While in the house amounted to 14 tails consisting of 3 species; Mansonia sp, Culex sp, and Aedes aegypti. The highest number of catches was 8 culex sp (57.1%) and the lowest catch was Aedes aegypti with 1 (13.3%).

Relative abundance, frequency and species dominance

In the house near the swamp found the dominance of the mosquito is Aedes aegypti with the acquisition of the dominance is 8 and with the frequency value is 0.08. Then the house near the lake obtained the highest dominant number of mosquitoes namely Culex sp and Aedes aegypti with the acquisition of the dominance is 20 and with the frequency value is 0.5, while the lowest dominant number of mosquitoes in the house is Mansonia sp with the acquisition of the dominance is 0.53 and with a frequency value of 0.08. The house near the forest obtained the highest mosquito dominance in the house is Culex sp with the acquisition of the dominance number is 34.2 and with the frequency value is 0.6, while the lowest dominant number of mosquitoes in the house is Aedes aegypti with the acquisition of dominance is 0, 57 and with a frequency value of 0.08.

Population Density

Inside the house (Indoor) near lake, the mosquito population density is caught inside the home of each person / h. The highest catching species of mosquitoes
are Culex sp and Aedes aegypti with 9.09 individuals per hour and the lowest catch is Mansonia sp with 2 per person per hour.

Outside the house (Outdoor) near the lake, the population density of mosquitoes caught outdoors each person/hr mosquito species with the highest catch is Culex sp with 27.2 for each person per hour and the lowest catch is Anopheles sp with 4.6 per person per hour.

**Mosquitoes Biting Activity Patterns**

Inside the house, it was found that the highest peak fluctuation is Mansonia sp caught with human baiting inside the house at 24.00 - 01.00 WIB (western Indonesian time) and Aedes sp caught with human baiting inside the house at 03.00 - 04.00 WIB located in the forest. The details are shown as follows, the highest fluctuation of Mansonia sp is at 24.00-01.00 WIB ie 7.57, Culex sp the highest peak of fluctuation is at 23.00-24.00 WIB ie 4.54, Aedes sp’s peak fluctuation is at 05.00-06.00 WIB ie 4.54 and Anopheles sp’s the highest peak of fluctuation is at 23:00 to 24:00 pm with 3.03.

Outside the house, the highest fluctuation of Aedes sp caught with human baiting is at 02.00 - 03.00 WIB located in the lake. The highest fluctuation of Aedes sp is at 02.00 - 03.00 WIB ie 12.1; Culex sp is at 02.00 - 03.00 WIB ie 7.57, Mansonia sp at 19.00 - 20.00 WIB ie 3.03.

**Environmental conditions**

Swamp, the environmental condition of Sanggu village is adjacent to the swamp of the waste water discharged directly to the soil, the number of trees and the existence of wild plants like bushes around the house, so it could support mosquito’s breeding which cause filariasis, besides, the optimum temperature conditions is 25- 28 °C and 84-90% humidity. Thus, a moist condition could also affect mosquito growth.

Lake. the environmental conditions of Sanggu villages is located around the lake which known as a plenty of water plants such as water hyacinth, therefore, it could support mosquito’s breeding, in addition, the optimum temperature conditions is ranging from 26-28 °C and the humidity level is 84-89%.

Forest. the environmental conditions of Sanggu village is close to the forest which known as much lushes, trees and puddles (which favoured by mosquitoes). It could support mosquito’s breeding, besides, the optimum temperature condition ranges from 26-28 °C and 84-89% for humidity’s level.

**Discussion**

The species of mosquito Mansonia sp and Culex sp:

**Mansonia sp**

These mosquitoes are always caught either by using human baiting outdoors which close to the swamp. The species of mosquitoes were found outside the house with the highest fluctuation at 19.00 - 20.00 WIB (3.03%) and the lowest fluctuation at 04.00 - 05.00 WIB (1.51%). The mosquitoes are very fond of a full water area with a water plants such as hyacinth, located in lake. In the house around the lake, found this mosquito species with the highest fluctuation at 22.00 - 23.00 WIB (1.51%) and in outdoors, found this species of mosquitoes with the highest fluctuation at 04.00 - 05.00 WIB (3.03%). As for the mosquito in the forest, they are very fond of a place with much of trees lush, especially if the tree has a cavity-range on the trunk. Inside the house around the forest, found the mosquito species with the highest fluctuation is at 24.00 - 01.00 WIB (7.57%). These circumstances is due to several factors, called temperature and humidity that support mosquitoes activity or biting with 25 °C temperature and 90% humidity level. Thus, it could affect mosquito’s activeness. And also 60% moist’s level is the lowest limit for mosquito to life.

**Culex sp**

These mosquitoes are active throughout the night and are always caught either by using human baiting outdoors or close to the swamp. This mosquito species was found outside the house near the swamp with the highest fluctuation at 22.00 - 23.00 WIB (6.06%) and the lowest fluctuation at 04.00 - 05.00 WIB (1.51%). This mosquito is also located in a lot of water plants such as water hyacinth. In the house around the lake, found the mosquito species with the highest fluctuation at 23.00 - 24.00 WIB (4.54%) and outdoors, found this species of mosquitoes with the highest fluctuation at 02.00 - 03.00 WIB (7.57%) and lowest in the hours before its 21.00 - 22.00 WIB (3.03%). This mosquito is also located in the area much of lush trees, and has cavities on the trunk. Inside the house near the forest, mosquito species are found the highest fluctuation at 02.00 - 03.00 WIB (4.54%), outdoors; the mosquitoes
are with the highest fluctuation at 23.00 - 24.00 WIB (1.51%). These circumstances is due to several factors, called temperature and humidity that support mosquitoes activity or biting with 25 °C temperature and 90% humidity level. Thus, it could affect mosquito’s activeness. And also 60% moist’s level is the lowest limit for mosquito to life.

Factors affecting mosquito communities:

1. Population Density

The mosquito population in the house of each person / hour of Aedes aegypti mosquito species is 2 amounts/person / hour near the swamp. Mansonia sp with 2 amounts/ person / hour, Culex sp with 9.09 amounts/ person / hour, Aedes aegypti with 9.09 amounts / person / hour and Anopheles sp 3.03 amounts/ person / hour near the lake. And found Mansonia sp with 7.6 amounts / person / hour and Culex sp with 12 amounts/ person / hour.

2. Figures of frequency and dominance of mosquitoes

The largest frequency number of Mansonia sp mosquitoes inside the house was 0.41 also in the forest and outdoors, and 0.41 near the lake. While the largest frequency number of Culex sp mosquitoes is 0.6 located in the forest and outdoors, 0.66 is located in the swamp. The largest dominant number of Mansonia sp mosquitoes in the 14.63% house located in the forest and outside of the house 8.43%. While the dominant number of Culex sp mosquitoes inside the house is 34.2% located in forest and out of house, 61.3% is located near the lake.

Frequency rate is the ratio between the numbers of species of mosquitoes found in the capture to the number of arrests which means the most species of mosquitoes found in the 12 hour arrest. The dominant figure is the product of the multiplication of relative and the mean frequency is the acquisition of the numbers obtained in the most dominant (high) mosquito species that bite humans.

Since the vaccine for prevention does not yet exist, thus, the only way to prevent is to avoid getting bitten by mosquitoes. Since the mosquitoes are very large in amount and widespread, this effort needs to be done by the whole community by doing as follows:

1. Clean the sewer / gutter
2. Maintain fish in ponds
3. Wear bed nets when sleeping
4. Apply the medicine or cream anti mosquitos

The treatment could use diethylcarbamazine citrate (DEC, Banocide®, Hetrazan®, Notezine®); Given DEC 3 x 1 tablet 100 mg for 10 consecutive days and paracetamol 3 x 1 tablet 500 mg in the first 3 days. This treatment has been shown to be more effective when followed with once-daily treatment with low-dose DEC (25-50 mg / kg BW) for 5 consecutive years or salt consumption given DEC (02-0.4 mg / kg BW) during 5 years.

Conclusion

The highest mosquito population density inside the house is Culex sp with 12 amounts/ person / hour located in the forest, while the lowest is Mansonia sp for 2 amounts / person / hr located in the lake. The highest population density of mosquitoes outside the house is Culex sp with 27.2 amounts / person / hr located near the lake, again, while the lowest is Culex sp with 2 amounts/ person / hour but located in the forest. There are 5 (five) species of mosquitoes caught at the time of research inside and outside the house, namely Mansonia sp, Culex sp, Anopheles sp, Aedes aegypti and Aedes albopictus. Species of mosquitoes caught at the time of the study were filariasis-transmitting vectors of Mansonia sp and Culex sp. While those that acted as filariasis transmission vectors were Culex sp most caught outdoors with 27.2 amounts / person / hr located in the lake.

Conflict of Interest: none

Relationship Between Knowledge, Attitude, and Stigma of Nurse Toward HIV/AIDS Mitigation on Dr. Doris Sylvanus Hospital Palangka Raya

Kristiani1, Husaini2, Erida Wydiamala3, Roselina Panghiyangani3, Eko Suhartono3
1 Master of Public Health Science, 2 Public Health Study Program, Faculty of Medicine, Lambung Mangkurat University, 3 Faculty of Medicine, Lambung Mangkurat University

Abstract

One of the obstacles prevention of HIV/AIDS is that the self-limiting from the nurses to people living with HIV. This study to analyze the relationship between knowledge, attitudes and stigma of nurse on HIV/AIDS prevention effort in dr. Doris Sylvanus General Hospital in Palangka Raya. This research used the quantitative research method with a cross sectional method. The study population was all nurses at inpatient and outpatient at dr. Doris Sylvanus General Hospital of Palangka Raya, with a sample of 174 respondents. The sampling technique used is purposive sampling. The research variables were nurse knowledge about HIV/AIDS, nurse attitude toward PLWHA and stigma nurse to PLWHA as independent variable and effort of HIV/AIDS prevention as dependent variable. The research instrument used was a questionnaire. Result got value p value knowledge = 0.000, p value attitude = 0.000, p value stigma = 0.000. The most dominant variable multivariate test results was knowledge obtained value Exp. (B) = 64.7. From the result proves that knowledge, attitude and stigma are variables on HIV/AIDS prevention efforts. Knowledge is the most influential variable on HIV/AIDS prevention efforts. There is a significant relationship between knowledge, attitude and stigma of the nurses have an effect on HIV/AIDS prevention efforts in dr. Doris Sylvanus General Hospital Palangka Raya.

Keywords: Level of Knowledge, Nurse, HIV/AIDS, Attitude, Stigma, PLWHA

Introduction

HIV-AIDS continuously increasing in Indonesia, and mostly attacks young and productive age. The number of HIV cases in 2015 that is 30,935, in 2016 is 41,250 people, an increase of 10,315 people with HIV. While in 2017 that is still 10 376 people HIV cases in the first quarter. The number of AIDS cases in 2015 is 7,185 people, and in 2016 that is 7,491 people, an increase of 306 cases of AIDS. While the year 2017 still 7 people AIDS cases in the first quarter. Central Kalimantan Province consists of 13 districts and 1 city. The total number of HIV cases in 2015 is 134 people, in 2016 that is 141 people, there is an increase of HIV cases that is 7 people. While the year 2017 in the first quarter is still 13 people HIV cases. For the case of AIDS in 2015 that there are 26 people, in 2016 that is 59 people, an increase in AIDS cases 33 people. While the year 2017 still 7 people in the first quarter.

Data from the Central Kalimantan Provincial Health Office, HIV risk factors in 2017 were on the sex workers (9%), male likes (52%), transvestites (6%), customers (3%), couples (12%), -other (18%). Injecting Drug User (IDU) is drug misuse still not found (0%). Factors associated with increased cases are caused by sexual behavior in high-risk groups, community communities contributing to HIV transmission significantly.

DOI Number: 10.5958/0976-5506.2019.02091.6
of cumulative for HIV cases there are 215 people, AIDS case there are 105 people, O DHA who drink Antiretroviral (ARV) there are 53 people and who do not take medicine there is 1 person. Hospital dr. Doris Sylvanus is a type B hospital that is the Regional General Hospital (RSUD) of Central Kalimantan Province in Palangkaraya City. RSUD dr. Doris Sylvanus has a Voluntary Counseling and Testing (VCT) clinic and a Clinic Care Support and Treatment (CST). The presence of stigma in among people living with HIV that is done by the health officer that is nurse still often happened. Fear of contact with ODHA clients due to lack of knowledge about the mode of transmission of HIV and nurse attitudes toward PLWHA causes HIV-positive clients to refuse to be examined because they do not want to know that they are HIV-infected will be treated with stigma. Level of nurse knowledge at RSUD dr. Doris Sylvanus in Kota Palangka Raya, that is good nurse knowledge (17%) is sufficient (37%), less (46%), while nurse attitude toward HIV/AIDS prevention is good (56%), enough (30%), and less (14%). While HIV/AIDS prevention efforts in dr. Doris Sylvanus in Kota Palangka Raya is good (50%), enough (15%) and less (35%).

Materials and Method

The type of research conducted in this study is quantitative by using cross sectional method. Population in this research is all nurses in outpatient and inpatient in dr. Doris Sylvanus in Kota Palangka Raya consisting of 426 nurses. Sampling technique is purposive sampling. In order to balance the sample of each room is adequate, then the balance between the number of members of the population based on each room (proportional sampling). The sampling process was grouped in 43 rooms to determine the number of samples, with a total sample of 174 respondents. The independent variable are knowledge, attitude and stigma. The dependent variable is the HIV/AIDS prevention effort.

Findings and Discussion

Source: Primary Data, 2018

Based on Table 1, it is known that out of 162 (93.1%) have a good knowledge. This is because nurses know that HIV disease can be transmitted through mother to child. More than 90% of HIV-infected children are obtained from their mothers. Viruses can be transmitted from HIV-infected mothers to their children during pregnancy, during labor and breast-feeding. The purpose of Anti Retroviral (ARV) in pregnant women was 127 respondents (74.2%) answered correctly. This is due to the purpose of providing treatment Anti-Retroviral (ARV) in pregnant women is to prevent infection arising from a decrease in the maternal immune, improve the quality of life and reduce transmission from mother to child and to others. Prevent the progressivity of the disease and inhibit the decline in maternal immunity. The goal of ARV therapy is to reduce the rate of HIV transmission, reduce morbidity and mortality associated with HIV, restore and maintain immune function and suppress viral replication maximally.

Prevention strategy of transmission to pregnant mother with HIV to baby there are 120 respondents (68.9%). This is because the knowledge of nurses is still lacking on the strategy of transmission from HIV to child.
mothers. Prevention strategies of transmission from pregnant women with HIV to infants are early detection and ARV administration as early as possible (> 6 months at delivery). Prevention strategies for transmission of HIV-infected pregnant women to their infants are ANC services, HIV diagnosis, ARV therapy, safe delivery, management of infant and child feeding, delayed regulation of pregnancy, ARV and cotrimoxazole prophylaxis in children and diagnostic examination in children.¹

The results of this study are in line with research conducted by Muzayin (2013) which shows the existence of knowledge relation to HIV/AIDS prevention efforts in Boyolali District. Muzayin’s research results have a weak to moderate value. In the results of this study there is also a low knowledge of respondents. Still, low knowledge is made possible by the limited knowledge of HIV-AIDS that health professionals get through formal curricula during education.²

The Relationship Between Attitude Toward HIV/AIDS Mitigation

Source: Primary Data, 2018

From the data of attitude relationship analysis toward HIV/AIDS prevention efforts, it was found that as many as 5 people (4.0%) of respondents had less attitude, but HIV/AIDS prevention efforts were lacking. And as many as 148 people (85.1%) of respondents have a good attitude towards HIV/AIDS prevention efforts are good.

Based on the research result of the relationship between nurse attitude toward HIV/AIDS prevention efforts, where respondents good attitude toward HIV/AIDS prevention efforts either that is counted 148 respondent (85.1%). And it was found that as many as 5 people (4.0%) of respondents have less attitude, but HIV/AIDS prevention efforts are lacking. Attitude is a combination of affective, behavioral, and cognitive reactions to an object. Attitudes are a continuation of knowledge accompanied by a willingness and a tendency to act in accordance with that knowledge. Thus a positive attitude of health workers to people living with HIV will encourage them to act and behave a good role in HIV/AIDS prevention efforts.³

From data of research result got that as many as 6 people (3.4%) have positive stigma to ODHA, but counting effort less. And as many as 149 people (85.7%) of respondents have a positive stigma against good people living with HIV, but HIV/AIDS prevention efforts are good. This research uses several questions to measure positive stigma of nurses to PLHIV it can be seen that from 159 respondents who have positive stigma toward PLWHA who choose the statement of criterion agree, which ranks first is statement assuming that PLWHA deserve to get the same health service as other patient there are 160 responden (91.9%) agree. This is due to people living with HIV in the same way as patients in general. The right of PLWHA to obtain health insurance is a mandate of Law No. 40 of 2004 about National Social Security System. One form of social protection to ensure all people in order to meet the basic needs of his life. 

The fourth order of statements assumes that people living with HIV have the same rights as other patients there are 152 respondents (87.3%) agreed. The fifth ranking is the statement felt not afraid to provide care to patients who have tattooed his body because although I consider that people tattoo has a risk of HIV infection there are 139 respondents (79.8%) agreed. PLWHA who have tattoos will not transmit HIV, because of the transmission of HIV from sexual intercourse, syringes used interchangeably, sperm fluid and breast milk. HIV enters the body in three ways: sexual intercourse, non-sterile needle use or contamination of HIV, HIV transmission from an HIV mother to the fetus in the womb. 

The third order of revelation felt less comfortable when talking with people living with HIV/AIDS there are 97 respondents (55.7%) states disagree. This is due to the lack of positive stigma towards PLHIV feels less comfortable talking with PLWHA, HIV transmission is from sexual hambungan, sperm fluid, using a syringe alternately and from an HIV mother to her jan. HIV enters the body in three ways: sexual intercourse, non-sterile needle use or contamination of HIV, HIV transmission from an HIV mother to the fetus in the womb. 

The fifth sequence of the statement assumes that the food equipment used by people living with HIV is disgusting there are 91 respondents (52.2%) states disagree. This is due to the lack of positive stigma of nurses to PLWHA that the food equipment used by PLWHA can infect HIV. HIV enters the body in three ways: sexual intercourse, non-sterile needle use or contamination of HIV, HIV transmission from an HIV mother to the fetus in the womb. 

The results of this study are in line with Pujiono’s (2016) study indicating a relationship of knowledge and stigma to people living with HIV that the better the level of knowledge about HIV/AIDS then people tend to stay away from negative attitudes toward people living with HIV/AIDS then the person tends to be negative towards people living with HIV. 

This research is in line with research of Nurjanah (2016) stated health worker that tends to stigma and discrimination against people living with HIV that is 15 people (22.4%) and health worker who do not stigmatize and discrimination that is 52 people (77.6%). Stigma and discrimination due to lack of knowledge about HIV/AIDS transmission, treatment and prevention of HIV/AIDS.

Source: Primary Data, 2018

Based on the result of bivariate analysis, the three variables that are knowledge, attitude and stigma are qualified to be continued to multivariate test by multiple logistic regression test because p = 0.000 value to know which variable is the most dominant related to HIV/AIDS prevention effort to the respondent. Odd s ratio of nurse knowledge variable about HIV/AIDS = 64.7 which means that nurse knowledge about HIV/AIDS is good 64.7 times bigger chance in prevention HIV/AIDS, compared to the lack of nurse knowledge about HIV/AIDS. Knowledge is a cognitive domain that is very important formation of a person’s actions. If the adoption of a new behavior or the adoption of behavior is based on knowledge, then what is learned, among other things, the behavior will be lasting, otherwise if the behavior is not based on knowledge then it will not last long.³

Odd s ratio of nurse nurse attitude variable to PLHIV = 42.4 which means that nurse attitude toward good PLHIV 42.4 times bigger chance in HIV/AIDS prevention, compared with attitude of nurses to PLWHA less. Odd s ratio of nurses’ positive stigma variable to PLHIV = 28.7 which means that positive stigma of nurses to good people living with HIV/AIDS is 28.7 times bigger chance in HIV/AIDS prevention, compared to positive stigma of nurses to PLWHA less.

Conclusion

There was a significant correlation between knowledge of nurse with HIV/AIDS prevention in dr.Doris Sylvanus Hospital

There was a significant correlation between attitude of nurse with HIV/AIDS prevention in dr.Doris Sylvanus Hospital

There was a significant correlation between positive stigma of nurse with HIV/AIDS prevention in dr.Doris Sylvanus Hospital with knowledge as the most influential variable on HIV/AIDS prevention efforts (Exp. (B) = 64.7)

Ethical Clearance: Before conducting the data retrieval, the researchers conducted a decent test of ethics conducted at the Faculty of Medicine, Lambung Mangkurat University to determine that this study has met the feasibility. Information on an ethical test that the study is eligible to continue. The feasibility of the research was conducted in an effort to protect the human rights and security of research subjects.

The Comparison of Inflammation Response in Chronic Rhinosinusitis Patients with Nasal Polyp and Without Nasal Polyp: A Study on Interleukin 33 and Eosinophil Contents

Abdul Qadar Punagi¹, Renato Vivaldi Kuhuwael¹, Eka Savitri¹, Ilham Jaya Patellongi²

¹Department of Ear, Nose, Throat, Head-Neck Surgery, Medical Faculty, ²Department of Statistic, Faculty of Public Health, Hasanuddin University, Makassar, Indonesia

Abstract

Background: The research aimed to perceive the comparison of inflammation response (IL-33 and eosinophil contents) in chronic rhinosinusitis with nasal polyp and without nasal polyp, and the pathomechanism of nasal polyp incident on chronic rhinosinusitis.

Method: This was the cross sectional research with 40 patients. Each sample underwent IL-33 serum content examination, and nasal mucosa swab.

Results: The research result indicates that IL-33 serum contents were significantly higher (p <0.05) in patients with Chronic Rhinosinusitis without Nasal polyp than with Nasal polyps, While the number of eosinophils content in chronic rhinosinusitis with nasal polyps was significantly higher (p <0.05) than without nasal polyps

Conclusion: IL-33 has higher content on chronic rhinosinusitis without nasal polyp, IL-33 increases eosinophil content in chronic rhinosinusitis without nasal polyp, and the eosinophil has higher content on chronic rhinosinusitis with nasal polyp.

Keywords: Chronic Rhinosinusitis, Nasal polyp, Interleukin 33, Eosinophil

Introduction

Rhinosinusitis is a disease commonly found in everyday practice. In the United States according to the National Ambulatory Medical Care Survey in 2001 12.3 million health care visits were attributed to chronic rhinosinusitis (SSR) or 1.3% of total visits per year. Chronic rhinosinusitis is a problem for general practitioners and ear, nose, throat (ENT) experts given the complex etiology and high prevalence. In Europe, rhinosinusitis is thought to account for 10% to 30% of the population. In the United States in 1996, total health spending directly related to rhinosinusitis was estimated at 5.6 billion dollars. Of that figure, 58.7% (about 3.5 billion dollars) is related to SSR. It is estimated that 13.4-25 million doctor visits per year are associated with rhinosinusitis and / or its consequences. As many as 14% of the American population had at least one episode of rhinosinusitis during their lifetime and about 15% were estimated to have SSR. New rhinosinusitis incident in adult patients who came to the Rhinology Subdivision of ENT Department Cipto Mangunkusumo hospital January-August 2005 from 435 patients, 69 % (300 sufferers) suffered from rhinosinusitis, in Makassar from three teaching hospitals for the period 2003-2007 were reported as many as 41.5% of all cases handled by Rhinology Subdivision.¹,²,³,⁴

Chronic rhinosinusitis can be divided into two subtypes: chronic rhinosinusitis without nasal polyps and rhinosinusitis with nasal polyps. Both groups of rhinosinusitis differ in terms of inflammatory profiles and their remodeling processes, differences in these may affect prognosis, comorbid asthma, appropriate surgical procedures, and pharmacological management.⁵

Further research on T-helper (Th) cells has found that there is a role of Th cells in the pathogenesis...
of chronic rhinosinusitis with nasal polyps. Th cells themselves are divided into Th1 and Th2 based on the resulting cytokines. Th1 cells produce interferon (IFN)-γ. IFN-γ and Th1 cytokines increase defense against primary intracellular microbes, by activating neutrophils and macrophages. While Th2 cells are associated with eosinophil inflammation, and Th2 cells produce IL-4, IL-3, IL-33, and IL-13.

Chronic rhinosinusitis with nasal polyps often accompanied by eosinophilic inflammatory Th2 cells, whereas chronic rhinosinusitis without nasal polyps is characterized by most Th1 cell response. IL-33 is more abundant in chronic rhinosinusitis mucosal tissue with nasal polyp than without nasal polyps. Chronic polynomial rhinosinusitis is subdivided into two types of disease based on the level of eosinophilic inflammation, especially for people in East Asia: eosinophilic chronic rhinosinusitis (ECRS) and non-eosinophilic chronic rhinosinusitis (NECRS).

This study aims to see the inflammatory responses (IL-33 content) in chronic rhinosinusitis with nasal polyps and without nasal polyps and the pathomechanism of nasal polyps in chronic rhinosinusitis.

Method

Research Site:

This study was conducted in outpatient clinic of Dr. Wahidin Sudirohusodo Hospital, and other hospitals in Makassar, Molecular Biology Laboratory of education hospital Unhas, and Pathology Anatomy Laboratory of Education Hospital Unhas for period of January – March 2018

Design and Research Variables:

The design of this study is cross sectional with analytic observasional. The independent group of this study was patient with chronic rhinosinusitis without nasal polyp and with nasal polyp, while the dependent variable was the inflammatory response (IL-33 content).

Samples

The sampling technique was performed randomly. In this study all patients who have been diagnosed as chronic rhinosinusitis based on the history, the ENT diagnostic examination were undergone CT scan of paranasal sinus coronal view. The sample size is 40 patients were divided into 2 groups. Patients in the first group (20 patients) categorized as chronic rhinosinusitis with nasal polyps, and the second groups categorized as chronic rhinosinusitis without nasal polyps. Patients from both groups were examined for IL-33 serum content.

Exclusion Criteria:

Patients with severe systemic disease (kidney disease, liver disease, malignancy, autoimmune disease, and heart disease), sinonasal tumors, patients with a history of Endoscopic sinus surgery, severe septal deviation, septal perforation, rhinitis atrophy, serum sample lysis.

Statistical Analysis:

Data were analyzed using Statistical Package for Social Sciences (SPSS) software (version 23.0 for Windows; SPSS Inc, Chicago, IL).

Research Ethics Aspect:

The study permit was obtained from Biomedical Research Ethics Committee on Human Faculty of Medicine Universitas Hasanuddin (Register No. 31 / H4.8.4.5.31 / PP36-KOMETIK/2018).

Results

Characteristics

From a sample of 40 people, aged 21 to 40 years, with a mean age of 30.40 for chronic rhinosinusitis with nasal polyps and 31.70 for chronic rhinosinusitis without nasal polyps, and consisted of 15 men and 25 women.

</tr>
</tbody>
</table>

From table 5 shown that serum IL-33 content were positively correlated with eosinophil content. Although higher IL-33 content followed with higher eosinophil count but not significant correlation in the statistical. (p>0.05)

Tabel 6. Correlation between IL-33 content against eosinophils in chronic rhinosinusitis patients without nasal polyps

<table>
<thead>
<tr>
<th>Variable</th>
<th>Eosinophil Counts</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>n</td>
</tr>
<tr>
<td>IL-33 level</td>
<td>20</td>
</tr>
</tbody>
</table>

From table 6 shown that serum IL-33 content was positively correlated with eosinophil content (r = 0.427; p = 0.030), meaning higher serum IL-33 content, the higher the eosinophil counts.

Discussion

In this study, samples were obtained between the ages of 20 and 40 years, with a mean of 30.40 years in chronic rhinosinusitis with nasal polyps, and 31.70 years in chronic rhinosinusitis without nasal polyps. This is in accordance with the research of Chen Y, et al., 2003 where the prevalence of chronic rhinosinusitis increases at age 20-29 years and 50-59 years.

The number of chronic rhinosinusitis patients with nasal polyps and without nasal polyps consisted of 15 men and 25 women. The distribution of sex and age in both groups of chronic rhinosinusitis patients may be considered homogeneous (p>0.05).

Based on the data in table 2 it was shown that the serum content of IL-33 serum with chronic rhinosinusitis were higher than controls; respectively for serum IL-33 (Median 788.50 vs. 154.71), and the result is significant (p <0.05). This is consistent with Ozturun et al., 2015 which found that serum IL-33 content in chronic rhinosinusitis with nasal polyps were higher than those in the control group. The influence of IL-33 on upper respiratory epithelium has an important role in chronic inflammation associated with chronic rhinosinusitis with nasal polyps by increasing the cytokine of Th2, which also mediates the occurrence of eosinophil infiltration.\textsuperscript{9,10}

Table 3 and graph 1 showed that serum IL-33 content were significantly higher (p <0.05) in patients with chronic rhinosinusitis without nasal polyps than with nasal polyps (median 859.65 vs 214.77). This is according to research by Smithgall MD, et al., 2008, that IL-33 if synergize with IL-12 can induce NK cells and cell iNKT which resulted in the release of inflammatory mediators IFN-γ which can release the release of neutrophils and cause inflammatory responses in chronic rhinosinusitis without nasal polyp.\textsuperscript{11}

Based on table 3 data, it shows that the number of eosinophils in nasal polyps was significantly higher (p <0.05) than without nasal polyps (median = 3.0 vs 2.0). In table 4 and graph 3 data also shows that the distribution of eosinophil counts in the nasal polyp group is more categorized as +4 and +3 (40.0% and 30.0%) than those categorized as +2 and +1 (20.0% and 10.0%); whereas in the group without nasal polyps is more categorized as +1 and +2 (50.0% and 30.0%) than +3 and +4 (15.0% and 5.0%); Chi-square test results shown significant differences (p <0.05).

The increasing of eosinophil in chronic rhinosinusitis with nasal polyps is also significantly consistent with Hulse KE, et al., 2015, which says that eosinophils are elevated in chronic rhinosinusitis with nasal...
polyps. Eosinophils will produce eosinophil cationic proteins that can cause epithelial cell damage, as well as proinflammatory molecules that contribute to type 2 inflammation, which is associated with the occurrence of nasal polyps.12

Based on Table 5 and Table 6 can be seen in both groups of chronic rhinosinusitis with nasal polyps and chronic non-nasal polyps rhinosinusitis, it was found that serum IL-33 content were positively correlated with eosinophil content. The higher the content of IL-33, the higher the eosinophil level but which is significant only in chronic rhinosinusitis without nasal polyps.

**Conclusion**

This study shown that IL-33 was higher content on chronic rhinosinusitis without nasal polyp, whereas IL-33 increases eosinophil content in chronic rhinosinusitis without nasal polyp, and the eosinophil was higher content on chronic rhinosinusitis with nasal polyp.

Comparison of Breastmilk Production between Vaginal Delivery and Caesarean Section with Regional Anesthesia at Lombok 22 Hospital, Surabaya City, Indonesia

Anggy Devyanti Prinska¹, Windhu Purnomo², Roedi Irawan³

¹Department of Maternal and Child Health, ²Department of Biostatistic and Demography, Faculty of Public Health, Airlangga University, ³Department of Pediatric, Faculty of Medicine, Airlangga University

Abstract

Breastfeeding is the one and only reliable nutritional source for baby. It is important that a mother ideally begins breastfeeding her newborn in the first hour after delivery. Actually, many factors could affect breastfeeding such as delivery type. The objective of this study was analyze and compare breast milk production between vaginal delivery and caesarean section with regional anaesthesia which has done Early Initiation of Breastfeeding (EIBF). The data used was primary data through filling questionnaires and interviews to subjects. This study was observational analytic with prospective cohort design. The population was all mothers who giving birth at Lombok 22 Hospital Surabaya and also has done EIBF. Sampling was simple random sampling and obtained 56 mothers into 2 groups. First group was 28 mothers who deliver by vaginal delivery. Second group was 28 mothers who deliver by caesarean section with regional anaesthesia. The result showed that there were a different breast milk production between vaginal delivery and caesarean section with regional anaesthesia (p<0.001). This study used postpartum pain as an intermediate variable. The result showed that there were a relationship between postpartum pain and breast milk production (p<0.001). Last, the result of multiple regression analysis showed that breast milk production was influenced by type of delivery (p=0.023; RR=8.047) and postpartum anxiety (p<0.001; RR=55.205).

Keywords: breast milk production; caesarean section with regional anaesthesia; postpartum anxiety; postpartum pain

Introduction

Breastfeeding is the one and only reliable nutritional source for baby. It is important that a mother ideally begins breastfeeding her newborn in the first hour after delivery. Breast milk is able to prevent disease and increase immunity in the baby’s body¹.

Actually, many factors could affect breastfeeding such as delivery type. Caesarean section is different from vaginal delivery. Vaginal delivery does not use anesthesia during labor, while caesarean section uses regional anesthesia around the abdomen during labor.

If the effect of regional anesthesia was lost, the mother would felt the pain around the incision wound c-section. It called postpartum pain. This pain makes the mother became worried about herself, so she just focused on her pain and her baby neglected. It called postpartum anxiety. So that, breast milk production was reduced²-³.

According to Grysztar’s Research, breastfeeding failures mostly in 45% mothers who deliver by caesarean section and 17% mothers who deliver by vaginal

Correspondence:
Anggy Devyanti Prinska
E-mail: anggi.devianti@gmail.com
delivery. It is because anaesthesia can inhibit the release of oxytocin, thereby reducing milk production. In addition, postpartum pain and postpartum anxiety can also let down reflex because of epinephrine released. That causes vasoconstriction in the alveoli.

Early Initiation of Breastfeeding (EIBF) is a way to improve breastfeeding success. Skin-to-skin contact has been suggested to improve sucking ability, improve infant receptivity, and sufficient milk supply.

The objective of this study was analyze and compare breast milk production between vaginal delivery and caesarean section with regional anaesthesia which has done Early Initiation of Breastfeeding (EIBF).

**Materials and Method**

This study was observational analytic with prospective cohort design. The population was all mothers which giving birth at Lombok 22 Hospital, Surabaya City, Indonesia and also has done EIBF. Sampling was simple random sampling and obtained 56 mothers divided into 2 groups. First group was 28 mothers who deliver by vaginal delivery, as a control group. Second group was 28 mothers who deliver by caesarean section with regional anesthesia.

Inclusion criteria of this study were: single baby, no congenital abnormalities, newborn with birth weight more than 2500 grams, and gestational age 37-42 weeks. This study used primary data through filling questionnaires and structured interviews to subjects. All of the questionnaires were calculated by the validity and reliability test. The independent variables were type of delivery, postpartum pain, and postpartum anxiety. The dependent variable was breast milk production which was measured on day 1 and 2.

SPSS Statistics 17.0 was used for data analysis. Bivariate analysis were compared using cross-tabulations and Chi-Square Test with $\alpha = 0.05$. A multivariable logistic regression model was created to examine the causal association between independent variables and breast milk production using Multiple Logistic Regression with $\alpha = 0.05$.

* Significantly correlate using Multiple Logistic Regression Test (p < 0.05)

There was a different production of breast milk between vaginal delivery and caesarean section delivery with anaesthesia regional (p < 0.05), is shown in Table 1. Most of mothers who had C-Section delivery with regional anaesthesia (76.9%) were able to produce breast milk less than vaginal delivery. In contrast, most of mothers who had vaginal delivery (73.3%) were able to produce breast milk more enough than C-Section with regional anaesthesia. It could be concluded that the adequacy of breast milk production was more experienced by mother who had vaginal delivery.

Table 1 shows that there was a correlation between postpartum pain and production of breast milk (p < 0.05). Most of mothers who felt severe pain (46.2%) and moderate pain (50.0%) were able to produce breast milk less than mothers who felt mild pain even did not pain at all (3.8%). In contrast, most of mothers who felt mild pain (63.3%) and did not pain at all (16.7%) were able to produce breast milk more enough than mothers who felt moderate pain (13.3%) and severe pain (6.7%).

Table 1 also shows that there was a correlation between postpartum anxiety and production of breast milk (p < 0.05). Most of mothers who felt anxious (92.3%) were able to produce breast milk less than mothers who did not anxious (7.7%). In contrast, most of mothers who did not anxious (83.3%) were able to produce breast milk more enough than mothers who felt anxious (16.7%). It could be concluded that the adequacy of breast milk production was more experienced by mother who did not anxious.

Table 2 shows that the results of multivariate analysis with Multiple Logistic Regression Test (α = 0.05). The result showed that breast milk production was influenced by type of delivery (p=0.023; RR=8.047) and postpartum anxiety (p<0.001; RR=55.205). The mothers who had caesarean section delivery with regional anaesthesia were at risk for produce not enough breast milk 8.047 times greater than mothers who had vaginal delivery. Then, mothers who felt anxious were at risk for produce not enough breast milk 55.205 times greater than mothers who did not anxious.

So that, postpartum anxiety most likely has an influence to breast milk production.

Discussion

Following approval from the institutional ethical committee, written informed consent from 56 respondents was obtained. The independent variables of this study were type of delivery, postpartum pain, and postpartum anxiety.

The first independent variable of this study was type of delivery. The result shows that the mothers who had caesarean section delivery with regional anaesthesia were at risk for produce not enough breast milk 8.047 times greater than mothers who had vaginal delivery. In other word, the production of breast milk transferred to baby born by caesarean section with regional anaesthesia is less than that transferred to baby born by vaginal delivery over the first and second days of life. Not only statistically significant in this study, but also in two studies had done before.

Studies said that caesarean section delivery might inhibit the success of breastfeeding because of the condition of the mother due to anaesthesia\(^{2,13}\). Although early initiation of breastfeeding (EIBF) has been done, the mother still weak and her mobility was limited. Most
of them just lying on the bed for 36-48 hours first.

During the in-depth interview, the mothers who had vaginal delivery looked more able to move actively than the mothers who had caesarean section delivery with regional anaesthesia. They were able to walk to the bathroom with or without the help of a nurse. They were also able to hold and hug their babies closely anytime to breastfed their babies. It caused the production of breast milk greater.

The second independent variable of this study was postpartum pain. The result shows that there was a correlation between postpartum pain and production of breast milk. Not only statistically significant in this study, but also in two studies had done before. Studies said that postpartum pain could inhibit the production of oxytocin. It was a hormone that affect the flow of breast milk. In addition, postpartum pain and postpartum anxiety also let down reflex because of epinephrine released. It caused vaso-constriction in the alveoli.

During the in-depth interview, the mothers who felt mild pain even did not pain at all could produce more enough milk than moderate and severe pain as much as 5-20 ml. Therefore, health services should provide some programs to reduce postpartum pain levels, such as prenatal yoga.

The third independent variable of this study was postpartum anxiety. Postpartum anxiety is closely related to postpartum pain. The result shows that the mothers who felt anxious were at risk for produce not enough breast milk 55.205 times greater than mothers who did not anxious. Nurliawati and Saraung also said that postpartum anxiety most likely affected the production of breast milk.

During the in-depth interview, they said that their babies were still crying louder even though it has been breastfed. Most of her families suggested to giving formula milk to her baby as a temporary substitute when their breast milk was low. It was a wrong solution, because actually breastfed process could improve sucking ability, improve infant receptivity, and then breast milk supply would greater.

Most of the mothers also said that they did not know what should they do, follow their families’ advice or still breastfeeding their babies patiently. Therefore, health services should provide some programs to reduce postpartum anxiety, such as giving education on how to relax, regulate breathing, and closer to their Lord.

**Conclusion**

The breast milk production was influenced by type of delivery and postpartum anxiety. Based on its conclusion, it is suggested to Health Service Centre to giving some programs to pregnant mother, especially in the selection of delivery types and how to enjoy their new life after baby birth. It is also suggested to society to keep supporting the mothers for breastfed.

Evaluation on Heavy Metals and Microbiological Contamination in Instant Papeda with Laor Koya (Polychaeta) as Supplementary Food for Pregnant Woman

Ety Yuni Ristanti 1,2, Muhamad Asrar3

1Doctoral Student Faculty of Public Health, Airlangga University, Surabaya, Indonesia, 2Maluku Health Polytechnic, Indonesia, 3Maluku Health Polytechnic, Indonesia

Abstract

Background. Having a safe meal is the human right. In fact, heavy metals and natural pathogenic microorganisms often contaminate the food people consume. Heavy metals and harmful microorganisms could ease the disease transmission with the food as the media.

Aim. This study aims to evaluate some of the heavy metals and microbiological contaminants on the formula of instant papeda enriched with laor (Polychaeta).

Method. Laor (Polychaeta) is substituted to Skipjack Tuna with a ratio of 100% : 0% (PI); 80% : 20% (PIKL1); 70% : 30% (PIKL 2) and 60% : 40% (PIKL 3). Atomic Absorption Spectrophotometry (AAS) was used to determine metal contamination. Total Plate Count (TPC) was used to determine the contamination numbers of total plate count. Most Probable Number (MPN) method determined Coliform. Isolation and identification method were used to determine Escherichia coli, Salmonella, and Staphylococcus aureus. One Way Anova test. Confidence Interval (CI) 95% was used to discover statistical analysis for metal contamination. Microbial contamination is descriptively analyzed.

Results. Substances level found in instant papeda with laor koya are as follows: Pb (Lead), the lowest level: 0.0106 mg/kg, the highest level: 0.0119 mg/kg. Cu (Copper), the lowest level: 0.0037 mg/kg, the highest level: 0.0075 mg/kg. Sn (Tin), the lowest level: 0.0062 mg/kg, the highest level: 0.0087 mg/kg. Hg (Mercury), the lowest level: 0.0015 mg/kg, the highest level: 0.0017 mg/kg. Total microbial contamination is 0 colony/mL. MPN coliform states 0 colony/mL, Staphylococcus aureus is 0 colony/mL, Escherichia coli and Salmonella shows negative result.

Conclusion. The metal emission does not exceed the maximum limit stated in Indonesian National Standard (INS) or Standard Nasional Indonesia (SNI) and Codex and there is no microbiological contaminant found in instant papeda with laor koya.

Keywords: Papeda, laor, heavy metals, microbiological contamination

Introduction

Papeda, a traditional food from East Indonesia made of sago, is usually consumed with skipjack tuna and yellow sauce. Laor, one of the typical biota which is swarming – an activity when a certain type of abundant sea worms abound around the water surface on a full moon for an external fertilization1 in March or April, demanded by the inhabitants of Maluku, Indonesia. Furthermore, the additional meal as the alternative for the expectants often use laor substitution served together with instant papeda.

DOI Number: 10.5958/0976-5506.2019.02094.1
According to Codex Alimentarius, some substances could contaminate the food processing, as in manufacturing, handling, storing and processing or even distributing activity since contaminants could be found from the surrounding. To avoid contamination and unsafe meals, the presence of these substances should be monitored carefully so the quality of the meal will not be affected. Moreover, heavy metals and harmful microorganisms could ease the disease transmission with the food as the media (2).

Heavy metals, both metalloids and chemical metallic with high atomic mass numbers and density are toxic to living things. During food processing, both metal contaminants from the food itself and contaminants from surroundings would expose the food (3). Heavy metals contamination is a serious threat in a food chain due to their toxicity, bioaccumulation and bio magnification (4).

Having a safe meal is the human rights. In fact, heavy metals and natural pathogenic microorganisms often contaminate the food people consume. On the other hand, such pathogens are harmful, causing various diseases with various severity, even bringing death while those cannot be detected organoleptically (visibly or noticeably). Consequently, when those pathogens are preserved and conditioned during an exposition for sale, the microorganism will grow and reach substantial levels of contamination (5).

One of the major public health issues encountered by developing countries is food borne diseases caused by microbiological agents (6). It is an important issue in public health due to the rapid and deadly infection (7) (8) especially the incidence of food poisoning arisen all over the world.

The objective of the study is to evaluate some of the heavy metals and microbiological contaminants on the formula of instant papeda enriched with laor (Polychaeta).

**Materials and Method**

Formulation of instant papeda with laor koya (Polychaeta) used the experimental design RAL (Completely Randomized Design) consisting of four treatments and four repetitions. The materials used were skipjack tuna fish and laor (Polychaeta). Previously, the materials were examined to check the proximate assessing and metal contamination in the Laboratory of Nutrition, Department of Nutrition, Faculty of Public Health, Airlangga University, Surabaya. Laor (Polychaeta) was formulated as koya by washing, drying in a temperature of 60°C for 12 hours, roasting, grinding and sifting. The skipjack tuna with yellow sauce was produced by cutting the fish into pieces, cleaning, boiling with the spices, and then pasteurizing and sterilizing.

The instant papeda with laor koya was produced by mixing sago with 60 ml of boiled water while stirring, then adding slowly 450 ml of boiled water while stirring to form Papeda porridge and setting aside. After that, 200 ml of water was boiled and added by the skipjack tuna along with the ingredients, simmer for 3 minutes. Then the fish with yellow sauce was served with papeda porridge and sprinkled by the laor koya.

Atomic Absorption Spectrophotometry (AAS) was used to determine the metal contamination and Total Plate Count (TPC) was used to determine the contamination numbers of total plate count. Most Probable Number (MPN) method determined Coliform. Isolation and identification method were used to determine Escherichia coli, Salmonella, and Staphylococcus aureus. One Way Anova test with Confidence Interval (CI) 95% was used to discover statistical analysis for metal contamination. Microbiological contamination was descriptively analyzed.

**Results**

Papeda, a traditional food from East Indonesia made of sago that is usually consumed with skipjack tuna and yellow sauce. To increase the nutrients, papeda is now developed by the addition of laor flour (Polychaeta). Furthermore, foodstuffs used should be clean, safe, high-quality and appropriate for the expectants (9)(10).

**Heavy Metals Contaminants Found in the Formula of Instant Papeda with Laor koya**
The content of metal contaminants in instant *papeda* does not exceed the safety limit appointed. Lead contaminants among those four formulas was found to be 0, 0106-0, 0119 mg/kg, while the maximum limit of lead contaminants according to Codex Stand 72-1981 was of 0.02 mg/kg (11), moreover the maximum standard based on Indonesian National Standard (INS) or *Standard Nasional Indonesia* (SNI) equals to 0.3 mg/kg. Furthermore, the statistical analysis states that there was no significant difference among the formulas of those four instant *papeda*.

Pb (Lead) contamination found at Ambon waters has not exceeded the limit or remains within normal limits, averaged out less than 0.004 mg/L (12). Lead is the most systemic toxic affected several organs in human body including the kidneys, liver, central nervous system, hematopoietic system, endocrine system, and reproductive system. Several studies stated when lead is absorbed by or exposed to the pregnant women, there will be possibility for low birth weight and premature birth, as well as abnormal developmental of nerves, since lead will be transferred to the fetus (13).

Means results of metal contaminants found in all four *papeda* formulas were as follows: Cu (Copper), 0.0037-0.0075 mg/kg; the maximum limit found in the special diet for the pregnant women, 20 mg/kg. Sn (Tin), 0.0062-0.0087 mg/kg; the maximum limit, 40 mg/kg. Hg (Mercury), 0.0015-0.0017 mg/kg; the maximum limit, 0.03 mg/kg. There was no significant difference among the formulas of those four instant *papeda* based on the statistical analysis results.

PIKL 1           : Instant Papeda with Laor koya 1
( 80: 20%)

PIKL 2           : Instant Papeda with Laor koya 2
(70: 30%)

PIKL 3           : Instant Papeda with Laor koya 3
( 60: 40%)

The formulas of instant papeda, PI (100: 0%), PIKL1 (80: 20%), PIKL2 (70: 30%) and PIKL3 (60: 40%), meet the quality requirements based on INS 01-7148-2005 on microbial contamination in special food of pregnant women. Results on microbial contamination found in instant papeda with laor koya were as follows: the total microbial plate found was 0 and the maximum number was $5 \times 10^4$ Colonies/g (mL). The number of MPN coliform was 0 and the maximum number was $1 \times 10^2$ Colonies/g (mL). There was no Escherichia Coli and Salmonella contamination, based on test results. There was no Staphylococcus aureus contamination found while the maximum number was $1 \times 10^2$ Colonies/g (mL).

The International Commission on Microbiological Specifications for Food (ICMSF) accepts the total aerobic plate count, the amount of Staphylococcus aureus, and the amount of Escherichia coli on cooked ready-to-eat foods between 0 – 103, while 104 – 105 is tolerable and more than 106 is unacceptable. A research by Henry et al., (2017) on those requirements resulted higher numbers than the reference.

Generally the low-acid meals such as meat, eggs, fish and other dairy products are the source of infection and poisoned by bacteria. Fresh fish are frequently contaminated by some bacteria such as Salmonella sp., Shigella, Escherichia coli, Enterococci and Clostridium. Escherichia coli is one of the bacteria that easily spread by contaminated water and ingredients with direct contact.

The hygienic process in preparing and processing meal is the key to avoid microbiological contamination. To promote a product, the guarantee of microbial quality and free pathogenic microorganisms is highly essential to ensure the consumers in consuming the products.

**Conclusion**

Summarily, instant Papeda with laor koya meets the quality requirements formulated by codex and Indonesian National Standard (INS) or Standard Nasional Indonesia (SNI) as the maximum limit of heavy metals contamination was not exceeded and was not polluted by microbes.

Capacity Building in Health Worker as an Alternative Solution to Solve Stunting Problem

Eska Distia Permatasari¹, Globila Nurika², Nyoman Anita Damayanti³

¹Magister Program of Administration and Health Policy, ²Magister Program of Environmental Health, ³Doctoral Program of Health Science, Universitas Airlangga, Surabaya, Indonesia

Abstract

Stunting is a public health issue that is the topic of world nutrition. The country of Indonesia is ranked fifth in the world with a short-term prevalence of 30-40%. The incidence of stunting in East Java amounted to 26.1% in 2015 occurred in the area of Surabaya City of 19.3%. This study aims to examine the problem of stunting, identify the cause factors, and provide an alternative solution to solve the problem of stunting in the work area of Puskesmas Tanah Kali Kedinding Surabaya. The study was conducted in April-May 2018. Primary data was obtained through indept interview on nutrition officer. The results showed that the intervention of stunting case in Puskesmas Tanah Kali Kedinding had not been done due to lack of knowledge and understanding of all officers regarding prevention and handling of stunting. The CARL method is used to get the most prioritized solution possible. The solution is to conduct capacity building on the prevention and handling of stunting at all Puskesmas officers. Thus all Puskesmas officers are able to implement the stunting intervention program in their working area.

Keyword: stunting, capacity building, health planning program.

Introduction

Stunting describes the chronic underweight status of growth from early life. The stunting state was presented with a standard z-score of height by age less than -2 standard deviation[1]. Stunted children closely related to conditions that occur over a long period of time such as poverty, poor hygiene and environmental health, poor parenting and low levels of parental education.

Cohort study of child growth in Bogor City by Agency of Health Research and Development, Indonesia Health Ministry in 2013 has successfully followed 220 mothers giving birth and monitored until their babies was 15 months. The results state that the growth of stunted babies is always left behind compared to normal babies. Studies shown other results that stunted babies may become normal when intervened appropriately. Conversely, a normal babies can also be stunting if with wrong parenting pattern[2].

Stunting problems in children can inhibit child growth and cause negative impacts such as intellectual decline, decreased productivity resulting in poverty and the risk of delivering low birth-weight infants[3][4]. Globally, about 1 in 4 children suffer from stunting[4]. Based on the Nutrition Status Monitoring survey results from 2014-2016, the percentage of stunting cases 0-59 months in East Java in 2014 by 29%. The number decreased to 27% in 2015 and 26.1% in 2016[5]. However, the decrease in stunting cases was not significant because the prevalence of stunted children would be a public health problem in 20% or more[1].

The prevalence of stunting in toddlers in Surabaya 2014 is 21.5%. Puskesmas Tanah Kali Kedinding is a puskesmas with stunting prevalence of 20.83% in 2012. Stunting cases increased to 21.86% in 2013 and 25.69% in 2014[6]. The incidence of stunting continues to occur in 2017. There were 105 children under five are stunted than 3,798 children (2.76%). Although the presentation seems to be declining from previous years but the absolute number is still high.

This study aims to examine the problem of stunting and stunting factors in the working area of Puskesmas Tanah Kali Kedinding Surabaya. This is done to provide a possible solution to solve of stunting issue.
Material and Method

The research was conducted by observational approach, using quantitative and qualitative data, and it was conducted at Puskesmas Tanah Kali Kedinding Surabaya in April-May 2018. Primary data was obtained through indepth interview to 2 nutrition officers of Puskesmas, which was a research informant. The data obtained were analyzed descriptively. The activity begins by analyzing the situation, determining the priority of the problem, identifying the cause of the problem, and prioritizing the solution.[7]

Situation analysis to determine the organization’s position is done by using SWOT. SWOT analysis is a strategic planning method used to evaluate strengths, weaknesses, opportunities and threats within an organization. The SWOT analysis guides to identify the positive and negative sides of the organization’s internal (S-W) and external organizational (O-T) conditions. Identify the cause of the stunting problem obtained by using fishbone. Fishbone is a tool that describes a systematic way to identify causes of a particular impact.

Priority problem and solution determination using USG (Urgency, Seriousness, Growth) and CARL (Capability, Accessability, Readiness, Leverage) methods. The USG method is one of the tools for compiling the priority sequence of problems to be solved. USG is done by determining the level of urgency, seriousness, and the growth of issues by determining the scale of values 1-5. The problem with the highest total score is a priority issue to be resolved soon. CARL is one of the tools to determine the priority of alternative health problem solutions[7]. CARL method is done by determining the score based on certain criteria, namely capability, accessability, readiness and leverage. An alternative solution that has the highest score is the most likely solution to run. The CARL method is used if the program implementer still has limitations in solving the problem. The use of this method emphasizes the ability of program implementers[7].

Findings

Overview of Nutrition Program

Puskesmas Tanah Kali Kedinding Surabaya is a primary health care which located in northern part of Surabaya. The location is near to the coast of Nambangan so the availability of high protein food is fulfilled. There are 2 nutrition officers at Puskesmas Tanah Kali Kedinding. The type and number of health staff in the Puskesmas in accordance with Ministry of Health Regulation No. 75 in 2014 that there is at least 1 nutrition officer for urban Puskesmas[8]. While the service program efforts to improve the nutritional status of the community that has been done, among others:

- Posyandu Program for toddlers
- Counseling of supplementary feeding for infants and toddlers
- Supplementary feeding for pregnant with chronic energy deficiency
- Supplementary feeding for malnourished infants and toddlers nutrition assistance
- Screening for toddlers malnutrition
- Family conscious of nutrition program
- Provision of vitamin A and iodized salt for children
- Provision of Fe tablets for pregnant and young women

Based on the program that has been done, there is no special program to solve the stunting problem. Stunting events are always encountered at the time of screening, however the discovery of stunting cases has never been acted upon.

Organizational Internal Condition and Situation Analysis

Base on SWOT analysis, it is found that the position of the organization is in quadrant 4. The picture shows that Puskesmas have weaknesses from internal organization and strong threat from external organization. The weakness of organization is derived from human resources factors both quantity and quality, and poor coordination among work units in running health programs. While the threat from external organizations is the lack of public knowledge about stunting and there is no follow-up stunting program from Surabaya Health Office.
Stunting situation analysis has been done and found that there are some problems related to stunting in terms of officer, community, and environment. Some of the problems that have been found are impossible to solve simultaneously because Puskesmas have resources limitation. It becomes the reason that necessary to prioritize the problem to determine which problems can be solved first. Determining the priority of the problem is done using USG method by considering the urgency, seriousness, and risk of growth level of the problem.

</tbody>
</table>
The priority result of the problem to be addressed is related to the absence of intervention to the stunting case (priority of nutrition officers only on the handling of malnutrition).

Determinant of Issues and Alternative Solutions

We identify the cause of the problem after deciding priority issues. Identification is done by using fishbone approach. Based on the approach, the root of the problem associated with the absence of intervention to the stunting case is because the Puskesmas staff does not have sufficient ability and knowledge about stunting and how to intervene. So alternative solutions that could be done is to carry out capacity building on the prevention and control in all Puskesmas staff. Selection of alternative solutions is done by using the CARL method with regard to capability, accessibility, readiness and leverage of proposed solutions.

Based on the cause problem identification, the most appropriate solution is capacity building about stunting. Some of the things that can be done when building capacity are:

Improving understanding of officers related stunting (factors causing and how to prevent & handling)

Increase knowledge and understanding of stunting policy from Surabaya City Health Office and Indonesian government

Improving the ability to implement an integrated stunting intervention program at the Puskesmas

Discussion

There are several studies that have been done in Indonesia found that stunting is associated with factors that cause maternal nutritional status during pregnancy (age, parity, BMI, upper arm circumference, psychology and social condition). Causes of stunting from family and environmental conditions can lead to infection in children and decrease the nutritional status of children[9]. Another determinant of stunting is behavioral factors that are inconsistent with the suggestion of healthy behavior, family economic status, and parental education status[10]. So some solutions to stunting solutions are mostly focused on handling them.

Based on the situation analysis of stunting problem in this research, the main factor causing the stunting situation actually comes from health service factor. As in Hendrik L. Blum’s theory that health care providers have contributed to the incidence of health problem. In line with Trihono’s research results in 2015 that the determinants of stunting causes are derived from health services and the success of intervention programs lies in the ability of health workers to implement stunting prevention programs[10].
The stunting problem that must be handled in Puskesmas Tanah Kali Kediniding Surabaya is related to the absence of any intervention in the stunting case. The identification result of problem is the lack of ability from nutrition officer in identifying stunting problem. Nutrition officer not understand how to determine the value of z-score, causes stunting, and how to handle stunting. The First 1000 Day Life Program (Scalling Up of Nutrition program in Indonesia) has not been integrated in prevention and stunting programs. Thus it can be concluded that the stunting program has not been well socialized by the Surabaya City Health Office so that the implementation has not been effective in Puskesmas Tanah Kali Kediniding.

Based on the research results found that capacity building is the solution of the stunting problem that occurred in the Puskesmas Tanah Kali Kediniding Surabaya. Capacity building activities undertaken at all Puskesmas officers are expected to improve their ability in identifying causes of stunting, prevention and handling of stunting problems.

The selection of the solution is in accordance with the Stunting Summary Book compiled by the National Team for Accelerating Poverty Alleviation 2017, that there are several possible causes of the ineffectiveness of the stunting intervention policy and program\textsuperscript{11}. Causal factors are among others:

- Policies and regulations regarding stunting intervention have not been used as a common ground for handling stunting.
- Ministries/institutions implement programs according to their responsibilities without good coordination among institutions.
- The planned stunting intervention programs have not been fully implemented.
- Existing programs/interventions still require improvements in program design, coverage, quality and objectives.
- Nutrition knowledge improvement program and healthy life behavior change has not been done.
- Community-based programs are not implemented maximally;
- The knowledge and capacity of both central and local governments in handling stunting need to be improved.

To strengthen human capacity to deliver priority nutrition interventions at scale, a country needs to develop a workforce strategy that uses evidence-based systematic approaches to produce sufficient numbers of skilled workers with the needed technical competencies in nutrition\textsuperscript{12}. This requires clearly defining the challenges and gaps in nutrition competencies and training, followed by the strategic scaling up of proficient nutrition competencies within various public service cadres. Without specific articulation of the nutrition competencies that are required of people working in this field, workforce development and continuing professional development will be inefficient\textsuperscript{13}.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{Figure2.png}
\caption{Strengthening Human Capacity Strategy to Implement Priority Nutrition}
\end{figure}
**Intervention at Scale**

Based on the previous study, the problem solving of stunting should not only focus on determining the cause of stunting from community but also the capacity of the implementing resources of the intervention program, specifically all of health workers in the Puskesmas. Without adequate capacity in terms of program implementers then the program will not be possible to run well and the program objectives will not be achieved.

**Conclusion**

The problem of stunting at Puskesmas Tanah Kali Kedinding Surabaya is no longer caused due to the nutritional status of pregnancy, family economic condition, environmental condition, but due to internal factors of Puskesmas. Based on the result of identification of cause of stunting problem which continuously happened is because have not implemented intervention in stunting case. This is due to the limited ability of health workers at the Puskesmas as the program implementer. So that the improvement of the ability of health workers about prevention and handling stunting can be used as an alternative solution to the settlement of the case.

Preparing Fit and Healthy Pilgrims in order to be able to Perform Hajj Optimally through Health Policy in Indonesia

Chandra Rudyanto¹, Rita Damayanti¹, Purnawan Junadi¹
¹Post-graduate Student, ¹Adviser; Senior Lecturer, ¹Senior adviser; Professor, School of Public Health, University of Indonesia, Depok, West Java, Indonesia

Abstract

Indonesia hajj health program aimed at enhancing and maintaining health and fitness of pilgrims as stipulated in national policy on hajj health management. However, the unavailability of funding sources becomes a main constraint for executing the policy. The MOH awarded Lumajang as the most outstanding district on hajj health management in 2014. Lumajang was able to allocate hajj health program in the annual regional budget. The objective of this study was to analyze the implementation of hajj health policy from the point of equity, efficiency, quality, and community empowerment in order to improve health status and physical fitness level of all hajj pilgrims in Lumajang. This research applied descriptive study and documentary review using original data on health policy implementation. The population of study were 710 pilgrims (jemaah). Most jemaah were 45-60 years old and 52% were men. The results revealed that most jemaah had high blood pressure (57,31%), some improvements in all BMI categories, and category of fair in physical fitness (49,31%). Moreover, there was zero death of 710 jemaah, in which 34 % of the total jemaah classified as a high health risk group. This study concluded that the policy implementation evidently could provide important benefit for hajj pilgrims of Lumajang in performing hajj ceremony process. The sustainability of hajj health program absolutely affected by the availability of funding sources, accessibility of health services, and support of community participation.

Key words: hajj pilgrims, health policy, physical fitness

Introduction

Hajj pilgrimage is one of the five fundamental pillars of Islam and becomes a mandatory for every moslem to perform it once in lifetime. Every year Indonesian pilgrims (jemaah) recorded as the largest in the world with approximately 210,000 people. They assemble in Saudi Arabia (SA) along with more than 3 million pilgrims from around 150 countries. The most of Indonesian jemaah classified as high risk pilgrims with age of 60 years and or have at least one health problem. The quantity of high-risk group tends to increase every year and still leads to the major health problem of Indonesian jemaah. Based on the Ministry of Health (MOH) data, number of high-risk pilgrims has risen from 50.6% (2011) and 46.6% (2012) to 56.19% in 2013. The study of Gaffar et al revealed that risk factors play a very significant role to death cases of jemaah. In the recent 10 years, death rate of Indonesia jemaah during hajj pilgrimage in SA reached 2.1 to 3.2 per 1000 jemaah. This figure indicated a 2-3 fold greater than death rate in Indonesia during a normal circumstance. Two types of disease categorized as the cause of death of jemaah are cardiovascular (50%) and respiratory diseases (24%).

One of successful indicators of Hajj Health Program (HHP) includes declining morbidity and mortality rates. Also, jemaah should be able to maintain and improve their health independently and cope with any health problem by themselves. According to Law no. 13 in 2008 regarding Hajj Pilgrims Management, government has obligation and responsibility in providing hajj...
services and jemaah protection. Derivative of this Law has been realized through the MOH’s regulation no. 442 in 2009 regarding Guidelines on Management of Indonesia HHP. This national policy defined the objectives of HHP, namely to improve jemaah health and enhance jemaah physical fitness prior to leaving for SA. This is consistent with the statement of Singka that health status of jemaah before leaving needs to be prepared so that jemaah could achieve optimal health condition. Also, Fertini confirmed that adequate health condition is urgently needed by jemaah since the hajj pilgrimage involves a very heavy physical activity.

In order for the national policy could achieve its objectives, the actors of HHP then become the responsibility of Regional Government and District Health Office (DHO). In general, HHP at DHO consists of health screening and health promotion. Both of components are very essential to establish healthy jemaah.

This study aims to analyze the implementation of hajj health policy from the point of equity, efficiency, quality, and community empowerment, particularly in protecting the high-risk group and increasing health and physical fitness levels for all jemaah in Lumajang. The study selected Lumajang district as a good example of health policy implementation. The context of policy issue raised is closely related to several factors that affect the implementation of the policy. The evidence suggests there are many districts do not implement the MOH’s regulation. DHO is currently facing budget constraints in which the budget for HHP has not included yet in the annualy regular regional budget. As a result, the development of HHP has not been run in accordance with the existing guidelines. In other words, the implementation of HHP conducted by districts are often not in line with the health policy issued by central government.

Method

This research applied descriptive study and documentary review using original data on health policy implementation. Four main types of data complied from this study, including the percentage of blood pressure, body mass index (BMI) and physical fitness, and to analyze the implementation of HHP in Lumajang. Level of jemaah’s physical fitness were measured by using a walking test of Rockport method. Population of study were 710 Lumajang jemaah who performed hajj pilgrimage in 2014. The study conducted in Jakarta from October to December 2015. The study used secondary data of blood pressure, body mass index (BMI) and physical fitness derived from the 2014 Lumajang HHP reports in 2014 and the 2011-2013 Profile of Hajj Health. Additional data were obtained from the results of literature review and discussions with Lumajang HHP managers. Data were analyzed quantitatively to obtain frequency distribution of blood pressure, BMI and physical fitness. Discussion focused on hajj health issue, then associated with the implications of HHP and the results of its implementation in the study area. Method of analysis and discussion was based on the analysis of policy implementation developed by the WHO to examine the extent to which the DHO office has taken up such a role. Indicators of analysis include equity, efficiency, quality, and community empowerment.

Results

Subject Characteristics and Outcomes

The proportion of sex includes men 52% and women 48%. The age group shows the variation of age group < 19 years = 0,32 %; 19-44 years = 32,79%; 45-59 years = 43,02%; and ≥ 60 years = 23,86. Measurement of blood pressure, BMI, and physical fitness level of Lumajang jemaah conducted twice, namely in the period of 6 months and 3 months before departure.

Most jemaah have high blood pressure as shown in Table 1. The result of health education and physical exercise program, which was conducted for 3 months, showed a decrease in blood pressure levels of jemaah from 59.43% to 57.31%.

Policy and Financial Support

The support of local government embodied in the form of Regent’s statement decree which regulated the implementation of HHP. The most important aspect in the content of the decree was the examination of prospective pilgrims has no charge (free). The operational costs and all expenses for health examination and health promotion were entirely charged to the 2014 Lumajang local budget. In general, total health spending at DHO in 2014 amounted to Rp. 211 123 977 790 ($ 17,600,000 US) or by 12.98% of total district budget. In specific, hajj health development fund of 2014 amounted to Rp. 134.8 million or 0.064% of DHO total health budget. This fund used to finance the hajj preventive-promotive program for 900 jemaah.

Discussion

The study found 49.31% of jemaah’s physical fitness measured by $\text{VO}_{2\text{max}}$ had category of fair. Astrand\(^1\) states that $\text{VO}_{2\text{max}}$ is the maximum amount of oxygen taken and used by someone while doing activities. If the $\text{VO}_{2\text{max}}$ value is low, then someone will become easy to feel tired, low in physical work ability and declining health condition.\(^10\) Decrease in physical activity and cardiorespiratory fitness levels due to age factor may lead to an increase in the risk of non-communicable diseases.\(^5\) Physical fitness level can be improved by doing physical exercise regularly.\(^20\)

Discussion of policy analysis refers to the concept of analysis of policy implementation developed by WHO. The analysis includes equity, efficiency, quality, and community empowerment. This concept is in line with the opinion of Robert\(^18\) which states that performance indicator of health system analysis can be measured through the aspect of access or equity, efficiency, and quality.

Equity

Definition of equity released by WHO stated that health service should be distributed equally.\(^22\) The results of implementation of hajj health policy in Lumajang showed that local government has guaranteed free and accessible health care services for all community. The local government provided health care services regardless of their resident status, employment and economy status. In other words, every jemaah has the same right to gain access to the service. DHO established 10 health centers (Puskesmas) out of 25 Puskesmas to carry out health examination and health promotion for jemaah. The examination schedule was made differently in 10 health service locations. The aim was to provide convenience for prospective pilgrims in choosing location and time available. If the pilgrims are unable to attend in 10 available schedules and locations, then they still have a chance and provided the option of choice of time to get service at DHO. This fact shows that district government is very attentive to prospective pilgrims and seeks to provide the best health services.

Efficiency

The number of deaths nil (zero death) becomes a measure of efficiency. The availability of resources should be utilized as much as possible to achieve impact indicator, such as health status of jemaah. It is also explained by Murray\(^16\) that the performance of a program could be appraised by how far the existing
resources have been utilized to achieve the goal of health programs. Measure of efficiency can simply be determined by comparing between the availability of health funding for HHP and health status of jemaah (before departure and after returning home). In 2014 DHO allocated budget for the HHP implementation of Rp. 134.8 million. This figure could be fully utilized to fund the development of the HHP, so Lumajang in 2014 was finally able to achieve the status of zero death. This means that all 710 jemaah with a high-risk group of about 34% could return to their homeland safely. In other words, none of Lumajang pilgrims died during the pilgrimage. This analysis was consistent with the definition of efficiency of WHO stating that the orientation of health service should be proactive by optimizing cost and technology. This fact indicated that the implementation of HHP according to the system approach has managed to achieve a predetermined impact indicator.

Quality

According to WHO, government should provide a qualified service for all citizens and improve quality of health services that is comparable to international health care quality. To obtain qualified health services for jemaah, local government has established a hajj operation team. Furthermore, the DHO issued a policy that regulates and establishes health screening and health coaching as both mandatory activities that must be followed by all jemaah before leaving for SA. If jemaah do not carry out all the stages, then they will not receive Hajj Health Handbooks (BKJH). If jemaah do not have BKJH, they do not meet the complete document as a requisite for departing. The results of medical examination and physical fitness test constitute an absolute requirement. The components are checked in physical fitness program, namely body weight, height, waist circumference, BMI and VO2max. DHO policy was issued in an attempt to nominate pilgrims who are eligible or ineligible to depart. The quality of health and physical fitness of jemaah are strongly associated with health promotion activities which have been done. Therefore, information on health status of jemaah registered in BKJH should really reflect health condition of jemaah. This policy is intended to prevent irregularities in data entry of BKJH. Waluya said that each institution could make an effort to prevent social deviations both persuasive and non persuasive and encourage and lead people to behave in accordance with the values and norms that have been established.

Community Empowerment

Community empowerment and self-reliance is one of the principles of HHP implementation, as mandated in MOH regulation. The essence of this principle is to encourage all jemaah to perform healthy lifestyle. Active community participation in HHP can be realized through the establishment of sport-health cadres (community health volunteers). DHO has a role in recruiting, training and fostering sport-health cadres. In 2012 there were 205 cadres who had been trained and increased to 207 in 2015. Cadres have an important role in providing access to health information, especially about benefits of completing health examination and performing physical exercise. The availability of access to health information and the establishment of good communication makes jemaah are interested in doing physical fitness exercises. Communication method used by cadres include home visits, counseling, and involving religious leaders or community leaders. In conducting home visits and group coaching, cadres equipped with recording and reporting instruments. Cadre is a motivator and role model trusted by society. This approach is in accordance with the opinion of Laverack who says that community empowerment built from individual, group to community at large. Cadres work voluntarily without incentives. Therefore, the sustainability of cadres support strongly influenced by cadres' motivation. Puskesmas should create activities that support the sustainability of cadres through involving cadres in Puskesmas programs, refreshing cadres, and providing rewards for the outstanding cadres.

Based on the above, it is not an exaggeration to say that policy makers and program managers have provided special attention to health promotion through the development of community-based hajj health. This fact is in accordance with the opinion of Beaglehole which states that community-based approach through health promotion training has contributed to the development of public health. By taking community as a partner, it means that government has given power and a wider space for community to play a role in managing resources. This opinion is supported by Laverack which states that health promotion could be seen as a tool to build community empowerment. Furthermore, Nutbean then clarifies the opinion by explaining that empowerment is the core of health promotion.
Conclusion

HHP has been successfully executed in Lumajang and in line with the MOH regulation no. 442/2009. The implementation of MOH policy is in accordance with WHO performance indicators including equity, efficiency, quality, and community empowerment. Health protection of jemaah, particularly high-risk group has been achieved through the preparation of pilgrims before leaving for SA with health promotion and the availability of access to qualified health services and support of community participation facilitated by sport-health cadres. The improvement of physical fitness level has been achieved through a 3-month physical exercise program. The implementation of fostering physical fitness based on the guidelines is able to protect and improve health of pilgrims in performing all stages of hajj ritual process.

Effects of BLS Education using a bed on the Quality of Chest Compression

Eun-Kyung Lee¹, Sun-Young Jung¹
¹Associate Professor, College of Nursing, Daegu Catholic University, The Research Institute of Nursing Science

Abstract

Purpose: This study aimed to change the teaching method to improve the performance of high quality chest compression. Method: A quasi-experimental approach with a nonequivalent control group research design was used. 46 subjects were recruited, and randomly assigned to two groups: the experimental group (23 participants; CPR performed on a bed) and the control group (23 participants; CPR performed on the floor). One participant of experimental group did not attend, and thus, 45 participants (22 experimental group and 23 control group) constituted the study cohort. Results: Results showed that new BLS training method used in this study was more effective in high quality CPR than previous method. Conclusion: Nurses may encounter a patient that has experienced on a floor, bed, or any setting, although student nurses are more like to witness cardiac arrest on a bed.

Keywords: BLS, Education, Chest Compression

Introduction

Medical personnel, especially nurses, must maintain cardiopulmonary resuscitation (CPR) skills because cardiac arrest often occurs unexpectedly and the ability to manage situations directly affects patient survival and outcomes¹. During the early stage of cardiac arrest, effective CPR (appropriate speed and depth of compression, complete relaxation between compressions, minimization of hands-off time, and the avoidance of excessive ventilation) is critical²,³,⁴, and therefore, nurses are required to administer CPR accurately and effectively.

Currently CPR training of healthcare professionals is conducted in accordance with the Basic Life Support (BLS) guidelines issued by the American Heart Association (AHA) and Korean Association of Cardiopulmonary Resuscitation (KACPR), and training involves demonstrating CPR on mannequins placed on the floor. However, results show that CPR quality is dependent on operator position, that is, whether he/she is kneeling on the floor, standing next to the patient’s bed, or kneeling on the bed⁵,⁶,⁷,⁸,⁹,¹⁰,¹¹. Also, it has been proposed that a backboard should be used to perform CPR due to the different widths and firmness of mattresses¹².

As previously mentioned, cardiac arrest in hospital occurs suddenly. So, the use of a backboard may be difficult. In the present study, we undertook to determine the need for change in the Basic Life Support (BLS) training method for student nurses by comparing the quality of chest compression in an experimental group, in which BLS training was conducted on a bed, to that of a control group, in which traditional training was conducted on the floor.

Material and Method

Design

A quasi-experimental approach with a nonequivalent control group research design was employed to evaluate the quality of chest compression after cardiopulmonary resuscitation training course on the floor as compared with training on a bed.
Sample

Nursing students in the third year of a baccalaureate nursing program were chosen as study subjects. The criteria for participation were willingness to participate in the study and not having BLS provider certification as a health care provider. A priori power analysis was performed using G*Power 3.1 software with an effect size of 0.8 and a power of 80% (one-sided test at an alpha value of 0.05), and it showed 21 participants were required per group. Assuming a 10% attrition rate, 46 subjects were recruited, and randomly assigned to two groups: the experimental group (23 participants; CPR performed on a bed) and the control group (23 participants; CPR performed on the floor). One participant of experimental group did not attend, and thus, 45 participants (22 experimental group and 23 control group) constituted the study cohort.

This study was reviewed and approved by a University Institutional Review Board. After obtaining approval, general characteristics, heights, weights, and chest compression data were measured and recorded. Participants were informed at the beginning of the course that participation was voluntary and that they could withdraw from the study at any time without prejudice.

Ethical consideration

This study was approved by the Institutional Review Board of D university (CUIRB-2016-0014).

Intervention

The only difference between the two groups was mannequin’s position. Neither group was informed that beds were being used in any training program and in the chest compression test. In accordance with norm, the control group was trained on the floor, whereas the experimental group was trained on a bed without a step. In order to avoid diffusion between the two groups, the control group (on the floor) underwent training on the first day of the experiment, and the experimental group (on the bed) were trained on the following day; 11 to 12 participants attended one of two 4-hour training sessions conducted on each day. A standard hospital bed frame (SSH-220, 200*70cm, Sungsim) with a foam mattress (185*65*6cm, soft foam with polyester coverage; Sungsim) was fixed at a height of 50cm. Both groups were trained on other BLS topics according to the 2010 AHA and 2015 KACPR CPR guidelines. The intervention was administered by the two authors who had BLS instructor certification issued by AHA and over 5 years of experience teaching BLS.

Data collection

Participants’ general characteristics, heights, weights, and chest compression qualities were recorded. Before BLS training, general characteristics were obtained using self-reported questionnaires and height and weight were measured using (BSM370, 15.5kg; Biospace, Korea). Chest compression qualities were evaluated using a Resusci Anne Simulator equipped with PC Skillreporting (Laerdal Medical, Stavanger, Norway) after the BLS training course. Participants were informed that the evaluation would be based on the data automatically recorded from the mannequins. Mannequins were positioned on the bed in the same manner as mannequins positioned on the floor.

Participants were instructed to complete 5-cycles of resuscitation. Chest compression qualities were evaluated according to the 2015 KACPR BLS guideline. Chest compression qualities were assessed using; correct compression (%; compression depth 5-6cm, lower half of the sternum), compression rate (n/min), mean compression depth (mm), correct chest recoil (%), correct hand position (%), and total hands-off time (sec).

Data analysis

The analyses were performed using IBM SPSS Statistics 19.0. $\chi^2$ or t test for comparison of general characters and outcome variables between two groups were used

Findings

Comparison of general characteristics between two groups

Forty-five students were enrolled in our study (control group: 23, experimental group: 22). No significant difference was found between general characteristics, that is, age, sex, CPR education, and previous chest compression experience, of the experimental and control groups. Furthermore, group mean heights and weights, which are important variables in the context of chest compression, were not different (Table 1).

### Comparison of outcome variables between two groups

There were significant differences in correct compression (t=2.13, \( p=.039 \)), compression rate (t=3.59, \( p=.001 \)), and mean compression depths (t=4.26, \( p<.001 \)). Correct compression was 64.00±35.26 % among participants of experimental group and 43.96±27.47 % for those of the control group. Compression rates were 119.86±10.05 times/ min and 128.57±5.70 times/min among participants of the experimental and control groups, respectively. We found mean compression depths were 50.77±6.56 mm and 41.78±7.54 mm among participants of the experimental and control groups, respectively. We found no differences in other variables between two groups (Table 2).

### Discussion

Over the last decade, the AHA has emphasized high quality chest compression during CPR. This study was attempted to change the teaching method to improve the performance of high quality chest compression. Results showed that new BLS training method used in this study was more effective in high quality CPR than previous method.

In this study, group correct compressions and mean
compression depths, indicating of proper hand position for chest compression of 5-6cm differed. This result supports previous reports regarding chest compression by doctors, nurses, and other medical professionals by showing chest compression depends on rescuer position. Rescuers performing chest compressions experience fatigue and exhaustion after 1 minute, which may reduce chest compression depth. Although the experimental group and the control group performed the same 5 cycles of CPR, the correct compression of the experimental group was 64.00% and the mean compression depth was 50.77mm. This indicates that the AHA and KACPR satisfy the chest compression guideline. This suggests that the experimental group is more familiar with chest compression on the bed than the control group. In addition, since CPR training is performed on the bed, it is possible that the strength of the chest compression needed to attain the recommended depth can be learned by considering the softness of the mattress during the training. The percentage of cardiopulmonary resuscitation performed by healthcare providers has been reported to be inadequate.

The causes of insufficient chest compressions vary, but the results of this study suggest that CPR training has only been performed at the bottom. For this reason, it is considered that chest compression of sufficient depth was not achieved in a hospital cardiac arrest situation. Therefore, it is recommended that doctors and nurses examine BLS training in hospitals bed to see if there is any change in the quality of chest compressions in the actual CPR situation.

According to another study, which examined chest compression by rescuers of height <170cm and weight <65kg, placing an object 10cm above the floor and below the knee was found to be effective. In the same manner, the use of a kneeling board could possibly lead to higher quality chest compression.

The AHA guideline states that at least hundred or more compressions per minute are needed to achieve adequate chest compression quality. In the present study, compression rates of the experimental and control groups were non-significantly different (119.86±10.05/ min and 128.57±5.70/min, respectively). However, the guidelines issued by the European Resuscitation Council (ERC) state that the quality of correct release is likely to decline if the chest compression rate exceeds 120 compressions per minute. The KACPR guideline, which comprehensively includes such recommendations, endorses a chest compression rate of 100 to 120 compressions per minute, which concurs with our results. The control group had a mean chest compression rate of 120 per minute and correct chest recoil 84.17±25.04% , which was non-significantly lower than 94.27±15.41% of the experimental group, this possibly explains why did not amount to a greater quality chest compression or speed. Furthermore, after performing chest compression with a mattress, one of the students in the control group commented, “I exerted more force because of the flexibility of the mattress and carefully checked for sufficient chest relaxation.” That is this student was motivated to increase the quality of chest compression.

No intergroup difference between correct hand position and total hands-off time were observed. It has previously been reported that height difference associated with the performance of CPR on a floor or bed affect chest compression depth and rate, but do not affect proper hand position on the sternum or minimizing hands-off time to less than 10 seconds. Consequently, educational materials do not need to be modified for different training environments, rather emphasis should be placed on establishing consistent guidelines.

AHA and KACPR emphasized minimizing hands-off time. In this study no intergroup difference between hands off time was observed. However, mean hands-off times in the experimental and control groups (9.82±1.22 and 10.48±1.44 seconds, respectively) were near to the maximum recommended by the AHA and KACPR (≤10 seconds). This is an area that requires training to shorten hands-off time during chest compression to increase the chance of patient survival.

In conclusion, nursing students would be better able to cope in the clinical practice were BLS training performed on a bed. Numerous opinions are held on the quality of CPR with respect to rescuer positions. We suggest students should receive training and education periodically to increase their abilities and preparedness to perform CPR anytime when faced with sudden cardiac arrest.

**Conclusion**

Nurses may encounter a patient that has experienced on a floor, bed, or any setting, although student nurses are more like to witness cardiac arrest on a bed. We suggest
current BLS training targeting medical professionals should include both on-the-floor and on-the-bed environments and that skills be improved by providing guidelines that allow would be rescuers to self-monitor the quality of chest compression.

Relationship of Family Support to Antenatal Care (ANC) Inspection in Work Area of Puskesmas Gunung Anyar Surabaya

Fama Alburuda¹, Nyoman Anita Damayanti¹
Faculty of Public Health, Airlangga University, Indonesia

Abstract

One indicator of the level of health quality of a region is the Maternal Mortality Rate (MMR). The maternal mortality rate in Surabaya is still high. At 2016, AKI is 85.72 per 100,000 live births. Antenatal Care (ANC) is a pregnancy examination to optimize the mental and physical health of pregnant women, so as to be able to deal with labor. This study aims to analyze the relationship between family support for ANC examination in pregnant women in the work area Puskesmas Gunung Anyar Surabaya. This analytic observational study used cross sectional approach. The population of this study is pregnant women in 2018 in the work area Health Center Puskesmas Gunung Anyar Surabaya as much as 1089 respondents. Sampling was done by using Random sampling system to get 75 respondents. Collected data is processed statistically using Spearman test. Spearman test result with 95% confidence level, obtained p value <0,022. Based on the test results, the hypothesis proposed is accepted in other words there is a relationship between family support with ANC examination. Furthermore, the correlation coefficient (r) 0.264 shows that there is a positive correlation and a strong relationship between the function of family support with compliance ANC examination. Based on this research it is suggested that health practitioner give counseling to the nearest family, especially husband to actively participate in supporting pregnant mother to conduct pregnancy examination in health service.

Keywords: Antenatal Care (ANC), Family Support, Maternal Mortality Rate (MMR)

PRELIMINARY

Maternal mortality rate (MMR) is one indicator of the health level of a region. In other words, the high maternal mortality rate, indicating the low level of health in the area. Maternal Mortality Rate (MMR) describes the number of mothers or women who died from a cause of death related to pregnancy or treatment disorder (excluding accidents or incidental cases) during pregnancy, childbirth and in the puerperium (42 days after delivery) without taking into account the length of pregnancy per 100,000 live birth. Maternal Mortality Rate is useful to describe mother’s nutritional status and health, environmental condition, health service level especially for pregnant mother, mother during childbirth and childbirth.

Based on the Indonesian Demographic Health Survey (SKDI) in 2015, the maternal mortality rate in Indonesia is still high at 305 per 100,000 live births. This figure is slightly decreased when compared with the SDKI in 2012, which amounted to 359 per 100,000 live births. The high maternal mortality rate makes Indonesia fail to achieve the Millennium Development Goals (MDGs) target of 2015 MDGs target is 102 per 100,000 live births.

Maternal Mortality Rate in Surabaya City in 2016 was 85.72 per 100,000 live births. This number decreased from the year 2015 which amounted to 87.35 per 100,000 live births.

Antenatal care (ANC) is a pregnancy test to optimize the mental and physical health of pregnant women. So that able to deal with childbirth, postpartum, preparation of breastfeeding and a reasonable return of reproductive health. An ANC visit is a pregnant woman’s visit to a midwife or doctor as early as possible since she feels she is pregnant for antenatal care or care. Antenatal care is to prevent obstetric complications whenever possible and to ensure that complications are detected as early as possible and adequately addressed.
Maternal and maternal mortality is influenced by several factors, namely late 3 risk factors that are late in making decisions at the family level, late referring, late to handle. In addition, too four factors are too young to be under 20 years old, too old over 35 years, too close to birth less than 2 years, and too many / more than 4 times of childbirth.

Late risk factors for family-level decision making are a lack of family support in their role against integrated ANC examination. Families are two or more of two individuals who are affiliated because of blood relations, marital relations or rapture and they live in one household, interacting with each other. A person’s life does not necessarily live individually, there is help from others. The family is the closest person to help and help each other, especially during pregnancy.

Based on the above description, it is deemed necessary to examine the relationship between family support with the status of ANC examination in pregnant women in the work area of Puskesmas Gunung Anyar Surabaya.

**Method**

This research is a research using quantitative observational analytic method. The study approach used is cross sectional which takes a sample from the population at one time. Population in this research is pregnant woman in work area of Puskesmas Gunung Anyar equal to 1089 pregnant mothers in year 2018. The sample in this research is pregnant woman taken by random sampling with amount of sampel determined counted 75 responden which then taken data of pregnancy examination through KIA book with the same time. Data analysis used SPSS Spearman test as correlation test of two categorical variables.

**Research Result**

Characteristics of respondents used in this study were assessed based on age, education, and income that can be seen in the distribution of the table below.

| Table 1. Characteristics of Respondents by Age, Education, and Revenue. |
|--------------------------|------------|--------------|
| **Variable**            | **N**      | **Persentase %** |
| Age                     |            |              |
| <20 year                | 24         | 32,0%        |
| 20-35 year              | 38         | 50,7%        |
| >35 year                | 13         | 17,3%        |
| Education               |            |              |
| Under Bachelor          | 30         | 40,0%        |
| Bachelor                | 45         | 60,0%        |
| Work                    |            |              |
| Not Work                | 31         | 41,3%        |
| Work                    | 44         | 58,7%        |

Based on table 1, it can be concluded that based on age the majority of respondents aged between 20-35 years. Based on the characteristics of education, most respondents complete education up to Bachelor Degree. While based on the work of more than half of respondents is working.

| Table 2. Distribution of respondents based on family support |
|--------------------------|------------|--------------|
| **Family Support**       | **N**      | **Persentase %** |
| Not Support              | 28         | 37,3%        |
| Support                  | 47         | 62,7%        |
| **Total**                | 75         | 100%         |

Based on table 2, it was found that 37.3% of respondents have not received family support. Furthermore, 62.7% of respondents have received family support.

| Table 3. Distribution of Respondents Based on ANC Inspection |
|--------------------------|------------|--------------|
| **ANC Inspection**       | **N**      | **Persentase %** |
| Not done                 | 3          | 4%           |
| Done                     | 72         | 96%          |
| **Total**                | 75         | 100%         |

Based on table 3, more than half of respondents are as many as 72 families 96% carry out the functions of ANC well. There are 3 families or 4% who have not done ANC well.
Table 4. Cross Distribution Between Family Support and ANC Inspection

<table>

</tr>
</tbody>
</table>

Based on table 4, out of 75 of respondents who were interviewed, obtained the result of 3 respondents have not done ANC examination and did not get family support. Furthermore, as many as 25 respondents have done ANC examination but did not get support from family. A total of 47 respondents have conducted ANC examination and received support from the family. This suggests that the more there is family support the compliance to carry out ANC examinations is increasing.

Based on statistical test result using Spearman hypothesis test with 95% confidence level so obtained p value <0,022 then hypothesis accepted. This means that there is a connection between the family support function and the compliance of the ANC examination. Correlation coefficient value obtained (r) 0.264 which indicates a positive correlation. indicating a strong relationship between family support functions and compliance with ANC examinations.

**Discussion**

The result of this research is $r = 0.264$, $p = 0.022$ ($p <0.05$) indicating significant relationship between family support function and compliance of ANC examination. It shows that the better a family plays an active role in supporting and motivating, it will be more obedient also pregnant women in the family to conduct ANC examination well and complete.

Families are two or more individuals who join because of blood relations, marriage and adoption in one household, who interact with each other in roles and create and maintain a culture.

Family support can be realized if the family function runs optimally. The five main aspects of family function are adaptation, partnership, growth, affection, and togetherness. With the implementation of these functions, then a prosperous family is formed with members who give each other support.

Family support is important in the realization of a positive thing. Family support sees that supportive people are always ready to provide help and help if needed. The nuclear family as well as the extended family function as a support system for its members, both in the form of emotional, instrumental, informative and rewarded.

Family support among others comes from the support of husband, family or other relatives, parents, and in-laws. Husband support is very important because the husband is the closest member who can reduce anxiety in pregnant women. In line with Hafidz (2007) in his research on the relationship of husband and parent role with pregnant woman behavior in ANC service, got result of significant relation between husband role and pregnant woman behavior in ANC service.

In line with research conducted by Rahayu in 2015, shows a link between family support and the implementation of the ANC. The lower the family support the possibility of non-compliance in carrying out the higher ANC. The results of this study are supported also by previous research by Agustini et al (2013) who also examined the relationship between family support with ANC visit of pregnant women at Puskesmas Buleleng I Bali.

**Conclusion**

Based on research results and the above discussion, can be concluded that there is a significant positive relationship between family support and ANC service coverage. The higher the family support, the higher the scope of a good ANC examination can be accomplished, thus reducing the risk of maternal death.

**Ethical Approval:** Related departments should be assured about the confidentiality of the results of questionnaires.

**Conflict of Interest:** The authors report no conflict of interest.

SUGGESTION

1. To health practitioners are expected to be more active to do tips in order to reduce maternal mortality by providing views or counseling to the nearest relatives, especially husbands in order to play an active role in supporting pregnant women to perform examination of pregnancy in health services.

2. It is expected that the next researcher can make this research as input and information for further research and can examine other factors related to pregnancy examination in health service.

The Implementation of Health Promotion in the Hospital in Ra. Basoeni Hospital in Mojokerto District

Rizka Lina Manfaati1, Oedojo Soedirham1, Rika S Triyoga1

1Department of Health Promotion and Behavioral Sciences, Faculty of Public Health, Universitas Airlangga, Indonesia

Abstract

Nowadays, the orientation of hospital services is not only focusing on curative and rehabilitative, but also prioritizing on preventive and promotive aspects in order to be a health promoter hospital.

The research was a qualitative study that analyze the implementation of health promotion in RA. Basoeni General Hospital based on Ministry of Health RI the standard of hospital as health promoter which includes the management policy aspects and intervention to the patient in health promotion aspects in relation to patient and family right. The research applied in-depth interview, observation and document study as data collection methods.

The research indicated that RA. Basoeni General Hospital had try to fulfilled the standard of Ministry of Health RI as health promotion hospital. The management policy aspect of RA. Basoeni General Hospital had been implemented in a strategic plan such as annual work plan. The human resources in RA. Basoeni General Hospital is sufficient in quantity, but training on health promotion in the hospital is needed to improve the quality. The budget had been included in the budget plan of RA. Basoeni General Hospital. The facilities and infrastructure were not good qualitatively, and quantitatively it must be increased. The documentation of intervention had been implemented routinely. The evaluation was also conducted in monthly or annually meetings. The study of patients intervention, and the assessment on health promotion requirement for the patients need was obtained from the medical record of health history of patient since the patient’s visit to the hospital. The access of information about health promotion for the patient had been presented either verbally or written, in addition it has also been presented in audio and visual forms.

Keywords: Standard of Ministry of Health RI on health promotion hospital, management policy aspect, Patient Intervention Aspect

Introduction

The hospital is a health facility that must be integrated into the health system in which it is located. Function as a resource center to improve public health in the region concerned. Reform of hospitals in Indonesia is needed because there are still many hospitals that only emphasize on curative and rehabilitative aspects only.¹,²,³

In Regulation Number 44 Year 2009 on Hospital in Article 1 mentions the definition of a hospital is a health service institution that provides full-scale private health services providing inpatient, outpatient, and emergency care services. Furthermore it is said that complete Health Service is health service which include promotive, preventive, curative, and rehabilitative.⁴,⁵

Health Promotion of Hospital is done in RSUD RA. Basoeni by delegating health promotion activities to every installation / work unit. Thus the activities undertaken are not integrated with the overall organization of the hospital. Based on the information received and the results of direct observation, the current health promotion effort in each hospital unit has not run optimally so that the patient and family in RSUD RA. Basoeni has not received patient and family rights for health promotion hospital activities. This is based on data obtained from preliminary surveys on 10 patients and families of outpatient that 4 of them have not received an explanation of disease prevention and health efforts. In
the suggestion box that is in the clinic room, according to RSUD RA. Basoeni in general hospital visitors complained about the lack of information about health by health personnel in RSUD RA. Basoeni Kabupaten Mojokerto.

**Method**

The research was a qualitative study that analyzed the implementation of health promotion of RA. Basoeni General Hospital based on Ministry of Health RI standard on the standard of hospital as health promoter that compliance the management policy aspects and intervention to the patient in health promoter aspects in RA. Basoeni hospital In mojokerto district. The research was applied indepth interview, observation and document study as data collection tools. Research subjects in this study consisted of informants and key informants. 

Key informants and informants in this study are as follows:

1. Key informants: Team leader health promotion of hospital RSUD RA. Basoeni Kabupaten Mojokerto with purposive sampling technique as many as 5 people.
2. Informant:
   a. Outpatient RSUD RA. Basoeni with purposive sampling technique in internist care as many as 11 people
   b. Family who accompany the outpatient RSUD RA. Basoeni as many as 11 people

**Results**

**Hospital Policy related Health Promotion of Hospital**

Health promotion of hospital program is part of the vision and mission of RSUD RA. Basoeni to commit to provide quality services include Promotional, preventive, curative and rehabilitative efforts. Hospital’s policy has also supported the implementation of health promotion of hospital with Decree of Director (SK) Number 124 / KEP / 416-212 / 2016 regarding the establishment of health promotion hospital team RSUD RA. Basoeni as found in the following in-depth interview statement:

“... health promotion hospital already have SK Director for the establishment of health promotion hospital Team ....” (JN, 42 years)

**Hospital Human Resources to run health promotion hospital**

Human resources owned by the hospital’s health promotion unit is still minimal, with no special staff with educational background and health promotion training. The task of carrying out the Health Promotion of Hospital (health promotion hospital) is still considered as a supporting activity only. This was conveyed by one of the informants as the result of the following in-depth interviews:

“... health promotion hospital implementation is perceived less well, the cause is the power handling health promotion hospital still feel that health promotion hospital only side activities, may be busy with patient service ..” (JN, 42 years)

**Health Promotion Hospital’s Fund**

The result of observation and interview with health promotion hospital coordinator got result from fund input indicator of health promotion hospital activity that can Provide health promotion hospital fund in RSUD RA. Basoeni still not stand alone but allocated with other activities. This is evident from the following in-depth interviews;

“...... for health promotion hospital fund has not been planned by itself. The collection of leaflets and honorariums can not yet appear on their own but in other activities ...” (AY, 38 years)

Readiness of funds in the work program is very important. Because every work program requires a lot of funds. Limitations of funds cause work programs that can be implemented also slightly.

**Hospital Infrastructure Facility in Running health promotion hospital**

Based on the results of in-depth interviews with informants obtained that existing facilities in the hospital has not supported the implementation of health promotion hospital program in RSUD RA. Basoeni. This is indicated by the absence of special room health promotion hospital so it still must be implemented in the lobby hall with a limited seat. In addition, facilities
and infrastructure extension is also still limited. The facilities include leaflets, audio-visual devices which, when damaged, can not be implemented, health promotion hospital activities due to long repairs and no reserves. The statement tersebuit line with the results of the following in-depth interviews:

“... The obstacles are on the infrastructure such as the current LCD is damaged so it can not be used, side effects are health promotion hospital activities can not run ...” (AY, 38 years)

Health promotion facilities are very important in the implementation of health promotion of hospital program. To improve the audience understanding it is necessary some audio visual media such as LCD, video that can change the knowledge and perception of patients about health. Media used by officers to share information to patients and their families in the form of leaflets and brochures.

The Implementation Process of Health Promotion Hospital in RSUD RA. Basoeni Kabupaten Mojokerto Year 2016

A good health promotion program should be built in accordance with a systematic and sustainable framework. Implementation process of health promotion hospital program in RSUD RA. Basoenei through the stages of planning, implementation and evaluation. This is as obtained from the following in-depth interviews:

“... In the work program reported to the director there is an evaluation of activities. If there are discrepancies will be analyzed the points that are not appropriate then what constraints are established and alternative solutions ... “(AY, 38 years)

“... Implementation is good, not just management but all involved in good coordination. Internal programs include extension of visitors, through media leaflets. For external activities through scheduled district radio and interactive questioning ... ”(AY, 38 years)

Intervention studies on patient needs and access to patient convenience for information on health promotion have been implemented since the first time the patient received health care and can be seen from the patient’s medical records. Access to health promotion information is obtained by means of oral, or written / leaflet explanations, as well as through audio visual media but is minimal. The information should be given to the hospital in order to assist the healing process of the patient. In addition, the patient’s family will become more understanding about health information related to their sick family.

“... Yes, it is very important to help the healing of sick families ...” (N, 24 years)

“... Information becomes the right of the family to speed up healing and family understand ...” (M, 32 years)

Patients are very lacking in getting information about the drugs to be consumed and the course of his illness to get well and healthy again. The informant also responded that education and health information is the right of the patient during hospitalization

“... About medicine and how to recover from my illness ...” (E, 60 years)

“... The unclear problem is how to let it not recur and recover quickly, prohibited food, when to stop the drug ...” (27 years)

“... It is not clear the problem of how to cure, it is not clear the administrative problem of BPJS assurance usage and must add how ...” (M, 39 years)

Family of patients who accompanied the patient during service in RSUD RA. Basoenei has generally received an explanation of the disease. The explanation comes from family members who were accompanied orally. The patient’s family usually feels that they have not received any explanation or information about efforts to speed healing and administrations and the types of drugs to be drunk.

Discussion

Result of research concerning policy commitment of health promotion effort at RSUD RA. Basoenei Mojokerto regency indicates that it has received strong commitment, this commitment is realized in the form of strategic plan which has been compiled in annual work plan. Every hospital health promotion effort has been implemented in accordance with the work plan. In the implementation of health promotion efforts of this hospital itself is implemented all installations in RSUD RA. Basoenei, where the implementation is done directly by the installation related to coordinate with the supporting field as the responsible for the implementation of all health promotion efforts of the hospital. Evaluation
efforts have also been undertaken based on the work plan that has been prepared beforehand, the evaluation is seen from the work whether it is in accordance with the work plan that has been set. For the improvement of the hospital’s health promotion efforts have started running but not all aspects can be improved, there are some obstacles that become obstacles in the effort of health promotion of the hospital.

Based on the research conducted by Lukman on the management policy aspect of Health Promotion in H.Adam Malik Hospital Medan policy commitment must be emphasized in the implementation of Health promotion in order to be able to run in accordance with the objectives of the hospital as a health service facility that provides full range of personal health services including promotive, preventive, curative, and rehabilitative as mandated in Law Number 44 Year 2009 about Hospital.\(^{(4,5,6)}\)

Health Promoting Hospital or hospitals that promote health in the world today has become a trend and is seen as a hospital for the future because it integrates all aspects of service holistically and inclusively to health on an ongoing basis. Holistic service aims that the services performed by hospitals are not only physiologically oriented but also covering all human dimensions including bio, psycho, socio and other determinants that are oriented towards salutogenic.\(^{(12)}\)

Related to the availability of human resources in the effort of health promotion of hospital in RSUD RA. Basoeni, from the results of the research note that in the planning of human resources for the implementation of health promotion efforts hospital in RSUD RA. Basoeni arranged in the structure of tasks and job descriptions written, especially for the responsible implementation of health promotion efforts namely the field of support. However, the establishment of officers in their implementation in other work units such as outpatient and pharmacy does not have specific jobdesk for resource persons for implementation in every installation. Specified resource persons are usually nurses, doctors or officers who are directly elected by the support field without any written structure and job descriptions. The human resources responsible in the implementation of health promotion efforts of existing hospitals are able to carry out the duties and responsibilities that have been given, but still found some obstacles that hinder the smooth implementation of health promotion efforts of the hospital that officials feel PKRS only as the supporting element only and not as the main task of health services.

The result of research related to the evaluation is known that the quality of human resources as a whole is good enough, but there are still some shortcomings related to the special abilities of the current human resources especially in outpatient. For improvement efforts to date the RSUD RA. Basoeni has not provided serious services and concerns regarding the quality of human resources available, it is known from the research that until now there has been no special training for health promotion’s officers related to the promotion of hospital health but only effective communication training.

Skilled human resources are needed in the implementation of health promotion of hospital activities. Improving the quality of human resources through education and training and the addition of human resources in quantity also support the implementation of health promotion of hospital well.\(^{(7)}\)

The development of health promotion in hospitals in Indonesia has increased quite rapidly. Technological advances also participate support the development of health promotion in Indonesia. The delivery of health information becomes faster in access. It is not possible to create a technology-based discussion group for patients with the same type of disease can be created by a hospital. Technological developments can also develop a mobile network device to detect, monitor, diagnose, so get advice and treatment. Promoting health through an integrated health care system will be an option in today’s technological advancement era.\(^{(1,2,11)}\)

Based on Regulation no. 36 of 2009 on Health, states that one of the resources in the health sector is a health service facility, where article 1 point 7 defines the health service facilities of a tool and / or place used to carry out health service efforts, whether promotive, preventive, curative as well as rehabilitative by the government, regional government or the community.\(^{(6)}\)

From the results of the study it is known that related efforts assessment of health promotion needs for patients, in the planning of health promotion efforts for patients has been implemented from the beginning of the patient entered the hospital. The form is a written report on the medical record of the patient’s medical history. Patients are also given information every health promotion will be held.
Conclusion

To comply the standards health promotion in the hospital include management policy aspect and patient intervention study that is by improving the quality of human resources for health promotion hospital activities through training of education capability, making health promotion hospital budget routinely and transparently in managing by health promotion hospital team, infrastructure to provide special space health promotion hospital in each unit and make guidance on patient education information in each service unit. Patient intervention studies and access to health information should benefit from more interesting audio-visual technology.

The Effect of Edutainment Usage on Improving Knowledge, Attitudes, Balanced Nutrition Fulfilling Behavior in the Prevention of Anemia and Changes in Hemoglobin Levels in Adolescent Girl

(Case Study Of SMPN 4 Banjarbaru)

Siti Nurhayani¹, Lenie Marlinae², Nia Kania³

¹Student of Public Health Magister Program, ²Environmental Health Department, ³Department of Pathology Anatomy, Ulin General Hospital, Medical Faculty Lambung Mangkurat University

Abstract

The prevalence of anemia in adolescent in Indonesia is high enough that 21.7% with anemia patient aged 5-14 year equal to 26.4% and 18.4% patient aged 15-24 year. Banjarabaru is the highest incidence of anemia in adolescents in South Kalimantan Province of 58.75%. Research Objectives is to analyze the effect of edutainment use on the improvement of knowledge, attitudes, behavior of balanced nutrition fulfillment in prevention of anemia and change of hemoglobin level in female adolescent. This research used Quasi Experiment design with pre-test and post-test group design approach. The number of samples of 90 young women taken with purposive sampling technique. The data obtained were then analyzed using Paired T-Test and Wilcoxon statistical tests for paired differential test, and Anova and Kruskall Wallis tests for unpaired test, followed by Post Hoc test for Anova test and Mann Whitney test for Kruskall Wallis test. The results of statistical analysis show that overall p value obtained <0.005 indicates that edutainment booklet and video edutainment have different effects before and after intervention to increase knowledge, attitudes, and behavior of balanced nutrition in prevention of anemia and changes in hemoglobin levels in adolescent girls.

Keywords: Edutainment, Knowledge, Attitude, Behavior, Anemia, Hemoglobin Level

Introduction

Anemia is a state of the body characterized by a deficiency in the size and amount of erythrocytes or at insufficient hemoglobin levels for the O2 and CO2 exchange function between the blood tissues. Based on Data Center and Information Ministry of Health of the Republic of Indonesia (2016) the average energy consumption in adolescents aged 13-18 years is 72.3% with the proportion of consuming <70% energy sufficiency (AKE) of 52.5% this shows that adolescents still consume energy below minimum requirements. Lack of energy required can lead to anemia. This is confirmed by Basic Health Research data of 2013 shows that the prevalence of anemia in Indonesia is 21.7% with anemia patient aged 5-14 year equal to 26.4% and 18.4% patient aged 15-24 years.

Data from South Kalimantan Health Office 2015 stated that the prevalence of female adolescent anemia in South Kalimantan is still quite high, that is 29.13% before the administration of tablets added blood, after the intervention of giving tablets plus blood result decreased to 13.64%. From 13 regencies, Banjarbaru city was 58.75%, which was the highest of adolescent anemia problem before giving tablet added blood followed by Regency of Banjar equal to 48.92% and Regency of Tanah Bumbu equal to 43.67%. This is corroborated with the results of data reports nutrition program Banjarbaru City in 2015 highest in SMPN 4 Kota Banjarbaru as many as 82.4% of adolescent girls who have anemia.

According to the Ministry of Health (2016), the impact of anemia on young women is able to lower the body’s resistance so that people affected by infectious diseases, decreased fitness and dexterity due to lack of oxygen to muscle cells and brain cells, and reduce
learning achievement and work productivity. Anemia is more prevalent in young girls than in children and in adulthood, as young women are at a time of growth and development and therefore need more sources of iron, in addition teens need more iron to replace the missing iron with menstrual blood. Adolescents with anemia then become pregnant will experience risks such as antepartum bleeding, abortion, premature birth, fetal growth and inflammation easily infected. Anemia in adolescents will result in lower ability and concentration of learning, interfere with growth so that the body does not reach the maximum, decrease physical ability, and result in a pale face.

Listiana research results (2016) showed that knowledge and attitude became one of the factors associated with the incidence of anemia in adolescents with a value of p-value of knowledge 0.002 and p-value attitude 0.001\textsuperscript{9}. Efforts that can be done to improve the application of balanced nutrition in adolescents in the prevention of anemia has not been optimal either direct efforts such as giving blood tablets or efforts not directly through counseling and socialization. This is corroborated by data from the Banjarbaru City Health Service report that after the intervention of blood-added tablets anemia still occurs on the second examination that is as much as 26.17% above the prevalence of anemia of South Kalimantan Province is 17.81%. So it is necessary other efforts to provide information related to nutrition in accordance with their needs one of them is to provide nutrition education in the form of edutainment counseling. Edutainment is one form of counseling or education that is packed in the form of fun entertainment\textsuperscript{10}.

According to Soul City Institute of Health and Development Comunication (2016) edutainment is one way of exploiting the enormous potential to influence individuals and society positively\textsuperscript{11}. The results of Bergmann’s study (2010) stated that over 600 (73%) of respondents showed positive responses favored learning with edutainment, and about 500 (66%) of respondents reported that they planned to make behavioral changes in healthy eating and physical activity. Only about 95 respondents (13%) did not want to plan to make changes, while the remaining 150 respondents (20%) answered still in doubt\textsuperscript{12}.

**Material and Method**

The method used in this research is quantitative research with Quasi Experiment design using pre test and post test group design approach. The samples in this study were 90 teenage girls.

Information: \textsuperscript{a} Uji Wilcoxon \textsuperscript{b} Uji Paired t-test
Based on table 1 on the variable level of knowledge obtained Wilcoxon test results that show \( p < 0.05 \) which means that there is a difference in the influence of knowledge between pretest and posttest on group edutainment booklet. The results of the Wilcoxon test showed \( p < 0.05 \) which means that there is a difference in the influence of knowledge between pretest and posttest in the video edutainment group. The results of the Wilcoxon test showed \( p < 0.05 \) which means that there is a difference in the influence of knowledge between pretest and posttest in video edutainment and booklet groups.

In attitude variable, the result of Wilcoxon test shows that \( p < 0.05 \) meaning that there is difference of attitude influence between pretest and posttest in edutainment booklet group. The result of paired t-test shows that \( p < 0.05 \) meaning that there is difference of attitude influence between pretest and posttest in video edutainment group. The results of the Wilcoxon test showed \( p < 0.05 \) which means that there is a difference in attitude influence between pretest and posttest in video edutainment group and booklet.

In behavioral variable, the result of Wilcoxon test shows that \( p < 0.05 \) meaning that there is difference of behavior influence between pretest and posttest in group edutainment booklet. The results of the Wilcoxon test showed \( p < 0.05 \) which means that there is a difference in behavioral influence between pretest and posttest in the video edutainment group. The results of the Wilcoxon test showed \( p < 0.05 \) which means that there are differences in behavior between pretest and posttest in video edutainment and booklet groups.

In the variable hemoglobin levels obtained Wilcoxon test results showed \( p < 0.05 \) that there is a change in hemoglobin levels between pretest and posttest in the edutainment booklet group. The results of the Wilcoxon test showed \( p < 0.05 \) that there was a change in hemoglobin levels between pretest and posttest in the video edutainment group. The result of paired t-test showed \( p \) value <0.05 which means that there is difference of hemoglobin level between pretest and posttest in video edutainment group and booklet.

Information: \( a=\text{Kruskall Wallis Test} \ b=\text{Anova one way} \)

The result of statistical analysis on knowledge, attitude, behavior and hb level of adolescent girls obtained \( p \) value <0.05. So it means that there are differences in the effectiveness of edutainment booklet, video edutainment and video edutainment and booklet in improving knowledge, attitude, behavior about the fulfillment of balanced nutrition in the prevention of anemia and changes in hb levels.

**Result**

Based on the results obtained scores edutainment video and booklet higher than the group that only get edutainment booklet and edutainment video. This shows that video edutainment media and booklets are more effective than other media. The effectiveness of a medium can be seen from the difference in the average increase achieved. The most effective medium is shown
The effectiveness of video edutainment and edutainment booklets is also seen from the mean rank values of each group seen in video edutainment combined with higher edutainment booklets than other groups.¹³ The use of video edutainment modifications and booklets in the intervention given to young women to the information conveyed will be more impressive in depth, thus forming a good and perfect understanding. Knowledge can be improved by providing education, this is in line with the results of research Buzarudina (2013) shows that counseling can increase youth knowledge.¹³ In addition to visual media in the form of booklets, audiovisual media is also considered more effective against the understanding of balanced nutrition in adolescents. This is reinforced by the statement Notoatmodjo (2007) one of the factors that affect knowledge by providing health education.¹⁴ Good knowledge will encourage a person to display an attitude appropriate to the knowledge he has gained. Based on the existing theory that knowledge can affect one’s attitude, with good knowledge it will manifest a good attitude too. This improvement in attitudes proves that young women have an attitude of receiving information about the fulfillment of balanced nutrition in the prevention of anemia after getting intervention. According to Bertalina (2015) this increase in knowledge and attitudes is derived from the learning process by utilizing all sense devices, of which 13% of knowledge is acquired / channeled through the senses of hearing and 35-55% through the sense of hearing and sight.¹⁵ The level of knowledge of one’s nutritional effect on attitudes and behavior in the selection of food that will ultimately affect the nutritional state concerned. This is in line with Rasouli’s (2010) research that health education programs are able to improve knowledge, attitudes and practices of nutrition fulfillment so as to have a positive effect on nutritional behavior either in children or adolescents or other age groups.¹⁶ Provision of nutrition education in young women is expected to increase the knowledge of young women about nutrition, especially about anemia, and is expected to change the diet so that the nutritional intake becomes better. An open mind and the characteristics of adolescents who are still in the learning phase will indirectly affect their habits. With nutrition education, adolescents will be more familiar with good habits in terms of fulfillment of nutritional intake, so as to practice it in everyday life. Health education is a process that bridges the gap between information and health behavior. Interventions conducted for 3 months not only change knowledge but also can change attitudes and behavior.

The 12-week study and four intervention interventions were able to change the hemoglobin level in female adolescents, especially for those with anemia, as seen in the reduction of anemia in each group, the edutainment booklet group by 20%, the video edutainment group 6.7% and a mix of video edutainment and booklets by 30%. This is supported by research by Peyman et al. (2014) that the provision of three months of balanced knowledge, motivation and nutritional behavior can show significant changes in Hemoglobin levels in anemic female adolescents. Nutrition education interventions have an impact on improving the knowledge, attitudes and behavior of adolescent girls who are iron deficient compared with controls for 3 months of intervention, in addition to an increase in mean rank of hemoglobin levels before and after intervention.¹⁷

**Conclusion**

1. Edutainment booklet has an effect on to increase knowledge of balanced nutrition fulfillment in prevention of anemia in adolescent girls.
2. Edutainment booklet effect on the attitude of fulfillment of balanced nutrition in the prevention of anemia in young women.
3. Edutainment booklet effect on the behavior of balanced nutrition in prevention of anemia in young women.
4. Edutainment booklet effect on hemoglobin levels in young women.
5. Video edutainment has an effect on increasing knowledge of balanced nutrition fulfillment in prevention of anemia in adolescent girls.
6. Edutainment video effect on the attitude of the fulfillment of balanced nutrition in the prevention of anemia in young women.
7. Video edutainment effect on the behavior of balanced nutrition prevention of anemia in young women.
8. Video edutainment effect on hemoglobin levels in young women.
young women.
9. Edutainment booklets and videos have an effect on increasing knowledge of balanced nutrition fulfillment in prevention of anemia in young women.
10. Edutainment booklets and videos affect the attitude of fulfillment of balanced nutrition in the prevention of anemia in young women.
11. Edutainment booklets and videos affect the behavior of balanced nutrition in prevention of anemia in young women.
12. Edutainment booklets and videos affect the hemoglobin levels in girls.
13. Edutainment booklets and videos more effectively increase knowledge about the fulfillment of balanced nutrition in the prevention of anemia.
14. Edutainment booklets and videos more effectively improve attitudes about the fulfillment of balanced nutrition in the prevention of anemia.
15. Edutainment booklets and videos more effectively improve the behavior regarding the fulfillment of balanced nutrition in the prevention of anemia.
16. Edutainment booklets and videos are more effective in increasing knowledge of balanced nutrition fulfillment in prevention of anemia in young women.

**Ethical Clearance**: this study approved and received ethical clearance from the Committee of Public Health Research Ethics of Medical Faculty, Lambung Mangkurat University, Indonesia. In this study we followed the guidelines from the Committee of Public Health Committee of Public Health Research Ethics of Medical Faculty, Lambung Mangkurat University, Indonesia for ethical clearance and informed consent. The informed consent included the research title, purpose, participants right, confidentiality and signature.

Measurement of Imparted X-Ray Dose to Patients Undergoing Voiding Cystourethrography/ Retrograde Urethrography at University of Maiduguri Teaching Hospital

Gurama A.D¹, Sa’ad U.A¹, Kurama M.B², Shettima AB², Gunda N.M²
¹Department of Medical Radiography Usman Danfodio University, Nigeria,
²Department of Medical Radiography University of Maiduguri, Nigeria

Abstract

Background: Retrograde urethrography (RUG) is a widely performed examination that involved irradiating radiosensitive organs like testes. It is therefore very important to know the amount x-ray dose imparted to individuals undergoing RUG cases.

Objective: To determine the imparted x-ray dose to patients undergoing VCUG/RUG cases at UMTH.

Method: A prospective study was conducted at UMTH using a prestige fluoroscopy machine with inbuilt DAP meter. The DAP meter was used to measure the imparted x-ray doses to 30 patients that came for RUG cases. Their ages ranged from 14 years to 77 years and weights ranged from 42kg to 73kg. The following technical factors were recorded: tube kilovoltage, focus-to-surface distance, screening time and miliamperage.

Result: The minimum and maximum measured DAPs for the RUG cases were 27.72Gycm² and 12.00Gycm². The mean measured DAP for the RUG cases was 18.32Gycm².

Data Analysis: The data was analyzed using SPSS version 16 statistical software.

Conclusion: The mean measured DAP was higher than reported in literature and also reference levels for UK, but still below those of Norway and NRPB. That meant they were practicing radiation protection in RUG examination but still need optimization to further reduce patient doses.

Keywords: Dose Area Product (DAP) and retrograde urethrography (RUG).

Introduction

Radiation dose from diagnostic radiology gives the highest combined absorbed dose to the populace when compared with other sources that uses ionizing radiation [1] (Suleiman et al., 2014). The International Commission on Radiological Protection and (ICRP) in 2007 reported that 36% of man-made radiation comes from Diagnostic Radiation, including 5% from general X-rays and fluoroscopy. [2] There has been a growing concern regarding the risks of radiation exposure from diagnostic X-ray examinations. At University of Maiduguri Teaching Hospital (UMTH), Voiding Cystourethrography (VCUG)/ Retrograde Cystourethrography (RCUG) is the most frequent fluoroscopic examination of all fluoroscopic examinations performed in both adult and children.

VCUG/RUG is a widely performed examination for radiological evaluation of the urethra and urinary bladder in adult and children done mostly under fluoroscopy. [1] (Suleiman et al., 2014). Radiation dose to patients during VCUG/RUG examination is very high due to screening and the number of projection per examination. Therefore, it is very important to measure the radiation dose to radiosensitive organs like testes since stochastic

Abshettima123@gmail.com
risks (such as mutation) are involved, which have no threshold dose. \textsuperscript{[1, 3]} (Suleiman et al., 2014; Livingstone, Koshy & Raj, 2004).

Ionizing radiation (such as x-rays) can potentially damage living tissues causing serious effects (like mutation). High radiation doses tend to kill cells, while low doses tend to damage or alter the genetic code of deoxyribonucleic acid (DNA) of irradiated cells. The effect is more pronounced in those cells that are rapidly dividing, rapidly growing and immature.\textsuperscript{[4]}

The testes are the site of production of sperm cells (male reproductive gametes) and sperm cells have almost all the above features and hence are very sensitive to x-rays (ionizing radiation). When these organs are being irradiated there is likely, a genetic change in the genetic material (DNA) would be seen and if so, the future offspring(s) of the irradiated person will inherit the abnormal DNA and therefore develop(s) abnormality (mutation).\textsuperscript{[5]}

Diagnostic radiology contributes a large amount of man-made radiation exposure to the human population. Measurement of radiation doses should therefore be given proper consideration with a view to keeping radiation doses imparted to patients “as low as reasonably achievable” (ALARA) with acceptable image quality.\textsuperscript{[1, 2]}

Radiation dose measurement in diagnostic radiology is the cornerstone for setting good practice standards as well as optimizing radiation protection to both staff and patients.\textsuperscript{[6, 7]}

The standard quantities used for dose assessment in radiography and fluoroscopy are Entrance Surface Dose (ESD) and Dose Area Product (DAP).\textsuperscript{[8, 9]}

Radiation doses imparted to patients can be measured using a Dose Area Product (DAP) meter.\textsuperscript{[10]} DAP is a useful quantity, because it can be easily measured. It is not directly related to risk other than that, for the same examination, a doubling in DAP represents a doubling in risk.\textsuperscript{[8, 9]}

Diagnostic Reference Levels (DRLs) are used in conjunction with dose audit, to test whether the average dose used for a particular examination is being restricted as far as reasonably practicable.\textsuperscript{[6, 8, 9]} The x-ray dose imparted to patients undergoing VCUG/RUG examinations at UMTH was not known, since there was no any local diagnostic reference level (LDRL) available. Those of the European countries are: for Norway is 20 Gycm\textsuperscript{2} (1996), for NRPB is 40Gycm\textsuperscript{2} (1996) and for UK is 12 Gycm\textsuperscript{2} (2005).

Hence, this study is aimed at determining the x-ray dose imparted to patients coming for VCUG/RUG examination at UMTH.

**Methodology**

A cross-sectional prospective study was conducted. Data was acquired through direct DAP meter measurements of the radiation dose imparted to consenting male participants aged 14 years and above. This study was performed using a Prestige SI Fluoroscopy machine with an over couch x-ray tube (Ultragen N A, Model number: ZA0UL00A, Serial number: 169533M07 Minimum added filtration: 1.5mmAl at 80kV). The radiation dose imparted to the patients during Retrograde Urethrography (RUG) examination were measured using a DAP meter which is inbuilt in the x-ray tube assembly. The readings from the DAP meter were used to estimate the radiation imparted to patients undergoing the examination. The following parameters were taken during every RUG examination: Focus to Surface Distance (FSD), Thickness of the patients, Age of the patients, Irradiated area, Screening time, the radiation imparted to patients were measured using DAP meter.

**Results**

A total of 30 patients who underwent RUG examination were included in this study. Their age ranged from 14 to 77years (mean age 48.43±17.88years). The range of measured DAP was from 12 Gycm\textsuperscript{2} to 27.72Gycm\textsuperscript{2} (mean 18.32 Gycm\textsuperscript{2}). Patients’ related parameters such as age, weight of the patients along with exposure factors used during the examination were shown in (table 1).

Out of the results, 27.72Gycm\textsuperscript{2} was found to be the highest value among the doses measured by the DAP meter. This corresponds to the patient with the serial number 10, which was exposed with 125kV and 0.5mA for 3.8minutes (228 seconds). While the lowest dose recorded by the DAP meter was 12.00Gycm\textsuperscript{2} which corresponds to the patient with the serial number 5 which was exposed with 115kVp and 0.4mA for 2.5minutes (150 seconds) (Table 1).

A comparison between the measured DAP (MDAP) and the UK/Norway international standards was done and found that the values obtained in the present study were higher than the UK standards. However, some were above and some are below that Norway reference level (Table 3). Only patient with the serial number 5 is exposed within the UK reference level (Table 3). The mean MDAP was found to be 18.32 Gycm$^2$.

Discussion

From the results, 27.72 Gy cm\(^2\) was found to be the highest dose measured in this study. This may be as a result of long screening time (3.8 minutes) and also increased mA (0.5) used which will increase the DAP value obtained. It can also be as a result of improper collimation of the irradiated area which will directly increase the DAP value. 12.00 Gy cm\(^2\) was found to be the lowest doses measured in this study. This may be as a result of short screening time (2.5 minutes, is the shortest) which will decrease the DAP value obtained as compare to that obtained above.

The mean MDAP obtained in this study was found to be 18.32 Gy cm\(^2\). There was a significant difference between this and that for international standards (12 Gy cm\(^2\) for UK, 20 Gy cm\(^2\) for Norway and 40 Gy cm\(^2\) for NRPB). However, the variation may be as a result of uncertainty in the DAP meter measurements due to the fact that no quality assurance programme was conducted to calibrate the DAP meter before conducting this research. Another possibility can be as a result of higher screening times obtained due to complexity of examinations which will also lead to increase values of DAP. It can also be as a result of increase in irradiated area (since no any evidence of collimation in almost all the films taken during the examinations) which will also increase the values of DAP. Furthermore, RUG examination is less frequently performed (once in a week), and since the operators of the machine are intern radiographers, they will not have enough time to gain much and maintain their skills. This will further increased the screening time and hence the increased DAP value obtained here.

Comparing the mean obtained here (18.32 Gy cm\(^2\)) with 3.16 Gy cm\(^2\) obtained by Merkle E., et al., in 1996 showed that a higher radiation dose was obtained in this study. Gyekye et al., in 2009 also found 3.55 Gy cm\(^2\) as the estimated DAP for RUG examination which is also lower than the one found for the present study. Livingstone, Koshy & Raj in 2004 found a range 0.54 Gy cm\(^2\) to 9.87 Gy cm\(^2\) as the estimated DAP which is also lower than range (12 Gy cm\(^2\) to 27.72 Gy cm\(^2\)) for the present study. Their values are all below the reference levels. This may be as a result of the methods they used since some methods (like clamp method) may be comfortable to the patients. The patients will be more cooperative and there may less screening time which results into decrease patients’ dose.

Conclusion

The mean measured DAP was higher than those reported in literature and also reference levels for UK, but still below those of Norway and NRPB. That meant they were practicing radiation protection in RUG examination but still need optimization to further reduce patient doses.

Ethical Clearance: Ethical clearance taken from the ethical clearance committee of the hospital but unfortunately the supporting document is missing due to loss of data.

Abstract

Malaria is still a major global health problem, killing more than one million people every year. The Naulu is one of the remote tribes in Seram Island of Maluku Province which is known to be a malaria endemic area, but the incidence of malaria was reported to be very low. This study aims to describe the Naulu perspective on malaria, causes of malaria, prevention and malaria control efforts. Research method is qualitative research with phenomenology design. Research subjects were people of Naulu, public figure and managing malaria program at primary health centers. To ensure that the people of Naulu do not suffer from malaria, microscopic examination for plasmodium were done with blood sample. The result of microscopic examination of 100 research samples showed only two samples were positive for malaria. The result of indepth interview got habit of society to make efforts of prevention and self treatment of malaria. This habits were gained from generation to generation from their predecessors. Such as using fumes from the dried skin of duku (Lansium domesticum) and consuming bitter foods. Treatment effort uses existing ingredients around the environment that are made independently of them by drinking boiled water of sambiloto (Andrographis paniculata) leaves, papaya (Carica papaya) leaves, or stem bark of pule (Alstonia scholaris R.Br) which reflects the lower incidence of malaria because of these traditional practices.

Keywords: malaria, naulu tribe, prevention, treatment

Background

Malaria is still a major global health problem, killing more than one million people every year. Almost all of these deaths are caused by Plasmodium falciparum, one of four species of malarial parasites that infect humans. The disease is still a significant public health problem worldwide. The World Health Organization estimates that 214 million cases of malaria occur worldwide by 2015. According to WHO, 13.8 million cases are caused by Plasmodium vivax, a parasitic species that predominates Southeast Asia and America continent where it contributes for more than 50% of malaria cases.

World Malaria Report, mentioned that malaria had was reported in 106 countries, even 3.3 billion people in the world lived in areas at risk of contracting malaria. In the world is 216 million cases, of which 28 million cases occur in ASEAN. There are 660 thousand people die every year due to malaria, especially toddlers (86%), 320 thousand of them are in Southeast Asia including Indonesia. During 2005-2013, the case of malaria throughout Indonesia tended to decrease, ie 4,10% (in 2005) to 1,38% (in 2013). In some places, it still showed a high incidence. As many as 80% of cases came from NTT, Maluku, North Maluku, West Papua, and Papua. The five provinces with the highest incidence and prevalence were Papua, East Nusa Tenggara, West Papua, Central Sulawesi and Maluku. Based on the data from the Health Department of Maluku Province, there has been a decrease in malaria cases in Maluku Province in which API was 16,51% in 2013 to 4,98% in 2016.

The prevention of malaria is important because of its enormous impact on human life. Orem, et al. categorized the impact of malaria into three dimensions, namely: health dimension, social dimension and economic dimension. Epidemiological research on the tribal community in India, contributed more than
40% of patients with malaria and more than 65% with *P. falciparum* and more than 50% of deaths caused by malaria (9). Singh’s research (10) in India found that tribal communities were 6% of the country’s total population who contributed more than 20% of the total number of malaria cases. At least 50% of deaths from malaria in India occurred in tribal communities (11). The study of Ganguly, et al (12) found that patients with asymptomatic malaria came from the tribal people.

The Naulu tribe in Seram island in Central Maluku Regency, Maluku Province is known as a traditional community that maintains customary practices consistently in the midst of rapid cultural changes around their environment. People’s habits are hunting and gardening in the forests as well as the work of most of the people. Gardening done from morning until late afternoon before returning to the house, hunting is done from afternoon until the next day. Sometimes two or three days just returned home depending on the catch obtained. According to Marchand (13), malaria is affected by work, behavior, ethnic background, distance from home to forest. The dominant factor for the risk of malaria is the frequency of overnighting in the forest and the distance of the house from the forest. The neighborhood of this community is still surrounded by dense forest, in the vicinity of their housing there are sago, coffee and cacao plants and other plants are quite lush. Forests are known as one of the factors that support the transmission of malaria (14).

The examination of plasmodium by microscopy of 100 people with fever or history of fever in the last three months using blood slides samples, indicating only two people had plasmodium in their blood samples, meaning that only two people who had positive malaria. Over the next month, a blood sample examination of 6 people with fever with temperature 39°C using RDT also showed negative results. This research aims to illustrate the perspectives of Naulu people and measure adopted by them on the causes, prevention and overcoming efforts for malaria infection.

**Material and Method**

The method used in this research is descriptive qualitative method (15) with phenomenology approach, which is a method to explicitly explore, analyze and describe a certain phenomenon as freely as possible from untested estimation (16). The research informants were selected by using purposive and snowball sampling, where the next participant was visited based on information from previous informant that could enrich the information obtained. Informants in this study were the people of the Naulu tribe, community leaders and the manager of malaria program of Primary Health Center that oversees the residence of the Naulu people. The characteristics of the participants selected were people of the Naulu tribe dwelling the research site for more than 5 years, had had malaria or family members had suffered from malaria. The number of samples was based on the information needed to be obtained based on the achievement of data saturation (16). In each group interviews were conducted on four to six people, resulting in a total of 20 in-depth interviews. 6 FGDs consisting of 6-10 people were conducted to obtain data on community knowledge about malaria and community habits in preventing and control the symptoms of malaria.

The collected through indepth interview with semi-structured questions, this technique was done with the aim that informants had the opportunity to express experiences related to the phenomenon being researched. Firstly, the researcher has included an in-depth interview guide, as a guide in finding information from informants, and observation format. The researcher is the native resident who lives and grows up in the place that is very close to the settlement of Naulu tribe so that the researcher will not find any difficulties to reach the place and has no difficulty to obtain data from the research site. To ensure the validity of the data, the researcher conducted data triangulation by means of the interview results validated by observations and secondary data. Data validity is also done by means of the source triangulation through validation with other data sources.

The process of data analysis using the method of data interpretation of nine steps according Collaizi (1978) in Speziale & Carpenter (16). This method was chosen because the analysis step is quite simple, clear and detailed to use in this research.

**Results and Discussion**

**The General Condition of the Naulu Tribe**

The Naulu tribe is one of the tribes who live on Seram Island in Maluku Province which has always been known as a traditional community that consistently maintains customary practices in the midst of rapid
social and cultural changes around their environment. Initially, the tribe resided on the tops of the mountain and was nomadic, but as the population grew and the facilities and infrastructure developed on Seram Island made the community descended to the south coast and joined the Sepa Muslim community since the 1880s (18). People of Naulu assume that the universe is guarded by certain spirits who must be respected in the deeds they do. For example, when installing a trap in a forest to catch animals, they must dedicate betel-nut and tobacco on the side of the trap. Similarly, when going to eat the game in the forest, all who will eat sitting around a place that has been presented food game that has been burned or cooked in bamboo. The big game will be divided in equal portions to all who will eat and excessed one portion equally to be given to the spirit of the slain animal. The portion for that spirit thrown into the four corners of the wind, saying it is theirs (19).

This tribe has a habit of hunting animals in the forest. This habit of hunting is done from the afternoon until the morning, or depending on the game. The dress used during hunting are their customary attire. They also have a habit of farming in the forest or looking for edible or salable forest products to earn money. The settlement of the Naulu tribe is close to the forest. The distance between their houses and the forest is not more than 100 meters. Around their house there are sago palm trees, cacao, coffee and other plants that make residential areas become very dense, in the northern part of their settlement there is dense forest. The temperature average is 26,50C where the average of the maximum temperature is 29,80C and the average of minimum temperature is 23,90C. The average rainfall amounts to 302,5 mm with an average number of rain days of 18 days. The average solar irradiation is 56.0% and the relative humidity is 85.6% (Central Bureau of Statistics of Central Maluku District, 2014).

The exact statistics figures are not known, as many cases occur in rural areas where people do not have access to the Public Health Centre or hospitals and thus they do not get health care, so that many cases cannot be documented (20). Various efforts have been done by the government and related agencies to prevent and cope with malaria disease but the case is still often happening especially in malaria endemic area. This last condition shows that there is tendency of a decrease in overall national burden, although there is an increase in some areas (21).

Prevention on Malaria

The people of Naulu know that malaria is caused by the bite of a malaria mosquito, but the symptoms do not appear immediately. Malaria symptoms appear when their body condition is less fit or the body’s resistance is decreasing. The immune system of the patient affects the appearance of clinical symptoms in patients with malaria. In endemic areas, adults and older children usually show minimal symptoms and death usually occurs in younger children due to severe anemia (22). This is possible due to the lack of basic immunity from continuous exposure to malaria plasmodium.

Realizing their environment and habits at risk of malaria, the people of Naulu tribe have a habit to prevent malaria. They consume bitter food as it can increase their resistance to malaria attack. A kind of food that is often consumed is papaya (Carica papaya) leaves and flowers that are boiled. In addition, the papaya leaves are also pounded to get the distillation, drunk by adding honey and yolks. Kovandan et al. (23) mentioned that the extract of papaya leaves showed good activity against plasmodium. To prevent themselves from mosquito bites, the people of Naulu have made prevention efforts in the form of indoor residual spraying (IRS). The IRS effort is not done as a paramedic does, but it is done by bloating their house by burning duku dried skin (Lansium domesticum) in the late afternoon.

Another phenomenon that researchers got is from the habits of the community in the form of hunting that no matter how many games they get, they will consume them immediately. Another food that also becomes their favorite is sago worms. They will be willing to exchange other meals if there are sago worms. The result of the study of Bustaman (24) showed that sago worm is one source of protein because it contains protein by 13.80%, fat by 18.09%, and water by 64.21% or higher than the protein content in eggs and slightly lower than the protein content in meat. This habit can lead to high blood protein of the Naulu people so they have improved immunity.

Overcoming Malaria

Associated with the treatment of the Naulu people against malaria, plants and parts of plants often consumed to treat malaria are papaya (Carica papaya) leaves, sambiloto leaves (Andrographis paniculata) or bark of pulai tree (Alstonia scholaris R. Br). Each part of the plants is processed by boiling, then the boiled water...
is drunk to reduce the symptoms of malaria. According to Zein et al., (25) the sambiloto leaves (*Andrographis paniculata*) has showed to be non-toxic and can eliminate fever and can enhance immunity with the effect of increasing leukocyte phagocytosis, increasing CD4+ and T lymphocytes and destroying plasmodium. The bark of the pulai tree (*Alstonia scholaris R. Br*) has been investigated to be antiplasmodial although it can not be recommended as a substitute for quinine and other cinchona alkaloids.

The study of Birhanu et al. (21) revealed that the behavior of seeking treatment for febrile illness is quite high in the community of malaria endemic areas, but the habit of seeking immediate care to a Public Health Centre is still very limited. This may be done because everyone, in general, has the motivation and enough ability to keep their health and overcome the disease themselves.

**Conclusion**

The low of malaria incidence in the Naulu tribe is not caused by people do not access health services but more caused by the habit that has been done for generations to prevent and overcome malaria disease using local wisdom; consumed bitter food as papaya leaves and flowers, burning duku dried skin in the late afternoon for prevented them from mosquito bites. Papaya leaves, sambiloto leaves or bark of pulai tree. Each part of the plants is processed by boiling, then the boiled water is drunk to reduce the symptoms of malaria

**Conflict-of-Interest:** the researcher has no conflict of interest with research informants and related parties at the study site or with other parties related to this research.

Abstract

Objectives: To examine social determinants of long acting and permanent contraceptive method (LAPM) use among currently married Indonesian women aged 15 to 49 years.

Method: Data were derived from a cross-sectional study in Tuban, Kediri, and Lumajang District (East Java Province) and Lombok Barat, Lombok Timur, and Sumbawa District (West Nusa Tenggara Province). Information was obtained from 5,930 respondents using a structure questionnaire. We estimated adjusted odds ratios to evaluate for social determinant factors associated with LAPMs use using multivariate logistic regressions.

Results: The prevalence of LAPMs use was 19%. The odds of LAPMs use among women who paid transport cost were higher than that among women who paid none. Similarly, LAPMs use were positively associated with LAPMs availability, encouragement to use LAPMs, perceived distance, knowledge about LAPMs, desire to have no more children, and contraceptive decisions jointly with husbands.

Conclusions: Our findings demonstrate the relatively low level of LAPMs use among currently married Indonesian women, and highlight social determinants that influence women to choose LAPMs. Further studies are warranted to include health provider perspective as well as collecting qualitative data in order to adequately assess behaviors of women associated with LAPMs use.

Keywords: Contraception; Long acting and permanent methods; LAPMs; Family planning

Introduction

Indonesia’s family planning program was once recognized as one of the most successful programs in the world. However, modern contraceptive prevalence rate (CPR) of 57% among Indonesian couples is lower than its neighbors of South Korea (67%), Vietnam (69%), and Thailand (70%).¹ Study showed that among ever married women in Indonesia who use modern contraceptives, 86% used short acting methods —mostly injectables (60%) and oral contraceptive pills (26%) — whereas only 7% used IUD, 6% used implants, and less than 1% underwent female sterilization.²

A large number of studies have demonstrated high efficacy, acceptability and continuation rates of long-acting and permanent methods (LAPMs).³ ⁴ In the Contraceptive CHOICE Project in the United States for example, women aged 14-45 years who used long-acting reversible contraception were 21 times less likely to become pregnant than women using short-acting methods like oral contraceptives.³ Furthermore, a total of 77 %
of the 7,486 women in the study\(^5\) chose a long-acting and reversible method. At 12 months, women who used long-acting and reversible methods of contraception had higher levels of satisfaction and continuation rates than women who used oral contraception.\(^6\)

Some studies have highlighted a number of factors related to utilization of LAPMs including healthcare providers,\(^7-9\) knowledge about LAPMs,\(^10,11\) and joint contraceptive decision with spouse.\(^10,12\) Little is known about the factors associated with LAPMs use in the Indonesian context. Understanding more about what may help women select and retain a form of contraception that suits them is particularly important at a time when contraceptive services are being transferred to local authorities.\(^13\) Given the particularly low use of LAPMs in Indonesia\(^2\), more research is needed to examine factors associated with utilization of LAPMs among currently married women in Indonesia.

**Method**

*Study participants*

Data were derived from a cross-sectional study conducted from March to October 2013 in Tuban, Kediri and Lumajang districts (East Java Province) and Lombok Barat, Lombok Timur and Sumbawa districts (West Nusa Tenggara Province). The study was conducted with the approval of the Ethics Committee of Indonesia University Faculty of Public Health, and written informed consent was obtained from all participants. The participants were married women aged 15-49 years. Using a multi-stage cluster design, 50 villages were selected from each district and one neighborhood was randomly selected from each village. In each neighborhood, 40 individuals in East Java and 50 in West Nusa Tenggara were selected randomly for interview. A total of 13,162 women were recruited with participation rate of 97.5%. The present study was based on currently married women who reported using a method of family planning in the previous month before the survey (n=8,503). Out of 8,503 eligible women, we excluded 60 participants who traveled to the contraceptive service provider more than 4 hours and whose contraceptive use was decided by other than spouse. We further excluded 2,453 participants with missing information on the variables we studied. Our final sample for analyses included a total of 5,930 participants.

**Data collection**

Women were interviewed using a structure questionnaire regarding their socioeconomic and demographic characteristics, knowledge and used of family planning, and reproductive history. LAPMs was defined as those methods that prevent pregnancy more than and equal to two years per application (Implants, IUD, male and female sterilizations). Detailed information on LAPMs use was ascertained by asking women the contraception type they had used in the last month prior to the survey. Access to the source of contraception method were assessed by asking respondent’s perception about distance to the service place, transport cost spent for commuting to the service points, and LAPMs availability. The time required to commute to the service place were grouped into quintile to define the perceived distance, and the highest quintile was used as a cut-off point. Perceived distance was near if the time was < 14 minutes, and far if the time was ≥ 15 minutes. Transport cost was defined none if there was no transportation cost needed, while less and more were cut off by mode of amount of money paid for transportation (Rp. 10,000 or USD 0.75). Women were asked regarding the LAPMs availability and whether LAPMs was the most recommended family planning methods. Women assessed whether they satisfied with the family planning services provided in the health care, and the answers were categorized in to three categories: ‘satisfied’, ‘neutral’, and ‘dissatisfied’. Knowledge about contraceptive methods was scored from zero to six, by computing six questions: two about appropriate spacing and limiting methods, and four about long-term LAPMs use (IUD, Implant, female and male sterilization). Desire for children were classified as wanted if the woman reported having wanted to become pregnant, undecided if she was not sure of having wanted to become pregnant, and wanted no more if she did not want to get pregnant. Woman was asked about who decided for her to use the contraception, and the answers were categorized into “herself” if she had an autonomy to decide, “husband” if she did not have an autonomy, and “joint with husband” if they discussed and decided together on contraception use.

**Statistical Analysis**

Associations between LAPMs use and selected social determinants of contraception among currently married woman were examined in terms of odds ratio
and 95% confidence interval, which were obtained from logistic regression analysis. Statistical adjustment was made for age (mean), education level (not complete primary, complete primary, and complete secondary and higher), residence area, wealth index (poor, middle, and rich), and parity (nulliparous, primiparous, and multiparous). A two-sided *P*-value <0.05 was considered as statistically significant. Statistical analyses were calculated using SPSS software (SPSS, Inc., version 15).

Results

Nineteen percent of currently married woman participated in the present study chose one of the three LAPMs (7.8% implant, 7.6% IUD, and 3.5% female sterilization). More than half of women were not able to correctly answer three out of six questions regarding contraceptive methods (Figure 1). Only 47% of women mentioned LAPMs as appropriate for limiting childbirth, whereas 78% identified injectables and oral pills as appropriate spacing methods. In addition, only a few women understood male and female sterilization as LAMPs, the proportions were 29% and 39%, respectively (data not shown).

We further examined associations between LAPMs use and selected social determinants of contraception among currently married women (Table 1). The odds of LAPMs use among women who paid transport cost for commuting to service point were markedly higher than that among women who paid none. Similarly, there were significant positive associations of LAPMs availability, encouragement to use LAPMs, perceived distance, and knowledge about LAPMs with LAPMs use among currently married women. Conversely, women who satisfied with provider service had significantly lower odds of LAPMs use relative to women who were not satisfied. The odds of LAPMs use in women who did not want more children were significantly higher compared to those who did. Moreover, women who made contraceptive decisions jointly with their husbands had a higher odds of LAPMs use compared with women who made decisions alone.

Discussion

In the present study the low use of LAPMs (19%) among currently married Indonesian women was similar with the previous findings showing that LAPMs were the least utilized methods of contraception.14,15 Results from the study in three regions including Asia have suggested that the limited use of LAPMs was driven primarily by a more substantial role in the provision of short-acting methods other than LAPMs.16 In addition, the present findings also implies a significant effect of methods availability on LAPMs use. One study showed an increased in modern contraceptive use across 113 countries when more methods were available to a large portion of the population.17 Interestingly, it is likely that financial matter, such as transport cost, was taken in to account when participants decided to use LAPMs. Furthermore, greater distance to the service provider (measured in relation to travel time) tended to promote greater odds of LAPMs use. Use levels for IUDs and female sterilization that were dependent on travel to clinics rise as travel time increases among currently married women in the Philippines.18

In Indonesia midwives are the main providers of contraception since the Village Midwife Program was introduced in 1989 by the government. The program’s primary goals were not only to improve the use of family planning services but also to enhance the mix of contraceptive products available to target populations.19 As previously noted, the village midwives in Indonesia influenced women to switch from pills to injectable contraceptives as opposed to switching to LAPMs.19 The relatively infrequent use of LAPMs may indicate the midwives in Indonesia have not been effectively advocated for these methods of contraception. Therefore, it was likely that women in the present study addressed only the quality of short-acting contraception methods served by the health care provider since LAPMs were not commonly used in Indonesia.2

Knowledge of different contraceptive methods is an important factor in a woman’s choice of LAPMs.10,11 The present findings were in line with previous studies showing that the low use of LAPMs were attributed to women’s lack of knowledge as well as their misperceptions about the methods.20,21 The findings from a study among young women aged 15-24 years showed that one third of women had a lack of knowledge about IUD-related amenorrhea and they would not use the IUD.20

In the present study, an increased use of LAPMs associated with desire for no more children was consistent with findings from the previous studies.22,23 Interestingly, the joint contraceptive decision-making with husband had also increased the LAPMs use even
though less than half (42.3%) of women received support from their husbands to use LAPMS. This suggests that there is a need of increasing spousal communication on family planning, particularly on the LAPMs use. Although men were reported as less involved in deciding which method to use and showed reluctance to discuss about contraception, the importance of communication between spouses regarding the LAPMs use have been emphasized in these studies.\textsuperscript{10,12}

Advantages in the present study were the large size of the study population, systematic consideration of important social determinants of contraception, and the high participation rate (97.5%). However, information about family planning collected only from married women in reproductive age was a limitation in the present study. In addition, we could not establish a cause-effect relationship between the social determinant factors of contraception and LAPMs use due to its cross-sectional design. We attempted to control for potential confounders of known factors in the multivariable analysis.

Table 1. Associations between social determinants of contraception and LAPMs use among currently married Indonesian woman.

Figure 1. Knowledge about LAPMs among currently married Indonesian women

Conclusion

We concluded that in order to increase the uptake of LAPMs, more actions should be taken by encouraging women to choose LAPMs, discussion between partners about LAPMs, and improving women’s knowledge about LAPMs. We suggest that further studies could include health provider perspective to understand determinant of LAPMs use as well as collecting qualitative data in order to adequately assess behaviors of women associated with LAPMs use.

Obstacles of Food Label Policy Implementation on Food Micro, Small and Medium Enterprises (MSME) in Jakarta and Semarang

Ida Farida¹, Dumilah Ayuningtyas¹
¹Faculty of Public Health, University of Indonesia, Depok, Indonesia

Abstract

Background: Food labels have an important role on consumers’ decision making when purchasing a product. The government has set various policies in an effort to ensure food safety through correct and clear labeling, including Regulation Number 18 in 2012 regarding Food. However, implementation of these policies is not optimal and many violations occur especially in Micro, Small, and Medium Food Enterprises (MSME). This research aimed to analyze the factors that affect the implementation of food labeling policies in food MSME in Jakarta and Semarang, Indonesia.

Method: This is a qualitative study aimed at identifying stakeholders’ views through in-depth interviews and Focused Group Discussions (FGD). Content analysis was performed to determine the thematic phenomena, in addition to observation of 12 MSME products in Jakarta and 7 products in Semarang as a form of triangulation to maintain data validity. The analysis was detailed by framework implementation of Edward III policy which includes four variables that affect the implementation of a policy, namely communication, resources, disposition, and bureaucracy structure.

Results: Observations of MSME food labels revealed major violations in Jakarta (91.6%) and Semarang (85.7%) as production codes were not printed on the labels. This low rate of policy implementation was caused by the lack of government support which limited socialization frequency, resource allocation, monitoring and evaluation that also affected coordination across sectors, causing a low success rate of the monitoring and maintenance program for food MSME.

Conclusions: Implementation of food labeling policies in food MSME in Jakarta and Semarang is not optimal as proven by the high rate of violations towards items to be posted on food labels. In response, the government should enhance the frequency of communication, resource allocation, monitoring and evaluation, as well as coordination across sectors to ensure optimum implementation of the policy in Jakarta and Semarang.

Keywords: Food labels, policy implementation, food MSME

Introduction

Food safety is part of human rights for a healthy life. This is mentioned in Regulation Number 36 in 2009 regarding Health, which states that food and drinks to be consumed by humans must meet health standards and conditions. This law requires that food and drinks that fail to meet certain standards, health conditions, and/or endangers health should not be distributed, removed from distribution, have their license revoked and confiscated to be destroyed. Therefore, an effort to fulfill safety standards is important for Small, Micro, and Medium Food Enterprises (MSME). One possible approach is to implement the food labeling policy. The government has established various labeling policies including Regulation Number 18 in 2012 regarding Food in an effort to ensure food safety by printing correct and clear information on food labels. Yet, its implementation in the field is not optimum, as there are many violations that occur especially by food MSME.
Food label is an important factor that affects a consumer’s decision when purchasing a food product and their trust towards food safety. In anticipation of a food labeling violation, the Indonesian National Agency for Drug and Food Control (NADFC) performs food label monitoring through NADFC Hall in Indonesia. Especially for the home food industry (PIRT), monitoring is done by NADFC, involving the local health government body. Monitoring in 2015 and 2016 showed that highest number of labeling violations was found in Semarang, and the lowest in Jakarta.

The author chose Semarang for this research with the consideration of the number of labels being monitored. This location has the highest number of violations compared to other regions. Jakarta was chosen as a region for branch-marking with the lowest number of violations. High number of incorrect labeling may be caused by several factors. Some primary obstacles in implementing this policy include the lack of monitoring and evaluation, poor government system, lack of budget and resources, and organization culture.

This research aims to analyze the obstacles faced in implementing food labeling policies in food MSME in Jakarta and Semarang from the aspects of communication, resources, disposition, and bureaucracy structure.

Research Method

This research was conducted from February to April 2018 in Jakarta and Semarang. A qualitative approach was adopted to identify stakeholder perception through an analysis of the factors affecting the implementation of food labeling policies, including communication, resources, disposition, and bureaucracy structure. Data was collected using in-depth interviews with informants from NADFC, NADFC Hall Jakarta and Semarang, Central Jakarta Regional Public Health Services, and Semarang Public Health Services. In addition, focused group discussion (FGD) was also conducted with food MSME owners in Jakarta and Semarang. Subsequently, content analysis was performed to identify the thematic phenomena, followed by a direct observation of 12 food MSME in Jakarta and 7 in Semarang as a form of triangulation to maintain data validity.

Research Results

Informant Characteristics

Twenty nine informants participated in this study. In-depth interviews were conducted with 8 informants, including 1 key informant from NADFC (BPP), 2 from Jakarta NADFC Hall (BBJ), 2 from Semarang NADFC Hall (BBS), 1 from Central Jakarta Regional Public Health Services (SDKJP), and 1 from Semarang Public Health Services (SFP-KS). There were 22 people who participated in the FGD, 15 were MSME owners in Jakarta (OIJ) and 7 from Semarang (OIS).

An Analysis of the Food Labeling Policy Implementation in Food MSME

An Analysis of MSME Food Labels

Appropriateness analysis is based on direct observation of labels brought by food MSME owners from Jakarta and Semarang during FGD, which included an explanation that food labels should contain product name, composition, weight/net weight, producer name and address, production code, expiry date, and license number. Analysis was performed on 19 food products, 12 from Jakarta, with 11 (91.6%) containing violations, while 6 out of 7 (85.7%) from Semarang also violated existing labeling policy. Analysis showed that the food labeling policy violation rates in Jakarta and Semarang are still high. The majority did not have production codes, 75% in Jakarta and 85.7% in Semarang. The number of labeling violations of food MSME in Jakarta and Semarang are shown in Table 1.

Source: observation of MSME food labels
The results of this research are similar to previous studies where all home food industry owners did not have proper food labeling. The majority of violations were in not printing the production code. Other studies have also shown that rates of labeling violations on imported food products in Bosnia and Herzegovina are still high.

Analysis of the Variables Affecting Food Labeling Policies

From the in-depth interviews and FGD, this research has identified various obstacles faced in the implementation of food labeling policies, including communication, resources, dispositions, and bureaucracy structures.

Communication

The different aspects of communication researched include transmission, clarity, and consistency. Transmission of food labeling policies from the NADFC Hall in Jakarta and Semarang, Central Jakarta Regional Public Health Services, Semarang Public Health Services, and food MSME have been carried out, but not optimally. This is caused by the lack of socialization on labeling policies that contribute to poor understanding of food MSME owners. Additionally, socialization by public health services through PKP is only aimed at new enterprises registering for a food distribution license. This was expressed during the interview and FGD, as quoted below:

“…Yes…it is very less from ideal to improve food MSME understanding…” (SDKJP)

“…Only once a long time ago in 2013…” (OIS)

To improve food MSME understanding regarding food labeling policies in Jakarta and Semarang, NADFC and the local public health service should allocate resources to add the frequency of socialization. Budget allocation is a key factor in the success of policy implementation. The results of this research are in line with the argument that failure in policy implementation in developing countries may be caused by the lack of resources.

Resources

Resource aspects that were researched include funding, resources, and facilities. From the funding aspect, all informants from Jakarta and Semarang stated that the funds to support food MSME monitoring and evaluation were sufficient. From the human resource aspect, the number of staff providing the education was limited. This was expressed in the interview, as quoted below:

“…There are not enough people because the area monitored in large. There is inspection of the production facility, distribution facility, labels, advertisements, and it is reported to us…” (BPP)

The lack of human resources affects the performance, especially monitoring and maintenance of food MSME. The results of this research are in line with the argument that failure in policy implementation in developing countries may be caused by the lack of monitoring. NADFC and the public health service centers in Jakarta and Semarang are expected to make the human resources available work more efficiently by providing training, increasing funding, frequency of socialization, and coordination across sectors. Facilities supporting the monitoring and maintenance programs in Jakarta and Semarang are sufficient.

Disposition

Disposition aspects researched include attitude and commitment of policy enforcers. All the informants from Jakarta and Semarang had similar attitude of supporting the food labeling policy. Support from the
NADFC and public health service centers were given by making monitoring and maintenance of MSME food labels as a Key Unit Indicator. However, MSME in Jakarta and Semarang felt that the support given by the policy enforcers, including NADFC and the public health centers, were not sufficient. This is because of the lack of awareness of the MSME in implementing the food labeling policies. This was expressed during the FGD, as quoted below:

“…So, I am just saying that this labeling is not an issue to our community, so we also are busy and think that even if we want to follow the rules, how big is the impact of not having the label? Even if it is MSME. Why? Because the government does not want to facilitate how to sell? They just show how to do it…” (OIJ)

The government organizations as the first line should have strong support and commitment to implement food labeling policies. Support from the government along with high commitment, including from just law enforcement towards the food MSME who violate labeling regulations. This is in agreement with the theory that law enforcement is effective in reducing the number of food labeling violations. Additionally, stronger socialization and training is expected to ensure clear message transmission from the government to the food MSME regarding the importance of labeling. Food labeling training is one way of increasing the knowledge and understanding of the industry regarding food safety, though the government should still be active by increasing the frequency of facility supervision to discuss food safety.

**Bureaucratic Structure**

Aspects relating to bureaucratic structure that were researched include mechanism and fragmentation. From the aspect of mechanism, all informants from Jakarta and Semarang had standard operating procedures (SOP) for MSME monitoring and guidance. The presence of SOP is related to the theory which stated that it can help communication between policy enforcers to ensure that aims and objectives of a policy is attained. However, almost all food MSME in Jakarta and Semarang state that the monitoring program is not performed well by NADFC and the public health service centers. This was expressed during the FGD, as quoted below:

“…Hall and public health service center also don’t monitor. They just give information… …” (OIJ)

“…Yes ...honestly, we only monitor and evaluate if there is a case. If not then... when there is new product or extension of the license. Seems like... because there is lack of human resources. So, to monitor, sometimes we don’t have people …” (SFP-KS)

If linked to the theory, monitoring is important to identify gaps between stakeholders. The infrastructure should be supported by a monitoring and evaluation mechanism, by providing multi-sectoral platforms that may be used to strengthen coordination between stakeholders. From the fragmentation aspect it is known that the responsibility to education the MSME is widespread across sectors throughout Indonesia, through according the informant from the Central Jakarta Regional Public Health Service Center, there is no technical team developed to deal with food MSME as each sector has their own programs. This is proven as there has been no coordination between sectors to synergize the maintenance of MSME. The results of this research are similar to the previous studies which show that the lack of coordination across sectors is an obstacle faced in the implementation of policies. President Instruction Number 3 Year 2017 identified NADFC as the coordinator to improve effectiveness of food monitoring by working together with several stakeholders including the public health service centers. It is hoped that this instruction would trigger NADFC to strengthen their infrastructure, communication, and coordination across sectors.

Based on the results, here are obstacles faced in the implementing of food labeling policies in Jakarta and Semarang, including communication, resources, dispositions, and bureaucracy structures.
Tabel 2: Obstacles faced in the implementing of food labelling policies in Jakarta and Semarang

<table>
<thead>
<tr>
<th>Aspect</th>
<th>Obstacles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Communication</td>
<td>lack of socialization, lack of knowledge and ability of policy enforcers, poor understanding of food MSME owners</td>
</tr>
<tr>
<td>Resources</td>
<td>lack of funding, lack of human resources</td>
</tr>
<tr>
<td>Disposition</td>
<td>lack of awareness of the MSME, lack of law enforcement</td>
</tr>
<tr>
<td>Bureaucratic structure</td>
<td>lack of monitoring and evaluation, lack of coordination across sectors, no technical team to deal with food MSME</td>
</tr>
</tbody>
</table>

Conclusion

Food labeling policy implementation by MSME in Jakarta and Semarang are considerably poor. This is proven by the high number of violations in the food labels printed by the majority of MSME in Jakarta and Semarang. The lack of support from the government limits the frequency of socialization, fulfillment of resources, monitoring and evaluation. This affects the coordination across sectors, causing a low success rate of the monitoring and evaluation program of food MSME. Therefore, the government should strengthen the communication through more frequent socialization of the food labeling policy, monitoring and continuous evaluation, as well as coordination across sectors for proper implementation of the policy in Jakarta and Semarang to be achieved.

Factors that Influence Nurse Performance in Applying Nursing Assurance in Interview Installation Ratu Zalecha Regional Public Hospital

Ibnu Ali Wardana1, Lenie Marlinae2, Nia Kania3
1Student of Public Health Magister Program, 2Environmental Health Department, 3Department of Pathology Anatomy, Ulin General Hospital, Medical Faculty Lambung Mangkurat University

Abstract

The success of hospitals in providing quality and professional services is highly dependent on how the nurse’s performance in applying nursing services. The achievement of customer satisfaction on inpatient service in 2015 in RSUD Ratu Zalecha is only 80% from the standard set that is more than 90%. The results of the nursing care documentation show that only 42% of complete nursing medical records are completed. Design study “Cross Sectional”. The samples were 42 female nurses who were assigned to the inpatient installation who had met the inclusion criteria by using simple proportional random sampling method. Data were collected using questionnaire, Reaction Timer, observation sheet and the result was analyzed using Chi Square and multivariate test (logistic regression). Most respondents (66.7%) were > 30 years old, had Diploma III (71.4%), had a working life (78.6%) > 5 years, medium workload (78.6%), fatigue (81%), light work fatigue (71.4%) using Reaction Timer, adequate competence (61.9%), and good performance (73.8%).

The result of bivariate test of workload significantly influenced nurse’s performance with p-value equal to 0.005 (sig value < 0.05), burnout did not significantly influence nurse’s performance with p-value 0.657 (sig value > 0.05), competence significantly influence the performance of nurse with p-value equal to 0.030 (sig value < 0.05). In multivariate analysis of workload and competency of influence significantly to nurse’s performance with p-value equal to 0.001 (sig value < 0.05) and workload is an independent variable having the biggest influence to nurse performance with value of Odds Ratio equal to 11.2.

Keywords: Work load, burnout, competence and nurse performance.

Introduction

Ratu Zalecha General Public Hospital is a hospital belonging to the local government of Banjar Regency with a qualification of class B hospitals that have been accredited plenary in 2017. At Ratu Zalecha General Public Hospital Martapura, based on the report of the strategic plan of hospitals from 2016 to 2021 obtained data that customer satisfaction at inpatient service achievement year 2015 only 80% from satisfaction standard of service to nursing service determined by Health Department that is more or equal to 90%, patient death more than 48 hours that is 0.4% from standard specified <0.24%.1

Fulfillment of Minimum Service Standards in yearly achievement ratio from 2012 to 2015 in Ratu Zalecha Regional Public Hospital average only 90.4% not in accordance with the targeted that is 100%. In the achievement of Bed Occupancy Rate (BOR) indicators, the annual achievement ratio from 2011 to 2015 averaged only 86.3% not in accordance with the targeted of 100% or more. Based on Hospital Quality Indicator data is Bed Turn Over (BTO) year, BTO national standard is 5-45 days. Meanwhile, from Ratu Zalecha Public Complaints Unit report on patient complaints delivered from October 2016 until August of 2017 as many as 77 cases of reports, while complaints on Inpatient Installations delivered as many as 20 cases of reports or 20%, of which about the attitude less friendly officers in communicating with patients2.

Based on result of research conducted Fitria et al.
(2014) in Ratu Zalecha Regional Public Hospital that nurses often experience fatigue and did not work with maximum\(^2\). Based on research from Khairunnisa et al. (2015) in Ratu Zalecha Regional Public Hospital, the result of nursing care documentation showed from 526 patients who underwent hospitalization only 42% from medical record of nursing care which complete and based on data from Medical Record Installation Ratu Zalecha Martapura Regional Public Hospital of 2017 on the completeness of medical record completion recorded by the nurses found that of 1297 inpatient files only 1096 complete files. While the ratio between the number of nurses and beds are 208: 230 in 2015 and 204: 259 in 2017\(^4\). This is reinforced from the calculation of the needs of nurse health personnel conducted in hospitals using the formula from Health Department in 2005, that the calculation of power needs recruitment of nurses and midwives in Ratu Zalecha Regional Public Hospital is still lacking, in 2016 Ratu Zalecha Regional Public Hospital shortage of 54 nurses at inpatient installation and in 2017 lack of 45 nurses\(^2\). Based on the above data it is necessary to research the factors that affect the performance of nurses in applying nursing care.

### Material and Method

The method used in this research is quantitative research with analytic observation design with Cross Sectional, with independent variables are work load, burnout, and competence with dependent variable is nurse performance in applying nursing care. Population in this research is all clinical nurses II which have female genital in charge of Inpatient Installation Ratu Zalecha Regional Public Hospital which amounted 52 people. Samples were taken using proportional sampling method with 41 respondents. Data analysis used univariate, bivariate and multivariate analysis.

### Findings

Based on the results of the study, the obtained distribution of the frequency factors affecting the performance of nurses in Table 1 below:

<table>

Based on the results of the study it is known that the respondents have heavy workload category as much as 9 (21.4%) respondents, 94.9% on average perform direct nursing activities (develop nursing plans in accordance with nursing diagnoses, observe patient condition and perform appropriate action based on observations) and an average of 94% perform indirect nursing activities (conduct discussions among fellow nurses or with superiors as well as with other health teams on patient, development, prepare patient medicines, prepare health support equipment for patients and the nurse carries out proper and correct nursing care reporting and reporting system according to the standard of nursing care.

Based on the result of respondents who have heavy category burnout as much as 8 (19%) respondents, it is known that 65.6% is experiencing weakening of activity and 58.6% on average experiencing weakening of motivation, and 65% experiencing physical attenuation. In attenuation of motivation, nurses who experience severe fatigue sometimes feel hard to think, tire to talk, not concentrate, and anxious to something at work that is as much as 8 (100%) of respondents. While respondents who have moderate fatigue (burnout) are 34
(81%) respondents, it is known that the average of 51% experience weakening of activity and average 42.6% experiencing of weakening of motivation, and 46.9% experiencing of physical weakening.

Respondents who have good competence as much as 16 (38.1%) of respondents, known average 96% have good competence by showing assertive attitude, empathy, and ethics and show compliance toward applying of standard and nursing guidance that is 7 (100%) response. Respondents have enough competence of 26 (61.9%) of respondents, it is known that average 75.9% from competence either by showing assertive attitude, empathy, and ethics that is as much as 17 (65.3%) respondent, respondent show assertive attitude, empathy, and ethics that is as much as 9 (34.7%) of respondents.

Based on table 2 using Fisher Exact test with 95% confidence level (α) to see the effect of work load on nurse performance in applying nursing care obtained p-value 0.005 <0.05. So it can be concluded that there is influence between work load on nurse performance in applying nursing care, with value odds ratio equal to 11.200. Using Fisher Exact test with level of trust (α) 95% (0.05) to see the influence of fatigue (burnout) to nurse performance in applying nursing care got p-value 0.657> 0.05. So it can be concluded that there is no influence between the work fatigue (burnout) on the performance of nurses in applying nursing care. To see the effect of competence on the performance of nurses in applying nursing care obtained p-value 0.030 <0.05. So it can be concluded that there is influence between competence on nurse performance in applying nursing care, with value odds ratio equal to 9.375.

Based on table 3 above the lower limit and upper limit of 95% CI that is lower boundary competence of 0.844 and upper limit of 99.687 are respondents who have good competence that shows poor performance of 9.1% compared with respondents who have enough competence showed a poor performance of 90.9%.

**Discussion**

Based on table 3 using Fisher Exact test with 95% confidence level (α) to see the effect of work load on nurse performance in applying nursing care obtained p-value 0.005 <0.05. So it can be concluded there is influence between work load on nurse performance in applying nursing care, with value odds ratio equal to 11,200. The results of this study are in line with the results of Hera et al (2016) study on the effect of dual role conflict, workload and work fatigue (burnout) with the performance of female nurses at Lagaligo Regional Public Hospital, East Luwu Regency with work load variable significantly influence the performance variable of nurse women with p value 0.021. Workload is the limit of the ability of each worker’s body in completing the work. Excessive workload and unbalanced or exceed the capacity of the physical capabilities borne by the nurse will have an impact on the poor productivity of the nurse’s work.

Using Fisher Exact test with level of trust (α) 95% (0.05) to see the influence of fatigue (burnout) to nurse performance in applying nursing care got p-value 0.657 > 0.05. So it can be concluded that there is no influence between the work fatigue (burnout) on the performance of nurses in applying nursing care. The results of this study are not in line with Hera et al’s (2016) study on the effect of dual role conflict, workload and work fatigue (burnout) with the performance of female nurses at Lagaligo Regional Public Hospital, East Luwu Regency with burnout variable significantly influencing variable performance of female nurse with p value 0.025. Burnout is a condition where there is a decrease in efficiency and resilience in work that will lead to decreased performance and increase the level of work errors that will affect the work or productivity work to be obtained.

The effect of competence on nurse’s performance in applying nursing care obtained p-value 0.030 <0.05. So it can be concluded that there is influence between competence on nurse performance in applying nursing care, with value odds ratio equal to 9.375. The result of this research is in line with Muqit research (2014) with the title of influence of competence and job satisfaction on the performance of hospital nurse Syafira Pekanbaru that competence have a significant effect on nurse performance with p value 0.021. The results of this study are also in line with research conducted by Haryanti (2015) with the results showed that employee competence has a significant effect in improving employee performance with p-value 0.022 <0.05.

Competence is an ability possessed by individuals both knowledge and skills supported by work attitude to perform or perform a job or task received. Education closely related to one’s competence, with good competence will increase work productivity.

**Conclusion**

Work load significantly influence the performance of nurses in applying nursing care at Inpatient Installation Ratu Zalecha Regional Public Hospital (p-value 0.005)

Burnout has no significant effect on the performance of nurses in applying nursing care at Inpatient Installation Ratu Zalecha Regional Public Hospital (p-value 0.657).
Competence significantly influence the performance of nurses in applying nursing care at Inpatient Installation Ratu Zalecha Regional Public Hospital ($p$-value 0.030).

Workload and competence significantly influence the performance of nurses in applying nursing care at Inpatient Installation Ratu Zalecha Regional Public Hospital ($p$-value 0.001).

The Effect of Quality of Work Life on Organizational Citizenship Behavior of the Employees

Vica Aulya Rivera1, Juliyan Puspa Sari1, Nyoman Anita Damayanti2

1Student of Health Policy Administration Program Study, Faculty of Public Health, Airlangga University, Indonesia, 2Lecturer of Health Policy Administration Program Study, Faculty of Public Health, Airlangga University, Indonesia

ABSTRACT

The long waiting time for pharmaceutical services may be assumed to be related to the employee performance of which it relates to the quality of work life of the pharmaceutical unit. To support the performance of employees, environment conducive to quality of work life is necessary. A good quality of work life (QWL) may affect organizational citizenship behavior (OCB). This research aimed to analyze the effect of quality of work life on organizational citizenship behavior of the employees of Pharmacy Unit at Gotong Royong Hospital Surabaya. This was the type of observational research using cross-sectional approach. The samples were taken by using saturation sampling as many as 18 employees of Pharmacy Unit at Gotong Royong Hospital Surabaya. The data obtained were analyzed by using simple regression analysis and t-test interpretation analysis for each dimension of quality of work life on organizational citizenship behavior. The findings of this research indicated that quality of work life had a significant effect on organizational citizenship behavior (p-value = 0.001) and an effect of 69.7%. The conclusion of this research was that the quality of work life significantly affected organizational citizenship behavior of the employees of Pharmacy Unit at Gotong Royong Hospital Surabaya.

Keywords: organizational citizenship behavior, quality of work life.

INTRODUCTION

Each organization is established to achieve optimal goals and benefits. In order to achieve these optimal goals and benefits, every organization must be able to take advantage of all its resources. Employees are the most important resource of an organization such as the hospital. The existence of an environment conducive to quality of work life will make the performance of the employees to be better. It is because of the motivation that can support employee performance in the environment conducive. The work environment, which can also be called the quality of work life (QWL), is influential in creating the organizational citizenship behavior (OCB). Organizational citizenship behavior deals with the study of what an individual does within an organization and how the effect of their behavior on organizational performance1. Meanwhile, quality of work life is a pleasant and unpleasant condition in the work environment based on the experience perceived by the individual in the workplace in which it affects his or her work attitude and behavior with the indicators of: a healthy work environment, job security, problem solving, career development, and participation of the organization. A good quality of work life that raises the morale will has a positive effect on improving organizational citizenship behavior2.

According to the previous research, it showed that the quality of work life is an important index indicating the extent to which individuals are able to satisfy their personal needs (such as the need for independence) while working in an organization3. Other studies have shown that there is a positive effect of quality of work life on organizational citizenship behavior2.

The long waiting time for pharmaceutical services in Pharmacy Unit of Gotong Royong Hospital Surabaya may be assumed to be related to the employee performance of which it relates to the quality of work life. Therefore, quality of work life (QWL) and organizational citizenship behavior (OCB) is one of the
most important factors for Gotong Royong Surabaya Hospital in running the performance management.

According to this background, a research was conducted on the effect of quality of work life (QWL) on organizational citizenship behavior (OCB) to the employees of Gotong Royong Hospital Surabaya aiming to analyze the effect of quality of work life on organizational citizenship behavior of the employees of Pharmacy Unit at Gotong Royong Hospital Surabaya.

Organizational Citizenship Behavior (OCB) is defined as a fact of behavior with no reward from the organization, so organizational citizenship behavior occurs without the expectation of reward in giving help. Organizational citizenship behavior is referred to as a cooperative behavior undertaken to support the continuity of the organization and arises without the command of any party/anyone. Organizational citizenship behavior refers to helpful, constructive and useful behaviors by the members of the organization and is valued or assessed by the higher-ranking members of the organizations. However, it is not directly related to individual productivity and unity in terms of implementation of the function or role of individuals within an organization.

There are 5 dimensions of organizational citizenship behavior. The five dimensions are conscientiousness, altruism, civic virtue, sportsmanship, and courtesy. Conscientiousness is a voluntary behavior that is not an employee’s duty or job. This dimension reaches far above and far ahead of a call of duty. Altruism is the attitude of the employees shown by the act of helping to each other; in this case is the co-workers. Civic virtue is a behavior of committing to the organization as a whole which aims to protect the organization. It is shown by the desire to participate actively in the organization. Sportsmanship is the desire to tolerate the inevitable difficulties and the burden of a job without complaining. Courtesy is a behavior that is shown to prevent problems that are related to work and occur in others as well as alleviate problems that are related to the job.

Quality of work life (QWL) is a pleasant and unpleasant condition in the work environment based on the experience perceived by the individual in the workplace in which it affects his or her work attitude and behavior. There are two ways to define the quality of work life (QWL). First, the quality of work life (QWL) is in line with the organization’s efforts in realizing organizational goals such as promotional policies, democratic supervision, employee engagement, and safe working conditions. Second, the quality of work life (QWL) is the employee’s perception to what extent they feel safe, satisfied with their work, and able to grow and develop themselves as human beings.

Walton (1974) mentioned that QWL is worker’s perception of the atmosphere and their experiences in their workplace. Therefore, there are 8 factors affecting QWL as follows:

- A fair and appropriate salary
- Safe and healthy working conditions
- Use of capacities
- Opportunities
- Social integration
- Constitutionalism
- Space that the work occupy in life
- Social relevance and importance of work

Employees who have a high quality of work life will encourage the emergence of organizational citizenship behavior (OCB), because they have greater possibility to speak positively about the organization, willing to help other individuals, have a performance that exceeds the normal estimate. This is shown by other research mentioned that quality of work life is an important index indicating the extent to which individuals are able to satisfy their personal needs (such as the need for independence) while working in an organization.

**MATERIAL AND METHOD**

This was a kind of observational research using cross-sectional approach. It was because the data collection of the variable was carried out within a certain period of time. The population of this research was all Pharmacy Unit employees at Gotong Royong Hospital Surabaya. The samples were taken by using saturation sampling (census) as many as 18 employees with the same number of population and sample.

The data of this research were primary data obtained with the instrument of questionnaire which contained questions related to organizational citizenship
behavior and quality of work life. The dimension of quality of work life were taken based on Walton (1974) consisting of a fair and appropriate salary, safe and healthy working conditions, use of capacities, opportunities, social integration, constitutionalism, space that the work occupy in life, as well as social relevance and importance of work\textsuperscript{8}. In addition, the scales of organizational citizenship behavior were taken based on organizational citizenship behavior dimensions consisting of conscientiousness, altruism, civic virtue, sportsmanship, and courtesy\textsuperscript{5}. The data obtained were then processed by using SPSS program. After obtaining the scores from the total of each dimension, they were tested by using simple regression analysis and t-test interpretation analysis for each of the quality of work life dimensions on organizational citizenship behavior.

RESULTS AND DISCUSSION

Characteristics of the Respondents

The following table shows the characteristic of the respondents who were employees of Pharmacy Unit at Gotong Royong Hospital Surabaya. Table 1 shows that almost all of the respondents (88.9\%) had the gender of female. Women are often considered to have higher OCB level than men based on organizational citizenship behavior components. Women are considered to be more relative to help people and more generous than men. In addition, based on the dimension of altruism, women have an attitude to avoid conflict and promote peace, and have a high desire to help the people around them\textsuperscript{9}. Table 1 shows that the age group of 30 and below is the most frequent group of the respondents. Table 1 also shows that the educational background of the respondents was dominated by senior high school. Employees with educational background of senior high school tend to be more involved in organizational citizenship behavior than those with higher educational background. This may be due to the idea that the higher the level of education, the lower the tendency of an employee to perform organizational citizenship behavior\textsuperscript{10}. That is because the employees with higher education degree will be more focused on task performance because they have a better chance of being promoted\textsuperscript{11}.

Table 1 shows that most respondents had been working in the Pharmacy Unit of Gotong Royong Hospital Surabaya for < 1 to 5 years.

Simple Regression Analysis

The results of simple regression analysis are shown in Table 2. From the results of calculation using SPSS program, it then obtained the results of regression equation as the following:

\[ Y = -6.527 + 0.658X \]

From the above regression analysis, it could be explained that:

The constant value was 6.527 and positive in which it could be interpreted that organizational citizenship behavior value before being influenced by independent variable (quality of work life) was negative.

The value of the regression coefficient \( X \) was 0.658 which described that if quality of work life was high or increasing or increased, while other variables remained the same (constant), then the organizational citizenship behavior would increase.

Table 2: The Result of Simple Regression Analysis

<table>

<td>0.001</td>
<td>.697</td>
<td>.486</td>
</tr>
</tbody>
</table>

Based on the significance value in simple regression analysis, it was concluded that quality of work life had an effect on organizational citizenship behavior of the employees. This was indicated by the significance value (Sig.) of 0.001 in which it was smaller than the probability of 0.05. Based on the coefficient determination (R2), it obtained a value of 0.697 in which it could be concluded that the effect of quality of work life on organizational citizenship behavior was equal to 69.7%. It was in line with the other research suggested that there was a positive effect of quality of work life on organizational citizenship behavior\(^2\). A research also revealed that there was a meaningful correlation between quality of work life and organizational citizenship behavior. Employees who have a high quality of work life will encourage the emergence of organizational citizenship behavior (OCB), because they have greater possibility to speak positively about the organization, willing to help other individuals, have a performance that exceeds the normal estimate\(^3,9\).

The t-Test Interpretation Analysis of the Dimensions of Quality of Work Life on Organizational Citizenship Behavior

Table 3 showed the results of t-test interpretation analysis of the quality of work life dimensions on organizational citizenship behavior. According to the calculations, t-table was 0.703.

Based on the findings of the research, it could be concluded that the most influential dimensions of quality of work life in the Pharmacy Unit of Gotong Royong Hospital Surabaya were opportunities and space that the works occupy in life. This could be seen in the t-calculate results of the opportunity (4.089) and the space that the work occupy in life (5.020) which were bigger than t-table (0.703) and the significance value was less than 0.005.

Opportunity is one part of the quality of work life that had effect on organizational citizenship behavior. It was because of the opportunities see how the work gives the employees opportunity to use and develop their skills and competences and whether the work poses a challenge for them to fully engage\(^2\). It was evidenced by a research which showed that opportunity is one of the
QWL parts that had the most effective and influential effect on OCB. A research showed that the space that the works occupy in life is part of the QWL that had the most effective effect on OCB. Space that the works occupy in life sees how far the job affects the personal life roles of the employees, such as family relationship. This dimension is a concept of a balanced role related to working hours, career demand, vacation time including leisure and family time.

If all dimensions of quality of work life can be improved and enhanced, then the organizational citizenship behavior in Pharmacy Unit of Gotong Royong Hospital Surabaya will also improve. It will then improve the stability of employee performance as mentioned in the other research.

**CONCLUSION**

The conclusions of this study are:

Quality of work life had strong and significant effect on organizational citizenship behavior. Meanwhile, the most influential dimensions of quality of work life in the Pharmacy Unit of Gotong Royong Hospital Surabaya were opportunities and space that the works occupy in life.

Based on the result of t-test to quality of work life dimensions on organizational citizenship behavior, it is necessary to improve the other dimensions of quality of work life other than the dimensions of opportunities and space that the work occupy in life so as to have effect on organizational citizenship behavior. This should be performed in order to improve the employee performance in the Pharmacy Unit at Gotong Royong Hospital Surabaya.

Baghdad Boil is Reemerging in Iraq

Riyadh K Lafta, Ashraf MA Hussain,

1Chair of Department of Family and community Medicine, College of Medicine, Mustansiriya University, Affiliated Prof, Global Health Department, University of Washington, Seattle, USA., 2Lecturer, Department of Family and community Medicine, College of Medicine, Babil University

Abstract

Background: Cutaneous Leishmaniasis is ranked third in disability-adjusted life years among the neglected tropical diseases and second most common insult of parasite-related deaths after malaria.

Objective: to figure out the trend of the Cutaneous Leishmaniasis in Iraq and portray the recent spike that may indicate reemerging of this disease.

Methods: Data was collected from the Department of Health Statistics in the Ministry of Health for the years (2000-2017), double checked and confirmed by data from other health facilities’ registries to fill the blanks and to enhance reliability. It was categorized according to the 18 Iraqi governorates; the total of each governorate was measured for each disease for all the years and then summed to obtain the total for Iraq. The results were conformed to the reports of the WHO, World Bank and UNICEF to define the trend of diseases for each governorate.

Results: A very high spike Cutaneous Leishmaniasis occurred in 2015-16 (p= 0.010). It affected males and females equally, adults (>15 years) more than children, and mostly in the middle and south regions of Iraq.

Conclusion: The findings of this study ring the bells for immediate intervention measures to stop the flare up and spread of this reemerging disease.

Keywords: Baghdad, Boil, Reemerging

Introduction

Cutaneous Leishmaniasis was previously known as “Baghdad boil” for it was highly endemic in Baghdad during the early decades of this century. It is ranked third in disability-adjusted life years among the neglected tropical diseases and second most common insult of parasite-related deaths after malaria.1-3

Leishmaniasis is a poverty-related disease that tends to affect the poorest section of the community, mediated by poor home conditions and environmental sanitation, and lack of personal protective measures.4 On National scale, it is associated with malnutrition, displacement, illiteracy, gender discrimination and lack of resources.5 Although not fatal, Cutaneous leishmaniasis is synonymous with stigma due to its associated disfiguring lesion that affects the social and economic wellbeing of the affected person.6

The estimated global incidence is about 0.7 to 1.2 million per year, it is widely prevalent in the Eastern Mediterranean Region where it is considered endemic in about 18 out of 23 countries in this region,7 and the estimated burden is about 100000 reported cases each year which is the highest burden worldwide, with the actual number estimated to be three to four times higher. Its complex epidemiology and ecology and lack of simple and applicable case management make its incidence data, and hence, its burden in the communities hard to estimate.7,8

Corresponding author:
Riyadh K Lafta,
E-mail: riyadhlafita@yahoo.com
Outbreaks of leishmaniasis are commonly associated with war, human migration and manmade environmental changes following agricultural practices and urbanization. In Iraq, Leishmaniasis (together with Schistosomiasis and Rabies) is among the neglected tropical diseases in the country. Its occurrence was dramatically decremented in the previous period through a comprehensive package of control hold by the Ministry of Health with the support of WHO.

We set this study to figure out the trend of Cutaneous Leishmaniasis in Iraq and portray the recent spike that may indicate the reemerging of this disease.

Methods: We collected morbidity data from the Department of Health Statistics in the Ministry of Health for the years (2000-2017). Data were collected month by month, double checked and confirmed by data from other health facilities’ registries to fill the blanks and to enhance reliability. Data were categorized according to the 18 Iraqi governorates; the total of each governorate was measured for all the years and then summed to obtain the total for Iraq. The results were conformed to the reports of the Iraqi CDC, WHO, World Bank and UNICEF.

The total population for each governorate was obtained from the Central Statistical Organization. The rate of occurrence was plotted against time (for the period from 2000 through 2017) to define the trend of the disease for each governorate.

Data were also categorized by gender and age, and were divided into three main categories: under 5 years, 5 - 15 years, and more than 15 years.

The ethical approvals were taken from the Family and Community Medicine Department, College of Medicine, Mustansiriya University, and the Iraqi Ministry of Health. No verbal consent was needed as we did not identify any patient, we did only treat the biometric patients’ registries.

Results

Following a long period of relatively low (but uncontrolled) incidence of Cutaneous Leishmaniasis, a very high spike occurred in 2015 and continued during 2016 and 2017 (p= 0.010). It affected males and females almost equally, adults (>15 years) more than children, and mostly in the middle and south regions of Iraq as shown in figures (1, 2, 3, and 4). Table (1) shows the distribution of cases for the studied 18 years by age, gender and maximum numbers of cases per year.

Discussion: During the seventieth; Leishmaniasis in Iraq was highly controlled with very sporadic cases. The increase in the number of cases started after the year 2001; the registered cases in 2001 were 625 with a rate of 2.3 /100000, while the rate in 2016 reached up to 45/100000, which means about 20 fold that of 2001. This was likely precipitated by the long economic sanction, and superimposed by the 2003 USA invasion and the years after, mostly attributed to the deterioration in the general and health services including preventive measures and disease control, lack of access to specialist diagnosis and treatment, shortage of medicines, and regressed environmental conditions and sand fly control, particularly following the internal displacement of millions of Iraqis as a result of ISIS overrun to about one third of the Iraqi land.

Cutaneous Leishmaniasis (or Baghdad Boil) usually flourishes up in bad living conditions like poverty, low sanitation, and displacement, which are all made available in many of the Iraqi localities in the last fifteen years due to the devastation in all aspects of life, destruction of the infrastructure and deterioration in the health services. Discontinuation of anti-malaria control programs has played a major role in the upsurge of sand fly density and, hence, the risk of infection.

The trend showed an outbreak every 4-6 years (2004, 2010 and 2015), with males and females almost equally affected, and an insignificant age difference. The outbreak in 2015 registered a very high rate that reached up to 47.5/100000 from a baseline of about 4/100000. This has occurred following the military operations done in the North and West of Iraq, and might be explained by the extensive population movements and migration of a susceptible cohort to the endemic foci, overcrowding, lack of hygiene with poor health services and upsurge in the sand fly and vector population.

Free uncontrolled population movement to and from Iran might also play a role in the frequent outbreaks.
as Iran had a relatively steady trend of Cutaneous leishmaniasis with an average incidence rate of about 25/100000 with the highest rate of 27.5 in 2011.  

The results of the current study showed no much difference between ages or between genders, this disagrees with a comprehensive overview study of Saudi cases of Cutaneous leishmaniasis, where (over 33 years) male cases accounted for 78% against 22% for females and with a study in Turkey where men outnumbered women (61% versus 39%).  

In KSA, 50% of the cases were within the age group (15-45) years, while a Lebanese study described that more than 70% of the cases occurred below the age of 15 years.  

The findings also revealed that there is more clustering of cases in the middle region of Iraq (including the peripheries of the Capital-Baghdad), and the Southern region, where the sanitation is relatively low, the weather is warm and the population of sand flies is large.  

At issue here is to remember that there is a great possibility of underestimation and underreporting of cases in the registries of the Ministry of Health. Many people find this problem too simple to worry about compared to the surrounding life stresses they are experiencing, others may have no money to pay for the treatment which is getting more expensive in the last years, and is not afforded by the governmental health institutions.  

WHO considered Cutaneous leishmaniasis as a major public health concern in the Eastern Mediterranean region necessitating establishing a strategic plan to handle the impact of the problem and achieve an effective program for control.

Solitary nodule with central necrosis and ulceration

Conclusion

The findings of this study indicate that there is a reemerging of Cutaneous Leishmaniasis in Iraq after a long period of control, and this rings the bells for immediate intervention measures to stop the flare up and spread of this disease in the time that it should disappear.

Determinant Factors: Work Productivity of Nurse Practitioner in RSUP Dr. M. Djamil Padang Indonesia in 2018

Fatima Nuraini Sasmita¹, Yulastri Arif², Sila Dewi Anggraini³
¹Master Program of Nursing Faculty of Andalas University, ²Nursing Faculty of Andalas University Padang Indonesia, ³Health Politechnic of Padang

ABSTRACT

Improving work productivity program of nurses in inpatient ward of Central Public Hospital (RSUP) Dr. M. Djamil Padang has shown good results. This condition is happened due to several factors that lead positive impact on the productivity of nurses working in the inpatient ward of RSUP Dr. M. Djamil Padang. This study aims to analyze the factors associated with work productivity of nurses in the dr. M. Djamil Padang in 2018. This study uses descriptive analytical research design with cross sectional study approach. It takes 168 nurses as sample with proportional random sampling. The result of this study is good worker nurse productivity 71%, good organizational characteristic is 81%, good work characteristic is 73% and good organization environment is 71%. In detail, there is a relationship of organizational characteristics, job characteristics and organizational environment with work productivity of nurses in dr. M. Djamil Padang. The writer’s suggestion for service institutions is to maintain and improve a conducive working environment by maintaining or improving the hospital’s managerial system by conducting managerial or leadership training activities.

Keywords: Organizational Characteristics, Job Characteristics, Organizational Environment and Work Productivity

INTRODUCTION

Hospital is a very complex service industry and highly dependent on the capacity and quality of their human resources. Association Productivity Organization (APO) defines productivity as the balance of input and output resulting in efficient and effective performance (1).

According to Schein (1997), characteristic of the organization is the basic pattern accepted by the organization to be able to act and solve problems, forming individuals who are able to adapt to the environment and unify organizational members (2).

This study aims to identify the relationship of organizational characteristics, worker characteristics and organizational environment with work productivity of nurses in the inpatient ward M. Djamil Padang in 2018.

MATERIAL AND METHOD

This study was a quantitative research. The method or design used was descriptive analytic study and using chi-square to know the relation of independent variable and devenden variable and used binary logistic multiple to know the determinant factor.

The population in this study was 528 nurses in Dr. M. Djamil Padang. The sample size was 168 nurses. The sampling technique in this study was proportional random sampling.

As additional data to complete the data will be conducted questionnaires on organizational characteristics, nurse characteristics, organizational environment and work productivity nurses. To measure the work productivity of nurses, the researchers used questionnaire that refers to Nahyeri’s theory (2006) with the 11 items of questions (3). To measure the organizational characteristics and job characteristics, the researcher modified the questionnaire from Kopelmen (1986) in Nursalam (2016) with a total of 12 statement items (4), and 8 statements and to measure the organizational environment using the questionnaire adopted from the PES-NWI questionnaire (Lake 2002).
Test the validity and reliability of the questionnaire conducted in RSUD Dr. Achmad Mochtar Bukittinggi with a total sample of 30 nurses.

**RESULT**

The frequency distribution of the work productivity variable with 71.4% of the work productivity of good nurses, 81% good organizational characteristics, and 73% good work characteristics and 71% good organizational environment.

Table: 1: The relationship between organizational characteristic with work productivity of nurses in the inpatient ward of RSUP

Chi-Square test results obtained p value = 0.000 (p <0.05) which means there is a relationship between organizational characteristics with work productivity nurses practitioner. The value of r=15 means that nurses with good organizational characteristics 15 times more impact on the productivity of the nurse work good.

</tbody>
</table>

Chi-Square test results obtained p value = 0.000 (p <0.05) which means there is a relationship between job characteristics and work productivity nurses practitioner. The value of r 5.0 means that nurses with job characteristic has 5.0 times more impact on good work productivity.
Table: 3: Relationship between organization environment and work productivity of nurse practitioner in inpatient ward of RSUP Dr. M. Djamil Padang

<table>

<td>12</td>
</tr>
<tr>
<td>Good</td>
<td>11</td>
<td>9,2</td>
<td>108</td>
</tr>
</tbody>
</table>

From table 3, it can be seen that 119 respondents who have good organization environment as many as 119 people (90.8%) are good work productivity and 11 people (9.2%) are poor work productivity. Meanwhile, from 49 respondents with bad organizational environment, there are 12 (24.5%) nurses with good work productivity and 37 (75.5%) with poor work productivity.

Based Chi-Square test results, it obtained p value = 0.000 (p <0.05) which means there is a relationship between the organizational environment and work productivity nurses practitioner. The value of r 30 means that nurses with good organizational environment 30 times more impact on good work productivity.

Table 4: Determinant factor: multivariate candidate selection of work productivity of nurse practitioner in the inpatient ward of Dr. M. Djamil Padang

</tr>
</tbody>
</table>

Table 5.5 shows that the most variable related to work productivity of nurses are organizational environment variable because it has the smallest value of p value and largest OR so that it can be concluded that work productivity of nurse practitioner controlled by organization environment. If the organizational environment is improved or enhanced, the work productivity of the nurse in general in the nurses in the inpatient ward of RSUP Dr. M. Djamil Padang can be increased by 21 times.

DISCUSSION

Description of Work Productivity of Nurse Practitioner in Inpatient Room of Dr. M. Djamil Padang.

The results showed (71,4%) work productivity of nurse practitioner in inpatient ward of Dr. M. Djamil Padang is good.

Research conducted by Elsa (2014) in Kandau Hospital showed 73% of nurses who have good productivity with sub items of different work productivity statements (6).

Research conducted in Dr. M. Djamil Padang show from 11 statements about work productivity of nurse practitioner distributed through questionnaires found most of the nurses (63.7%) showed good hospital efficiency, most nurses (57.1%) expressed good hospital commitment, and most nurses (54.8%) showed the effectiveness of good hospital.

Description of organizational characteristics in Inpatient Room of Dr. M. Djamil Padang.

The results showed (81%) organizational characteristics in inpatient wards RSUP Dr. M. Djamil Padang are good.
The study conducted by Muadi (2009) states the characteristics of the hospitalization organization installed BRSUD Waled Cirebon with both components of the statement of different organizational characteristics(7).

Research conducted in Dr. M. Djamil Padang from 12 statements about the characteristics of the organization distributed through questionnaires found that almost all nurses (92.9%) expressed good leadership system, almost all nurses (89.3%) showed Goal setting and MBO in both hospitals and almost all nurses (86.3%) showed good organization hospital.

Description of work Characteristics in Inpatient Room of Dr. M. Djamil Padang.

The results showed (73%) job characteristics in inpatient wards RSUP Dr. M. Djamil Padang are good.

The results of this study differ from the results of research conducted by Na Nan ang Pukkeeree (2013) which states that the average score of job characteristics is still not good where the average value of about 3.82 to 3.94 (8).

Research conducted in Dr. M. Djamil Padang from 8 statements about the characteristics of the work distributed through questionnaires found that almost all nurses (91.7%) stated good hospital feedback, almost all nurses (90.5%) stated good hospital performance targets and almost all nurses (86.9%) stated the design of work in hospital well.

Description of Organization Environment in Inpatient Room of Dr. M. Djamil Padang.

The results showed (71%) of the environment in the inpatient ward of Dr. M. Djamil Padang is good.

Research conducted by Amriyati et al (2003) states the organization environment in Banyumas hospital is good with sub items of different organizational environment statement (9).

Research conducted in Dr. M. Djamil Padang from 31 statements about the organizational environment distributed through the questionnaire obtained almost all nurses (91.1%) showed college nurse-doctor relationship in the hospital well, almost all nurses (79.2%) stated employee human resources and skills in the hospital well, and almost all nurses (77.4%) showed nurse managers skills, nurse leadership and nursing support either.

Organizational Characteristics and Its Relationship to Work Productivity of Nurse Practitioner in Inpatient Room of Dr. M. Djamil Padang.

Results of research on the relationship of organizational characteristics with Work Productivity of Nurse practitioner in Inpatient Room of Dr. M. Djamil Padang illustrates that good organizational characteristics have more proportion to increase the productivity of good nurse work for 112 people (82.4%) and 24 people (17.6%) resulted in work productivity of poor nurse practitioner. Statistical test results can be seen that there is a significant relationship (p value = 0.000) between organizational characteristics and work productivity nurses practitioner.

The results of the questionnaire analysis found that the optimal training and development conducted by hospitals where almost half of nurses (45.8%) stated that training and development in hospitals was poor and almost half of nurses (41.1%) stated that the hospital selection system less good where the lowest point nurses declare placement / assignment not in accordance with the profession. This is the factor causing the less good characteristics that impact on the productivity of work nurses are less good implementers.

C. Work Characteristics and Its Relationship to Work Productivity of Nurse Practitioner at Inpatient Room of Dr. M. Djamil Padang.

Result of research concerning relation of work characteristic with work productivity of nurse practitioner in inpatient ward of RSUP Dr. M. Djamil Padang illustrates that the characteristics of good work have more proportion to increase the productivity of good nurse work for 99 people (81.1%) and 23 people (18.9%) to produce work productivity of poor nurse executor. Statistical test results can be seen that there is a significant relationship (p value = 0.000) between job characteristics with work productivity nurses implementing.

The same study also obtained from a study
conducted by Yuxiu, Kunaviktikul and Thungjaroenkul (2011) suggests that there is a significant relationship between job characteristics and work performance at a moderate level ($r = 0.36, p < .01$).

The results of the questionnaire analysis found almost half of nurses (28%) stated that the work schedule determined by the hospital for the poor nurse became the factor causing the bad work characteristics so that the work productivity of the nurses became less good.

D. Organizational Environment and Its Relationship with Work Productivity of Nurse Practitioner in Inpatient Room of Dr. M. Djamil Padang

Result of research concerning relation of organization environment with work productivity of nurse practitioner in inpatient ward of RSUP Dr. M. Djamil Padang illustrates that a good organizational environment has a higher proportion of good nurse productivity increase of 108 people (90.8%) and 11 people (9.2%) produces less good worker nurse. Statistical test results can be seen that there is a significant relationship (p value = 0.000) between the organizational environment with work productivity nurses implementing.

The results of research conducted by Rahman (2015) The influence of work environment on nurse performance significantly and positively related, thus the work environment can affect the performance of nurses which is realized from a nurse attitude that reflects the feeling of love to the existing environment.

The results of the questionnaire analysis found that almost half of nurses (48.2%) stated that nursing field in improving the quality of nursing service was poor and almost half of nurses (28.6%) stated that the participation of nurses in the hospital was not good to be the cause of the poor organizational environment so that the productivity of nurse work becomes less good.

E. Determinant Factor Work Productivity of Nurse Practitioner in Inpatient Room of Dr. M. Djamil Padang

The result of multiple linear regression analysis shows that there is strong correlation ($R = 21.226$ and $p = 0.000$) between organizational environment factor and work productivity of nurse in hospital ward. Mjamil Padang. However, the results of this study is different from previous research, the results of research by Susanti (2014) found from the results of his research that the most dominant factor influential is the management system.

For the research conducted by the researchers themselves found that the organizational environment factor is the most dominant factor found to have an effect on the work productivity of the nurses in the inpatient room of RSUP Dr. M. Djamil Padang.

**RECOMMENDATION**

This research is very important for management in Dr. M. Djamil Padang hospital which is in the scope of nursing service as an effort to improve the work productivity of nursing

**RELEVANCE OF THE STUDY**

This research will produce an overview of the application of Organization characteristic, work characteristic and organizational environment on the work productivity of nursing in hospital, especially in Padang and Indonesia in general.

**CONCLUSION**

Organization characteristic, work characteristic and organizational environment have significant relation with quality of nursing service in Dr. M. Djamil Padang. With the determinant factor is the organizational environment that has a greater factor in affecting the work productivity of the nurses. Therefore, researchers can further explore other factors that affect the productivity of nurses working in hospital

**Conflict of Interest:** No conflict of interest arose in this study

**Sources of Funding:** This study was conducted using a source of funds derived from the researcher himself

**Ethical Clearance:** This study has passed of the medical reseach ethics of the Dr. M. Djamil Hospital Padang Indonesian.

Abstract

Background: Indonesia is a developing country with a high prevalence of type 2 diabetes mellitus (DM). Lifestyle behaviours related to type 2 DM cases and studies about its risk factors in Indonesia remain limited. This study aimed to identify the risk factors of type 2 DM in South Sulawesi.

Method: A cross-sectional study was conducted amongst patients undergoing treatment at a centre hospital in south Sulawesi from 2014 to 2016. Data were extracted from medical records. A logistic regression was used to identify the risk factors of type 2 DM.

Result: A total of 1500 patients were included in the analysis. A total of 288 (19.2%) participants had type 2 DM. In the multivariate analysis, we identified exercise (OR 1.84; 95% CI 1.23-2.77; p=0.0030), stress (OR 2.27; 95% CI 1.44-3.57; p=0.0010), total cholesterol level (OR 2.53; 95%CI 1.80-3.56; p=0.0001), hypertension (OR 1.58; 95%CI 1.18-2.14; p=0.0020), education level (OR 0.66; 95%CI 0.51-0.87; p=0.0030), and age (OR 1.02; 95%CI 1.01-1.03; p=0.0070) as significant risk factors for type 2 DM.

Conclusion: The prevalence of type 2 DM in South Sulawesi remains high. Exercise, stress, cholesterol level, hypertension, education level and age were factors that significantly increased the risk of type 2 DM. Health behaviours and knowledge are recommended to prevent the risk of type 2 DM.

Keywords: Risk factors of type 2 DM, Indonesia.

Introduction

An estimated 422 million adults worldwide were living with diabetes in 2014. The prevalence of diabetes has nearly doubled since 1980, from 4.7% to 8.4% in the adult population, and most cases are type 2 diabetes mellitus (DM). The International Diabetes Federation (IDF) reports that the prevalence of type 2 DM in low-middle income countries is increasing. Indonesia is ranked seventh in terms of the most diabetic cases worldwide (10.0 million) and third in terms of people with impaired sugar tolerance.

Complications often occur amongst diabetic patients including heart attack, stroke, renal disease, leg amputation, loss of vision (retinopathy) and neurological disorders. According to the WHO report, 6% of all deaths in Indonesia are caused by diabetes. In addition, diabetes also has a large economic impact on the state and the national health system. This is due to the increased use of health services, loss of productivity and long-term support to overcome diabetes-related complications such as kidney failure, blindness and heart failure.

The prevalence of type 2 DM is higher in urban cities than in rural areas. A study in China reported that the prevalence of type 2 DM is a public health problem, and the increasing number of diabetes cases is due to the rapid transition from a rural to urban lifestyle. Lifestyle has been identified to increase the risk of type 2 DM.

Corresponding author:
Ridwan Amiruddin,
E-mail: ridwan.amiruddin@gmail.com
cases. Low physical activity and occupational stress increase the risk of the incidence of type 2 DM. In addition, dietary fat intake, tobacco use and alcohol consumption were shown to affect the incidence of type 2 DM.

The increasing prevalence of type 2 DM in low-middle income countries shows that without an effective strategy for better management of diabetes, there will be an increase in diabetes complications. In Indonesia, the prevalence of type 2 DM and diabetes mortality remain high. In addition, information about the risk factors of type 2 DM in urban areas is limited. This study aimed to identify the risk factors of type 2 DM in urban cities. South Sulawesi is a useful study site because it has the same characteristics as other urban cities in Indonesia.

Method

A cross-sectional study was conducted amongst adult patients (≥18 years) who registered at Wahidin Sudirohusodo and Unhas hospitals in South Sulawesi between 2014 and 2016. The sample included outpatients and inpatients who have complete data according to the research variables. The data were collected from medical records from July to December 2016. The variables included age, sex, education level, occupation, smoking history, total cholesterol levels, hypertension, exercise, BMI, and stress.

A logistic regression was used to identify the risk factors associated with the prevalence of type 2 diabetes. Variables with a p-value <0.25 were included in the multivariate analysis. Stepwise regression with backward elimination approach was used to find the last model. All analyses were performed using Stata version 12 software.

Ethical approval was obtained from the ethics committee of the Faculty of Medicine, Hasanuddin University (Number: 925/H04.8.4.5.31/PP36-KOMETIK/2016).

Result

Patient characteristics:

A total of 1500 participants were included in the analysis with a median age of 59 years. A total of 19.20% of the participants had type 2 DM. Most (51.33%) were male, and most (54.53%) had a low education level (did not complete senior high school). As many as 61% of the participants had jobs. Nearly a quarter (22.60%) of the participants had a history of smoking. Additionally, 13% of participants had a high cholesterol level and 61% had hypertension (systole ≥ 140 mmHg and diastole ≥ 90 mmHg). Most (83%) of the participants had lack of exercise and had an average body mass index of 27.73 kg/m², and as many as 7% of the participants experienced stress.

Risk factors of type 2 DM:

In the bivariate analysis, variables that had a p-value <0.25 were included in the multivariate analysis. After all variables in the model were selected using stepwise regression with backward elimination, the last model showed that the significant variables were age, education level, cholesterol, hypertension, exercise, and stress. Participants over 59 years old had a higher risk of type 2 DM than that of participants younger than 59 years (OR 1.01, 95% CI: 1.01-1.03). A high education level (completing high school and college education) had a higher risk of type 2 DM than a low education level (OR 0.66; 95% CI: 0.50-0.86).

Participants who had high cholesterol levels (a total cholesterol level ≥200 mg/dl) had a two-fold higher risk of type 2 DM than those with low cholesterol levels (OR 2.76, 95% CI: 1.97-3.87). Participants with hypertension (systole ≥ 140 mmHg and diastole ≥ 90 mmHg) had a higher risk of type 2 DM than those without hypertension (OR 2.45; 95% CI: 1.74-3.45). Participant’s lack of exercise had a higher risk of type 2 DM than those who exercised (OR 1.92; 95% CI: 1.29-2.88). Participants who experienced stress had twice the risk of type 2 DM than those without stress (OR: 2.13; 95% CI: 1.35-3.48).

Discussion

We found a high prevalence of type 2 DM (19.20%) amongst patients at Wahidin Sudirohusodo and Hasanuddin university hospitals in South Sulawesi. Likewise, other developing countries have reported high prevalence rates of type 2 DM. In the multivariate analysis, we identified age, education level, cholesterol level, hypertension, exercise, and stress as risk factors of type 2 DM.

Sociodemographic factors including age and education level were identified as risk factors of type 2 DM. The incidence of type 2 DM was higher amongst participants aged > 59 years than participants aged ≤ 59 years. Similar results have been identified in other countries showing that age was a risk factor of type 2 DM. Other studies have shown that the incidence of diabetes increases significantly amongst people 60 to 70 years old.

Education level is related to knowledge of how to prevent illness, choosing one’s own health behaviours, and using the health care system. Previous studies have shown that a low education level is a strong predictor of type 2 DM. In this study, education levels were also identified as predictors of type 2 DM. However,
participants with a high education level had an increased risk of type 2 DM compared to those with a low education level. We reported that most (51.8%) of the participants with a high education level had jobs. People who have jobs consume fast food because of their busy lifestyles. A previous study has shown that fast food consumption more than twice a week increased the risk of a type 2 DM prognosis.14

We found that total cholesterol levels were the strongest risk factor for type 2 DM. Participants with total cholesterol levels ≥ 200 mg/dl had twice the risk of developing type 2 DM than those with total cholesterol levels <200 mg/dl. Similar results were identified in some developing countries showing that total cholesterol levels independently increased the prognosis of type 2 DM.15 Total cholesterol levels directly affect β cell metabolism, which interferes with insulin secretion.16 This study suggests that dietary education is important to prevent type 2 DM, particularly dietary fat intake and dietary fibre intake.17

Indonesia has a high prevalence of hypertension; the Ministry of Health reported that 25.8% of the population was diagnosed with hypertension.18 In fact, the hypertension prevalence may be even higher because most hypertension cases are undiagnosed.19 In this study, hypertension was identified as a risk factor for type 2 diabetes mellitus. Participants with hypertension had 1.5 times the risk of developing type 2 DM compared to those without hypertension. Previous studies have shown that hypertension increases hyperglycaemia, which is a cause of type 2 DM.5,20

Lifestyle was identified as being associated with metabolic disease, particularly low physical activity.8 In this study, we found that the prevalence of type 2 DM cases was higher amongst participants who had lack of exercise. Participants who exercised over 4 hours per week, i.e., walking, cycling, swimming and gardening, had a decreased risk of type 2 DM. A systematic review showed that exercise was a risk factor of type 2 DM.21 This result suggests that risk factors of type 2 DM can be modified to reduce this disease in communities.22,23 Previous studies have found that regular exercise 150 min per week is effective in preventing type 2 DM amongst elderly patients.8,24

Previous studies have also reported that stress is an independent risk factor of type 2 DM.25,26 Our study supports those results that stress increases the risk of type 2 DM. High-level stress (on a 5-point scale) induces hyperglycaemia, which is the cause of type 2 DM and death.27 A previous meta-analysis showed that psychosocial stress at work increases the risk of type 2 DM.6 Lifestyle factors such as diet, physical activity, and psychosocial support are recommended to reduce the risk of type 2 DM.28

Limitations: Our study used secondary data. Patients who did not have complete data for all variables were excluded.

Conclusion

We identified age, education level, total cholesterol level, hypertension, exercise, and stress as factors that significantly increased the risk of type 2 DM.

Recommendation: This study suggested that type 2 DM can be prevented by healthy life behaviours. Healthy life behaviours such as providing healthy food and regular exercise are recommended to reduce risk of type 2 DM. Moreover, government programmes that support providing public spaces for refreshing and exercise are necessary.

Satiation and Satiety in High-fiber Meatball Consumption

Siti Mei Saroh¹, Calista Segalita¹, Trias Mahmudiono¹

¹Departement of Nutrition – Faculty of Public Health, Universitas Airlangga, Jl. Mulyorejo Kampus C, Surabaya, Indonesia

Abstract

One effort to reduce the prevalence of obesity is by increasing the consumption of dietary fiber. Dietary fiber can decrease weight, because it can increase the satiety and prevent excessive calorie consumption. Substitution of banana blossom and mocaf rich in fiber to meatball is expected to be a healthy and fiber-rich food alternative to reduce the prevalence of obesity. The purpose of this study is to determine the acceptance, nutritional content and test the level of satiety of meatballs banana heart products.

This study is a cross-factorial design experiment, 3 best formulas were selected from 7 formulas by 3 trained panelists, then the best formula was selected by 25 untrained panelists. Data were analyzed by Friedman and Wilcoxon test. Nutritional content is calculated using Nutrisurvey. The satiety study used cross-over trial design. 14 subjects were Airlangga University students, aged 17-25 years. The satiety level was taken with a Visual Analog Scale (VAS) questionnaire consisting of hunger and satiety question.

The results of this study indicate that F3 with 20% substitution of banana blossom, and 15% mocaf flour is the best formula in terms of the acceptability and fiber content. Nutrition calculations show that per 100 grams F3 contains 178.9 kcal energy, 29.6 grams of carbohydrates, 13.1 grams of protein, 2.7 grams of fat and 1.6 grams of fiber. There was no significant difference in the value of hunger after eating (p = 0.122) and the value of satiety after meal (p = 0.080). However, there is no difference in the level of satiety between the modified meatballs and meatball control. This is believed to be due to insufficient fiber content to give effect to hunger and satiety.

Keywords: meatballs, satiety study, banana blossom, dietary fiber, modified cassava flour

Introduction

According to WHO in 2016, 39% of adults over 18 years in the world are overweight (BMI ≥25 kg/m²), while obese (BMI ≥ 30 kg/m²) contribute 13% in the population (¹). Nearly 2 billion adults are overweight and over half a billion are obese (¹). Numbers of studies have reported that every weight gain, there is an increased risk for coronary heart disease, type 2 diabetes, cancer, hypertension, stroke, sleep disorders, respiratory disorders, osteoarthritis, and reproductive disorders (irregular periods and infertility).

Several factors affect obesity. Variety, balanced and nutritional dietary pattern that have traditionally been made from fresh, high fiber and herbal spices have shifted to a fast-food consumption which high-fat, high-salt and sugar and low dietary fiber (¹). The high availability of fast food and high energy density leads to high consumption of unhealthy foods (²). Therefore, to lose weight, it is necessary to reduce the consumption of calories. Many strategies to lower calorie intake, such as limiting the portion of the meal. however, this approach tends to trigger hunger and dissatisfaction (³). Another alternative solution is to encourage the consumption of foods that are low in calories per gram or foods that are low in energy density.
Increased intake of dietary fiber is very important to prevent obesity. There are different mechanisms to how dietary fiber can help to lose weight. Foods that contain dietary fiber may decrease calories. According to research that dietary fiber intake is associated with the prevention of weight gain because it can increase satiety or taste (5). Adequate fiber intake can decrease appetite to 5%, decrease long-term energy intake by 2.6% and lose weight to 1.3% (Wanders, 2005). If individuals consume foods that provide more satiety per calorie, then the overall intake of calories will be smaller without sacrificing a feeling of fullness and satisfaction (2). This can hinder excessive energy intake and can help in weight loss.

Indonesia is a country rich in its abundant resources such as bananas and cassava. In 2016 banana production increased by 59.36% compared to the previous year. Bananas can be exploited widely. The heart of bananas is part of a banana that can be processed into nutrient-rich foods. Every 100 grams of banana heart contains 5.7 fibers (5). The heart of bananas also contains saponins that serve to lower bad cholesterol and increase body resistance against the growth of cancer cells. Besides bananas, the availability of cassava in Indonesia is quite abundant up to 19.9 million tons in 2009. Cassava can be processed into Modified Cassava Flour (mocaf) rich in fiber (6). Unfortunately, the consumption of banana and mocaf in the community is very less. Lack of heart consumption of bananas due to the processing and presentation of banana heart is not practical. Developing ready-to-eat products from the heart of bananas will greatly benefit the community to increase consumption of dietary fiber (7). Banana and mocaf’s heart is a potential resource that can produce new foods rich in food fiber and high economic value.

The substitution of banana heart and mocaf meal on the common food consumed by the community has the potential to improve nutrition especially fiber content. Meatballs is one of the fast food favorites of all circles. Meatballs are usually sold directly ready to eat or packed in frozen food products. This study will examine the effect of banana heart substitution and mocaf flour on the receiving power, and the level of glut of fiber-rich meatballs as one of the efforts in increasing fiber intake is useful to prevent obesity.

Mocaf flour can be used for the manufacture of meatballs because it has good adhesive power (8). The average fiber content of mocaf flour by 2.75% can increase the fiber content in food products. But the protein content of mocaf flour is lower than wheat flour. Thus, the addition of mocaf flour cannot reach 100%. Meatball is a popular food product in every circle, one of them students. Its ready-to-eat and delicious flavors become one of the preferred food alternatives for students. According to research conducted. Based on research of meatball consumer characteristic in Gorontalo, that consumer of average age meatball productive (19-25) with student status. Therefore, student can be the right respondent for acceptance test and also level glut in the banana heart meatballs.

The heart of bananas has a considerable nutritional value. The heart of bananas is rich in vitamins, flavonoids and proteins. According to research conducted by Sheng et al (2010) banana heart contains energy of 51 kcal, 1.6 g protein, 0.6 g fat, total carbohydrate including 9.9 g, 5.7 g food fiber, ash /Ash 1.2 g, calcium 56.0 mg, phosphorus 73,3mg, Iron 56.4mg, 13.0mg copper, Potassium 553.3mg, 48.7mg Magnesium, Vitamin E (mg / kg) 1.07mg. High fiber content in the heart of bananas can be consumed as a supplement to increase the intake of dietary fiber. The content of vitamin E in the heart of bananas protect fatty acids by counteracting free radicals. The heart of bananas also contains antioxidants that can reduce the risk of chronic diseases such as cardiovascular disease. According to Wickramarachchi and Ranamukhaarachchi SL (2005) the banana heart contains Quercetin, a type of flavonoids that can prevent oxidation of Low Density Lipoproteins (LDL) from free radicals. The heart of bananas also contains good quality proteins because they contain essential amino acids. The heart of bananas also contains saponins that can lower LDL or bad cholesterol, increase immunity to infections and inhibit cancer cells.

Many studies use the heart of bananas as a supplement to increase the fiber content of certain food products. Research conducted by Elaveniya and Jayamuthunagai (2014), the heart of bananas is added to the manufacture of biscuits. The addition of banana hearts increases the content of dietary fiber by 20% more than control biscuits (7). In the manufacture of abon with the addition of banana heart contains food fiber of 17,81%. The addition of fiber to the food product may affect the palatability of the food product (7). The addition of banana heart to beef meatball with soybean meal substitution has an effect on to organoleptic test on meatball that is on color, taste,
elasticity and acceptability parameter, but it does not affect the texture of meatballs.

**Material and Method**

This research consists of two stages. The first stage is the development of meatball substitution formula of banana heart and mocaf flour. This one-phase study is a purely experimental study. The second stage is a test of acceptance and test of glutness level. For power test receipt is a quasi experimental research using organoleptic test. Test the level of glut of the meatballs used method cross-over trial.

Factorial experimental design with Randomized Complete Randomized Design (RAL) design. With the first factor (J) is the formulation of chicken and banana heart with 3 treatments.

The sample of this research is chicken meatball which substituted banana heart and mocaf flour with different composition. Things to consider in the presentation of the sample are the dosage, temperature, presentation suggestion, favorite test questionnaire. In the test Satiety, according to Karalus (2012), the study sample can be drawn from sub-populations that meet the following inclusion criteria: age 17-24 years, healthy BMI (18.5-27 kg / m2), and accustomed to breakfast. The number of panelists in advanced research is usually more than 25 people. For this study 25 panelists selected from students of Faculty of Public Health Airlangga University who have been selected through screening and willing to sign informed consent. Panelists in advanced research are the same subjects on the test of glutness level.

Samples were obtained from the population entering inclusion criteria. In the first week of treatment, participants willing to approve informed consent will be randomized by simple random sampling to get participants who received control meatballs and participants who received meatball treatment. In the second week of treatment, the sample was crossed. Participants who previously received a meatball control given the meatballs modifications and vice versa.

**Findings**

Subjects in this study were women ages 19-23, students of Airlangga University, and had normal nutritional status. Nutritional status affects the subject’s sensitivity to changes in satiety. People with severe obesity (morbid obesity) who have very high levels of fat will experience leptin resistance, a condition in which the hormone leptin produced very high but does not affect the decrease in appetite (9). In some studies it also mentions gender affecting satiety (10). However, in a study cross-over trial, subjects became their own control, so differences in subject characteristics did not significantly affect the results of the study.

Based on table 1 can be seen that there is no difference between meatball F0 and meatballs F3 on the value of hunger and satiety. This is not in accordance with reviews in previous studies which show that dietary fiber intake is positively associated with satiety. Mathern et. al (2007) studied the effects of 0.4 and 8 g of fiber on foods fenugreek on appetite sensation. The study showed that 8 g of fenugreek had a higher satiety compared to foods containing only 0.4 grams of dietary fiber. Likewise Gustaffon et. al (2008) showed that a portion of carrots containing 6 grams of dietary fiber could significantly satisfy a portion of carrots containing only 3 g of dietary fiber when fed into mixed foods. It is difficult to explain why this study is incompatible with both studies. However, there are various possibilities that may affect the test of glut. The first factor is that small doses of fiber have no significant effect on hunger. According to various studies conducted when dietary fiber less than 6.5 has a small effect on glut when measured by subjective measurements such as Visual Analog Scale (2). For example, Mattes et.al (2007) found no significant difference in glut when subjects consumed a snack bar containing 4 g fiber with a snack bar containing 1 g fiber. Similarly, in studies comparing fiber-rich milk containing 3 g of dietary fiber to non-fiber foods, it showed that there was no significant difference in satiety or taste (11). Therefore, a higher fiber dose is needed to influence satiety.

According to the study that the addition of a dose of dietary fiber will also lead to a decrease in calories or energy density accompanied by increased satiety (12). According to table 2 along with the addition of banana hearts containing dietary fiber, the lower the number of calories it contains. However, the decrease in the number of calories also has no effect on satiety. In addition the amount of fat content tends to be the same between meatball control and meatballs modifications. So the effect on satiety tends to not exist.
Another factor is the presence of macro nutrients that affect the satiety of the protein. Based on research, foods that are high in protein can also affect the level of glut or satiety. Food can have an optimum effect on appetite control when foods are high in protein, dietary fiber and low in fat(2). F0 meatballs consist of 100% chicken meat and beef rich in protein without blending the banana heart. This causes the meatballs F0 to have a higher protein content (15.2 g) than F3 (12 g), although the fiber content of F7 meatballs (ordinary meatballs) is 0 g. As a study conducted to determine the effect of high protein breakfast on obese women, showed that breakfast with 25% protein content can increase glut and there is a significant difference between breakfast with regular protein with a high protein breakfast. Therefore, protein content should also be considered in the measurement of glut.

Conclusion

There was no significant difference in hunger and satiety between controlling meatballs and banana heart meatballs. Although the content of dietary fiber can decrease the number of calories per gram, but the amount of dietary fiber is less significant to give satiety effect.

This study has the limitations of fasting blood glucose test is not performed on the respondents. In addition, this study also did not measure the amount of food intake as a result of the satiety of previous foods because it is difficult to hold the subject to be in the laboratory within 5 hours more to measure the intake of subsequent meals.

The Influence of Lead (Pb), Zinc (Zn), Ratio Lead (Pb) to Zinc (Zn) in Attention Deficit Hyperactivity Disorder (ADHD)

Yunias Setiawati1, H J Mukono2, Joni Wahyuhadi3, Endang Warsiki4

1Doctoral Program of Health Science, Faculty of Public Health, Airlangga University; Indonesia; 2Department of Environmental Health, Faculty of Public Health, Airlangga University; Indonesia, 3Neurosurgery Department, Faculty of Medicine, Airlangga University; Indonesia, 4Psychiatric Department, Faculty of Medicine, Airlangga University; Indonesia

Abstract

Background: Attention Deficit Hyperactivity Disorder (ADHD) is a common childhood psychiatric disorder often encountered in clinical practice with major symptoms of inattention, hyperactivity, and impulsivity. Pollution of lead (Pb) is thought to be a cause of ADHD that affects the cognitive deficit of the brain. Zinc supplementation (Zn) can improve the symptoms of ADHD by increasing dopamine transporters binding. The aims of this study is to compare the level of Pb and Pb to Zn ratio on the subject of ADHD and normal children.

Method: This is an observational analytic study with case control design on 44 respondents. Statistical analysis using non-parametric test Man Witney.

Result: There is no significant difference of Pb level in children with ADHD and normal children with p = 0.431 and there is a significant difference of Zn level in ADHD and normal children with p = 0.011 and significant difference in Pb to Zn ratio with p = 0.015.

Keyword: Lead (Pb), Zinc (Zn), Ratio Pb to Zinc (Zn), ADHD

Background

Exposure to lead (Pb) in the environment has a neurotoxic effect resulting in behavioral disorders and cognitive deficits(1). For decades there has been considerable effort to reduce lead levels in the environment(2). Lead may adversely affect cognitive disorders, decreased IQ scores, learning disabilities in mathematics, reading and verbal memory(3).

Metaanalysis study by Goodlad et al concluded that the diagnosis of ADHD is increasing, thus attracting researchers to analyze the factors of heavy metals as factors causing ADHD(4). Lead is the most responsible for mental disorders and thus requires clinical attention(5). In humans, small amounts of metal can adversely affect health and psychological disorders such as ADHD(6). Pb adversely affects the child in the form of mental retardation disorder and impulsivity(7–9). Pb exposure is more common in hair than blood. Pb levels in hair tend to be more sedentary and reflect Pb levels in the subjects compared with temporary blood(10–15). While the trace elements Zinc (Zn), is an essential nutrient in animals and humans(16,17). In ADHD children it is suspected that there is a decrease in Zinc levels that cause concentration and attention disorder(11,18). The impact of high lead levels and low levels of Zinc can lead to impaired cognitive function and learning disabilities in children(19). Measurement of Pb and Zinc levels in hair and Zinc to Pb ratio is expected to help reduce the risk of ADHD severity(21). Zinc plays an important role in the metabolism of neurotransmitters and prostaglandins, by maintaining the function and structure of the brain. Dopamine plays an important role in the pathophysiology of ADHD and the melatonin hormone plays an important role in the regulation of...
dopamine, as of the administration of Zinc is expected to improve ADHD symptoms. Zinc levels of children with ADHD are thought to be lower than normal children. With the administration of Zinc supplementation, it will be able to correct the existing disorder \(^{(17,20,21)}\).

**Method**

This is a a case control study in grade 1 to grade 6 students of Bina Karya Elementary School Surabaya. With the use of random sampling formula, we get the number of samples of 23 ADHD subjects and 21 non ADHD subjects who meet the inclusion criteria. The inclusion criteria of the study were ADHD patients aged 6-12 years old, mothers of ADHD patients with minimum junior high school education, able to communicate using Indonesian, cooperative, and did not experience severe psychosocial stressors.

Examination of lead and zinc levels were used hair samples by Atomic Absorption Spectrophotometry (AAS) method. Abbreviated Conners Teacher Rating Scale is used to assess ADHD scores. This scale was developed by C. Keith Conners, Ph.D. While the validity and reliability in the Indonesian has been done by Sasanti Juniar in 1999.

To assess the psychosocial stressors, it used Social Readjustment Rating Scale by Holmes and Rahe (1967).

The results in table 1 show 44 respondents consisting of 23 respondents ADHD and 21 respondents non ADHD. From the age of children found the most age is less than 12 years with a percentage of 46.3% in non-ADHD respondents and 53.7% of ADHD respondents. The order of the most children is the first child of 56.52%. The highest maternal education in ADHD and non ADHD respondents was others each was 11 (50%). Maternal age in respondents ADHD mostly in the range 39-45 years of 11 people (57.9%), while the mother of respondents non ADHD as many as 9 people (64.3%). Most mothers of ADHD and non-ADHD children do not work and with the most income is less than Rp 1000,000 per month. Husband and wife relationship is poor on the mother of ADHD respondents of 3 people (100%) and the relationship between family members is poor as many as 5 people.

Discussion

From the demographic data of the respondents, the result of the sample of ADHD, boys patients were 16 children and girls were 7 children. This result is consistent with previous findings that the prevalence of ADHD is greater in males in comparison between 3-4 boys versus 1 girl(22–24). From the demographic characteristics of mothers that consist of age, education, occupation, and income, it is found that the age of mothers in ADHD children is majority older than mothers of non-ADHD children. This result is inconsistent with previous studies which concluded that the maternal age of ADHD children was younger than that of non-ADHD children(25). This result can be obtained because the parents’ knowledge of the problems is still low so they do not understand how to handle their children disorder.

The results of the research was the majority of mothers are other education, namely elementary and junior high school, this result obtained based on interviews that many mothers was married at a young age and can not continue to higher education because there is no cost and some others mothers experience pregnancy.

From the data about the occupation of the mother found that most mothers was unoccupied. In parent interviews it is found that most mothers should take care of their children at home because many father work outside as a driver, private employee and work as a handyman. This result is also in accordance with previous research that the mother of many ADHD children who have lost their job or can not work because they have to take care of their own ADHD child(25).

The results of maternal earnings working on mothers of ADHD and non-ADHD children were the largest in less than a million rupiah but the majority stated the results were sufficient. This result is because most of the respondents are Javanese who put togetherness, gotong royong and nrimo culture and emphasize the existence of life as flowing water surrender to God and shame to express the shortcomings(26,27).

Statistical analysis used Mann Whitney non parametric comparative test. The data were not normally distributed and there was no significant difference between Pb levels in ADHD and non ADHD children. This result is consistent with the theory that causes of ADHD this day is unclear. High levels of Pb may cause cognitive, emotional and behavioral disorders but Pb is not the determining factor that causes ADHD. This theory also corresponds to results in the field showing high Pb levels in non-ADHD subjects(28). The results showed that Pb levels in ADHD respondents were lower than those for non-ADHD respondents but this condition still requires clinical attention because Pb is toxic and a global health problem in the environment and may
interfere with biochemical processes in the brain. Lead exposure still requires more research because it is an important issue in the global health of the world, especially in developing countries.

There was a significant difference in Zinc levels in ADHD children and non ADHD. From the above results it can be considered to administer zinc on ADHD subjects. This result is consistent with the literature which states that in ADHD subjects there is deficiency or excess of Zn level. Zinc plays an important role in protein and DNA synthesis, wound healing, bone structure and improvement of the immune system. Zinc deficiency may involve impaired growth, loss of hair, diarrhea, immune system decline and dermatitis. Zinc deficiency also causes late growth process, late puberty, erectile dysfunction and hypogonadism in men. It is said that 5% of the world’s population suffers from zinc deficiency. Zinc is a trace element because the concentration in plasma is only about 12-16 μM, in the body there are 2-4 grams of zinc with a majority in skeletal bone and muscle. The body does not store zinc and zinc intake is obtained from food. The recommended dosage for girls and boys ages 4 to 8 months is 5mg, 14 to 18 years of age in women by 9 mg and men by 11 mg. The concentration of zinc persists constantly in hair, skin, heart, muscle, as in plasma, liver, bone and testes. Chronic zinc deficiency is more sedentary in hair than in plasma. Zinc is an essential micronutrient of physiological metabolism. Zinc plays an important role in catalyzing enzyme activity, contributing to protein structure and gene expression regulation. Other studies suggest excess zinc levels may also cause ADHD.

There was a significant difference between the ratio of Pb to Zn in ADHD and non ADHD children. From the examination there are differences in the ratio of Pb and Zn where the high Pb level come with lower Zn level. Chronic lead exposure adversely affects physical growth, development of the nervous system, memory impairment, learning disorders, cognitive deficits, psychological and behavioral disorders. Infants and children are at high risk of lead pollution, with levels below 10 μg/100 ml may cause growth disturbance. Much effort has been made to reduce lead exposure in infants and children. The chelation program is used as the ultimate management but the therapeutic process is risky, with 50% suffering the side effects of losing the minerals needs. The chelation is also not useful in improving cognitive, behavioral and neurocognitive disorders. Therapy on lead can increase the cytotoxicity and astrocite activity. Lead exposure causes astrocite damage. Lead can increase lysosomal density and nucleus inclusions, increase the area of reticulum of endoplasma, increase lactic dehydrogenase (LDH) damage, and decrease the levels of the sulfydryl group that can be overcome by antioxidant administration. The lead deposit in astrocite leads to the accumulation of protein in the endoplasmic reticulum, increased protein response, and breakage of cell cycles.

**Conclusion**

There was a significant difference between Zinc levels in ADHD and non ADHD subjects and Pb/Zn ratios in ADHD and non ADHD subjects.

A Study About Incidence of Dapsone Syndrome in Patients on Multidrug Therapy for Hansens Disease

Soorya B1, Jayakar Thomas2
1Junior Resident, 2Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

Dapsone is a parent sulfone drug. It was synthesized by Fromm and Whitmann in 1908. Robert Cochrane introduced dapsone for the treatment of Hansen’s disease in India. Dapsone is used for variety of dermatological conditions other than Hansen’s disease. Dapsone syndrome is a hypersensitivity reaction first described by Lowe and Smith in 1949. The name dapsone syndrome was given by Allday and Barnes in 1951. Dapsone along with anticonvulsants, allopurinol, sulfonamides, minocycline and NSAIDs are commonly associated drugs for drug induced hypersensitivity. Dapsone syndrome has also been reported in psoriasis, lichen planus, acne vulgaris and erythema elevatum diutinum and dermatitis herpetiformis.

Keywords: allopurinol, sulfonamides, minocycline

Introduction

Dapsone which is chemically 4, 4-Diamo diphenyl sulphone is a sulfone drug used for variety of dermatological conditions like Hansen’s disease, blistering disorders, infections like leishmaniasis, mycetoma etc, Neutrophilic vasculitis, collagen vascular disorders, erythema elevatum diutinum, follicular mucinosis, acne vulgaris etc. Dapsone is completely absorbed and peak concentration attained within 2 to 4 hours. Plasma half life for dapsone is 28 hours. The standard dose is 100mg per day for adults and in children 0.9-1.4 mg/kg.

It is retained in the skin, liver, kidney and mucosa. It acts by inhibiting dihydro folate reductase which is involved in the conversion of PABA (para amino benzoic acid) involved in folic acid synthesis. It is used in other dermatological conditions is based on scavenger like function, inhibition of alpha-1 protease, neutrophilic chemotaxis, eosinophilic chemotaxis, prostaglandin D2, prostaglandin E2, myeloperoxidase hydrogen peroxide halide system and it interferes with humoral and cell mediated immunity.

Methodology

A cross sectional study was done with 50 patients diagnosed with Hansen’s disease and on multidrug therapy attending the Department of Skin and Sexually Transmitted diseases. All the patients were subjected to Complete history

Complete physical examination

Dapsone syndrome also known as five week dermatitis or sulfone syndrome is an idiosyncratic hypersensitivity systemic syndrome which may end fatally if not identified and treated early. Dapsone syndrome usually occurs 4 to 6 weeks after starting therapy.

DISCUSSION

It is thought to be a hypersensitivity reaction because of interval between starting the therapy and presentation of clinical symptoms. It was also thought that metabolic differences in production and detoxification of reactive oxygen species are responsible for hypersensitivity. Dapsone is metabolized by oxidation – N- hydroxylation and N-acetylation.

Toxic intermediate metabolites (nitrosamines) and compounds of N-hydroxylation pathway are responsible for methhemoglobinemia, hemolytic anemia and
Dapsone syndrome. Dapsone syndrome is influenced by genetic and environmental factors. It manifests as exfoliative dermatitis, skin rashes with pruritis, fever, hepatitis, hepatosplenomegaly, lymphadenopathy, acute renal failure, myocarditis and cholangitis.

Basic Needs & Importance:

Pulmonary and pancreatic involvement also been reported. Cutaneous lesions can be maculopapular rash or vesiculo pustular reaction like SJS and TEN. Other manifestations are conjunctivitis, arthritis and white tonsillar membrane. Onycholysis can also be seen. Mortality rate is 13-15%. Commonest cause of death is due to liver failure, shock, sepsis, bone marrow failure and pulmonary insufficiency.

Extract From Some Studies:

Differential diagnosis includes infectious mononucleosis, viral exanthema, hepatitis B infection, rifampicin hypersensitivity and lepra reaction. Treatment is by immediate stopping of the drug and oral steroids, antipyretics, antibiotics, topical emollients and other supportive measures. For Hansen's patients, dapsone is stopped and other two drug clofazimine and rifampicin are continued.

Conclusion & Recommendations

Out of 50 patients studied, 1 patient showed features of Dapsone syndrome (hepatitis, hepatosplenomegaly, maculopapular rash, peripheral neuropathy, fever and arthritis).

Dapsone syndrome is a fatal idiosyncratic hypersensitivity systemic syndrome. Early onset and partial forms is found to be more common than previously reported. Hence awareness about this condition, early diagnosis and proper management are needed to prevent mortality.

A Study of Skin Tumors Over the Face

Padam Kumar M1, Jayakar Thomas2
1Junior Resident, 2Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

Skin tumors over face are common clinical presentation. Most commonly noticed are trichoepithelioma, syringoma, angiofibroma and xanthelasma. Their incidence been in doubt. We hereby report a summary of 20 patients who presented with a tumor over face. Tumors of the skin range from small papules to large fungating masses. They are infrequent in people with brown skin and occupy a small space in medical and public perceptions of the role of a dermatologist

Keywords: trichoepithelioma, syringoma, tumor

Introduction

Some tumors are commonly seen, others are extremely rare and still others mimic non-neoplastic disorders. They also form an important component of some genodermatoses. Certain tumors are easily recognized clinically, based on the characteristic site of presentation, size, color, distribution, and symptoms, while others can only be diagnosed by histopathology, immunohistochemistry, or other diagnostic techniques. About a third of sweat gland tumors contain TP53 gene mutations1. They arise de novo while some arise from normal appendageal structures. They present as smooth papules or nodules that grow slowly to a small size. Multiple lesions are a reliable clinical clue to the benign nature of the condition. The most common cutaneous tumors seen over the face are trichoepithelioma, syringoma, angiofibroma and xanthelasma.

Methodology:

Twenty patients with skin tumors over the face were included in our study. A detailed history was elicited including details regarding duration, history of evolution, progression and treatment modalities if any. Complete physical and dermatological examination were done in all patients2. Skin biopsy performed in all patients to confirm the diagnosis.

Table 1: Commonly observed skin tumors on face.

<table>
<thead>
<tr>
<th>CUTANEOUS TUMORS OVER THE FACE</th>
<th>%</th>

<tr>
<td>Xanthelasma</td>
<td>6(30%)</td>
</tr>
</tbody>
</table>

Discussion

Some tumors may consist completely or partly of undifferentiated cells that cannot be recognized as resembling a normal appendage3. The commonly observed tumor in our study were trichoepithelioma, syringoma and xanthelasma. Syringomas are fairly common tumors that occur more frequently in women. The classical presentation is of multiple, skin-colored, dome-shaped, and flat papules some of which have characteristic angulated borders. The papules are 1-3 mm in size and occur around the eyes.

Extract From Some Studies:

Trichoepithelioma, hamartoma of the hair germ made out of youthful islands of basaloïd cells with central, crude follicular separation and indenation of a cell stroma. It presents with a smooth knob, more often than not on the face. Most basic age gatherings are youthful grown-ups. Numerous sores, which are acquired via autosomal prevailing transmission are viewed as

various, little silvery injuries on the centrofacial skin.

Xanthomatosis is a cutaneous appearance of lipidosis wherein plasma lipoproteins and free unsaturated fats are subjectively adjusted, bringing about a morphologic change as lipids amass in froth cells in the tissues.

**Basic Needs & Importance:**

The upper eyelid and the region around the inner canthus are the most common sites of involvement, although in severe hypercholesterolemic conditions (e.g. familial hypercholesterolemia) they may occur circumferentially or on the outer aspects of the eye varying from 2 to 30 mm in length. Frequent symmetry with the tendencies to permanency, multiplicity, and coalescence are characteristic.

**Conclusion & Recommendations**

A total of 20 patients (9 males and 11 females) were included in the study. Most common age group was in the range of 41-50 (34%) followed by 51-60 years (51%). Skin tumors commonly observed were trichoepithelioma 8(40%), syringoma 6(30%) and xanthelasma 6(30%) In this study, among the skin tumors we found trichoepithelioma as the commonest tumors accounting for 40%. Treatment includes electrocautery, surgical excision, curettage, cryotherapy and dermabrasion. High energy pulsed carbon dioxide laser can also be used for treatment.

Significance of Pase Score in Psoriasis: A Cross-Sectional Study in a Tertiary Care Hospital

Deepthi Ravi¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

To look at the PASE (Psoriatic Arthritis Screening and Evaluation score) with the PASI (Psoriatic region seriousness record) score, NAPSI (Nail psoriasis seriousness list) score, CASPER (Classification Criteria for Psoriatic Arthritis) criteria, term of ailment and span of medicines.

Associate the PASE score with the clinical examination discoveries. Psoriatic joint inflammation is an interminable foundational incendiary condition described joint inflammation related with psoriasis of the skin and nails with negative rheumatoid factor and nonappearance of rheumatoid knobs. Gauge of the commonness ranges at 0.3 to 1% of the all inclusive community and at 25% in patients with cutaneous psoriasis.

Keyword: rheumatoid, Psoriatic Arthritis

Introduction

Psoriatic joint pain is a ceaseless fundamental fiery condition portrayed joint pain related with psoriasis of the skin and nails with negative rheumatoid factor and nonattendance of rheumatoid knobs.

Gauge of the pervasiveness ranges at 0.3 to 1% of the all inclusive community and at 25% in patients with cutaneous psoriasis. Early finding will help avert unhelpful examinations and treatments and help in treating the patient in beginning periods of the malady. Already early finding was not of significance because of the nonattendance of medications which had the option to change the course of sickness¹.

Methodology

A cross sectional study including 100 patients clinically diagnosed as psoriasis & age above 18 will be taken for the study after taking a written informed consent.

PASE score according to the questionnaire will be calculated along with PASI, NAPSI, CASPER scores.

PASE score will be compared with the other scores as well as the clinical examination findings of the patient as well as the treatment medication and duration.

Discussion

Psoriatic Arthritis Screening & Evaluation (PASE):

The scale ranges from ‘Unequivocally Agree’ to ‘Strongly Disagree’. PASE absolute score is determined by summing the scores for every one of the 15 things¹. The all out score ranges from at least 15 to a limit of 75³. PASE has two sub-scale scores, indications and capacity. The side effect sub-scale has 7 things, and the greatest indication score is 35. The capacity sub-scale has 8 things, and the most extreme capacity score is 40. Cut off score for PsA is 40.

Extract From Some Studies:

Up to 30% of patients with psoriasis experience the ill effects of simultaneous psoriatic joint pain, and both the sicknesses have more terrible personal satisfaction results contrasted with the all inclusive community.
There is restricted writing looking at personal satisfaction results between these sicknesses. We look to think about personal satisfaction results between both these gatherings.

Conclusion & Recommendations

Regardless of forceful treatment, physical personal satisfaction was more regrettable in psoriatic joint pain patients contrasted with psoriasis patients. The psychological personal satisfaction records were equivalent in both the gatherings were still underneath the populace standard. These outcomes propose requirement for screening for psoriatic joint pain in patients with psoriasis to lessen the weight of physical personal satisfaction and screening for early indications of mental sicknesses in both these malady populaces.

Comorbid Conditions Associated with Atopic Dermatitis

S.R.Sruthy¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute.

Abstract

To study the various comorbid conditions associated with Atopic dermatitis. Atopic dermatitis (AD) is now becoming very common and is being diagnosed in a vast majority of children.

AD is known to be associated with several comorbidities. The connection seems to be due to more than one reason – genomes, skin barrier dysfunction, and inflammation.

Keywords: Atopic Dermatitis , Disorder, AD

Introduction

There are conflicting results about the association between AD and diabetes. Multiple large-scale epidemiological studies demonstrated that obesity is a risk factor for atopic disorders, including asthma and atopy.

Obesity is considered to be a trigger or exacerbating factor for AD, and not merely an epiphenomenon. The associations between AD, obesity, and other metabolic factors in some patients.

Methodology

A cross sectional study was conducted on 30 patients diagnosed with Atopic dermatitis.

Investigations done were

• Complete physical examination
• Blood pressure
• Fasting blood sugar
• Ultrasound abdomen (fatty liver)

There are conflicting results about the association between AD and diabetes. Multiple large-scale epidemiological studies demonstrated that obesity is a risk factor for atopic disorders, including asthma and atopy.

Fillagrin and other genetic mutations involved in AD result in both an AD phenotype and increased risk for obesity and its sequel. Obesity is considered to be a trigger or exacerbating factor for AD, and not merely an epiphenomenon¹.

Discussion

The associations between AD, obesity, and other metabolic factors have important clinical ramifications. These associations highlight the importance of maintaining ideal BMI suggest that weight loss may actually improve AD in some patients².

Extract From Some Studies:

Adipokines play an important role in allergic inflammation. Adiponectin tend to be lower in obesity. Leptin is an adipokines that is unregulated in obesity³. It has been shown to induce eosinophils in vitro and stimulate chemokines. Leptons may play a role in allergic asthma³.

Basic Needs & Importance:

Patients with AD were found to have increased fatty liver. It is possible that the association between fatty liver and AD is secondary to circulating free fatty acids in chronic obesity⁴. 
Conclusion & Recommendations

Out of 30 patients 16 patients had associated comorbidities. 7 patients were obese. 2 patients were diagnosed to have fatty liver on ultrasound abdomen. 4 patients had elevated fasting blood.

Our information uncover a striking relationship between psychological well-being issue and AD in the US pediatric populace. The seriousness of the skin sickness changes the quality of the affiliation.

Imminent accomplice studies are expected to confirm these affiliations and to investigate hidden instruments. Methodologies to avoid AD or to forcefully treat early skin aggravation may change the danger of psychological well-being issue in danger kids.

A Study on Incidence of Knuckle Pebbling in Diabetes

P. Keerthana Bhaskar¹, Jayakar Thomas²
¹Junior Resident, ²Professor; Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

This study attempts to find out the incidence of Knuckle pebbling in diabetes. Knuckle pebbling is a common dermatological finding of Diabetes mellitus. They are called as Huntley’s papules or Finger pebbles.

In this, Knuckles and dorsal fingers show pebbling. They usually come with complain of dryness of hand. Patient may give history of poor glycaemic control. Sand paper like appearance of skin is seen over the knuckles and the interphalangeal joints. It is the cutaneous marker of diabetes.

**Keywords:** diabetes, glucose.

Introduction

Patients with diabetes tend to have thicker skin. There is no positive history of trauma I such cases. Epidermal hyperkeratosis and disorganised collagen in dermis with perivascular infiltration is seen on dermatopathological examination¹.

A cross sectional study was done with 30 Diabetic patients. All the patients were subjected to

Complete history

Complete physical examination

Methodology

Knuckle pebbling is more commonly seen with Diabetes. These are the cutaneous markers of Diabetes. Knuckle pebbles are seen as multiple, grouped, minute papules. They are seen over knuckles, dorsum of the fingers, periungual region³.

These pebbles are seen more commonly with Diabetes than as individual presentation. It can be seen in association with Acanthosis nigricans. Knuckle pebbles are different from knuckle pads.

Extract from some case studies/life scenarios:

Cutaneous examination shows diffuse xerosis and rough skin which gives sand paper like appearance over knuckles arranged in cobblestone pattern. This condition may not be present with pruritus.

<table>
<thead>
<tr>
<th>CUTANEOUS SIGNS IN DM</th>
<th>NUMBER (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Knuckle pebbling</td>
<td>11 (30)</td>
</tr>
<tr>
<td>2. Acanthosis nigricans</td>
<td>9(11)</td>
</tr>
<tr>
<td>3. Periungual skin pebbling</td>
<td>3(11)</td>
</tr>
</tbody>
</table>

Basic Needs & Importance:

Looking into pathogenesis of this in association with Diabetes is not yet clear. Collagen Hydration secondary to polyol accumulation and glycosylation of collagen which is not enzymatic action contributes to pathogenesis of skin thickening in Diabetes².

Dermatopathology examination with H&E staining of biopsy from knuckles shows hyperkeratosis of the epidermis, enlarged papillary dermis; collagen bundles are thickened and vertically oriented along with elastic fibers. Along with this mild perivascular infiltration is seen

**Corresponding Author:**
**Dr. P. Keerthana Bhaskar**
Junior Resident, Department of Dermatology
Sree Balaji Medical College & Research Institute.
Conclusion & Recommendations

Out of 30 patients studied, 13 patients showed features of knuckle pebbling. Almost all of the Diabetic patients selected for the study showed thickening of the skin.

Knuckle pebbling is seen in almost half of the Diabetic patients. Other than the knuckle pads, few diabetics showed pebbling over fingers and periungual region where few were seen along with Acanthosis Nigricans.

Generally, ulnar side of the skin over fingers is smoother than radial side. On clinical examination if both sides feel the same, then that patient is likely to have Diabetes mellitus4.

There is no specific treatment for knuckle pebbles. There can be improvement with good diabetic management.

Significance of Dyslipidemia in Males with Androgenetic Alopecia

Manoharan¹, Jayakar Thomas¹
¹Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

To think about the frequency of dyslipidemia in guys with androgenetic alopecia. Androgenetic alopecia normally known as male pattern hairlessness is the most widely recognized reason for balding in men. There is androgen-mediated conversion of susceptible terminal hair follicles to vellus hairs. Many studies have evaluated lipids to be the pathogenic factor for coronary artery disease in Androgenetic alopecia patients. So its detection at an early stage is very important.

Keywords: lipids, androgenetic alopecia

Introduction

This study is designed to substantiate the incidence of dyslipidemia in Indian males with androgenetic alopecia, as screening of Androgenetic alopecia patients for dyslipidemia can lead to early intervention and prevention of patients from developing cardiovascular complications like coronary artery disease in the future¹.

Androgenetic alopecia or male pattern hair loss is the most common cause for baldness in males characterized by progressive loss of hair. It is a common psychosocially and cosmetically distressing condition. The thick, pigmented terminal hairs gradually transform to thin, short, indeterminate hairs and finally to non-pigmented vellus hairs. The dihydrotestosterone is responsible for the shrinkage of the hair follicle that is genetically sensitive to it.

Methodology

A cross-sectional study was conducted in 15 male patients diagnosed with androgenetic alopecia. Androgenetic alopecia was diagnosed based on family history, clinical findings and the pattern of thinning of hair ².

Discussion

The age of these patients was between 18 and 35 years. An informed written consent was obtained from each of these patients. These patients were subjected to full history taking, thorough general and dermatological examination. Those patients with systemic disorders, other alopecia’s and on any medication that could affect the lipid metabolism, smoking and alcohol intake, cancer were excluded from the study ⁵.

The patients were subjected to a 12 hour fasting period after which a venous blood sample was taken for lipid profile which includes

- Total cholesterol (CHO),
- High density lipoprotein (HDL-C),
- Low density lipoprotein (LDL-C),
- Triglyceride (TGL),
- Very low density lipoprotein (VLDL),
- Total cholesterol and HDL-C ratio

Corresponding Author:
Dr. D. Manoharan
Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute
Extract From Some Studies:

The basic type represent the shape of the anterior hair line (L,M,C,U) the specific types represent the density of hair on specific areas like the vertex and frontal areas (V & F) and the final is based on the combination of the two types. Androgens are found to decrease the HDL-C.

Conclusion & Recommendations:

Out of the 15 patients evaluated 8 patients showed abnormal lipid profile.

We suggest that all males with Androgenetic alopecia must be evaluated for fasting lipid profile as abnormal lipid profiles are considered as early indicator for cardiovascular risk. Early intervention can prevent patients from developing coronary artery disease.

Ethical Clearance- No ethical clearance was necessary for this research work

Radial Cutaneous Nerval Biopsy in the Detection of Leprosy in Patients

Paavai.S1, Jayakar Thomas2
1Junior Resident, 2Professor, Department of Dermatology, Sree Balaji Medical College and Hospital, Chennai.

Abstract

To examine the job of spiral cutaneous nerval biopsy in the early conclusion of sickness and to separate unadulterated neural infection from different neuropathies. Sickness is an incessant irresistible granulomatous infection brought about by Mycobacterium leprae that basically influence shallow tissues, particularly the skin and fringe nerves.

Mycobacterial disease causes a wide exhibit of cell safe reactions. These immunologic occasions at that point evoke the second piece of the sickness, a fringe neuropathy with possibly long haul results. Infection is an especially regular reason for neuropathy in creating nations.

Keywords: leprosy, nerves, biopsy

Introduction

In all patients with sickness, the nerve tissue is perpetually included. The dermal nerves are tainted in all the skin injuries, including uncertain disease of adolescence. Nerve trunks are extended unmistakably in 40-55% of patients and this occasionally originates before tactile misfortune in the relating nerve an area. Clinical examination is frequently lacking to dependably analyze diseased neuropathy1.

Methodology

A cross sectional investigation was done in 30 patients who show highlights of vague Hansen’s (badly characterized hypopigmented patches with negative cut skin smear for AFB and uncertain skin biopsy) and those with thickened fringe nerves will be incorporated into the examination. Educated oral and composed assent is gotten from all members2.

Extract from some case studies/life scenarios:

AFB recoloring by a decent Fite-Faraco strategy and stains for axon and myelin were done. Wherever represented, examinations, for example, a glucose hindrance test, a X-light discharge spine, a collagen workup, electromyography, and nerve conduction studies were done to square other potential purposes behind periphery neuropathy. All of the patients were presented to

• Complete history
• Complete physical examination
• Nerve biopsy

Basic Needs & Importance

A histological finding of unclear was made when the nerve demonstrated lymphocytic interruption; tuberculoid sullying, when an assault of epithelioid cells with or without goliath cells and lymphocytes was seen; fringe uncleanliness, when in spite of the above invade some froth cells were open; and lepromatous issue, when macrophages piled up with AFB and a round cell assault were seen. When the biopsied nerve displayed a mononuclear enter with fibrosis and hyalinization, a conceivable examination of unhealthy neuritis was made3.

The activity of winding cutaneous nerve biopsy in the illness is considered. It is a by and large direct opd
system, a cutaneous nerve biopsy is a huge illustrative mechanical assembly, particularly for basic neuritic uncleanliness⁴.

Conclusion & Recommendations

Out of 30 patients studied, 24 patients showed highlights of uncertain Hansen’s. Macrophages and Schwann cells stacked up with living creatures and trash (foamy cells) appear in the epineurium, endoneurium, and perineurium.

In the perineurium, foamy macrophages enter and separate individual layers, fibroblasts and perineurial cells duplicate, and collagen is deposited⁵. This produces onion-cleaning of the nerve fascicles. Development of connective tissue (peri-and endoneurial fibrosis) isn’t as obvious as in tuberculoid (TT) disease⁶. Mycobacterium leprae living creatures are incredibly different and are as often as possible seen in globoid bundles on Ziehl-Nelson recolored paraffin-introduced models.

They are found in all the nerve compartments and impact a colossal grouping of cells, including perineurial cells, fibroblasts, cells of the macrophage histiocyte heredity, Schwann cells, and endothelial cells⁷.

A Study of Nail Changes in Bullous Disorders

S.R. Sruthy¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

To observe nail changes in all patients attending skin OPD in Sree Balaji Medical College. “Face is the mirror of the mind”; likewise nails are a reflection of both internal and external disease.

Functions of nail are to assist in picking up small objects, to protect the distal digit, to improve fine touch sensation and to enhance aesthetic appearance of hands. Nail disorders comprise 10% of all dermatological conditions.

Keywords: bullous, nail disorder.

Introduction

The accurate recognition and description of nail findings is the crucial first step in diagnosing a nail disorder. The worldwide incidence of nail disorders is increasing and it continues to spread and persist.

However, appendageal structures like nail and hair may be as good reflectors as skin for presence of many systemic disorders. Cosmetic appeal of well manicured nails is undeniable; at the same time their efficacy as a diagnostic tool is well known.

Methodology

Twenty patients with bullous disorders were included in our study. All patients were subjected to:

Full history taking complete physical examination was done in all patients.

The nails changes were observed in all patients and interpreted accordingly.

<table>
<thead>
<tr>
<th>NAIL CHANGES</th>
<th>PERCENTAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paranoychia</td>
<td>40%</td>
</tr>
<tr>
<td>Onychomadesis</td>
<td>30%</td>
</tr>
<tr>
<td>Nail dystrophy</td>
<td>10%</td>
</tr>
<tr>
<td>No nail changes</td>
<td>20%</td>
</tr>
</tbody>
</table>

Discussion

Nail disorders are seen in various dermatoses like fungal infection, psoriasis, lichen planus, vescicobullous and collagen vascular disorders. In our study, infections were found to be the most common condition affecting nails. Paronychia (both acute and chronic) was found to be the most common among them.

Most of the patients were females and were housewives by occupation. This explains the increased presentation of paronychia patients in our study. It can affect one or multiple digits.

Extract From Some Studies:

Any finger might be included. The underlying change begins with loss of fingernail skin because of overexposure to water, caustics and cleansers and subsequently the nail crease is isolated from the nail where a little pocket is framed. These unusual interstices are hard to keep dry.

It stays soggy for an extensive stretch after wet work and the clammy furrows are subsequently attacked by growths and microorganisms which produce endless...
aggravation and trademark swelling of the nail folds. It is frequently joined by pruritus, agony and nail changes. This constant procedure may have intense flare ups.

Nail dystrophy is certainly not a typical appearance in bullous issue, can either be idiopathic or be related with an assortment of incendiary and different issue like lichen planus, psoriasis, alopecia areata, ichthyosis vulgaris, dermatitis, vitiligo, essential biliary cirrhosis and IgA lack.

Nail changes additionally happen following utilization of specific medications. In our examination we have seen medication actuated melanonychia following utilization of zidovudine and NSAIDs. Different medications like beta blockers, ACE inhibitors, malignant growth chemotherapy, carbemazepine and so forth additionally actuate nail changes.

**Basic Needs & Importance:**

Nail involvement in pemphigus, paronychia and onychomadesis is the most common, as seen in our study. Pitting, cross ridging, discoloration, trachyonychia, onychorrhexis, onycholysis, subungual hyperkeratosis, and complete destruction of nail plate are some of the other nail abnormalities reported in various studies.

Periungual or subungual bullae producing hemorrhagic onycholysis should alert the clinician about the diagnosis of epidermolysis bullosa (EB).

Nail changes are milder in EB simplex, similar to nail dystrophy and onychomadesis. Onychogryphosis of extraordinary toe nails might be an element of EB simplex.

Serious nail changes like onychodystrophy and anonychia are seen in junctional and dystrophic EB (DEB).

Few clinical features are pointers to the diagnosis of junctional EB (JEB). Anonychia during neonatal period may be the presenting symptom. Drumstick appearance of the distal digits covered with granulation tissue is typical of Herlitz JEB. Hemorrhagic paronychia in neonates is also a hallmark sign of this disorder. Pseudosyndactyly (3-5%), hair loss and gross dental defects are seen in non-Herlitz JEB.

Toenails are dystrophic and frequently absent in DEB. Total anonychia is seen in recessive DEB and Mitten deformity of hands and feet is the pointer to the diagnosis of the generalized recessive form of DEB (Hallopeau-Siemens variant).

**Vesiculo-bullous disorder**

Longitudinal leukonychia is a diagnostic sign of HAILEY HAILEY, and may be helpful to differentiate this disorder from immunobullous disorders.

**Conclusion & Recommendations**

In our examination we found that, Bullous issue as often as possible reason nail anomalies, especially paronychia and onychomadesis are the most well-known discoveries. We likewise discovered that, nail association in pemphigus vulgaris is uncommon. In this sickness, nail signs present, by request of recurrence, as perpetual paronychia, onychomadesis, onycholysis, Beau’s lines and trachyonychia. Likewise in pemphigus vulgaris (PV) nail irregularities can even go before skin findings.

Nail injuries frequently backslide just before summed up ailment worsening or repeat. Extreme nail changes are regularly connected with broad and serious sickness. Fingernails are all the more usually influenced. A report in the writing partners hemorrhagic nail anomalies with poor visualization in patients with PV. Nail scarring and pterygium have likewise happened in couple of patients, which is an uncommon entanglement of bullous pemphigoid. Nail misfortune has been sporadically announced in epidermolysis bullosa acquisita.

No cutaneous examination is finished without a cautious assessment of the nails. Nails remain an understudied but then very open structure that loans itself for examination and evaluation.

In our examination, contaminations were observed to be the most widely recognized condition. Keeping the nails perfect, dry and cut is basic to keep up cleanliness and avert diseases.

In this period of well-created cosmetology world, nail turns into a zone of stylish concern and needs further investigations for preventive measures.

Clinical Types of Vitiligo

Paavai.S¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

To study the clinical types of vitiligo seen in the vitiligo clinic in our hospital. Vitiligo is an acquired, progressive melanocytopenia of unknown etiology. It is characterized by circumscribed achromic macules to patches often associated with leukotrichia. Overall prevalence is 1%.

Even though there is no sex predilection, it is commonly seen in females.

Various theories like autoimmune theory, genetic, neural, and biochemical theory have been proposed.

Keywords: leukotrichia, melanocytopenia, achromic macules

Introduction

Among which autoimmunity seems to play a significant role, as it is associated with other autoimmune diseases such as diabetes mellitus, thyroid disorders, hyper-parathyroidism, psoriasis, alopecia areata, rheumatoid arthritis, SLE, hypertension, etc.

Vitiligo is usually symmetrical, commonly involving face, lips, hands, arms, legs and genitals. It can be classified into segmental, acrofacial, generalised and universal or by pattern of involvement as focal, mixed and mucosal types. Various other morphological forms include trichrome, quadrichrome, pentachrome, blue and inflammatory vitiligo¹.

Methodology

A cross sectional study was done with 50 patients diagnosed with vitiligo (all types). All the patients were subjected to

- Complete history
- Complete physical examination

<table>
<thead>
<tr>
<th>Types</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vitiligo vulgaris</td>
<td>60%</td>
</tr>
<tr>
<td>Segmental vitiligo</td>
<td>9%</td>
</tr>
<tr>
<td>Mucosal vitiligo</td>
<td>30%</td>
</tr>
<tr>
<td>Acral vitiligo</td>
<td>1%</td>
</tr>
</tbody>
</table>

Discussion

Hair over the lesion may be either normal/ white. It can also be associated with cutaneous/ ocular/ auditory/ systemic disorders (hyperparathyroidism, hypothyroidism, adrenal cortical insufficiency, pernicious anemia, diabetes mellitus, lupus, psoriasis, rheumatoid arthritis). The present study is done to know about the epidemiology of Vitiligo in an urban city hospital².

Conclusion & Recommendations

Total of 50 patients were included in the study. Vitiligo vulgaris is found to be the most common type among these patients with a percentage of 60. It is followed by mucosal (30%), Segmental (9%) and acral vitiligo (1%).

For effective management of vitiligo, early diagnosis and early treatment will improve the quality of life of the patient and prevents the further progression of the disease³.

A Study of Childhood Psoriasis

Soorya B¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

This study attempts to find out the incidence of childhood psoriasis and the mean age of onset of the disease in children. Psoriasis is a chronic immune mediated inflammatory disease.

It is characterized by Chronicity, inflammation and hyper proliferation. It presents as erythematous silvery white scaly plaques over the extensor aspects of extremities and trunk. Childhood psoriasis is not an uncommon entity.

Keywords: inflammatory disease, children, Psoriasis

Introduction

The true prevalence of childhood psoriasis is not known. It differs from adult psoriasis by age of onset, female preponderance, treatment options and clinical features.

It has bimodal age of onset, depending on this it is divided into two types – Type 1 usually starts by 15-40 years of age and consist of >75% of cases and has strong association with HLA Cw6. Type starts after 40 years and is less severe form. Psoriasis is not uncommon in childhood¹.

Methodology

A cross sectional study was done with 100 children diagnosed with psoriasis (all types). All the patients were subjected to

- Complete history
- Complete physical examination

<table>
<thead>
<tr>
<th>Clinical types</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plaque psoriasis</td>
<td>47%</td>
</tr>
<tr>
<td>Guttate psoriasis</td>
<td>23%</td>
</tr>
<tr>
<td>Erythrodermic psoriasis</td>
<td>5%</td>
</tr>
<tr>
<td>Palmo plantar psoriasis</td>
<td>25%</td>
</tr>
<tr>
<td>Pustular psoriasis</td>
<td>0%</td>
</tr>
</tbody>
</table>

True prevalence of childhood psoriasis is not exactly known yet. The earlier the onset, the worse is the prognosis. In children, lesions may be physically disfiguring and will have psychological impact².

Discussion

Typically childhood psoriasis presents as guttate form, but in India plaque type is the commonest. Rare types are erythrodermic psoriasis, pustular psoriasis and psoriatic arthritis. Precipitating factors for childhood psoriasis are infections, obesity, stress, vaccination and trauma. Palms and soles involvement is rare. Nail involvement occurs in one third of cases³.

Extract From Some Studies:

In children pityriasis amiantacea represents scalp psoriasis of adults. Psoriasis can occur in infants and they usually affect napkin area. Genital Flexural psoriasis and periumbilical regions are common manifestation of disease in infancy⁴.

Basic Needs & Importance:

The remission rate in children is higher than adults. They are used for milder form of the disease. For moderate to severe disease narrow band UVB and systemic therapies are used. Systemic therapy is not well accepted in children due to accumulation of drugs, low acceptance, and risk of teratogenicity⁵.

Conclusion & Recommendations

Total of 100 patients were included in the study. Plaque type of is found to be the most common type
among these patients with a percentage of 47%. It is followed by palmo plantar psoriasis (25%), guttate (23%) and erythrodermic psoriasis (5%).

More clinical studies are required to explain the safety levels of phototherapy, systemic therapies and biologic for the treatment of childhood psoriasis which may provide promising future.

Review Article

Congenital Heart Diseases and Its Impact in Mordern Times

Eswar.¹ J. Krishna Kumar², S. Gopala Krishnan²
¹Student, ²Professor, Dept. of community Medicine, Sree Balaji Medical College, Chrompet, Chennai

Abstract

This following research is done on the study of the prevalence, age wise distribution and clinical spectrum of congenital heart disease. It is the leading cause of infant mortality in the recent decade. Our recent studies and improvements in various fields of medicine show promising treatment and prognosis and the level of mortality is expected to fall in the future.

This study was conducted with reference to over 1200 patients who were diagnosed with congenital heart disease. A prevalence of 26.4 Per 1000 persons was observed in the last decade.

The magnitude of the problems puts the patient for a long time effects and patients were forced for various lifestyle changes. Ventricular septal defect was the commonest lesion followed by the atrial septal defect. Tetralogy of fallot was the commonest cyanotic heart disease. Maximum number of childrens with heart disease were diagnosed between 0 to 3 years of age.

Keywords: mortality; long term effects; lifestyle changes

Introduction

Congenital heart disease is defined as the presence at birth of a gross structural abnormality of the heart, great arteries or great veins that is actually or potentially of functional significance. Congenital heart disease accounts nearly one-third of all major congenital abnormalities. Only in 1930, there was a growing interest in congenital heart disease. Early attempt of cardiac shunt procedures were made in 1940. In 1950’s, the development of heart-lung bypass machine made the era of cardiac surgery possible. From this origins most patients were able to reach adulthood. The number of adults with some form of congenital heart disease is growing rapidly and the therapy becomes increasingly effective due to the advancements in modern era.

Magnitude of the problem: Congenital heart disease (chd) are relatively common with a prevalence ranging from 3.7 To 17.5 Per 1000 live births. According to a status report on congenital heart disease on india, 10% of the present infant mortality maybe accounted for by chd. The prevalence of chd is not uniform across the country. The incidence of chd does not appear to be changing substentially over time. What has changed substentially over the last 20 to 30 years is the survival data of the patients. Approximately 20000 cardiac surgical procedures are performed for congenital heart disease per year. Various modern diagnostic methods and surgeries have paved way to increased pre intervention before complications and survival capacity in various childrens.

Types of congenital heart diseases

Common examples of congenital defects that may be missed in childhood thus diagnosed for the first time in adults life including atrial septal defect, pulmonary stenosis, bicuspid aortic valve and coarctation of aorta. In some patients unoperated chd, the defect is relatively mild and surgical or other intervention has not been required. Alternately, patients may have a significant structural abnormalities that is amendable to surgical intervention. Majority of adults with chd will have had some type of surgical intervention in the past. Patients who have had some operative intervention for their chd fall into two major category. In one group survival to adulthood was expected despite the presence of their congenital defect, but their quality of life or longevity has been enhanced due to their operative intervention.
In second group of patients, their survival to adulthood is related solely or chiefly due to their surgical intervention.

Specific cardiac defects seen in the study

Bicuspid aortic valve:

Bicuspid aortic valve is reported to occur in 1-2% of the general population in which two of the leaflets of the aortic valve fuse during development in the womb resulting in a two leaflet valves (bicuspid valves) instead of the normal three-leaflet valves(tricuspid valves) . Patients with bicuspid aortic valve may have a normal lifespan without ever developing evidence of significant vascular disease . Bicuspid aortic valve may progress to aortic stenosis . Alternatively aortic valves maybe regurgitant leading to aortic regurgitation and ultimatelyo congestive heart failure . Patients with bicuspid aortic valve are at significant risk of developing infective endocarditis . Patients need to be instructed about the importance of prophylaxis against subacute bacterial endocarditis . In addition, patients with bicuspid aortic valve have structural abnormalities of their thoracic aorta (cystic medial necrosis) and risk of aortic dissection.

Coarctation of aorta:

It is the narrowing of the aorta. It is associated with other heart conditions. It usually presents with no symptoms and the condition often isn’t detected until adulthood. Patients present with enlarged heart and murmur. It is seen in adults as a discrete narrowing of the aorta at the level of ligamentum arteriosum. When a patient has a coarctation the left ventricle has to work harder. It is twice common in boys than in girls. It is seen in Turner’s syndrome. Patients with coarctation of aorta may have hypertension in upper extremities but have low blood pressure and decreased pulse in their lower extremities. 50% to 80% of patients have a associated bicuspid aortic valve. Patients are also at risk for accelerated coronary artery disease. Once the diagnosis of coarctation of the aorta has been made and the presence of significant obstruction (750 mm hg) has been confirmed, correction is warranted. Mortality for unoperated coarctation of the aorta is 30% and 75% of the patients will be dead by age 50 if unrepaired. Surgical treatment resection of coarcted segment with a patch angioplasty or resection with placement of an interposition tube graft. Ballon aortoplasty and stenting is also an option but is still considered experimental.

Atrial septal defect:

Atrial septal defect is a common form of congenital heart disease and a one of the most common diagnosis among adults with congenital heart disease. Ostium secundum defect (in the central position of the atrial septum) is the most common occurring in 75% of the case. It presents as a hole in the wall between the heart’s upper chamber (atria). The presence of a left to right shunt results in a volume overload of the right atrium, right ventricle and pulmonary arteries which places patients at risk of developing right heart failure and atrial arrhythmias. Survival beyond the age of 40 to 50 occurs in less than 50% of patients with large shunts and majority of surviving patients over the age of 50 will be symptomatic with dyspnea, fatigue, and palpitation. Because of the long-term morbidity associated with unpaired atrial septal defect, surgical closure of the defect is recommended when the diagnosis made unless there is evidence of severe pulmonary vascular diseases.

Ventricular septal defect:

Ventricular septal defect is the most common form of congenital heart disease. The defect is due to the abnormal connection between the lower chamber of the heart. It is often diagnosed at birth, but it can occur in adult after surgery or a heart attack. The patients present with bluish tint to the skin, lips and fingernails, enlarged heart and murmur, shortness of breath. The incidence of ventricular septal defect has increased from 1.0 to 1.6 per 1000 live birth in recent years. The increase in incidence is due to improved detection of small, isolated ventricular septal defect by modern diagnostic technique such as echocardiogram, electrocardiogram, cardiac catheterization. Adults having ventricular septal defects have lifelong risk of bacterial endocarditis usually involving tricuspid valves.

Pulmonic stenosis:

It is a condition characterised by obstruction to blood flow from the right ventricle to the pulmonary artery. It can be due to isolated valvular (90%), subvalvular or supravalvular obstruction. It comprises approximately 10% of all congenital heart disease. A slight female predominance exists. Patients with mild to moderate pulmonic stenosis are usually asymptomatic. The degree of stenosis may progress over time. The treatment with ballon valvuloplasty, the stenosis can be successfully relived in all cases. There is a risk of
endocarditis. The prevalence is 1.65/1000 Live births in recent years.

Patent ductus arteriosus:

The diagnosis is usually made in childhood. It is a condition wherein the ductus arteriosus fail to close after birth. Patients present with shortness of breath, tachycardia, machine like heart murmur. Patent ductus arteriosus is idiopathic. The risk factors includes premature births, congential rubella syndrome, chromosomal abnormalities. Prevention includes administration of indomethacin on the first day of life of premature infants. The patients having patent ductus arteriosus should be referred for closure of ductus for survival. Closure is done either via surgical technique or catheter based technique. Patients with large shunts are at risk, for developing severe pulmonary vascular diseases with shunt reversal (eg/- eisenmenger syndrome). Once pulmonary vascular disease develope, closure is contradicted.

Tetralogy of fallot:

The components of tetralogy of fallot include a large ventricular septal defect, an aorta which overrides both the right and left ventricle, stenosis of the right ventricular outflow tract( which may be below, at or above the pulmonic valve level) and right ventricular hypertropy. This condition of defects results in cyanosis due to inadequate pulmonary blood flow and right to left shunting across the ventricular septal defect. The vast majority of patients present with cyanosis at birth. Only 66% of patients will be alive at one year, 40% at three years, 11% by the age of twenty, 6% by the age of thirty and 3% by the age of forty. Survival above 60% is rare. Patients present with blue tinged skin and shortness of breath and heart murmur. Treatment is carried surgically to increase pulmonary blood flow thus decresing the level of cyanosis. Operations such as waterston shunt, potts shunt, and blalock-taussing shunt provide substantial relief of cyanosis and improved survival and quality of life. Post operative surgical interventions is imperative, because long term shunts may cause inoperable pulmonary vascular disease. Most significantly patients with repaired tetralogy of fallot are at risk for arrhythmias (mostly atrial arrhythmias) manifests years after the original surgery. Sudden mortality may occur in advanced ages (0.5% To 7%). The sudden death may be due to ventricular arrhythmias although it is not clearly demonstrated.

Conclusion

This overview demonstrates, the signs, treatment, and prevalence of the congenital heart diseases. These patients are care by pediatric cardiologist usually. It is a chronic disease which has lasting effect on both the patient and his or her family. There is some evidence that patients with congenital heart disease may be at increased risk of psychiatric illness such as depression and panic disorders although this is not clearly proven. Mortality rates have decreased in the recent years due to the various improvements in the medical field by diagnosing the defects at birth and improving the survival and way of life of the patients. There will be significant reduction in the complications in future due to the technical advancements we would see in the upcoming future.

Ethical Clearance- no ethical clearance was necessary for this research work.

Histopathological Study of Different Clinical Types of Leprosy

SnehaK1, Jayakar Thomas2
1Junior Resident, 2Professor, Department of Dermatology, SreeBalaji Medical College & Research Institute

Abstract

To study the histopathological features of different clinical types of leprosy. Leprosy is a chronic disease caused by Mycobacterium leprae, infectious in some cases and affecting the peripheral nervous system, the skin, and certain other tissues like the bones, eyes, reticuloendothelial system, kidney and testes.

Mycobacterium leprae is a capsulated, straight or slightly curved, non-motile, non-sporing, acid-fast, rod shaped organism. The polar forms of leprosy are the tuberculoid leprosy and lepromatous leprosy. The sub-polar forms are the borderline tuberculoid, borderline - borderline and the borderline lepromatous.

Keywords: leprosy, lepromatous, Mycobacterium leprae

Introduction

Leprosy or Hansen’s disease or Hanseniasis is a chronic disease caused by Mycobacterium leprae which is an acid-fast organism. Mycobacterium leprae is an obligate intracellular parasite seen predominantly within the macrophages. It is the only mycobacterium that infects the peripheral nerves.

Many classification systems of leprosy exist. The Ridley and Joplig Classification is the five systems of classification consisting of Typical tuberculoid (TT), Borderline tuberculoid (BT), Borderline - borderline, Borderline Lepromatous and Lepromatous leprosy (LL).

Methodology

We conducted a cross sectional study of 20 patients diagnosed with leprosy. The recruited patients were subjected to full history taking, thorough general and dermatological examination, skin smear study and skin biopsy for histopathology.

<table>
<thead>
<tr>
<th>TYPE OF LEPROSY</th>
<th>NUMBER (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Typical Tuberculoid</td>
<td>1 (5)</td>
</tr>
<tr>
<td>2. Borderline Tuberculoid</td>
<td>8 (40)</td>
</tr>
<tr>
<td>4. Lepromatous Leprosy</td>
<td>4 (20)</td>
</tr>
<tr>
<td>5. Histoid Leprosy</td>
<td>2 (10)</td>
</tr>
</tbody>
</table>

The other types of leprosy are Pure Neuritic leprosy, Histoid leprosy and Lepra Manchada.

The three cardinal signs of leprosy are hypopigmented, anaesthetic patch, nerve enlargement and demonstration of Mycobacterium leprae in slit skin smears. Other symptoms are glove and stocking type of anesthesia, paralysis, epistaxis, pedal edema and subcutaneous nodules in histoid leprosy.

Basic Needs & Importance:

The common investigations done are slit skin smear and skin biopsy.

A 4mm punch biopsy is taken from the skin lesion and the histopathological features are studied.

The histopathological feature of TT is thinning of epidermis with perivascular and periappendageal inflammatory infiltrates consisting of lymphocytes and epitheloid cells with Langhan’s giant cells and tuberculoid granuloma in the dermis.

Extract From Some Studies

The Borderline tuberculoid spectrum shows thinned out epidermis, with periappendageal and perivascular infiltrates consisting of lymphocytes with foreign body giant cells and granuloma formation in the dermis.

The Borderline lepromatous type of leprosy shows atrophic epidermis with subepidermal clear zone and macrophage granuloma in the dermis. The Lepromatous
leprosy shows atrophic epidermis with subepidermal clear zone, with foamy macrophages containing bacilli and macrophage granuloma in the dermis.

Discussion

Histoid leprosy shows atrophic epidermis with subepidermal clear zone, with lesion in lower dermis and subcutis with pseudocapsule formation. The lesion consists of spindle shaped cells.

Treatment of leprosy is Multi drug therapy which is paucibacillary if the lesions are 2 to 5, one or no nerve involved or multibacillary if the lesions are more than 5 and one or more nerve involved.

Conclusion & Recommendations

A total of 20 patients were included in our study consisting of 14 male and 6 female patients. The age group was between 30 to 68 years. Out of the 20 patients, the borderline tuberculoid spectrum was the commonest with the histopathological feature of thinned out epidermis, with peri-appendageal and perivascular infiltrates consisting of lymphocytes with foreign body giant cells and granuloma formation in the dermis.

We conclude that the different types of leprosy have its characteristic histopathological features. The commonest type of leprosy in our study was the Borderline tuberculoid leprosy.

Histopathological Correlation of Lipodermatosclerosis

S.R.Sruthy¹, Jayakar Thomas¹
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

To watch Histopathological discoveries in patients with clinical findings of lipodermatosclerosis. Lipodermatosclerosis (LDS) is a restricted unending irritation and fibrosis of skin and subcutaneous tissues of lower appendages, as a sequalae of ceaseless venous hypertension.

The pathogenesis is multifactorial, coming about because of exceedingly complex cooperations happening in and around the endothelial cell, including enormous assortment of cytokines, development factors and MMP’s.

Keywords: Histopathological, Lipodermatosclerosis, hypertension

Introduction

Clinically it is seen progressively regular in ladies with high BMI and displays also characterized, indurated plaques around the lower limits more often than not on the average angle. LDS in intense stage is portrayed by diffuse provocative edema, erythema and delicacy of the skin and in perpetual state described by indurated zones of pigmentation and fibrotic narrowing of the lower leg. There are various reports on the histopathological discoveries of LDS. Subsequently an endeavor is made to depict histopathological discoveries in LDS.

Methodology

A sum of 5 patients with endless Lipodermatosclerosis were incorporated into the investigation. All patients were exposed to

- Complete history
- General and Dermatological Examination
- Consenting patients were exposed to punch biopsy of the lower appendages.

Lipodermatosclerosis, otherwise called “sclerosing panniculitis,” is a fiery procedure of the subcutaneous fat that intensely introduces as average lower leg torment, erythema, delicacy, and warmth.

Endless infection is outstanding for “bound down, sclerotic” hyperpigmented, lower furthest point skin in a “transformed champagne bottle” appearance. These progressions are identified with venous inadequacy with resultant extravasation of fine substances. Pathogenesis theories include:

A. Fibrin sleeve development prompting hypoxia

B. Elevated grid metalloproteinase and fibrinolytic middle person movement causing collagen annihilation and ulceration

C. Leukocyte-intervened endothelial harm.

Extract From Some Other Studies

Histology is eminent for the accompanying movement that incorporates thickening of the pannicular septa and mellow penetration of fiery cells prompting early focal adipocyte putrefaction, fibrosis of the septa with stringy strands anticipating halfway into the fat lobule, lipid filled macrophages and lessening in useful adipocytes, and eosinophilic pseudomembrane arrangement on H&E thought to an outcome of adipocyte breakdown.
Discussion

This grouping of occasions can be an outcome of any procedure prompting fiery cell penetrate, including edema and medication reaction. Lipodermatosclerosis is analyzed dependent on the nearness of trademark signs and indications.

Skin biopsy or blood tests are typically not required to affirm a finding but rather can be performed in uncommon cases. ultrasound and attractive reverberation imaging (MRI) might be utilized to acquire more data with respect to the seriousness of the condition and to decide the best treatment approach.

Basic Needs & Importance:

Lipodermatosclerosis is essentially treated with pressure treatment to improve venous deficiency. Different modalities for overseeing venous deficiency incorporate leg rise; not sitting or remaining in one spot for significant lots of time; ordinary exercise; and weight reduction if overweight or fat.

Some influenced individuals may expect meds to counteract blood thickening; decrease torment and irritation; as well as increment blood stream. Contingent upon the seriousness of the condition and the reaction to starting medicines, vein medical procedure might be suggested.

Conclusion & Recommendations

Histopathology of 5 cases contemplated, 4 indicated epidermal decay. Increment in pigmentation of basal layer was noted in 3 cases. Dermal changes were evident in 3 cases, indicating edematous changes, pseudo-scleroderma changes, gentle septal invades. 2 cases indicated extravasation of RBC’s. No proof of panniculitis was noted.

Histopathological discoveries of LDS are predictable with epidermal diminishing, increment pigmentation, pseudoscleroderma changes, extravasation of RBC’s and with incessant fiery invades.

Ethical Clearance- No ethical clearance was necessary for this research work

Source of Funding- Self funded project

A Study about Incidence of Inflammatory Bowel Disease in Psoriasis Using Scopy

P Keerthana Bhasakr¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

This investigation endeavors to discover the rate of IBD in psoriasis utilizing Scopy. This study incorporates 50 psoriasis patients. Psoriasis and IBD are ceaseless, fiery malady sharing invulnerable pathogenetic instruments.

The most significant hereditary relationships include the chromosomal loci 6p22, 16q, 1p31, and 5q33 which guide a few qualities associated with intrinsic and versatile resistance.

Keywords: IBD, Psoriasis, pathogenetic instruments

Introduction

Extended vulnerability of the epidermal limit in skin and stomach related framework underlies the expanded relationship of allergens and pathogens with red hot receptors of safe cells. The resistant response among psoriasis and IBD is near and contains phagocytic, dendritic, and basic killer cell, close by a milieu of cytokines and antimicrobial peptides that strengthen T-cells.

The particular similitudes in the pathogenesis are likewise reflected in the wide covering of their restorative methodologies. There is proof Th1 and Th17 and administrative T-cells and cytokine ¹.

Methodology

This is a review concentrate done at the Department of Skin and Sexually Transmitted sicknesses of a tertiary consideration medical clinic in South India. Endoscopy was done to the psoriasis patients to preclude IBD.

<table>
<thead>
<tr>
<th>Study of Patients</th>
<th>Number%</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. PSORIASIS(alone)</td>
<td>48(50)</td>
</tr>
<tr>
<td>2. IBD</td>
<td>2(50)</td>
</tr>
</tbody>
</table>

Discussion

There are two pathogenetic minutes, including inborn invulnerability activated by obscure improvements and versatile insusceptibility because of cytokines discharged from cells of the natural safe framework.

Th2 and assume a key job in incendiary procedures and tissue harm in ceaseless conditions, for example, psoriasis, immune system uveitis, adolescent diabetes, rheumatoid joint inflammation, Crohn’s malady, and different sclerosis².

Th17 demonstrates significant capacity in antimicrobial resistance on epithelial and mucosal boundaries through the generation of cytokines(IL-22) which invigorate epithelial cells to synthetize antimicrobial proteins.

Extract From Some Other Studies:

In this way, absence of Th17 cells may prompt expanded defenselessness to pioneering contaminations and hyper-IgE disorder.
Th17 separation is by all accounts the nearness of TGF and IL-6 in the microenvironment in which T-naïve cells remain.

IL-23 is associated with the advancement of explicit populaces of Th17 cells, yet neglected to demonstrate separation².

**Basic Needs & Importance:**

Th17 cells limit have a critical activity in various resistant framework sicknesses and infections. The IL-17 that they produce progresses the chemotaxis of neutrophils and monocytes and the development and commencement of T lymphocytes and neoangiogenesis.

Beside psoriasis, Th17 cells have been related to other combustible skin infections, for instance, ominously helpless contact dermatitis, atopic dermatitis, essential sclerosis, and Behcet’s sickness close by other skin conditions likw Acanthosis and parakeratosis.

The authoritative T cells/T-silencers are a subpopulation of T cells spoke to significant specialist in smothering the surprising activation of the resistant structure to keep up a key separation from unreasonable responses and to shield the strength to self in different organs, including stomach related framework and skin.

The excitement for these cells has extended starting late in association with their possible use in the treatment of immune system ailment³.

**Conclusion & Recommendation**

Out of 50 patients considered, 2 patients had incendiary inside illness.

Psoriasis and IBD are provocative infections constantly related, sharing resistant pathogenetic systems. They speak to hindrance and association between the internal and the external sides of the human body. Hence, at these dimensions, insusceptible procedures assume a key job in keeping up homeostasis and in continuing obsessive procedures.

Psoriasis and IBDs bolster the theory of a typical pathogenesis which is found in helpful covering of both.

Clinical Study of Different Types of Ichthyoses

P. Keerthana Bhaskar¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

To study the different types of ichthyoses, ichthyoses are a clinically and hereditarily heterogeneous gathering of skin issue, described by diffuse, for the most part uniform and determined example of scaling. It is a disorder of keratinization. It can be congenital or acquired. Ichthyoses result from strange epidermal separation or digestion. Blemished epidermal desquamation, prominent inflammatory component, associated with epidermal hyperproliferation is seen in ichthyoses.

Keywords: hyperproliferation, Ichthyoses, ichthyoses

Introduction

Ichthyoses is a group of disorder characterized by dry skin with measuring all over the body. It is a disorder of cornification. The ichthyoses can be congenital or acquired. Ichthyoses result from abnormal epidermal differentiation or metabolism. Congenital ichthyoses are ichthyosis vulgaris, X-linked recessive ichthyosis, non-bullous ichthyosiformerythroderma, lamellar ichthyosis, harlequin ichthyosis, bullous ichthyosiformerythroderma, ichthyosis bullosa of Siemens and ichthyosis hystrix.

Methodology

We conducted a cross sectional study of 20 patients diagnosed with Ichthyoses both congenital and acquired attending Dermatology outpatient department. The recruited patients were subjected to full history taking, thorough general and dermatological examination.

<table>
<thead>
<tr>
<th>TYPE OF ICHTHYOSIS</th>

</table>

Discussion

Ichthyoses is a group of disorder characterized by dry skin with measuring all over the body. It is a disorder of cornification. The ichthyoses can be congenital or acquired. Ichthyoses result from abnormal epidermal differentiation or metabolism. Congenital ichthyoses are ichthyosis vulgaris, X-linked recessive ichthyosis, non-bullous ichthyosiformerythroderma, lamellar ichthyosis, harlequin ichthyosis, bullous ichthyosiformerythroderma, ichthyosis bullosa of Siemens and ichthyosis hystrix.

Extract From Some Studies:

The ichthyosiform disorders are Netherton’s disorder, Sjögren–Larsson disorder, Chanarin–Dorfman disorder, Refsum’s ailment, Kallmann’s disorder, Multiplesulphatasedeficiency disorder, Conrad–Hünemann-Happle disorder IBIDS, KID syndrome, CHILDS syndrome, Ichthyosis follicularis with alopecia and photophobia and Neu–Laxova disorder.

Ichthyosis vulgaris is the most widely recognized of the acquired ichthyoses, with autosomal overwhelming legacy.

The skin is dry and layered in the neonatal age, yet more as a rule scaling is clear from 2 months of age. The scale is white or dim, little, branny, and semi-disciple with turned-up edges. It is most regular on the extensor surfaces of the arms and lower legs, and typically saves the flexural creases.
The storage compartment, particularly the stomach divider, is frequently mildly affected and the nappy (diaper) region is saved.

Bullous ichthyosiform erythroderma is an autosomal dominant issue of keratinization which is related with rankling in its initial stage. It is generally called epidermolytic hyperkeratosis. It normally gives delicate skin which offers approach to dynamic hyperkeratosis.

A mild, generalized erythroderma is available during childbirth. Limp blisters, peeling and shallow disintegrations at locales of minor injury or friction are evident inside the initial couple of long stretches of life.

Different highlights are palmoplantar hyperkeratosis bringing about repetitive agonizing fissures, contractures, sclerodactyly and foot distortion with impaired function. Lamellar ichthyoses is an autosomal passive disorder. During childbirth there is nearness of collodion layer. The scales are enormous, dim darker or dim and firmly adherent. In serious cases the scales are thick, unbending scale which irregularly shed or parts, causing erythematous patches and profound, difficult gaps, particularly around flexures and on the digits, palms and soles.

**Basic Needs & Importance:**

This are the original causes for acquired ichthyoses are malnutrition, malabsorption, essential fatty deficiency, Shwachmanson syndrome, renal failure, primary hyperparathyroidism, hypopituitarism, hypothyroidism, diabetes, sarcoidosis, leprosy, HIV, GVHD, myelodysplasia, underlying malignancy like Hodgkin’s lymphoma and due to drugs like nicotinic acid, cimetidine, allopurinol, hydroxyurea and clofazamine.

Treatment is by application of topical emollients, liquid paraffin and keratolytics. The emollients must be applied at regular intervals. Genetic counselling is important in patients with family history of ichthyoses disorder.

**Conclusion & Recommendations**

A total of 20 patients were included in our study. The age group was between 7 years and 50 years. Among the study population, 30% had ichthyoses vulgaris, 25% had acquired ichthyoses due to drugs, 20% due to hypothyroidism, and 15% due to leprosy, 5% due to bullous ichthyosiformerythroderma and 5% due to lamellar ichthyoses.

Ichthyoses vulgaris was found to be the commonest in our study. Regular follow-up with topical emollients are advised for these patients. Genetic counselling must be given for those patients with family history of ichthyoses as a preventive measure.

A Study on Impetigo - Causative Agents

Asha D¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

To study the causative agents of Impetigo.

Impetigo is a superficial, contagious, pyogenic infection of the skin. It is the most common skin infection in children. It is of two types, bullous and non-bullous impetigo.

Staphylococcus aureus is the commonest organism causing bullous impetigo, non-bullous type is caused by staphylococci and streptococci or both in combination.

Keywords: Staphylococcus, pyogenic infection, skin

Introduction

Impetigo is a contagious, superficial bacterial infection of the skin. It is the most common skin infection in children. Clinically impetigo can be divided into the bullous and non-bullous forms¹.

Bullous impetigo is a superficial cutaneous infection with staphylococcus aureus. Non-bullous impetigo can be caused by both staphylococcus aureus and streptococcuspyogenes.

Preschool and young school-age children are most often affected. Over-crowding, poor hygiene, scabies, fomites predispose to these infection.

Non-bullous impetigo starts as a thin-walled vesicle on an erythematous base which ruptures rapidly with exuding serum that dries to form yellowish brown crusts.

Methodology

We conducted a cross sectional study of 20 patients diagnosed with Impetigo attending our Dermatology outpatient department. The recruited patients were subjected to full history taking, thorough general and dermatological examination, and investigated for pus culture and sensitivity from the skin lesion or blister fluid².

Extract From Some Studies:

Gradual and irregular peripheral extension occurs without central healing. The crusts dry and separate to leave erythema,

which heals without scarring. The common sites involved are face, around the nose and mouth, and the limbs. The common age group affected are preschool and primary school children.

In bullous impetigo, the bulla are larger and persist for 2 or 3 days. The contents are first clear, later cloudy. They rupture to leave behind thin, flat, brownish crusts³.

Basic Needs & Importance:

Central healing with peripheral extension may give rise to circinate lesions. Face, body and buccal mucous membrane are the common sites involved. Neonates and infants are commonly affected.

The complications of streptococcal impetigo are poststreptococcal acute glomerulonephritis, urticaria, scarlet fever, erythema multiforme and cellulitis⁴.
Discussion

The investigations done are pus culture and sensitivity from the blister fluid to find out the organism involved.

Treatment is with topical antibacterials like mupirocin, neomycin and fusidic acid and systemic antibiotics.

Conclusion & Recommendations

A total of 20 patients were included in our study. The age group was between 8 months to 7 years of age. Impetigo was commonly seen in school-age children. The non-bullous type was the commonest type of impetigo in our study. Out of the 20 patients, 50% had growth of streptococcus pyogenes, 30% had staphylococcus aureus growth and 20% had growth of other organisms.

Non-bullous impetigo in school-age children was the commonest type of impetigo in our study. Preventive measures like education on proper hygiene, encouraging hand washing, avoidance of overcrowding, prompt treatment of scabies must be implemented in these patients.

Incidence of Pure Neuritic Leprosy among Patients attending Leprosy Clinic

T. Shri Sindhuja¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of DVL, Sree Balaji Medical College & Hospital, Chromepet

Abstract

To study the incidence of pure neuritic leprosy among patients attending Leprosy clinic in Department of DVL, SBMCH. Pure neuritic has been recognized as a distinct sub group of leprosy, by Indian Association of Leprologists. It constitutes a good percentage of leprosy cases reported from India, which contributes to more than half of global leprosy numbers.

Unfortunately, a large number of these patients present with Grade 2 disability at the time of initial reporting itself due to the early nerve involvement and late recognition of symptoms.

By definition, a diagnosis of pure neuritic leprosy is made when, skin lesions are absent, presence of nerve thickening and anesthesia along the distribution of the affected nerve, deformity and/or trophic changes.

Keywords: leprosy, Pure neuritic

Introduction

On follow-up, skin lesions are noted to develop in up to 20% of pure neuritic leprosy cases, in turn indicating its progression to manifest as a cutaneous disease. For further confirmation of diagnosis of pure neuritic leprosy, nerve biopsy, and/or nerve conduction studies can be done¹.

‘Wade’ in 1952 was the first to recognize poly-neuritic cases as a separate group. IAL consensus classification of leprosy in 1981 persisted with ‘Pure neuritic leprosy’ as one of types of leprosy.

Upper limb nerves are more commonly involved. Ulnar nerve is the most commonly involved nerve in upper limb. Lateral popliteal nerve is the most commonly affected nerve in lower limb.

Methodology

A cross sectional study of 50 patients diagnosed with Hansen’s disease (all types).

Investigations done were

- Thorough history taking
- Inspection to rule out presence of hypopigmented hypoanesthetic patch
- Complete examination to fulfill criteria of PNL
- Nerve examination to confirm presence of AFB or nerve conduction study

| Number of Mononeuritic PNL | 6 |
| Number of Polyneuritic PNL | 10 |
| Total number of PNL recorded | 16 |

Basic Needs & Importance

Any nerve trunk can be involved by PNL, eg: supra orbital nerve, great auricular nerve etc. PNL constitutes about 4-11% of leprosy patients as reported by various Indian studies. It is reported higher in south India, up to 18% of new cases. Males are more commonly effected, between 15-35 years of age².

It is reported less in other parts of world such as Africa, where MB leprosy is more common.
PNL confirmation is best done by nerve biopsy, especially from a branch of a sensory nerve.

Extract from some case studies/life scenarios:

Any nerve trunk can be involved by PNL, e.g., supra orbital nerve, great auricular nerve etc. PNL constitutes about 4-11% of leprosy patients as reported by various Indian studies. It is reported higher in south India, up to 18% of new cases. Males are more commonly affected, between 15-35 years of age.

It is reported less in other parts of the world such as Africa, where MB leprosy is more common.

PNL confirmation is best done by nerve biopsy, especially from a branch of a sensory nerve.

Complications of PNL include nerve abscess.

**Conclusion & Recommendations**

Total of 50 patients were included in the study. 16 patients (32%) had pure neuritic leprosy. Of the 16 cases, 6 patients (12%) had mononeuritic and 10 patients (20%) had polynueritic type of pure neuritic leprosy. Most common nerve involved was ulnar nerve.

**Conclusion**

Management of pure neuritic leprosy requires multidrug therapy along with appropriate dose of systemic corticosteroids. Measures for pain management, self-care of limbs and physiotherapy are important to prevent as well as manage disabilities in this group of patients.

Effective management can be brought about by early diagnosis and initiation of treatment.

**Discussion**

Subsequent development of skin lesions (most commonly, borderline tuberculoid) is well known, with many case reports in the published literature.

The fact the skin lesions are observed in PNL cases over months and years, indicate that PNL is an early form of leprosy in some patients. Identifying PNL (as a group) and clinically diagnosing PNL cases early, means identifying leprosy early, before skin is involved.

Early Identification of PNL and its treatment, naturally limits the extent and progression of nerve damage.

Clinicopathological Study of Oral Leukoplakia

S.R.Sruthy¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

This study is to evaluate the possible etiological factors responsible, the epidemiological pattern, role of adjuvant vitamins and anti-oxidants in oral leukoplakia.

Persistent leukoplakia, has a potential for malignant transformation. Anti-oxidant supplements have beneficial effect in subjects with reduced risk factors.

Leukoplakia is the most common potentially malignant disorder of the oral mucosa, recently redefined as “a white plaque of questionable risk having excluded (other) known disorders that carry no increased risk factor for cancer”.

Keywords: leukoplakia, oral disorder.

Introduction

“A white patch or plaque that cannot be characterized clinically or pathologically as any other disease”.

In 2005 the definition was changed into: “A white plaque of questionable risk having excluded (other) known disorders that carry no increased risk factor for cancer”. It is therefore a diagnosis of exclusion from other oral white lesions such as leukokeratosis, infective lesions such as (candidiasis, syphilitic oral lesion, oral hairy leukoplakia),lichen planus, lupus erythematosus, dyskeratosiscongenita, white sponge nevus, submucosal fibrosis and frank carcinomas.

Methodology

A prospective study of a hundred patients presenting with oral white lesions. All patients were subjected to:

- Complete history
- Dermatological examination
- Biopsy

Extract from some case studies/life scenarios:

<table>
<thead>
<tr>
<th>Age group in years</th>
<th>Males</th>
<th>Females</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>18-40</td>
<td>22</td>
<td>5</td>
<td>27</td>
</tr>
<tr>
<td>36-56</td>
<td>27</td>
<td>22</td>
<td>49</td>
</tr>
<tr>
<td>56-75</td>
<td>15</td>
<td>7</td>
<td>22</td>
</tr>
<tr>
<td>76-90</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Our study included a hundred patients, out of which 65 were Male and 35 were Female. From100 cases of our study the most common site was found to be Buccal mucosa (46%), 16.5% of ulcerative leukoplakia were confirmed histologically to be malignant³.

Discussion

Leukoplakia is the most common potentially malignant disorder of the oral mucosa, recently redefined as “a white plaque of questionable risk having excluded (other) known disorders that carry no increased risk factor for cancer”.

Extract from some studies: The sore grows to rough appearance with surface crevices (thick homogeneous leukoplakia), certain sores create surface anomalies (granular or nodular leukoplakia), warty
papillary surface projections (verrucous leukoplakia), or blended red and white sores (dotted leukoplakia or erythroplakia). The remarkable variation that is proliferative verrucous leukoplakia is described by far reaching multifocal locales of inclusion frequently in patients with known hazard factors.

Those patients with idiopathic leukoplakia have the most astounding danger of creating malignant growth. Every now and again oral white patches happen, auxiliary to some recognizable neighborhood bothering. For instance, thickened hyperkeratotic sores are as often as possible seen over edentulous zones of alveolar edges (edge keratosis), ceaseless tongue biting (morsicatiolinguarum) or interminable cheek biting (morsicatiobuccarum).

**Basic Needs & Importance:**

Every single such sore are optional reactions to an incessant bothering which prompts compensatory hyperkeratosis of the epithelium creating as a defensive wonder, like the improvement of a callus.

Leukoplakia is the most well-known precancerous sore of the oral mucosa. Its involving factors, such as biting and smoking of tobacco is generally predominant in our nation. Oral disease is the commonest harm in Indian guys. We have discovered that 63% homogenous, 18% ulcerative, 16% nodular and 3% verrucous sort of injuries in this study.

**Conclusion & Recommendations**

Malignant transformation was seen in 23.5% of mild dysplasia and 54.5% of severe dysplasia. An antioxidant and multi vitamin supplement was administered apart from complete abstinence from alcohol and tobacco was done for a period of ten months which consisted of 4300 IU of vitamin-A.

Assessment of Efficacy and Safety of Methotrexate in Chronic Treatment Resistant Urticaria

Jayakar Thomas
Professor, Department of Dermatology, Sree Balaji Medical College and Hospital, Chennai

Abstract
To evaluate the efficacy of methotrexate in the treatment of chronic spontaneous urticaria poorly responsive to antihistamines. Urticaria is a common condition affecting 15-20% of the general population at least once during their lifetime.

Females have a slightly higher prevalence (61%) than males. It clinically manifests as wheals, which are transient, well-defined, superficial erythematous or pale swellings of the dermis and usually associated with itching.

Keywords: resistant urticaria, methotrexate

Introduction
The lesions may appear pale centrally during the initial stage of fluid collection. Very rarely, a vesicle or a bulla can develop in an urticarial plaque. Wheals may vary in size (small or large), number (single or multiple) and may differ in shape, time of onset and duration. No mark is usually left behind when wheals resolve, but there may be secondary changes due to rubbing or scratching. Urticaria can affect any part of the body including the palms and soles. Systemic symptoms are often associated with urticaria.

Methodology
They are malaise, headache, abdominal pain, diarrhea, arthralgia, dizziness, syncope or even anaphylaxis.

Chronic urticaria is characterized by recurrent episodes occurring at least twice or week which last for 6 weeks or more. Causes of chronic urticaria are endocrine abnormality (e.g. hyperthyroidism), collagen vascular disease and malignant diseases (e.g. lymphoma, leukemia) or idiopathic. Diagnosis of chronic urticaria is often clinical, hence it requires guided investigations based on detailed clinical history and examination.

Extract from some case studies/life scenarios:
A down to earth way to deal with ceaseless idiopathic urticaria depends on the seriousness of the ailment and the patient’s response to treatment. Antihistamines are considered as first-line drugs for treating interminable idiopathic urticaria. Second-line medications incorporate foundational corticosteroids, polyclonal stabilizer, doxepin, nifedipine, leukotriene rivals, terbutaline, thyroxine and sulfasalazine. Third line medications are immunosuppressants like methotrexate, cyclosporine and biologicals like omalizumab. The present investigation is on the adequacy of methotrexate in the treatment of ceaseless unconstrained urticaria ineffectively reacting to antihistamines.

Discussion
This investigation incorporates 20 patients of ceaseless urticaria who are not reacting to antihistamines. A nitty gritty history was inspired including insights about length, history of advancement, recurrence of assaults, conveyance of individual sores, sustenance and nourishment added substances, past treatment, known unfavorable reactions, occupation and relaxation exercises, enquiry about the potential wellspring of
contamination, past and family ancestry of atopy, related sickness, for instance, fever, joint torments, thyroid, and other immune system illnesses, and an appraisal of the effect of the ailment on the patient’s personal satisfaction.

**Extract from some studies**

Complete physical and dermatological examination were done in all patients. Complete blood tally, differential white cell check, erythrocyte sedimentation rate (ESR), thyroid capacity tests were performed routinely. Fasting blood sugars, fasting lipid profile, liver capacity test, renal capacity tests and electrocardiogram were done in every one of the patients. Significant microbiological examinations were completed to affirm the clinical diagnosis. For urticarial vasculitis, skin biopsy was performed in all patients with sores going on for more than 24 hours. Patients were treated with MTX in the wake of decision out contraindications, for example, liver or lung ailment and positive serological tests for hepatitis B and C.

**Basic needs & importance:**

**Inclusion Criteria**

All patients (males and females above 18 years) attending skin OPD who are clinically diagnosed with urticaria are included in this study.

**Exclusion Criteria**

1) Pregnancy and lactation
2) Pulmonary tuberculosis - Active/old case of tuberculosis
3) Focal sepsis
4) Immunosuppression
5) Chronic liver/renal disease

A total of 20 patients with chronic urticaria were taken up for this study. 12 males and 8 females were affected. Seven patients with CIU treated with methotrexate 2.5 mg every 12 hours, two days a week for 6 weeks period. Statistically significant improvement was observed in itching, presence of wheals and sleep quality. Then the dose was increased to 7.5 mg/week.

There was no difference in the extension of lesions and presence of angioedema.

**Conclusion & Recommendations**

Perpetual urticaria (CU) has a wide range of clinical introductions and wheals may happen practically day by day in certain people or it might happen occasionally in others. It might present as backslide few to a little while later after reduction of urticaria.

Treatment of patients with unending idiopathic urticaria includes lessening side effects with least intrusive treatment. The objective of the treatment is to decrease indications until unconstrained goals happens. The underlying administration of constant urticaria ought to be coordinated by the consequences of a full clinical evaluation.

Numerous nonpharmacological and pharmacological mediations are accessible, however none is acknowledged all around. A commonsense way to deal with interminable idiopathic urticaria is dependent on the seriousness of the infection and the patient’s reaction to treatment. Antihistamines are the main line drugs for treating ceaseless idiopathic urticaria. Second-line medications incorporate fundamental corticosteroids, leukotriene rivals, nifedipine, terbutaline, pole cell stabilizer, doxepin, thyroxine and sulfasalazine. Other restorative procedures for troublesome or safe urticaria incorporate including leukotriene opponents, corticosteroids, cyclosporine, methotrexate cyclophosphamide, intravenous immunoglobulin, omalizumab, mycophenolate mofetil, tacrolimus and thin band UVB.

**Discussion**

Methotrexate is frequently used in dermatology is claimed to be deep in chronic urticaria of the idiopathic, steroid dependant types and autoimmune urticaria. It binds extracellularly to dihydrofolatereductase, thereby preventing the conversion of dihydrofolate to tetrahydrofolate. It was thought that this directly inhibited epidermal cell hyperproliferation specifically during the S-phase of mitosis.

It is now believed that the inhibition of folate dependent enzymes such as AICART (5-aminomiazole carboxamideribonucleosidetransformylase), involved in purine synthesis, is the main mechanism of action.
Conclusion

This inhibition leads to intracellular accumulation of AICAR and release of adenosine, which has potent antiinflammatory effects, into the extracellular space. Other potential mechanisms include modulation of adhesion molecules such as ICAM-1.

The most important risk factor for methotrexate toxicity is impaired renal function. Pancytopenia can occur at any time during therapy with methotrexate.

The most important risk factor for methotrexate toxicity is impaired renal function. In this study we found that itching, presence of wheals reduced, no extension of lesions and presence of angioedema. Hence it can be given for all patients with chronic resistant urticaria.

Ethical Clearance - No ethical clearance was necessary for this research work

A Study of Non Melanoma Skin Cancers Occuring Over the Psoriatic Plaque

Sooky B¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract
This study attempts to find out the incidence of non melanoma skin cancers in psoriasis patients. Psoriasis is a chronic, relapsing, inflammatory and proliferative skin disease associated with cutaneous and systemic diseases.

Patient with psoriasis are at increased risk of developing NMSC (non melanoma skin cancers) and lymphoproliferative disorders.

Keywords: Skin cancer, psoriatic plaque.

Introduction
Psoriasis, a chronic inflammatory and proliferative disorder, associated with numerous cutaneous and systemic disorders. Non melanoma skin cancers (Squamous cell & Basal cell carcinoma) and lymphoproliferative disorders can occur over the plaques of psoriasis. Basal cell carcinoma is a locally invasive epidermal malignant tumor and is the most common skin cancer, accounting for about 68%. Squamous cell carcinoma is an epidermal keratinocyte tumor and accounts for 28% of all skin cancers. BCC is common in males. Females with psoriasis are at high risk for developing SCC¹.

Methodology
A cross sectional study was done with 70 patients diagnosed with vitiligo (all types). All the patients were subjected to

- Complete history
- Complete physical examination
- Skin biopsy

<table>
<thead>
<tr>
<th>Type of NMSC</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQUAMOUS CELL CARCINOMA</td>
<td>2%</td>
</tr>
<tr>
<td>BASAL CELL CARCINOMA</td>
<td>1%</td>
</tr>
</tbody>
</table>

Discussion
The risk of developing carcinoma are high in patients with severe psoriasis and those who are managed with methotrexate, cyclosporine, MMF, biologicals - TNF alpha inhibitors, arsenic, topical tar and PUVA².

In BCC the tumour cells escapes immune recognition and apoptosis by cytotoxic T lymphocytes by

- Failure of tumor cells to express Fas antigen (CD95), hence there is absence of T cell killing by Fas ligand (CD95L),
- Lack of expression of class II MHC antigens on the cell surface,
- Over expression of Bcl-2 (gene products of cell survival),

An abnormal distribution and elevated levels of Protein kinase D, a keratinocyte pro-proliferative signalling enzyme is suggested to precipitate proliferative
disorders such as psoriasis and BCC.

**Extract From Some Studies:**

Patients with severe chronic psoriasis and on systemic therapy should be emphasized the importance of regular follow up and histopathological examination to reduce the development non melanoma skin cancers¹.

In the majority of psoriasis patients managed with PUVA therapy, the initiator of p53 mutations in BCC is due to therapeutic or environmental UV-B exposure and only a small portion by PUVA itself.

**Basic Needs & Importance:**

Squamous cells have lower tolerance for DNA damage & a lower apoptotic threshold, which makes apoptosis a predominant protective mechanism against SCC⁴.

**Conclusion & Recommendations**

Total of 70 patients were included in the study. Out of 70 patients 2% had squamous cell carcinoma arising over psoriatic plaque and 1% has basal cell carcinomas⁵.

Recent studies have shown increased expression of SCC antigen and proliferation regulators like WNT 5A, STAT-1, Defensin B4, Keratin 16, and SERPIN B3 in psoriatic skin compared to normal skin. Biopsy specimen of patient with SCC - shows persistent activation of regulators of keratinocyte growth and differentiation like Src-family tyrosine kinases.

A Study on the Patterns of Dermatophyte Infection of Feet

Asha. D¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, SreeBalaji Medical College & Research Institute

Abstract

To study the patterns of dermatophyte infection of feet.

Dermatophytosis is a superficial fungal infection of the keratinized tissue. The causative organisms are called dermatophytes, which have the ability to invade hair, nails, and the skin of the living host.

Infection of feet by a dermatophyte is called tineapedis. Tineapedis is commonly caused by Trichophytonrubrum, Trichophytonmentagrophytes var. interdigitale and Epidermophytonfloccosum.

Keywords: foot infections, skin disorders.

Introduction

Dermatophytosis or ringworm infection are superficial fungal infection caused by keratinophilic fungus belonging to the three genera: Microsporum, Trichophyton and Epidermophyton.

They are classified according to the site of infection as tineacapitis, tineabarbae, tineacorporis, tineacruris, tineapedis, tineamanuum, tineaunguium, tineafaciei, tinea incognito.

Tineapedis or foot ringworm or athlete’s foot is a dermatophyte infection of feet. The common organisms causing tineapedis are Trichophytonrubrum, Trichophytonmentagrophytes var. interdigitale and Epidermophytonfloccosum.

The trichophytonrubrum is the commonest among the three. It is more common in males than females¹.

Methodology

We conducted a cross sectional study of 20 patients diagnosed with Tineapedis attending our Dermatology outpatient department. The recruited patients were subjected to full history taking, thorough general and dermatological examination and investigated for 10% KOH - wet mount and culture.

<table>
<thead>
<tr>
<th>DERMATOPHYTE</th>
<th>NUMBER (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Trichophytonrubrum</td>
<td>16 (80)</td>
</tr>
<tr>
<td>2. Trichophytonmentagrophytes var. interdigitale</td>
<td>3 (15)</td>
</tr>
<tr>
<td>3. Epidermophytonfloccosum</td>
<td>1 (5)</td>
</tr>
</tbody>
</table>

Discussion

The lateral toes are most often affected, particularly in the web space between the fourth and fifth toes, followed by the interspace between the third and fourth toes. The commonest cause is occlusion of toe clefts through wearing shoes, sharing socks, macerated and moist toe clefts, using community bath and swimming pools, humidity, hyperhidrosis, walking barefoot, with history of atopy and immunosuppressive states like diabetes and HIV.

Extract from some studies

The commonest presenting symptom is itching with peeling, maceration and fissuring affecting the lateral toe clefts, and spreading to involve the undersurface of the toes. There are vesicles, pustules which breaks down to form erosion with scaling. The commonest type is the intertriginous dermatitis type. The other types
are chronic papulosquamous, vesicular, acute ulcerative and moccasin foot.

The investigations done are wet mount preparation with 10% KOH from scrapings from the scales and culture with Sabouraud’s dextrose agar culture medium.

**Basic Needs & Importance:**

Tichophytonrubrum shows velvety, red pigment colonies, trichophytonmentagrophytes var. interdigitaleshow white cottony colonies and epidermophytonfloccosum shows yellowish green powdery colonies on culture.

Treatment is by avoidance of the predisposing factors and topical and systemic antifungals.

**Conclusion & Recommendations**

A total of 20 patients were included in our study. The age group was between 15 years to 35 years. 14 males and 6 females with tineapedis were included in our study. The most common type of tineapedis was the intertriginous type. The growth of fungus was confirmed by Wet mount preparation with 10% KOH and the type of fungus were identified by their characteristic growth in Sabouraud’s dextrose agar culture medium. The dermatophyte infection with trichophytonrubrum was seen in 80% patients, 15% with Trichophytonmentagrophyte var. interdigitale, and 5% with epidermophytonfloccosum.

The commonest organism causing tineapedis in our study was Trichophytonrubrum. Preventive measures like changing frequent footwear, drying the feet well after bathing, refraining from sharing articles including socks and community baths are to be followed by patients as these are the commonest predisposing factors for tineapedis.

**Ethical Clearance**- No ethical clearance was necessary for this research work

A Comparison on Efficacy of Topical 1% Permethrin and Oral Ivermectin for Pediculosis Capitis

Padam Kumar. M1, Jayakar Thomas2
1Junior Resident, 2Professor, Department of Dermatology, Sree Balaji Medical College and Hospital, Chennai

Abstract

Pediculosis capitis is a common health problem worldwide among school going girls. It is caused by Infestation with the head lice (*Pediculus humanus capitis*).

Topical 1% permethrin is most promising agent used worldwide. Newer agents like oral Ivermectin is also available for the treatment of pediculosis capitis. Here we conducted a study comparing the efficacy of topical permethrin with the oral ivermectin.

Keywords: pediculosis capitis, skin disorders.

Introduction

To compare the efficacy of topical permethrin and oral ivermectin in treatment of pediculosis capitis.

Pediculosis capitis is a common health problem worldwide among school going girls. It is caused by Infestation of the head lice (*Pediculus humanus capitis*). Among available topical treatment modalities, 1% permethrin, a pyrethroid, is the most effective topical agent with few side effects.

It acts by prolonged opening of the voltage gated sodium ion channels on the conduction system of the parasite and resultant palsy.

Thus post application brushing of wet hair with the louse comb helps in removal of head lice1.

Following details were observed.

<table>
<thead>
<tr>
<th>Days after treatment</th>
<th>Clinical Efficacy of 1% Permethrin (symptomatic improvement)</th>
<th>Microbiological Efficacy of 1% Permethrin (cure rate)</th>
<th>Clinical Efficacy of Ivermectin (200 mcg/Kg) (symptomatic improvement)</th>
<th>Microbiological Efficacy of Ivermectin (200 mcg/Kg) (cure rate)</th>
</tr>
</thead>
<tbody>
<tr>
<td>At 7 days</td>
<td>76%</td>
<td>80%</td>
<td>84%</td>
<td>90%</td>
</tr>
<tr>
<td>at 14 days</td>
<td>88%</td>
<td>93%</td>
<td>90%</td>
<td>94%</td>
</tr>
</tbody>
</table>

Methodology

In this quasi-experimental study, a total of 60 patients with head lice were enrolled and randomly divided in 2 groups of 30 each. Topical 1% permethrin application for 1 hour before hair wash and followed by wet combing with a louse comb was advised to one group and oral Ivermectin as 200μg/kg, single dose was advised to the other group.

In both groups, detailed symptomatic clinical history was noted and the examination for nits and head lice were carried out at day 0, 7 and 14. The treatment was repeated at the end of one week. Response to treatment was judged on following parameters: decrease in severity of pruritus, nonappearance of new nits/lice2.

Extract from some case studies/life scenarios:

Corresponding Author:
Dr. Padam Kumar. M,
Junior Resident, Department of Dermatology, Sree Balaji Medical College and Hospital, Chennai.
Basic Needs & Importance

Application has to be repeated after a week so as the nits turns into the adult lice. High incidence of resistance to permethrin is reported. Ivermectin is an orally available drug for various parasitic infections and also for Pediculosis capitis. It is effective, inexpensive and easy to administer with no known drug interactions and limited side effects.

It acts primarily at the Glutamate-gated chloride ion channels and secondarily at the γ-aminobutyric acid-gated chloride ion channels.  

Discussion

The most frequent presentation of pediculosis is pruritus; other common manifestations include excoriations, cervical lymphadenopathy, and rarely blepharitis and conjunctivitis. Beyond physical manifestations, there are negative social effects and potential economic effects on households.

In our study we found that topical permethrin is less efficacious compared to the oral Ivermectin at the end of one week after single treatment. But on second treatment with a gap of 1 week. Both were equally efficacious clinically and microbiologically in control of head lice infestation.

Conclusion & Recommendations

There is no significant difference regarding efficacy of topical permethrin and oral ivermectin both clinically and microbiologically, when used in treatment of pediculosis capitis, provided they are used correctly and are repeated at the end of one week. A combination treatment would possibly bring a higher cure rates.

Incidence of Scabies among Family Members in an Urban Setup

Padam Kumar. M¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

To screen the close contacts and the family members of patients clinically diagnosed with scabies. Scabies is a common ectoparasitic infection caused by Sarcoptes scabiei var hominis. It more commonly occurs in rural areas and its exact incidence in urban setup been unknown.

This study has been undertaken to highlight the importance of screening and treating the close contacts and the family members of scabies.

Keywords: scabies, urban setup.

Introduction

Scabies is a common parasitic infection caused by the itch mite Sarcoptes scabiei var hominis, an arthropod of the order Acarina. Scabies happens in both genders, at all ages, in every single ethnic gathering, and at all financial levels. Scabies is a parasitic skin illness endemic in asset poor networks in low-salary nations. It is prevalent higher in numbers in a rural setup among close contacts due to lack of sanitation and over crowing. Its frequency of occurrence among close family members in urban areas is unknown. Scabies was demonstrated to be progressively predominant among ladies and youngsters and more typical in winter than in summer. Scabies is commonly a disturbance by virtue of extraordinary night time tingling, rash, and its capacity to spread among individuals; superinfection may likewise happen.

Methodology

Consenting 450 Family members of 100 cases of scabies diagnosed clinically were screened for the evidence of scabies based on symptomatic clinical history and thorough clinical examination. Scrapings for wet mount examination were also taken in doubt to confirm the diagnosis. All the index cases and their contacts with the evidence of scabies were treated with topical 5% Permethrin cream. The study was conducted in a tertiary care center in an urban area.

![Fig. 1: Age wise distribution of Family contacts to scabies.](image1)

![Fig. 2: Sex wise distribution of Family contacts to scabies.](image2)
Discussion

The analysis of scabies lays to a great extent on the history and clinical examination of the patient, just as on the clinical history of the family and the nearby contacts. Exemplary appearances of scabies incorporate summed up and serious tingling, normally saving the head and face. Pruritus is more awful around evening time. The sores are found generally in the finger networks, on the flexor surfaces of the wrists, on the elbows, in the axillae, on the bottom and genitalia, and on the bosoms of ladies. Incendiary pruritic papules are available at generally sites. Tunnels and knobs (for the most part in the genital locales and axillae) are explicit creators of scabies yet now and again might be missing.

Extract from some studies

Numerous medications are available for treatment such as 5% permethrin, Ivermectin (200 mcg/Kg), Lindane, Malathion, Crotamiton, Benzyl benzoate, and the Precipitated sulfur.

Basic Needs & Importance

Nearly 450 family members of the index case of scabies screened, 180 close contacts were diagnosed to have scabies (40%), children of age less than 20 years and adults above the age of 61 years were more often affected (30% each category), compared to the family members of age 21 and 60 years.

Conclusion & Recommendations

Thus a higher incidence of scabies is prevalent in the society as compared to the presenting cases to the hospital. The need to screen and treat the close contacts or the family members is of utmost importance to keep the endemicity of the ectoparasite.

100 cases of scabies had 450 family members. Children less than 20 years and adults above 61 years were more often affected. 62% of Females and 38% of males were affected. The age wise distribution and sex wise distribution is given in Fig. 1 and Fig. 2 respectively. Prevalence of scabies among close contacts was 40%.

Treatment of close family members or close contacts of scabies is of utmost importance due to higher prevalence rates of infection among them even in urban setup.

Role of Focal Infections in Urticaria

Chinthaamani. KPR¹, Jayakar Thomas²
¹Junior Resident, ²Professor, Department of Dermatology, Sree Balaji Medical College & Research Institute

Abstract

To contemplate the rate of central diseases in patients with urticaria, who are going to the skin outpatient division. Urticaria comprises a gathering of sicknesses that offer an unmistakable skin response design. Diseases, as a trigger for urticaria has been talked about for a long time yet at the same time the accurate job and pathogenesis of pole cell actuation by irresistible procedures is hazy.

In unconstrained intense urticaria, there is no uncertainty for a regular relationship to contaminations. While in physical or contact urticaria, the proof for contaminations is peaceful less and the reduction of unconstrained interminable urticaria has been accounted for after effective treatment of industrious diseases.

Keywords: focal infections, urticaria.

Introduction

The relationship among urticaria and overpowering diseases has been talked about for >100 years.

In any case, a causal association with head or surging sickness is hard to set up. The reason behind this work was to play out a purposeful examination of the passed on events of urticaria related with bacterial defilements.

We give an umbrella breakdown of bleeding edge careful investigations and other significant manifestations on the abnormal relationship of urticaria and bacterial ailments. We completed a Medline search, for English language articles spread until January 2014, utilizing the watchwords ‘urticaria’ and ‘microorganisms/bacterial sickness’; a subsequent examination was performed in get-togethers of little living creatures and utilizing every germ name as a catchphrase.

The annihilation of the debasement could, in all honesty, brief the destinations of urticaria. Exceptional examinations and proficient research are undeniably expected to even more plausible explain the genuine control of life forms in the pathogenesis of urticaria and their relative power.

Methodology

A cross sectional study was done with 30 patients who were diagnosed with urticaria (all types). All the patients were subjected to

- Complete history taking
- Complete physical examination
- Dental and ENT examination

<table>

Extract From Some Other Studies:

Different bacterial debasements have been associated with urticaria sign, for example, Helicobacter pylori, Streptococcus, Staphylococcus, Mycoplasma pneumonia, Salmonella, Brucella, Mycobacterium leprae, Borrelia, Chlamydia pneumonia, and Yersinia enterocolitica.

Every so often the skin appearances, portrayed as urticaria, could be acknowledged by the nearness
of the microorganism in the skin, or for the activity of their dangerous substances, or to the enhancement authorization mediated by surrounding safe structures.

**Discussion**

Urticaria is described by the event of irritated wheals anywhere on the skin. Wheals are brief raised erythematous injuries going in size from a couple of millimeters to centimeters in width and can wind up blended. The tingling can be consuming or pricking and is commonly more terrible at night or evening time related with rest unsettling influences.³

**Basic Needs & Importance:**

The devastation of the sullying could, in all honesty, lead to the objectives of urticaria. Impending examinations and efficient research are plainly expected to all the more probable clarify the certified activity of microorganisms in the pathogenesis of urticaria and their relative power.⁴

**Conclusion & Discussions**

Out of 30 patients examined, 12 patients (40%) had dental focus of infection, 6 patients (20%) had upper respiratory tract infection and 2 patients (7%) had urogenital tract infection. 10 patients (33%) did not have any evidence of focal infection. A high incidence of focal infections, were found in patients with urticaria. This suggests that infections may play a significant role in pathogenesis of this skin disorder. Treatment of infective foci may play a significant role in the remission of the disease process.

Use of Social Networking Sites and Depression among Medical Students

Arkaprava Chakraborty\(^1\), R. Uma Devi\(^2\), S. Gopalakrishnan\(^3\)
\(^1\)Student, \(^2\)Professor, \(^3\)Professor & Head of the Department. Department of Community Medicine, Sree Balaji Medical College and Hospital, Chennai

Abstract

Social networking sites (SNS’s) offer a straight forward way to converse among people and sustain relationships among them. For the past decade, there is a huge change in the field of communication because of the rapid development of social networks.

The purpose of the study was to identify the impacts of Social Networking Sites (SNS’s) on the medical students and to ascertain the reasons behind using social media.

This cross-sectional study was carried out on 100 undergraduate medical students in Sree Balaji Medical and Hospital, Kanchipuram (dist.), Tamil Nadu. A self-administered questionnaire designed for the study was distributed among the students.

Of the 100 students, majority belongs in 20-22 years age group (63%) and 38% spend 1-3 hours per day mostly to keep in touch with friends and family (85%). Three participants were found to have moderately severe depression whereas 40% were having minimal depression and 31% were having mild depression.

Internet addiction has become a major problem for medical students. Students should be counseled about the merits and demerits of internet addiction. Duration of internet use must be restricted by parents and authorities to avoid the increasing risk of internet addiction which ultimately leads to depression.

Keywords: Social Media, Internet Addiction, Medical Undergraduates.

Introduction

Social networking sites (SNS’s) can be defined as “a group of Internet-based applications that allow the creation and exchange of user-generated content.” For the past decade, there is a huge change in the field of communication because of the rapid development of social networks.\(^1\) Use of internet has increasingly influenced all aspects of society and the exponential rise of the global users. There is an escalating number of people that spend their time chatting and browsing the social networking sites. It indicates that it has become an integral part of the daily lives of people of modern era.\(^2\)

Social media networks offer a straightforward way to converse with peers and get peer feedback, as well, which may influence a young adult’s self-esteem. By using Facebook, Whatsapp, Instagram, etc communicate with multiple people at one time is very easy nowadays. Social media may also make it easier for users to monitor activities of people they have not seen in a while as well as reconnecting with new and old friends.\(^3\)

Internet use is growing in leaps and bounds in India. According to internet and mobile association of India, approximate number of urban active internet users was 42 million in 2008 compared to 5 million in 2000. With approximately 120 million internet users in 2011, India now ranks third regarding the size of digital population in the world. The number of internet users in India has grown five fold since 2005.\(^4\)

Dr. S. Gopalakrishnan
Professor, Department of Community Medicine, Sree Balaji Medical College and Hospital, Chennai-600044.
Easy access and social networking are two major factors of addicting behavior among young adults. Internet Addiction Disorder (IAD) causes neurological complications, psychological disturbance and social problems. Surveys in the United States and Europe found high prevalence rates between 1.5% and 8.2% respectively. Therefore, it is very important to establish the relationship between the use of social networking sites and depression.

**Materials and Method**

This cross-sectional study was carried out in Sree Balaji Medical College and Hospital, Kanchipuram (dist.), Tamil Nadu, India, from April to June, 2019. The study population comprises of 100 undergraduate medical college students and interns. The study was carried out after obtaining institutional ethical clearance. A self-administered questionnaire designed for the study was distributed among the students who were present at the time of administration of questionnaire.

Questions regarding number of accounts in social networking sites, gadgets used, login status, average time spend on Internet, usual time for Internet use, purpose of use of social media, etc were enquired. It also contained Patient Health Questionnaire (PHQ). The PHQ consists of 9 questions to evaluate the respondent’s level of depression. Each of the questions was scored according to the options given. The minimum score is 0 and maximum score is 3. At the end, all scores are added to find out the total score and categorised individuals as minimal, mild, moderate, moderately severe, severe depression.

Verbal consent was taken before administering the questionnaire. They were told that the data being collected were anonymous, confidential and for research purpose only and that their participation was voluntary. Data analysis was done, where categorical variables were summarized by frequencies and percentages.

**Results**

Among the 100 participants, majority belonged to the 20-22 years age group (63%) and 56 were female students. About 61% were residing at their college hostel only [Table: 1]. The participants having 5+ social networking accounts are 35% and almost all of them (99%) use mobile as common gadget to access SNS’s. [Fig: 1 and Table: 2]
Around 64% participants use social media during evening and 38% spend 1-3 hours per day. Around 45% people post every few months, 21% post every few weeks and only 6% post daily on social media. [Fig: 2 and Table: 3]

Discussion

Social networking is important for medical students for their future contacts among themselves. Nowadays, many social networking sites are available around the globe and medical students are now using different types of media according to their status of life to spend their time. Thus, social networking sites have completely changed the way that adolescents interact and gather information.1

In this study, majority of 99% participants access SNS’s using mobile. Around 75.5% access SNS’S through smartphone in a study conducted by Medha R, Sharmistha B, Abhijit M. With the advent of newer technology, smartphones have become the preferred device for SNS’s use, mainly due to their portability.5 Smartphones are ubiquitous with their user-friendly interfaces and advanced computing capabilities.6

In also shows that around 64% participant’s uses internet during evening while 61% uses internet at night. Whereas, 38.06% participants uses internet during evening and majority of 49.03% preferred using internet at night in a study conducted by Santanu G, Supantha C.4

Around 18% uses SNS’s for 30-60mins, 25% uses SNS’s for 3-6hrs and 38% uses SNS’s for 1-3hrs. Hence, duration wise, around 86% students reported to use SNS’s for >6hrs while 53% participants log in and off occasionally during the day. On the other hand, 80% students reported to use SNS’s for >4hrs and two-third of the participants remain log in and off occasionally during the day in a study conducted by Lisa B, Dipta KM, Gautam KB.3

In the present study, 40% of the total respondents were having minimal depression, 31% having mild depression, 16% having moderate depression and only 3% were suffering from moderately severe depression. Around 90% of participants reported depression of various grade in this study while Kulsoom et al. reported a high prevalence of depression (43%) among the participants and Yusoff et al. noted very low prevalence of depression.2

A total of 49% students face trouble concentrating on studies on several days of the week. A study among college students of Oman showed that 36% of the participants felt that spending time on SNS’s had distracted as well as affected their study timings.7

In summary, the present study shows significant association of high usage of social media with depression among medical students in Sree Balaji Medical College and Hospital, Kanchipuram(dist.), in the present socio-cultural context.

Conclusion

The present study revealed that a large proportion of medical undergraduates have an affinity towards using SNS’s. Although majority of students use SNS’s for various purposes but using SNS’s in odd hours leads to depression. In this modern era, using internet is a necessary part for medical education but it is the duty of the medical college authorities as well as the guardians of the students to check that use of internet should not be in an improper way. A regular check by the guardians as well as by the college authorities regarding the misuse of internet is very helpful. Medical undergraduates must be encouraged to use internet for research work and creative purposes. Awareness among the students about the demerits of prolonged internet use both from health and social point of view should be highlighted by the college authorities via organizing workshops, debates and seminars and prevent students from getting addicted to internet. Thus, we all should be aware of the knowledge that the advantages of internet must not be lagging behind the unhealthy use of internet and its addiction.

Study on the Awareness of Breast Cancer and Prevalence of Breast Self-Examination among Urban Women in Chennai

Subiksha Senthilkumar¹, Swetha N. B², Gopalakrishnan S³
¹Third Year Undergraduate, ²Assistant Professor, ³Professor and HOD, Department of Community Medicine, Sree Balaji Medical College and Hospital

Abstract

Background: Breast cancer is currently the most common cancer occurring in Indian women. In India, one woman is diagnosed with breast cancer every 4 minutes and one woman dies of breast cancer every 8 minutes. The age standardised rate is approximately 25.8 per one lakh women and is expected to rise to 35 per one lakh women in 2026. Approximately 60% of patients with breast cancers are diagnosed in advanced stages. The aim of this study is to assess the knowledge of breast cancer and the practice of breast self-examination among urban women.

Method: This is a cross-sectional research study carried out in Valasaravakkam locality in Chennai. A pre-tested, semi-structured questionnaire was used which contains socio-demographic details, and questions about risk factors of breast cancer, practice of breast self-examination and mammography. The data was collected through interview after obtaining informed consent from the subjects.

Result: Responses were collected from 100 women within the age group of 18-55. A little more than 90% of the women have heard of breast cancer. Media and Educational Institutions play a key role in expanding the awareness of breast cancer. Most women identified family history as a cause and a lump in the breast as a sign of breast cancer. 68% of women have heard of breast self-examination but only 40% of them practice it. 66% of the women knew about mammography, and 10% women have had a mammography done before.

Conclusion: This study concluded that the awareness of the breast cancer was good but the knowledge and practice of breast self-examination was poor, which is vital for the early detection and treatment of breast cancer.

Keywords: Mammography, Risk factors, Signs

Introduction

Cancer is one of the deadliest diseases in the world and holds second position in being the cause of most number of deaths across the globe. As of 2018, cancer has been estimated to have led to about 9.6 million deaths worldwide¹. Breast cancer is the most common form of cancer occurring in women and is the second most common cancer globally, closely following Lung cancer.

It affects both sexes of developed as well as developing countries, but 100 times more common in females than males. Breast cancer constitutes to 12.3% of all cancers and an estimated 20,88,849 new cases were diagnosed in 2018². In India, the incidence of breast cancer is up to 30.9 per 1,00,000 women³. 1,62,468 new cases and 87,090 deaths due to breast cancer were reported in India in 2018⁴.

Some of the recognized risk factors of breast cancer include the following – Age, ethnicity, personal and family history - women who have previously suffered from breast cancer have a risk of recurrence and it has been estimated that 8 out of 10 women battling breast cancer...
cancer do not have a family history, but about 5% to 10% of the cases are assumed to have occurred as a result of mutation in the BRCA1 and BRCA2 genes which are inherited from parents. Early menarche (before 12 years) and late menopause (after 55 years) are also risk factors for development of breast cancer as it provides longer periods of exposure to hormones oestrogen and progesterone.

Combination Hormone Replacement Therapy (HRT) increases the risk of breast cancer by about 75% even when used for 2-3 years, whereas the oestrogen only HRT increases breast cancer risk only when used for more than 10 years. Dietary habits like excessive consumption of alcohol added sugars, fat from processed foods and red meat increase the risk while foods rich in fibre, low fat milk and dairy products, colourful fruits and vegetables, foods rich in vitamin D and Soy reduce the risk of breast cancer. Smoking, obesity, socio-economic status, radiation to chest and increased use of oral contraceptives are also said to increase the risk of breast cancer. Women previously diagnosed with certain benign conditions of the breast like Fibroadenoma, Fibrosis, Ductal hyperplasia and many others are at a risk of developing breast cancer.

The most suitable economical method to combat breast cancer is the prevention of cancer itself. Primary prevention of the cancer can be initiated by reducing the risk factors through widespread promotion of cancer education among the general population so as to help women identify the risks, signs and symptoms of breast cancer. Early detection of breast cancer and the removal of tumour in its early stages influences the survival of the patient. Clinical Breast Examination and Mammography have proved to be useful screening tests for the early detection of breast cancer but feasibility poses a bigger issue. According to the American Cancer Society’s guidelines for women at average risk of breast cancer aged 40-44, yearly Mammography is optional and women aged 45-54 should get Mammography done every year and women older than 55 can get Mammography done yearly or every alternate year.

Breast self-examination is an easy, economically feasible, non-invasive screening method that can be practised by women for routine examination of their breasts and early detection of breast cancer. Although the efficacy of breast self-examination has not been determined, it helps establish the importance of breast health among women. Breast self-examination is encouraged from 18 years of age and is to be done every month, 3-5 days after the onset of menstrual cycle as the breasts are not as tender or as lumpy during this time of the cycle.

Post-menopausal women can perform breast self-examination on the same day of every month. Some of the changes suggestive of breast cancer that can be noted during breast self-examination are change in the position or shape or size of nipples, drawing in of nipples, any bleeding or abnormal discharge of fluid from nipples, change in the size of breasts, change in the appearance of skin over breasts, pain in the breasts or under the armpits and lumps in breasts or under the armpits.

This study aims to assess the knowledge and awareness of breast cancer and the extent of practice of breast self-examination among urban women.

Materials and Method

This is a cross-sectional research study carried out in Valasaravakkam locality in Chennai. The study subjects included 100 women aged between 18-55 years. The sampling method was convenient sampling technique. The period of study was from April 2019 to July 2019. This study was approved by the Ethical Committee of the Institute. A pre-tested, semi-structured questionnaire was used which contains socio-demographic details, and questions about risk factors of breast cancer, practice of breast self-examination and mammography. The data was collected through interview after obtaining informed consent from the subjects and was analysed using Microsoft Excel and the results are represented as charts and tables.

Results

100 female subjects aged between 18-55 years took part in the study. Almost all the subjects were literate. About 91% of them had heard of breast cancer.

Source of information - Half of them conceded media (TV, Radio, Internet) and Educational Institutions to be the source of their awareness on breast cancer. Other sources include Family/Friends and Hospital staff (Doctors, Nurses). Figure 1, 2 and 3 depicts the awareness of women on risk factors, preventive measures and important signs suggesting breast cancer.
Figure. 1: Awareness of risk factors of breast cancer (multiple responses were analysed)

![Bar chart showing awareness of risk factors of breast cancer]

Figure. 2: Awareness of factors preventive against breast cancer (multiple responses were analysed)

![Bar chart showing awareness of factors preventive against breast cancer]
Clinical screening for breast cancer - Of the 100 women, 8% have undergone clinical screening for breast cancer while the remaining 92% have not. 77 of the 92 women who didn’t go for a clinical screening responded that they didn’t feel the requirement for it. 4 of them were unaware, 4 felt too embarrassed to see a doctor, 3 claimed to be too busy to visit a doctor, 2 were too scared to visit a doctor and 2 felt that visiting a doctor is too expensive.

Table 1: Awareness and practice of Breast Self-Examination (n=100)

</tbody>
</table>

Of the 40% who practiced BSE - 19 did it occasionally, 11 performed rarely, 6 practiced every month, and 4 did it every week. 36% said BSE should be started from 30 years of age, 31% said from 18 years of age, 21% said from puberty, and 12% said after menopause. When questioned about the ideal regularity to practice BSE, 52% chose monthly, 19% chose weekly, 19% chose yearly and 10% chose rarely.

Mammography - 66% have heard of mammography and 10% have had a mammography done before. 33% said mammography should be done only when an abnormality is found upon BSE, 21% said yearly, 6% said occasionally, 5% said monthly, 1% said weekly and 34% didn’t know about it.

Discussion

The data analysis of the study has shown that most of the women identified family history as a risk factor for breast cancer. Three-fifth of the subjects feel that regular practice of breast self-examination and breastfeeding can be preventive against breast cancer. The signs of breast cancer that were chosen by more than half of the participants were lump in breast, abnormal discharge from nipple, pain and change in shape or size of breasts. The recognition of signs of breast cancer is fundamental.
in its early detection as it affects the treatment and improves chances of survival. It is important for women to learn about the various risk factors that lead to breast cancer.

This study revealed that most of the study population was aware of breast cancer and breast self-examination. However, their knowledge and practice of BSE and history of clinical screening is deficient. In a study done by Deniz et al., 49% of the women did not perform BSE and 67.2% had never had a clinical screening done.

The sizeable number of the women who haven’t undergone a clinical screening previously throws light on the lack of importance given to breast health screening. Most of them believed that it was unnecessary as they felt that they were too young to undergo screening for the disease. These findings were found to be consistent with that of a national survey.

This survey uncovered that more than half of the total study population didn’t know how to perform a self-examination. Almost an equal percentage of them were unaware of the right age at which regular examination, clinical screening and mammography should be done. About half of them were aware about the ideally required regularity for practice of BSE. A similar study by Madhukumar et al. stated that only 18% of the women knew about BSE.

Breast cancer is a major global health concern as it is one of the top three cancer types plaguing the human populace in terms of incidence and mortality. According to the GLOBOCAN 2018 database released by the International Agency for Research on Cancer (IARC), breast cancer is the fifth leading cause of death – responsible for about 6,27,000 deaths which accounts to 6.6% of the total number of deaths. Public health records point that the overall burden of breast cancer in women is extensive and on the rise because the incidence rate is far higher than any other cancer in both developed and developing countries. Breast cancer is the most commonly diagnosed cancer in women – 24.2% of the total cases, that is, about 1 in 4 of all the new cases diagnosed in women worldwide are breast cancer and it is the most commonly occurring type of cancer in 154 of the 185 countries included in GLOBOCAN 2018.

Every year, the incidence and mortality rate continues to increase as most cases are diagnosed only in the advanced stages. The inhibitions with respect to talks about breast health should be cleared by a strong emphasis on the weight of the issue and encouraging women to be more open about it.

**Conclusion**

This study concluded that the awareness of breast cancer in this study population is good. On the other hand, their knowledge and practice of BSE is lacking. Women should be educated about the importance of a healthy lifestyle and reproductive history in the battle against breast cancer.

Enlightening them about the modifiable risk factors like diet, exercise, alcohol consumption, etc., may improve the chances of preventing breast cancer by inspiring them to assume better habits. In India, discussions on breast cancer are highly impeded due to cultural restrictions or taboos.

Women feel too shy or too embarrassed to consult a doctor on matters concerning their breast health.

Media and educational institutions have played a critical role in spreading the awareness of breast cancer. Breast health education and training in BSE should be imparted at school and college levels. Nation-wide cancer awareness campaigns and community-level health care organisations should be implemented in both urban and rural areas to reach out to a larger population. Women should also be explained about the various modes of treatment, management of breast cancer available across the country and the chances of survival and recovery.

Staphylococcal Scalded Skin Syndrome- A Casereport

Swathy Asokan¹, Anantha Eashwar², S.Gopalakrishnan³
¹UG Student, ²,³PROFESSOR, Dept of Community medicine, SBMCH, ch-44

Abstract

Staphylococcal scalded skin syndrome [SSSS] or Ritter’s disease is a vesiculating skin disease most commonly caused by Staphylococcus aureus, a gram positive commensal which asymptomatically colonizes the skin. Rarely, few strains cause SSSS. A study in the Czech Republic showed an incidence of approximately 25 cases per 100,000 children younger than one year of age. It can occur in outbreaks, particularly in nurseries. It is far less common in adults. When they do occur, cases in adults typically involve those with immunosuppression such as HIV/AIDS, severe renal impairment or renal failure, or in those withmalignancy.

Keywords: Ritter’s disease, exfoliative toxins, desmolglein, nikolsky sign

Introduction

Staphylococcal scalded skin syndrome [SSSS] or Ritter’s disease is a vesiculating skin disease caused by the bacteria Staphylococcus aureus phage group 2 strains 55 and 71, most commonly seen in children below 5 years of age. There is generalized erythema of the skin with blisters, and scales are seen in the later stages. Areas prone to movement, flexural areas, are most commonly initially involved. In children, the perioral area, eyes and ears, in infants, the diaper area and the area around the bellybutton are most often affected. The rash spreads rapidly with a propensity to affect the perioral area and areas where the skin creases, especially on the legs, arms, groin and neck. The top layer of the epidermis detaches from the underlying layers resulting in loose blisters and shallow erosions. Affected skin may slough off in sheets. Sloughing results in the exposure of moist, reddish tissue very close to the top of the epidermis and gives the skin a scalded or burned appearance. The application of gentle pressure to the skin will cause sloughing which is known as a Nikolsky sign, and it is imperative for the diagnosis of SSSS. These manifestations are due to the production of exfoliative toxins produced by the bacteria which takes a hematogenous route of spread and binds to a target protein in the superficial layers of the epidermis. It has many differential diagnoses like Toxic epidermal necrolysis, epidermolysis bullosa, Stevens-Johnson syndrome etc. Due to high morbidity and many differential diagnoses with different treatments, timely diagnosis is very critical.

Methodology

Condition During Admission:

A 3 year 3 months old male child presented on 26/03/2019 with complaints of painful vesiculobullous lesions and low grade fever for one day. The lesions developed following scratching of the skin and worsened drastically in the next 24 hours. The child was looking sick, toxic and irritable. There was history of itching, no history of any drug intake, burning micturition or bowel and bladder symptoms. He had a previous history of nebulisation.

On examination, the child was conscious and alert. His height and weight measurements were done and were found to be 93cm and 11.9kg respectively. His temperature was 102°F, pulse rate 160/min and respiratory rate 32/min. Oxygen saturation and hydration were normal. On general examination, all entities were normal. ENT was normal and there was watering from the eyes. CVS examination showed normal S1, S2 and no...
murmur. On RS examination bilateral air entry was equal with no added sounds. Abdomen was found to be soft on palpation, organomegaly and tenderness were absent. There was no neurological deficit seen. On examination of the skin and mucous membranes, it was found that mucous membranes were spared while the skin showed erythematous, vesiculobullous/ impetigenous lesions in the perioral area, axillae and the groin with a positive nikolskysign.

SSSS is a clinical diagnosis and lab diagnosis is only for completion sake. His blood investigations showed leucocytosis and there was a negative CRP. His preliminary blood culture was sterile.

TREATMENT:

After taking the dermatologist’s opinion, he was treated with IV fluids, IV antibiotics and other supportive measures.

IV fluids:
0.9% GNS
Antibiotics:
Inj. Augmentin given for 3days
Inj. Amikacin given for 3days Supportive measures:
Syp. Augmentin
Syp. Atarax
Syp. Malidens
Tab. Montair5
Application of liquid paraffin on the affected areas

CONDITION DURING DISCHARGE:

He improved with the above treatment, so he was discharged with oral medication. He was conscious, oriented and afebrile with stable vitals at the time of discharge.

Drugs advised at discharge:
Syp. Augmentin Duo 6ml BD 1-0-1*4days
Syp. Flora BC 5ml BD 1-0-1*3days
Syp. Atarax 4ml TDS*3days

Discussion

SSSS, a rare skin condition which primarily affects children, was first described by a German physician, Von Rittershain, in 1878. The exfoliative toxins, type A and B (ETA and ETB), produced by the bacteria, cleave desmoglein complex 1. Disintegration of desmosomes anchoring the stratum granulosum causes exfoliation⁴. As stated previously, not all phage types of staph is associated with Ritter’s disease. Since this disease is a
manifestation of the toxin produced by the bacteria and not the bacteria itself, the culture will be negative here.

SSSS can mimic other exfoliating diseases such as Toxic epidermal necrolysis (TEN) and Steven Johnson syndrome (SJS). Lack of mucosal involvement, target lesion and history of any recent drug intake differentiates SSSS from SJS and TEN. For now, diagnosis is only reached by exclusion and specific techniques to detect the particular toxin, such as polymerised chain reaction (PCR) are not readily available in some clinical settings[5].

This condition causes severe morbidity and mortality, if not treated properly. The mortality rate in adults is as high as 60% and in children it is 4%. Complications of SSSS include pneumonia, dehydration and sepsis, although the last one is relatively rare. Electrolyte and fluid management is important as dehydration can lead to electrolyte imbalances[5].

In this case, a prompt diagnosis of SSSS and treatment resulted in rapid healing and timely discharge. The classical presentation of the disease with painful, erythematous vesiculobullous lesions mainly in the perioral and flexural areas with a positive nikolsky sign facilitated in reaching a quicker diagnosis. Thus there were no complications or later complaints reported.

Epidemics and Pandemics in India throughout History: A Review Article

Swetha G1, Anantha Eashwar V M2, Gopalakrishnan S2
1UG Student, 2Professor, Department of Community Medicine, SBMCH, Chrompet, Chennai

Abstract

India has encountered several epidemics and pandemics throughout history. This review article talks about such outbreaks known to have occurred in the 19th-21st century and are arranged in accordance to chronology. For this review, a variety of sources were used by searching through PubMed, NCBI and several others. Different forms of prints such as books, websites, and journals were used as references in this article. The necessity to review this title is because the information is scattered and to source them and compile them into a single article could help the medical practitioners and healthcare workers to understand what this country has been through in the past and what reforms have to be made by them, the community and the government in preventing such outbreaks in the future.

Keywords: epidemics, skin deficiencies

Introduction

India, being a third-world country, has encountered a variety of epidemics and pandemics through time. Several accounts of influenza, cholera, dengue, smallpox and several others have been recorded throughout history; while we have been able to eradicate some; many diseases still continue to pose a threat to the community. It is not uncommon for sudden and rapid outbreaks to occur in India and many articles direct the cause for this in such developing countries being malnutrition, lack of sanitation and lack of a proper public health system [1,2]. According to Park, epidemics is an unusual occurrence in a community or region of disease, specific health-related behavior or other health-related events clearly in excess of expected occurrence. It is a sudden, severe widespread outbreak of a disease pre-existing in the community. A study by John T. Watson, et all analyses the relationship between epidemics and natural disasters and establishes that there is a rise in the occurrence of epidemics post-disaster though incidence in India has not been emphasized [3]. However, another article by Sen states those in recent years, cholera outbreaks in India have been due to the breakdown of sanitation during natural disasters [4]. A study by Moore, Cristopher, and Mark displays that the epidemic trends modify when the transmission exceeds the threshold station the infectious nature of it [5]. Pandemics, on the other hand, refer to the worldwide spread of diseases. These are the global health problems that need to be addressed and treated viciously along with proper measures to avoid transmission to other countries. There have been a significant number of pandemics throughout history and in many instances; their control had been difficult because of the lack of a proper, working global surveillance system [6]. These pandemics show trends of developing microbial resistance and as a result, the death toll is usually high in pandemics than epidemics as concluded by the study comparing the mortality rate of influenza pandemic and epidemic [7]. As far as India is concerned, there have been only two major, significant pandemics throughout history. While cholera had been predominant throughout the 19th century with increasing death tolls every year, the influenza pandemic came later on in the early 20th century [8,9]. The influenza pandemic was short but devastating and after a long time, quite recently, came yet another flu pandemic by the H1N1 strain [10]. Though, it is almost impossible to analyze all epidemics and Pandemics throughout Indian history, effort has been made to include most of the significant ones.
19th Century:

Ist Cholera Pandemic (1817):

This is considered to be the first major epidemic of the 19th century in British-colonized India and was described as probably the most terrifying of all [11]. The first case was reported on 23rd August 1817 by a civil surgeon of Jessore [12]. The overall estimation of the mortality is not available as the data collection in India began much later, probably in the late 1860s. As for the geography, it is important to note that the year 1817 had brought a very heavy rainfall leading to flooding which could have been the cause for such a rapid spread [13]. While the Europeans living in India then and the elite were not seriously affected, the slum dwellers and people in rural poverty were hit the worst [14]. This was probably due to the differences in living conditions, personal hygiene and practices.

IInd Cholera Pandemic (1829):

The second outbreak started around 1826 from Bengal and spread through the rivers to various parts of northern India. After affecting the United Provinces (UP), its impact was huge on areas around Punjab and Delhi but most significant is its pandemic spread to countries like China [12,15]. Cholera spread far and wide, all along the trade routes from China affecting several cities and villages alike. In each place, it lasted for a few weeks and killed hundreds of people everyday [16].

IIIIrd Cholera Pandemic (1852):

This third cholera pandemic started around 1852 and lasted till the late 1860s. It is significant in history because of its spread to countries that were until then not affected. Though India was not its major area of impact, in the later phase of pandemic, small spurts of cases were noted in Bengal. It spread to several other countries like Persia, Arabia and then to Russia [12,15]. This was due to the worldwide spread of El Tor serotype of Vibrio which was initially endemic to India [17].

IVth Cholera Pandemic (1863):

This began around 1863. While some suggest that the major cholera epidemic in 1865 was brought to Mecca by the Haj pilgrims from India, others disagree stating that it was a just a recrudescence [18,15]. However, it is agreed that it was from Mecca that the infection spread to several countries [19,20]. The Kumbh Mela at Hardwar in April 1867 has been considered to be responsible for the epidemic spread of cholera in northern India [11]. The Madras Presidency in 1877 was the worst hit and the cholera epidemic was responsible for about 10% of the annual mortality then [21].

Vth Cholera Pandemic (1881):

The fifth cholera pandemic was considerably less fatal as compared to the previous four. It was during this pandemic (1881-1869) that Robert Koch proved that cholera was transmitted through the fecal-oral route, after studying the outbreaks in Calcutta and Egypt [22]. It spread to United Provinces and Punjab after which it spread to other countries like Afghanistan, Persia, parts of Russia and then to Europe [23].

Bombay Plague Epidemic (1896):

This plague began in September 1896 in colonial Bombay creating a lot of social and political frenzy. The rapid growth of commerce in Bombay led to an increase in population and thereby overcrowding. The anti-plague campaign was started to battle this epidemic and it was based on the belief that the focus of the infections was from the slums. The plague killed thousands and many people were forced out of the city [24].

VIth Cholera Pandemic (1899):

The sixth cholera pandemic began around 1899 and major outbreaks were noted in Bombay, Calcutta, and Madras [8]. While the infection throughout the 20th century was caused by O1 serotype of Vibrio cholera and confined mostly through the Asian subcontinent, the sixth cholera pandemic brought about surprising challenges. This cholera infection was caused by an unknown, non-O1 serotype of V.cholera and spread to many distant countries including the United States [25]. The sixth cholera pandemic lasted for about 25 years (1899-1973) [26].

20th Century

Influenza Pandemic (1918):

This is also known as the Spanish Flu of 1918-19. This has been known to have caused around 20-50 million deaths worldwide and is considered most devastating [27]. This was caused by the H1N1 strain of Influenza and was severe. The first episode of the disease began
in early 1918 and later in autumn, it began to spread all around the world, India considered to be the foci [28]. The second wave of the attack began in Bombay in 1918 and spread to other parts of northern India and Sri Lanka from where it spread worldwide [29]. Improvement in the virulence and velocity of the virus strain and the monsoon bringing humidity are considered to be the key factors in increasing the severity and spread [28].

**Polio Epidemic (1970-1990):**

India was the worst affected by polio among the developing countries until the late 1990s after which the EPI was initiated [30]. The incidence of polio in India was very high in both urban and rural states and the most affected was the state of Uttar Pradesh [31]. Its worst sequel was reported to be post-polio paralysis and in the district of Vellore, about 6/1000 preschool children were affected [32]. It was in 1964 in Bombay and 1965 in Vellore that the oral polio vaccine was introduced [33]. India had a choice between Salk’s IPV and Sabin’s OPV. Even after the introduction of the OPV in EPI there was no improvement to be noted for 10 years [33]. But with improvement in surveillance, the desired results were achieved and India was declared polio-free status in January 2011 and emphasis has been laid on maintaining the guard to prevent resurgence [30].

**Small Pox Epidemic (1974):**

It is known as one of the worst small pox epidemics of the 20th century. India contributed to about 85% of this epidemic worldwide. This epidemic broke out in three different villages of West Bengal, Bihar and Odissa but it was impossible to establish a connection between the men hence it was treated as three different epidemics. The disease was introduced into different areas by different sources. While over 15,000 people died in this epidemic, thousands of the survived but most of them but most ended up with disfigurement and blindness [34, 35]. Small pox was eradicated in by the WHO small pox eradication program. It was the first disease to be combated globally and was declared eradicated by WHO in 1980 [36].

**Plague Plague Epidemic (1994):**

Plague cases in Surat were first reported in Sept 1994 and which it spread to other cities in India. Fewer than 1,200 people were found positive and it lasted for less than two weeks but it is considered important due to its high fatality and created worldwide repercussions. It is said to have been initially difficult for doctors to diagnose it but when they did, all necessary precautions are taken to contain its spread [37].

**21st Century**

**(2001-2003)**

**Plague of Northern India (2002):**

The Plague of Northern India broke out in Shimla district of Himachal Pradesh in February 2002. It was a small and less serious epidemic. Also, as soon as the plague was detected, immediate measures were taken like fumigation, evacuation, and chemoprophylaxis that lead to further control of the epidemic [38].

**Dengue Epidemic (2003):**

In 2003 during September, there occurred an outbreak of DF/DHF in Delhi. It reached its peak around October-November and lasted until early December. The mortality rate was around 3%. It became a major outbreak in India in spite of the widespread preventive measures taken to control DF [39].

**SARS Epidemic (2003):**

SARS (severe acute respiratory syndrome), is considered as the first serious infectious disease outbreak of the twenty-first century. It initially started in the Guandong province of China in 2003 and spread quickly to about 30 countries across Asia, Americas and Europe and accounted for a total of 8,439 cases and 812 deaths, within 7 to 8 months [40,41].

**(2004-2006)**

**Meningococcal Meningitis Epidemic (2005):**

In early 2005, a sudden surge had been noted in meningococcemia and meningococcal meningitis cases in India. Cases were reported from Delhi and the surrounding states of Uttar Pradesh and Maharashtra. Around 430 cases of meningococcal meningitis were reported as of June 2005 [42]. Case management, early detection through surveillance was aimed at prevention of spread [43].

**Chikungunya Outbreak (2006):**

Around 3.4 million cases of Chikungunya were reported in Ahmedabad 2006 with 2,944 deaths.
estimated. The mortality rate in 2006 epidemic was substantially increased when compared with that in the previous four years [44]. In December, there occurred another epidemic in South India where the states of Andhra Pradesh, Karnataka and Tamil Nadu were affected. The volatile nature of this epidemic was attributed to the herd immunity to the then isolated genotype [45]. Major efforts were taken for mosquito control and several awareness campaigns were initiated by the television and print media [46].

**Dengue Outbreak (2006):**

The outbreak began in early September of 2006 and the first case was reported from Delhi. By the end of September, it began to spread to other states like Rajasthan, Kerala, Gujarat, Chandigarh and Uttar Pradesh [47]. The ministry of health set up a control room to monitor the outbreak and provide technical assistance that led to the efficient management of the disease [48].

**(2007-2010)**

**Gujarat Jaundice epidemic (2009):**

Modasa town in Gujarat witnessed the outbreak of hepatitis B in 2009[49] This is of significance because almost all outbreaks of viral hepatitis in India were considered to be due to hepatitis E which is feco-orally transmitted [50]. It was a long-lasting epidemic and control was achieved by mass public awareness and health actions.

**H1N1 Flu Pandemic (2009):**

The H1N1 Flu pandemic began in May 2009 and spread globally by July 2009. By August 2010, it was declared pandemic and around 18,500 deaths were reported from all around the world [51, 52]. Three strains of influenza viruses were circulating then of which the Inf A (H1N1) and Inf A (H3N2) viruses were largely replaced by the pdm H1N1 strain [53,54].

**(2011-2014)**

**Odisha Jaundice Epidemic (2014):**

The outbreak began in November 2014 in Kantalbai, a remote village in Odissa. This led to a district level investigation and it was confirmed to be jaundice caused by the Hepatitis E virus [55]. This 2014 Odisha Jaundice epidemic was one of the many outbreaks in Odisha and the most common cause being HEV [56]. This is transmitted enterically and has affected several people, especially of the low socioeconomic category. Surveillance for clean water and sanitation was proposed as the control measure [57].

**(2015-2018)**

**Indian Swine Flu Outbreak (2015):**

It refers to the outbreak of the 2009 H1N1 flu pandemic in India which was still present as of March 2015. This outbreak in 2015 is considered as a resurgence of the infection and the most plausible reasons are considered to be low temperature, decreasing host immunity and failure of vaccination campaign after 2010 [58]. According to the NCDC data in India, Rajasthan, Maharastra, and Gujarat were the worst affected states in India during this pandemic [59].

**Nipah Outbreak (2018):**

The virus was first noted in the late 1990s in Singapore and Malaysia. The natural host for this disease is the fruit bat and transmission is from direct person to person contact [60]. This Nipah virus outbreak began in May 2018 in Kozhikode District, Kerala. This is the first Nipah virus outbreak reported in Kerala and the third known to have occurred in India, with the most recent previous outbreak being in 2007 [61]. Spread of awareness about this infection, isolation of the infected and post-outbreak surveillance led to the control of this outbreak [62].

**Conclusion**

India has stood strong through several epidemics and pandemics. Good medical care and efficient researches have made it possible to fight every infection and luckily, we have been able to even eradicate a few. It can be established that throughout time, many infectious diseases have become widespread due to the mere lack of sanitation and crowded environment. The tropical climate and the seasonal rains in India is yet another important factor contributing to several vector-borne infections outbreaks in the past and many more to come. Though it has been difficult to compile all the epidemics and pandemics due to lack of sufficiently available data and errors in data preservation, sincere efforts have been put into including most of the important, notable ones. This is written with a hope that it may help medical
professionals understand where they had gone wrong in controlling an outbreak in the past or how they succeeded to lead by example. It is also a sad truth that India will have to face several more such outbreaks in the days to come but preparedness has to be given immense importance and control of spread should be the number one priority of the doctors and other health care workers.

A Review on Common Oral Mucosal Lesions Associated with Pediatric Patients

Rajesh E¹, K.M.K.Masthan², Sangeetha Priya.P³, N. Aravindha Babu⁴
¹Reader, ²Professor and Head of the Department, ³Graduate Student, ⁴Professor, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital Bharath Institute of Higher Education and Research

Abstract

Pediatric oral pathology deals with the conditions causing or resulting from morbid anatomic or functional changes in the structures of the mouth in the pediatrics. Children and adolescents exhibit a wide spectrum of oral lesions including hard and soft tissue lesions of the oral maxillofacial region. Oral pathoses in children are often missed since obtaining detailed history and performing thorough clinical examination and more difficult in comparison with an adult. Oral lesions in children include mucosal conditions, developmental anomalies, neoplastic, reactive or inflammatory lesions. Thus this review article provides a brief note on the oral lesions commonly dealt with pediatric patients.

Keywords: Developmental, Neo-natal, Mucosal lesions, Hemangioma.

Introduction

The diseases of the oral cavity comprise an important part of the pediatric specialty and in pediatric dentistry, yet many are misdiagnosed or left untreated because of less understanding, resources and parental education. Although the variety of lesions are usually confined to the oral cavity, they might provide certain clues to the underlying more serious systemic conditions. These may vary from physiological variations linked to development, to tumors. And majority of the diseases that manifest with oral features in the neonates being asymptomatic and benign, commonly resolve without any intervention. However, a thorough clinical examination and knowledge of the various lesions is essential for accurate diagnosis, management, as well as proper parental counseling.

BASIC CLASSIFICATION ON COMMON ORAL MUCOSAL LESIONS AMONG PEDIATRIC PATIENTS:

CYSTS

EPSTEIN PEARL

This is an non-odontogenic, keratin-filled cyst results from epithelial remnants entombed along the fusion line of the palatal halves, with no gender predilection. They are apparently entrapped epithelial remnants. They are smooth, whitish, keratin filled 1-4 mm papules. These are clinically asymptomatic and appear as nodules in the mid-palatal raphe region along the line of fusion. They resolve in the first 3 months hence treatment is not needed. Their incidence is 7.3/1000 live born male newborn babies \[1,2,3,4,5\].

GINGIVAL CYSTS OF NEWBORN/NEONATES:

Gingival cyst also called as Dental lamina cysts arise from remnants of dental lamina. The gingival cysts are frequently observed in newborns (13.8%) with no gender predilection. These asymptomatic, multiple, 1-3 mm, nodular, creamy white lesions present on the crest of dental ridges, sometimes appearing blanched as though from internal pressure \[6\]. Histopathology shows keratin-filled true epithelial cysts. These lesions are present on birth and are self-resolving hence do not require any intervention \[5\]. Prevalence ranges from 25-53\% \[7\].

BOHN’S NODULE:

Bohn’s nodules are remnants of minor salivary gland epithelium. They are keratin-filled cysts with prevalence of 47.4\% with no gender predilection. They are mostly asymptomatic, smooth, whitish keratin filled nodules or papules ranging from 1-3 millimeter arise on the buccal and lingual aspects of the ridge away from the midline \[6\], also present along the junction of the hard and soft palate as they are derivatives salivary gland structures \[8\]. They resolve in the first 3 months of life and have an Incidence of 47.4\% \[9\].

ERRUPTION CYST:

This soft tissue benign cyst arises around an erupting tooth when the dental follicle separates from the crown of tooth and results in fluid collection within this space \[10\]. The pathogenesis involves impediment of eruption by overlying dense fibrotic mucosa. Clinically they present dome shaped and may appear normal to blue-black, purple or brown in color subject to the amount of blood in the cystic fluid after trauma (hematomas), compressible swelling within the mucosa, overlying the erupting tooth. It may also be transparent. Since the tooth erupts through the lesion it resolves. Surgical opening of the roof of the cyst is indicated if it becomes infected or does not rupture. The prevalence of eruption cysts of is 22\% \[11,12\].

EPIDERMOID AND DERMOID CYST:

They are benign developmental disorder with an incidence of 7\% in the head and neck region and 1.6\% in the oral cavity. An epidermoid cyst is lined by epidermis where as a dermoid cyst is lined with adnexa glands. Surgical enucleation is the treatment of choice and recurrence is rare \[13\]. Treatment includes surgical enucleation. Recurrence is rare. \[14\]

LESIONS DUE TO TRAUMA

MUCOCELE:

Mucocoele common lesion in children and adolescents, that arises due to rupture in the minor salivary glands excretory duct, with subsequent leakage of mucin into the adjacent connective tissues that later may be surrounded in a fibrous capsule, occurring in approximately 2.7\% of patients under the age of one \[15\]. It can be of two types: Extravasation and retention mucoceles, the former affecting the lower lip most frequently. Extravasation type often affects the younger age group and results due to trauma \[16\].

Diagnosis can be confirmed by FNAB and histopathological evaluation. Conventional treatment includes surgical excision to minimize the risk of recurrence. \[17\]

RANULA:

Ranulas are a rarity in newborns, presenting as a swelling in the floor of the mouth and are commonly caused by extravasation of mucin than retention cyst. The incidence is estimated to be approximately 0.74\%. If the lesion is superficial, the mucosa may have a translucent bluish color \[6\]. Diagnosis can be arrived with the aid of FNAB, MRI, and histopathological assessment \[18\]. Treatment includes observation for asymptomatic cases, aspiration, cryosurgery, marsupialization, or surgical excision with or without sublingual gland depending upon the variant (cervical or plunging ranula) \[19\].

RIGA-FEDE DISEASE

Riga-Fede disease is a rare benign reactive mucosal
disease. The most common contributory factor is trauma due to the rubbing of natal or neonatal tooth during feeding on the ventral tongue surface, lip, gingival, vestibular mucosa, palate and floor of the mouth [20]. Clinically, the lesion appears ulcerated, unifocal/multifocal, and occasionally painful. Inability to diagnose and treat this lesion may result in dehydration and inadequate nutritional intake [21]. Treatment should be conservative and focus on creating round, smooth incisal edges. Alternatively extraction is the treatment of choice. Diagnosis is confirmed by clinical examination and histopathology to rule out bacterial, fungal infections, immunologic diseases, and neoplasia as causative factors for ulcers [22]. Prevalence of natal-neonatal teeth ranges from 1:6000 to 1:800 [23].

**BREASTFEEDING KERATOSIS:**

Breastfeeding Keratosis Recently, Kiat-Amnuay and Bouquot reported a case of breastfeeding keratosis, nonresponsive to antifungal drugs, in a 2-month-old child. It is a type of frictional keratosis from exuberant sucking in a breastfeeding infants. History elicited from parents revealed unusual habit of active lip sucking habit in-between the feeding sessions. Clinically it is a well-demarcated, nonsloughing, white, keratotic plaque of the lower lip mucosa, just inside the vermilion border. The plaque has an aslight irregular surface, had no surrounding erythema. Cytopathology revealed no mycotic structures. With diminution of habit, the lesion regressed by the 4th week with no recurrence. [24].

**INFECTIONS CAUSED MUCOSAL LESIONS**

**NEONATAL CANDIDIASIS:**

Neonatal Candidiasis Disseminated is the second most common cause of mortality with a reported incidence of 2 to 20% in preterm newborns. The transmission of Candida can be vertical or due to external contaminations [25]. The most common opportunistic Candida species include Candida albicans (75%) followed by Candida glabrata, Candida krusei, Candida tropicalis, and Candida parapsilosis. The risk factors comprise immature immune system, prolonged catheterization, prolonged hospital stay, etc. Oral manifestations include white plaques on oral mucosa, composed of hyphae, epithelial cells, and necrotic tissues [26]. The prominent systemic features include meningitis, urinary tract and cardiovascular infections. Diagnosis is confirmed by blood culture, urine and CSF. Treatment incorporates preventive measures [27].

**NEONATAL HERPES SIMPLEX VIRUS:**

Herpes simplex virus 1- (HSV)1 causes orolabial lesions. They are transmitted during parturition and depend on maternal infection (primary or recurrent), maternal antibody, intact mucocutaneous barriers, duration of membrane rupture and delivery [28]. The incidence ranges from 1 in 3,000 to 20,000 live births-cesarean or normal. The incubation period varies from 4 to 21 days after delivery, with symptoms appearing between 6 and 21 days. The eruptions commonly involve the mouth, scalp, face, soles of the feet, and palms of the hand. Characteristically, vesicular eruptions appear as single unit or in clusters, measuring about 1 to 3 mm in diameter, which often ulcerate within a few days [29]. Diagnostic modalities include serological tests, polymerase chain reaction amplification analysis of cerebrospinal fluid (CSF), and viral cultures. Treatment and prophylactic measures involve antiviral therapy with acyclovir [30].

**IMMUNOLOGICAL**

**NEONATAL PEMPHIGUS VULGARIS**

Neonatal pemphigus vulgaris is a rare autoimmune, vesiculobullous disease caused due to transmission of maternal immunoglobulin G auto antibodies which counter transmembrane glycoprotein desmoglein three. It manifests as multiple mucosal, cutaneous or mucocutaneous ulcerations after birth. These are intraepithelial blisters and are seen on soft palate, buccal mucosa, verutra surface of the tongue, gingiva and lower lip [31]. In more advanced stages desquamative or erosive gingivitis may be present. The other oral manifestations include sialorrhea, halitosis and brown or blackish crusts at the vermilion border. Symptoms resolve in 2 to 3 weeks and the diagnosis is confirmed by histopathology and immunofluorescence. The incidence is 0.68 cases per 1,00,000 persons per year [32].

**BENIGN NEOPLASM**

**HEMANGIOMA:**

This is a most common benign vascular neoplasm emerging as a macule on birth but may appear a few weeks after and regresses into spotted pigments. It appears on neck and head, trunk, extremities, lips, tongue, buccal mucosa, palate and uvula and has a
slight female predilection. Predisposing factors include infantile age, infant birth weight, childbearing age, gestational hypertension, Kasabach-Merritt syndrome [33]. Diagnosis is made by history, Fine-Needle Aspiration Cytology (FNAC), MRI, and/color doppler USG, histopathology, and immunohistochemistry ruling out other vascular malformations [34]. Treatment guidelines are based on the stage of the lesion and includes drugs (propranolol, corticosteroids, α-interferon), lasers (CO2, diode, flash lamp pulsed dye), and surgical corrections. Complete resolution occurs in 70% cases but around 40 to 50% of the cases show permanent changes in the skin, such as telangiectases, stippled scarring [35].

LYMPHANGIOMA:

Lymphangiommas are benign neoplasms of the lymphatic channels with 50% of cases noted at birth and 90% of cases developing before the age of 2. The prevalence is 1–3/10,000 live births, affecting both the genders equally, involving 75% of the head and neck region followed by trunk, abdomen, and extremities [36]. Treatment modalities include surgery, cryotherapy, electrocautery, sclerotherapy, steroids, embolization, and ligation, laser surgery (neodymium-doped yttrium aluminum garnet, CO2) and radiation therapy. Recurrence is high, 39% in case of tongue, followed by hypopharynx and larynx [37].

CONGENITAL EPULIS OF NEWBORN

Also called as Granular cell tumor (or) Neumann’s tumor is one of the rare benign tumors of oral cavity . It arises as gingival mucosal mass on the anterior maxillary ridge. The etiology is unclear hence the lesion is perhaps hormone related, degenerative or reactive The tumor shows a female predilection (8:1–10:1 ratio) [38]. The lesion occurs three times more commonly in the maxilla than mandible, frequently involving the alveolar ridge near the canine region. Clinical presentation includes a single and firm with a regular surface. It maybe multilobed, sessile or pedunculated, pink or red lesion not tender to palpation. The diameter varies from a few millimeters to over 7cm covered by a smooth normal/reddish mucosal surface [39]. Larger lesions cause mechanical obstruction in feeding and respiration in neonates. Diagnosis is confirmed by USG, CT/MRI, and histopathology, which appears similar to other granular cell tumors in adults, but is distinguished based on its exclusive origin from the neonatal gingiva, the scattered presence of odontogenic epithelium, lack of interstitial cells with angulate bodies, and the more elaborate vasculature. Treatment includes complete surgical excision with no reported cases of recurrence [40].

Malignant Neoplasm

In a 40-year review of solid malignant neoplasm in neonates by Hasen Xue et al, it was revealed that malignant neoplasms are extremely rare in newborns and involvement of oral tissues even rarer. The majority of cases involved head and neck followed by trunk and extremities. Oral cavity involvement was seen in only two cases: Malignant melanoma (hard palate) and spindle cell sarcoma (tongue) [41]. In another review of 60 years by Campbell et al, only one case of rhabdomyosarcoma (tongue) was observed. Such cases require prompt diagnosis and multimodal management for a diseasefree survival [42].

Conclusion

Neonates presenting with intraoral lesions mandate precise diagnosis, management, and parental reassurances and counseling. Hence management of oral pathology in neonates should encompass a thorough knowledge of various oral lesions and the ability to clinical and radiographic examination inclusive of any added investigation for precise diagnosis, prognosis, treatment outcomes and parental counseling.

Verrucous Carcinoma- A Case Report

Malathi.l¹, Masthan K.M.K², Rajesh E¹, Aravindha Babu²

¹Reader Dept of Oral Pathology, ²Professor & Head Dept of Oral Pathology Sree Balaji Dental College & Hospital, Bharath Institute Of Higher Education and Research

Abstract

Verrucous carcinoma is a variant of squamous cell carcinoma. It most typically affects the mouth with buccal mucous membrane being the most typical site affected. Clinically its proliferative finger like projections or a cauliflower like growth could be a typical feature towards diagnosis. It’s more common in tobacco user and more predilection in males. The histopathological diagnosis of verrucous carcinoma is quite difficult and need immense expertise to report a case of verrucous carcinoma. Though verrucous carcinoma is a benign lesion with minimum aggressive potential however long standing cases shows transformation into squamous cell carcinoma. Here in we discuss the clinical and histopathological finding of the case of 80 year old male patient with oral verrucous carcinoma on buccal sulcus as a differential diagnosis with possible etiology, management of the lesion.

Keywords - verrucous carcinoma, buccal mucosa, incisional biopsy, cauliflower like growth.

Introduction

Oral Verrucous carcinoma is a variant of squamous cell carcinoma which was 1st delineated by Lauren V Ackermann in 1948 therefore it was called ‘Verrucous malignant neoplastic disease of Ackermann” or “Ackermann’s Tumor”¹. Different names utilized in literature are Buschke-Loewenstein tumour, florid oral papillomatosis, epitheliomacuniculatum, and carcinoma cuniculatum². Common site of incidence is mouth, other sites being pyriform sinus, larynx, nasal cavity, esophagus, external auditory canal, paranasal sinuses, legs, scrotum, skin, perineum, penis, vulva, vagina, and uterine cervix³, 4. Oral verrucous carcinoma features a predilection for male in sixth decade with a slow growing rate and becomes regionally invasive if not treated properly. But, there is a rare distant metastasis⁶. Clinically, it is featured as a plaque like lesion with finger like projections resembling cauliflower⁵. Any type of Tobacco as smoking and smokeless type, alcohol and opportunist infective agent, infections are the foremost associated etiologies with Oral Verrucous Carcinoma⁶, 7. So early diagnosis and surgical excision of the lesion is the most appropriate treatment modality of verrucous carcinoma.

Case Report

An 80 year old male patient reported with a painful growth in the right buccal mucosa for the past 3 months. Patient had a habit of betel nut chewing since 40 years, 5-6 times/day. On general examination patient had normal gait posture, well oriented, moderately built and conscious. No evidence of icterus, pallor, cyanosis, clubbing was present. Single left submandibular lymph node was palpable and was firm, mobile and tender on palpation. Clinical intra oral examination revealed a soft growth of 2x1.5 cm in size, well defined with irregular invasive if not treated properly. But, there is a rare distant metastasis⁶. Clinically, it is featured as a plaque like lesion with finger like projections resembling cauliflower⁵. Any type of Tobacco as smoking and smokeless type, alcohol and opportunist infective agent, infections are the foremost associated etiologies with Oral Verrucous Carcinoma⁶, 7. So early diagnosis and surgical excision of the lesion is the most appropriate treatment modality of verrucous carcinoma.

biopsy was taken. The histological cut was performed and stained in hematoxylin and eosin. The hematoxylin and eosin stained histopathological section of the given specimen showed hyperplastic parakeratinized stratified squamous epithelium with underlying connective tissue stroma. Wide elongated reteridges are seen with pushing margins. Parakeratin plugging was seen(fig-1). Pseudoepitheliomatous hyperplasia was noticed (fig-2). The fibrous connective shows moderate cellularity and diffuse mild chronic inflammatory cell infiltrate with increased vascularity. Therefore, the histopathology diagnosis confirmed the diagnosis of verrucous carcinoma.

Discussion

Verrucous carcinoma, as mentioned most typically affects older male with adverse habits of tobacco and alcohol. Lesions usually develop at the location wherever the tobacco is placed habitually. In Ackerman’s study, eleven out of eighteen patients (61%) with squamous cell carcinoma of buccal mucosa were tobacco chewers. Other etiologic factors like poor dental hygiene, ill-fitting dentures, low socioeconomic status, tobacco chew, snuff, alcohol use, and smoking also causes verrucous carcinoma. Some of the similar factors that predispose people to the event of premalignant lesions like, submucous fibrosis (SMF), erythroplakia and leukoplakia. Untreated long standing leukoplakia has been reported to transform into Verrucous Carcinoma. Oral verrucous carcinoma are largely massive, exophytic, soft, and fungating growth with pebbly surface having regionally aggressive nature. Enlarge lymph nodes are typically palpable. Diagnosis of verrucous carcinoma histopathologically is quite difficult and needs expertise to diagnose.

The term “verrucous” was applied for lesions showing a exophytic keratotic surface composed of blunt or sharp epithelial projections with keratin-filled invaginations (plugging). The microscopic anatomy of Verrucous Carcinoma, for instance, verrucous surface and “elephant feet” like down growth superficial to compress the underlying connective tissue and usually showing least or absent cytologic atypia seen. By flow cytometry, Verrucous Carcinoma could be a diploid lesion; on the contrary, the traditional squamous cell cancer typically shows genomic instability and aneuploidy. As a result of its benign cytological features, besides the focal basal cell nuclear hyperchromatism, distinction from Verrucous carcinoma and verrucous hyperplasia (VH) can’t be primarily based solely on microscopic anatomy features. Differential diagnosis of verrucous carcinoma includes: (i) Proliferative verrucous leukoplakia, (ii) squamous cell carcinoma showing verrucoid feature (iii) verruca vulgaris (iv) keratoacanthoma. (v) Pseudoepitheliomatous hyperplasia. The simplest treatment modality of Verrucous Carcinoma is surgical resection. So, the patient is additionally suggested for surgical removal of the lesion and regular follow up. Although Verrucous Carcinoma doesn’t show distant metastasis, supra omohyoid neck dissection is usually considered as a result of its benign cytological features, besides the focal basal cell nuclear hyperchromatism, distinction from Verrucous carcinoma and verrucous hyperplasia (VH) can’t be primarily based solely on microscopic anatomy features. Differential diagnosis of verrucous carcinoma includes: (i) Proliferative verrucous leukoplakia, (ii) squamous cell carcinoma showing verrucoid feature (iii) verruca vulgaris (iv) keratoacanthoma. (v) Pseudoepitheliomatous hyperplasia. The simplest treatment modality of Verrucous Carcinoma is surgical resection. So, the patient is additionally suggested for surgical removal of the lesion and regular follow up. Although Verrucous Carcinoma doesn’t show distant metastasis, supra omohyoid neck dissection is usually considered as a result of the slow growth pattern surgical margins are compromised. The presence of carcinoma in place of clinically improper resections will lead to the development of recurrence of invasive cancer in apparently traditional epithelial tissue or previous excision sites. Radiation therapy is contraindicated in treatment of Verrucous Carcinoma as radiation induced anaplastic transformation.
Conclusion

In most of the cases verrucous hyperplasia, verrucous carcinoma, verrucous keratosis are clinically indistinguishable from each other. Thus histopathological proof is important to allow an acceptable diagnosis. Verrucous carcinoma presents as thick verrucous keratotic lesion that is additional common in males and is typically painless. Verrucous Carcinoma related to leukoplakia or submucous fibrosis is also a sign of “field cancerization” and might cause multiple recurrences, therefore it’s extremely suggestive, that such patients should be kept under regular follow up.

ODONTOPHOBIA is dental anxiety. Often people have an extreme level of anxiety from dental visits and treatment practices carried over by dental surgeons. It may arise from their past painful experiences while visiting the dentist. Due to their extreme fear or odontophobia the patients’ oral health are hampered largely. Not only the patients avoid getting treated from dentists but finds all sorts of bizarre excuses for being spared from the same. This mainly happens due to lack of proper knowledge or awareness regarding the dental field or proper desensitization in their early childhood when fear and anxiety were seeding inside. This review literature, will shed some light on various factors associated with anxiety as well as proper management of the same. A thorough knowledge in this field will not only help the dentists to understand their patients but also motivate the patients towards dental treatment.

Keywords: Dental anxiety, conditioning pathway, vicarious pathway, informative pathway, verbal threat pathway, parental pathway, Cognitive behavioral therapy.

Introduction

The term odontophobia is often called as Dental Fear or Dental phobia or Dentist Phobia or Dental Anxiety. This is considered as multidimensional complex phenomenon and no single variable is responsible for its development. It is a unique phobia with some special psychosomatic components that impact on the dental health of odontophobic persons. For some individuals the fear is so great that normal life is impaired. Most of the time individual experiences fear and anxiety which is out of proportion than actual danger present in the situation. This often leads to avoidance behaviour. The incidence of fear and anxiety consistent throughout the world. According to Diagnostic and Statistical Manual Of Mental Disorders (DSM-IV) criteria for Dental phobia, is a marked and persistent fear of clearly discernible circumscribed objects or situations. In most of the studies it is seen people from low socioeconomic classes are prone to dental anxiety more than that of higher socioeconomic classes. Women show more dental anxiety than male also children reported more anxious than adults. These psychosomatic factors relating dental procedures affects their attitudes behaviour and practice. Thus in this group of individual it is seen that not only they avoid dental treatment but also tend to have poor oral health. Since dental practices not only depends upon the techniques applied or the technical skills of dental professionals but also on patients, their attitudes and behaviour, these psychological issues and misconceptions can disrupt the harmonious relationship between dentists and patients. Thus understanding the factors behind the etiology of such withdrawal behaviour may help the dentists as well as researchers with coming up new interventions that may reduce dental avoidance behaviour.

Signs & Symptoms of Odontophobia

This type is categorized under special phobia according to DSM-IV. In DSM-IV it has stated that an intense irrational fear of dentists or receiving dental care
Dental anxieties are generally associated with personality types and one’s susceptibility towards anxiety rather than being a part of a precious painful dental treatment (4). Exposure, observations even sometimes thoughts of it causes an immediate anxiety reaction. Following are the symptoms and signs of odontophobia: Profuse sweating, Hyperventilation, High blood pressure, Feeling of terror, Rapid heartbeat, Nausea, Irrational fear of teeth, Panic attacks, Shortness of breath, Dry mouth, Anxiety, Trembling.

PATHWAYS OF FEAR

5 pathways that are thought to specifically relate to dental fear and anxiety: Cognitive Conditioning, Vicarious, Verbal Threat, Informative, and Parental.

CONDITIONING PATHWAY: Conditioning is a process where the participant learns through personal experience that the event or stimulus heralds a detrimental outcome (5,6). In 1927 Pavlov published his seminar paper on conditioned reflexes where he showed animals can learn to associate a conditioned stimulus with a new non-conditioned stimulus so that non-conditioned stimuli cause a conditioned response. Here, the animal (dog) began to associate food and salivating with the sound bell, thus anytime the bell sounds he will start to salivate (7). In a similar attempt to correlate physiological responses with fear, Rachman (8) in 1975 successfully demonstrated that responses like sweating, increased heart rate occur when individuals experience fear are evident with odontophobia that is whenever patients come in contact with dental environment (9, 10-12). In summary, the conditioning pathway appears to be the most commonly utilized pathway by patients.

INFORMATIVE PATHWAY: The informative pathway is another indirect pathway for fear acquisition, which does not require the presence of an unconditioned stimulus. As far back as 1977, studies (13) noted that the instructional process of child rearing may lead to biases for commonly encountered fears. Children learn to fear the dental environment from dental phobic elders, negative connotations advertised by media (e.g., television, movies), and friends with personal negative experiences.

VICARIOUS PATHWAY: The vicarious pathway is an indirect pathway for fear acquisition that does not require the presence of an unconditioned stimulus. Studies suggested that fears can be socially transmitted, either vicariously (observationally) or via information, without an individual directly experiencing trauma themselves (13). Although it is well accepted that fears can be acquired by observing others responding fearfully to a particular stimulus (e.g., Bandura, 1969), there is little research on whether children can acquire fears in this way. In adults, the majority of evidence for vicarious learning of clinical fears comes from questionnaire studies that require phobic individuals to retrospectively attribute their fear to direct conditioning, verbal information, or vicarious learning (14).

VERBAL THREAT PATHWAY: The verbal threat pathway presents another indirect pathway for fear acquisition that does not require the presence of an unconditioned stimulus. To explain the origin of a fear that is not seen or experienced, it is essential to understand the “emotion” of fear. This “emotion” is known as the “tripartite,” and appears to govern onset and origin of fears generated by the verbal threat pathway (15-19). Many articles examining the effects that “word of mouth” made the children become fearful of a stimulus or situation when they hear or read that it may be dangerous. Through various studies it is found out that self-reported fears increase as children were given violent/dangerous/threatening information about a particular stimulus, irrespective of its actual threat (17, 18, 20-22) by an adult. Simultaneously, it has been found that giving positive information results in a decrease in children’s self-reported fear (23, 24). In short, one interpretation of the verbal threat pathway is that fear is induced when an authority figure threatens an individual with a painful experience. In the case of dental fear, painful and/or negative experiences are linked to dental visits. A “visit to the dentist” is literally used as a form of punishment for bad behavior.

PARENTAL PATHWAY: The parental modeling pathway presents another indirect pathway for fear acquisition that does not require an Unconditioned Stimulus. The concept of parental modeling is supported by research (25) which demonstrates a sample of 40 children between the ages of 9 and 12 years, where children’s fear was directly related to their mother’s dental fear. Specifically, mothers who expressed heightened levels of fear in front of their children were more likely to have fearful children.
DIAGNOSIS AND TREATMENT OF ODONTOPHOBIA:

Dental phobia can be diagnosed using standardized scales such as Corah’s Modified Dental Anxiety Scale.

So prior to any appointment of such patients dental practitioners should take initiative to take care of some psychological aspects in his/her mind in order to carry on a successful dental treatment. A visit of psychologists are generally required to deal these type of patients and to motivate them to undergo the procedure thereby reducing the fear.Certain Anxiety treatments for phobias like a) Relaxation technique, b) Systemic desensitization c) Cognitive behavioral therapy, d) Modelling techniques. Brief detail are as follows:

RELAXATION TECHNIQUES: With increased incidence of odontophobias nowadays many dental practitioners arranging therapist session with the patients, where one to one interactions takes place between trained psychiatrist and patient. They are motivated in different ways and guided to control their fear & anxiety regarding dental environment. This is based on the principle of exposure and gradual desensitization. With increasing number of sessions amount of exposure is raised gradually. In this way patient learns to tolerate dental anxiety stimulated by the exposure of dental services with the help of relaxation techniques.

SYSTEMIC DESENSITIZATION: This behavioral technique was developed by Joseph Wolpe in 1958 for treatment of anxiety disorders including phobias. The process of systemic desensitization undertakes a gradual process of reducing a person’s anxiety towards a particular stimulus. This treatment can be administered in various settings, it has three basic steps:

STEP 1: Patients asked to imagine pleasurable things, do calming breathing exercises, meditation or any other type of muscle relaxation techniques

STEP 2: Patients are asked to formulate a list of imaginative phobic situations, rate each of them from 100 to 0 level of anxiety felt by the patients. After that the list used by therapist and patient to construct an anxiety hierarchy.

STEP 3: Once the person learns to efficiently master the relaxation techniques and has constructed the hierarchy of anxiety, in this final step therapist administers various treatments and asks the patient to slowly move the imaginary anxiety hierarchy, starting with least anxiety-provoking situations and associating the situation with the learned relaxation techniques. This is known as Counter Conditioning.

COGNITIVE BEHAVIORAL THERAPY (CBT): Psychological treatment used for mood and anxiety disorders as well as phobias. This therapy includes the reformation of maladaptive thoughts and beliefs acquired by the person about some particular things. It is very helpful in dentistry and to overcome dental fear or odontophobia. The cognitive components of the therapy examines the person’s thoughts and patterns of thinking and focuses on reducing those by cutting down the negative emotions and actions that are build up from those.

MODELLING: Developed by Albert Bandura. In this technique the person observes others (models) and learns from them how to face phobic situations without getting afraid and relaxed. In this way the patient learns to encounter the phobic situations.

PHARMACOLOGICAL: The use of nitrous oxides and benzodiazepines has long been used to reduce anxiety.

HYPNOTHERAPY: Perhaps one of the least understood treatments for dental fear is hypnotherapy (HT). HT attempts to create a state of unconscious change, whereby the individual forms new responses, attitudes, and behaviors to previously feared stimuli. Few studies have analyzed the clinical effectiveness of hypnotherapy. In 1995, research reported that when compared to psychophysiological therapies such as CBT, HT did not significantly reduce dental fear.

RECENT ADVANCES: COMPUTER ASSISTED RELAXATION LEARNING

A recent development in the treatment of dental fear, computer assisted relaxation learning (CARL) is a self-paced treatment for dental phobic individuals for treating needing phobia. The program begins with introducing
its purpose, followed by activities and videos on how to cope with their fear. This program is based on theory on Systemic Desensitization. In recent study on 2013 researchers stated that CARL significantly reduce self-reported general and injection-specific dental anxiety.

Conclusion

In this article different types of fear their psychological factors and their origin in dentistry along with management have been discussed. This psychological review would help dental practitioners to get an clear idea about the psychological state of this specific category of patients and the amount of stress they undergo in presence of dental stimuli. The techniques for management discussed here can be used in day to day dental practise to ensure proper painless treatment to the patient. It will also help the patients to improve their oral health by visiting a dentist on regular basis which will in turn improve their physical health too without having dental anxiety.

Prophecy of Orofacial Diseases with the Help of Amniotic Fluid

N. Aravindha Babu, R. Jayasri Krupa, K. M. K. Masthan, F. Gulshan

1 Professor, 2 Reader, 3 Head of the Department, 4 Post Graduate Student, Department of Oral Pathology & Microbiology, Sree Balaji Dental College, Chennai, BIHER

Abstract

Amniotic fluid is a yellowish clear fluid that protects the fetus in the uterus. Amniotic fluid forms an accepted physical barrier against fetal trauma and defense against fetal infection. Amniocentesis is primarily used to detect birth defects in an unborn baby. The other invasive techniques such as chorionic villus sampling, percutaneous umbilical blood sampling, fetoscopy. Orofacial disease, neural tube defects and various syndromes can be detected by this procedure. This diagnosis helps us to know about the defects thereby giving choice of possible treatments, terminating or continuing the pregnancy.

Keywords: Amniotic fluid, Amniocentesis, Placenta, Micrognathia

Introduction

Amniotic sac is a bag in which amniotic fluid is present. This fluid provides room for fetal growth, movement and development. The fetal pulmonary development takes place around 20 weeks. The fluid protects the fetus from trauma and maintains the temperature. Amniotic fluid also aids in the dilatation of cervix during labor. The volume of amniotic fluid raises in accordance to the gestational weeks. About 500 ml of amniotic fluid enter and leave the amniotic sac each hour. The volume increases up to 1000 ml at about 28 weeks of gestation and then gradually decreases. The condition in which there is reduced amount of fluid is termed as Oligohydramnios. The condition in which there is increased amount of amniotic fluid of about 2000 ml or more is termed as Polyhydramnios. Low levels of amniotic fluid would be due to underproduction, loss or it can be idiopathic. Underproduction can be the result of absent or dysfunctional kidneys, urinary tract obstruction, abnormal placental function, or maternal dehydration. Elevated amniotic fluid is due to decreased absorption, overproduction or idiopathic. Decreased absorption typically results from failure of fetal swallowing from etiologies such as tracheal atresia, tracheal or bowel obstruction, or neurologic abnormalities such as Anencephaly, Chromosomal abnormalities, Non-immune Hydrops, and Diabetes mellitus can also be reasons for polyhydramnios1.

Objectives

The main objective of the prenatal diagnosis is to provide information about the presence or absence of genetic disease and malformations thus reducing anxiety among high risk groups. Some of the diseases for which prenatal diagnosis available includes congenital malformation, chromosomal disease, non-genetic fetal disease, multiple malformation syndrome, metabolic disorder, neuromuscular disorder and hematological disorder. There are invasive and non-invasive techniques. The non-invasive methods include Ultrasound, Fetal cell detection in maternal circulation and Magnetic Resonance Imaging. The invasive methods include Amniocentesis, Chorionic villus sampling, Peri-
implantation genetic diagnosis.

**Amniocentesis**

Amniocentesis is a procedure in which the amniotic fluid is withdrawn with a needle and is sent to the laboratory for genetic testing. The cells shed from skin of fetus and float in the amniotic fluid. Genetic amniocentesis is usually done between 15 and 20 weeks of pregnancy. Amniocentesis done before 15 weeks has been associated with higher rate of complications. A 22 gauge long needle is inserted through uterine wall into the fluid filled space. Approximately 20 ml of amniotic fluid is withdrawn which is being aided by ultrasound to avoid injury to the fetus. The fluid which is withdrawn is sent for culture in which the procedure takes place in an incubator. Various tests are being performed in the cultured cells like chemical analysis, DNA analysis and chromosomal analysis.

### Amniocentesis procedure

**AMNIOCENTESIS PROCEDURE**

- The prenatal diagnosis is indicated in the following conditions
- Advanced maternal age of above 35 years.
- Chromosomal abnormalities in previous pregnancies.
- Rhesus sensitization.
- Consanguineous marriage.
- Elevated levels of AFP (alpha fetoprotein) in blood.
- Abnormal parental karyotyping.
- Genetic testing.
- Endocrine disorder.
- Infection and parasitic disease during pregnancy.
- Fetal therapy
- Lung maturity.

### Complications:
- Maternal complications are rare. The Ultrasound guidance has minimized the risk of fetal injury.
- Miscarriage may happen which is expected to be less than 1%.
- Needle injury are rare.
- Soreness may occur at the injury site
- Mild cramping and spotting may also be seen.

### Other Invasive Method

1. **Chorionic Villus Sampling:** Involves sampling and culturing of the chorionic villi (ideally 10 to 20 mg), that make up part of the placenta providing information about foetal genetic and chromosomal status (via karyotyping and In Situ Hybridization), and is done between 10 to 12 weeks of gestation, thus providing earlier and more than 99% accurate results. It can be done either trans-cervically or trans-abdominally, using ultrasonography guidance.

2. **Percutaneous Umbilical Blood Sampling (PUBS):** It is used when rapid chromosome analysis is needed, particularly toward the end of pregnancy, when ultrasonography has detected abnormality in the foetus pointing to a chromosomal abnormality. However, usually it is performed after 19 to 20 weeks of gestation.

3. **Fetoscopy:** It is an endoscopic procedure performed trans-abdominally during or after the 18th week of pregnancy, allowing access to the foetus, the amniotic cavity, the umbilical cord, and the foetal side of the placenta. It is used to evaluate the foetus for birth defects, such as spina bifida, and collection of blood sample from the umbilical cord, which is then analyzed in the laboratory for genetic or chromosomal disorders.

### Orofacial Diseases Diagnosed by Amniocentesis

The orofacial disease commonly diagnosed by
The manifestations include low birth weight, Clubbed feet, Micrognathia, Cleft lip and palate. Due to the medical problems associated with Edward syndrome, most babies affected will die before the end of pregnancy or are stillborn. Around 5-10% of the babies born alive with Edwards syndrome live longer than one year. These children often have a severe intellectual disability and may require specialized nursing support.  

Edward syndrome

- Cru di chat syndrome: It is also known as 5p syndrome. It is a genetic condition that is caused by deletion of genetic material on small areas of chromosome 5. Although it is a well-defined genomic disorder, individuals with this syndrome show phenotypic and cytogenetic variability. The manifestations include low birth weight, severe cognitive speech, motor disabilities, Microcephaly, Micrognathia, Hypertelorism and flat nasal bridge. Other abnormalities include Cystic hygroma, Epignathus, Myoblastoma. Metabolic disorders like Hurler syndrome, Hunter syndrome, Gauchers disease, Maple syrup disease. Malformations, although not very frequent, may be present includes Cardiac, Neurological and Renal abnormalities, Preauricular tags, Syndactyly, Hypospadias, and Cryptorchidism.

Cru di chat syndrome

- Down syndrome: It is also called trisomy 21. Down syndrome is one of the most common birth defects that causes severe developmental delay, distinct facial features and cardiac manifestations. The manifestations include oblique eye fissures, flat nasal bridge, Micrognathia, Microdontia, Macroglossia and Fissured tongue. Excessive joint laxity and low IQ.

Down syndrome

- Cleft lip and palate: Cleft lip occurs 1 in every 600 live births. It is a common birth condition occurring alone or as a part of genetic condition or syndrome. Clefts of the lip and/or palate (CLP) are common birth defects of complex etiology. CLP can occur in isolation or as part of a broad range of Chromosomal, Mendelian or Teratogenic syndromes. Although there has been marked progress in identifying genetic and environmental triggers for syndromic CLP, the etiology of the more common nonsyndromic (isolated) forms remains poorly characterized. The manifestations include Speech disorder, Feeding problems, Physical deformity, Hearing loss, Nasal congestion or snoring.

Cleft lip and palate

- Edward syndrome: It is also called as trisomy 18. It is a condition causing severe developmental delay due to an extra chromosomes 18.
• Patau syndrome: It is also called as trisomy 13. A condition in which person has an extra chromosome 13. It is a heterogenous disorder encompassing multiple malformations including central nervous system, cardiac and urogenital anomalies\textsuperscript{10}. The manifestations includessevere Craniosynostosis, Craniofacial abnormalities, Symmetric syndactyly of hands and feet, Cleft lip and palate, Micrognathia, Prominent bilateral cleft lip.

**Patau syndrome**

![Image of a baby with Patau syndrome](image)

**Conclusion**

The rise of amniocentesis as a tool for accurate prenatal diagnosis has made it possible to identify many orofacial genetic disorders and treat few of them. Invasive and Non-invasive prenatal diagnosis has been a great tool in detection of various syndromic conditions. It has evolved as a boom to the recent prenatal screening thus reducing the threat of birth of syndromic children and other complications.

Abstract

Hormonal variations in different stages of women’s life have a pronounced influence on oral health. Fluctuating levels of sex hormones (estrogen, progesterone and androgen) during different life stages in women such as puberty, menstruation, pregnancy, menopause has a direct and indirect effect on oral health. Alterations in the subgingival microflora, salivary flow, gingival crevicular fluid, epithelial keratinisation and bone are noticed when there is a change in the hormonal levels. Steroid sex hormones have its effects mainly on periodontal and gingival health. This review article focuses the influence of sex hormones in the various reproductive cycles of women on oral health.

Keywords: Hormones, Oral, Estrogen, Menopause, Menstruation, Pregnancy

Introduction

Female life are characterized by vast changes in reproductive hormones which result in significant changes throughout the body including oral cavity. Hormonal fluctuations during puberty, menstruation, pregnancy and menopause influence a woman’s oral health. Increased and decreased sex hormones also have an effect on oral health. Localization of estrogen receptor and progesterone receptor has been reported in the human periodontium. This demonstrates the significant influence of estrogen and progesterone on the periodontium. Steroid sex hormones (androgens, estrogens, and progesterone) have an effect on cellular growth, proliferation, and differentiation of keratinocytes and fibroblasts in the gingiva. The review discusses the diverse oral presentations by the effects of various hormones at varying stages of a woman’s life cycle.

Sex hormones and oral health

Androgen: Androgen contribute to the growth and reproduction in both men and women. Female body produces a small amount of androgen. In women, the androgens are converted into either testosterone or estrogen by the ovary. Testosterone receptors are identified in periodontal tissues. The receptors on the fibroblast tend to rise in inflamed gingiva. Testosterone inhibits the effects on cyclooxygenase pathway of arachidonic acid metabolism in gingiva inhibiting prostaglandin secretion. It increases matrix synthesis of fibroblasts and osteoblasts by periodontal ligament.

Estrogen: Estradiol (a most potent estrogen) and esterone is secreted by ovary. Estradiol is the physiological estrogen which is more abundant in premenopausal women. Receptors for estrogen are identified in gingiva, periosteal and periodontal ligament fibroblasts and osteoblasts. Estrogen reduces osteoclastic activity and it induces apoptosis. In menopause where a minimal level of estrogen is detected systemic bone loss is seen. Frequency of bone loss in postmenopausal stage anticipate tooth loss. Estrogen deficiency causes upregulation of immune cells, and osteoclast leading to increased production bone-resorbing cytokines.

Progesterone: Progesterone is secreted by placenta, corpus luteum and adrenal cortex and is active in bone metabolism. Progesterone increases the production of prostaglandins and inhibits proliferation of gingival fibroblasts. It alters the rate and pattern of collagen production in gingiva followed by reduction in repair and maintenance potential.

Women’s reproductive life cycle and oral health

Puberty:

Increased prevalence of gingivitis can be correlated...
during puberty. Puberty gingivitis characterised clinically by the presence of inflammation of the facial and marginal gingiva sometimes extending to involve the attached gingiva and interdental papillae. In subgingival microflora, there is a higher incidence of black pigmented bacteriodes and gram-negative rods when compared with healthy sulci in puberty. There is an increase in a particular species such as *Spirochetes*, *Capnocytophagia*, *Actinomycetes* and *Eikenellacorrodens*. *Capnocytophagia* have been associated with increased bleeding. There is an absence of attachment loss and bone loss associated with puberty gingivitis. This gingivitis is reversible following puberty.

Menstruation:

The menstrual cycle is a 25-30 day period controlled by the secretion of sex hormones which has a responsibility of continued ovulation till menopause. Muhelmann was the first person to report gingival changes during menstrual cycle. He coined the term “gingivitis intermenstrualis” to describe a condition of bright red hemorrhagic lesions in the interdental papilla. Increased sex hormones during menstrual cycle moderates the development of localised gingival inflammation. Some women experience oral changes due to monthly fluctuation of hormones, that include bright red hypertrophic gingiva and salivary glands, canker sores or gingival bleeding. This condition is termed as menstruation gingivitis, occurring a day or two before the start of period and clears up after period has started. Exudates from inflamed gingiva is elevated during menstruation suggesting aggravation of existing gingivitis. Other oral changes are burning sensation, recurrent oral ulcers and herpes labialis and infections with Candida albicans had been reported. This has been attributed to alterations in immune response.

Pregnancy:

Progesterone and estrogen are elevated during pregnancy due to the continuous production of hormones by corpus luteum. Pinard (1877) recorded the first case of pregnancy gingivitis. Increased level of progesterone causes gingival diseases during 8th month of pregnancy, a condition called pregnancy gingivitis. Pronounced inflammatory response of gingiva, bleeding upon provocation and increase in gingival exudate are characteristics of pregnancy gingivitis. Pregnancy associated pyogenic granuloma (Granuloma gravidarum) can also occur anytime during pregnancy. It is sessile or pedunculated protuberant mass more commonly seen in interproximal area of maxilla. These changes are reversible following parturition. During pregnancy estrogen, progesterone and chorionic gonadotropin affect microcirculatory system by causing swelling of endothelial cells and pericytes of the venules, increased vascular permeability, and vascular proliferation.

Periodontal infection increases during early gestation due to alterations in immune system which is due to the hormonal changes during pregnancy. Increased number of *P. gingivalis* and *P. intermedia* (periodontopathogens) are noted. Periodontal infection is associated with adverse pregnancy outcomes. Researchers suggest that maternal periodontitis has been associated adverse pregnancy outcomes such as preeclampsia, gestational diabetes and fetal loss. The increased risk also suggests that periodontitis may be an independent risk factor for adverse pregnancy.

Menopause:

Menopause is the physiological process occurring in fifth decade life of a woman. As a consequence of advanced age, numerous oral changes occurs in menopause. It includes altered taste and burning sensation in mouth, greater sensitivity to hot and cold foods and beverages, decreased salivary flow resulting in dry mouth. Burning pain, most commonly involves the anterior two-thirds, dorsum, lateral borders of the tongue, anterior hard palate and mucosa of the lower lip. Burning mouth syndrome is most commonly reported by the perimenopausal women. Oral mucosal changes differs from atrophic pale appearance to menopausal gingivostomatitis, characterised by dry and shiny gingiva which bleeds easily and reduction in flow of saliva. Xerostomia occurs in 25% to 50% of women. Reduction in flow rate occurs due to decrease in the level of estrogen at the menopausal stage in women. Persistent sensation of dry mouth is experienced by menopausal and postmenopausal women. Decrease in salivary flow is responsible for increase in caries, candidiasis, plaque formation which in turn cause gingivitis and periodontitis. Association between psychological symptoms in menopausal women and oral discomfort is one of the reason for altered salivary flow indicating psychological stress. Other possible disease are oral candidiasis, pernicious anemia and nutritional
disorders. Decline in estrogen during menopause frames a greater risk for bone loss leading to osteoporosis and periodontitis. Postmenopausal women lose 30% to 50% of trabecular bone and 25% to 35% of cortical bone mass that was present between the age of 20 and 30 years. Alterations in the sex hormones during menopause is considered to be a factor for inflammatory changes in gingiva. Hormone receptors are identified in the basal and spinous layer of the epithelium and connective tissue. In perimenopausal women, the incidence of Oral lichen planus is higher than in general population and increases significantly the severity of depression. Lichen planus can be mediated by declined level of estrogen and progesterone directly or indirectly. Trigeminal neuralgia is observed frequently due to compression of branches of trigeminal nerve. It is characterised by searing, stabbing or lancinating pain in the middle and lower third of face. Other neurological disorders such as atypical facial pain / neuralgia and Alzheimer’s disease affect postmenopausal women. Menopausal women also suffer from erosion of enamel, perimolysis, enlarged parotid glands, angular chelitis, dehydration and bulimia.

Conclusion

Fluctuations in sex steroid hormones have a major impact on women’s oral health. The various phases in the reproductive lifecycle of women such as puberty, menstruation, pregnancy and menopause influences women’s oral health. It is of prime importance that dental care professionals are aware of these gender-specific oral health concerns. The addition of periodontal care with obstetric management may improve pregnancy outcomes. It is vital that clinicians consider periodontal care as an integral component of prenatal care. Recognition that women of different ages have specific oral health concerns will likely lead to improved oral health status in women of all stages.

Role of Chemotherapy and Radiotherapy in Salivary Gland Neoplasms

N.Anitha1, N. Aravindha Babu2, E.Rajesh1, G. Nishanth3

1Reader, 2Professor, 3Post Graduate Student, Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, BIHER

Abstract

Oral cancer is the second most common cancer in India. Salivary gland tumors are rare and have very wide histological heterogeneity, thus making difficult to generate high level evidence. The major salivary glands are parotid, submandibular and sublingual glands. A wide variety of conditions including obstructive, infectious, autoimmune and neoplastic pathologies affects salivary glands. In this review clinical features, investigations, chemotherapy and radiotherapy are included and mainly focuses the management approaches. Surgical management being ideal for salivary gland neoplasms, radiotherapy and chemotherapy also give hand for better treatment outcomes. The choice of radiotherapy and chemotherapy depends upon the grade and stage of the disease. The treatment plan differs for each case and we had highlighted the common treatment protocols that can be followed for salivary gland malignancies.

Keywords: Chemotherapy, Radiotherapy, Salivary gland tumors.

Introduction

Salivary glands are exocrine glands in mammals that produce saliva and acts as a primary barrier for oral health [1]. Neoplasm is defined as ‘A neoplasm is an abnormal mass of tissue, the growth of which exceeds and is uncoordinated with that of the normal tissues, and persists in the same excessive manner after cessation of the stimulus which evoked the change’[2]. Oral cancer is the second most common cancer in India accounting for 40% of all cancers. Salivary gland malignancies are less common and represents approximately 5% of all head and neck cancers [3]. We are aware of the role of chemotherapy and radiotherapy in squamous cell carcinomas, but have limited knowledge of their implementation in salivary gland malignancies. It is important to know about the treatment options so that clear cut treatment modalities can be framed for different salivary gland tumors [4].

Clinical Features

Parotid gland is most commonly involved in salivary gland neoplasms. Malignant tumors of salivary gland shows different patterns. The most common tumors are Adenoid cystic carcinoma, Mucoepidermoid carcinoma and Acinic cell carcinoma. About 64-80% are located in parotid (common in superficial lobe), 7-11% in submandibular glands and reminder being distributed between the sublingual (1%) and the minor salivary glands(9-23%) [3]. Clinically the malignant tumors will present with rapid rate of growth, facial nerve involvement and cervical lymphadenopathy. Common sites of distant metastases are the lungs, bone and liver [4]. The annual incidence of salivary gland neoplasm ranges from 1.5 to 4.0 per 100000 in different parts of the world [5]. Surgery is the initial treatment for salivary gland malignancies [4]. But for high grade tumors surgery alone is not sufficient for complete resolution. Radiotherapy in patients with high risks improves the locoregional control in selective patients [6].

Investigations

The diagnosis of salivary neoplasms is essential to proceed with treatment[4]. Fine needle aspiration cytology and core biopsy are the investigative techniques, with accuracy ranging from 87% to 96% for FNAC but the risk of seeding tumor cells is negligible.
Ultrasound guided core biopsy of salivary gland, especially the parotid gland tumors is very useful in the tissue diagnosis where we cannot get conclusive diagnosis from the FNAC alone[4]. Ultrasound guided core biopsy is done under local anaesthesia by using 18-20G needle [7]. It has 100% diagnostic appearance and we can do Immunohistochemistry thus avoiding unnecessary open biopsies [8]. For small tumor masses of salivary gland, punch biopsies can be done [9]. Frozen section is another investigation and it needs experienced pathologists to avoid false reports. The major advantage in this is for benign tumors the accuracy rate is 98.7% [10]. Ultrasonography can compliment these investigation and less expensive with accuracy rate of 100% [8].

CT and MRI can be done for malignant tumors or when deeper parotid lobe lesion is suspected. MRI is particularly recommended for demonstrating the interface of tumor and surrounding tissues especially the facial nerve when parotid gland is involved [4]. The advantage of MRI includes elimination of dental artifacts and the ability to distinguish between a tumor and obstructed secretion [8].

Management:

Surgical excision is the first line of management for salivary gland neoplasm. Surgical management of primary tumor is by wide margin excision. Clinically high grade of tumors should be managed with excision of the gland plus 2 cm margin of apparently healthy tissue [10]. Primary radiotherapy may be applicable in operable patients were palliation can be achieved. The role of heavy ions such as proton and carbon ion therapy is being explored and is as yet resolved [3].

Chemotherapy plays a palliative role. Integration between radiotherapy and chemotherapy provides increased local control of tumor. In advanced metastatic carcinomas there are few cases which was treated with a chemotherapeutic agent. Cisplatin is considered as a back bone of polychemotherapeutic regimes. The most commonly used regime for squamous cell carcinoma is cisplatin and fluorouracil. Mean duration of complete response for the drug is 7 to 18 month[11] and relapsed disease cisplatin, antracycline, paclitaxel and vinorelbine are the most effective agents. But combined therapy was more toxic than individual chemotherapy agents [12]. In salivary gland tumors of advanced stage or metastatic carcinomas, chemotherapeutic agents were used in few cases. For malignant salivary gland tumors such as mucoepidermoid carcinoma and adenocarcinoma Taxol is found to be effective. Combination of carboplatin and taxol given among 14 patients in a study showed 2 partial responses and stabilized disease in 7 patients. Whereas combined cisplatin, adriamycin and cyclophosphamide showed total response rate between 27% and 50%. The protocol cisplatin, adriamycin or epirubicin and with flurouracil had total response between 37% and 47% when compared to combination of cisplatin, bleomycin, adriamycin/VP-16. [13].

Recent studies have evaluated the molecular targets in salivary gland tumors and these chemotherapy drugs have achieved response rates between 6% to 20% and stable diseases of 25-40% cases. It was identified as C-Kit is tyrosine kinase receptors plays an important role in development of haematopoietic cells, melanocytes and germ cells which is expressed more in salivary gland neoplasms. Inhibitors of anomalous tyrosine kinase have been identified as Imatinib [14].

Epidermal growth factor is an important mediator of cell growth, cell differentiation and survival. In salivary gland tumors these factors are also increased and cetuximab is the drug of choice for this abnormality[15].

In a retrospective study various chemotherapeutic drugs or targeted drugs such as adruamycin, carboplatin, methotrexate, docetaxel, bacilli calmett Guerin were offered for patients with distant metastasis. However the survival rates are same as without chemotherapy (35.2% vs 27.6% respectively [16].

A review of systematic therapy in the management of distant metastasis of salivary gland tumors by Lagha et al showed that the most effective chemotherapeutic agent seems to be platinum, 5-Fluorouracil and Anthracyclines, and recommended that symptomatic locally recurrent or metastatic patients adapt platinum combined with doxorubicin to maximize the likehood of a response and for cases of slow disease progression and asymptomatic patients, a single agent therapy is sufficient. Adjuvant chemotherapy has no proven role in the treatment [16]. Chemotherapy in most of the studies elected to the meta-analysis was done a palliative intent[17].

Radiation therapy is considered as ideal treatment modality for salivary gland tumors and used as both curative and palliative methodology [18]. The parotid
salivary gland consist purely of the serous gland are the most sensitive compared to the submandibular glands from a clinical perspective \(^{(19)}\). The radio sensitivity of the parotid salivary glands may be because they contain heavy metal granules. During treatment, the ionizing radiation causes the destruction of the metal granules by means of a metal-catalyzed induction of lipid peroxidation causing release of lytic enzymes into the cell’s cytoplasm, hence autolysis of cells are evident. The ionizing radiation causes the salivary glands to undergo structural degradation and eventual death of the affected cell \(^{(20)}\). Atri et al found that dose tolerance of the salivary glands varied between 32 Gy and 46 Gy. However, the curative dose of head and neck tumors may rise to 60 Gy or more. This value is more than the dose tolerance range of the salivary glands. Above the dose tolerance range of the salivary glands may lead to permanent injury and dysfunction of the salivary glands and causes xerostomia \(^{(21)}\). Despite the knowledge that the degree of injury of the salivary glands is dose related the mechanism behind the destruction of salivary gland by ionizing radiations are not well known. Furthermore, the side effects which are a consequence of xerostomia remain difficult to quantify\(^{(22)}\).

Traditional treatment for salivary gland carcinomas is surgery. For high grade tumors combined with radiotherapy will give a better prognosis. In a study conducted by florida university treatment outcomes of radiotherapy alone and combined with surgery is compared. Their study showed better result in the local control of the tumor. Radiotherapy with reference to other two studies conducted in different universities they have concluded that the surgery and the post surgical radiotherapy shows increased local control and survival in advanced stage or high grade tumors\(^{(5)}\).

In a study of 53 patients with advanced salivary gland tumor treated with fast neutron radiation therapy, the follow up of 42 months showed about 92% of patients with locoregional control \(^{(23)}\). By this study they concluded that for high grade tumors the neutron radiation alone is needed.

**Conclusion**

The use of Radiation and chemotherapy technique during treatment of head and neck tumors minimizes the salivary gland injury thus reducing the degree of xerostomia and related side effects among patients treated for head and neck tumor. Management of people treated for head and neck tumors needs a multidisciplinary approach involving dentists with dental care during and after radiation therapy. The optimal treatment for salivary gland carcinoma is surgery. Postoperative radiation therapy is associated with an improved outcome for patients with advanced stage disease, incomplete resection, and/or high grade histology. A modest subset of patients are cured with radiation therapy alone. Neutron radiation therapy may be associated with an improved outcome for patients with macroscopic disease but probably better results in moderate and severe cases.

Comparison of Centring Ability of Different Rotary and Reciprocating Systems- An In Vitro Study

Venkatachalam Prakash¹, Arun Antony², Suresh Mitthra³, Alagarsamy Venkatesh¹, Paramasivam Vivekanandhan¹, Arunajatesan Subbiya⁴

¹Professor, ²Private Practitioner, ³Reader, ⁴Professor & Head, Department of Conservative Dentistry & Endodontics, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research, Narayananapuram, Pallikaranai, Chennai, Tamilnadu, India

Abstract

Background: Several rotary Ni-Ti and reciprocating have been evolved with variable tapers, variable pitch diameters, M-wire technology and non cutting tip that are claiming to maintain original canal shape with emphasis on centering ability.

Aim: To compare the centring ability, apical third canal transportation and change in canal curvature of different rotary and reciprocating systems, in vitro.

Materials & Method: Fifty mesial canals of freshly extracted molars with completely formed apices, angles of curvature 15° - 25° and radii of curvature <10 mm were selected. Teeth were decoronated with a standard length of 15mm and randomly assigned into five groups, which include K3, ProTaper Next, WaveOne, Reciproc and stainless steel hand K-files. Pre–instrumentation and post–instrumentation CBCT were taken. Centring ability, apical third canal transportation and change in angle of curvature were calculated for each group and compared.

Statistical Analysis: One way ANOVA and Post Hoc Tukey- B tests were used to analyze the data.

Results: With regards to centring ability ProTaper Next showed the maximum centring ability and the least was for Hand K- files. Apical third canal transportation was found to be maximum in Hand K- files and minimal in ProTaper Next. Reciproc produced the least change in canal curvature followed by ProTaper Next, K3 and Hand K-files respectively.

Conclusion: Within the limitation of this study, it may be concluded that ProTaper Next has the best centring with least canal transportation. Reciproc proved to be as good as ProTaper Next.

Keywords: Centring ability, apical third canal transportation, angle of curvature.

Introduction

Proper cleaning and shaping establishes the necessary conditions for the success of the root canal treatment. Numerous investigators have proved that effective cleaning and shaping are adversely affected by highly variable and complex root canal anatomy. The flexibility of Ni-Ti instruments allowed 360° rotation in root canal preparation without much alteration of...
root canal configuration. Several rotary Ni-Ti systems have been evolved with variable tapers, variable pitch diameters, M wire technology and non cutting tip that are claiming to maintain original canal shape with emphasis on centering ability.

Off late, much research is focused on reciprocating motion which postulates reduction in Ni-Ti instrument separation, which commonly occurs in a 360° rotation, without a warning. By repeating the clockwise and counter clockwise rotation, balanced force technique is simulated, which according to many, does better cleaning and shaping with less cyclic fatigue. Not many studies have been done in the reciprocating systems with reference to centering ability.

Schilder has emphasized that root canal preparation should present a continuous taper from apical to coronal, preserving the apical foramen and not altering the original canal curvature which should be the principal aim in the centering ability of any instruments. Hence, a comparative analysis of two rotary and two reciprocating systems has been evaluated in this study with reference to centering ability, apical third canal transportation and change in canal curvature.

**Materials and Method**

**Sample preparation:**

Fifty mesial canals of freshly extracted molars, with fully formed apices with angles of curvature 25° to 35° degrees and short radii <10 mm were stored in 10% formalin. Ethical committee clearance was obtained from Sree Balaji Dental College and Hospital Ethical Committee, Bharath University (protocol Reference no. SBDCECM 106/14/09). Access cavity was done with a #4 round carbide bur. For more uniform samples, decoronation was done and a final dimension of 15 mm working length was achieved for each tooth.

**Image Analysis:**

Roots were embedded into impression compound and were positioned in a custom made specimen holder. All teeth were scanned by “ORTHOPHOS XG 3D” Cone Beam Computed Tomography CBCT scanner (Sirona systems, Germany) before and after instrumentation. Exposure parameters were 120kv and 5mA. The field of view was 8cm in diameter and 8 cm in height. Slices were 800 x 800 pixels, with a resolution of 0.160 mm.

Three virtual sections from each tooth, the number of the tooth, and its level were recorded onto a magnetic optical disk. The sections were 1) 3 mm from apex, 2) 6 mm from apex and 3) 9 mm from apex. After initial CBCT, the root canals were instrumented by using manufacturer recommended technique. A final CBCT image was taken and data were analyzed. Acquired data was used to calculate the centring ability and apical third canal transportation. The angle of curvature & radius of curvature was standardized.

**Evaluation of Centring Ability:**

The mean centring ratio indicates the ability of the instrument to stay centred in the canal. The pre-instrumented and post–instrumented shortest distance at 3 , 6 and 9 mm were measured from the edge of the canal to the periphery of the root, both in mesial and distal directions by using “Sirona CBCT software.”

Calculation was done for each section by using the following formula by Gambill et al:

\[
\frac{(a_1 - a_2)}{(b_1 - b_2)} \text{ or } \frac{(b_1 - b_2)}{(a_1 - a_2)},
\]

where \(a_1\) and \(a_2\) represent the shortest pre instrumentation and post instrumentation mesial distances, respectively, and \(b_1\) and \(b_2\) represent the shortest pre instrumentation and post instrumentation distal distances, respectively. According to this formula, a result of 1 indicates perfect centring.

**Evaluation of Canal Transportation:**

Transportation was calculated according to the formula of Gambill et al:

\[
(a_1 - a_2) - (b_1 - b_2),
\]

where \(a_1\) and \(a_2\) represent the shortest pre instrumentation and post instrumentation mesial distances, respectively, and \(b_1\) and \(b_2\) represent the shortest pre instrumentation and post instrumentation distal distances, respectively.

**Root Canal Preparation:**

A size 10 K-file was placed into the canal until it was visible at the apical foramen, and the working length was established 0.5 mm short of this length. The teeth were randomly divided into 5 different experimental groups (10 teeth each). All root canals were instrumented to the working length with sizes 10, 15 K-files by using a step-back technique, followed by respective rotary and reciprocating systems according to manufacturer recommended instructions. Instrumentation was done with the help of “VDW Gold Reciproc motor” (VDW, Germany).
Teeth were randomly divided into 5 experimental groups depending upon the respective rotary and reciprocating systems used for cleaning and shaping:

- Group A = K3 (n=10)
- Group B = ProTaper Next (n=10)
- Group C = Wave One (n=10)
- Group D = Reciproc (n=10)
- Group E = Stainless steel hand K - files (n=10)

Final apical preparation diameter for Group A and Group B (Rotary group) was 25/06 and for Group C and Group D (Reciprocating group), it was 25/08. Group E (control group) were shaped by using balanced force motion of pre-curved hand K-files with a step-back technique. Final apical preparation size was 25/02 taper.

After the use of each file, canals were irrigated with 3 ml of 3% NaOCl solution. For all groups, when root canal instrumentation was completed, 1 ml of 17% ethylene diamine tetraacetic (EDTA) acid was used for 1 minute followed by a final flush of saline. Figure 3 is a schematic representation of the methodology.\

**STATISTICAL ANALYSIS:**

Statistical analysis was done using one way ANOVA and the multiple comparisons between the experimental groups were done using Post Hoc – Tukey B test. A probability value less than 0.05 was considered to be statistically significant ($P < 0.05$).

### Results

An overview of the summary statistics indicates that, the least centring is found to be for hand K- Files and the highest is found in ProTaper Next. Post-Hoc Tukey- B tests carried out on centring ability showed that there was a significant difference between ProTaper Next, WaveOne and hand K- files ($P < 0.05$) [Table 1]; [Figure 2].

As far as “apical third canal transportation” is concerned, Hand K files were found to have the maximum transportation and it was minimal with ProTaper Next. Post- Hoc tests for apical third canal transportation showed that there was a significant difference between ProTaper Next, WaveOne and Hand K- files ($P < 0.05$) [Table 2]; [Figure 3].

With respect to “Change in Canal curvature” the least mean value was found with Reciproc and the highest with hand K files. Reciproc proved to be producing the least change in canal curvature followed by ProTaper Next and K3 respectively. Post Hoc - Tukey B tests for change in canal curvature showed that, there was no significant difference between Reciproc, ProTaper Next a n d K3 respectively. But there was a significant difference between them as compared to WaveOne and hand K- files respectively ($P < 0.05$) [Table 2]; [Figure 3].

| Table 1- Mean values of centring ability at 3,6 & 9 mm |
|----------------|----------------|----------------|----------------|----------------|
|                | K3             | ProTaper Next  | WaveOne        | Reciproc       | Hand K files   |
| Centring ability at 3mm | 0.7730 | 0.8890 | 0.6650 | 0.7320 | 0.2820 |
| Centring ability at 6mm | 0.6820 | 0.8220 | 0.5890 | 0.6640 | 0.2750 |
| Centring ability at 9mm | 0.4780 | 0.5800 | 0.3780 | 0.4660 | 0.1070 |

**Figure 2** – Graph showing the mean of centering ability
Discussion

The goal of instrumentation is to produce a continuously tapered preparation, with effective cleaning and shaping that maintains the canal anatomy, keeping the foramen as small as possible without any deviation from the original canal curvature. However in root canals these goals are not easy attainable and root canal instrumentation becomes even more difficult in curved canals.

Several studies have confirmed the superiority of Ni-Ti files over stainless steel file in shaping the root canals without much aberrations in canal anatomy. Metallurgy and instrument design are the two principal factors that decide the centring ability of any rotary instrument.

Two of the main characteristics of Ni-Ti alloy, are shape memory and super elasticity. The elastic limit of Ni-Ti alloys in bending and torsion is two to three times higher than that of stainless steel instruments. These unique properties are related to the fact that NiTi is a so-called ‘shape memory alloy’, existing in two different crystalline forms: austenite and martensite. The austenitic phase transforms into the martensitic phase on stressing at a constant temperature and in this form needs only light force for bending. After release of stresses the metal returns into the austenitic phase and the file regains its original shape.

Several strategies have been used to improve the fatigue resistance of NiTi endodontic instruments. These strategies include electro polishing, ion implantation, surface coatings, and heat treatment. Heat treatment has proven to create a more optimal phase transition point between austenite and martensite. Research has shown that M-wire, a metallurgically improved version of NiTi, reduces cyclic fatigue by 400% when comparing files of the same D0 diameter, cross-section, and taper. The scanning transmission electron microscopy study found presence of martensite and perhaps R-phase in the cross-sections of M-Wire, which is absent in the microstructure of conventional Ni-Ti wire. M-wire technology has been used in ProTaper Next, Wave One and Reciproc files. Hani.F.Ounsi et al concluded that, the difference in shaping ability of different rotary instruments may be related to respective geometric characteristics of the instrument design which includes cross section, helical angle, pitch, number of blades and cutting angle.

Reciprocating Movement:

During reciprocation, the instrument rotates in counter-clockwise and clockwise directions, with approximately 120° of difference between both movements. To complete 360° rotation, each instrument has to complete 3 cycles. Therefore it requires, 10 cycles of reciprocation per second, equivalent to 300 rpm according to Yared. When the instrument rotates in the counter clockwise direction, it will advance in the canal and engage dentin to cut it. When it rotates in the opposite direction (smaller rotation), the instrument will be immediately disengaged. The end result related to both Clockwise (CW) and Counter Clockwise rotations (CCW), produces an advancement of the instrument in the canal. Consequently, advancement of instrument would be almost self regulatory with the gentle guidance of operator. This action reduces the cyclic fatigue, risk of taper lock, file separation and apical extrusion of debris. In reciprocating movement proposed by Yared wherein he states that instrument engages in the canal when rotating in CCW direction and disengages in CW directions.
Centering ability of ProTaper Next at 3, 6 and 9 mm as compared to other groups exhibited the highest centering ability and least apical third transportation [Table 1 & 2]. The results obtained can be attributed to designed feature of instrument where 0 - 3 mm has a centered mass and axis of rotation from D1 to D3. The offset design (D4 - D16) has enabled the instrument to be better centered in apical third of the canal. The offset design minimizes the engagement of the file with dentine thereby increasing flexibility compared to symmetrical portion of apical third. Hence it might be emphatically stated that offset design of ProTaper Next has remarkably improved the centering ability.

Among the other groups K3 prove to be marginally better than Reciproc and distinctly better than WaveOne and hand K-files in canal centering ability and apical third canal transportation (Table 1 & 2). Hence a concept of design like asymmetrical cross section, variation in helical angle and flute depth has proven to play a major role.

Between Reciproc and remaining other groups (i.e. Wave One and Hand K-Files) Reciproc exhibited better centering ability with least apical third canal transportation [Table 1,2]. This could be attributed to S shaped geometry with a double cutting edge and having a smaller cross sectional area which increases the flexibility. The positive rake angle in Reciproc allow cutting dentine chips that curl away from the edge of the blade as compared to WaveOne which has a negative rake angle that scratches the dentine surface. The radial lands in WaveOne tend to burnish the cut dentine on to the root canal wall so Ni-Ti instruments with active cutting edge blades are superior to instruments with radial land with respect to debris removal capacity. Hence radial land present in the tip region of WaveOne instrument maybe responsible for more transportation and lesser centering ability as compared to other groups. Significant difference at 9 mm generally for all groups as compared to 3 and 6 mm may be attributed to canal geometry.

**Conclusion**

- Within the limitation of this study, it may be concluded that even though ProTaper Next owing to its offset design, produced the best centering with least canal transportation. However, the fear of instrument separation without a warning for 360° rotary instrument is ever prevailing.
- Reciproc instrument with a reciprocating motion has proved to be as good as ProTaper Next could be safely used as compared to the other systems of rotary endodontics, is evident from the results obtained in this study.

Accidental Large Extrusion of Epoxy Resin Sealer in the Periapical Area – A Case Report with three Years Follow up

Nagarajan Geethapriya¹, Arunajatesan Subbiya², Suresh Mitthra³, Venkatachalam Prakash⁴
¹Reader, ²Professor and Head of the Department, ³Associate Professor, ⁴Professor, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research (BIHER), Velachery Main Road, Narayanaapuram, Pallikaranai, Chennai, Tamil Nadu, India

Abstract

Aim: To evaluate the post operative complications and tissue tolerance of accidentally extruded epoxy resin sealer in a mandibular second molar.

Background: AH plus sealer has been widely used in dentistry as root canal sealer. In our case report the sealer had extruded beyond the mandibular second molar, close to the mandibular canal. Previous reports of paresthesia have been documented after extrusion of endodontic materials into mandibular canal. In our case, the extruded sealer has remained inert and the patient is asymptomatic.

Case Description: Three dimensional obturation of root canal determines the ultimate success of root canal treatment. While doing so the obturating material and the sealer should not extrude into the periapical region. Such an extrusion may cause irritation to the periapical tissues and lead to post operative pain. Despite taking precautions there may be accidental extrusion of sealer due to inadvertent instrumentation. The fate of such extruded sealer depends upon the type of the sealer. Here is one such case report involving accidental epoxy resin sealer extrusion which had remained inert over a follow-up period of three years.

Conclusion: The treatment outcome has not been affected by the extruded sealer since the root canals have been adequately obturated. AH plus has been well tolerated by the periapical tissues and the patient is asymptomatic for the past three years.

Clinical Significance: This case report shows that sealer extrusion cases show long term success rates if the root canals are adequately obturated and the extruded sealer is well tolerated by the periapical tissues.

Keywords: Sealer, AH plus, extrusion, periapical region, inert

Case Report

Introduction

The basic principles of endodontic treatment includes elimination of all diseased root canal contents, adequate cleaning and shaping, and a three dimensional obturation. Ideally, the obturating material and the sealer should be limited to the root canal and should not extrude into the periapical tissues. However, inadvertent instrumentation of the root canal can damage the apical constriction allowing not only the irrigating solutions,
medicaments and microorganisms but can also cause extrusion of sealers. Despite taking necessary precautions there are circumstances in which it is not possible to control limitation of the material to root canal, and some apical extrusion occurs. The fate of the extruded filling material will depend on its solubility in the tissue fluids and susceptibility to phagocytosis. Lower healing rate that are associated with overfillings is a result of the cytotoxicity of the root filling material. However, extrusion of sealer or gutta-percha does not have a direct correlation to treatment failure provided the periapical area is free of infection. Sealer extrusion has reported to cause symptoms such as pain, hyperesthesia and paraesthesia. Paraesthesia has been reported after the extrusion of endodontic materials into the mandibular canal when in contact with alveolar nerves as a result of the neurotoxicity of their components.

Among the root canal sealers AH-Plus represents the gold standard in clinical practice and the reference material for other types of sealers in laboratory and clinical research. Though AH-plus is biologically inert and has a good antimicrobial property it was found to be cytotoxic and not considered as biocompatible. While unintentional extrusion of zinc oxide and eugenol-based sealers gets completely removed over time, but removal of AH-Plus was significantly lower when compared with all the other sealers. The aim of this paper is to describe a case of an epoxy resin sealer (AH-Plus) extrusion in the periapical area during root canal treatment of a mandibular second molar without involving the mandibular canal which has remained inert but without any significant resorption over a period of three years.

Case Report:

A 45yr old female patient reported with the symptoms of decay and pain in the lower right back tooth region. The pain was intermittent and aggravated during sleep. There was no contributory medical history. On clinical examination, dental caries found in relation to 47. An intra oral periapical radiograph (IOPA) showed the involvement of the pulp with no periapical lesion.

Under rubber dam isolation, an access cavity was prepared and the working length was determined with #15 K files (MANI, Inc, Japan) using the apex locater (J Morita Root ZX mini, J Morita Corporation, Japan). The canals were cleaned and shaped using rotary ProTaper (Dentsply, Maillefer, Switzerland) from Sx to F2, with copious irrigation of 3% sodium hypochlorite and saline. The canals were then obturated with F2 gutta-percha (ProTaper Universal Gutta Percha points, Dentsply, China) using AH-plus (Dentsply, DeTrey, Konstanz, Germany) as the sealer. While coating the canals with the lentulo spirals -size 2, 21mm (Dentsply, Maillefer, Switzerland) there was accidental extrusion of AH plus sealer approximating the inferior alveolar canal, which was revealed in the post operative IOPA (Figure 1).

The patient was recalled after a week and he was asymptomatic and hence a crown preparation was done and a crown was placed. Subsequent recall of the patient was done after a month, 6 months, one year (Figure 2) and three years (Figure 3). There were no signs or symptoms due to the extrusion of the sealer, clearly stating that AH-plus sealer is inert and well tolerated by periapical tissues.
Discussion

André Schroeder developed the prototype of the first resin based sealer AH-26 (Dentsply DeTrey, Konstanz, Germany) in 1955. Though it is still available in the market, the sealer was replaced by AH-Plus in 1995. Setting time for AH-Plus varies between 492 min and 1440 min. The addition of nanoparticles is responsible for extending setting time by 5 minutes. The degree of radiopacity is an important factor, which controls the homogeneity of a root canal filling. AH-plus has very good radiopacity which can be appreciated on the radiograph. Flow is another important property which determines the quality of a sealer. According to American Dental Association (ADA) specification, a sealer should have a minimum flow of 20 mm/10 min or 17 mm/10 min, respectively. A high flow rate can increase the risk of apical extrusion which in turn can compromise apical healing and induce inflammatory reactions in the periapical tissues. AH-plus has been reported to have a film thickness of 8.0 to 43.65 micrometer(μm) which is accepted by the ANSI/ADA standards.

Low solubility and high dimensional stability are important properties required for a root canal filling material. High solubility of the sealer may result in small gaps and micro-leakages along the filling material, which in turn promotes ingress of bacteria. Dissolution of the sealer may also release components from the sealer which are responsible for irritation and inflammation of the periapical tissues. In a study by Borges et al, AH plus showed 3% weight loss.

The flow properties of a sealer are influenced by the viscosity of the material, temperature and humidity. According to Lacey et al, AH-Plus was the only sealer which showed no temperature dependent change in viscosity. AH-plus also shows good penetration into dentinal tubules. An ideal sealer should adhere well to the root canal wall and also to the gutta percha. Nunes et al concluded that AH-Plus had a significantly greater adhesion to dentine than Epiphany and that bond strength could be improved by a final irrigation with Sodium Hypochlorite (NaOCl) and Ethylene Di amine Tetra acetic Acid (EDTA). When calcium hydroxide is used as intra canal medicament, and if the remnants are not removed completely, it will negatively influence the adhesion of AH-plus.

AH-Plus is also known to have a good antibacterial effect against Enterococcus faecalis when freshly mixed, but there was no or only a minimal effect after a setting time of 48 hours. Biocompatibility of a root canal sealer is very important because of its close contact to the periapical tissues. Extrusion of filling material may induce periapical inflammation, delayed healing and also adversely affect the outcome of root canal treatment. In a study by Eldeniz AU et al, AH-Plus was severely cytotoxic in the freshly mixed state and slightly cytotoxic after 7 days on mouse fibroblasts but did not exert any cytotoxicity to human gingival fibroblasts. Some studies examined cytotoxicity of root canal sealers by measuring their effect on cytokine production. Brackett et al reported that there was no cytokine secretion after 12 weeks. Secretion of tumor necrosis factor α (TNFα) was measured 6 hours after mixing which completely disappeared in aged samples after 1 year. In our case, there was extrusion of AH-plus. Though the sealer had not been resorbed, the patient was asymptomatic on three years follow up. This proves that AH-plus is biocompatible and well tolerated by the periapical tissues.

Conclusion

In our case the amount of extruded sealer was substantially less and hence the patient has been asymptomatic. Treatment outcome is not significantly affected by the extruded sealer as long as the root canals are adequately treated. Success rates in overfilled
cases are significantly higher in teeth with no lesion in comparison with teeth with apical periodontitis. In our case there was no periapical lesion and prognosis was good. AH plus has been well tolerated by the tissues though it has not been resorbed.

Clinical significance:

Accidental extrusion of epoxy resin sealer did not cause any foreign body reaction. Though it has not been resorbed, it has been well tolerated by the periapical tissues and the patient has remained asymptomatic on three years follow up. This implies that sealer extrusion cases also show long term success rates if the root canals are adequately obturated.

Abstract

Purpose: The aim of this in-vitro study was to evaluate the effect of pre-heating on the degree of monomer conversion, polymerization shrinkage and micro hardness of a silorane based composite.

Method: P90 low shrinkage composite was used for this study. A total of 30 samples were made and groups divided into A, B & C : Group A - the control group, Group B- the pre heated group, Group C - the pre cooled group. The degree of monomer conversion, polymerization shrinkage & micro hardness was measured using FTIR spectrometer, Stereomicroscope & Vickers hardness testing machine respectively. Statistical analysis was done using One way ANOVA and post hoc Dunnett test.

Results: The mean values for degree of conversion, polymerization shrinkage and microhardness for groups A, B, C were the following : 63.22%, 74.61%, 46.80%; 0.25%, 0.36%, 0.26%; 65.79 MPa, 72.69 MPa, 67.01 MPa respectively.

Conclusions: The silorane composite when pre heated there was a significant increase in the degree of conversion and microhardness. There was no significant difference in the polymerization shrinkage among the experimental groups.

Keywords:- Degree of monomer conversion, micro hardness, polymerization shrinkage, pre heated, pre cooling, silorane composites.

Introduction

Various advances have been made in the filler technology of composite resins to improve the wear resistance, decrease the water sorption and to provide a better surface finish. During polymerization, on exposure to visible blue light in the electromagnetic range (410-500nm) high molecular weight monomers are converted to highly cross linked, low molecular weight, long polymer chains. The major drawbacks of the existing composite resins were the unwarranted polymerization shrinkage. A major advancement in composite resin matrix occurred when Weinmann et al in 2005 [1] , discovered of a new monomer system Silorane (3, 4,-epoxy cyclo hexyl cyclo polymethyl siloxane). The term silorane represented the hybrid monomer system made up of siloxane and oxirane. The resin matrix silorane monomer has a siloxane core and along with four oxirane functional groups attached as side chains. This combination of siloxane and oxirane produces the biocompatible and low shrinkage silorane composite.
For a complete polymerization to occur, the percentage of monomer conversion should be high. Heating the composite resin under isothermal condition improves the degree of conversion and shortens the curing time to form a highly cross linked polymer chain with improved mechanical properties \[2\]. Therefore the purpose of this in-vitro study was to evaluate the effect of pre-heating on the degree of monomer conversion, polymerization shrinkage and micro hardness of a silorane based composite.

**Method**

A commercially available, photo activated silorane based composite P90 (3M ESPE, St. Paul, U.S.A, Shade A3), was used in this study\[1]\ . A total of 30 cylindrical specimens, with specific dimensions of about 5x2 mm (5mm-wide and 2mm-height) was fabricated using a brass mould for the standardization of the samples. This mould was constructed as two parts with a split in between for easy disassembly of the cured specimen. The whole assembly was made to rest in the brass block, with four corner slots for additional support. The inner surface of the jig was polished to prevent adhesion of composite resin to the mould. Composite material was placed as a single increment within the brass mould and well adapted. A thin mylar strip was placed over the material and digital pressure was applied to ensure the composite was tightly adapted to the walls \[4\] . Light polymerization was performed with quartz-tungsten-halogen light curing unit (Elipar 2500- 3M ESPE, St. Paul, MN, USA) for 20 seconds at 600 mW/cm\(^2\) and periodical monitoring of the curing light intensity was done with radiometer (Optilux Model 100, SDS Kerr; Donbury, CT, USA) according to the manufacturers’ recommendations.

**GROUP A:**

This is the control group (n=10), without any pre-heating or pre-cooling the composite was kept at room temperature.

**GROUP B:**

For preparing the samples (n=10), composite was placed in the digital electric oven and maintained at 68\(^\circ\)C. The required amount of composite was then dispensed into the brass mould and immediately carried to the spectrometer and spectra were obtained. Care was taken to maintain the duration of transferring the specimen from the oven and recording the spectra to be less than 40 seconds to prevent the heat loss.

**GROUP C:**

All the samples in this group (n=10) were prepared by cooling the composite material in a digital weatherometer, which was maintained at 10\(^\circ\)C.

**MEASUREMENT OF DEGREE OF CONVERSION (DOC):**

The DOC was analyzed using Fourier Transformation Infrared Raman (FTIR) spectrometer (Thermo Scientific Inc., Waltham, USA). The infra red spectra were collected with 128 scans at the range of 4000 cm\(^{-1}\). Based on the absorbance frequencies, the percentage of un-reacted C=C (aliphatic) converted to C-C (aromatic) was calculated by using the formula below and the results were tabulated [Table 1]. Post irradiation spectra were obtained after 24 hours \[5\].

\[
\text{DOC} \% = \left\{ 1 - \frac{[C_{\text{aliphatic}}]}{[C_{\text{aromatic}}]} \right\} \times 100
\]

**MEASUREMENT OF POLYMERIZATION SHRINKAGE:**

The calculation of Polymerization shrinkage was measured after 24hrs using stereomicroscope (HZ CS02-700X, Olympus, Japan). The readings obtained at eight different places and the average was calculated. Shrinkage was calculated by measuring the difference between the standard diameter of the mould and the diameter of the specimen at 24 hours after polymerization. The percentage of polymerization shrinkage was calculated using the formula and the mean values tabulated [Table 1] \[6\]:

\[
\% \text{ of shrinkage} = \frac{\text{diameter of the sample}}{\text{Standard diameter of the mould}} \times 100
\]

**MEASUREMENT OF MICRO HARDNESS:**

Vickers micro hardness test with micro duromax 4000E (Richard Polyver 2 MET) was performed for all the experimental samples in this study. A
total number of 5 indentations were made on the irradiated surface and the mean values were noted on Table 1.

Statistical analysis was done using statistical package of social sciences (SPSS) version 10.0 and the data were analyzed using one way analysis of variance (ANOVA) and the multiple comparisons between the experimental groups were done with post hoc-Dunnett test. A probability value less than 0.05 was considered to be statistically significant (P < 0.05) [Table 2].

\[
\left\{ 1 - \left[ \frac{C_{\text{aliphatic}}}{C_{\text{aromatic}}} / \frac{U_{\text{aliphatic}}}{U_{\text{aromatic}}} \right] \right\} \times 100
\]

Results

Regarding the results obtained for polymerization shrinkage, there was no statistically significant difference among the experimental groups. The mean values were 0.25%, 0.36%, 0.26% for the three experimental groups represented in the bar graph [Figure 1].

The results represented by the bar diagram showed [Figure 2], the mean percentage of the degree of monomer conversion with the heating group showing the maximum conversion. The mean values were as follows for the experimental groups A, B, C – 63.22%, 74.61%, 46.80% respectively. The DOC values were calculated by FTIR spectra [Figure 3].

There was a statistically significant difference in the Vickers hardness values of the pre heated group (group B) compared to the other two experimental groups. The pre heated group showed an increase in the micro hardness (72.69 MPa) compared to the control (65.79 MPa) and the pre cooled group (67.01 MPa) [Figure 2 & 4].

Discussion

To overcome the polymerization shrinkage in dental composites, nano-composites were introduced which contain high filler content (80 to 90% of resin matrix) resulting in reduced polymerization shrinkage, high viscosity and stickiness of the material which makes the insertion, adaptation more difficult and also yielding lower conversion rate\(^8\). To overcome all these drawbacks, studies have shown that the process of chair-side pre-heating of composite prior to the polymerization process significantly increases the free radical reactivity, reduces the viscosity thus increasing the flow enabling superior adaptation of the composite to the cavity walls. Pre-heating of composite resin also reduces the percentage of un reacted residual monomer by leading to increase in the degree of monomer conversion and increase in the rate of polymerization reaction.

Polymerization of siloranes composite used in this study occurs via a cationic ring opening reaction which results in low polymerization contraction compared to the methacrylate based resins. The cationic cure starts with activation of the initiator (camphorquinone, an electron donor, an acidic cation) which opens the oxirane ring and generates a new acidic centre. After the subsequent attraction to a new oxirane monomer, the epoxy ring is opened to form a chain or in the case of interaction among multiple monomers, a network is formed. This process gains space and counteracts the volume loss that occurs when the chemical bonds are formed, thus leading to a reduced volumetric shrinkage. This cationic ring opening reaction has three components-camphorquinone, iodonium salt and electron donor. In this redox reaction the electron donor decomposes the iodonium salt to an acidic cation which starts the ring opening polymerization process\(^1,9\).

The clinical success of composites depends on various material characteristics like polymerization shrinkage, depth of cure and mechanical properties. Handling characteristics like paste viscosity, packability, stickiness and polishing play a role. Recently preheating of composite resins has been advocated to reduce paste viscosity which in turn improves the marginal adaptation, monomer conversion and decreases the curing time. Pre cooling the composite resin prior to curing initially results in contraction of the resin matrix and expansion of the matrix occurs as it returns to room temperature when placed in the mould cavity before curing. This expansion
masks the underlying shrinkage in the mould cavity and further counteracts the polymerization shrinkage stress [10-14]. As there are few studies in literature evaluating the influence of temperature on the mechanical properties of silorane composites, hence the purpose of this study was to evaluate the effect of pre-heating and pre-cooling prior to the photopolymerization on the degree of conversion, polymerization shrinkage and microhardness of a silorane based composite.

According to the results obtained, group B (pre-heated group) exhibited increase in the DOC and microhardness compared to group A (control- room temperature) and group C (pre-cooled group). The elevation in temperature, increases free radical mobility, greater monomer cross linking and increases the rate of polymerization leading to the rise in the degree of monomer conversion. The process of pre-heating of the composite improves the mechanical properties with greater strength, rigidity and better wear resistance to degradation in the oral cavity [14].

Hardness of composites is directly proportional to the amount of polymer cross linking and the depth of cure of the material. The higher microhardness value of the pre heated group is characterized by the enhanced polymer cross-linking and greater degree of conversion than light curing at room temperature. Moreover, Eliades and his colleagues suggested that higher microhardness values are related to the higher inorganic filler loading in the silorane composite. The increase in the microhardness enables the material to withstand masticatory forces, resist fracture and wear [12,14].

According to Daronch and his colleagues it was estimated that when composite is pre-heated upto 60°C and removed from the heating device, there is a temperature loss by 50% after 2 min and 90% after 5 min. Hence in the current study care was taken to reduce the transfer time (the mean time between removing the composite from the heating device, placement into the brass mould and light polymerization) to 40 secs to minimize the negative effect of heat loss. Daronch and his researchers also stated that pre heated composites reduces the light exposure time upto 75% resulting in better monomer conversion and thereby reducing the curing time [2].

The results showed that there was a reduced polymerization in all the three experimental groups with no statistically significant difference between the groups. This can be attributed to the cationic ring opening polymerization of the silorane composite. This clinical study also proved that pre heating or pre- cooling of the silorane composite does not affect the polymerization shrinkage. But according to the values obtained high shrinkage was found in the pre-heated group followed by the room temperature group this could be attributed to the fact that as the reaction rate increases there will be an increase in the stresses produced resulting in higher volumetric shrinkage. The pre cooled group was found to have lowest shrinkage values due to the fact that refrigerated composite samples were smaller than the room temperature samples as the temperature increases they slowly expand which could mask the underlying polymerization shrinkage [15].

**Conclusion**

Therefore, within the limitations of this study, it can be concluded that,

- The silorane based composite when pre-heated there was a significant increase in the degree of monomer conversion (74.61%) and microhardness (72.69 MPa) when compared to the pre cooled and room temperature groups.
- Regarding the polymerization shrinkage of the silorane composite there was no significant difference between the experimental groups.
- The process of chairside pre-heating significantly improves the mechanical properties of siloranes.

Resistance Mechanism of Enterococcus Faecalis – A Review

Geeth Deepika¹, Venkatachalam Prakash², Arunajatesan Subbiya³, Paramasivam Vivekanadhan², Balasubramaniam Anuradha⁴, Arumugam Karthick⁵

¹Senior Lecturer, ²Professor, ³Professor and Head of the Department, ⁴Reader, ⁵Associate Professor, Department of Conservative dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education & Research, Chennai, Tamilnadu, India

Abstract

Enterococci are normal commensals of humans that can survive extreme environmental challenge and it is partly shielded from the defense mechanisms of the body. The virulence factors of E. faecalis that may be related to endodontic infection and the periradicular inflammatory response and a large part of the tissue damage is probably mediated by the host response to the bacterium and its products

Keywords: Enterococcus faecalis, virulence factors, root canal infection

Introduction

Enterococci are normal commensals and can cause a wide variety of diseases (Jett et al., 1994)¹. Enterococcus faecalis has the ability to resist harsh environmental conditions such as pH by potassium proton pump mechanism(Evans et al., 2002)³, antimicrobial effect of calcium hydroxide(Byström et al., 1985; Distel et al., 2002)³, starvation. In addition to that with the help of various virulence factors Enterococcus faecalis has the ability to resist the host defense mechanism. E. faecalis, moreover, can enter the viable but non-cultivable (VBNC) state during unfavourable environmental condition and return back to normal after the condition becomes favourable (Lleò et al., 2001)⁶

Resistance To pH by Proton Pump:

Proton pump functions by controlled transport of cations across the cell membrane (Booth et al)⁹. Enterococcus faecalis survives in alkaline /acidic pH due to the existence working potassium /proton antiport system. In alkaline pH Cations/protons gets pumped into the cell to lower the internal pH thus making the bacteria favourable for survival against medicaments inside the root canal. In the acidic pH a cation antiport system raise the internal pH by expelling protons across the cell wall and thus maintaining pH homeostasis. Calcium hydroxide seems to be ineffective at killing Enterococcus faecalis because of the effective proton pump mechanism. Calcium hydroxide is used as an intracanal medicament has a pH OF 12.5 and it cleaves into Ca⁺⁺ and OH⁻ when negatively charged ions penetrate the bacterial cytoplasm elevating the pH the proton pump derives the positively charged k⁺ ions into the cells to acidify the cytoplasm. At pH 11.5 - Enterococcus faecalis unable to survive. As a result of buffering capacity of dentin it is unlikely that a pH of 11.5 can be maintained in dentinal tubules with calcium hydroxide sterilization techniques.

Starvation Resistance:

Enterococcus faecalis survives even under starvation when compared to other microorganisms and it remains dormant until favourable conditions becomes available. Hyaluronidase supply nutrients for the bacteria since the product disaacharides are transported and metabolized intracellularly by bacteria(Hynes and Walton 2000)³. Enterococcus faecalis may also feed on serum components present in the fluid in the dentinal tubules and it has the ability to survive without nutrient supply inside the root canal.

Aggregation Substance

Enterococcus faecalis with the help of this virulence factor binds to the extracellular matrix protein including type 1 collagen which is the main organic component of dentin (Lindhe & Goldberg)⁸. It serves as the protective factor against host defence mechanism by promoting oposonin independent adherence. They cause
phagocytosis of Enterococcus faecalis by macrophages and thus promoting its intercellular survival time. Aggregation substance gets binded to possess superantigen activity (Schlievert et al)\(^9\) Fig 1. These molecules cause inflammation by stimulating the T lymphocytes and thus leading to the release of massive number of cytokines (inflammatory mediators) causing tissue damage. Inflammatory mediators such as IL-6, IL-8, TNF alpha, IL-1beta have tissue damaging property.

**SEX PHEROMONES**

Sex pheromones function as signalling peptides for Enterococcus faecalis. Plasmid transfer by conjugation takes place by sex pheromone system (Clewell and Weaver et al)\(^10\). Thus the recipient strain secretes the plasmid into the medium which the sex pheromone does not carry and the donor strain producing the AS adhesion helps in the conjugal transfer of the plasmids which is being replicated once the copy is acquired the recipient strain stops producing that particular pheromone and they continue to secrete sex pheromones for other plasmids and the process is continued (Fig 1). In addition to it sex pheromone also contributes to the bone resorption (Torabinejad et al)\(^11\).

**LIPOTEICHOIC ACID**

Lipoteichoic acid is present on the cell surfaces of bacteria. (Wicken and Knox)\(^12\). They are amphipathic molecules that bind to eukaryotic cells with the help of its lipidic moiety and it stimulate the release of inflammatory mediators causing tissue damage to the host. (Fig 1) LTA is a constituent of the binding substance of the bacteria and it act as a receptor on the cell for the aggregation substance (AS).

**EXTRACELLULAR SUPEROXIDE PRODUCTION**

Superoxide anion is an oxygen radical which is highly reactive and causes inflammation. Superoxide anion are produced by both host cells and bacteria and it causes tissue damage (Fig 1). Thus superoxide anion is able to kill the microorganisms by phagocytosis and on the other way the bacteria with the help of this superoxide anion causes lytic of erythrocytes.

**GELATINASE**

It is an extracellular zinc containing metalloproteinase from Enterococcus faecalis (Bleweis and Zimmerman)\(^13\). As gelatinase belongs to MMP family it is produced by inflammatory cells, fibroblasts, osteoclasts. Host gelatinaase helps in regulating and remodelling the tissues (Fig 1). They are highly present in inflamed pulp than healthy tissues and also has the effect of degrading the dentin organic matrix. (Tjaderhane et al)\(^14\) Gelatinase causes the disease to be progressed due to its cytotoxic and tissue destructive potential.

**BACTERIOCINS**

Cytolysin, AS – 48, BC- 48 have been isolated from strains of Enterococcus faecalis and have been reported to have inhibitory action on gram positive action.

**Conclusion**

Enterococcus faecalis with the help of virulence factors it has the ability to adhere to the cell, colonize, invade the host and cause damage .Thus it has the quality to face stressful conditions inside the root canal when compared to other microorganisms present in the canal. Enterococcus faecalis has the potential to cause infection of root canal and by penetrating deep into the dentinal tubules leading to periodontal inflammation.

Abstract

The acid-etch technique for bonding composite resins to enamel has revolutionized the practice of restorative dentistry. Although bonding resins to dentin has proved to be a difficult challenge. Ongoing advances have improved the reliability and predictability of dentinal adhesion.

Keywords :- Composite resin, acid etching, bonding, adhesives.

Introduction

The revolutionary work of Michael Buonocore nearly 50 years past marked the beginning of successful ‘adhesive’ dentistry. Buonocore was able to demonstrate that the treatment of enamel with phosphoric acid resulted in a porous surface, which could be infiltrated by resin, to generate a strong micromechanical bond. However, the clinical application of acid etching was not realized until 15 years soon after when resin composites became available as a result of the work of Bowen’s group. In contrast to micromechanical bonding to tooth tissue, chemical bonding was developed by Smith and resulted in the introduction of polycarboxylate cement.

Enamel etching

Buonocore reported in 1955 that acid, can be used to modify the surface of enamel to “render it more receptive to adhesion.”¹ It was revealed that acrylic resin could be bonded to human enamel after conditioning with 85% phosphoric acid. Buonocore predicted many potential uses for this technique, including Class III and Class V restorations and pit and fissure sealants. Most of the enamel etchants contain 30-40% phosphoric acid and produce shear bond strengths of composite resin to enamel of about 20 MPa.²

Development of resin/ dental adhesives

Although advance of dentin adhesives began in the early 1950s³,⁴,⁵ steps forward was very slow until recent years. In the early 1960s, Bowens synthesized a “surface-active comonomer” that could apparently mediate water-resistant chemical bonds of resins to dentinal calcium.⁶ However, marketable products based on this comonomer showed very reduced clinical performance.⁷

A “second generation” of dentin bonding agents was developed for clinical near the beginning of 1980s. With the exemption of ScotchbondTM Dual-Cure (3M Dent al Products Division, St. Paul, MN)and Bondlite (Kerr Corporation, Glendora, CA), second-generation bonding agents are no longer obtainable. Nearly all of these materials were halophosphorous esters of unfilled resins.

such as Bis-GMA (bisphenol A-glycidyl methacrylate) or HEMA (hydroxyethyl methacrylate).3

They bonded to dentin through improved surface wetting and ionic communication between the phosphate groups and calcium in the smear layer. These agent had shear dentin bond strengths of only about 1-10 MPa, 9,10,11 which was too weak to counteract the polymerization shrinkage of composite resin. Therefore, composite usually separated from dentin, forming marginal gaps that permitted microleakage.

The experimental performance of phosphonate esters used without enamel etching or mechanical maintenance was poor, with quite elevated percentages of cervical restoration failure over 1- to 3-year evaluation periods.12-17

Third-generation adhesives were introduced in the United States in the late 1980s. These systems removed the smear layer to permit resin penetration into the underlying dentin 15 Shear dentin bond strengths of agents such as Scotchbond 2 (3M), Gluma, Tenure (DenMat Corporation, Santa Maria, CA), Prisma Universal Bond 3, Syntac and XR-Bond (Kerr) were typically greater than those of the second-generation agents. Though their performance was still unpredictable, even in laboratory studies. Although these dentin adhesives were more efficient than their predecessors in reducing microleakage at dentin and cementum margins18,19 they did not eliminate marginal leakage20,21 These systems provided better retention rates and marginal integrity than earlier adhesives22,23

Fourth-generation adhesives

The consequent generation of dentin bonding systems appeared in the early 1990s and is still extensively used. Most of these systems are based on the “total-etch” technique, or concurrent etching of enamel and dentin, typically with phosphoric acid. Development in dentin bond strengths by etching was first established by Fusayama in 197924,25 but the concept of total-etching25 only recently gained acceptance in the United States. Etching of dentin traditionally was discouraged because facts from previous studies seemed to show that phosphoric acid etching of dentin caused pulpal inflammation.26,27 However, very little acid in fact penetrates dentin, so it seems unlikely that the acid is directly responsible for nearly all pulpal damage.28 Much data now indicates that lack of an adequate marginal seal is the major cause of pulpal inflammation associated with permanent restorations. Slight or no inflammation may happen if restorations are sealed well enough to prevent bacterial invasion of the pulp.29,30

The bonding mechanism of the fourth-generation adhesive systems is a three-step process: (1) condition, (2) prime, and (3) bond. Conditioning (or etching) removes the smear layer, opening the dentinal tubules, increasing dentin permeability, and decalcifies the intertubular and peritubular dentin. Elimination of hydroxyapatite crystals leaves a collagen meshwork that can shrink due to the loss of organic support. After the conditioner is rinsed off, a primer consisting of a solvent with one or more hydrophilic resin monomers is functional. Primer molecules contain two functional groups—a hydrophilic group and a hydrophobic group. The hydrophilic group has a likeness for the dentin surface and the hydrophobic (methacrylate) group has an likeness for resin. The primer wets and penetrates the collagen meshwork raise it about to its original level. The primer also raises the surface energy, and thus the wettability of the dentin surface. Unfilled resin is functional and penetrates into the primed dentin, copolymerizing with the primer to outline an intermingled layer of collagen and resin frequently termed the “hybrid layer”.28 Improvement of this hybrid layer of dentin and resin, which was described by Nakabayashi et al. in 198229 is thought to be the primary "bonding mechanism of most adhesive systems. Many investigators have reported shear bond strengths for these materials that advance or exceed the typical enamel bond strength of 20 MPa.

Fifth-generation dentinal adhesives

For the reason that the three-step bonding systems are perceive by some as being too complicated and time-consuming, manufacturers have attempted to shorten systems by combining certain steps. The common means of simplification is mixture of the primer and bonding-agent steps to make “one-bottle adhesives”.28,29,30

Various one-bottle adhesives are now presented, including Prime & Bond 2.1, One-Step, OptiBond Solo (Kerr), Single Bond (3M), and Tenure Quik with Fluoride. They require conditioning of enamel and dentin before applying of the primer/adhesive, and nearly all necessitate two or more applications of the latter. Considering the fact that these materials are promoted
as “simplified” systems, bond strengths reported for the one-bottle adhesives have been disconcertingly variable. Some investigators have reported values similar to those of conventional three-step systems while others have reported lower values. Much of the variation in bond strengths may be due to technique factors. The acetone-based systems in particular show to call for a dentin surface that is neither too moist nor too dry.30

Bond strengths

Much of the dental materials literature, bonding systems have been compared by their shear bond strengths. However it must be well-known that laboratory bond strengths do not openly predict clinical performance. In a typical test, extracted human or bovine teeth are ground flat, an adhesive system is applied, and a composite resin post is bonded to the surface. A loading force is useful to shear or draw the composite from dentin. Laboratory tests generally ignore the special effects of polymerization shrinkage, pulpal pressure, dentinal fluid, and tooth flexure. Bond strength testing is not entirely without value, yet--as more and more data are generated by various laboratories, a rough rank order of adhesives is possible and provide a sound basis for predicting clinical performance 31, 32

A current study of fourth-generation dentin adhesives reported bond strengths to primary dentin between 9.9 to 17.9 MPa 32

Clinical factors in dentin bonding

A number of clinical factors influence the longevity of bonded composite restorations. A list of guidelines to help ensure clinical success and durability follows:

Use proper isolation. Hydrophilic bonding systems may tolerate saliva contamination to a certain degree. However, evidence for such tolerance remains minimal and the mechanism is not well understood, so proper isolation using rubber dams or alternative methods is considered essential to clinical success with current adhesive systems.

Bond to enamel. Every time a restoration is bonded to dentin, the adjacent enamel should be etched. Years of experience have proved that enamel etching is a very consistent method of bonding resins to tooth structure. In addition, when bevels are used, they offer a gradual transition of composite material onto the tooth and thus a better esthetic result.

Roughen sclerotic dentin. Bonded restorations are further likely to fail when they are bonded to highly sclerotic dentin) Light roughening by means of a diamond or carbide bur may provide more micromechanical locking between resin and dentin. While not encountered as often in pediatric dentistry as in adult restorative dentistry, sclerotic dentin is encountered beneath some carious lesions.

Use mechanical retention. With adhesive restorative materials, supplemental mechanical retention (pins, grooves, slots) is often not essential However, the operator should use mechanical retention in cases where adhesive bonding may not be adequate to retain or properly seal a restoration.

Current dentin adhesives bond to dentin that is at least slightly moist. Systems that contain acetone primers are predominantly well suited for bonding to wet surfaces 32 although the optimum degree of surface moistness varies with specific products. However as a general rule, dentin should not be desiccated. If dentin is dried excessively to check the enamel etch, it should be moistened to improve bond strengths. The “moist bonding” technique is used because desiccation of etched dentin can effect collapse of the unsupported collagen network, inhibiting adequate wetting and penetration by the primer or primer/adhesive. On the other hand, the clinician must be aware that pooled moisture should not be allowed to continue on the tooth, as excess water can dilute the material and reduce its effectiveness. A glistening, hydrated surface is the ideal appearance.

Apply and dry primers correctly. Dentin primers and fifth-generation primer/adhesives must be applied in adequate quantity. Some materials require multiple coats, and others probably benefit from application of multiple coats or longer application times. Also, solvents must be driven off completely with compressed air before the bonding agent or composite is applied.

Do not over-thin the bonding resin. Relevance of the resin bonding agent is the simplest step in a three-step bonding sequence. However, if the resin is aggressively air-thinned, oxygen inhibition prevents complete polymerization and results in lower bond strengths. Thinning the bonding agent with a dry brush is better than thinning with compressed air blasts. 33 For direct composite restorations, the bonding agent should be light-cured before the restorative material is placed to
optimize the bonding system’s performance.

Use a flexible restorative system. Flexible restorative materials (e.g., microfill composites) and “stress-breaking liners” (filled bonding resins) may advance the marginal quality of bonded restorations by compensating for stresses generated by polymerization shrinkage and tooth flexure.14,15

Fill incrementally. All composites shrink during polymerization. One means of reducing overall polymerization shrinkage is to place and cure composite in increments. Although there is now some controversy about whether this technique provides better marginal adaptation it still seems advisable, and is necessary when composite thickness exceeds 2 mm (to provide for adequate light curing).

Delay finishing. The bond strength of resin to enamel and dentin is greater at 24 h than immediately after placement. Some of this improvement in bond strength actually occurs within the first few minutes, so a brief delay in finishing may help to preserve the integrity of delicate margins.

“Rebond” margins. The concept of rebonding is based on the assumption that gaps are likely to occur in at least some marginal areas of any direct composite restoration. The margins are re-etched and sealed with special low-viscosity resin.16,17

**Conclusion**

Advances in adhesive dental technology have changed restorative dentistry. The acid-etch technique for enamel bonding led to the development of revolutionary restorative, preventive, and esthetic treatment methods. More recently, developments in resin/dentin bonding have moved adhesive dentistry an even higher level. Many systems are now available to reliably and durably bond resin to dentin. However, these systems must be used properly to optimize their clinical performance.

Review on Inhibition of Osteoclastic Activity by Mineral Trioxide Aggregate (MTA)

Balasubramaniam Anuradha¹, Ramu Shobhana², Suresh Mitthra¹, Dhakshinamoorthy Malarvizhi³

¹Reader, ²First Year Postgraduate Student, ³Associate Professor, Department of Conservative Dentistry And Endodontics, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research, Narayanapuram, Pallikaranai, Chennai, Tamilnadu, India

Abstract

Mineral trioxide aggregate (MTA) is a calcium silicate-based cement which has a unique property in remodelling the bone. It is commonly used as a repair material in endodontics and has various clinical applications. It can initiate the osteoblasts to cause bone formation and has been proved in various articles. MTA causes an increase in the production of interleukin (IL)-1α, IL-1β, IL-6 and osteocalcin. IL-1α and IL-1 β interact with receptors on osteoblasts which in turn activate osteoclast. Osteocalcin is an abundant protein, present in the bone and acts as an indicator of bone matrix production. There are certain studies suggesting that MTA can inhibit osteoclastic activity. Osteoclasts which are multinucleated giant cells, differentiate from myeloid precursors via cytokines Macrophage colony stimulating factor (MCSF) and Receptor activator of nuclear factor kappa-β ligand (RANKL) supplied by osteoblasts and/or osteocytes. MCSF and RANKL are critical cytokines that contribute to the differentiation and function of osteoclasts. However, the underlying reason behind MTA showing inhibition of osteoclastic activity remains unclear. The purpose of the review is to present a comprehensive opinion of articles on action of MTA on osteoclasts.

Keywords: Mineral trioxide aggregate, osteoclast, bone resorption, RANKL

History

MTA is a commonly used material in conservative and endodontic dentistry. This material was introduced as an experimental material by Professor Mahmoud Torabinejad at the Loma Linda University, California in the year 1993. The main goal behind introducing MTA was to eliminate any communication between interior and exterior of the tooth. Hence, it became a material of choice in cases of intraradicular or furcation perforations and in cases of root end filling.

Earlier Gray MTA (GMTA) was available in the market. It was in the year 2002, White MTA (WMTA) was introduced to overcome the discoloration and esthetic problems caused by GMTA. Thus, MTA can be classified into GMTA and WMTA.

In the year 1993, when MTA was first described in the dental scientific literature. In 1998, it was approved for endodontic use by the US Food and Drug Administration. In the year 1999, it was commercially available as ProRoot MTA (Dentsply Tulsa).

Clinical Applications

It is used as an apical barrier in teeth with immature apices, repair of root perforations, root-end filling,
capping, and pulpotomy. It has an excellent property to regulate bone remodelling.

**COMPOSITION**

- Tricalcium silicate
- Dicalcium silicate
- Calcium sulfate
- Tricalcium aluminate
- Tetra calcium alumina ferrite
- Bismuth oxide.

**ACTION OF MTA IN THE CELLULAR LEVEL**

MTA enhances the proliferation of gingival fibroblasts, dental pulp cells, periodontal ligament cells, and osteoblasts better than other commonly used retrofilling materials, such as amalgam, Super-EBA, and intermediate restorative material (IRM). MTA also enhances the induction of osteoblast attachment and spreading and induces differentiation and mineralization of osteoblasts. It has been well-established that MTA extracts containing calcium and silica ions inhibit osteoclastogenesis and bone resorption to promote bone reconstruction.

**ABOUT OSTEOCLASTS**

Osteoclasts (OCLs) are multinucleated giant cells that derive from a hematopoietic monocyte or macrophage lineage.

Osteoclastic bone resorption takes place in various steps which are: proliferation of osteoclast progenitors, differentiation of progenitors into multinucleated osteoclasts, and apoptosis as well as clear zone (actin ring) and ruffled border formation (activation). Four proteins crucial for osteoclast development and activation are macrophage colony-stimulating factor (M-CSF), the receptor activator of NF-κB ligand (RANKL), its receptor (RANK), and its decoy receptor osteoprotegerin (OPG). The RANKL/RANK signalling pathway activates osteoclastic bone resorption and regulates osteoclast differentiation from monocyte/macrophage progenitors together with macrophage colonystimulating factor (M-CSF) in vitro and the addition of OPG into these culture systems prevents osteoclast formation. It is therefore believed that the balance of RANKL and OPG expression is critical for regulating osteoclast differentiation and function.

**OSTEOCLASTIC ACTIVITY OF MTA**

Certain studies were conducted to find the relation between MTA and osteoclastic inhibition. One among them is the study conducted by Daisuke Hashiguchi et al. In his study he made efforts to hypothesize that MTA stimulates bone formation not only by stimulating osteoblast activity but also by decreasing osteoclast number. The study also included the cellular and molecular mechanisms by which MTA inhibits osteoclast differentiation. Mouse cultures were used to check osteoclastic inhibition by MTA. It was found that MTA solution did not inhibit RANKL-induced osteoclastogenesis, proving that Primary osteoblastic cells (POBs) are targets of MTA. MTA solution suppressed the 1α,25-dihydroxyvitamin D3 which caused reduction of osteoprotegerin (OPG) mRNA and protein in POBs. MTA solution did not inhibit osteoclastogenesis in cocultures of bone marrow cells (BMCs) and POBs from OPG-deficient mice. It was found that MTA solution dose-dependently inhibited osteoclast formation in cocultures. It has been reported that the values of calcium ion release from freshly mixed MTA were higher during the first 3 hours and tended to subsequently decrease. Thus, it was hypothesized that the release of calcium ions from MTA would inhibit osteoclast formation in cocultures. However, the addition of exogenous calcium chloride as a source of calcium ions to the culture medium in the absence of MTA solution did not inhibit osteoclast formation in cocultures. Furthermore, the increased calcium concentration in the supernatant medium induces osteoclast formation in cocultures, indicating that the inhibitory effects of MTA solution do not depend on the calcium ion concentration of the culture medium. MTA solution inhibits osteoclast formation in cocultures induced by 1α,25(OH)2D3, but not in RANKL-induced osteoclastogenesis, suggesting that the target cells of MTA are POBs.
In another study by Daisuke Hashiguchi et al in 2011,[22] further evaluated inhibition of bone resorption by MTA. It was found that 20% MTA reduced the resorbed area made by osteoclasts without affecting osteoclast numbers. In contrast, a high concentration (50%) of MTA solution strongly inhibited osteoclastic bone resorption and there was reduction in Tartrate-resistant acid phosphatase (TRAP), a marker enzyme of osteoclasts. F-actin dots (actin rings) are ringed structures that are commonly associated with bone-resorbing activity of osteoclasts. In the study, control cultures with complete and well-defined actin rings were observed, whereas ring formation was reduced in the presence of MTA solutions. The study also included c-Src kinase activity which increases the osteoclastic bone-resorbing activity. Hence, it was examined whether MTA solution affects the tyrosine phosphorylation and tyrosine kinase activity of c-Src. Phosphorylation of Tyr416 was stimulated after treatment with RANKL for 10 min but 20% MTA solution significantly suppressed RANKL-induced c-Src phosphorylation. Furthermore, mRNA expression levels of cathepsin K and mmp-9, boneresorption mediated genes, were analyzed by real-time PCR, and expression of these mRNAs was reduced by MTA solution. The study also showed that MTA caused apoptosis of purified osteoclasts within 18 hours. Along with apoptosis of purified osteoclasts, disrupted actin ring formation was also seen with 20% MTA solution. There was reduction in the number of purified osteoclasts when 50% MTA solution was used. Nuclear condensation, a typical phenomenon in apoptosis, was also observed in the presence of 50% MTA, which indicates that 50% MTA solution induced apoptosis in mature osteoclasts. The study also analysed relation between Bim, a pro-apoptotic protein and MTA with the help of Western blot technique.

In a study by Cheng X et al[23] demonstrated that MTA suppressed RANKL and autophagic marker protein LC3-II, which are often involved in osteoclastogenesis. To validate whether MTA directly affects autophagyMDC staining, western blot analysis and ultrastructural analysis were carried out. This proved that MTA has a significant role in autophagy inhibition. Autophagy inhibition by MTA was pharmacologically activated by using rapamycin, an autophagy activator[24], to check for the potential role of the autophagic pathway in MTA mediated anti-osteoclastogenic activity. This explained that MTA directly inhibits autophagy activity, and rapamycin reversed the low-level autophagy activity inhibited by MTA.

A study by Miri kim et al suggests that MTA show an inhibitory effect on Osteoclast differentiation and function similar to alendronate, a bisphosphonate with increased anti-resorptive property. According to the study it occurs via inhibition of Extracellular signal Regulated Kinase (ERK) signalling pathways and IκB phosphorylation.[25]

**Conclusion**

From this article it can be concluded that MTA shows a significant action on osteoclastic inhibition and retards bone resorption. Further studies are still required to support the effect of MTA on inhibition of bone resorption by osteoblasts.

Type of article: Review

Application of Silver Nanoparticles in Conservative and Endodontics

Suresh Mitthra¹, Loganathan Saatwika², Balasubramaniam Anuradha¹, Arunajetasan Subbiya³

¹Reader, ²First Year PG Student, ³Professor and Head, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai, Chennai, Tamilnadu, India

Abstract

With the advent of nanotechnology, silver finds its applications in various domains - pharmacological research, clinical diagnosis, immunostimulant moderator, tumor destruction etc. With mounting advances in the field of nanotechnology, silver occupies a significant position in bio-nanomedical applications. More recently various formulations of silver nanoparticles (AgNP) have been synthesized and incorporated for treatment, therapeutic and prophylactic purposes which offer better patient compliance. Because of its greater surface area and small particle size, they possess excellent anti-microbial properties without affecting the mechanical properties of the material. This review highlights the synthesis, mechanism of applications of silver nanoparticles in Conservative Dentistry and Endodontics.

Key words: Silver nanoparticle, biofilm, nanodentistry, anti-microbial efficacy.

Introduction

Silver nanoparticles (AgNP) are microscopic particles with at least one dimension less than 100nm. They are larger than atoms and molecules but smaller than bulk solid. Due to their large surface area more atoms come in contact with the reactant providing better bioavailability and anti-microbial action without altering the mechanical properties of the material(1). It has low bacterial resistance, long term antibacterial and antifungal action (2) and is widely used in medical field for sterilization of wound sutures, endotracheal tubes, surgical instruments, bone prosthesis etc. For biofilms that are resistant to antimicrobial agents, AgNPs penetrates the cell membrane and causes the death of microbes (3). With mounting advances in the field of nanotechnology, silver occupies a significant position for a gamut of bio-nanomedical applications. More recently various formulations of AgNPs have been synthesized and incorporated in dentistry due to its anti-microbial properties. Through their incorporation in composite resins, they are used in restorations, adhesives to enhance the mechanical properties and prevent accumulation of biofilms (4). AgNPs are used in prosthetic dentistry where they are incorporated into polymers as tissue conditioners to prevent denture stomatitis. AgNPs coated implants inhibits the binding of planktonic bacteria thus inducing infection control and favouring wound healing. In Endodontics, Nanosilver gutta percha improved anti-bacterial efficacy of gutta percha (5) by exerting inhibitory activity against Enterococcus faecalis and Candida albicans. AgNPs as irrigant are effective and possess marked bactericidal activity compared with sodium hypochlorite (6). This review aims to highlight the applications of AgNPs in Conservative dentistry and Endodontics.

E-mail: saatwika.l@gmail.com

DOI Number: 10.5958/0976-5506.2019.02341.6
SYNTHESIS OF SILVER NANOPARTICLES:

AgNPs are synthesized through physical, chemical and biological methods. Physical methods include ball milling, thermal evaporation, lithography and vapour phase. In chemical methods it is synthesized through sol-gel processing and solution based synthesis. Biological methods of synthesis include the use of bacteria, fungi and yeast. It is also synthesized from plant extracts in which root extracts of *Salvadora persica* is made to react with silver nitrate for 2 hours in 90°C. Biological methods are considered biocompatible and eco-friendly, hence it is the most frequently used method for synthesis.(1)

MECHANISM OF ANTIMICROBIAL ACTIONS OF SILVER NANOPARTICLES:

Silver ions cause destruction of the peptidoglycan bacterial cell wall and lysis of the cell membrane. They bind to DNA bases and causes condensation of DNA, thereby the bacterial cell loses its ability to replicate preventing bacterial reproduction through binary fission. They also denature ribosomes inhibiting protein synthesis and causes degradation of plasma membrane.(7) AgNP has anti-microbial activity against gram negative bacteria creating pits in the cell wall of bacteria.(8)

SILVER NANOPARTICLES IN CONSERVATIVE DENTISTRY:

Composites:

Dental caries is the most common among various diseases in oral cavity due to acid attack from cariogenic bacteria such as *Streptococcus mutans and Lactobacillus spp*. Nowadays, composite restorations are preferred due to esthetic consideration. But these restorations, do not have a long clinical record in most of the cases in comparison with other restorative materials due to secondary caries,(10) microleakage and imperfect sealing between the restorations and the cavity margins.

Hence, to improve the antimicrobial properties of composites, AgNPs has been incorporated into composite resins and adhesive systems as filler particles. The most common technique is adding a monomer, usually 2-(tert-butylamino) ethyl methacrylate, in order to improve Ag salt solubility in the resin solutions.(11)

Dentin Hypersensitivity:

Pressure transferred hydro-dynamically to the pulp is the main cause of dentinal hypersensitivity. Sensitive tooth have twice the diameter and eight times the surface density of dentinal tubules than those in non-sensitive teeth. These characteristics allow the passage and condensations of AgNPs into the dentinal tubules which offers a rapid and long lasting relief byselectively and precisely sealing the dentinal tubules in minutes.(12)

Biofilm:

A research was done by Cheng et al in 2013 (13) to investigate the mechanical properties and biofilm formation of AgNPs incorporated into composite resin. According to this study there was no alteration in the mechanical properties of composites when the AgNP was added at a concentration of 0.028 and 0.042. But there was a 75% reduction in the colony forming units of *Streptococcus mutans* when the AgNP concentration was 0.042. Thus this study proved that AgNP incorporation to composite resins had better antimicrobial and mechanical properties even at low concentrations.

BondStrength:

Melo et al(14) added 0.1%AgNPs by mass to adhesive systems to evaluate the bond strength of composite resins. This study showed a reduction in the metabolic activity of the biofilm without compromising the bond strength.

Anti-Microbial Effect:

Li-et al in 2015 (15) assessed the bacterial inhibition for short and long distance by incorporating 0.05% of AgNP in mass to the adhesive system. The results showed reduced colony forming units and acid production on biofilm near and away from the adhesive, thus proving long distance antimicrobial potential.

Biocompatibility:

To assess the biocompatibility, 0.05% concentration of AgNPs was added to human gingival fibroblasts to check the viability. This study proved that the cytotoxicity was not changed by the addition of AgNPs, suggesting the clinical application of this material.(16)

GIC:

New NanoAg-GIC developed in 2018 (17) proved to exert its antibacterial effect by diffusion. Oxidative dissolution of silver ions from the cement matrix are efficient in arresting caries and preventing the
development of oral biofilms on their surface. Therefore, AgNPs incorporated into GIC provide the release of a quick boost of silver and fluoride ions to be exchanged with carious dentin, proving to be a suitable material in the management of cavitation in high risk patients.

**Dental Porcelain:**

Methods to toughen porcelain have been initiated due to problems such as fragility, chipping and fracture of dental porcelain. Higher fracture toughness and increased Vickers hardness are seen when AgNPs are incorporated into dental porcelain (18). In dental porcelain AgNP affect the behaviour of sub-critical crack growth. The stress corrosion susceptibility co-efficient was increased with the addition of AgNPs. Studies have investigated that, without producing any colour changes, leucite reinforced glass ceramic has the ability to increase its mechanical properties by staining slurries containing AgNPs (19).

**SILVER NANOPARTICLES IN ENDODONTICS:**

Complete eradication and prevention of bacteria from the root canal system is important for successful endodontic treatment. However, bacteria still persist in the root canal system even after meticulous root canal instrumentation, disinfection and obturation (20). Hence it is essential to develop advanced endodontic disinfectants to eliminate bacteria and prevent persistent infections or reinfections.

*Enterococcus faecalis* is commonly associated with persistent periradicular lesions (21). It possess certain virulence factors such as cytolysin, lytic enzymes, aggregation substance, pheromones, and lipoteichoic acid which makes it most resistant to anti-microbial agents (22).

Since *E. faecalis* invade dentinal tubules and cementum, it resists most of the root canal disinfectants and survives for longer periods inside the dentinal tubules even in nutrient depleted conditions in an obturated canal (23). Various nanoparticles (NPs) have been used in root canal irrigants and in intra-canal medicaments. NPs possess a unique mode of action, exhibit potent antimicrobial activity and provide a long term effective treatment at the site of infection at much smaller doses. Among various NPs - AgNPs are biocompatible and possesses a broad spectrum activity. When compared with 2% CHX, 100 ml and 20 ml of AgNPs has the highest zone of inhibition 19.55 mm and the lowest zone of inhibition 10.32 mm against *E. Faecalis* respectively, indicating it can be used as an alternative antimicrobial agent for endodontic disinfection (24).

**Silver Nanoparticals As Irrigant Against Biofims and infected dentinal tubules:**

When compared with chlorexidine, AgNp solution was significantly less effective (P < 0.05) in biofilms when irrigated for 5 min, but no significant difference was observed at 15 and 30 min. Sodium hypochlorite had significantly greater antimicrobial activity compared with AgNp and chlorhexidine solutions which was associated with a lower number of viable bacteria in all time intervals tested (P < 0.05). Significant difference (P < 0.05) was observed with the use of the AgNP between 5 and 15 min, 15 and 30 min and 5 and 30 min, with a reduced number of viable bacteria at longer time intervals (25).

**Conclusion**

In Conservative Dentistry, AgNPs containing restorative materials have superior anti-microbial properties, reduction of recurrent caries and increase the longevity of the restoration, by decreasing the formation of bacterial biofilms.

In Endodontics, biosynthesized AgNPs emerge as novel antimicrobial agents for endodontic disinfection with effective antibacterial efficacy against most resistant endodontic pathogens. The AgNP solution is a suitable root canal irrigant as it was effective in dissolving *E. faecalis* biofilm and eliminating this microorganism from infected dentinal tubules.

Role of Fillers in Composite Resin – A Review

Newbegin Selvakumar Gold Pearlin Mary¹, Bharadwaj B², Venkatachalam Prakash³, Arumugam Karthick⁴

¹Senior Lecturer, ²First year Post Graduate, ³Professor, ⁴Associate Professor, Department of Conservative Dentistry & Endodontics, Sree Balaji Dental College & Hospital, Bharat Institute of Higher Education & Research, Narayananapuram, Pallikaranai, Tamil Nadu, India

Abstract

Composite resin is widely used in dental practice because of its esthetics. Dental composites incorporated with fillers has a great effect in practice as it brings about reduced microleakage, polymerisation shrinkage, low opacity for better esthetics and better colour stability. Shape, size and distribution of filler particles play an important role in color stability of composites. Microfilled hybrid composites have better finish and polish. Nanofillers composites have best finish and polish thereby providing very good esthetics and stability.

Keywords: Microfilled hybrid composite, Color stability, Polymerisation shrinkage, ONCOMER

Introduction

Resin composites are used for restorative purposes because of its good esthetic and its ability to bond to enamel and dentin¹. Polymerisation shrinkage has been the greatest problem in dental composites ever since they have been brought into practice. The fillers help play an important role in crack pinning and microcrackinduced toughening². The inorganic and organic resin particles functions to strengthen a composite, decrease the thermal expansion, minimise the polymerisation shrinkage and reduce the amount of swelling caused by water sorption. The materials used in fillers are quartz, amorphous silica, colloidal silica, ceramics, glass fillers with metals organically modified ceramics³. Filler shape is also another important factor that stabilises color of the composite resin and other properties like filler particle size and content also have a significant influence⁴. A filler particle size and distribution is directly correlated to optical properties. It also provides a very low opacity thereby improving aesthetics⁵.

Role of fillers

• Strengthen the composite resin
• Reduction in polymerisation shrinkage
• Increases hardnesst and decreases wear
• Improved workability by increased viscosity
• Reduction of matrix material
• Reduction in water sorption, softening and staining.
• Reduction in thermal expansion and contraction
• Increased radiopacity and diagnostic sensitivity
• Increased fracture resistance
• Increased abrasion resistance
• Increased compressive strength, tensile strength and modulus of elasticity
• Increased translucency
• Increased durability and better handling properties

DOI Number: 10.5958/0976-5506.2019.02342.8
Classification of fillers

1. Based on filler particle size and shape
   • Tradition – 1-50micrometre
   • Hybrid
     a) Large
     1–20micrometre glass
     0.04micrometre silica
     b) Midfiller
     0.1-10micrometre glass
     0.04micrometre silica
     c) Minifiller
     0.1-2micrometre glass
     0.04micrometer silica
     • Packable hybrid
     • Flowable hybrid
     • Homogenous microfiller
     • Heterogeneous microfiller

2. According to Skinner (1962)
   • Traditional - 8-12micrometre
   • Small particle filled composites - 1-5micrometre

   • Macrofiller composites – 0.1-100micrometre
   • Microfiller particles – 0.04micrometre
   • Hybrid composites

   • Densified composite Midway filled
   • Ultra fine Midway filled
   • Fine Midway filled
   • Ultra fine cement filled
   • Fine cement filled
   • Homogeneous microfine composite
   • Heterogeneous microfine composite
   • Splintered prepolymerized filler
   • Agglomerated prepolymerized filler
   • Spherical prepolymerized filler

5. According to Bayne and Heyman (1988)
   • Megafill
   • Microfiller
   • Midfill
   • Minifill
   • Microfill
   • Nanofill

Role of filler loading in color stability

Filler particle size, shape and distribution play a major role in color stability of composite resins. The composite fillers were classified into 4 categories based on their morphology. They are prepolymerized, irregular shaped, both prepolymerized and irregular shaped and round particles. Filler loading is mainly influenced by filler morphology. Composites containing prepolymerized filler particles has the lowest filler content thereby decreasing the colour stability whereas spherical particles have maximum filler content providing increased colour stability6.

Role of fillers in finishing and polishing

Finishing and polishing are most important steps in restoring the anatomical and morphological form of teeth in order to achieve better aesthetics7. The average size of filler particles in microfilled composite is 0.04um. When this type of fillers in composite resin was used, the surface roughness of the restoration reduced to a certain extent compared to that of early type of composite resin8. Micro hybrid composites were introduced which had a average size of 0.01um to 2um. Studies have shown that microfilled composites have better polish when compared to micro hybrid composites and physical properties and wear resistance of restoration was found to be better in micro hybrid restorations9. Recently, Nanofilled composites have been introduced which ranges from 5 to 100nm. They have widespread
distribution of filler particles which are smallest of size and thus increases filler load, resistance to wear and fracture, reduced polymerisation shrinkage, better polished surface and translucency of the restoration.

Newer advances

1. Nanofilled composites

Nanofilled composite resin have better polish and gloss retention. It has a refractive index of 1.51 which is similar to that of a tooth. Hence the color stability is increased. Nanofilled composite resin exhibits higher wear resistance than that of hybrid composite resin materials.

Nanomers

- Primary zirconia and silica nano particles 5-20nm
- Nano hybrid composites
- Nanodiamond filler

2. Flake shaped glass filler

These are thin flat platelets which improves color stability by increasing transparency. They have high flowability and smooth surface.

3. Polymethacrylate filler particle

4. Leucite containing ceramic fillers

Addition of 3% Nano ZnO to clearfill resin composite decreases the shear bond strength whereas in Z-350 group had increased shear bond strength. At the same time NZnO particles lowered the microleakage in composite resin. Adding polymeric nanofillers, metallic nanofibers and inorganic nanofillers produces the formation of interface interaction and poststretching nanofibers results in reinforced effect in dental composites. A study showed that Dental composites filled with thiourethane-silanized inorganic fillers showed 35% lower stress while doubling mechanical properties values.

5. ORMOCER

Ormocer being a complex organic matrix contains 3-dimensionally linked inorganic-organic copolymers (ormocers). The additive aliphatic and aromatic dimethacrylates present in Ormocer has high wear resistance as compared to microfilled or microhybrid composite thereby resisting discoloration. Excessive water sorption causes decrease in life of a composite resin by expanding and plasticizing the resin component, hydrolyzing the silane, and thereby resulting in micro crack formation. Therefore the micro cracks or interfacial gaps present at the interface between the filler and matrix allow stain penetration and discoloration.

Conclusion

We conclude that, nanofilled composites retain polish and translucency and produce a smooth glossy surface better than microfilled composites and have equivalent physical properties and wear resistance to that of micro hybrid composites thereby providing better esthetics.

Nonsurgical Management of Periapical Lesion with External Root Resorption Followed by Orthodontic Treatment in Maxillary Lateral Incisor

Ramachandran Tamilselvi1, Ravi Megavarnan2, Venkatachalam Prakash3, Arunajatesan Subbiya4
1Reader, 2Senior Lecturer, 3Professor, 4Professor & Head, Department of Conservative Dentistry & Endodontics, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research, Chennai, Tamilnadu, India

Abstract

The aim of this case report is to discuss the radiological outcome of a nonsurgical management of periapical lesion with external resorption followed by orthodontic treatment of the maxillary lateral incisor. A 33-year-old female reported with missing tooth in the maxillary anterior region as a result of surgical extraction of maxillary left canine tooth. Patient was referred for intentional root canal treatment in 22 followed by fixed prosthesis. The radiograph revealed external resorption in 21 and 22. After preparation of the access cavity, the necrotic pulp was removed and the canal irrigated using 5.25% sodium hypochlorite solution. The canal was then dried and packed with calcium hydroxide for 6 weeks. After removal of calcium hydroxide, canal was disinfected, dried and four millimetres of MTA orthograde filling was carried out. After 24 hrs, root canal was obturated with back fill using system B. At 1-3-6, month recall, the tooth was asymptomatic with no pain on percussion or palpation. Radiographic examination demonstrated continued thickening of root canal walls, root lengthening and apical closure.

Key words: External root resorption, Calcium hydroxide, Orthograde filling.

Introduction

Root Resorption is defined as mechanical & chemical injury to the protective tissue and stimulated by infection (or) pressure. It is a dental complication that can lead to loss of tooth. Fuss et al (1) classified root resorption as, 1. Apical root resorption (orthodontic movement), 2. Inflammatory root resorption (impacted tooth or tumour), 3. Internal root resorption (pulpal infection), 4. External resorption & cervical resorption (periodontal infection).

Bacteria in the pulp space and dentinal tubules triggers the osteoclastic activity on the root surface resulting in periapical lesion.

Case Report

A 33 yr female came to the dental office with the chief complaint of missing maxillary left canine tooth and gives history of impacted canine that was removed surgically 3 months from the day of visit. Patient was referred to our department for intentional root canal treatment in 22 followed by fixed prosthesis.

On clinical examination, mesially tilted left maxillary lateral incisor with no evidence of dental caries, non tender on percussion, without any sinus opening, soft tissues are apparently normal, vital status of the tooth 22 is nonvital. On radiographic examination presence of radiolucent area of around 1x1.5 cm in size that surrounds the lateral surface of 21 and encloses the root apex of 22 with disturbed apical constriction in relation to 22 (Figure-1).
On clinical examination and radiographic findings the tooth # 22 was diagnosed to be necrosed with external inflammatory resorption. Hence, root canal treatment was advised in 21 and 22 to prevent further resorption.

Local anaesthesia was administered using 2% lidocaine with 1 : 100 000 epinephrine. The tooth was isolated using a rubber dam (Hygenic Dental Dam, Coltene Whaledent, Langenau, Germany). An access cavity was prepared using an Endo Access bur (Dentsply Maillefer, Ballaigues, Switzerland) in a high-speed air turbine handpiece (NSK PANAR AIR, Nakanishi Inc., Tochigi-ken, Japan) with copious irrigation. Upon accessing the pulp chamber, no haemorrhage was noted from the root canal, necrotic pulp was removed from the canal. The working length was determined by placing a size #25 K file (Dentsply Maillefer) in the canal and taking a periapical radiograph (Figure-2). Cleaning and shaping was performed with step back technique MAF #55 k-file in 22, #60 k-file in 21 irrigation of the canal was performed using 10 mL of 5.25% sodium hypochlorite solution (Dentpro, Chandigarh, India) to further disinfect the canal. The canal was then dried with sterile absorbent paper points (Dentsply Maillefer).

Calcium hydroxide was introduced in the canal with a lentulo spiral (Dentsply Maillefer) and packed with the blunt end of sterile paper points. The access cavity was then sealed with 4 mm of Cavit (ESPE, Seefeld, Germany)Figure-3

The patient recalled after 6 weeks for the review, tooth was asymptomatic to percussion and palpation tests. Confirmatory radiograph was taken, that shows evidence of bony trabeculae formation and reduction in the size of periapical lesion (0.5cm) in 22(Figure-4), followed by rubber dam isolation, access cavity was reopened and the medicament was flushed out of the canals using sterile saline solution (Nirma healthcare Ltd, Gujarat, India). The canal was then dried with paper points. 4mm of orthograde filling was carried out with white MTA and temporarization done with wet cotton and Cavit (ESPE) in 22.(Figure-5). After 24 hrs root canal was obturated by backfill using system B in 22 and cold lateral compation was carried out in 22 using MTA filapex sealer (Figure-5). With the concern from orthodontic department, minor tipping of 22 was carried out with orthodontic appliances.After a month there was no history of pain or discomfort. The clinical examination revealed that no sensitivity or pain was present to percussion and palpation tests.

At 3rd month recall the patient continued to be asymptomatic. The radiographs showed continued root repair and reduction in the severity of lesion and no progression of resorption due to orthodontic treatment (Figure-6).At 6th month recall The radiographs showed continued root repair and satisfactory healing of resorative sites (Figure-7).
Tronstad et al (4) described the pathogenesis of external root resorption which is initiated on mineralized or denuded area of root surface that is prolonged by mechanical irritation along with stimulation of resorbing cells, in turn increases the acidic phosphatase level and also increases the osteoclastic activity (stimulated macrophage progenitor cells) – RANK-RANKL-OPG system, down regulation of osteoprotegerin & upregulation of receptor activator of nuclear ligand, followed by infectious inflammation by release of macrophage chemotactic factor, osteoclast activating factor, prostaglandins, bacterial endotoxins.

External Root resorption mostly requires surgical approach by elevating the flap followed by root end preparation and retrograde filling.

This case report presents the non-surgical approach in treating large periapical lesion with external root resorption using calcium hydroxide as intra canal medicament and orthograde filling for the root end repair, and the nature of the orthodontic movement of endodontically treated tooth with external resorption.

Calcium hydroxide eliminates the bacteria when used as an intracanal medicament (5) and arrests the inflammatory root resorption as well as promotes the stimulation of healing in treating resorption. Tronstad (4) described the action of calcium hydroxide in resorption.
case as follows,

Ca(OH)₄ diffuse from the dentin

Changes acidic environment to alkaline

Activation of alkaline phosphatase

Initiate osteoblastic activity

Deposition of cementum osteo dentin

Hammarstron et al (6) stated that high Ph calcium hydroxide is the reason for the bactericidal effect and causes irritation to the surrounding tissues that had stimulated pulpal defense and repair (7). The long term calcium hydroxide is more effective than short term in resorption (8). Intra canal medicament with calcium hydroxide can arrest resorption and initiate healing if resorption located apically rather cervically. On follow-up visit after 3 month of calcium hydroxide, periapical radiograph revealed arrested root resorption process and decrease in size of periapical radiolucency. Rosenberg and Murray et al (9) described the microtensile fracture strength of dentin is reduced by 23-43.9% following root canal filling by calcium hydroxide. Ca(OH)₄ in canal followed by MTA shows no significant decrease in the strength of dentin in pulpal necrosis & immature root formation (10).

MTA as orthograde filling showed 66% of cementum formation and the layer formed are consistent in contour and uniform thickness (11). MTA is a cemento conductive material and permits cementoblast attachment & growth and production of mineralized matrix gene & protein expression. The diffusion of Ca⁺ through the defect in dentin in MTA filled root shows a significant increase in concentration with increase in time. MTA Fillapex was used as it was proven that the presence of MTA in sealer did not improve the bone tissue repair, rather it provided, re-establishment of original bone tissue structure and inflammatory response decrease over time (12).

Conclusion

Despite the serious damage to the root by external root resorption, nonsurgical root canal therapy arrested the root resorption and regenerated the periapical tissue. Though the outcome cannot be predicted, it is worth an effort to try to slow down the resorption process and maintain the tooth as long as possible in the arch for esthetics, mastication.

Regenerative Endodontics-Clinical Procedure and Tooth Discolouration: A Review

Arunugam Karthick¹, Tamizharasan Sangavi², Venkatachalam Prakash³,
Newbegn Selvakumar Gold Pearlin Mary⁴

¹Associate Professor, ²First Year Postgraduate Student, ³Professor, ⁴Senior Lecturer, Department of Conservative Dentistry & Endodontics, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research, Narayanapuram, Pallikaranai, Chennai, Tamil Nadu, India.

Abstract

Regenerative endodontics in discoloured tooth involves introduction of stem cells into the disinfected canal space followed by medications and sealing of the dentinal tubules. Discolouration is more an important factor for many people to achieve an aesthetic smile than restoring the normal alignment within the arch. Tooth discoloration induced by endodontic material is one major concern in dentistry. The three main factors that affect discoloration are intracanal medicament, coronal barrier and dentin bonding agent. Recent studies show that sealing dentinal walls of access cavity with dentin bonding agent helps to avoid discoloration of tooth.

Keywords: Tissue regeneration, Scaffolding matrix, Coronal barrier, Dentin bonding agent, Biomineralization

Introduction

In the regenerative endodontics, damaged structures and cells in the pulp–dentin complex are replaced with live viable tissue, which restore normal physiologic functions. Regeneration rather than replacement of tissues with an artificial substitute is an emerging and exciting field of medicine [1]. Tooth discoloration creates a wide range of aesthetic problem, and considerable amounts of time and money are invested in the attempts to improve the appearance of discolored teeth. Change in tooth structure changes the appearance of the tooth due to transmitting and reflecting property [2]. Some discolorations are located on the outer surface of the tooth structure, others are caused by stain taken up by the enamel or dentin, and some occur during tooth development and result in an alteration of the light transmitting properties of tooth structures [3]. Tooth discoloration induced by endodontic materials is usual concern for treatment quality. Transmission of material discoloration by hard tissue causes tooth discoloration hence Selection of material is crucial to use in esthetic zone [4]. Many studies have shown that discoloration is a significant negative outcome following regenerative endodontic procedures. A combination of ciprofloxacin, metronidazole and minocycline is suggested for bacterial disinfection. Lenherret al [5] reported that the calcium hydroxide dressings did not show any discoloration or differ from the negative controls at any time point. The purpose of this literature review was to investigate findings and reports on the crown discoloration following regenerative endodontic treatment.

Regenerative endodontic procedures (REP)

REP has paradigm shift in management of immature
teeth resulting in root lengthening, wall thickening and apical closure\(^6\). Regenerative endodontics is defined as the “biological procedure to replace affected tooth structures, such as dentin, cells of pulp dentin complex and root structures”\(^7\). The biological concept of regenerative endodontics involves the triad of stem cells, scaffold platforms and signaling molecules\(^8\). The clinical considerations for regenerative endodontic protocols are disinfection of the root canal system; provision of a scaffold in the form of a blood clot that forms after laceration of the periapical tissue to induce bleeding and introduce mesenchymal stem cells within the root canal; and an adequate coronal seal to prevent reinfection\(^9\). The current recommended clinical protocol for REPs is described by the American Association of Endodontists\(^10\).

**Intracanal medicaments**

The success of revascularization/revitalization therapy depends on efficient disinfection of the root canal system. The traditional triple antibiotic paste (TAP) consisting of ciprofloxacin, metronidazole, and minocycline has good antimicrobial properties in infected root canals\(^11\). Despite these positive features, numerous case reports have shown that minocycline causes visible crown discoloration\(^12\). A practical way to prevent discoloration is replacing minocycline with an antibiotic that does not stain teeth. It is reported a successful regenerative endodontic treatment of a maxillary central incisor by using cefaclor instead of minocycline. Study of a successful Single visit regenerative endodontics used irrigation of NaOCl and chlorhexidine gluconate and MTA placement without bleeding\(^13\). Earlier reports describes the use of calcium hydroxide as the vast majority of published cases seem to have employed a combination of antibiotics as the preferred intracanal medicament \(^7\). However, these antibiotic pastes have been shown to be cytotoxic to the survival of SCAP in concentrations equal to or higher than 1 mg/mL in in vitro studies. In contrast, the disinfection of root canal space with calcium hydroxide promoted the proliferation of SCAP\(^14\). Calcium hydroxide increased the liberation of growth factors from dentin, whereas antibiotic paste negatively influenced growth factor release after the use of EDTA\(^15\). The AAE clinical considerations in regenerative endodontic advocate the use of either a combination of antibiotic paste or calcium hydroxide paste\(^10\). A retrospective radiographic study employing a quantitative analysis of teeth treated with REPs showed that teeth medicated with calcium hydroxide had a significantly greater increase in root length than the teeth medicated with the combination of antibiotic paste. Importantly, teeth treated with the combination of antibiotic paste had significantly greater increases in root canal wall thickness. The placement of calcium hydroxide within the canal appeared to favourably affect the outcome of the treatment. When calcium hydroxide was restricted to the coronal half of the root canal, as demonstrated radiographically, the median increase in the dentinal wall thickness was 53.8%. This contrasted with just a 3.3% increase when calcium hydroxide was present in the apical half of the root canal. The percentage of change in root length was not affected in either of these different clinical protocols\(^16\). The results of a cohort study of 12 teeth medicated with a triple antibiotic paste showed apical closure in 66.7% of cases, increased root wall thickness in 41.7%, and increased root length in 41.7% of cases. In comparison 11 teeth medicated with calcium hydroxide showed apical closure in 54.5% of cases, increased root canal thickness in 45.4%, and increased root length in just 27.3% of cases. These findings were considered comparable outcomes, and hence, the application of either medicament is supported for use in the regenerative endodontic procedures \(^16\). Histologic evidence of successful treatment in this study demonstrated that the introduced method of root canal disinfection is a promising protocol for immature necrotic teeth, and the use of triple antibiotic paste may not be necessary. Studies introduced novel methods to shorten the treatment period and also prevent tooth discoloration by omitting the intracanal medication process.

**Coronal barriers**

**Mineral trioxide aggregate**

Mineral trioxide aggregate (MTA) is a biomaterial that is being investigated for endodontic applications since the early1990s \(^17\). In 1993 MTA was first described in the dental scientific literature and In1998 it was approved for endodontic use by the U.S. Food and Drug Administration \(^18\). The MTA materials are a mixture of a refined Portland cement and bismuth oxide, and are reported to contain trace amounts of SiO2, CaO, MgO, K2SO4, and Na2SO4\(^19\). The major component, Portland cement it is a mixture of dicalcium silicate, tricalcium silicate, tricalcium aluminate, gypsum, and tetra calcium alumino ferrite\(^20\). MTA solidify like...
other mineral cements, in which the anhydrous material dissolves, followed by the crystallization of hydrates in an interlocking mass \(^{[21]}\). The basic framework of the hydrated mass is formed by the interlocking of cubic and needle-like crystals in which the needle-like crystals form in sharply delineated thick bundles that occupy the inter-grain space between the cubic crystals \(^{[22]}\). The effect of mixing MTA powder with different liquids and additives has shown that the choice of preparation liquid can have an effect on setting time and compressive strength\(^{[23]}\). In 2002, white MTA, was introduced as ProRoot MTA (Dentsply Endodontics, Tulsa, OK, USA) to address esthetic concerns. After that time, two forms of MTA materials were categorized: the traditional gray MTA and WMTA. Scanning electron microscopy (SEM) and electron probe microanalysis characterized the differences between GMTA and white MTA and found that the major difference between gray MTA and white MTA is in the concentrations of Al\(_2\)O\(_3\), MgO and FeO\(^{[24]}\). The mechanisms how white MTA influences on coronal tooth discoloration and those by which blood exacerbates this discoloration are not fully elicited. The possible mechanism is the oxidation and incorporation of the remaining iron content within the white MTA powder into the calcium alumino ferrite phase of the set white MTA cement. Even though white MTA has 9% of the iron oxide of gray MTA, this quantity may be adequate for causing discoloration. White MTA also interacts with erythrocytes. Discoloration of traumatized teeth results from the hemolysis of erythrocytes and the accumulation of hemoglobin and hematin molecules within dentin tubules. The slow hydrating process of white MTA may permit the absorption and subsequent hemolysis of erythrocytes from the adjacent pulpal tissue, thus resulting in both material and subsequent tooth discoloration\(^{[25]}\). The descriptions of various bioactive molecules including growth factors lead to exciting alternative treatments of dentin-pulp complex. The usage of growth factors alone in regenerative treatment approaches tried to be developed imitating the physiological events of the body has been questioned\(^{[26]}\). Newly formed tissues in the canals could extend to the surface of MTA or occupy half of the canal space after 3 months. The growth of the tissue into the canal seemed not limited by the blood supply with an apical opening of 0.8 mm in diameter. When tissues engineered in the laboratory are implanted into the human body, only cells within 100–200 mm from the nearest capillary can attain sufficient diffusion of nutrients to survive. Thus, a voluminous tissue be pre-vascularized for achieving immediate and sufficient blood supply after implantation. MTA is a good material for pulp capping and apexification, which can induce dental pulp cell differentiation and the secretion of mineralized tissue. 0 Cells in new vital tissues in the apical pulp were more immature with larger and deeply stained nuclei. These cells pertain more potential for multilineage differentiation. Cementum-like tissue was along the internal root canal walls. In some cases, cementum-like tissue inside the root canal was connected with root surface cementum. The source of stem cells responsible for bone-like and cementum-like tissues is not clear, possibly from the periapical tissues\(^{[27]}\). Discoloration after treatment of teeth that were treated with calcium hydroxide might be related to presence of MTA in cervical portion of the root canal space. A recent report on pulp capping in anterior teeth revealed that presence of white MTA in the crown can cause considerable discoloration. In clinical and radiographic follow-ups, both teeth was functional, the apices formed and periapical lesions were healed. However, the roots were not developed. After 6 years, because of moderate discoloration and caries, teeth received root canal therapy and were permanently restored with casting dowel core and full crown restorations \(^{[28]}\). A disadvantage of the MTA is discoloration of the coronal dentin when placed in the canal. McTigue et al \(^{[29]}\) reported that 14 teeth discolored. The first 10 cases were treated with TAP including minocycline, which was then discontinued and substituted with clindamycin because of concerns with discoloration. Gray MTA, which has been linked with tooth discoloration was used in the first 12 cases, and this was then substituted with white MTA because of concerns with discoloration. Although 7 of the discolored teeth occurred when minocycline and gray MTA were used, 7 teeth also discolored when neither minocycline nor gray MTA was used \(^{[12]}\). These authors noted that white MTA has been implicated in tooth discoloration. Spectrophotometric analysis of coronal discoloration induced by gray and white MTA, found that both materials discolored teeth. However, the effect was more marked with gray MTA.

**Calcium silicate-based materials**

The bio-mineralisation ability of Biodentine initiates calcium and silicate uptake by the dentin, which in turn would cause chemical and structural modification of dentin that may result in higher acid resistance and
physical strength. Calcium silicate-based cements adhere to root dentin to form a crystalline bond in a biochemical process termed bio-mineralisation\cite{30}. Hence, the use of Biodentine as an obturation material may eventually improve the resistance of the endodontically treated immature teeth against fracture. Compared to other tricalcium silicate cements biodentin has greater compressive strength, which is attributed to the low water/cement ratio made possible by the water soluble polymer in the liquid. Discoloration is either a result of materials ingressing into dentinal tubules or by material remnants in the pulp chamber, which get darker over time and is transmitted through the hard tissues. The consistent with the literature as Biodentine exhibited color stability independent of oxygen and light irradiation. Biodentine TM, as a suitable material, has been suggested for the purpose of dentin-pulp complex regeneration in the clinical setting. The author stated that biodentin TM helps in revascularisation and maintenance of pulp vitality and root maturation\cite{7}. In a study on evaluation and comparison of occurrence of tooth discoloration after the application of various calcium silicate-based cements revealed that there was no significant difference between discolouration of tooth using Biodentine (Saint Maur des Fosses, Septodont, France), OrthoMTA (BioMTA, Seoul, Korea), and EndoSequence Root Repair Material (ERRM; Brasseler, Savannah, GA) in the presence of blood. Absence of blood, ERRM and Biodentin exhibited less tooth discoloration than OrthoMTA.

Dentin bonding agents

One of the methods to decrease discoloration is using dentin bonding agents. Kim et al\cite{7} examined the performance of this prevention technique for tooth discoloration. In this study teeth treated with dentin bonding were evaluated with naked eye and then with colorimeter. In the eye assessment teeth did not have any change in color, but in the colorimeter assessment they had. They concluded that using dentin bonding agents before placement of the triple antibiotic paste might not completely prevent tooth discoloration. The dentin bonding agent can only decrease the intensity of the discoloration \cite{7}. One possible way to minimize discoloration is to seal the dentinal walls of the access cavity with dentin bonding agent\cite{12}. Sealing the dentinal tubules of the chamber prevents the coronal discoloration produced through tri-antibiotic medication while maintaining the pulp revascularization\cite{6}. The administration of the dentin bonding agent before filling the pulp cavity with MTA prevented the MTA component from penetrating into the dentinal tubules which decreased discoloration. Applying a dentin bonding agent before MTA placement can minimize tooth discoloration. Keskin et al\cite{4} reported that discoloration induced by calcium silicate-based materials diminished by the administration of a double layer of dentin bonding agent in the access cavity or via treating with internal bleaching. The application of dentin bonding agent, to seal dentinal tubules before placement of the white and grey MTA, prohibited dental discoloration.

Scaffolding Matrix

3D scaffolds are the essential parts of the tissue engineering triad. An ideal scaffold can be significantly facilitate attachment, migration and proliferation of stem cells, and 3- D spatial organization of stem cells and infiltration of host cells. While the current REP protocol assumes an endogenous scaffold from fibrin of clotted blood, other autologous sources such as PRP and platelet-rich fibrin (PRF) have also demonstrated comparable outcomes in animal as well as human clinical reports. In addition to providing a structural matrix for stem cells, functional modifications to scaffolds can uniquely add to their utility in a REP. In cases where adequate bleeding to the CEJ cannot be evoked scaffolding material can be supplemented with chemoattractants that can facilitate stem cell migration. To this end, a recent in vitro study evaluated several chemoattractants and found Granulocyte-Colony Stimulating Factor (G-CSF) and Fibroblast-Growth Factor-2 (FGF-2) to have considerable chemoattractive properties for SCAP \cite{17}. The PRF clot forms a strong natural fibrin matrix, which concentrates almost all the platelets and growth factors of the blood harvest \cite{4} and shows a healing matrix, including mechanical properties no other platelet concentrate offers. The PRF can be considered as a natural fibrin-based biomaterial favourable to the development of a micro vascularization and able to guide cell migration into wound area. For higher success rate, more demand exists to develop new biocompatible material that reduce pulp inflammation and promote the formation of dentin pulp tissues \cite{7}. However, it was shown that the newly grown tissues into the root canal space have little similarity to normal pulp tissue but with more resemblance to cementum, periodontal ligament, or bone. The cause of this outcome is possibly related to the lack of stem cells derived from remaining vital
pulp and apical papilla, which are destroyed by severe endodontic infection. Stem cells responsible for newly regenerated tissues might be derived from several other sources, including systemic blood or local tissue such as bone [12]. Furthermore, whether these newly formed tissues can function like normal pulp and stabilize the tooth without giving rise to further infection or canal obliteration still remains unknown.

**Conclusion**

In conclusion 3 factors affect discoloration including intracanal medication, coronal barrier and using dentin bonding agent. It has been suggested that one possible way to avoid discoloration is to seal the dentinal walls of the access cavity with a dentin bonding agent. The recent review in dental traumatology does seem timely because there does appear to be a lack of evidence and conflicting results as well as a paucity of prospective studies.

A Stitch in Time Saves Nine – A Simple IOPA in Time Saves Tooth

Sankar Narayanan R¹, Amudhan A², Venkatesh³, Sindhu Poovannan⁴, Aravindhswamy R M⁴
¹Senior Lecturer, ²Reader, Oral Medicine and Radiology, ³Professor, Conservative Dentistry and Endodontics, ⁴Post Graduate, Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER

Abstract

Foreign bodies / objects are substances that are non-native to the area of interest. They may frequently cause irritation or allergic reactions. An unnoticed foreign body may lead to deteriorating sequelae. Self introduced foreign body into the root canal of mandibular incisors is a rare occurrence. This Case discusses about a 13 year old boy who self introduced a metallic foreign object into the root canal of 32. A simple IOPA on time helped in appropriate management of the tooth and prevented deteriorating sequelae.

Key Words: Self introduced foreign body, mandibular incisor.

Introduction

Foreign bodies are objects that are not native to the body and have been introduced accidently or by design. Foreign body ingestion is quite common among children; likewise forceful impaction of foreign objects into the tooth has also been reported in literature[¹, ²]. Staple pin, straight pin, paper clip[³], nail, sewing needle, incense stick, beads are the various foreign objects that have been forced into the tooth[⁴, ⁵]. Exposed pulp chambers due to trauma or caries provide an opportunity for such foreign body impaction. Patients tend to introduce such objects either to relieve pain or clear food debris plugged into the canal[⁶]. This acts as a focus of infection. If unnoticed the foreign body may lead to abscess formation or even deteriorate to osteomyelitis with sinus tract formation[⁷].

Foreign objects inside the root canal system create hindrance to proper BMP and obturation.

Such foreign objects when deeply impacted within the canal can be challenging to manage[⁸]. Several retrieval methods are employed to remove disengaged endodontic instruments within the canal. Depending on the location and position of the foreign body within the root canal similar methods can be used to retrieve them however no standard technique has been recommended[⁹, ¹⁰]. This article discusses a case of a 13 year old boy who forcefully introduced a metallic foreign object inside the root canal of mandibular lateral incisor and its diagnosis and management.

Clinical Case:

A 13 year old boy reported to Oral Medicine and Radiology department, Sree Balaji Dental College and Hospital, Chennai with a chief complaint of pain and discharge from the oral cavity in relation to the lower front teeth region for the past two weeks. (Figure 1) History revealed that the boy had pain that was continuous, sharp and lancinating in nature. Pain did not subside upon medications. Patient did not give any history of previous endodontic management of the tooth. Patient had no medical history or systemic illness.

On examination, a fracture exposing the pulp chamber was evident along with pus discharge in 32. (Figure 2) An IOPA was taken in relation to 31,32,33 region. Radiograph revealed a radiopaque foreign object in the apical third of root and extending well into the periapical region of 32. (Figure 3)
Root Canal Treatment was planned to retrieve the object and save the tooth. Patient was referred to the Department of Endodontics for further management. After the Clinical and Radiographic examination of the tooth access opening was performed and redefined to ease the access of the fractured fragment under microscope. Attempt was made to retrieve the foreign object using H-file. (Figure 4) The file was inserted into the canal and used to engage the foreign object. (Figure 5) The H-file dislodged the foreign object into the pulp chamber and it was retrieved. (Figure 6) The object was 16 mm in length. (Figure 7) An IOPA was taken to confirm the complete retrieval of foreign object. (Figure 8) An open dressing was given in the first appointment. Patient was recalled after three days and clinically evaluated. The tooth was asymptomatic. The canals were wet which was evaluated by paper points and an open dressing was given for the patient. After five days the patient was recalled for the next visit and upon clinical evaluation the patient was asymptomatic. The canals were found dry following which DentoCal was placed and access temporized with Zinc oxide Eugenol (Anabond Stedman Pharma research Pvt Ltd).

Patient reported after two days with pain. Calcium hydroxide medicament was removed and open dressing was given. Patient was recalled after three days for calcium hydroxide medicament placement and access temporized with Zinc oxide Eugenol (Anabond Stedman Pharma research Pvt Ltd).

Following two weeks recall visit the patient was recalled for BMP and obturation. The tooth 32 was found to be asymptomatic; subsequently the tooth was obturated by lateral compaction (FIGURE 9).

On a one month follow-up patient was asymptomatic and showed no sensitivity to percussion or palpation. The soft tissues were healthy.
Discussion

Self introduction of foreign objects into the pulp chamber and root canals is a rare occurrence in adults. Staple pins and needles are frequently forced into the root canals. In this case the patient did not give any previous history of dental treatment for 32. Following trauma the tooth was fractured exposing the pulp chamber which lead to food lodgment and discomfort to the patient. The patient gave a history of inserting sharp pin into the pulp chamber to relieve pain and discomfort. However patient did not recall any history of broken pin inside the tooth. In this case exposure of the pulp chamber provided an opportunity for the child to self introduce a metallic foreign object into the canal.

Patient had not reported for treatment of the fractured tooth earlier. After the forceful impaction of metallic pin, pain and pus discharge was elicited from the tooth which directed the patient to report for dental management. Upon careful clinical examination a provisional diagnosis of Ellis class III fracture in 32 was made. IOPA taken for the tooth of interest revealed a radiopaque foreign object in the apical third which extended into the periapical region. The presence and location of the foreign body explains the elicitation of pain and pus discharge.

In this case a 20 size H-file was used to engage and retrieve the foreign body. BMP and obturation was performed in the following visits. After treatment tooth was asymptomatic. Precise diagnosis and selection of correct retrieval method dictate the success of the treatment. Extraction was not necessary for the tooth and a simple, cost effective IOPA has saved the tooth.

Conclusion

Immediate attempt to retrieve such foreign bodies when detected in root canal system must be made. Simple IOPA and non surgical procedures can save tooth from extraction and help to restore normal function and esthetics. Non compliance to non surgical methods may demand surgical management of tooth with impacted foreign body.

Plasma Cell Gingivitis- A Case Report

Hemalatha.V.T.1 Mani Sundar N', Sankar Narayanan R3, Krishna Raj4

1PhD Research Scholar & Associate Professor, Department of Oral Medicine and Radiology, India, 2PhD Research Scholar, 3Senior Lecturer, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, Bharath Institute Of Higher Education and Research, Pallikaranai, Chennai, Tamil Nadu, India, 4Senior Lecturer, Department of Periodontics, Rajah Muthiah Dental College and Hospital, Annamalai University, Chidabaram, Tamil Nadu, India

Abstract

Plasma cell gingivitis (PCG) is a rare condition of the gingiva, characterized by infiltration of plasma cells. Being a rare benign condition of the gingiva, PCG is characterized with erythematous and edematous gingivitis. The biologic phenomenon of the hypersensitive reaction appears to be chief etiology behind this occasionally presenting clinical entity. Plasma cell gingivitis has a close resemblance to discoid lupus, lichen planus, cicatricial pemphigoid or leukemia, and HIV gingivitis. It is known to present as a hypersensitive response to allergen, but sometimes it could present as a clinical entity with unknown etiology.

This paper reports a 60 year old female patient with the complaint of bleeding and swelling of gingiva since 2 months. On detailed history, patient was first diagnosed as drug induced gingival enlargement and based on histopathological findings, a diagnosis of plasma cell gingivitis was made.

Keywords: Gingival enlargement, hypersensitivity, plasma cell gingival enlargement, plasma cell gingivitis.

Introduction

Gingival overgrowth or gingival enlargement is a common trait of gingival diseases featured either isolated or generalised with varied appearances. Numerous types of gingival enlargement are classified on the basis of etiology, systemic factors and pathological findings and its diagnosis may require extensive investigations due to varied clinical and histopathological features. One of the causes of conditioned gingival overgrowth is plasma cell gingivitis (PCG). It is an uncommon condition characterised by diffuse infiltration of non-neoplastic plasma cells in the sub-epithelial tissue. The etiology is difficult to elicit; however specific known allergens have been found to be responsible, e.g., toothpaste, khat, food, chewing gum, and also of unknown origin. Clinically, it manifests as bright red oedematous gingival swelling usually localized and sharply demarcated from the mucogingival junction. PCG such as atypical gingivitis, plasma cell gingivostomatitis, plasmacytosis of the gingiva and allergic gingivitis.

Case Report

A 60 year old female patient reported with a chief complaint of unesthetic swelling of gums in upper and lower region of teeth since 2 months with burning sensation of the mouth on taking hot food. Over the period of time, gingival enlargement occurred in the entire quadrants with progressive increase in size with mild mobility of teeth which restricted patient’s dietary habits. The medical history revealed that patient was under history of amilodipine since 10 years. Oral examination revealed generalized severe gingival inflammation and enlargement covering up to the middle half of the clinical crown [Figure 1]. Erythema was pronounced in relation to the maxillary and mandibular anterior region and also associated with mild gingival enlargements in posterior region. There was no generalized loss of attachment. Generalized pseudo pockets ranged from 4mm to 6mm. Bleeding on slight manipulation. Macroscopically the gingiva appeared oedematous with loss of stippling. There is no history of change of oral hygiene products like toothpaste or consumption of chewing gums. There was no history of loss of appetite, fever or lack of sleep. The clinical examinations of drug induced gingival...
enlargement and plasma cell gingivitis was considered.

Orthopantomographic examination revealed a generalized moderate horizontal bone loss. Routine hemogram and biochemical tests were within normal limits and microscopic examination of the representative gingival tissue showed focal ulceration, prominent inflammation with fairly large number of plasma cells. There is also abundant fibroepithelial hyperplasia [Figure 2]. The histopathological final diagnosis of the above case is plasma cell gingivitis.

Prior to local management, the patient was thoroughly assessed by a physician and a suitable premedication therapy was instituted. Under local anaesthesia, the enlargement was resected segment wise by a modified flap surgical procedure. There were no postoperative complications and the healing was uneventful. [Figure 3] The patient was followed up for a period of 2 months regularly.

Figure 1: Severe Gingival Inflammation and Enlargement

Figure 2: Inflammatory Cells – Predominantly Plasma Cells Are Seen

Figure 3: Post Operative Image Showing Healing And No Evidence Of Inflammation

**Discussion**

Plasma cell gingivitis is a rare condition, characterized by diffuse and massive infiltration of the plasma cells into the connective tissue. The first case was reported by Kerr *et al.* in 1981, when they observed gingival enlargement in gum chewers, which disappeared the discontinuation of the chewing habit. Plasma cell gingivitis has been classified into three types by Garguilo, Timms *et al.*, as an immunological reaction to allergens, neoplasia or of unknown origin. In our case, the etiology was unknown (and hence, can be classified as the third variant of PCG).

Clinically, PCG presents as a diffuse reddening, together with edematous swelling of the gingiva, with a sharp demarcation along the mucogingival border. In our case, the patient presented with a fiery red gingival enlargement, localized to the anterior segment of the jaws, refractory to oral prophylaxis. These findings are consistent with earlier reports. Although the co-existence of PCG with aggressive periodontitis and psoriasis has been reported, no such association has been reported earlier with muscular dystrophy.

On the other hand, gingival swelling in PCG may result in the accumulation of plaque and calculus providing conducive environment for bacterial proliferation, and breaching the epithelial barrier in established gingivitis. This may result in activated immune response by secretion of various cytokines such as interleukin (IL)-12, IL-18 by dendritic cells, tumor necrosis factor (TNF)-α, IL-6, IL-8, macrophage inflammatory protein (MIP)-1 alpha by gingival fibroblasts and matrix metalloproteinase (MMP), laminins by periodontal fibroblasts. These cells contribute to bone resorption via cytokine production and receptor activator of nuclear factor-kB ligand (RANKL). Further bacterial antigenic challenge activates adaptive
immunity with T cells and B cells playing the central role in progression of the lesion\(^9,10\). Adding to this, the proliferative plasma cell infiltrate in PCG can further aggravate the condition. The activated antigen specific B cells in PCG differentiate into plasma cells which secrete antibodies against the foreign antigen. It has been observed that activated B cells can induce bone resorption in RANKL dependent manner by production and release of different cytokines\(^11\).

Therefore, the antigenic challenge in PCG can aggravate periodontal tissue breakdown in two ways. Firstly, the individual’s innate susceptibility along with inability to maintain proper oral hygiene in area of gingival swelling (PCG) and secondly due to the release of inflammatory mediators, cytokines and proteases, activating bone resorption pathways. Whether PCG appeared first or GAP can only be known with patient’s awareness of the disease process since its initial presentation, as this will help in depicting the exact history, signs and symptoms. To conclude, this case underscores the importance of comprehensive history taking and diagnostic investigations for varying clinical presentation of gingival conditions. PCG is the oedematous swelling of the gingiva generally due to an allergic reaction. The presentation of PCG may be localised or generalised depending on the genetic and immune susceptibility of the individual in association with environmental factors. Further, assessment is needed to underpin the mechanism explaining concurrence of PCG with aggressive periodontitis.\(^1\)

Histopathological examination of PCG reveals plasma cell infiltration in a dense collagenous stroma. Histologically, this condition must be differentiated from other aggressive conditions, such as, leukemia, plasmacytoma, multiple myeloma, and Waldenstrom’s macroglobulinemia, to facilitate early treatment for a better prognosis.\(^12,13\)

Several medical and surgical therapies have been tried for the management of plasma cell gingivitis, with variable success. The medical treatments tried include, topical/ systemic antihistaminics, corticosteroids, antimicrobials, and surgical modalities, including, excision by laser, electrocoagulation, and so on.\(^14\) Our patient responded to periodontal flap surgery accompanied with an antibiotic prophylaxis and analgesics for a week.

**Conclusion**

The importance of detailed history-taking, examination, and conduction of appropriate diagnostic tests, to arrive at a definitive diagnosis, is emphasized. An early diagnosis would direct the clinician toward an appropriate treatment plan, especially for unusual conditions masquerading as common lesions, which are refractory to conventional therapy.

A Ray of Hope - Photodynamic Therapy

Sankar Narayanan R1, Amudhan A2, Wasim Ahamed SG3, Kavitaa Nedunchezian4

1Senior Lecturer, 2Reader, Department of Oral Medicine and Radiology, 3Senior Lecturer, Department of Oral and Maxillofacial Surgery, Sree Balaji Dental College and Hospital, BIEHER, 4Consultant Maxillofacial Radiologist, Venkateshwara Diagnostics, Chennai

Abstract

Photodynamic therapy (PDT) involves utilization of a photoactive dye (photosensitizer), which gets activated upon irradiation of light to a specific wavelength in the presence of oxygen leading to the generation of free radicals, which eventually destroys the targeted cell. Applications of PDT in dentistry are growing rapidly: the treatment of oral cancer, bacterial and fungal infection therapies, and the photodynamic diagnosis (PDD) of the malignant transformation of oral lesions. PDT has shown good potential in the treatment of oral leukoplakia, oral lichen planus, and head and neck cancer. Photodynamic antimicrobial chemotherapy (PACT) has been efficacious in the treatment of bacterial, fungal, parasitic, and viral infections.

Key Words: Photosensitizer, Lasers and Head & Neck Cancers

Introduction

Photodynamic therapy (PDT) is defined as "the light induced inactivation of cells, microorganisms, or molecules." Also known as photo radiation therapy, phototherapy, or photo chemotherapy.

Prof. Hermann von Tappeiner coined the term "photodynamic", to describe oxygen-consuming chemical reactions in vivo. PDT involves the administration of photosensitizing compound and accumulation of sensitizer molecules in the target cells followed by a selective irradiation of lesion using visible light. Drug and light are individually non-toxic and in conjunction they mutilate tissues.

PDT has been approved for treating selective malignancies which are intraoperative and for intra-cavitary use in U.S., Canada, Germany, France, Japan and Netherlands. It has also been used in diseases like psoriasis vulgaris, warts, bacterial infections, diseases of the epidermal appendages, atherosclerosis and rheumatoid arthritis as an investigational treatment.

Historic Credits:

Oscar Raab, observed the death of *Paramecium caudatum* after light exposure in the presence of acridine orange.

Tappeiner and Jesionek in 1904, used topical eosin and visible light to treat skin tumours, condylomata and lupus vulgaris.

Policard, Figge, Auler and Banzer, Weiland and Manganiello, independent of each other, reported the tumour localization of haematoporphyrin.

Dougherty et al., spearheaded the lucrative use of PDT to treat cutaneous cancers and other malignancies.

Mechanism of Action:

Upon irradiation with light of an appropriate wavelength, the photosensitizer undergoes transition from low-energy-state "ground state" to a higher-energy "triplet state." The triplet-state sensitizer reacts with...
biomolecules to generate free radicals and radical ions or with molecular oxygen to produce singlet oxygen. These cytotoxic species in turn causes oxidation of cellular constituents such as plasma membranes and DNA, resulting in cell death. Clinically, PDT reaction is cytotoxic and vasculotoxic.

There are two proposed mechanism behind which PDT works:

Type I mechanism: Electron/hydrogen transfers directly from the photosensitizer producing ions or there is an electron/hydrogen removal from a substrate molecule to form free radicals. The free radicals react with oxygen rapidly and result in producing highly reactive oxygen species.

Type II mechanism: Electronically excited and highly reactive state of oxygen is released, which is termed as singlet oxygen. Since these reactions are mediated through singlet oxygen species, it is accepted as the major pathway in microbial cell destruction.

However in both the proposed mechanism, damage is created by oxygen tension as well as photosensitizer concentration.

The variables in PDT are:

1. Photosensitizers: This may be systemic or topical

2. Oxygenation of the tissues: Experimental attempts have been made at improving the effectiveness of PDT by manipulating the tumor O$_2$ content, but it has not been proven clinically as yet.

3. Light source: Lasers (coherent) and incoherent sources.

Photosensitizers:

Many natural and synthetic photoactive compounds have a photosensitizing effect.

Ideal photosensitizers are:

- High absorption coefficient in the spectral region of the excitation light
- A triplet state of appropriate energy (ET/95 kJmol$^{-1}$) to allow for efficient energy transfer to ground-state oxygen,
- High quantum yield of the triplet state (FT/0.4) and long triplet-state lifetimes (T/1 ms) since the efficiency of the photosensitizer is dependent on the photo-physical properties of its lowest excited triplet state, and
- High photo-stability.

Several kinds of photosensitizers may be associated with laser, but each will have applicability dependent on the absorption of the light and wavelength. Most photosensitizers are activated by light between 630 and 700 nm, corresponding to a penetration depth of 0.5 cm (630 nm) to 1.5 cm (at ∼700 nm).

The main photosensitizers found in the literature are: hematoporphyrin derivatives (620–650 nm), phenothiazine, like toluidine blue and methylene blue (620–700 nm), cyanine (600–805 nm), phytotherapeutic agents (550–700 nm), and hytalocyanines (660–700 nm).

Photofrin and hematoporphyrin derivates (620–650 nm) are the first-generation sensitizers whereas the 5-aminolevulinic acid (ALA), benzoporphyrin derivative, lutetium texaphyrin, temoporfin, tinethyletiopurpurin, and talaporfin sodium are the second-generation sensitizers. Foscan (temoporfin), the most potent second-generation photosensitizer, has been found to be 100 times more active than photofrin in animal studies.

5-Aminolevulinic acid can be applied intravenously, orally, or topically to allow greater tumor selectivity. 5-ALA is the sole photosensitizer to be applied topically. The remaining types can only be delivered intravenously. Topically applied ALA provides some advantages such as complete lack of systemic photosensitivity and lack of necessity of avoiding exposure to light after the treatment. A major disadvantage of topical application is the low treatment depth and penetration which is around 1–2 mm. Therefore, this approach is useful for the successful treatment of superficial tumors like premalignant and malignant lesions, leukoplakia and recalcitrant leukoplakia, corner of mouth, buccal, labial, gingival, mandibular oral mucosa, dysplasia, squamous cell carcinoma, verrucous hyperplasia, and extraoral verrucous carcinoma.

Light Source:

The activating light is most often generated by lasers or in some cases by arc lamps or fluorescent
light sources. Typically, the light must be of a specific wavelength as described by some; however, even broad-spectrum light can activate photosensitizers such as toluidine blue. Lasers are the most preferred sources of light used in PDT. The laser light can be focused through a fiber optic to deliver the proper amount of light. Most of the light photons at wavelengths between 630 and 800 nanometers (nm) travel 23 cm through the surface tissue and muscle between input and exit at the photon detector. As high-power lasers may induce trauma to surrounding tissues through thermal injury, low-power light with a photosensitizer is an attractive alternative therapy. Currently, diode lasers, which are much cheaper and more portable than metal vapor or tuned dye lasers, have become the preferred light source. The choice of photosensitizers used in dentistry is strongly dependent on the light source used. Currently, light sources of a specific wavelength mostly applied in photodynamic therapy are helium–neon lasers (633 nm), gallium–aluminum–arsenide diode lasers (630–690, 830, or 906 nm), and argon lasers (488–514 nm). The wavelengths of these sources range from visible light to the blue of argon lasers or from the red of helium–neon and gallium–aluminum–arsenide lasers to the infrared area of some diode lasers. High-level-energy laser irradiation is not used to activate the photoactive dye because a relatively low-level exposure produces a high bactericidal effect. Non-coherent light sources, such as tungsten filament, quartz halogen, xenon arc, and phosphor-coated sodium lamps, are used for the treatment of larger areas. Nonlaser sources such as light-emitting diodes (LED) are recently used in PDT because of their inexpensive, flexible, and lightweight properties.

PDT in treating Oral Lesions:

PDT is a relatively minimally invasive treatment form of malignant and premalignant lesions of head and neck including the oral cavity, the pharynx, the nasal cavity, and the larynx. These tumors are generally treated with conventional treatments, such as surgery, chemotherapy, and radiation, which may cause many side effects, including jaw pain, mouth sores, dysfunctional salivary glands, and difficulties in chewing, swallowing, and talking.

Selective tumor destruction and its minimal invasiveness are the main advantages of PDT over conventional treatments based on the preservation of healthy tissues.

Treatment regimen is appropriate for basically two groups of pathologies: these are early neoplastic lesions (premalignant and in situ carcinoma) and advanced recurrences after previous surgery or radiotherapy, respectively. Outcomes of the treatment are less satisfactory in the treatment of advanced carcinomas with PDT. This is probably due to a limited ability to adequately deliver laser light to the tumor bed. However, the possibility of an effective treatment of early-stage tumors and premalignant lesions with the preservation of the surrounding normal structures is often a great benefit.

Sharwani et al. examined patients with clinically suspicious oral leukoplaikia and showed that dysplastic lesions have significantly higher red fluorescence than benign oral lesions without changes in green autofluorescence.

Kubler et al. evaluated the effectiveness of mTHPC-mediated PDT in 25 patients with primary squamous cell carcinomas of the lip. During 12 weeks of the evaluation period, complete response has been shown by 24 of the patients (96%). Only one patient has shown a partial response and has been successfully retreated by mTHPC-mediated PDT, with a complete response at 7 months after retreatment. The functional results were excellent in all patients, without any signs of restricted mouth opening or impaired lip closure.

Copper et al. performed a study to examine the long term efficacy of mTHPC-mediated PDT in the treatment of 29 early-stage squamous cell carcinomas of the oral cavity and oropharynx. In 25 tumors (86 %), a complete remission of the primary tumor was obtained. Four lesions developed local recurrent disease after 1–6 months. All of these cases were salvaged by surgery and/or radiotherapy. None of the patients complained about impairment of mastication, swallowing, articulation, or speech after PDT.

Hopper et al. demonstrated that tumor clearance was accompanied by excellent cosmetic and functional results, without impact on the patient’s performance status. Adverse events in the immediate post-treatment phase were limited to pain (82 %) and swelling (10 %) at the treatment site due to the tumor necrosis caused by PDT. They concluded that mTHPC-mediated PDT is a safe and effective method of dealing with early oral
squamous cell carcinoma with a number of advantages over conventional treatments in terms of improved organ function and cosmetic appearance. Lin et al. [21] indicated that the laser light-mediated topical ALA-PDT is also very effective for oral verrucous hyperplasia (OVH) and oral erythroleukoplakia lesions (OEL). Therefore, they suggested that topical ALA-PDT using either LED or laser light may serve as the first-line treatment of choice for OVH and OEL lesions.

Sieron et al. showed that PDT is a useful and effective method for the treatment of premalignant lesions of the oral cavity and the palliation of advanced lesions of the oropharynx and larynx [15].

PDT, which may have immunomodulatory effects and may induce apoptosis in the hyperproliferating inflammatory cells that are present in psoriasis and lichen planus. This may reverse the hyperproliferation and inflammation of lichen planus. Aghahosseini et al. demonstrated that methylene blue (MB)-PDT seems to be an effective alternative treatment for the control of OLP. [22]

Candidiasis, caused by Candida species, is the most frequently encountered infection of the oral cavity. Immunocompromised states, diabetes mellitus, dental prostheses, xerostomia, and prolonged use of antibiotics or immunosuppressive drugs are the predisposing factors for oral candidiasis to ensue.

Antimicrobial photodynamic therapy has been evaluated as a promising method of treatment of oral candidiasis to overcome the problems associated with antifungal resistance. The mechanism of antimicrobial photodynamic therapy inactivation of fungi is completely different from that of antifungal agents. The reactive oxygen species promote perforation of the cell wall and membrane, thereby permitting the photosensitizer to translocate into the cell. Once inside the cell, oxidizing species generated by light excitation induce photodamage to internal cell organelles and cell death [1].

Dovigo et al. [23] in an in vitro study, attempted to describe the association of Photogem® (Photogem, Moscow, Russia) with LED for the photoinactivation of fluconazole-resistant (FR) and American Type Culture Collection strains of C. albicans and Candida glabrata. They treated suspensions of each Candida strain with five Photogem® concentrations and exposed them to four LED light fluences (14, 24, 34, or 50 min of illumination). It was observed that the fungicidal effect of PDT was strain dependent. Significant decreases in biofilm viability were observed for three strains of C. albicans and four strains of C. glabrata. The authors concluded that although antimicrobial photodynamic therapy was effective against Candida species, fluconazole-resistant strains showed reduced sensitivity to PDT. Moreover, single-species biofilms were less susceptible to antimicrobial photodynamic therapy than their planktonic counterparts.

Herpes is a common infectious disease that is caused by human herpes viruses. Several treatments have been proposed, but none of them prevents reactivation of the virus. Treatment with low-level laser therapy has been considered as an option in the treatment of herpes labialis, decreasing the frequency of vesicle recurrence and providing comfort for patients. The lesions have healed rapidly and no significant acute side effects have been noted [24].

Advantages of PDT

- Selective uptake of photosensitizers to particular tissue layers, precise directing of laser light using optical fibers,
- lack of scarring, and highly selective tissue necrosis, which is achieved by localizing the drug to the proliferating tissue, are the potential advantages of PDT.
- It can be performed in out-patient or day-case settings and repeated doses can be given without the need for total dose limitations.
- Resistance to treatment does not develop with repeated treatment [12].

Limitations of PDT

- PDT requires direction of the light to the appropriate site and tissue depth to be effective. Optimal light delivery with laser and collaboration and coordination between clinicians is complex and availability of the necessary light sources has been a problem. Currently, low-cost portable light sources are more readily available.
• PDT is an ablative procedure and does not yield material for histological diagnosis. Diagnosis should be made before treatment.

• Persistent skin photosensitivity, lasting for weeks with some photosensitizers, limits the use of PDT as a therapeutic regimen. PDT is also less effective in treating large tumors because the light cannot pass far into these pathologies. PDT is a local treatment and generally cannot be used to treat cancer that has spread widely (metastasized)\(^1\).

**Side effects**

The side effects of PDT depend on how the treatment is performed and it will vary between individuals. The side effects produced vary according to:

• What part of the body is treated
• The type of photosensitizing drug given
• The time between administration of the drug and light application
• The skin sensitivity to light following treatment

The major side effect of PDT is residual systemic photosensitization, which lasts for several days or weeks depending on the administered photosensitizer. When administered systemically, residual skin photosensitivity may ensue for a period.

Daylight may be a means of activation of photosensitizer, resulting in first- or second-degree burns. The patients are therefore instructed to avoid exposure to bright light or sunlight until the drug is completely eliminated. Also, skin and eyes should be protected from intense exposure of light.

Furthermore, though PDT treatment is not a painful procedure, pain may be experienced by patients several hours after PDT. Pain relief medications prior or after the laser treatment may be advocated. When used for the treatment of tumors, though damage to health tissues is minimal, burns, swelling, pain, and scarring in the nearby tissues are likely.

Other side effects that are less frequent are coughing, trouble swallowing, stomach pain, painful breathing or shortness of breath, allergic reactions, change of liver parameters, etc.\(^{[12]}\)

**Conclusion**

Applications of PDT in dentistry are growing rapidly such as the photodynamic diagnosis of malignant transformation of oral lesions and the treatment of head and neck cancer, as well as bacterial and fungal infections.

The advantages of photodynamic therapy compared with surgery or radiotherapy are reduced long-term morbidity and the fact that photodynamic therapy does not compromise future treatment options for recurrent, residual, or another primary disease. Based upon the present analysis of pertinent literature, where tumors are concerned, PDT appears to be a promising technique for early neoplastic lesions (premalignant and in situ carcinoma) and advanced recurrences after previous surgery or radiotherapy. Also, superficial infections as well as bacterial and fungal infections seem to be areas which hold promise to incorporate photodynamic therapy as a treatment option more frequently in the future. Further evidence-based accumulation of data is definitely required to make a definite statement.

In conclusion, PDT is a useful modality for the treatment of head and neck tumors and precancerous lesions which present inform or under conditions that pose considerable difficulties in their management by conventional approaches.

Dentigerous Cyst Masquerading as Mucocele in Right Maxillary Sinus- A Rare Case Report

Nithya.S.J1, Sankar Narayanan R2, Buggavetti Pradeep Kumar3

1Postgraduate, 2Senior lecturer, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, 3Senior lecturer, Department of Conservative Dentistry and Endodontics, Mamta Dental College and Hospital, Khammam

Abstract

Dentigerous cyst is the most common type of developmental odontogenic cyst, which develops around the crown of an unerupted tooth. The dentigerous cyst occurs mostly 95% with unerupted permanent dentition and 5- 6% with unerupted supernumerary teeth. Here we report a case of dentigerous cyst mistakenly diagnosed as maxillary mucocele by an ENT specialist. Hence ENT specialist, oral physician, and radiologist should be aware of such presentation of dentigerous cyst when maxillary sinus is involved.

Keywords: Dentigerous cyst, supernumerary tooth, mucocele, maxillary sinus.

Introduction

Dentigerous cyst is the second most common type of odontogenic cyst after radicular cyst1. It occurs commonly between 20 to 40 years with a male predilection. It is more commonly associated with mandibular third molars followed by maxillary third molars, maxillary canines and premolars.2

Dentigerous cyst involving anterior maxilla is very rare. About 5% of all dentigerous cysts are attributed with supernumerary teeth. Pitts in 1924 first described the occurrence of dentigerous cyst with supernumerary teeth and Lustman and Bodner in 1988 observed a case of dentigerous cyst in association with the supernumerary teeth3. They are often painless and remains silent until there are secondarily infected4. When a dentigerous cyst occurs in the maxilla it causes displacement of teeth into the maxillary sinus or involve sinus by causing nasal obstruction and discharge from the nose4.

We present an unusual case of dentigerous cyst mimicking as mucocele in the right maxillary sinus with two unerupted supernumerary teeth in the anterior maxilla.

Case Report

A 21 year old male patient diagnosed as mucocele of right maxillary sinus was referred to us by an ENT specialist to give dental fitness before surgery. Patient had nasal obstruction and discharge from his right nostril for which he consulted ENT specialist. After examination he was advised for CT and CT revealed a soft tissue mass (HU -30) possibly mucocele or polyp with complete opacification of the right maxillary sinus with expansion and thinning of the anterior wall of the sinus (Figure 1).

On examination patient had pain along with swelling in his right side of the face for the past one month. Swelling started one month before and has gradually increased in size to attain the present size. Patient also revealed watery discharge from the right nostril and blockage during the night.

All the vital parameters were found to be within normal limits. On extra oral examination a mild diffuse solitary swelling was present in relation to the right side of the face. Intra-oral examination of hard tissues revealed dental caries in relation to 46, 47 with
generalized Grade (+) stains & calculus. Soft tissue examination revealed a mild diffuse swelling seen in the right buccal vestibule from the distal aspect of 14 regions to mesial aspect of 17 regions. Also obliterating of the buccal vestibule seen. It approximately about 1 x 1.5 cm with ill-defined margins and surface smooth. On palpation the swelling was tender, cystic in consistency, slightly compressible but not reducible. No blood or pus exudate seen. Expansion of buccal cortex was present (figure 2).

A maxillary Occlusal radiograph was taken which showed a well-defined radiolucency encircling the apical portion of 21, 11,12,13,14 region with two small teeth like structures embedded in the maxillary bone. One structure was present in relation to the lateral aspect of 12 and 11 and the other in relation to the left side of nasal septum (Figure 3). A thorough examination of the CT axial sections revealed radiopaque tooth like structure in the anterior maxillary bone along with perforation of the buccal cortex (Figure 4). FNAC was performed which showed clear straw-coloured fluid, that confirmed the diagnosis of cyst (figure 5). A provisional diagnosis of odontogenic cyst associated with impacted supernumerary teeth was considered. Patient and the ENT specialist was explained about the diagnosis.

Incisional biopsy was done in relation to 14, 15 regions (figure 6). The histopathological report revealed that there was 3 to 6 layers of cystic lining consisting of non-keratinized stratified squamous epithelium with cholesterol cleft seen in the connective tissue which confirmed the diagnosis of dentigerous cyst (figure 7). The tooth was removed with surgical enucleation of cystic lining and sinus content was cleared. Endodontic treatment was done from 21 to 16. Follow-up was done periodically. After 1 year of follow up patient revealed discharge from the surgical site. IOPA (FIGURE 8), Occlusal (FIGURE 9) and OPG (FIGURE 10) were taken. Curettage was done and the patient was advised to undergo RE-RCT in 13 14 as it was obturated short of apex. Post-operative PNS view of right maxillary sinus showed no haziness was present (FIGURE 11).
FIGURE 4: CT reveals unerupted morphologically altered two tooth structure present in the maxillary bone along with perforation of buccal cortex.

FIGURE 5: Clear straw coloured fluid obtained by aspiration

FIGURE 6: Biopsy done in relation to 14, 15 region.

FIGURE 7: Histopathological image showing epithelial lining and connective tissue of cyst

FIGURE 8: IOPA of 11, 21 reveals ill-defined radiolucency seen in relation to apical portion of 11 & 21.

FIGURE 9: Maxillary occlusal radiograph shows diffuse ill-defined radiolucency present in the palatal region.
Discussion

Dentigerous cysts account for about 16.6% of all jaw cysts. About 95% of these cysts involve permanent dentition and only 5% are associated with supernumerary teeth. Mesiodens was first named by Bolk in 1917, is the most frequent type of supernumerary tooth and is situated in the maxillary anterior incisors region. It is a rare entity with a prevalence of 0.15–1.9% with slight male predilection6.

Radiographically, the dentigerous cyst shows a well-defined unicocular radiolucency with sclerotic borders that is associated with the crown of an unerupted tooth, although, once infected, it may show ill-defined borders. The cyst-to-crown relationship shows several radiographic variations such as central, lateral and circumferential7. Panoramic radiograph, IOPA, Occlusal radiograph, and Water’s view are commonly used for investigating the dentigerous cyst involving the maxilla and sinus. The structure of a tooth present in the anterior maxilla cannot be clearly detected on panoramic radiographs due overlapping structures present. In our case, we used maxillary occlusal radiograph and CT scan for detailed evaluation of dentigerous cyst associated with unerupted supernumerary teeth. CT scan showed clear visualization of size, extent, invasion of the cyst into the maxillary sinus and surrounding structure.

The differential diagnosis for a dentigerous cyst in our case includes odontogenic keratocyst, median palatine cyst, nasopalatine duct cyst, radicular cyst and adenomatoid odontogenic tumor. However, mucocele, retention cyst and pseudocysts are also considered in the differential diagnosis when maxillary sinus expansion involved. All these diagnoses were excluded due to the presence of unerupted supernumerary teeth in the palate.

The standard treatment for a dentigerous cyst is enucleation of cyst followed by extraction of the cyst associated with an impacted or unerupted tooth. For extremely large, marsupialization may be done. In the present case enucleation cyst with the removal of both the unerupted supernumerary teeth was performed. The potential complications of DC cyst include transformation into ameloblastoma, squamous cell carcinoma and intraosseous mucoepidermoid carcinoma8.

Conclusion

Dentigerous cyst involving the supernumerary tooth in maxilla remains asymptomatic and once cyst is secondarily infected it may cause expansion of jaw, displacement of teeth, invasion of the cyst into the sinus and nasal blockage. Initially these cyst present as mucocele or polyp in the sinus and when the sinuses are completely opaque in radiographic findings it is necessary to rule out any unerupted teeth present in maxilla in order to avoid unnecessary surgery.

Reliability of Saliva as a Diagnostic Fluid

Sankar Narayanan R¹, Shruthi Parthasarathy², Bhuminathan Swamikannu³, Jayesh SR³
¹Senior Lecturer, ²Post Graduate, Department of Oral Medicine and Radiology, ³Professor, Department of Prosthodontics, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

Abstract

Saliva can be used as a diagnostic tool for the detection of various systemic and oral diseases. There has been a long standing debate that saliva based diagnostics can be employed in our day to day practice. The reliability of saliva is equal to that of serum. Patients have a psychological fear for any blood based examinations. Saliva overcomes such fear as it is collected noninvasively with accurate results. This article focuses why not saliva be an alternative fluid to blood??

Keywords – Saliva, Serum, Diagnostics

Introduction

In the current scenario, with a plethora of new diseases, a great demand exists for the need of a more cost effective, non-invasive diagnostic platform with more accuracy and also comfortable to the patient. Saliva, being a magical fluid in the oral cavity, is one of the most important and versatile body fluids, that has various properties which substantiates it as an efficient diagnostic tool, for the early detection of various systemic and oral diseases.

Composition and Properties of Saliva:

Saliva contains 99% of water and 1% of other organic and inorganic components including enzymes, immunoglobulins, antimicrobial factors, glycoproteins, glucose, nitrogenous products, traces of albumin, polypeptides and oligopeptides, and a variety of electrolytes. In addition, it also contains oral mucosal transudate, mucus of the nasal cavity and pharynx, non-adherent oral bacteria, food debris, desquamated epithelial cells, blood cells, and traces of medications or chemical products. It exhibits gustatory function and helps in primary digestion of carbohydrates and fats. It acts as a buffer system to maintain homeostasis in the mouth. It also exhibits lubricative and protective functions¹.

Saliva Vs Serum:

The acinar cells of the salivary glands are highly permeable and are enveloped by capillaries which permits free exchange of blood based molecules into the saliva. This transcellular and paracellular movement of blood derived products could potentially influence the molecular contents of oral fluids². Thus consequently the circulating biomarkers of a disease absorbed by the salivary glands may possibly alter the biochemical composition of saliva. Hence saliva may act as an excellent substrate through which the individuals disease status can be determined.

There are various advantages of collecting saliva for diagnostic purposes when compared to serum. It is a non-invasive method for sample collection, easy to use, inexpensive and a safer technique. It gives real-time diagnostic values and there is no need for trained medical staff. In addition to this multiple samples can be obtained easily, Collection and screening can be done at home. It is also more economical in sampling, shipping and storage when compared to serum³.

Various oral samples include saliva, gingival crevicular fluid (GCF), oral swabs, dental plaque, and volatiles. The most reliable type of sample is a swab that contains DNA which is used to analyse disease related DNA sequences and Single nucleotide Polymorphisms (SNP)⁴.
Inspite of so many advantages, a controversy still exists whether to completely rely on it for diagnosis, as the quantity of analytes and biomarkers expressed in saliva are diminished when compared to serum. However with the help of various molecular methods and nanotechnology we can easily overcome the issue.

ROLE IN DETECTING SYSTEMIC DISEASES:

Saliva provides a plethora of biomarkers which is helpful in detecting various systemic diseases like diabetes mellitus, cardiac disorders, infectious diseases and even autoimmune diseases like cystic fibrosis. Coronary artery diseases and acute myocardial infarction may be triggered due to deposition of fat tissues in the vessel wall induced by inflammation. Thus there is always an increase in the serum cholesterol levels and C-reactive protein levels. Studies also prove that, salivary CRP levels were found to correlate with plasma CRP levels obtained from blood samples of a population at risk for cardiovascular complications. It is also possible to detect cardiac troponin, a biomarker for the detection of Acute Myocardial Infarction in saliva that is released in response to cardiac cell necrosis. Research show the presence of myoglobin and myeloperoxidase in myocardial infarction patients which highly correlate with their ECG findings.

Diabetes mellitus is also one of the most common diseases which is prevalent in the Indian subcontinent. Saliva of diabetic patients is known to express around 52 types of altered proteins in high levels. Hence salivary proteomics is an interesting option for diabetic patients who wish for non-invasive diagnostic procedure.

Certain salivary biomarkers were exclusively detected in patients with end stage renal diseases which includes cortisol, nitrite, uricacid, sodium, chloride, pH, amylase and lactoferrin. Also with the help of salivary nitrates and uric acid levels, indication for hemodialysis can be determined easily in chronic kidney disease patients.

Various autoimmune disorders like cystic fibrosis and Sjogeren's syndrome can be detected in saliva. Salivary analysis shows increased concentrations of sodium, chloride, elevated levels of IgA, IgG, lactoferrin, albumin, various inflammatory mediators like eicosanoids, PGE2, thromboxane B2, and interleukin-6 in patients with Sjogeren's syndrome.

Saliva harbours a wide range of biomolecules including microbial antibodies, which takes the diagnosis of infectious diseases to a next level. Saliva primarily contains IgA or secretory antibodies which is derived from the saliva itself. It also contains IgG and IgM antibodies which are derived from the serum in response to infections. A saliva-based enzyme-linked immunosorbent assay (ELISA) is available to screen suspected HIV patients. Around 25% of HIV-positive individuals are not aware of their infection. They account for the majority of new incidences of HIV transmission events every year. This test is highly accurate and might help in screening more new cases in a easier way.

Also investigations have demonstrated the efficacy of hepatitis A virus (HAV) immunizations by assessing salivary IgG concentrations. Unlike HAV, both hepatitis B virus (HBV) and hepatitis C virus (HCV) are commonly associated with chronic liver diseases and can eventually result in severe liver-related complications such as cirrhosis and hepatocellular carcinoma. These antibodies can be easily detected in the saliva. In addition, using antigen capture methods, IgA antibodies specific to dengue virus have also been found in saliva. Likewise many viruses, including Ebola virus, HSV, EBV, HHV, and CMV, are most successfully detected using PCR methodologies.

Also bacterial infections like H. pylori and M. tuberculosis produces a type of IgG which can be detected in saliva of chronic gastritis and peptic ulcer patients.

Saliva plays a vital role in detection and monitoring of drugs. Drug levels of lithium, carbamazepine, barbiturates, benzodiazepines, phenytoin, theophylline, and cyclosporine can be estimated through saliva as these drugs diffuse into the body fluids. Legal drug levels of alcohol and tobacco, and illicit drug levels of marijuana, cocaine, and amphetamines can also be determined in cases of drug and substance abuse.

As blood sampling by using needle-stick is not stress free, recent studies rely on the use of saliva as a useful tool for the assessment of hormonal response especially cortisol and testosterone to acute exercise or training.

Role in oral diseases:

Saliva is a useful platform to monitor various oral diseases and conditions. Most common diseases of the oral cavity, dental caries and periodontitis are monitored by estimating the level of bacteria like Streptococcus
sp., Lactobacillus and other periodontal pathogens. The total antioxidant capacity of saliva is reduced in case of any kind of oxidative stress to the oral cavity. Oral infectious diseases of bacterial, viral or fungal etiology can be detected.

Oral cancer biomarkers are also detected in saliva, which might help in early diagnosis of the disease reducing its fatality. Some of them include, oncogenes (e.g. C-myc, c-Fos, C-Jun), anti-oncogenes (e.g. p53, p16), cytokines (e.g. TGF-β1, IL-8, and IL-1 β), growth factors (e.g. VEGF, EGF and IGF), extracellular matrix-degrading proteinases (MMP1, MMP2, MMP9), hypoxia markers (HIF-α, CA-9), epithelial-mesenchymal transition markers (e.g. E-cadherin, N-cadherin and β-catenin), epithelial tumor factors (CYFRA 21-1), cytokeratins (CK13, 14 and 16), microRNA molecules and hypermethylation of cancer-related genes.

Future Directions:

Similar to the availability of salivary diagnostic kit for HIV, Saliva assays may soon be marketed for antibodies to hepatitis A and B and to measles, mumps, and rubella. The saliva test for markers of breast cancer, will also be marketed by Medic Group USA, may be available in the recent years. The future requires a collaboration between imaging and biomarker-based investigations. When biomarkers will provide quantifiable characteristics, imaging will provide special features of the disease area and amplify the biomarker visualization. A comprehensive database of biomarkers needs to be developed, integrating genomics, proteomics, metabolomics, and imaging features of a broad spectrum of disease states.

Conclusion

Thus saliva is a reflection of the whole body and contains a huge profile of biomolecules that aids in easy diagnosis of various systemic and oral diseases. Proper knowledge about the biology of saliva and its function will help in early detection of diseases and prompt treatment thereby reducing the morbidity and mortality of ant disease.

Interferons in Oral Diseases- A Review

Sankar Narayanan R1, Bhuminathan Swamikannu2, Jayesh SR2, Buggavetti Pradeep Kumar3

1Senior Lecturer Department of Oral Medicine and Radiology, 2Professor, Department of Prosthodontics, Sree Balaji Dental College and Hospital, BIHER, 3Senior Lecturer, Department of Conservative Dentistry and Endodontics, Mamta Dental College and Hospital, Khammam

Abstract

The Interferons are a group of multifunctional proteins involved in the activity of the immune system. They are antiviral agents. There are mainly three types of Interferons in the humans namely Interferon Alpha (IFNA) Interferon Beta (IFNB) and Interferon Gamma (IFNG). Interferons (IFNs) came into limelight with their use in hepatitis infections. It has been used in various cancer treatment modalities. This article throws light on its applications in oral diseases particularly in oral potentially malignant disorders.

Key Words – IFNs, Diseases, Cancer.

Introduction

What are Interferons?

Interferons are a group of proteins called cytokines produced by white blood cells, fibroblasts, or T-cells as part of an immune response to a viral infection or other immune trigger. The name of the proteins comes from their ability to interfere with the production of new virus particles. They have effect on immune system and inhibit the tumor growth. They provide signaling to the immune system during viral infections. They are broadly classified into two types Type I IFNs namely IFN-α secreted in direct response to a viral infection predominantly synthesized by leukocytes and IFN-β synthesized by many cell types in particular by fibroblasts. Type II IFN or IFN-γ which is synthesized by activated T lymphocytes and natural killer cells in response to the recognition of infected cells as reviewed by Goodbourn et al. Cytokines due to their immunomodulatory properties are more commonly used in haematology, oncology, hepatology and dermatology.

Over hundred cytokines have already been identified and the literature continually informs of new discoveries (Xing and Wang 2000).

History of Interferons

The first interferon was discovered in 1957 by Alick Isaacs and Jean Lindenmann. During their investigation, they found that virus-infected cells secrete a special protein that causes both infected and noninfected cells to produce protein that prevent viruses from replicating. They named the protein interferon because it interferes with infection. Initially, scientists thought there was only one interferon protein, but subsequent research showed that there are many different interferon proteins. In 1986, interferon-alpha became the first interferon to be approved by the Food and Drug Administration (FDA) for hairy-cell leukemia. In 1988 was also approved for the treatment of genital warts, proving effective in nearly 70% of patients who do not respond to standard therapies. In that same year, it was approved for treatment of Kaposi’s Sarcoma in patients suffering from AIDS. In 1991, interferon-alpha was approved for use in chronic hepatitis C Hodgkin’s lymphoma and malignant melanoma. In 1993, another class of interferon, interferon-gamma was approved by FDA for the treatment of a form of multiple sclerosis. Interferon-gamma may also have therapeutic value in the treatment of leishmaniasis, a parasitic infection that is prevalent in parts of Africa, America, Europe, and Asia.
How Interferons work?

Interferons work to stop a disease when they are released into the blood stream and then bind to cell receptors. After binding, they are drawn inside the cell's cytoplasm, where they cause a series of reactions that produce other proteins that fight off disease. Scientists have identified over 30 disease fighting proteins produced by interferons. In contrast to antibodies, interferons are not virus specific but host specific. Thus, viral infections of human cells are inhibited only by human interferon.

Interferons and the immune system

In addition to altering a cell’s ability to fight off viruses, interferons also control the activities of a number of specialized cells within the immune system. Type I interferons can either inhibit or induce the production of B lymphocytes. Interferon-gamma can also stimulate the production of a class of T lymphocytes known as suppressor CD8 cells, which can inhibit B cells from making antibodies. Another role of interferon-gamma is to increase immune system function by helping macrophages to function. These scavenger cells attack infected cells and also stimulate other cells within the immune system. Interferon-gamma is especially effective in switching on macrophages to kill tumor cells and cells that have been infected by viruses, bacteria and parasites.

Premalignant lesions and Interferons

The global incidence of oral cancer is about 500,000 cases per year with a mortality of 270,000 cases. Some oral cancers initiate as denovo lesions while some lesions are preceded by oral premalignant lesions and conditions. Many oral SCCs develop from premalignant conditions of the oral cavity. The role of IFNs in developing a premalignant lesion was studied by Urata et al. and Sato et al. IFN activity were increased the sera of patients with oral potentially malignant lesions when compared with the controls.

Interferons in OSMF

OSMF is characterized by fibrosis at the submucosal level, that ultimately leads on to progressive restricted mouth opening. In a study by Haque et al., it was highlighted that IFN-γ is an anti-fibrotic cytokine. They conducted this study to investigate in vitro the action of IFN-γ on fibroblasts stimulated by arecoline in OSMF patients. Furthermore, they also studied the effect of intra-lesional administration of IFN-γ on the fibrosis in those patients. They also analyzed the inflammatory cell infiltrates and the cytokine levels before and after the treatment in the lesional tissue. The results revealed that the increased collagen synthesis in response to arecoline was inhibited by IFN-γ (0.01-10.0 U/ml) in a dose-related manner. In an open uncontrolled study, administration of intra-lesional IFN-γ showed improvement in the patients’ mouth opening, with a net gain of 8 ± 4 mm (42%). In addition, the patients also reported reduced dysesthesia and improved suppleness of the buccal mucosa. Reduction in the inflammatory cell infiltrate, and cytokines level was observed in the post-treatment immunohistochemistry. Hence, the effect of IFN-γ on collagen synthesis acts as a key-factor in the treatment of such patients, and thus intra-lesional injections of IFN-γ might act as a significant therapeutic modality in OSMF.

Interferons in Oral lichen planus

OLP is an immunologically mediated lesion present in a wide variety of patterns have a 0.8% chance of turning into malignancy. The study was conducted to investigate the potential involvement of IFN-γ in the pathogenesis of OLP in biopsy specimens from 10 OLP patients, the topographic distribution of cells expressing IFN-γ mRNA was determined by an in situ hybridization technique. Approximately 1% or fewer lesional cells were found to be IFN-γ mRNA-positive, and the majority of these cells were found lining the basement membrane. A slightly higher number of phytohemagglutinin (PHA)-induced IFN-γ-producing cells were found in the blood from 11 other OLP patients. IFN-γ response toward Candida albicans was same in OLP and control blood cells, highlighting normal immunological function in the OLP patients. These findings suggest that T-cells activation and IFN secretion occur locally and are not seen to reflect in the peripheral blood. It is also inferred that the disease is regulated by less number of T cells.

Interferons in Leukoplakia

It is now well established that there is an association between human papillomavirus (HPV) virus and proliferative verrucous leukoplakia. HPV being a virus has the capability to induce IFNs. IFN-α delays the tumor growth.
**Conclusion**

Since their discovery about 60 years ago, IFNs have been used in available protocols for clinical treatment of viral diseases. IFN-α, IFN-β are currently used to treat hepatitis B and C viral infections. Although initial research shows that interferons are beneficial in treating premalignant oral diseases. Nevertheless, it is also evident that additional research is needed to more clearly explain the oromucosal administration and to determine optimal doses and dosing schedules, and to identify disease indications and circumstances in which beneficial effects can be most reliably achieved.

Periosteal Reactions and Its Significance

Sankar Narayanan¹, Jemima Judith², Bhuminathan Swamikannu¹, Jayesh Sr³

¹Senior Lecturer, ᵃ²Post Graduate Student, Department of Oral Medicine and Radiology, ᵃ³Professor, Department of Prosthodontics, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

Abstract

The periosteum covering the bony cortex consists of an outer and inner layer. The inner layer of the periosteum is the site of separation and subperiosteal haemorrhage because it’s less adherent. When the bone is insulted, it results in periosteal reaction. There are different variables that affect the periosteal response appearance like the rapidity of the phase of the disease, intensity, duration of the injury and age of the patient. The appearance and the pattern of periosteal reaction aids the imaging characterization of bone lesions and assesses their aggressiveness and their differential diagnosis, but not specific for a particular diagnosis. This article outlines the forms and patterns of periosteal responses that can guide to the diagnosis of underlying disease process.

Keywords: Periosteal reaction, bone neoplasm, periostitis, radiology, periosteum.

Introduction

Bones have a thin outer membrane called the periosteum. The fundamental response of bone to disease processes or other insults lead to periosteal elevation from the cortex followed by new bone formation by vascular proliferation and thickening of the bone.¹ ² Periosteal new bone formation, periostitis, and reactive bone formation are its different terms. Periosteal reaction (PR) occurs when the cortical bone is insulted by various insults like tumor, infection, trauma, certain drugs, venous stasis and some forms of arthritis.³ Each periosteal reaction may follow a particular pattern and may provide a clue for differentiating benign and malignant disease process. Once the new bone is ossified, PR is observed on conventional radiography, CT, MRI, ultrasound, and bone scintigraphy in the early stages. It is more aggressive in children than adults because the periosteum is active and is less attached to the cortex.⁴

Types of Periosteal Reactions

- Nonaggressive- Bone deposition has a slower progression and is less intense with an uninterrupted pattern. Commonly seen after healing or treatment ¹ ³
- Thin
- Solid
- Thick
- Irregular
- Septated
- Aggressive- These are interrupted patterns and has rapid bone deposition over a short period of time, which deny the periosteum time to develop new bone.
- Laminated (onionskin)
- Spiculated
- Perpendicular/hair-on-end
- Sunburst
- Disorganized
- Codman’s triangle

Solid periosteal reaction- It is a nonaggressive periosteal elevation representing a benign, slow process with continuous new bone formation.¹ The matrix between a single layer and the cortex or between numerous lamellations ossifies as the insult continues, resulting in solid PR. The main characteristics are the uniform
density and the absence of change in appearance over time. It may be thin (figure 1) or solid (figure 2), thick irregular (figure 3) straight or undulating.\textsuperscript{1,2} Thick PR (ie, greater than 1 mm) may be associated with a benign lesion reflecting a chronic persistent insult. Thin simple periosteal elevation may also be seen in either benign or malignant lesions. It can be seen in stress fractures, osteomyelitis, osteoid osteoma, chondroblastoma, LCH, and healing fractures.\textsuperscript{5} Aggressive tumours like osteosarcoma, Ewing’s sarcoma, and metastases are rarely associated with solid PR.\textsuperscript{6} It may also be seen in post-treatment of malignant tumours.

\textbf{Septated periosteal reaction} – It is a non-aggressive PR. In some cases of the subperiosteal aneurysmal bone cyst, the reactive bone may have well-defined septations mimicking an aggressive lesion.\textsuperscript{7} (Figure 4)

\textbf{Laminated periosteal reaction} – In multilamellar PR, sheet-like layers of mineralized new bone is deposited around the cortex separated by loose
connective tissue and vascular dilatation, forming an onion skin or laminated appearance. (Figure 5) It was originally thought that alternating cycles of fast and slow bone injury resulted in the concentric layers. However, the latest studies indicate that various layers are formed in the adjacent soft tissue due to the modulation of fibroblast sheets, which develop the osteoblastic potential to create new bone sheets. It occurs in benign tumours like Garre’s osteomyelitis, LCH, aneurysmal bone cyst and malignant conditions with aggressive cellular tumours like Ewing sarcoma, osteosarcoma, pulmonary hypertrophic osteoarthropathy, chondroblastomas and rarely with metastases. It is also seen in premature infants.

Figure 5: Onion skin or laminated appearance

**Spiculated periosteal reaction** - It is an aggressive PR in which the fine spicules of periosteal bone is projected from the cortex. Linear new bone spicules originate from ossification along newly formed periosteal vascular channels and fibrous bands (Sharpey’s fibers) stretched out of the cortex. (Figure 6) The spicules themselves are not tumour but they course along the direction of tumour growth. The spicules associated with malignancy are long and slender, whereas spicules associated with the benign disease are short and thick.

Figure 6: Hair on end appearance periosteal reaction

**Sunburst periosteal reaction** - The bony spicules radiate or fan out from the cortex in a divergent pattern instead of perpendicular to the cortex giving a sunburst or sunray appearance. (figure 7) In this aggressive periosteal reaction, the extension of spicules into the bone epicenter is seen. It is a sign of malignancy as is frequently associated with osteosarcoma with cortical destruction, secondary to prostatic carcinoma, rarely in aggressive osteoblastic metastasis and is associated with metastatic neuroblastoma in pediatric patients. It may be observed in benign lesions such as hemangiomas and osteoblastomas.

Figure 7: Sunburst appearance
Codman’s triangle- It is an aggressive PR and it is a specific category of a disrupted version of the lamellar periosteal reaction.\(^1\)\(^,\)\(^8\) (figure 8) When periosteum is locally elevated off the cortex and destroyed by the leading or extreme edge of tumor, pus, or hemorrhage, it is called Codman’s triangle and the remaining periosteal cuff is seen at the lesions’s margin.\(^5\)\(^,\)\(^9\) It is usually tumor-free, but secondary infiltration can occur through the open end.\(^2\) It can be observed in active or aggressive benign tumours, osteosarcomas and other aggressive primary malignant bone tumors or bone metastases, in osteomyelitis, in trauma, and in benign, but active tumors, such as aneurysmal bone cysts and in Ewing’s sarcoma.\(^1\)\(^,\)\(^4\)\(^,\)\(^8\)

![Figure 8: Codman’s triangle](image)

Disorganised/complex periosteal reaction- A combination of different types of PR may also result in complex patterns. This bizarre and disorganised appearance is by the random distribution of reactive bony spicules. It occurs in leukemia, lymphoma, malignant lesions, a benign lesion with malignant changes, the aggressive forms of osteosarcoma and as a complication of a benign or malignant lesion by a fracture or infection.\(^5\)\(^,\)\(^10\)

Conclusion

The knowledge about the types of periosteal reaction observed on the conventional radiographs and other radiographic modalities is necessary as it guides the practitioner in diagnosing the lesion present.

Soft Tissue Applications of Lasers- A Review of Literature

T. Manigandan¹, S. Kishore Kumar², Julius Amaladas³
¹Professor, Research Scholar, Department of Oral Medicine & Radiology, ²Vice Principal, Professor, Department of Orthodontics, ³Professor and Head, Department of Biochemistry, Sree Balaji Dental College & Hospital, Bharath University, Chennai, Tamil Nadu, India

Abstract

Laser is a special light source that has a higher power and better quality of beam compared to the other light sources. There are certain features inherent to each type of laser such as the spot size, wavelength, or radiance that is important for the kind of application intended. Since its first use in 1960, lasers are now evolved to be used in all aspects of dentistry. The aim of this review is to describe the application of lasers in oral soft tissue procedures. Soft tissue lasers are becoming popular among the clinicians due to their potential value in surgical procedures providing surface sterilization, dry surgical field and increased patient acceptance. Lasers are effective in ablation of various potentially malignant disorders, obtaining biopsy, periodontal plastic surgeries and providing incisions in surgical conditions.

Keywords: Carbon dioxide laser, laser, Nd:YAG laser, selective absorption, soft tissue

Introduction

In 1917, the theory of “stimulated emission” was put forward by Albert Einstein, stating that photons could “stimulate” the emission of another photon that would possess identical properties to the first. Townes and Schawlow worked on a study together that led to the development of LASER (Light Amplification by Stimulated Emission of Radiation). In 1962, laser was used in dentistry for the first time by Goldman. Since 1962, lasers have been used for soft tissue surgery of oral cavity with significant advantages compared to other treatment modalities. The first experiment with lasers in dentistry was reported in a study about the effects of a pulsed ruby laser on human caries (Husein 2006).

The most common lasers used in surgery emit wavelengths in the infrared part of the spectrum: Nd:YAG (λ=1,064nm), Er:YAG (λ=2.94μm), and CO2 laser (λ=10.6 and 9.6μm). These lasers cause significant tissue heating due to the thermal energy produced, causing denaturation of proteins, decomposition of tissue, micro explosion of cell water and charring. Argon lasers emit wavelengths within the visible portion of the spectrum (between 458 and 515nm), whereas excimer lasers emit wavelengths in the ultraviolet part of the spectrum. The lasers within the ultraviolet spectrum have the ability to ionize tissues. Diode lasers emit wavelengths of 670 to 1551nm. With the recent advances and developments of wide range of laser wavelengths and different delivery systems, lasers could be applied for the dental treatments including periodontal, restorative and surgical treatments (Lee 2007).

The aim of this review is to describe the soft tissue applications of lasers in dentistry.

Applications of lasers

Lasers are widely used in dentistry for cavity and root canal preparations, scaling and root planing, gingival and periodontal surgeries, coagulation and hemostasis, biopsies, excision of tongue lesions, TMJ disorders, exposure of implants and preprosthetic surgery.\(^3\)

Diagnosis of lesions

Laser capture microdissection (LCM) greatly improved the efforts in describing the molecular basis of malignancy. In early 1970s primitive UV laser was first used by Isenberg et al. but their approach required massive space occupying instruments to dissect subpopulations of cell types. The first commercialized system was devised by Lance Liotta, Emmert-Buck and co-workers in mid 1990s for accurately and efficiently dissection of cells from histo-logical tissue sections of solid tumors (Domazet et al. 2008).\(^4\) This technique variably helps in early detection of oral squamous cell carcinoma by detecting the biomarkers and establishing protein fingerprint models (Mehrotra & Gupta 2011).\(^5\)

Low level laser therapy

Low level laser therapy (LLLT) is defined as laser treatment in which the energy output is low enough to produce nonthermal and biostimulatory effects. It is a new treatment modality and has the advantages of being painless with no side effects. LLLT has effectively used in pain during orthodontic therapy, acceleration of healing process in wound, reduction of bacterial load in ulcerative conditions like aphthous ulcer, infections etc. (Hong-Meng et al. 1995)\(^6\)

Effects of laser on soft tissues

Laser can lead to warming, welding, coagulation, protein denaturation, drying, vaporization and carbonization causing the histological changes such as intracellular vacuolization, cellular hyper-chromatism and loss of intracellular structure, with the degree of charring of the tissues. (Kende et al. 2011)\(^7\)

Application On Oral Lesions

Recurrent aphthous ulcers appear as a yellowish white pseudo membrane surrounded by erythematous halo. The ulcer is painful on palpation. Recently Low Level Laser Therapy (LLLT) has been used. It helps in immediate pain relief and accelerates wound healing. According to De Souza et al, 75% of the patients reported that there is a significant pain relief in the same session after laser treatment and the lesion is totally regressed in 4 days. When steroids are used, it takes 5-7 days for regression.\(^8\) Bladowski et al also found that diode laser used at low levels reduces the wound healing period to half compared to pharmaceutical method.\(^9\) Dr. L.J Walsh conducted study on the mechanism of action of LLLT and he concluded that LLLT reduces pain and accelerates wound healing by perhaps „stimulating oxidative phosphorylation in mitochondria and modulating inflammatory responses”\(^10\). It is best to treat aphthous ulcers within the first 48 hours. A 400 micron tip is used for small lesions or an LLLT(8mm) is used for larger lesions. The laser is started in a defocussed mode 5-8mm away from the lesion and advanced towards the periphery 2-3mm away. Continual movement from the periphery to the centre is done. A period of 15-20 seconds is given between the laser „passes” allowing the tissue to cool. The area is rubbed with a wet gloved finger to determine if there is reduced pain felt. Likewise a 2nd and 3rd pass need to be done to completely reduce the pain. After each pass, the area should be palpated to check for reduced pain. It is believed that this laser treated area is less likely to reappear with a new lesion, if treated 1-2 times.

Leukoplakia Verrucous Carcinoma is defined by WHO as „a white patch or plaque that cannot be characterized clinically or pathologically as any other disease”. Diffuse lesions cannot be managed by excision. In such lesions, carbon dioxide lasers can be used in a defocussed mode to produce cross hatched pattern. The disadvantage of vaporization is that, a specimen cannot be taken and sent for pathological examination, so, the histology of the lesion cannot be determined.\(^11,12\)

Lichen planus is a common dermatologic disease that often affects oral mucosa. It usually affects the middle aged adults. The skin lesions of lichen planus have been described as purple, pruritic papules. The oral lesions are exhibited in two forms: reticular and erosive. The reticular form is characterized by interlacing white lines called Wickham’s striae. The erosive form appears as erythematous area with central ulceration. Erosive lichen planus can be controlled by laser treatment. Carbon dioxide laser should be used along with selected local and systemic medications. This laser is set on a continuous, defocused mode and the usual cross hatched pattern is used. The contact Nd:YAG laser with round...
probe can also be used. This condition cannot be cured by laser treatment, it is used for palliative treatment. It has been reported from patients that there is a significant decrease in burning sensation from the lesion. Hong-Sai reported that there is an improvement in the histologic appearance after laser therapy.\[^{13}\]

**Recurrent Herpetic Simplex Lesions**\[^{19,20}\]. Alfonso et al looked at 232 patients using an AlGaAs diode laser in the prodromal stage, in the stage of vesicles, in the crust stage and in lesions infected secondarily. In addition the laser radiation was also applied on the vertebrae C2-C3 where the resident ganglion of the virus is located. It was found that 100% of the prodromal stages, 95% of the vesicular stages, 91% of the crust stages were able to cure within the first 48 hours. The patients with secondarily infected lesions needed more than 48 hours to cure, although not more than 5 days[21]. Schindl and Neumann did a study on LLLT for delaying the recurrence of the lesion outbreaks. It was found that the recurrence free interval in the laser treated group was 37.5 weeks and in the placebo group, it was 3 weeks \[^{14}\].

**Nicotina** appears as a collection of red dots surrounded by a halo of white keratin. These red dots are due to the ductal openings of the minor salivary glands in response to the inflammation. After finishing the process, the final lased surface layer is left undisturbed to act as barrier and help in the protection of the healing surface. A palatal splint is fabricated to help the patient protect the lased surfaces during eating and drinking. An Nd:YAG contact round surgical probe can also be used in a similar manner to the carbon dioxide laser.\[^{15}\]

**Oral Papillomatosis** is reactive tissue growth that usually develops due to ill-fitting dentures, poor denture hygiene or due to wearing the denture 24 hours a day. It usually occurs on the hard palate beneath the denture base. It is usually asymptomatic. The mucosa is erythematous and has a papillary surface. \[^{16}\]. Diffuse lesions can be managed by vaporization with CO2 laser after selective punch biopsies have been taken. The laser is set on continuous defocussed mode and using the cross hatching method, the area of the lesion is covered. The lased tissue surface is wiped off with saline soaked sponge. The contact Nd:YAG laser with a round probe can also be used to eliminate the lesion by stroking the surface in a similar cross hatched manner without lifting the tip of the probe from the surface of the lesion.

**Peripheral Ossifying Fibromas** occurs solely on the soft tissue overlying the alveolar process. It is a common gingival growth that usually arises from the interdental papilla. The etiopathogenesis of peripheral ossifying fibroma is unclear but trauma or local irritation due to dental plaque, calculus, ill-fitting dental appliances and poor-quality dental restorations can lead to the development. These lesions can be effectively treated with Er,Cr:YSGG. Iyer VH et al. reported that the outcome was painless experience to the patient, minimal intraoperative bleeding in the surgical field and excellent healing of the operated area in 1 week period (Iyer et al. 2012) \[^{17}\].

**Denture-induced fibrous hyperplasia** is a response of tissues to a chronically ill-fitting denture and present as a benign condition which frequently coexists with denture stomatitis. Kumar NJ et al. successfully treated the case of denture induced fibrous hyperplasia with the help of carbon dioxide laser and concluded that CO2 lasers could be an excellent alternative to conventional modalities (Kumar, Bhaskaran 2007) \[^{18}\].

**Mucoceles** are benign lesions of the oral cavity that develop due to extravasation or retention of mucous from salivary glands in the subepithelial tissue generally in response to trauma. Pedron IJ et al. on the basis of findings of their study concluded that laser treatment provides satisfactory results and allowed for a satisfactory histopathological examination of the excised tissue in case of mucocele (Pedron et al. 2010) \[^{19}\].

**Hemangiomas** are benign vascular proliferations consisting of numerous capillary structures usually present on the tongue, lips, mucous membrane and gingiva. Genovese WJ et al concluded that application of gallium arsenide (GaAs) high potency diode laser in the treatment of hemangioma reduced bleeding during surgery, with a consequent reduction in operating time and promoted rapid postoperative hemostasis (Genovese et al 2010)\[^{20}\].

**Lymphangioma** is often asymptomatic and is detected with the appearance of a slow growing painless cystic mass covered by healthy mucosa. Despite being a congenital benign lesion, lymphangioma may cause severe esthetic deformities, and surgical excision is the main treatment. Dos Santos Aciole GT et al reported that the use of CO2 laser was practical, easy to carry out and effective on the treatment of oral lymphangiomas,
with no lesion recurrence within the follow-up periods (dos Santos Aciole et al. 2010) 21.

Superpulsed low-level laser therapy (LLLT) seems to be a good choice as a non-invasive treatment for tempomandibular joint pain while exhibiting a low cost for the patient. Many authors have reported significant pain reduction with low-level laser therapy in acute and chronic musculoskeletal pain conditions (Ninomiya, Hosoya et al., 2007) 22. Hence the therapeutic effect of diode laser on TMJ can be conferred through its photodynamic effects, alteration in blood flow, and mechanisms for reducing the inflammatory response of body in TMJ against environmental factors. 23

**Applications In Periodontics**

Laser is a viable alternative to the scalpel for various soft tissue procedures such as frenectomy, gingivectomy and gingivoplasty, de-epithelization of reflected periodontal flaps, removal of granulation tissue and crown lengthening.

**a)** Gingivectomy: Pick RM et al presented a 12 cases of phenytoin hyperplasia removed surgically by the CO2 lasers and hence laser gingivectomy and suggested that in the future the laser may offer an alternative or an advancement to current procedures now used in dentistry (Pick et al. 1985) 24.

**b)** Crown Lengthening: Lasers have been promoted for clinical crown lengthening without gingival flap reflection for both esthetic and prosthetic reasons. The only existing supports for such applications are non-controlled case reports (Cobb 2006). 25

**c)** Frenectomy: Laser surgery may be considered a useful tool for the clinician in performing frenectomy. According to Kafas P et al. diode laser frenectomy may be performed without infiltrated anaesthesia with the optimum healing postsurgically (Kafas et al. 2009) 26.

**d)** Tissue Pigmentation Reduction: Recently, laser has been widely used and is even preferred over the scalpel technique procedures for depigmentation (Roshna & Nandakumar 2005). 27

**Applications In Conservative Dentistry And Endodontics**

Soft tissue lasers have been successfully used for the removal of coronal pulp and immediate pulp capping due its thermal and hemostatic effect. Lasers causes modification of the tubular structure of dentin by melting and fusing of the hard tissue or smear layer and subsequent sealing of dentinal tubules leading to reduction in sensitivity of teeth. Laser radiation has the ability to remove debris and smear layer from the root canals due to its potential to kill the microorganisms by its thermal effects. 3

**Applications In Orthodontics**

Lasers are widely used in Orthodontics for aesthetic gingival re-contouring, soft tissue crown lengthening, exposure of soft-tissue over the impacted teeth, removal of inflamed and hypertrophic tissue, frenectomy in case of highly attached frenum causing hindrance to tooth movement in diastema cases, tissue removal at the site for mini screw and Low Level Laser Therapy for reduction in pain experienced during the orthodontic therapy. 3

**Advantages (Naik 2010) 28**

- Dry surgical field and better visualization.
- Tissue surface sterilization and reduction in bacteremia.
- Decreased swelling, edema and scarring.
- Decreased pain.
- Faster healing response.
- Increased patient acceptance.
- Minimal mechanical trauma.
- Negotiates folds in tissues.

**Disadvantages (Mahajan 2011) 29**

- They are relatively high in cost.
- Operations of lasers require specialized training.
- Dental instruments mainly used are both side and end cutting thus; a modification of clinical technique is required.
- No single wavelength will optimally treat all dental disease.
- There is inability to remove metallic and cast-
porcelain defective restorations by erbium family lasers.

- Harmful to eyes and skin.

**Conclusion**

The application of lasers has been recognized as an adjunctive or alternative approach in soft tissue surgeries. Laser treatments have been shown to be superior to conventional mechanical approaches with regard to easy ablation, decontamination and hemostasis, as well as less surgical and postoperative pain in soft tissue management.

A White Man Carrying Red Card-An Unusual Presentation of Oral Squamous Cell Carcinoma

Harshada Raghunanthan¹, Sankar Narayanan R², Nalini Aswath³
¹Student, ²Senior Lecturer, ³Professor, Head of the Department, Department of Oral Medicine and Radiology, SreeBalaji Dental College and Hospital, BIHER, Chennai

Abstract

Background: Oral mucosal lesions are common these days due to the exposure to limitless environmental insults. Most of the oral mucosal lesions are present in the buccal mucosa, tongue, palate, alveolar mucosa, floor of the mouth are benign, premalignant or malignant.

Case presentation: A 42 year old patient came with a chief complaint of whitish plaque in the right buccal mucosa which happened to occur due to parafunctional habit. But on further investigation it was proved to be well differentiated squamous cell carcinoma of right buccal mucosa. Conclusion:

Keywords – Squamous cell carcinoma, Premalignant lesion, leukoplakia

Introduction

Oral cavity is the mirror of our body. There are numerous lesions we see in our day to day life. These lesions can be white, red or mixed beginning from innocuous to malignancy. Most of the white lesions are seen in buccal mucosa, tongue, gingiva and alveolar mucosa.¹,² So a thorough history taking, physical examination and blood investigations should always be succeeded by biopsy of the white lesion to analyze the histopathological status.³ Studies have shown that every white lesion have a chance to change to malignancy. Therefore any white lesion in the oral cavity is to be suspected.

Case Report

A 42 year old male patient came to the department of Oral Medicine with a chief complaint of whitish patch in the right side of the mouth for past 3 months. Patient gave a history of wearing fixed partial denture for past 6 months and complains of cheek biting while chewing. There was no pain or burning sensation in the associated area. He had a habit of smoking beedi before 2 years. Patient’s medical and family history were non contributory.

On general examination patient had normal gait and posture and was well oriented, conscious and moderately built. No evidence of pallor, icterus, cyanosis and clubbing was present. A single right submandibular lymph node was palpable which was about 1 x 1cm in size approximately, oval in shape, firm, mobile and non-tender. Intra oral examination revealed a solitary well defined greyish white plaque present in right buccal mucosa which was approximately 2x1 cm in size and 1cm away from the right commissure along the occlusal plane. The surface of the lesion was rough. The margins were well defined. On palpation it was firm in consistency, non-tender, doesn’t bleed on palpation, indurated and fixed to underlying structures. FPD placed in relation to 17 to 27 in upper arch and 45 to 37 in the lower arch.
Correlating with the history and clinical finding provisional diagnosis was given as frictional keratosis and differential diagnosis as leukoplakia. Excisional biopsy was performed.

Histopathological features revealed severely dysplastic surface epithelium with underlying connective tissue stroma and malignant epithelial cells were seen invading the connective tissue in the form of islands. Well formed keratin pearls were also seen within the tumor islands. Suggestive of Well differentiated squamous cell carcinoma.

A CECT was performed and it showed Mild asymmetry and prominence of soft tissue in the anterolateral aspect of oral cavity on the right side. No definite enhancing lesion identified. Small submental and bilateral submandibular nodes was also seen.

Surgical excision of the lesion along with supra-omohyoid neck dissection was done. The patient was advised to report every 6 months for review.

Worldwide, it is estimated that there were approximately 274,300 new cases of and 127,500 deaths attributed to cancer of the oral cavity during 2002. India has world's highest number (nearly 20%) of oral cancers with an estimated 1% of the population having oral premalignant lesions. Most of the oral cancer are squamous cell carcinomas. Clinically they begin as white
hyperkeratotic patch mostly and microscopically, these lesions may exhibit oral epithelial dysplasia (OED), a histopathologic diagnosis characterized by cellular changes and maturational disturbances indicative of developing malignancy. Any white lesion in the oral cavity can be either benign, pre-malignant or malignant.

Lesions of chronic frictional keratosis from parafunctional habits (cheek biting or chewing) and benign alveolar ridge keratosis, common on the retromolar pad, all represent frictional keratosis and will also exhibit hyperkeratosis and acanthosis. As such, when a clinician receives a report of “hyperkeratosis, acanthosis, or epithelial hyperplasia,” without further comment, the lesion could represent an entirely benign lesion caused by friction or a true leukoplakia with the potential of developing dysplasia or invasive cancer. A study done by Simi in the 2012 revealed the 72% of white lesions occur in the right buccal mucosa. White patches may be isolated or involve multiple areas and have variable presentations including linear patterns, plaque like lesions, diffuse patches and mixed white and erythematous areas.

The dental professionals should be aware of mucosal lesions pattern and presentation to detect early diagnosis and management. The oral cavity is vulnerable to a limitless number of environmental insults because of its exposure to the external world. The use of tobacco products in our country has increased. Even after public education and awareness programs conducted people prefer these products. Tobacco always have a greater impact in oral lesions as it has many carcinogenic substances in it.

**Conclusion**

All white lesions need not be malignant but malignant lesions can be a white lesion. Every dentist should possess an eagle eye in tracing the oral mucosal lesions however small it is. It is important to investigate the lesion with a thorough history, examination and appropriate investigations. Oral medicine plays a major role in identification of the lesion and treatment planning.

Antibacterial Effectiveness of Cinnamon Chewing Gum on Streptococcus Mutans

Ponnudurai Arangannal1, S Nithya, Jeevarathan J2, Vishnu Rekha3, Mahalakshmi Krishnan4, Kesavaram Padmavathy5

1Professor and Head, Department of Pedodontics, Sree Balaji Dental College, Pallikarani, Chennai,
2Private Practitioner, Chennai, 3Professor, Dept of Pedodontics, Sree Balaji Dental College, Pallikarani, Chennai, 4Professor & Head, Sathyabama Dental College, Chennai, 5HOD, Dept of Microbiology, 6Professor, Dept of Microbiology, Sree Balaji Dental College, Pallikarani, Chennai

Abstract

Aim: The aim of the present study is to evaluate the effectiveness of Cinnamon (Big Red) and Regular (Juicy Fruit) chewing gum on Streptococcus mutans. Method: The present study was undertaken recruiting 60 students, of Sree Balaji Dental College and Hospital, aged 18-19 years. The subjects were divided into 2 groups [Group I- Cinnamon (Big Red) chewing gum (n=30) and Group II-Regular (Juicy fruit) chewing gum (n=30)]. Baseline (unstimulated) saliva samples were collected from all the selected subjects and they were instructed to chew one pellet of their respective chewing gums thrice daily for nine successive days. The unstimulated saliva samples were collected on the 10th day. Standard microbiological assay was performed to determine the salivary levels of Streptococcus mutans. Statistical analysis was performed using student’s t test (SPSS Version 18.0). Results: The results of the present study reveals that Cinnamon chewing gum is highly efficient in reducing the salivary levels of Streptococcus mutans compared to juicy fruit. Conclusion: The results obtained from the present study demonstrates the beneficial (antibacterial) effect of Cinnamon chewing gum compared to juicy fruit in reducing the salivary levels of Streptococcus mutans, a noted cariogenic bacteria.

Keywords: Cinnamon, Chewing gum, Streptococcus mutans

Introduction

Chewing is an important biological function that begins the process of ingestion and digestion, thereby affecting the entire body. The simple act of chewing helps to relieve anxiety and improves alertness and also helps in reducing stress levels.1 Chewing gum is defined as a "Solid preparation with a base consisting of gum which should be chewed and not swallowed, providing a slow and steady release of the medicine contained."2 Prehistoric men used to chew lumps of resin from mastic (mastiche), and/or sapodilla tree (chicle). Later the spruce tree resin was used, that got replaced by paraffin wax which became the new base for chewing gum. In 1869, Thomas Adams produced the first modern chewing gum using chicle. The modern day chewing gum contains synthetic resins for better quality, texture and taste.2 In the developing countries, drugs are not only expensive but also have many side effects during treatment for any disorders, that is why now in this era it is being emphasized to search medicinally valuable plants and predict their biological activity. Scientific evidence is accumulating and many of the plants have medicinal properties that alleviate symptoms or prevent diseases.3

Cinnamon has been a favorite spice around the world not only because of its health benefits but also because...
it flavors and preserves food. Cinnamon (Cinnamomum cassia) of the family Lauraceae is also known as Sweet wood and Gui Zhi. It contains medicinally important essential oil in leaves, fruits inner and outer bark. Much of cinnamon’s bioactivity resides in its oil, which is about 90% cinnamaldehyde. It is used mainly in medicine, foods and cosmetics, and also contains both anti-fungal and anti-bacterial properties that can be used to prevent food spoilage due to bacterial contamination. The active principles in the cinnamon spice are known to have anti-oxidant, anti-diabetic, anti-septic, local anesthetic, anti-inflammatory, rubefacient (warming and soothing), carminative and anti-flatulent properties.

The aim of the present study is to evaluate the effectiveness of Cinnamon (Big Red) and Regular (Juicy Fruit) chewing gum on *Streptococcus mutans*.

**Materials and Method**

This is a case controlled study in which the study group consisted of 60 subjects in the age group of 18-19 years irrespective of sex. The subjects volunteered to participate after verbal and written information. Ethical clearance was obtained from institutional ethical committee (SBDCEM104/12/12), Sree Balaji Dental College and Hospital, Chennai. Informed consent was obtained from all the subjects.

**Subject Selection Criteria**

Subjects aged 18-19 years.

Systemically healthy subjects.

No history of antibiotic therapy for the past 3 months.

No history of oral prophylaxis done 3 months prior to the study.

No fixed or removable orthodontic appliance or prosthesis.

Caries-free oral cavity.

Non-allergic to gum ingredients.

Absence of TMJ disorders.

The subject’s personal data including their name, age, sex and address and their past medical and dental history (general health, antibiotics taken previously and whether oral prophylaxis was done) was recorded on a proforma. The oral cavity of all the subjects was examined on the dental chair with a mouth mirror and probe by a single examiner. Pertaining to the subject selection criteria and after oral examination, 60 subjects were selected out of 80 subjects examined.

Oral prophylaxis was done using ultrasonic scaler for all the 60 subjects and the subjects were then instructed to abstain from oral hygiene measures for the next 24 hours. They were also instructed not to eat, drink or chew gum one hour prior to saliva collection on the first and the tenth day.

Subjects were randomly divided into two groups of 30 each:

- **Group I** - Cinnamon chewing gum (Big Red, Wrigley’s, USA)
- **Group II** - Regular chewing gum (Juicy Fruit, Wrigley’s, USA)

**Sample Collection**

The baseline saliva samples (unstimulated saliva) were collected in the microbiological laboratory by instructing the subjects to spit in a sterile disposable plastic container for 60 seconds. Ten microlitres of unstimulated saliva sample was measured using micropipette and inoculated into Mutans Sanguis Agar by spread plate method for determining the salivary levels of *Streptococcus mutans*. The subjects were then given Cinnamon (Big Red) and Regular (Juicy Fruit) chewing gum and instructed to chew one chewing gum for 20 minutes for nine successive days thrice daily (i.e., after breakfast, lunch and dinner).

The subjects were asked to return to the microbiological laboratory on the tenth day and the unstimulated saliva samples were collected by instructing the subjects to spit in a sterile disposable plastic container for 60 seconds. Ten microlitres of stimulated saliva sample was measured using micropipette and inoculated into Mutans Sanguis Agar by spread plate method for determining the salivary levels of *Streptococcus mutans*.

Ten microlitres of unstimulated saliva samples that was inoculated onto Mutans Sanguis Agar by spread plate method, was placed in the candle jar and incubated at 37°C for 24 hours. Based on the colony morphology (rough, heaped, irregular colonies resembling frosted glass) *Streptococcus mutans* group of colonies was
identified and colony forming units (cfu) were counted.

Results

The data obtained was statistically analysed using student’s t test (SPSS Version 18.0). P value < 0.05 was considered significant and the following results were obtained.

Discussion

Dental caries is a significant multifactorial disease and microorganisms along with diet plays a major role in its causation. *Streptococcus mutans* is reported to be the etiological agent for initiation of dental caries.6,7,8,9

Dr. William F. Semple, a dentist from Ohio, first patented chewing gum. Chewing gums not only serve as a tasty confectionary but possess several properties that are advantageous to the oral tissues.2 Chewing gums act as a salivary stimulant that increases the salivary flow, enhances the salivary remineralisation potential, and cleanses the mouth.

Aspirin containing chewing gum was the first medicated chewing gum introduced in the commercial market in 1928. In 1991, the Commission for European communities approved chewing gum as a term for pharmaceutical dosage. Medicated chewing gums serve as a vehicle for the slow and steady release of specific medicinal/therapeutic products such as antibiotics, nicotine, phosphates, fluorides, etc.2

Currently various studies have reported that short term usage of xylitol containing candies, snacks and chewing gums, induce a significant reduction in the levels of salivary *Streptococcus mutans*.10,11,12,13 Also, chlorhexidine chewing gums are reported to reduce oral *Mutans Streptococcus (MS)* load and also exhibits significant substantivity.

Plant products have long been used in the traditional medicine for the treatment of infectious diseases.14 A large variety of plant extracts have been reported to possess antibacterial activity against *Streptococcus mutans*. Cinnamon oil is reported to possess antibacterial activity against both gram positive and gram negative bacteria.15

Shan et al, (2007)16 has also reported that cinnamaldehyde is the major active constituent of cinnamon. The hexane extract of cinnamon (100 mg/ml) is reported to possess excellent antibacterial activity against *Streptococcus mutans* that corresponds to 100 µg/ml of the ampicillin concentration.17 Previous studies have reported that cinnamon has potent
antibacterial activity against *Streptococcus mutans*. Therefore, Cinnamon containing chewing gum [Big Red (Wrigley’s)] was selected for the study, and provided for Group I subjects to evaluate the role of cinnamon in reducing the oral *Streptococcus mutans* load.

A majority of the gums available in the market have added sweeteners that eventually increase the availability of dietary sucrose followed by low pH due to sugar metabolism. This in turn causes the highly mineralised tooth enamel to be vulnerable for decay. Also, there is an increase in the load of cariogenic bacteria such as *Lactobacilli* and *Streptococcus mutans* that survive in acidic pH. Therefore, Regular [Juicy Fruit (Wrigley’s)] chewing gum was provided for group II subjects for comparison.

The results of the present study shows a significant decrease in the mean bacterial load (cfu/ml) of *Streptococcus mutans* between the baseline value (0 day) and the 10th day in the saliva of Group I subjects-Big Red (cinnamon) chewing gum. Conversely, there was a significant increase in the mean *Streptococcus mutans* load (cfu/ml) between the baseline value (0 day) and the 10th day in the saliva of Group II subjects–Regular (Juicy fruit) chewing gum.

Both Big Red as well as Juicy fruit chewing gum contain sugar at a concentration of 2g per serving (i.e., 6g per day). However, in the present study, in spite of the presence of sweeteners at similar concentration, significant reduction of salivary *Streptococcus mutans* load was observed after chewing cinnamon gum thrice daily for a period of nine successive days. This signifies the role of cinnamon in reducing the salivary *Streptococcus mutans* levels and this could be attributed to the predominant active compound cinnamaldehyde as documented by other researchers.

Cinnamaldehyde causes inhibition of the proton motive force, respiratory chain, electron transfer and substrate oxidation, resulting in uncoupling of oxidative phosphorylation, inhibition of active transport, loss of pool metabolites, and disruption of synthesis of DNA, RNA, proteins, lipids, and polysaccharides. In addition, the hydrophobicity exhibited by this biocide is reported to enable them to partition into and disturb the lipid bilayer of the cell membrane, rendering them more permeable to protons. Extensive leakage from bacterial cells or the exit of critical molecules and ions ultimately leads to bacterial cell death.

Our results are in line with Filoche et al, (2005) who has reported that cinnamon oil alone and in combination with chlorhexidine digluconate are potent antibacterial agents against planktonic and biofilm cultures of *Streptococcus mutans*. Cinnamaldehyde is reported to act against the plasma membrane of bacteria similar in action to that of chlorhexidine. Fani et al, has reported the Minimum Inhibitory Concentration (MIC) of cinnamon oil against *Streptococcus mutans* to be 3.12%.

**Conclusion**

The results obtained from the present study demonstrates the beneficial (antibacterial) effect of Cinnamon chewing gum compared to juicy fruit in reducing the salivary levels of *Streptococcus mutans*, a noted cariogenic bacteria.

Cinnamon (Big Red) chewing gum showed a significant decrease in the *Streptococcus mutans* colony forming units. Regular (Juicy Fruit) chewing gum showed a significant increase in the *Streptococcus mutans* colony forming units.

Within the limitations of the study, it could be speculated that Cinnamon based chewing gum effectively reduces the salivary load of *Streptococcus mutans*.

Morphological Pattern of Palatal Rugae among Adolescents

Ponnudurai Arangannal¹, Chithralekha², Jeevarathan J³, Vishnurekha⁴, Amudha. S⁵, Aarthi J⁶, Vijayakumar M⁷

¹Professor and Head of the Department, Sree Balaji Dental College, Pallikarani, Chennai, ²Assistant Professor, Government Hospital, Nagapatinam, TamilNadu, ³Professor, Sree Balaji Dental College, Pallikarani, Chennai, ⁴Professor & Head, Sathyabama Dental College, OMR, Chennai, ⁵Senior Lecturer, Sree Balaji Dental College, Pallikarani, Chennai

Abstract

Palatal rugae have been considered relevant for human identification due to its stability, and is equivalent to the fingerprint, in that it is unique for each individual. It is known as Palatal rugoscopy or Palatascopy. In the fields of forensic odontology, palatal rugoscopy is still in infancy as till date as the study of palatal rugae has not been extensive. Although palatal rugae appear to possess the features of an ideal forensic identification parameter as uniqueness, postmortem resistance. Hence palatal rugae can be used in postmortem identification provided an antemortem record exists.

Aim: Study of Morphological pattern of palatal rugae among adolescents from Tamilnadu Dravidian population was performed.

Methodology: 100 subjects were selected from different geographical areas between 17-19 years with equal distribution from undergraduate students of Sree Balaji Dental College and Hospital, Chennai, India. Maxillary impressions were made using Alginate impression material. 100 casts were made with Type III dental stone using vibrator. Rugae patterns were highlighted with sharp graphite pencil using magnification loop. Results:

Total distribution of rugae shapes of the studied samples, showed a maximum distribution of Line pattern 436 (32.8%), followed by Sinuous 352 (26.3%), Point 184 (13.9%), Composed 152 (11.34%), Curve 125 (9.39%), Angle 77 (5.88%), Circle 6 (0.45%). The distribution of individual rugae patterns among Males and females demonstrated the uniqueness of rugae pattern in different individuals, thus it is an effective reliable source of Identification provided ante-mortem records are available.

Conclusion: This study clearly demonstrated the uniqueness of rugae pattern in different individuals, thus it is an effective reliable source of Identification provided ante-mortem records are available.

Keywords: Rugae, Palate, Rugoscopy, Maxilla

Introduction

“Identity” is a set of physical characteristics, functional or psychic, normal or pathological, that define an individual. Proper identification of the deceased is very important to claim certification of death and for personal, social and legal reasons. Forensic dentistry is a specialty in dentistry which occupies a primary niche within the total spectrum of methods applied to medico-
Nowadays deaths due to high-speed transportation accidents and acts of terrorism are on the rise and identification of these victims is a major goal of forensic science. Methods of identification commonly employed are visual identification, fingerprint, dental records comparison and DNA profiling. Although DNA profiling is accurate, it is expensive and time consuming for use in large populations. Visual identification and fingerprints are limited by postmortem changes associated with time, temperature and humidity but dental tissues have been shown to withstand these conditions.

Palatal rugae are protected from trauma and high temperatures by lips, cheek, tongue and buccal pad of fat, teeth and bone. Physiologically the palatal rugae aid in oral swallowing, taste perception, participate in speech, chewing process, suction in children and in medico-legal identification process. The key factors which make palatal rugae one of the investigative tools in forensics are its internal position, stability, perennity etc. Qualitative characteristics of palatal rugae such as shape, direction and unification remain stable throughout the life. Harrison Allen stated that palatal rugae can be considered as an alternative source for identification.

Studies have demonstrated that no two individuals rugae pattern are alike in their configuration and that characteristic rugae pattern of the palate does not change as a result of growth. Even between twins, the studies have indicated that the patterns are similar but not identical.

Variations in rugae shape are evident in different populations. Thomas and Kotze in 1983 indicated rugae pattern were unique to each ethnic group and can be successfully used as a medium for genetic research.

**Methodology**

The Study was conducted at Department of Paedodontics and Preventive Dentistry in Sree Balaji Dental College & Hospital, Chennai, Tamilnadu, after obtaining approval from Institutional Ethical Committee (No.SBDCECM104/13/04). The sample consisted of 180 undergraduate students enrolled from 1st and 2nd year BDS. The subjects were informed about the nature of the study and for selection Convenience Sampling Technique was used. All participants who agreed to participate were distributed with a proforma which provided data like Age, Sex, Date of Birth, Native place, History of Orthodontic treatment, Orthognathic surgeries, Congenital anomalies, Palatal surgeries etc..

**A. Selection Criteria:**

100 subjects (Males-50 and Females-50) who fulfilled following Inclusion criteria;

- Age: 17-19 years.
- Same geographical area (Tamilnadu Dravidian population).
- No history of orthodontic treatment.
- No history of previous orthognathic, palatal surgeries.
- No congenital anomalies / malformations, were selected and an written informed consent was obtained. All these data collection were done by the principal investigator and numbered from 1-100.

**B. Methodology**

**Collection of Palatal prints :**

The participant was made to sit upright on the dental chair and appropriate perforated metal tray (ETN, Germany) was selected for the maxillary arch. The Alginate impression material (Neocolloid, Zhermack, Italy) was mixed as per the manufacturer’s instructions and loaded in the selected tray. A little amount of alginate was placed firmly against the rugae in the palate after thorough drying with cotton. The impression is washed under tap water to remove any debris and disinfected by immersing in sodium hypochlorite (1% NaOCl) (Prime Dental, Prime Dental Laboratories Private Ltd, Delhi) for half-an-hour. The impressions were then allowed to dry naturally. Type III dental stone (Denstone, Mumbai) was mixed as per the manufacturer instructions and poured with the use of vibrator to avoid air bubble formation. All the cast were made free of air bubbles and voids especially at the anterior third of the palate. Thus maxillary study models were obtained and numbered (1-100) accordingly on which to place the Calccorrugoscopy for interpretation.

**C. Method of Identification**

The elevations on the cast were highlighted by a sharp graphite pencil (2 HB) (Fig.3) under adequate
light and magnification loop (2.5x Keeler, Britain) (Fig.1.2) by the principal investigator. The highlighted rugae were interpreted on the study cast by the principal and co-investigator according to Trobo’s classification\(^7\) (Fig.2) as,

![Figure 1. Highlighted rugae on the cast](image1.jpg)

The Data was recorded in separate data sheets by principal and co-investigator and were subjected to statistical analysis using Independent samples t-test to assess:

### Results

This study was undertaken to evaluate the shape of palatal rugae distributed among Dravidian adolescents in Tamilnadu population and to determine the predominance of rugae pattern among Genders.

Males 50, Females 50. Total distribution of rugae pattern on maxillary casts in 100 subjects were tabulated in Table 1. It showed a maximum distribution of Line pattern 436 (32.8%), followed by Sinuous 352(26.3%), Point 184(13.9%), Composed 152(11.34%), Curve 125(9.39%), Angle 77(5.88%), Circle 6 (0.45%).

Distribution of individual rugae pattern among males is tabulated in Table 2, where the number of individual rugae pattern is shown with minimum of 0 and maximum of 9. The Total number of rugae pattern among 50 samples shows, 88 Point, 209 Line, 55 Curve, 42 Angle, 181 Sinuous, 3 Circle. There were 88 Point, 209 Line, 55 Curve, 42 Angle, 181 Sinuous, 3 Circle in the 50 studied samples. Our study also aimed at analyzing individual rugae pattern among 50 males which specifies 9 Line rugae pattern in1 individual, 7 Sinuous pattern in 1 individual, 7 Point in 1 individual, 5 Curve in 1 individual, 4 Angle in 1 individual,1 line in 1 individual,1 sinuous in 1 individual. None of the males had similar pattern of rugae distribution.

Distribution of individual rugae pattern among females is tabulated in Table 3, where the number of individual rugae pattern is shown with minimum of 0 and maximum of 11. The total number of rugae pattern among 50 samples shows, 96 Point, 227 Line, 70 Curve, 35 Angle, 171 Sinuous, 3 Circle. There were 96 Point, Line 227, 70 Curve, 35 Angle, 171 Sinuous, 3 Circle in the studied 50 samples. It was noted with 11 Line pattern in 1 individual, 8 Sinuous in 1 individual, 3 Angle in 1 individual, 6 Sinuous in 1 individual. None of the patterns were identical in each individual.

Table 4 shows, the comparison of rugae patterns between males and females. Statistical analysis was performed using Independent samples T test (SPSS version 18.0) which showed that the values are not statistically significant (P<0.005).
Comparison of rugae patterns between two examiners is tabulated in Table 5. Statistical analysis was performed using Independent samples T-test, which showed that values of Examiner 1 and Examiner 2 are not statistically significant.

Discussion

Palatal rugae develop as localized regions of epithelial proliferation and thickening in the hard palate. According to English et al. (1988) the characteristic rugae pattern did not change as a result of growth, remaining stable from the time of development until oral mucosa degenerate after death.9

Limson et al. (2004) and Filho et al. (2009) used photographs taken by digital cameras, transferred to the hard disk of computer and later analysed these images using a software programme.10,8 According to Pueyo et al. (1994),15 analysis of maxillary cast is the most commonly used techniques as it is simple, cost effective and more reliable. Hence in our study dental casts were used to record the palatal rugae details.

The most common shape observed in the present study was straight forms accounting for more than (32%) followed by sinuous (26%) compared to other forms (Trobo’s classification). This finding is consistent with the study by Sreenivasan Madankumar et al. (2013) who reported that, straight forms were more prevalent followed by other forms in a group of Chennai population (Thomas and Kotze classification).16 Nayak et al. (2007) categorised South Indians from Western Indians and inferred that straight forms to be higher and statistically significant in South Indians and Curved forms in Western Indians (Kapali et al classification).17 Moreover circular form were least in number among the studied Tamilnadu dravidian population. Our findings were in accordance to Shankar Shanmugam et al. (2012) where straight forms of rugae was also found to higher among South Indian population and circular forms were found to be very few in number in their study.18 Both line and straight are almost the same shape, but termed due to different classifications. Carlos Santos et al. (2011) reported straight rugae type to be predominant followed by sinuous in Portuguese population,19 Dennis E.O. Eboh (2012) reported that Line pattern (27.2%) to be predominant followed by sinuous (21.1%) in Urhobos of South-Southern Nigerian population.20 Abdellataif et al. (2011) found circular shape to be rare or even absent in one group of Saudi population.21 Thomas and Kotze studied the rugae patterns of 6 South African population to analyse interracial difference. Their results indicate that rugae were unique to each ethnic group and can be successfully used as a medium for genetic research.

Our results were similar to Dennis Eboh et al. (2012) reported with more number of rugae in female Urhobos (Southern Nigerians) when compared to males but it was not statistically significant.20 The present study also agrees with Kashima et al. (1990) who compared the palatal rugae shape of Japanese and Indian children and found there was no significant difference between male and female in either group.22 Some authors suggest the presence of sexual dimorphism in the biometric feature of palatal rugae. Fahmi et al. (2001) studied the rugae patterns in Saudi males and females and showed results with significant difference.23

Conclusion

The following conclusion can be drawn based upon the present study,

Line was the predominant shape of palatal rugae seen among the studied adolescent group of Tamilnadu Dravidian population.

Comparison of rugae patterns between males and females showed no statistical significant difference, thus there was no sexual dimorphism in the rugae pattern.

This study clearly demonstrated the uniqueness of rugae pattern in different individuals, thus it is an effective reliable source of identification provided ante-mortem records are available.

Abstract

Background: DMF index has got proven limitations and hence new system was introduced. Hence, there is a need to collect contemporary data in accordance with the new system.

Aims: Aim of the present study was to assess the prevalence of dental caries among schoolchildren in fishermen community using the International Caries Detection and Assessment System (ICDAS II) criteria.

Methodology: The total number of school children who participated in this study was 541 aged between 6 - 14 years. Caries prevalence was assessed using ICDAS-II code by the chief researcher. The results were tabulated and subjected to statistical analysis and Binomial test was used to compare different groups.

Results: The overall prevalence of dental caries among the schoolchildren was 82.3%. with no significant difference between the genders. Non-cavitated (or) early enamel caries lesions was highly prevalent among the student population, among the teeth assessed CARS (Caries Associated with Sealants and Restorations) criteria showed that only 1.1% of the surveyed population had secondary caries.

Conclusion: It is recommended that continuous monitoring and effective implementation of preventive and restorative programs to be carried out in schools to increase the dental disease awareness thereby reducing the caries prevalence.

Keywords: Caries, ICDAS II, CARS

Introduction

Dental caries has historically been considered the most important global oral health burden and is still a major health problem globally as it affects 60-90% of school-age children and the vast majority of adults. Dental caries experience in children was relatively high in America (DMFT=3.0), Europe (DMFT=2.6), while the index was lower in most African countries (DMFT=1.7). In India, the prevalence of dental caries was 55.5% in 1940 and it rose to 68% in the 1960s. According to National Health Survey (2004), the prevalence of dental caries was reported to be 51.9% in 5 year old children, 53.8% in 12 year old children and 63.1% in 15 years-old teenagers.

In Tamil Nadu according to various studies done in 12 year old children, the point prevalence of dental caries...
was reported to be 61.2% (Gopinath VK et al., 1999) and 80% (Kumar PM et al., 2005). These extensive studies were done using DMFT index. However, there are severe various limitations to DMF index. Taking this into consideration, an index that is able to record these lesions to plan primary preventive measures would be ideal, as accepted by the Dental Caries Consensus Development conference 2001 and International Consensus Workshop on caries clinical trials held in Scotland, 2002. To overcome the limitations, International Caries Detection and Assessment System (ICDAS) was proposed. Jablonski-Momeni A et al. in 2008 stated that ICDAS -II has good reproducibility and accuracy for the detection of occlusal carious lesions at different stages of the disease. The validity and reproducibility of ICDAS have already been tested in many in-vitro and clinical studies. Large epidemiological studies have been conducted using ICDAS hence ICDAS has been internationally recommended for dental health surveys.

Though there are many studies in the literature involving prevalence of caries in different population, there are no studies related to fishermen’s community, implementing the new classification of caries detection. So, this study was planned to assess the prevalence of dental caries in school children using ICDAS -II criteria in fishermen community in Pulicat, Tiruvallur district, Tamil Nadu.

Materials and Method

This was a cross-sectional study carried out among children aged 6 – 14 years of fishermen community. Pulicat is a well-known seashore village in Tiruvallur district with predominantly fishing being the occupation of male population residing there. The list of recognized schools in the Pulicat village was obtained from the Tiruvallur district administrative office by the researcher. A consent form and self-administered questionnaire to participate in the study were given to the students to be duly filled by the parents/school teachers prior to the researcher visit to the school. The subjects whose parents are fishermen were included in the study. Students who were absent on the day of examination and students who were migrants to that area were excluded from the study.

After the inclusion and exclusion criteria were applied, 541 children were evaluated. Data collection was done, and Dental examination of the subjects was performed in the schools. During the regular school hours, under adequate natural light based on WHO guidelines (WHO 1997 Oral Health Survey). Socio-demographic details were obtained that included their name, age, sex, class, religion, parents occupation, oral hygiene practice and teeth identification (FDI System). After obtaining the details, the children were instructed to brush their teeth with tooth brush and tooth paste provided by the researcher and Dental examination for CARS detection criteria were used on the teeth affected by secondary caries.

The data obtained was analyzed using SPSS Version 21, using Binomial test was used to compare different groups: Gender, Age -wise prevalence, ICDAS codes, CARS Detection. P value <.05 was considered significant.

Results and Discussion

Dental caries is a common dental disease occurring during childhood, and it continues to be a major public health problem. Dental caries is a multi-factorial, microbial, infectious, transmissible disease of hard tissues of teeth characterized by the demineralization of inorganic structures and subsequent breakdown of organic moieties along with remineralization of the demineralized structures until there is cavitation. The World Health Organization (W.H.O) in 2003 has ranked dental caries as number three among all chronic non-communicable diseases that require worldwide attention for prevention and treatment. A World Health Organization (WHO) estimation of global DMFT for year-old children was about 200,335,280 among 188 countries included in their database.

In recent years, there is an increase in prevalence of dental caries in developing countries, which may be due to the increasing consumption of sugars and inadequate exposure to fluorides. In India, the prevalence of dental caries was 55.5% in 1940, and it rose to 68% in the 1960s. According to National Health Survey (2004), the prevalence of dental caries was reported to be 51.9% in 5 year old children, 53.8% in 12 year - old children. In Tamil Nadu, according to studies done by Gopinath VK et al. 1999 and Kumar PM et al. in 2005 in 12 year old children the point prevalence of dental caries was reported to be 61.2% and 80% respectively.

One of the factors to be considered when planning for the enhancement of dental care facilities in a particular
population is to know the prevalence of dental diseases and their treatment need of that population. Literatures show numerous studies on different population and community schoolchildren but data on fishermen population is sparse. Hence, this study was planned to assess the prevalence rate of dental caries among 6 - 14 year old fishermen community schoolchildren at Pulicat village, Tiruvallur district, Tamil Nadu.

Table I shows the distribution of samples from the 7 schools participated in this study. The total sample comprised of 258 – males and 283-females in the age of 6 -14 years. Traditionally, caries has been measured by WHO criteria using DMFT/S index, where only teeth or surfaces with cavitated lesions extending into the dentine have been counted. In recent decades, several caries assessment criteria have been developed to identify the presence of this pathology. A review of 29 systems of tooth decay investigation criteria concluded that most of them are ambiguous and does not identify the different stages of the disease process. ICDAS (International Caries Detection and Assessment System) is the globally recommended method to assess prevalence of dental caries. This method estimates the early enamel lesions and helps in planning the early treatment and also helps in monitoring caries pattern at the population level. It allows assessing the tooth decay activity and compare data from distinct sites and in different periods.

Table II shows the prevalence of dental caries recorded in the fishermen community school children in selected sample population. Among the 541 children, 445 children were affected with dental caries, with the prevalence rate of 82.3%. This suggests that fishermen community schoolchildren have higher prevalence of dental caries. This could be due to the lack of preventive and restorative dental care facilities as well as awareness among population in this region. Similarly, Grewal H et al. in 2011 (Delhi) and Shingare P et al. in 2012 (Maharashtra) also have reported caries prevalence of about 80% and 81% respectively for schoolchildren between the age group of 6 -14 years. But this was assessed using DMFT/deft index in which the early enamel lesions have not been included, whereas in our study we used I CDAS-II criteria which included early enamel lesion. By comparing our result with the above studies dental caries prevalence was found to be relatively higher in these studies. This can be due to the different dietary patterns and different types of food available in the urban region. Since, literature does not have any studies in the fishermen community on prevalence of dental caries our study result cannot be compared.

Table III represents the distribution of caries code in the study population which was assessed and analyzed according to ICDAS II. In the sample of 541 subjects, 12,944 teeth were assessed and coded by ICDAS -II criteria. Among the teeth assessed 10,877 were coded 0, which is about 84.10%, While 2,067 (15.90%) teeth were coded 1 to 6 with values of 3.23% for code 1, 6.01% for code 2, 3.43% for code 3, 1.20% for code 4, 0.84% for code 5, 1.19% for code 6. Out of 15.90% teeth coded with a score of 1 to 6, 9.24% subjects were presented with early enamel lesion i.e., code 1 (First visual change in enamel: opacity or discoloration is visible at the entrance to the pit or fissure after prolonged air drying, which is not or hardly seen on wet surface) and code 2 (Distinct visual change in enamel, when wet there is a curious opacity white spot lesion and/or brown discoloration which is wider than the natural fissure/pit). These codes represent the non-cavitated/early lesions in the enamel as per the ICDAS criteria which would not be accounted if assessed using DMFT index. This draws attention towards providing preventive treatment modalities so as to control the progression of dental caries to this study group.

Table IV represents the distribution of dental caries among gender in the fishermen community of our study population. There were 258 males and 283 females. The prevalence was 82.3% in females (233 subjects) and 81.2% in males (212 subjects). In our study, females had a slightly higher prevalence of caries (1.1%) than males, which was not statistically significant. The same was observed in studies conducted by Kumar PM et al. 2005 (Chennai) and Grewal H et al. 2011(Nainital) where higher caries prevalence was present in females than males with the following percentage differences of 7.1% and 4.16% respectively in the age group between 6 -14 years. Most of the Indian studies show more caries prevalence in females than males which could be attributed to the negative attitude of parents towards oral care for females. Study done by Lukacs JR et al. in 2006 in Canary Island has also reported that caries rate was higher in females than males which may be due to earlier eruption of teeth in girls, hence longer exposure of girl’s teeth to the cariogenic oral environment. In contrary, Ismail et al. 2008 reported boys being more affected than girls, and this
variation could be attributed to the different age group and geographic locations of that study. Table V shows the age-wise prevalence of dental caries in 6-14 year old children. Caries prevalence was 81.9% and 81.6% in 6 and 7 years of age respectively, there was a slight decrease in 8 years old children to 80.5% which may be due to the loss of carious primary incisors. On the other hand, among 9 years old children prevalence rate was increased to 86.4% which could be due to the early carious lesion in the first permanent molar and among 11 years caries rate decreased to 62.5%, which may be due to increase in the level of manual dexterity of the child improving their oral hygiene and loss of carious primary molars. Caries prevalence increased to 75.0% and 83.3% among 12 and 14 years old children which may be due to early lesion present in the newly erupted premolars and second molars. Studies reported by Dash JK et al. in 2002, Goyal A et al. in 2007 and Dhar V et al. in 2007 suggested that, increase in caries prevalence with advancing age appears till 9 years could be due to an increased exposure of the susceptible tooth to existing poor oral hygiene conditions. Shingare P et al. in 2012 suggested that reason behind the decreased prevalence at the age of 11-14 years could be due to increase in the level of manual dexterity of the child, increased awareness about oral health and also the process of post eruptive maturation, which makes tooth more resistant to caries as compared to immature tooth.

Table VI shows CARS (Caries Associated with Restoration and Sealants) detection criteria on the teeth with secondary caries. There were only 6 children (1.1%) had secondary caries on teeth. The results presented here, corroborate with other dental caries prevalence reports, which indicates that this disease continues to be very frequent and is globalised in this age group.

**Conclusion**

The overall prevalence of dental caries among the schoolchildren was 82.3%. Non-cavitated (or) early enamel caries lesions were highly prevalent among the student population, among the teeth assessed CARS (Caries Associated with Sealants and Restorations) criteria showed that only 1.1% of the surveyed population had secondary caries. It is recommended that continuous monitoring and effective implementation of preventive and restorative programs to be carried out in schools to increase the dental disease awareness thereby reducing the caries prevalence.

Management of Atrophic Maxilla – A Review

Muthumani T1, Buggaveeti Pradeep Kumar2

1Associate Professor, Department of Oral and Maxillofacial Surgery, Sree Balaji Dental College and Hospital. BIHER, Chennai, 2Senior Lecturer, Department of Conservative Dentistry and Endodontics, Mamta Dental College And Hospital, Khammam, Telangana

Abstract

The placement of implants in the alveolar bone remains a challenge because of the resorption of the residual ridge resulting in insufficient bone volume in one or more dimensions. A severely atrophied maxilla presents serious limitations for conventional implant placement. This presents challenge to the surgeon for implant placement in harmony with the planned prosthesis. Important aspects that need to be considered for implant placement in posterior atrophic maxilla are discussed in this article and both surgical and non-surgical options are suggested.

Key Words: Atrophic maxilla, buttresses, implants, maxillary sinus, osteotomy, bone graft, sinus lift, zygoma implant, pterygoid implant, tilted implant, mini-implant.

Introduction

The reconstruction of edentulous, atrophic jaws according to functional and esthetic factors not only restores chewing function, but leads to positive psychosocial effects and thus also improves the patient’s quality of life.22 The rehabilitation of edentulous jaws with osseointegrated implants has been proven to be a predictable treatment over the time. A sufficient and long-term stable bone site is the basis of successful implant therapy. Implant rehabilitation has shown higher success rates of 84–92 %, when sufficient bone is available in maxilla. But, atrophy in maxilla is not an uncommon finding and conventional implant placement gets complicated in such situations.1

However, due to atrophy or periodontal disease, local conditions of edentulous ridges may be unfavorable for implant placement. In maxilla, centripetal pattern of alveolar resorption, pneumatization of maxillary sinuses, presence of nasal fossae and nasopalatal duct, poor bone quality complicate implant placement.28 In particular, severe atrophy of the edentulous maxilla (class VI according to Cawood and Howell 1988 classification), may result in insufficient bone volume and unfavourable vertical, transverse, and sagittal interarch relationship, due to the tridimensional resorption pattern of long-standing maxillary edentulism. Finally, maxillary sinus pneumatization may further reduce the available bone for a safe and reliable implant-supported dental rehabilitation. This may render implant placement impossible or incorrect from a functional and esthetic viewpoint.2

Several surgical procedures have been developed to increase local bone volume in deficient anatomical regions. These techniques pose a series of inconveniences, such as the need for multiple surgical interventions, the use of extraoral bone donor sites (e.g., iliac crest or skull) - with the morbidity involved in surgery of these zones - and the long duration during which patients remain without rehabilitation during the graft consolidation and healing interval. These factors complicate patient acceptance of the restorative treatment and limit the number of procedures carried out.3

In order to overcome such limitations, different therapeutic alternatives have been proposed, such as, short implants, or implants placed in specific anatomical areas like the pterygoid region, the tuber or the zygoma. Any of these procedures requires considerable surgical
expertise and has its own advantages, limits, surgical risks and complications involving biological and financial costs.¹

Sinus floor elevation

The sinus lift operation has been used since the early 1980s to gain vertical bone height in atrophic regions of the posterior maxilla, prior to the placement of dental implants (Boyne and James 1980).² Two techniques used are: The classical approach through a lateral window and for less severe bone loss, the osteotome technique (Summers Sinus floor elevation). The lateral window osteotomy is the most commonly used and reported technique for sinus augmentation, in which a fenestration is made through the buccal bone, the Schneiderian membrane is freed from the maxilla and elevated. During this elevation procedure, the space created between the residual maxillary ridge and the elevated Schneiderian membrane is filled with a grafting material. This way, a bone volume is created that may allow for implant placement, either simultaneously with the elevation procedure when the residual ridge allows for primary implant stability or at a second stage after healing of the grafted site.³ The lateral approach to sinus augmentation is a successful procedure, with percentages of success close to 100%.³⁵,²⁷,¹⁴ An alternative to the most commonly used lateral (major) window approach involves the apical displacement of crestal bone using the osteotome technique. The Summers Sinus floor elevation procedure, introduced by Summers [1994] is less invasive, less time-consuming and reduces postoperative discomfort to the patient.³³ The procedure consists of elevating the Schneiderian membrane with osteotomes through a crestal approach, placing simultaneously the bone grafting material and the implant. After a healing period of 3-6 months, implants are osseointegrated and become surrounded with bone over the implant apex.²³

Distraction osteogenesis

Distraction osteogenesis, first described in the treatment of long bone fractures by Ilizarov, is a procedure based on the gradual separation of a mobile but fully vascularised bone segment from the basal bone, leading to the formation of an intervening soft callus which gradually transforms to mature bone.¹⁶ Chin and Toth and Hidding et al. were the first to report clinical use of distraction osteogenesis for alveolar ridge augmentation. The technique involves freeing a bone segment (the transport segment) from the basal bone, but retaining attachment via the lingual periosteum.⁹ Gaggl et al. have described a simplified technique for alveolar ridge augmentation using “distraction implants”, which do not require subsequent removal. Studies have indicated that when implants are well fixed in the distracted bone and basal bone, they survive as long as implants in native bone and also the vertical bone loss, if any, was similar to that reported for implants placed in native bone. Although failures of implants have been reported in implants placed in distracted bone, most authors consider implantation following distraction to be a highly effective and useful technique.²⁶

Treatment without bone modification

Since the development of osseointegrated dental implants, the standard procedure has been to place implants vertically within the alveolar bone. However, when the amount of available bone in the maxillary alveolar crest is <10 mm in the vertical aspect and 4 mm in the horizontal aspect, the prognosis for implant treatment is poor. Alternative methods in which the severely resorbed alveolar crest is used for implant placement without bone grafting have been presented and include placement of implants in anatomic buttresses, palatal positioning of implants and the tilted placement of implants along the anterior maxillary sinus wall.²⁵

Anatomical buttresses

The skull presents a series of dense bony buttresses that conform a protective frame around the different craniofacial cavities such as orbit, nasal fossae or passages, oral cavity and paranasal sinuses with mostly fragile walls. These buttresses distribute forces through the solid facial bone structure, and are distributed strategically throughout the three facial thirds of the skull. In this context, the middle third portion presents two anterior buttresses namely, frontomaxillary and frontozygomatic buttresses and a posterior pterygomaxillary buttress.²⁹

Frontomaxillary or canine buttress

This region normally presents a compact cortical layer and dense medullary bone – thus allowing the placement of long implants with parasinusual angulation. Krekmanov and Rangert introduced implants parallel to the anterior wall of the sinus, combined with vertical implants in the anterior region, in a series of 20 patients.
This procedure made it possible to extend the fixed prosthesis ≥9 mm. No implants were lost during the 2 years of follow-up.17

**Frontozygomatic buttress**

This support is located in the region of the upper first molar, forming the so-called zygomatico-alveolar crest, which continues laterally along a concave trajectory to the zygomatic process of the maxillary bone and posteriorly, to the zygomatic bone. Two management options exist in this region.

**Trans zygomatic implants**

Trans-zygomatic implantation is a novel technique involving the positioning of two bilateral implants measuring between 35 mm and 55 mm in length, which are anchored to the zygomatic bone following an intrasinusal trajectory. These implants in turn must be combined with a minimum of two implants in the anterior sector and stent-fixated by means of a prosthetic superstructure.29 The availability of the zygoma implant has provided a viable alternative for treatment of extremely atrophied maxilla. The zygomatic implant is a self-tapping titanium implant with a machined surface, available in 8 different lengths of 30–52.5 mm. The threaded apical part has a diameter of 4 mm and a crestal part of 4.5 mm. The implant head has an angulation of 45° and an inner thread for connection of abutments in order to compensate for the inclination of implant insertion with respect to zygoma. The implant has an oxidized rough surface with a smooth body and wide crestal neck.

The authors consider that this variant affords improved contact between the bone and implant, with optimum implant positioning, and a better postoperative course.30 Balshi and Wolfinger reported the case of a 20-year-old patient presenting ectodermal dysplasia rehabilitated with two zygomatic implants in combination with four anterior implants and two implants positioned in the pterygomaxillary region – thereby avoiding graft-based maxillary reconstruction.5 A survival rate of 96-100% has been reported for this treatment modality.10,11,21,31

**Pterygomaxillary buttress**

Tulasne in 1989 described the technique for placing implants in this region. According to him, the pterygomaxillary implant should anchor in the pterygoid process or even traverse the latter, avoiding the posterior portion of the sinus and major palatal duct. To accomplish this, the implant should be directed posteriorly, superiorly and medially. The length of the implant is normally between 15 mm and 20 mm.32 In a study, Pi published the results of 177 pterygomaxillary implants in 136 patients, with a follow-up of 1-10 years. The success rate was 97.2%.7 As per the various studies the success rate of this technique was between 88% and 98%.36,34,3,12

**Mini-Implants**

Mini-implants were first introduced in the literature as the “Miniplant” by Barber and Seckinger, in 1994 with an external connection. This study was followed by Sendax, who considered the ultra-small single piece implant. The primary intention was to support an interim prosthesis, as it was expected these implants would be easily removed. However, it was noted that removal of these implants from the bone was difficult as they appeared to have osseointegrated. Histologic studies later confirmed that bone appeared to be integrated to the surface of the ultra-small implant at the light microscopic level, and the bone appeared to be mature and healthy.

The GOMI have defined the term mini implant as an “implant fabricated of the same biocompatible materials as other implants but of smaller dimensions. Implants can be made as one piece to include an abutment designed for support and/or retention of a provisional or definitive prosthesis”.20 The diameter threshold is not specified by the GOMI for these implants. Also, the literature is not clear regarding the terminology associated with reduced diameter implants. The terms mini implants, narrow diameter implants, and small diameter implants have been used interchangeably. Additionally, the use of terms such as provisional implants, transitional implants, and orthodontic implants has further added to the confusion. In spite of these multiple terminologies, no consensus on the definition of reduced diameter implants exists in the literature.

The advantages of using mini implants for definitive prosthodontic treatment are: Low cost, ability to be placed in narrow or wide ridges, simplified treatment procedures, flapless surgical procedure reducing postsurgical discomfort and morbidity for patients. Also, majority of miniimplants are designed as a
1-piece implant with the ability to immediately load the prosthesis. The disadvantages of mini-implants for definitive prosthodontics treatment are: the need for multiple implants because of the unpredictability and lack of current scientific guidelines and understanding; limited scientific evidence about long-term survival; potential for fracture of the implant during placement; lack of parallelism between implants is less forgiving because of the 1-piece design; reduction in resistance to occlusal loading. However, Bertil has recommended the use of miniimplants (preferably three implants) in clinical situations with vertical height of 5–8 mm and width of 4–5 mm, to support a posterior maxillary fixed prosthesis.13

Pterygoid Implants

The use of pterygoid implants was described by Tulsane JF in 1992 and was subsequently used by many other researchers. Pterygoid implants have the advantage of allowing anchorage in the posterior atrophied maxilla, eliminating the need of sinus lifts or bone grafts. In addition posterior cantilever can be eliminated and axial loading is improved. These implants can be placed in two different locations such as pterygoid process or in a most anterior position, the pterygomaxillary process. The findings in the literature show no clear differences between these two locations and no consensus exists regarding the nomenclature of these implants. However, the implant length and angulations vary between these two locations. Shorter implants are generally placed in the pterygomaxillary region with angulation of 10–20 to simulate the proper angulation of the third molar. On the other hand, the longer implants are anchored to the pterygoid plate of sphenoid bone.7

Tilted Implants

As early as 1999, tilting of dental implants in the posterior region of the jaw was demonstrated as an alternative to bone grafting for atrophied jaws. If the distal implant was tilted, a longer dental implant and a more posterior implant position could be achieved. The theory behind this philosophy was that a greater anterior-posterior position of implant would distribute the occlusal forces; therefore, the transverse force placed on the tilted implants would not be detrimental to them. In the maxilla, the distal implants could also get benefitted from the cortical bone wall of the sinus and the nasal fossa. Bellini et al. investigated the stress patterns at the bone-implant interface of tilted implants using three-dimensional finite element analysis and found that the numerical values of compressive stress were lower in the tilted implant configurations. He also found that tilting of the implants reduces the cantilever length by increasing the inter-implant distance. This may have produced a better load distribution, thereby reducing the stress level of the splinted implants. As a result, a biomechanical advantage is gained by using the tilted implants. Within the limitations, this study supports the use of tilted implants to treat the edentulous maxilla.6 Menini et al. has systematically reviewed 1,623 implants placed in the maxilla of 324 patients. Of these, 778 implants were tilted. The overall weighted cumulative success rate was reported as 98.62%. They have suggested the use of tilted implants for full-arch immediate loading rehabilitations of the maxilla with a favorable short term prognosis.

Conclusion

Maxilla is different in its function, physiology, and bone density from the mandible. These differences, along with its varied anatomy, challenge the implant placement in harmony with planned prosthetic restoration. However, a thorough knowledge of various augmentation procedures, materials and proper patient selection will result effective long-term solutions in the management of the atrophied maxilla. Important aspects that need to be considered for implant placement in posterior atrophic maxilla are discussed in this article and both surgical and non-surgical options are suggested. There is no consensus as to which treatment modality is superior to the other in literature. The decision to opt for either of the options, therefore, depends upon patient factors, and ultimately, the expertise and skill of the clinician.

Psychosomatic Disorders Affecting Mouth- A Review Article

L. Malathi¹, Aravinda Babu², K.M.K Masthan³, Sudakshina Mukherjee⁴
¹Reader, ²Professor, ³Head Of Department, ⁴Post Graduate Student, Dept of Oral Pathology & Microbiology, Sree Balaji Dental College & Hospital, Chennai, BIHER

Abstract

For the past few years, a gradual rise of psychiatric disorders representing a major public health problem came into being. Anxiety and depression are two most prevalent psychiatric diseases. Oral mucosa being reactive to emotional influences like stress, anxiety, depression, act as a window to reflect clues about overall health and sometimes it becomes the first sign of a disease. Often patients complain certain oral discomforts cause of which remain undetermined. These symptoms often thought of mental or emotion in origin and can be termed as “ORAL PSYCHOSOMATIC DISORDERS” representing a new category of syndrome called Medically Unexplained Oral Symptoms/Syndromes (MUOS). Often dentists find it challenging to treat such patients due to lack of any convincing physical explanation of the same. This review highlights the correlation between psychological factors and its subsequent responses on oral health resulting certain orofacial pathologies, struggles in handling patients, challenging treatment plans and involvement of counselling and psychiatrists referral at early stages which could ensure betterment of patient by early diagnosis of his or her mental status and treating the same.

Keywords: psychosomatic-disorders, burning mouth syndrome, psychosomatic dentistry.

Introduction

A wide spectrum of psychiatric disorders affects oral and paraoral structures which have a definite psychosomatic cause, but unfortunately they remain unrecognized because of common and limited nature of this presenting features (¹). The term psychosomatic derived from Greek word “psyche”and “soma”. “psyche” in earlier times meant soul and mind which now implies behaviour, “soma” refers to physical organism of the body. In 1818, German psychiatrist Heinroth was first to use the term “Psychosomatic”. In 1922, Deutsch introduces the psychosomatic medicines. Sigmund Freud systematically studied a case of now famous “Anna O” who was suffering from what then called hysteria (³). Many dental patients are seen coming with chief complaints of oral symptoms after dental treatment such as chronic pain or occlusal discomfort for which most of the time the cause remains undetermined (²). This makes the treatment challenging for the dentists especially in oral symptoms like chronic tooth pain or burning mouth syndromes where in most cases there is absence of any convincing physical manifestation leading to categorize them under psychosomatic disorders. Delusional diseases like Oral Cenesthopathy that is when patients become certain of the presence of foreign bodies in their oral cavity makes them stubborn and definitely negative towards the psychiatric referral by dentists. Thus by definition we can say that- “Psychosomatic disorders are defined as disorders characterized by psychological changes that originate partially from emotional factors”.

RELATIONSHIP BETWEEN “PSYCHE” AND “SOMA”

Two concepts to explain the relationship between “psyche” and “soma”
SPECIFIC HYPOTHESIS: Expression of a predetermined disease or illness occurs due to a specific stimulus or conflicts or stressors. After stress is suppressed through the ANS, however the sympathetic responses becomes alert for heightened aggression or flight or parasympathetic nervous system responses may be altered for increase vegetative activity. Such prolonged alertness and tensions can produce psychological disorders and eventually pathology of organ or viscera.

NON-SPECIFIC HYPOTHESIS: Generalized stress created the preconditions for a number of not necessarily predetermined diseases. According to hypothesis four varieties of reactions occur due to stress.

EFFECTS OF STRESS ON ORAL MUCOSA:

Oral cavity is one of the target areas on psychological state of human mind. It can reflect general health of individual. Stress response activates autonomic nervous system, mainly sympathetic via hypothalamic-pituitary-adrenal (HPA) axis, which secrete corticotropin-releasing factor (CRF) and Arginin-Vasopressin (AVP), leading to release of Adrenocorticotropic hormone (ACTH), eukaphalines, and endorphins. Thus stress response functions act as a positive, bidirectional feedback loop. Unlike under non-stressful conditions when both CRF & AVP are secreted in circadian and pulsatile manner with approximately 2-3 secretory episodes per day, these in acute stress are enhanced resulting increased ACTH and cortisol. Various other factors like Angiotensin II, Cytokines, and lipid mediators of inflammations are released which acts on various components of HPA axis potentiating its activity.

CLASSIFICATION FOR PSYCHOSOMATIC DISORDERS PERTAINING TO DENTAL PRACTICE BY SHAMIM (2014)

PAIN RELATED DISORDERS:

- Myofascial pain dysfunction syndrome (MPDS)
- Atypical facial pain
- Atypical odontogenic pain
- Phantom pain

DISORDERS RELATED TO ALTERED ORAL SENSATIONS:

- Burning Mouth Syndrome
- Idiopathic xerostomia
- Idiopathic Dysgeusia
- Glossodynia
- Glossopyrosis

DISORDERS INDUCED BY AUTOIMMUNE DISORDERS:

- Oral lichen planus
- Recurrent Aphthous stomatitis
- Psoriasis
- Mucous membrane pemphigous
- Erythema multiforme

DISORDERS INDUCED BY NEUROTIC HABITS:

- Dental and Periodontal diseases caused by bruxism
- Biting of oral mucosa (self mutilation)

DISORDERS CAUSED BY ALTERED PERCEPTION OF DENTOFACIAL FORM AND FUNCTION:

- Body dismorphic disorder

MISCELLANEOUS DISORDERS:

- Recurrent herpes labialis
- Necrotizing Ulcerative gingivostomatitis
- Chronic periodontal disease
- Cancerophobia
- Delusional Halitosis

MYOFASCIAL PAIN DYSFUNCTION SYNDROME: It became topic of interest in both medical and psychological fields over past two decades. The conventional definition of myofascial pain syndrome is characterize by regional pain originating from hyperirritability spots located within taut bands of skeletal muscles, known as Myofascial trigger Points (MTrPs).

SIGNS AND SYMPTOMS: Unilateral dull pain in
the ear or preauricular region that commonly worsens on awakening, tenderness of one or more muscle of mastication on palpation and limitation or deviation of the mandible on opening.

**RECURRENT APHTHOUS STOMATITIS**
Most common type of ulcerative disease of the oral mucosa. There are three variants described—Minor, Major, Herpetic-form. Etiology is multifactorial—Trauma, stress, Hormonal, immunologic, drugs etc. Psychological stress may play a role in the manifestation of Recurrent Aphthous Stomatitis, and it may serve as a trigger or a modifying factor rather than being a cause of the disease.

**IDIOPATHIC XEROSTOMIA**: Xerostomia is defined as the subjective feeling of oral dryness and it is the result of salivary gland hypofunction. Xerostomia is a common complaint among older adults and 30% of population aged 65 and more prevalent in post menopausal women than men. Etiology—multifactorial. The sensation of dry mouth may be regarded as a subjectively felt Somatic Symptom. Mason and Glen (1967) have stated that as the secretion of saliva is regulated by ANS and is subjected to reflex stimulation from physical and psychic causes, then xerostomia may result from four basic causes in which factor affecting salivary centre are primary cause—emotions, fear, excitement, stress, Depression. Diseases like: brain tremor, Parkinson’s disease, Drugs like antidepressants, anticonvulsants, antipsychotics, anticholinergics and alpha-agonists.

**ORAL LICHEN PLANUS**: Oral Lichen Planus is a mucocutaneous disorders which affect skin, oral and other mucous membranes. Among all forms Erosive form of Oral Lichen Planus is commonly associated with Psychotic factors. Though etiology of lichen planus is not clear but various psychological factors contributing to pathogenesis of lichen planus are stress, anxiety, depression and increased cortisol level; MEDICALLY UNEXPLAINED ORAL SYMPTOMS: Patients with “oral psychosomatic disorders” are reluctant to accept diagnosis since the problem is purely psychogenic. He reported that the estimated prevalence of MUOS among dental patients ranges from 5-10% or more.

**CHRONIC ORAL PAIN**: Burning Mouth syndrome, Atypical odontalgia. The impact of chronic oral pain on quality of life should not be ignored. Burning Mouth Syndrome and Atypical odontalgia both are chronic pain disorders that occur without any evident cause, and they are often regarded as psychogenic conditions. Few patients with chronic oral pain are treated with psychiatrists. Burning Mouth Syndrome are characterized by a burning sensation involving tongue or other oral sites, usually in the absence of clinical and laboratory findings. Patients with Burning Mouth Syndrome are often informed about their clinically normal oral cavity even though they have severe pain and thus do not receive any treatment. They become at last frustrated, anxious and worried about serious diseases like Cancer. Compared to Burning Mouth Syndrome, Atypical Odontalgia is not as commonly seen in other medical settings and has received substantial attention from dentists in recent years. Association for the Study Of Pain defines Atypical Odontalgia as severe throbbing pain in a tooth without major pathway. Ineffective treatment of this type of chronic dental pain often is considered to be treatment failure. Thus repeated ineffective dental treatment like Root canal, Filling even Dental extractions are carried out which further results in iatrogenic changes to the treated tooth leading difficulty in performing further diagnostic evaluations. The lack of knowledge about pathophysiological mechanisms of this pain conditions can be considered as a major reason for problems in their diagnosis and management.

**ORAL CENESTHOPATHY**: Characterized by foreign body sensations despite the lack of any medical evidence for them. Also can be called as oral Dyesthesias or Somatic Delusions. There are certain unusual complaints regarding oral cesthopathy like some patients would complain of unusual oral sensations such as excessive mucus secretion or a slimy sensation, and others complain of a bizarre oral sensations such as a feeling of coals or wires present within oral cavity.

**HALITOPHOBIA**: Some patients complain of oral malodour that is in-perceptible to others. These patients are categorized under halitophobia or delusional or psychosomatic halitosis. A related disorder, Olfactory reference syndrome (ORS), which is called “Jikoshu-Kyofu” in Japan, a condition where patients believe that they are exuding unpleasant odour. It has been reported that 75% of his Olfactory Reference Syndrome patients were preoccupied with bad breath. These patients are actually halitophobic.
OCCLUSAL DISCOMFORT: Occlusal discomfort is a problem unique to dentistry, some patients irritate their dentists because of their unreasonable complaints, demands and incomprehensible claims concerning dental treatment. PHANTOM BITE SYNDROME (PBS) characterized by persistent uncomfortable sensation of occlusion without evidence of occlusal discrepancy. Patients complain that their occlusion is wrong and their “bite is off.” They thus visit multiple dentists for bite correction.

ODONTOPHOBIA: The provocation of anxiety by dental treatment is universal phenomenon. Can be variously called as dental phobia. These patients due to their extensive dental anxiety often suffer from various dental problems owing to their avoidance of seeing a dentist.

CANCEROPHOBIA: The belief that cancer inevitably leads to death is widespread. This may contribute to society cancerophobia and with subsequent frequent delays in seeking medical attention and treatment for suspected cancer.

DYSMORPHOPHOBIA: Belief in a cosmetic defect in a person of normal appearance. These patients often seek treatment to correct the supposed deformity. The complaints may range from mild unattractiveness to ugliness. Since face and its components like teeth, nose, mouth, ears, eyes and chin make up a large percentage of structures for which patients seek and undergo cosmetic surgery.

PRIMARY DYSMORPHOPHOBIA- is neurotic or psychotic characteristic diagnosed in the absence of any other psychiatric illness.

SECONDARY DYSMORPHOPHOBIA- arises secondary to depression, schizophrenia, anxiety

DENTAL AND PERIODONTAL DISEASES CAUSED BY BRUXISM: Bruxism is the excessive grinding of the teeth which is a parafunctional activity. This results in many dental problems such as abrasions, hypersensitivity, periodontal destructions, temporomandibular joint dysfunction. Exact pathology is unknown, however stress, anxiety play a vital role and considered risk factors. Behavioral problems and potential emotional problems have been found to be potential risk factors for bruxism in children.

NEUROENDOCRINE BIOMARKERS:

</tr>
<tr>
<td>NORADRENALINE</td>
<td>CHRONIC STRESS-Decrease in release of brain noradrenaline ACUTE STRESS :- Elevation of both plasma and brain nor-adrenaline</td>
</tr>
</tbody>
</table>
**METABOLIC MARKERS** :-Since metabolic changes are quantifiable they can be used as biomarker in chronic stress.

<table>
<thead>
<tr>
<th>PARAMETERS</th>
<th>RELATION IN RESPONSE TO STRESS</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERUM CHOLESTEROL (NORMAL:120-250mg/dl)</td>
<td>Decreases with chronic stress level</td>
</tr>
<tr>
<td>SERUM ALBUMIN (NORMAL:3-6g/dl)</td>
<td>Reduces the level by either increasing the rate of degradation or decreasing the rate of synthesis</td>
</tr>
<tr>
<td>WAIST-HIP RATIO</td>
<td>Higher for chronically stressed individual as greater vulnerability to stress increases exposure to stress-induced cortisol which in turn fuels central fat deposition (40,41)</td>
</tr>
<tr>
<td>GLYCOSYLATED HAEMOGLOBIN</td>
<td>Chronic stress linked to hyperglycaemia which in turn increase the levels of glycosylated haemoglobin</td>
</tr>
</tbody>
</table>

**IMMUNOLOGICAL BIOMARKERS** :-Change in circulating level of cytokines can be used as biomarkers like IL-6, TNF-alpha, CRP and IGF-1. Studies suggested that chronically stressed individual are biased towards a humoral immunity oriented cytokine production, for unknown reasons. (42)

**MANAGEMENT**:-Can be classified as: Management of Diseases with psychological factors playing important role in pathogenesis and Management of Medically Unexplained oral Symptoms.

**MPDS (MYOFASCIAL DYSFUNCTION SYNDROME):** A number of successful treatment outcomes have been reported, including occlusal splints, physiotherapy, muscle relaxing appliances (43). Tricyclic antidepressants as Amitriptyline and Nortriptyline and cognitive behavioral therapy are often generally helpful.

**MANAGEMENT OF IDIOPATHIC XEROSTOMIA:**

**PATIENT EDUCATION** : Patients should receive detail information about potential causes of dry mouth. Patients thus be encouraging to have preventive oral health care such as dental hygiene habits and regular dental visits. Another palliative action to minimize symptoms and prevent oral complications is water intake, drinking water frequently and remaining hydrated.

**PREVENTIVE THERAPY** : It includes use of chemical radiotherapy protectors to improve the therapeutic index in radiotherapy. However vast majority of these are too weak in terms of radioprotection, too toxic or without any apparent mechanisms to ensure selective normal tissue protection. Some of these compounds are Sulphydryl compound, Amifostine Ethylphosphorothioic acid which is an oxygen scavenger that may protect salivary glands from free radical damage during radiation therapy without attenuation of the Anti Tumor effects in many experiments performed. Amifostine has been approved for prevention of xerostomia in head and neck squamous cell carcinoma patients undergoing radiotherapy (45).

**SYMPTOMATIC TREATMENT:** saliva substitute are available in various formulation examples like lozenges, sprays, mouth rinses, gels, oils, chewing gums or toothpastes. Most available in market is Carboxymethylcellulose (CMC), mucins, Xanthan-gum, hydroxyethylcellulose, linseed oil, or polyethylene oxide (46). Advances in hydrogel technologies and development of buccal mucoadhesive polymers, allows continuous release of substances that maintain oral hydration and also dental benefits. (47)

**ORAL LICHEN PLANUS MANAGEMENT** :- A positive response to medium potency corticosteroid treatment, such as acetate triamcenolone 0.1% powerful fluorinated steroids as flucinolone acetonide 0.05% and 0.1% and more high potency halogenated corticosteroids like clobetasol propionate 0.05%. Surgical excision, cryotherapy, CO2 laser and ND.YAG laser have all been used in the treatment of Oral Lichen Planus.

**MANAGEMENT OF RECURRENT APHTHOUS ULCER**: Antiseptic alcohol free
mouthwash, spray or gel (chlorhexidine gluconate) may be recommended (48).

**MANAGEMENT OF IDIOPATHIC DYSGEUSIA:** Zinc supplementations aid in treating taste disorders by promoting proliferation of normal taste buds even in patients without zinc deficiency (49).

**MANAGEMENT OF MEDICALLY UNEXPLAINED ORAL SYMPTOMS (MUOS)**

Patients of this category tend to keep on develop newer symptoms once the previous one get obliterated. Even with obvious improvements these patients tend to concentrate on the minimal symptoms and keep on irritating the concerned dentists with the same. They are reluctant to listen to the advice of the dentists and keep pestering for new treatment plans. This makes the dental treatment more difficult although the efficacy of treatment with antidepressants is certainly important, patient dentist interactions are more critical (50). New type of dentistry called “psychosomatic” dentistry has to play a vital role in managing such patients where patients’ mental and oral status has to be understood and therapeutic techniques are implemented accordingly. Psychiatric referrals also becomes difficult for these patients since they are most often reluctant to go to the psychiatrist and the psychiatrist also do not able to understand oral complaints without the vivid knowledge about dentistry. Psychiatric also dislike patients with constant dental complaints wanting no business with them-which make the matter worse. But however it has been reported that some patients with MUOS are thought to actually have psychiatric conditions like depression, bipolar disorder and severe obsessive-compulsive disorders. Dentists should have sufficient training to be able to recognize such mental disorders (51) so that patients are not shunted between dentists and psychiatrists.

**Conclusion**

Mind and Body are interconnecting. Dentists come across these type of patients on daily basis. Hence, sufficient training of the dentist to successfully recognize the problem and efficient management accordingly has become a necessity in modern and developing world which is under constant stressful lifestyles. This entity opens up a bridge between dentistry and psychiatry also can be called as Psychological Dentistry. So Psychiatric department separately could be an important part of Dental hospitals where early referral and subsequent counselling can improve the condition.

Eagles Syndrome- A Case Report with Literature Review

S.G.Wasim Ahamed¹, Kavitaa Nedunchezian²

¹Senior Lecturer, SreeBalaji Dental College & Hospital, BIHER, ²Consultant Oral Physician & Maxillofacial Radiologist

Abstract

The symptoms brought by compression of vital neurovascular and muscular elements adjoining the styloid process due to elongation of styloid process or ossification of the stylohyoid or stylomandibular ligament, is termed as Eagles syndrome. Reporting a case of a 27 year old patient diagnosed with Eagles syndrome.

Keywords: Syndrome, orthopantomograph, Facial, Glossopharyngeal

Introduction

First elucidated by the American otorhinolaryngologist Watt Weems Eagle in 1937, Eagle syndrome (ES) or stylohyoid syndrome (SS), a rare condition that occurs due to elongation of the styloid process or calcification of the stylohyoid ligament, characterized by painful sensation in the head and neck region.¹,²

The normal styloid process measures approximately 2.5–3.0 cm in length, exceeding which is said to be an elongated styloid process.² Most of the patients with styloid elongation are asymptomatic and only four percent of affected individuals are known experience the symptoms.³ Symptoms are experienced only when the elongated ossified structures exert pressure on the various vital structures in the cervico-facial region. Symptoms include pain in cervico-facial region, pharyngeal discomfort, painful neck movements, change in voice, painful tongue movements, increased secretion of saliva, otalgia and headache.

Tip of elongated styloid process can be felt by digital palpation over the tonsillar fossa, if pain is reproduced or referred to face, head, neck or ear the presumptive diagnosis of elongated styloid process is very likely to be present.

Radiographic imaging serves the ultimate investigative tool in establishing the diagnosis. The radiographic views includes orthopantomograph (OPG), lateral-oblique mandible, lateral head and neck radiograph and Towne radiograph plain film etc. A threshold length of 3 cm is accepted as abnormal by current conventions. Lateral views are the best to show the length of the styloid process, but antero-posterior views are also required to determine bilateral involvement and lateral deviation. Computed tomographic scans have proven to be useful in difficult cases to endorse diagnosis, especially with 3-D reconstruction it possible to envision the exact spatial orientation of the styloid processes.

Medical and surgical management are available for treating styloid elongation, the former can provide only short term relief. Conservative treatment modalities included transpharyngeal injection of local anaesthetics (lignocaine) and corticosteroids, nonsteroidal antiinflammatory agents (NSAIDS), diazepam, application of heat and traditional Chinese herbs. Transpharyngeal manipulation with manual fracturing of the styloid process, does not usually relieve symptoms, but also has the risk of damaging the nearby neurovascular structures. The most satisfactory and effective treatment is surgical shortening of the styloid process through either an intraoral or external approach.⁴

Case Report: A 27 year old female patient complained of pain in throat region which radiated to the head, neck, shoulder and ear region. The patient has...
been experiencing pain since 3 years. Pain is intermittent, fluctuating between moderate to severe in intensity and aggravates on turning the head, also complains of tinnitus at times with otalgia. Past surgical history revealed that patient had undergone tonsillectomy 15 years before. On clinical examination odontogenic and temporomandibular joint related cause was ruled out, tenderness was present on bilateral palpation over the peritonsillar fossa and tip of styloid process was felt. Radiographic evaluation of the OPG revealed bilateral elongation of the styloid process (Figure 1), confirming diagnosis of Eagles syndrome.

**Figure 1: OPG revealing the presence of bilateral styloid elongation.**

**Discussion**

ES is a clinical condition, where there is abnormal ossification of the stylohyoid apparatus, consisting of the styloid process, attached stylohyoid ligament and the lesser cornu of the hyoid bone.[5] Eagle hypothesized two types of the syndrome, the Classic type and the Carotid artery type. Classic type often noticed in patients with history of tonsillectomy and arises secondary to the stimulation of the Trigeminal, Facial, Glossopharyngeal and Vagus cranial nerves or their associated branches. Eagles speculated that post tonsillectomy, these individuals develop scarring near the styloid apex which subsequently compresses or stretches nerve structures in the space surrounding the styloid process, causing pain. In carotid artery type, the styloid process gets associated with the carotid nerve plexus and causes a foreign body sensation in the pharynx and cervical pain on rotation of the head. The present case is of classic type, reported with history of tonsillectomy and experienced pain in throat often radiating to the head, neck, shoulder and ear region, pain often aggravating while turning the head. The patient also experienced tinnitus at times with otalgia. Clinically tip of the elongated styloid process is felt on digital palpation over the tonsillar fossa, which also precipitates pain, also evidenced in the present case. OPG confirmed the presence of bilateral styloid elongation.

Partial and complete calcification of the stylohyoid ligaments, have been reported in literature.[5] The present case didn’t show any evidence of calcification associated with stylohyoid ligament.

Compression on internal carotid artery due to styloid elongation, can lead to transient ischemic attack. Vagus mediated cardiac inhibition due to ES causing sudden death has been recorded in literature and only during the autopsy it was revealed that the elongated styloid process had been compressing both the carotid sinuses, radiographic films had failed to show the anatomical changes.[6,7]

It is easy to misinterpret ES and associated differential diagnosis, for instance ES can be atypically present as exertional headache, beginning in the right ear and radiating to the neck and to the vertex, similar kind of pain distribution was noted in the present case.[8,9] Another reported case was with diffuse bilateral stylohyoid chain ossification which can mimic symptoms of ES was diagnosed as temporomandibular joint disorder.[10]

Radiographic imaging plays a key role in providing a confirmatory diagnosis. Plain film radiography is sufficient to show the elongation, but CT scans seems to provide a better visualization of the styloid elongation and adjoining neurovascular and muscular elements.

**Conclusion**

ES can be mistaken for many other conditions, which can be excluded by eliciting detailed history, clinical examination, and radiological investigations. The fact that styloid process with normal length is not normally palpable, and simple digital palpation over the tonsillar fossa can help us arrive at a presumptive diagnosis. Definitive diagnosis can be arrived only with radiographic evaluation. Resection of the elongated styloid process is the treatment of choice for long term benefit.

Assessment of Articular Disc Position before and after Gnathological Splint Therapy in Symptomatic Temporomandibular Disorder Patients Using Magnetic Resonance Imaging

Okram Robin¹, K. Gnanashanmugham², A. ArifYezdani³,
¹Post graduate Student, ²Professor, ³Professor and Director, Dept. of Orthodontics and Dentofacial Orthopedics, Bharath Institute of Higher Education and Research, Sree Balaji Dental College and Hospital, Narayanapuram, Pallikaranai, Chennai-Tamilnadu, India

Abstract

Introduction: Early and accurate diagnosis followed by therapy would be the ideal approach to reduce pain, discomfort or morbidity associated with temporomandibular disorders. The purpose of the study was to evaluate if gnathological splint therapy could capture or change the position of the displaced articular disc in temporomandibular disorder subjects using magnetic resonance imaging as the diagnostic tool.

Materials and Method: The study population consisted of 14 clinically symptomatic and orthodontically untreated temporomandibular disorder patients within the age range of 12-30 years (mean 20 years). The patients underwent gnathological splint therapy for six months and the pre and post articular disc position was evaluated with Magnetic Resonance Imaging.

Results: The amount of articular disc changes post splint therapy was almost similar on both the right and left side of the TMJ, with a mean difference of 1.4mm on right side and 1.3mm on left side.

Conclusion: Articular disc recapture was seen in patients having anterior disc displacement with reduction subsequent to gnathological splint therapy.

Keywords: temporomandibular disorder, Roths’ power centric bite, gnathological splint, mandibular positioner indicator.

Introduction

Temporomandibular disorder (TMD), a widely debated topic continues to generate interest among the orthodontic fraternity. In 1950s more emphasis was placed on the alignment of teeth, stability of intercuspal position, esthetic value of proper tooth positioning and the effect of improper occlusion on masticatory muscle function. Ronald Roth(1981) highlighted the importance of orthodontic treatment planning to the musculo-skeletonally stable position of the TMJ, prescribed a mutually protected occlusal scheme for stability and advocated the use of splints to deprogram the muscles in centric discrepancy cases. It was opined that the condylar slide from centric relation to maximum intercuspation should not be more than the permissible limits in the antero-posterior(A-P), vertical and transverse plane and if the slide exceeded the limits it may predispose the patient to TMD.¹ ³

Magnetic resonance imaging (MRI) is currently the most accurate imaging modality for identification of disk position in the TMJ. It does not produce any adverse effects nor poses any significant risks outside those found in daily living at the field strength used for imaging.⁴⁵⁶
Materials and Method

The study population consisted of 14 clinically symptomatic and orthodontically untreated TMD patients within the age range of 12-30 years (mean age 20 years) who reported to the Department of Orthodontics, Sree Balaji Dental College and Hospital, Chennai. Institutional Ethical Committee clearance was obtained for the study. The study procedures along with the possible complications were verbally explained to all the patients and written consent was obtained.

Fabrication of gnathological splint

Maxillary and mandibular impressions were taken using an irreversible hydrocolloid impression material in sterilized metal rim-lock trays. Face-bow transfer records were taken using the Axioquick Expansion Kit AX, (SAM Prazisionstechnik GmbH, Fussbergstr 1, Germany) to record the relationship of the maxilla to the cranium.\(^7\) (Fig. 1)

Centric Occlusion (CO) Bite registration

A thin dimensionally stable piece of Miltex beauty wax was used to record the patient’s habitual occlusal position or CO. It was softened in warm water and the bite was taken. The CO bite is an important record used along with the CR bite in quantifying condylar displacement with Mandibular Position Indicator (MPI).

Centric Relation (CR) Bite Registration

This method was used to obtain the best achievable seating of the condyles in the fossae for that day. A true CR can be registered only after the stabilization of condylar position.

Centric relation bite (Roth power centric bite) (Fig 2) was taken with Delar bite registration wax, one in the anterior region and the other in the posterior region.\(^8,9\)

MPI Data

MPI data consists of three graphs: right and left sagittal graphs and a transverse graph [Fig 3]. The graph at the bottom quantified condylar displacement in the frontal plane. A discrepancy of greater than 0.5mm in both the planes was an indication for treatment.

Articulation

The maxillary model was mounted using face-bow transfer record to the articulator with the mounting plate and mounting plaster (Fig 4). The incisal guide pin was adjusted to a level of 3mm above the point of first tooth contact (fulcrum) to provide space for splint fabrication. Splint was fabricated with cold cure acrylic resin. It was then inserted in the patient’s mouth and checked for centric stops and mutually protected occlusal pattern. The patient was advised to wear the splint full time.

Protocol demanded that the patient be recalled every month and the splint be checked for centric stops and mutually protected occlusal pattern.\(^10\) It has been reported that reduction in muscle stiffness and lesser resistance exhibited by the mandible was due to deprogramming of the muscles by the splint.\(^11\)

MRI was taken pre and post treatment and the following measurements were done.

Establishment of Reference Points/Plane

To measure the articular disc position in pre and post splint MRI, the following stable reference points/plane were established.

Reference plane (RP): Line that connected the superior most point in the glenoid fossa to the inferior most point on the articular eminence.

Condylar loading point (CLP) - A stable point on the condylar head. Determination of the loading surfaces of the condyle and the posterior slope of the articular eminence was based on the biomechanical model of Smith et al.\(^12\) It was assumed that condylar reactionary forces during maximum intercuspation was directed essentially perpendicular to the posterior slope of the articular eminence and that the CLP corresponded with the closest joint space perpendicular to the posterior slope of the articular eminence.\(^12-16\) Condylar reactionary forces were assumed to act through an angle of 32.5 degrees superior and 32.5 degrees inferior to the perpendicular to the posterior slope of the articular eminence through the CLP during unilateral biting.\(^12\)

Midpoint of the articular disc – A point designated in the middle of the intermediate band of the articular disc (thinnest portion of the disc).

Measurement criteria

The midpoint of the intermediate band of the articular disc usually corresponds with the CLP in normal and
healthy joints without disc displacement. Any difference between these two points is measured in mm from the midpoint of intermediate band of the articular disc to the perpendicular line projected from RP to CLP (Fig 5).

**Results**

The mean value was 2.507(mm) in the right side TMJ before treatment and 1.107(mm) after treatment. The difference between the two effectively gave the change in articular disc position in the right side joint. The position of articular disc showed improvement towards the normal. In four patients, the articular disc position was recaptured completely and partial recapture was achieved in the remaining patients.

The mean value was 1.936(mm) in the left side TMJ before treatment and 0.636(mm) after treatment. The difference between the two effectively gave the change in articular disc position in the left side joint. The position of articular disc showed improvement towards the normal. In five patients, the articular disc position was recaptured completely and partial recapture was achieved in the remaining patients.

Test of significance using paired t- Test showed a statistically significant difference (p=.000) in the articular disc position before and after treatment, with the mean difference of 1.4mm on the right side after treatment with the splint. (Table 1).

Test of significance using paired t- Test showed a statistically significant difference (p=.000) in the articular disc position before and after treatment, with the mean difference of 1.3mm on the left side after treatment with the splint. (Table 2).
Table 1: Test of significance using paired t-Test showed a statistically significant difference (p=.000) in the articular disc position before and after treatment in the Right joint.

Discussion

Temporomandibular joint internal derangement (TMJ-ID) is a disorder which is related to articular disc-condyle disharmony characterized by clinical signs and symptoms such as limitation of mouth opening, joint sounds, deviation and deflection during mouth opening and closing. It also has a significant effect on the growth and development and normal functions of the orofacial structures.\textsuperscript{13-16} Disc displacement with reduction occurs when the disc is placed anteriorly relative to the condyle and the condyle passes over the thick posterior band of the disc at the beginning of mouth opening. Painful clicking may occur at this time. Once maximum opening has occurred, the condyle can capture the disc, and a normal relationship occurs between the condyle and
the disc. However, in maximum intercuspation, the disc once again becomes situated anterior to the condyle.\textsuperscript{17}

It has been reported that clinical examination for the diagnosis of anterior disc displacement with reduction has an accuracy of 43–75%.\textsuperscript{18} This suggests that a clinical examination should be done together with other imaging methods in order to determine the relationship between the articular disc and condyle. Arthrography and Computed Tomography are 2 imaging methods generally employed for diagnosis of a TMJ-ID.\textsuperscript{19,20} In recent years, magnetic resonance imaging (MRI) has been used because it is an effective, noninvasive method that does not appear to cause any biological hazard.\textsuperscript{21-22}

Disc-repositioning appliance has been widely used and accepted in the treatment of disc displacement with reduction.\textsuperscript{23-24} Splints are thought to work by reducing the amount of parafunctional activity and limiting the extent of potentially harmful movements.\textsuperscript{25-26} Dawson\textsuperscript{27} and Okeson\textsuperscript{28} insisted that the condyles should be seated against the articular disc in their most supero-anterior position against the postero-superior slope of the articular eminence and centered transversely. Gnathological splint deprograms the muscles from the distracted position and moves the condyle to a more optimal and stable CR position. It is important to establish centric occlusion (CO) in CR position (CR = CO).\textsuperscript{29} Roth power centric bite was chosen to record the maxillo-mandibular relationship because it avoids tooth contact and allows the patient’s own mandibular elevator muscles to seat the condyles in a producible neuromuscular position which is CR.\textsuperscript{30-31}

The influence of disc-repositioning splints on the disc position has been studied by various authors. Our study was however designed to study the exclusive effect of the gnathological splint on articular disc position.

MRI was selected for use in this study because of its high specificity for identification of condyle disc relationships. Kurita et al\textsuperscript{32} indicated that the recapture of the disc by disc-repositioning splint therapy could be established clinically at a rate of 70%. However, they also suggested that clinical results should be supported with MRI because of the high rate of false-negative clinical results after application of a disc-repositioning splint, a point reiterated by Ikeda K et al.\textsuperscript{32} The reference points (CLP, RP, midpoint of articular disc) used for measurements in MRI were according to Smith et al\textsuperscript{33} and Nebbe et al\textsuperscript{33}. Condylar reactionary forces during maximum intercuspation were directed essentially perpendicular to the posterior slope of the articular eminence and that the CLP corresponded with the closest joint space perpendicular to the posterior slope of the articular eminence.\textsuperscript{12,34-36} Nebbe et al\textsuperscript{33} and Smith et al\textsuperscript{33} used CLP, glenoid fossa, Frankfurt horizontal plane, posterior slope of articular eminence, and midpoint of articular disc as reference points. They had used reference planes transferred from corresponding lateral cephalograms to assess disc length and displacement.\textsuperscript{12,33} Our study used glenoid fossa, CLP, articular eminence and midpoint of articular disc as landmarks for measurements with the landmarks modified slightly to avoid using multiple imaging techniques like cephalogram and CBCT and undue radiation exposure.

Improvement in articular disc position after 6 months of splint therapy was observed with a significant statistical difference in mm improvement in the articular disc position. The measurements clearly indicated that the articular disc had moved favourably towards the normal position. All the patients demonstrated significant improvement in disc position with four of them showing complete disc recapture and the rest partial recapture. In a similar study done by Hatice et al\textsuperscript{17} unilateral partial capture of articular disc (right TMJ) was observed on bilateral MRI scans in contrast to our study where bilateral disc capture was observed. Also, all their subjects exhibited partial recapture while the subjects in our study showed complete bilateral recapture in four and partial recapture in the rest. Gnathological splint was used full time even during function for a duration of six months in contrast to Hatice et al\textsuperscript{17} methodology where the duration of splint wear was 9 weeks and removal during meals. Another similar study done by Eiji Tanaka et al\textsuperscript{37} showed lack of disc recapture when splint was worn for 9 weeks only at night time.

**Conclusion**

Articular disc recapture was observed in all the 14 subjects exhibiting anterior disc displacement with reduction treated with gnathological splint therapy.

The amount of favourable articular disc changes, post splint therapy were almost similar on both the right and left side of the TMJ, with a mean difference of 1.4mm on right side and 1.3mm on left side.
Complete disc capture was observed in four subjects with partial capture in the remaining ones.

MRI supported the clinical results with great specificity.

A Literature Review of Temperomandibular Disorders in Orthodontics - A Goal Directed Approach

Saravanan1, Faisal Tajir2
1Professor, Sree Balaji Dental College and Hospital, Pallikaranai, Chennai, Tamil Nadu

Abstract

Temporomandibular Joint Disorder (TMD) is a collective term embracing several clinical problems that involve the masticatory musculature, the temporomandibular joint (TMJ). The concept of occlusion, condylar position, and its relationship to orthodontics has been a source of controversy over the years. Although goals of orthodontic treatment include alignment and stability of tooth positions, periodontal health, optimal facial and dental esthetics, and a functional occlusion, the interrelationship of these factors and condylar position is largely unknown.

Keywords: Temporomandibular Joint, Articular eminence, Condyle, Mandible.

Introduction

Temporomandibular Joint Disorder (TMD) is a collective term embracing several clinical problems that involve the masticatory musculature, the temporomandibular joint (TMJ). Gnathological treatment goals also include equal maximum intercuspation-centric relation (MI-CR) condylar position with the articular disc in place, a mutually protected occlusion (cuspid rise and anterior guidance with posterior disocclusion), centric stops to all centric cusps, and a Class I buccal segment relationship with a 3-mm overbite and a 3-mm overjet.

Centric Relation is defined as the “maxillomandibular relationship in which the condyles articulate with the thinnest avascular portion of their respective discs with the condyles in the anterior superior position against the slopes of the articular eminence. This position is independent of tooth contact.” Centric occlusion is defined as “the occlusion of opposing teeth when the mandible is in centric relation”. This may or may not coincide with the MI position.

The association between orthodontic treatment, abnormal condyle and disc position, and temporomandibular disorders (TMD) has been studied for many years.

Temporomandibular Joint Disorder (TMD) is a collective term embracing several clinical problems that involve the masticatory musculature, the temporomandibular joint (TMJ) and associated structures, or both.

The relationship between occlusion, occlusal factors and temporomandibular dysfunction remains a controversy. However it is believed that occlusal factors play a significant role predisposing to TMD. Therefore loss of vertical dimension, number of contacting teeth, orthodontic malocclusion (specifically, crossbite, anterior open bite, and deep bite), occlusal interferences, and deflective contacts are some of the important contributing factor in TMD.

Okeson reported that a premature contact can make the condyle to displace from the disk as the mandible pivots from this premature occlusal contact and moves into maximum intercuspation. This takes place due to neuromuscular adaptation eventually resulting in maximum intercuspation of teeth without taking into account the final condylar position. Thus the resulting condylar displacement may be considered a specific etiological factor predisposing to TMD signs, symptoms, and dysfunction.
Roth has also emphasized the relationship of TMD and occlusal interference and has advocated the importance of treating patients to centric relation.

The seated condyle position/centric relation is an anatomically determined position that is considered to be repeatable and reproducible. Okeson describes it as most orthopaedically and musculoskeletally stable position of mandible that is essential for optimal TMJ form and function. Therefore determination of CR is a preparation for analysing the condylar position and skeletal malrelationships. There is sufficient evidence to show that a difference exist between the MIC/CO, determined by full intercuspation of opposing teeth and where the condyles are in CR. This positional difference is known as condylar displacement.

Larger displacements were observed in all the dimensions for symptomatic patients, predominantly in vertical and sagittal plane. However Solberg found a higher prevalence of TMD signs and symptoms in subjects with a transverse occlusal slide.

The Need For Instrumentation

Condylar displacement must be isolated as a specific etiological factor in TMD. Various 3 dimensional methods have been used to assess the condylar position nevertheless. Dental instrumentation (an articulator mounting in the SCP/CR and condylar graph measurements) has proven to be valid, reproducible, accessible, cost-effective, non-invasive, and highly accurate. The articulators provide an added dimension that helps in gathering more information of the pre-treatment occlusion in static occlusion and also permits the visualization of various functional movements. It helps in measuring the quantum of centric relation-centric occlusion discrepancy and also to determine the first point contact in centric relation. Hand-held dental casts do not help in achieving orthopaedic stability in this regard. They can mislead the practitioner, since they do not relate to the temporomandibular joint position and also displays only the interarch relationship without considering joint positions.

CR-CO Discrepancy

It is generally agreed that a difference exists between the occlusion dictated condylar position (CO) and the orthopedic stable joint position (CR). According to Roth, the clinically acceptable difference between CR and MI in terms of condylar position as measured by Condylar Position Indicator (CPI) is approximately 1 mm anteroposteriorly, 1 mm vertically and 0.5 mm transversely. Discrepancies greater than these values may possibly contribute to the development of TMD.

Hoffman, Silverman, and Garfinke used a modified articulator to measure differences in condyle position between centric relation (CR) and centric occlusion (CO) in anteroposterior (A-P), superoinferior (S-I), and mediolateral (M-L) dimensions. They found that CR does not coincide with CO in the majority of cases.

Girardot found larger horizontal and vertical condylar displacements in dolichofacial (open-bite) skeletal patterns than in brachyfacial (deep bite) skeletal patterns. The vertical component of the condylar displacement was result of posterior premature occlusal contacts.

Thomas W. Utt used MPI to compare CR and CO in 107 patients to determine magnitude, frequency and direction of this difference. He concluded that range of displacement between superior-inferior or antero-posterior is at least 2 mm on both sides and transverse shift of 0.5 mm or greater. The direction of the condylar displacement found in more recent condylar position instrumentation studies by Wood and Elliott, Shildkraut’s and Wood, has been most commonly posterior-inferior, next-most commonly anterior-inferior, and least commonly straight inferior. These findings support the concept of vertical condylar displacement as a result of posterior premature occlusal contacts.

Cordray did a prospective study to statistically evaluate the 3-dimensional nature of dental interarch displacement and condylar displacement between the SCP/CR and maximum intercuspation or centric occlusion (MIC/CO). Measurements were done by condylar position instrumentation, and evaluated for frequency, direction, and magnitude of displacement. The most prevalent types of directional change in condylar position were inferior (down) (97.0%) and distal (posterior) (66.7%) when the teeth were brought into MIC/CO. The mean difference in condylar position between the SCP/CR and MIC/CO was 0.86 mm in the horizontal plane, 1.80 mm in the vertical plane, and 0.26 mm in the transverse plane.
Earlier studies have shown MI-CR vertical discrepancies measured by the MPI or CPI instrument to be between 0.7 to 0.8 mm, horizontal discrepancies to be approximately 0.6 to 0.7 mm, and transverse discrepancies to be approximately 0.27 to 0.3 mm. However Crawford \( ^1 \) defined a problematic clinical discrepancy as larger than 1.0 mm (horizontal and vertical) and 0.5 mm transverse and Utt et al \( ^4 \) defined 2.0 mm (horizontal and vertical) and 0.5 mm transverse as the outer boundaries.

**Methods of Evaluating CR:**

A variety of different clinical techniques are being used to obtain centric jaw relation record. The anterior jig developed by Lucia and the leaf gauge introduced by Long are interocclusal deprogramming appliances used prior to registering CR. They were designed to diminish proprioceptive activity, promote muscular relaxation, and as a result, facilitate jaw manipulation. These instruments are classified as short-term deprogrammers \( ^12 \).

Dawson \( ^12 \) used a method of bilateral manipulation wherein the mandible is guided superiorly while operator applies downward pressure with the thumb to seat the condyle in the most superior position. However excessive pressure could result in reflex contraction of the masticatory muscles thereby making this method technique sensitive.

In this regard, Roth's \( ^13,14 \) power centric bite registration has the benefit of both hand manipulation and an anterior stop to seat the condyle in the most superior position using patients own musculature.

**Splint Therapy for TMD:**

Splint therapy has proven to be the most effective technique for deprogramming the neuromusculature and alleviating the signs and symptoms of TMD. Studies \( ^17,18 \) have shown that a properly conducted splint therapy and/or neuromuscular deprogramming reveals previously undetected contacts as a result of masticatory muscle relaxation and subsequent mandibular repositioning. The most reliable deprogramming is achieved through full-time wear of a full-coverage upper stabilization splint constructed in the SCP/CR, especially in patients who present with signs and symptoms of TMJ dysfunction \( ^19,20 \). Stabilization splints are recommended for a period of 3 to 6 months in patients with TMD. It believed that splints normalize the neuromuscular pattern by deprogramming the muscle splinting, relaxing the musculature thereby eliminating the signs and symptom of TMD.

In 1987 Girardot \( ^15 \) stabilized 19 symptomatic subjects with full-time wear of a full-coverage upper stabilization splint until symptoms were relieved and tracked condylar position before and after splint therapy with CPI. It was concluded that decreasing the condylar displacement (seating the condyles with stabilization splint therapy) positively correlated with the relief of TMD.

Wahlund \( ^16 \) evaluated the effectiveness of a flat-plane occlusal stabilization splint, compared to a control splint consisting simply of palatal acrylic. The results showed that stabilization splints were highly effective for the treatment of TMD.

Occlusal splint therapy has been shown to be an effective treatment in the relief of symptoms associated with craniomandibular disorders. Kemper and Okeson also proved that it is an effective treatment modality for the relief of headache pain \( ^21,22 \).

**Clinical Implications:**

1. SCP/CR is a desirable treatment goal for reorganization of the occlusion. It is especially desirable in the following cases\(^5\):
   - When restoring posterior occlusal stability by occlusal adjustment or tooth restoration.
   - When treating mandibular dysfunction.
   - When restoring the dentition with multiunit restorations.
   - When treating patients with complete denture prosthetics.
   - When treating patients orthodontically.
   - When positioning the condyle during orthognathic surgery.

2. When occlusal correction is performed accurately, it is clear that the correction of both the occlusion and condylar position is remarkably stable.

Orthodontic cases should be compared to gnathologically restored cases, not to an untreated population.
Since an increase of condylar displacement (CPI value) from 1 to 2 mm was shown to aggravate symptoms of TMD dramatically, it may be in the patient’s best interest for the clinician to reduce or minimize the pretreatment condylar displacement as much as possible.

**Conclusion**

The role of occlusion in the development of TMD remains a controversy. However, this literature review reports that although TMD is multifactorial, occlusion and occlusal factors play a pivotal role as predisposing factors. Nevertheless splint therapy have been found to be beneficial in treating patients with TMD. Therefore, orthodontic treatment should aim at treating patients to an orthopedically stable joint position wherein the stable intercuspal position of teeth is in harmony with the musculo-skeletally stable position of the condyles in the fossa.

Composite Resin Twin Blocks for Correction of Angle’s Class II Malocclusion

Kannan Sabapathy¹, Mansi Giri²
¹Professor & Head of Department, ²Post Graduate Student, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research, Chennai, India

Abstract

Functional appliances and technique evolved during the 20th century from the early night time appliances to increased day time wear, and finally to full time wear with the Twin Block. Scientific evidence is now available from improved techniques to investigate growth modification in functional therapy, and the potential of functional forces to modify bone growth. A new paradigm for successful treatment presents a philosophical challenge to combine the benefits of orthodontic and orthopedic techniques and to extend our horizons in the treatment of malocclusion that requires dental and skeletal correction.

Twin Block appliances are simple bite blocks that are designed for full-time wear.

Keywords: Twin block, Malocclusion, Temporomandibular, Cephalometrics

Introduction

Skeletal class II malocclusions are commonly seen to be caused due to a retrognathic and/or retro-positioned lower jaw.¹ The Twin block appliance (TBA) was introduced by W.Clark in 1977. Due to increased compliance, efficacy and the advantages over other functional appliances became the appliance of choice in correcting such defects.² Despite this, the compliance rate with twin block appliance is still not as good as compared to Fixed functional appliances (FFA).³

Fixed Twin Blocks are pre-formed occlusal blocks with inclined planes, designed to fit over the occlusal surfaces of the upper and lower posterior teeth. Heat cured acrylic resins are the most popular material for fabrication of these twin blocks. They are cemented using Glass Ionomer cements. This article discusses the innovative use of Composite Resins used in Restorative Dentistry, for the fabrication of Fixed Twin blocks. The advantages and ease of fabrication of these composite twin blocks are discussed with a case report.

Case History

An 11 year old patient reported with chief complaint of an unpleasant profile and smile.

Photographs (Fig.1), radiographs and dental impressions were taken at his first visit. A VTO was taken which was followed by a consultation with a detailed explanation a week later.(Fig.1 & 2)

Clinical examination revealed a convex profile with deep mentalabial sulcus, incompetent lips, obtuse nasolabial angle and retruded chin. No gross facial asymmetry was observed. The patient was seen to have...
growth remaining according to the evaluation of cervical maturation staging of CVMI stage 4 which indicated the commencement of growth spurt within the years. Occlusion observation showed a Class II malocclusion (Right: Class II, Left: Class II) with deep overbite of 5mm and overjet of 8mm. The maxillary and mandibular dental midlines were coincident accompanied by the deviation of the maxillary midline from the facial midline.

Space analysis revealed tendency for mild crowding in lower dentition with a constriction of the maxillary arch indicating the need for expansion. Periodontal problems and temporomandibular joint disorders were not found. Cephalometric values showed a Class II skeletal pattern with orthognathic maxilla and retrognathic mandible according to WIT’s appraisal, ANB, SNA and SNB values respectively. The patient had an average mandibular plane and with clockwise rotation of the occlusal and palatal plane. The lower anterior facial height was seen to be decreased with decreased mandibular base and average mandibular height. The labiolingual inclination of the maxillary incisors were seen to be increased. From the above clinical and cephalometric findings the patient was diagnosed with Skeletal Class II pattern with Class II division 1 malocclusion.

Treatment Plan

The treatment plan was drawn up as follows:

1. Phase I - Functional appliance therapy – Two step advancement with Twin block appliance

2. Phase II - Fixed appliance therapy Phase I of treatment involved the use of functional appliance (Clark Twin Block appliance) to reduce the overjet, achieve class I molar relationships and gain anchorage at the start of treatment to simplify the fixed appliance stage. Furthermore, there is the theoretical advantage of improving the patient’s profile by causing a small skeletal change. The design of the upper component of the twin block involved an acrylic baseplate which covers the palate and occlusal surfaces of the first molars and second premolars. There was an inclined plane at the end of the mesial end of the acrylic block. A labial bow was used for anterior retention of the appliance. A midline screw was also included. The lower component consisted of a lingual acrylic baseplate covering the edge of the lower incisors. Both blocks had Adams clasps on the first molars to provide posterior retention.

Bite registration was performed with advancement of 6mm and bite opening of 4mm following the rule of 10. Removable twin block was fabricated with labial component and expansion screw in the maxillary segment and a conventional lower component with the inclined planes of 70 degrees. This appliance was delivered to the patient who demonstrated improved profile on insertion. The patient was instructed on the use and maintenance of the appliance. In the subsequent review appointments patient displayed tendency for non-compliant behaviour with absence of the pterygoid response and general pristine state of the appliance. The patient and parents was counselled on the benefits and need for compliance that could halt the progress of treatment. After 3 months the decision was taken to cement the bite blocks with glass ionomer cement to enhance compliance and effectiveness of the treatment protocol. The patient reported 10 days after cementation of the appliance with positive signs. But the patient displayed repeated cemention failure of the cemented bite blocks. Acrylic blocks. This cemental failure was noted to happen due to poor mechanical undersurface of the acrylic blocks to enhance cementation strength. Also Glass ionomer cement produces chemical bonding on the enamel surface of natural teeth, such bonding of GIC is not possible on the acrylic surface of twin blocks.

So a decision was made to replace the acrylic bite blocks with Silorane composite (Filtek Silorane®) bite blocks. These resins are popular in Restorative dentistry for restoring dental cavities and defects. The bite blocks were fabricated intraorally with a direct technique in increments after etching the enamel with 37% phosphoric acid. Silorane composite was built in increments to prepare the upper and lower bite blocks, bilaterally and in synchrony. The lower bite blocks was built and cured with the composite. Diamond abrasives were used to precise the shape and establish 70 degrees of inclination. Later the upper bite blocks were built on upper occlusal surface. Before curing the composite resins shaped as upper blocks, the lower occlusal surface and the lower inclined plane surface of the bite blocks was reflected to uncured composite by making the patient bite in advanced mandibular
etation with bite opening. Petroleum Jelly was used as separating media between cured lower block resin and uncured upper block resin. With this reflected shapes on uncured composite, Ultra violed light was exposed and the blocks were cured. Later the cured blocks were trimmed out for flash excess and polished with abrasive discs and rubber cups.

Patient was reviewed every month and the trimming of the bite blocks was commenced (fig.2) after 8 months of treatment. Sequentially after commencement of trimming of the blocks, the natural permanent occlusion developed from Class II to Class I relation.

After 12 months of functional appliance therapy phase II fixed appliance therapy for retention was commenced.

The labial brackets (0.022” slot MBT prescription) were directly bonded to the maxillary and mandibular dentition. Alignment and levelling of the maxillary and mandibular start were started simultaneously with 0.014” Niti progressing to 0.016” Niti, 0.016x0.022 “Niti, 0.017x0.025” Niti , 0.017x 0.025”SS, 0.019x0.025” Niti and finally to 0.019x0.025” SS wire over the duration of 18 months.

The patient presented with a straight profile with Angles Class I occlusion and competent lips was restored (fig.3). A symmetric, harmonious relationship of the facial soft tissue and a pleasant profile was obtained after treatment. The skeletal and molar relationship were corrected and lip competence was also achieved. Significant improvements in the vertical facial proportions and occlusal function were noted. Occlusal records revealed well interdigitated and aligned dentition with Class I occlusion on both sides and a normal overjet.

Lateral cephalometric films showed proper labiobuccal angulation of the upper and lower incisors and correction of skeletal Class II pattern was corrected to Class I. Cephalometric tracings revealed that almost every value had been brought into the normal range.

![Figure 1: PRETREATMENT PHOTOGRAPHS](image-url)
Discussion

Functional treatment of Class II malocclusion is best initiated during or slightly after the pubertal growth spurt. Considering the occlusal development, this period correlates in most patients with the late mixed or early permanent dentition. Here, in this case, the patient was in the late mixed dentition and, thus, at an ideal age to start with the treatment.

In this case, the treatment objectives were achieved largely due to the good compliance by the patient after placement of the fixed twin block. The patient’s chief complaint was an unpleasant profile due to a retrognathic mandible. The overjet reduction, in this case, was achieved by the favorable growth of mandible with the forward movement of lower incisors.

Thus by reducing the overjet with the functional appliance, the patient’s confidence improved.

The positive outcome at the end of treatment is due to the skeletal and dentoalveolar changes produced by the appliance. Post treatment the patient experienced an increase in the SNB angle by four degrees, from 74 degrees to 78 degrees (Table.1); this was most likely a result of increased mandibular growth. Ideally all functional appliances for Class II correction including twin-block are constructed from bite registrations. This is taken while the mandible is postured in a forward and downward position. The rationale for this clinical procedure is that favorable mandibular growth changes occur after mandibular displacement. The changes mainly involve the mandibular condyle, which shows additional growth in a superoposterior direction, with an increased bone apposition at the posterior aspects of
The advantages of twin block include simple and aesthetic appliance design, reduced chairside time and comfortable wear of the appliance. Major favorable effects induced by twin block therapy after the pubertal growth spurt compared to earlier phases are greater skeletal contribution to the correction of the molar relation, larger and clinically significant increments in total mandibular length. More posterior direction of condylar growth, a biological mechanism which enhances supplementary mandibular lengthening and reduces the amount of forward condylar displacement in favor of effective mandibular growth and reshaping.

The choice of the material for fabrication of the bite blocks was Silorane which is composed of Siloxanes and Oxirans; as this product class aims to have lower shrinkage, longer resistance to fading and less marginal discolouration. The silorane monomer ring differs obviously from the chain-monomers of hybrid composites. The hydrophobic properties of the material are caused by siloxanes. Exogenous discoloration and water absorption are reduced. The oxirane rings are responsible for the physical properties and the low shrinkage.

Siloranes are polymerized by a cationic reaction in contrast to methacrylates, which crosslink via radicals. A comprehensive study of Filtek Silorane® was carried out by Weinmann et al. (2005)[10]: It confirms the low shrinkage (< 1%) and found that the light stability of the silorane was seven times longer than for methacrylates. The siloranes low shrinkage leads to a lower contraction stress (Ernst et al. 2004[11], Bouillaguet et al. 2006[12]).

Ilie et al. 2007[13]). The silorane-based filling material was shown to have both low water absorption and water solubility (Palin et al. 2005[14]). Dentists both value and recognise the challenge of the relatively high viscosity.

Moreover Composite twinblocks demonstrate good bonding created over acide etched enamel surface primed by bonding agents. Such bond strength is impossible to achieve with cements and acrylic bite blocks. Loose bite blocks, delays functional therapy and produces inefficient results. Also loose bite blocks has a risk of aspiration or swallowing by the patient.

The feel of composite resin blocks and occlusal force transmission via these blocks, mimics so much as natural dentition, when compared to acrylic blocks.

Intra oral trimming of the blocks is very comfortable and precise with diamond burs supported with water coolant sprays, Trimming Acrylic with diamond burs is fussy as acrylic flakes on trimming.

Also there is no need for lab support in fabricating composite twin blocks as required for fabricating Acrylic Twin Blocks.

Thus, the placement of the fixed composite bite blocks aided in the compliance of the patient during the course of the treatment and ease of repair and trimming when required at the various stages of the treatment without derailing the treatment course usually caused due to breakage and loss of the appliance.

There was a marked comfort and efficiency in the overall treatment for the Orthodontist and the patient in the overall treatment stages with Twin Blocks built with composite blocks as compared to twin blocks fabricated with Acrylics.

A Novel Classification Method for Midpalatal Suture
Morphology In Indian Population- A CBCT Study

E.Thulasi Ram¹, M.S. Kannan²
¹Senior Lecturer, ²Professor and Head of Department, Sree Balaji Dental College and Hospital,
Pallikaranai, Chennai, Tamil Nadu

Abstract

The aim of this present study is to classify midpalatal suture morphology in Indian population by CBCT images. MATERIAL AND METHODS :CBCT scan for 40 subjects in the age group of 8 to 25 years were taken for the study. Cross sectional image analysis in axial plane using CBCT was performed and radiographic stages of midpalatal suture maturation were assessed for the above age group of 8-25 yrs, as described in the study by Angeleri et al (AJODO 2013) into stage A/B/C/D/E. RESULTS: Stage A and B typically were observed up to 13 years of age, whereas stage C was noted primarily from 11 to 14 years. Fusion of the palatine (stage D) and maxillary (stage E) regions of the midpalatal suture was completed after 14 years . CONCLUSION: This new non-invasive method of classification might provide reliable parameters for the clinical decision between conventional and surgically assisted RME for adolescent and young adult patients.

Key Words: Mid Palatal Suture, Palate, Sutural Ossification

Introduction

Expansion of maxillary arch was introduced by Angell in orthodontics over 150 years ago. Opening of mid palatal suture through slow or rapid expansion appliances was advocated by many authors for correction of transverse discrepancies like the posterior crossbites and for coordination of the maxillary and mandibular dental arches prior to orthopedic or functional treatment of Class II and Class III malocclusions ¹⁻⁷. The effectiveness of skeletal and dental movement depends on the rate of expansion, the age of the patient, the amount of force applied, and the appliance type.⁸⁻¹² However, details of the morphology and the maturation of the midpalatal suture have been investigated only in histologic studies, occlusal radiographs and an animal study with multislice computed tomography.¹³⁻¹⁶

There are conflicting views about the closure of midpalatal suture as a reliable indicator of skeletal maturation. Chronological age is no longer an indicator for a real morphological status of the midpalatal suture closure. According to Persson and Thilander earliest obliteration can be seen in the posterior palate of a 15-year-old girl and there may be no obliteration at all in a 27-year-old female. Earliest obliteration in male was found in 21 years and no obliteration at all in a 32-year-old male.¹⁷

Many research studies have promoted the use of the computed tomography for the diagnostic procedure like localization of impacted teeth, amount of root resorption, study of cleft palate, site planning for orthodontic implants, diagnosis of deformities of face and jaws, bone regeneration, evaluation of ossification of different craniofacial sutures, the position of the condyle in the glenoid fossa of the temporomandibular joint, etc.¹⁸⁻²³

Therefore we studied the midpalatal suture morphology in Indian population and classified them according to their maturational stages by CBCT images.

Material and Method

CBCT scan for 40 subjects in the age group of 8 to 25 years were taken for the study. Radiographic stages of midpalatal suture maturation were assessed for the above age group of 8-25 yrs, as described in the study by Angeleri et al (AJODO 2013)²⁴.CBCT equipment used in this study is Kodak 9500. The settings were 90 kVp; 10 mA; field of view 18x21cm; exposure time 15 seconds with a spatial resolution of 10 line pairs per
centimeter and an isotropic 0.2-mm voxel size was used. The institutional review board of Bharath University reviewed and approved the study. Informed consents were obtained from all patients or their parents or guardians.

CareStream3D Imaging software was used to assess the mid palatal suture maturation stage. Each subject was seated in an upright position with the Frankfort horizontal plane (superior aspect of the external auditory canal to infraorbital rim line) parallel to the ground during the scanning process. In the sagittal view, the patient’s head was adjusted so that the anteroposterior long axis of the palate was horizontal. Cross sectional image analysis in axial plane using CBCT were performed and following steps were executed for defining the maturational stages of the midpalatal suture.

Stage A, the midpalatal suture is almost a straight high-density sutural line with no or little interdigititation(Fig 1).

Stage B, the midpalatal suture assumes an irregular shape and appears as a scalloped high-density line.(Fig 2) Stage C, the midpalatal suture appears as 2 parallel, scalloped, high-density lines that are close to each other, separated by small low-density spaces in the maxillary and palatine bones (between the incisive foramen and the palatino-maxillary suture and posterior to the palatino-maxillary suture). The suture can appear either in a straight or an irregular pattern(Fig 3).

Stage D, the fusion of the midpalatal suture has occurred in the palatine bone, with maturation progressing from posterior to anterior. The suture still can be seen as 2 high density lines separated by small low-density spaces.(Fig 4)

Stage E, fusion of the midpalatal suture has occurred in the maxilla. The actual suture is not visible in at least a portion of the maxilla. The bone density is the same as in other regions of the palate.(Fig 5)

**Results**

The maturational stages of the midpalatal suture observed in the sample are shown in Table 1.

Stage A was noted in the early childhood period from 8 to almost 10 years of age. Stage B was present mainly up to 13 years of age in 6 of 10 subjects (4 boys, 2 girls). Stage C was observed mainly from 11 to 15 years of age (6 boys and 3 girls). However, one 11-year-old girl was in stage C. No subject from 5 to almost 11 years of age had fusion of the midpalatal suture.

From 11 to almost 14 years of age, 4 of 7 girls and 1 of 6 boys had fusion of the midpalatal suture in palatine bone. For subjects between 14 and 18 years of age, 1 of 3 girls and all the 4 boys had fusion of the midpalatal suture in palatine (stage D) bone. 5 of 6 girls and 3 of 4 boys in 18-25 group had fusion of maxillary bone (stage E).

**Discussion**

The midpalatal suture has been described as an end-to-end type of suture with characteristic changes in its morphology during growth. The sutures of the skull have been convincingly demonstrated to be sites of skeletal growth. Several well-documented studies have shown that the application of controlled mechanical forces during the skeletal growth period will affect the craniofacial growth through remodeling changes in sutural articulations. With advancing age, however, sutures are normally obliterated by calcified tissue.

Chronologic age is unreliable for determining the developmental status of the suture during growth, as evidenced by our study, in which subjects older than 11 years presented at all stages of midpalatal suture maturation. According to our study sutural ossification proceeds from posterior to anterior region and there is increased sutural activity with increase in age.

The progress in the ossification in the anterior part of the suture is irregular with advancement in the skeletal maturity as reported by Revelo and Fishman. Ossification also increased in the posterior part of the suture. Our finding was also in accordance with the Melsen who also reported that there is greater sutural activity during the period of pubertal growth spurt.

Persson and Thilander gave the explanation for this in their histological study on human autopsy specimens. They studied the extent of ossification in oronasal section of the intermaxillary suture in subjects with the age group of 15 to 35 years. They found the degree of obliteration was more posteriorly than anteriorly. They have also quoted Davida who reported that midpalatal suture in human skull starts to close posteriorly without exception. It showed greater degree of obliteration posteriorly than anteriorly. Ossification occurred very late anterior to incisive foramen. They have also speculated that the midpalatal sutures obliteration indexes indicate that there is a greater activity in the sutural closure of the palate between 20 and 25 years of age and when the fusion index is below 5% it could be expanded using conventional RME orthopedic forces.

Bacetti has reported that the effects of maxillary separation by means of the Haas expander appear to reach anatomical skeletal regions far from the midpalatal suture only when treatment is delivered before the peak in skeletal growth velocity. Wertz stated that with increased age the fulcrum of maxillary separation tends to be displaced more inferiorly, nearer to the activating force. In children, the fulcrum may be as high as the frontomaxillary suture whereas in adolescents the fulcrum is much lower. These differential, age-dependent effects may be attributed to the increased resistance to maxillary separation by the circummaxillary structures because of increased calcification in the sutural skeletal structures. Thus our study was conducted to assess the exact amount of ossification seen at each stage.

As reported by Angelieri, at stages A and B a conventional RME approach would have less resistant forces and probably more skeletal effects than at stage C, when there are many initial ossification areas along the midpalatal suture. Initial diagnosis of stage C might indicate that the timing of RME is critical because the start of fusion of the palatine portion of the suture could be imminent. Patients in stage D and E can be better treated by surgically assisted RME because fusion of the midpalatal suture already has occurred partially or totally, hampering the RME forces from opening the suture. Thus the exact amount of ossification and the site of ossification will help the orthodontists and the oral and maxillofacial surgeons to plan the exact the site for the midline cortical osteotomy.

**Conclusion**

The findings of this study could elucidate the diagnostic stage of sutural maturation, which also helps in assessing the surgically assisted RME that increases morbidity and treatment costs. This new non-invasive method of classification might provide
reliable parameters for the clinical decision between conventional and surgically assisted RME for adolescent and young adult patients.

Abstract

Objective: The aim of this study was to Evaluation of altered temporomandibular disc position in symptomatic TMD patients with pre and post gnathological splint therapy.

Materials and Method: This study included ten patients with a mean age of 21.5 years with maxillary transverse deficiency treated with the skeletal expander. The study consisted of 15 patients with a mean age of 25 years with clinically symptomatic and orthodontically untreated TMD patients with splint therapy. Statistical analysis was performed using paired t-test. Results: The mean AS, SS, and PS values for right TMJ that was 0.2mm (SD ±0.6mm), 0.5mm(SD± 0.3mm), 0.4mm(SD±0.1mm), respectively and the mean difference between AS, SS, and PS values for left TMJ was 0.2mm (SD±0.1mm), 0.5mm (SD ± 0.05mm), and 0.2mm (SD± 0.2mm). The ratio of AS to SS to PS was 0.2to 0.5to 0.4. No significant sex difference was noted in joint space distances. The results showed less variability of condylar position in the fossa than in normal subjects.

Conclusion: Gnathological splints can be used as effectiveness mean for treatment of such patients. This can be easy made good comfort to the patients.

Keywords: TMJ, splint, MRI, Joint space.

Introduction

The temporomandibular joint (TMJ) is a compound articulation of the articular surfaces of the temporal bone and the mandibular condyle¹. The TMJ functions uniquely in that the condyle both rotates within the fossa and translates anteriorly along the articular eminence. The condyle’s ability to translate the mandible can have a much higher maximal Incisal opening than would be possible with rotation alone. The joint is thus referred to as “Ginglymodiarthrodial.”² a combination of the terms Ginglymoid (rotation) and Arthroidal (translation). TMD is a prevalent disorder most commonly observed in individuals between the ages of 20 years to 40 years. Approximately 33% of the population has at least one TMD symptom and 3.6-7% of the population has TMD with sufficient severity to cause them to seek treatment³. The etiology of TMJ disorders remains unclear, but it is likely multifactorial. Capsule inflammation or damage and muscle pain or spasm may be caused by abnormal occlusion, parafunctional habits (e.g., bruxism , teeth clenching, lip biting), stress, anxiety, or abnormalities of the intra-articular disk. Treatment of TMJ disorders are varied. But dental occlusal splinting and permanent occlusal adjustment have been the mainstays of TMJ disorder treatment. Occlusal splint therapy may be defined as “the art and science of establishing neuromuscular harmony in the masticatory system by creating a mechanical disadvantage for parafunctional forces with
removable appliances. Conventional tomographic x-rays are commonly used to view the temporomandibular joint area. However, because of poor quality of images and variability in interpretation of anatomic areas, it failed to provide necessary information for diagnosing optimal condylar position. Magnetic resonance imaging (MRI) is a non-invasive, non-ionizing procedure that produces highly sensitive and specific tomographic images in any plane with excellent soft tissue contrast and reduced biologic hazards. Magnetic resonance imaging (MRI) has become the gold standard for examination of soft tissues of the TMJ. The purpose of the study was to evaluate joint spaces before and after splint therapy by MRI.

**Materials and Method**

The sample for the study was recruited from the patients who reported to the Department of Orthodontics at Sree Balaji Dental College and Hospital. Ethical approval was obtained from the Institutional Review Board and informed written consent was obtained from all the participants. The sample consists of fifteen patients within the age group of 22–30.

**Inclusion Criteria:** Clicking sound in TMJ area, Tenderness of muscles of mastication, Deviation of the lower jaw on opening, Unilateral or bilateral headaches, shoulder pain and/or neck pain, Generalised attrition/mobility of teeth.

**Exclusion Criteria:** Developmental anomalies, Degenerative disc conditions, Orthodontically treated patients.

**Splint fabrication:**

The study was initiated with Maxillary and mandibular impression which were taken using an irreversible hydrocolloid in sterilized metal rim-lock trays and poured with Type 4 Gypsum, facebow transfer, Roth’s power centric bite registration, centric occlusion bite registration, articulation, CO-CR discrepancy. After assessing the CO-CR discrepancy splint was fabricated and delivered. Face-bow transfer records were taken using the Axioquick Expansion Kit AX, (SAM Prazisionstechnik GmbH, Fussbergstr 1, Germany). It records the relationship of the maxilla to the cranial base.

Figure 1: Face bow transfer (a) frontal view (b) profile view

The wax bite recorded in patient’s initial CR, which should not be mistaken for terminal CR. It is difficult to capture one’s true CR at chair-side during initial visit. A true CR can be registered only after the stabilization of condylar position. Centric relation bite (Roth power centric) was taken with Delar bite registration wax in two sections, one in the anterior region and the other in the posterior region. The patient was seated in the dental chair reclined at an angle of 45° to the floor. To take the anterior section, the wax (2–3 layer thickness) was cut in a shape and appropriate size to register from canine to canine. The wax was then heated until soft in a water bath at 138°F. The wax bite was then placed in the patient’s mouth extending from canine to canine. The patient’s mandible was then manipulated (to CR) to make an interocclusal registration in the anterior section. The patient was then instructed to close until the posterior teeth were discluded approximately 3 mm in the area of the second molars. While in the closed position, an air syringe was used to begin the cooling process. The anterior record was then removed, and stored in chilled water. The posterior section was trimmed wide enough to include the last molar extended across the arch. The wax was then softened and placed on the maxillary posterior teeth. With the posterior section in place, the chilled anterior portion was placed back in position again. The patient was then guided in the same manner to close into the hardened anterior segment and asked to bite as firmly as possible and hold it. This allowed the patient’s musculature to aid in seating the condyle in CR position. Both the bites were then removed and stored in chilled water.

With the help of face-bow transfer record, the maxillary model is mounted to the articulator with the mounting plate and mounting plaster. Sufficient time is allowed for the plaster to set. The incisal guide pin is raised by 3 mm. To mount the lower model, the articulator is inverted, the centric wax bites are placed on the maxillary model, and the mandibular model is placed into the wax. A mounting plate is fastened to the lower
The splint was fabricated on an articulator. Upon closure of the arches, there were simultaneous centric stops with mandibular buccal cusp. Clearance of 0.005” was provided for the anterior teeth. Splint was fabricated with cold cure acrylic resin at a position with 3 mm clearance from the fulcrum. The splint was then allowed to set for sufficient time. With the splint still not removed from the articulator, initial trimming was done to establish centric stops and mutually protected functional occlusal pattern. The splint later was adjusted in the patient’s mouth to do further trimming to establish the same [Figure 2]. The patient was advised to wear the splint full time.

**Measurements:** The condylar joint spaces before and after 6 months of gnathological splint therapy was assessed by MRI.

Statistical Analysis

(If P-Value is <0.05 then statistically significant)

The Normality tests Kolmogorov-Smirnov and Shapiro-Wilks tests results reveal that the variables (Vertical and Horizontal distances) follow Normal distribution. Therefore to analyse the data parametric methods are applied. To compare the mean PAIRED SAMPLE t-test were used for each measurement to evaluate the average differences between the right and left side of the each sample. To analyse the data SPSS (IBM SPSS Statistics for Windows, Version 22.0, Armonk, NY: IBM Corp. Released 2013) is used. Significance level is fixed as 5% (p= 0.05)

Result

Table 1 and 2 shows the pre and post treatment outcomes of mean value of 15 patients in terms of change in the Anterior, Superior, Posterior joint space (AS, SS and PS) (Measured in mm) in the right and left side joint respectively.

Table 3 and 4 shows the mean difference between AS, SS, and PS values of pre and post-treatment for right TMJ that was 0.2mm (SD ±0.6mm; p-value 0.002), 0.5mm(SD± 0.3mm; p-value 0.001), 0.4mm(SD±0.1mm; p- value 0.005), respectively and the mean difference between AS, SS, and PS values of pre and post-treatment for left TMJ was 0.2mm (SD±0.1mm; p- value 0.001), 0.5mm (SD± 0.05mm; p- value 0.001), and 0.2mm (SD±0.2mm; p- value 0.004), respectively.

The result of this study hence showed that there was statistical significant difference in the all anterior, superior, and posterior space both in the right and left side joint pre and post treatment and the values of post treatment approached the mean values reported by Kazumi et al.

Discussion

Some TMD patients awake with TMD pain that only last m minutes to hours, suggesting that nocturnal factors are the primary contributors to these symptoms. In this third patient group, patients generally report that either their awaking or daytime symptoms are worse, suggesting that the nocturnal or diurnal factors are more significantly contributing to their symptoms. Therefore it’s best that the splint is worn 24 hours a day for best effective treatment and so full time wear of gnathological splint was advocated in this study. Roth power centric bite registrations anatomically seat the condyles in anterior superior position within the fossa.

It has been reported that clinical examination for the diagnosis of anterior disc displacement with reduction has an accuracy of 43–75%. This suggests that a clinical examination should be done together with other imaging methods in order to determine the relationship between the articular disc and condyle. In recent years, magnetic resonance imaging (MRI) has been used because it is an effective, noninvasive method that does not appear to cause any biological hazard.

The goal of our study was to check the condylar disc position, joint space in pre and post gnathological splint therapy for six months using MRI in patient with TMD problems. Subject were patients who had an anterior disc displacement with reduction before treatment. Our study was designed to identify the condylar disc position, joint space.

Kazumi et al (2009) in his study on optimal condylar position in the fossa on sagittal CBCT images in functionally optimal joints without displacement reported that mean AS,SS, & PS values are 1.3mm(SD±0.2mm),2.5mm(SD±0.5mm) and2.1mm(SD±0.3mm), respectively. The ratio of AS to SS to PS was 1.0 to 1.9 to 1.6. In our present short term study the patients are symptomatic of TMD and post treatment results were taken after six months. In my study using MRI, the post treatment values approximate the results provided by Kazumi et al.

All the symptomatic patients who were selected in this study exhibited resolution of symptoms such as pain located around the TMJ , pain that was referred to the neck , head and ear and pain that was located immediately in front of the tragus of the ear, projecting to the ear, cheek, and along the mandible. The restricted jaw motion was also resolved in all of the study patients but joint noise such as clicks and crepitus resolved only for a little more than 60% of the patients in the span of just four weeks of total six months.

Conclusion & Summary

TMD should be treated like any other musculoskeletal complaints. If TMD is left untreated, symptoms can be worsen and extend far beyond the jaw and the mouth area. Gnathological splints can be used as effectiveness
mean for treatment of such patients. This can be easy made good comfort to the patients.

Oral Manifestations in Association with Chronic Renal Failure Patients - A Clinical Study

E.Rajesh¹, K.M.K Masthan², Sudha Jimson¹, N.Aravindha babu³, N.Anitha¹, L.Malathi¹
¹Reader, ²Professor and Head of the Department, ³Professor, Department Of Oral Pathology and Microbiology, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education and Research, Chennai.

Abstract

Aims and objectives: The aim of this study is to analyze the oral manifestations in Chronic renal failure patients, to assess the incidence of oral manifestations among male and female patients and to rank the commonly occurring oral manifestations in such patients.

Materials and method: The study was conducted by selecting patients suffering from chronic renal failure. The study group consist of 100 chronic renal failure patients. Patients between the age group 13 – 75 years were taken into the study. Patients with other systemic conditions like diabetes mellitus and hypertension were included in the study. Childrens upto 13 years of age were excluded in the study.

Result: Out of 100 patients, 66 patients were males and 34 patients were females. 15% of patients presented with halitosis. 14% of patients with xerostomia. 13% of patients with periodontitis. 10% of patients with leukoplakia. 9% of patients with depapillation. 7% of patients with gingival enlargement. 6% of patients with bad taste. 5% of patients with candidiasis and 2% of patients with central papillary atrophy of tongue.

Conclusion: In the study, drug associated oral manifestations like xerostomia, bad taste, gingival hyperplasia were found and other conditions such as halitosis periodontitis, leukoplakia, depapillation, candidiasis, central papillary atrophy of tongue were also found which may be related to immunosuppression.

Key words: Chronic renal failure, leukoplakia, candidiasis, periodontitis.

Introduction

Chronic renal failure is permanent loss in renal function or kidney injury over a period of months or years and it has become a public health problem. It is defined as a progressive decline in renal function associated with a reduced glomerular filtration rate. The terminal stage of this disease has serious health outcomes which carry high economical and social costs, requiring dialysis and renal transplantation in order to improve the quality of life. The most common causes are diabetes mellitus, glomerulonephritis and chronic hypertension. In older individuals, the most common causes are renovascular disease and diabetes mellitus, although other causes include polycystic kidney disease and pyelonephritis. Most of the affected people are not aware of the disease at an early stage because they are asymptomatic. Some symptoms of the disease include feeling generally unwell, swelling of hands, legs or feet and blood in urine.

The incidence and prevalence of patients with chronic renal failure (CRF) is increasing worldwide. The prevalence range in India was found to be 0.86% with Chennai and 0.79% with delhi. In Bhopal among 572,029 patients the average incidence was found to be 151 and 232 per million population respectively. The reported incidence of CRF is 337, 90, 107 and 95 per million population (pmp) in USA, Australia, New
Zealand and UK respectively\(^5\). The prevalence has been growing by 6.8% annually during the past 5yrs. The incidence rate is increased from 33.3 patients per million people in 1993 to 167.8 pmp in 2005 in Brazil\(^6\).

The disease can give rise to wide spectrum of oral manifestations, affecting the hard and soft tissues of the mouth and individuals with such disease will probably continue to require oral health care\(^3\). This study was done to analyze the oral manifestations in CRF patients. To assess the incidence of oral manifestations among male and female patients and to rank the commonly occurring oral manifestations in such patients.

**Materials and method**

Our study consists of 100 CRF patients. Both males and females were included in the study. Patients between the age group 13-75years were included in the study. Patients with other systemic conditions like diabetes mellitus and hypertension were included in the study. Childrens upto 13years of age were excluded in the study.

Intra oral examination was done for those patients to diagnose the oral manifestations. Patients were examined clinically using a mouth mirror, william’s periodontal probe to check the periodontal pockets and further examination for mucosal changes was also carried out. The incidence of oral manifestations among male and female patients and the commonly occurring oral manifestations were observed in the study.

**Discussion**

The incidence of chronic renal failure (CRF) continues to rise worldwide and, as a consequence, increasing number of individuals with such disease will apparently require oral health care. Chronic renal failure and its treatment have systemic and oral manifestations\(^1\).

The prevalence of oral lesions in renal failure patients increase with accompanying systemic diseases. For example diabetic patients have more oral manifestations compared with non-diabetic patients. According to Proctor R et al\(^1\) a variety of oral lesions including potentially malignant oral lesions and oral cancer have been found to be associated with chronic renal failure patients. So a clinical study was designed to find the oral manifestations associated with chronic renal failure patients. In recent years, the pattern of oral manifestations has been changed, primarily as a consequence of drug therapy and immunosuppressant drugs. The incidence of CRF increases with age, males are more commonly affected than females\(^1\).

In our study of 100 CRF patients 66% were males and 34% were females with respect to age and the highest frequency was between 40 – 60 years of age which correlates with the study done by proctor et al\(^1\).

**Periodontitis**

Periodontitis is one of the common clinical manifestation seen in chronic renal failure patients (Figure 1). Patients under renal dialysis are at high risk for developing periodontal disease. It is recommended that patients under treatment for renal failure should be examined periodically by dentist for oral health. Factors such as systemic diseases and usage of drugs play a major role in the development of periodontal disease\(^7\).

Patients receiving hemodialysis have been suggested to present a certain degree of immunosupression. Based on the finding by Ismail Marakoglu et al\(^7\) chronic renal failure does not seem to be an additional risk factor for more severe periodontal destruction and this was consistent with our study where only 13% of patients had periodontitis. Klassen J T, Krasko B M et al\(^8\) evaluated 45 chronic renal failure patients and reported 100% of them presented with some type of periodontal disease which does not correlate with our study.

**Xerostomia**

Xerostomia or dry mouth is the abnormal reduction of saliva and can be a symptom of certain diseases. Possible cause include restricted fluid intake, side effects of drug therapy and mouth breathing\(^1\).

Mosannen mozafai et al\(^9\) suggested that xerostomia is a common finding with prevalence of 73.2% in renal failure patients. Another study by Madiha Sanai et al\(^10\) also suggested that xerostomia is the most common oral finding in chronic renal failure patients. This is not in agreement with the present study where only 14% of patients had xerostomia.

**Candidiasis**

As a result of long term immunosuppression therapy, patient’s immune response is reduced which makes them more susceptible to develop infections. Fungal infections have the highest degree of mortality rate
despite its lower incidence compared to bacterial and viral infections. There is an increased prevalence of oral candidiasis and the causative agent is candida albicans\(^\text{(11)}\).

Hemodialysis could affect the oral micro flora. They found isolation of candida was more significant in patients on hemodialysis in comparison to healthy individual which might be due to the immunodeficiency in these patients\(^\text{(12)}\). In the present study among 100 patients only 5% of cases have been reported with candidiasis (Figure 2) and it does not correlate with the study conducted by Estela De La Rosa Garcia et al\(^\text{(13)}\) in a group of 99 patients of which 17.2% of cases expressed candidiasis.

**Gingival enlargement**

Gingival enlargement is also a common clinical manifestation seen in chronic renal failure patients (Figure 3). It appears within 1-3 months after initiation of treatment with the associated medications. According to Proctor et al\(^\text{(1)}\) gingival overgrowth normally begins at the interdental papillae and is most frequently found in the anterior segment of the labial surface. Gingival enlargement secondary to drug therapy is the most reported oral manifestation of renal disease. It can be induced either by cyclosporine and/or calcium channel blockers. It principally affects the labial interdental papillae, although it can become extensive, involving the gingival margins, lingual and palatal surfaces\(^\text{(1)}\). The main cause of gingival enlargement is cyclosporine and calcium channel blocker such as niphedipine. Gingival enlargement was more severe in patients taking both drugs\(^\text{(9)}\).

Mahnaz Sahebjamee et al\(^\text{(14)}\) in their study found the prevalence of gingival enlargement to be 7% which is consistent with our study showed 7% of cases characterized by firm nodular gingival overgrowth seen on both buccal and palatal aspects, which could be associated with usage of drugs during the treatment.

**Bad taste**

Bad taste is one of the early symptoms seen in chronic renal failure patients, which may be a metallic taste or unpleasant odor in the mouth particularly in the morning. Approximately 30% of patients with advanced chronic renal disease were reported to have a bad or a metallic taste in their mouth, which has been associated with metabolic changes, diverse drugs, a reduced number of taste buds and change in both salivary flow rate and composition\(^\text{(15)}\) which was not in agreement with our study where in only 6% of patients complained of bad taste in the oral cavity.

**Halitosis**

Halitosis is common and can affect people of all ages. The prevalence of persistent oral malodor in a recent Brazilian study was reported to be 15% which match with our study showing the prevalence of same 15% in Indian population\(^\text{(16)}\). The prevalence of oral malodor was three times more common in males than in females and the risk was slightly three times higher in people above 20 years of age compared with those aged 20 years or below. In our study 12 patients were males and 3 patients were females, the association between the presence of halitosis with respect to gender is coherent with the study conducted by Nadanovsky P et al\(^\text{(17)}\). Tessier JF et al\(^\text{(18)}\) estimated that more than 50% of the population has halitosis which differed with our study.

**Depapillation**

In the present study 9% of patients diagnosed with Depapillation of tongue (Figure 4). Out of which 5 patients were males and 4 patients were females. The association between the manifestation of Depapillation with respect to age show increased prevalence between 50-60years of age.

**Leukoplakia**

Before the era of dialysis, Leukoplakia and oral candidiasis were not uncommon in patients with advanced renal failure. The increased rate of Leukoplakia in renal failure patients was a consequence of their immunosuppression or drug therapy. The third most commonly diagnosed lesion was Leukoplakia with a prevalence of 10%\(^\text{(19)}\). This finding corresponds to our present study showing 10% of cases with Leukoplakia in the oral cavity (Figure 5).

**Central papillary atrophy of tongue**

Klassen J T and Krasko B Met al\(^\text{(8)}\) found 1% of central papillary atrophy of tongue cases among chronic renal failure patients (Figure 6). In our study 2% patients had central papillary atrophy of tongue which proves to be significant with the above statement.
Results

Among the 100 chronic renal failure patients in our study 66 patients were males and 34 patients were females (Table 1 and Graph 1). Minimum age of 13 years and maximum age of 73 years were observed in the study. Among the patients 21% were between the age group 1-30 years, 18% were between 30-40 years, 24% were between 40-50 years, 25% were between 50-60 years and 12% were above 60 years (Graph 2). In the present study 15% of patients presented with halitosis. 14% of patients with xerostomia. 13% of patients with periodontitis. 10% of patients with leukoplakia. 9% of patients with depapillation. 7% of patients with gingival enlargement. 6% of patients with bad taste. 5% of patients with candidiasis and 2% of patients with central papillary atrophy of tongue (Table 2 & Graph 3).

Oral mucosal lesions seen during the study

Figure 1 – Periodontitis
The accomplishment of present study is to evaluate the oral manifestations associated with chronic renal failure patients. Drug associated oral manifestations like xerostomia, metallic taste, gingival enlargement were predicted in our study which highlights that those medications for renal failure are at high risk for these adverse effects. Other conditions such as halitosis, periodontitis, Leukoplakia, Depapillation, candidiasis, central papillary atrophy of tongue were also identified in our study which may be related to immunosuppression.

Further course of the study can be conducted by comparing the incidence of oral lesions between different categories of renal patients and with wider sample size which will give better conclusion to confirm that these
manifestations are solely due to renal failure and also aid in early institution of appropriate oral health care which could prevent the progression of these conditions which otherwise might culminate in loss of teeth and malignancies.

Review Article

Transposition of Teeth and its Management in Orthodontics

S Kishore Kumar¹, K.C.Subhiksha², T.Shoba³
¹Professor, ²Post graduate, Department of Orthodontics, ³Associate Professor & Head of the Department, Department of Pathology, Sree Balaji Dental College and Hospital, BIHER

Abstract

Transposition refers to an interchange in the position of two adjacent teeth within the same quadrant of the dental arch. It can be either complete transposition wherein all the structures of the teeth are parallel in the transposed position or incomplete where this complete transfer of structures are not seen. Various theories and factors have been proposed to determine the etiology of transposition but it is found to be most of genetic origin. Transposition compromises the esthetic and functional abilities of a dentition.

Keywords: transposition, ectopic eruption, genetics

Introduction

Transposition was first reported in the 19th century. It was Harris in the year 1849, who described it as an aberration in the position of tooth in the first edition of his “A dictionary of dental sciences biography bibliography an medical terminology”¹. Since then it has been an alteration whose term has undergone continuous changes.

Transposition was initially defined as the positional interchange of two teeth within the same quadrant. It was Peck et al who defined transposition completely as a dental anomaly characterized by the exchange of position between two adjacent teeth, especially in relation to their roots, or the development and eruption of a tooth in a position normally occupied by a nonadjacent tooth².

Tooth transposition is frequently seen in association with other dental conditions like hypodontia, microdontia, rotated and malpositioned adjacent teeth, retained deciduous teeth, ankylosis, teeth with dilaceration of roots³⁻⁵.

Ectopic eruption is a large category wherein the teeth present an abnormal eruptive pathway, of which transposition may be considered as the extreme type. The other types include pseudo transpositions or incomplete, partial, simple, or coronal transpositions⁶⁻⁸.

Since transpositions compromise the esthetic and functional abilities of a dentition, it is important to have adequate knowledge of it. This review article throws light on the literature, prevalence, etiology, clinical management of transposition of teeth.

Prevalence

The prevalence of transposition in various countries have been studied. A rate of 0.38% was reported in Turkey⁹, 0.13% in Saudi Arabia¹⁰, 0.43% in an Indian population¹¹ and 0.14% in Nigeria¹². These studies were conducted in samples of dental patients. Prevalence rates in European studies were 0.03% among Swedish school children¹³, 0.25% in a sample of Scottish orthodontic patients¹⁴ and 0.09% among Greek dental patients. A study of composite African sample dental casts and a skeletal sample of Nubians found a prevalence rate of 0.51%.¹⁵ The great diversity observed may be attributed to limitations inherent with epidemiological studies.

An interesting correlation of transposition with Down’s syndrome and cleft lip was also observed in studies. The incidence of transposition in patients with
down’s syndrome was observed to be 14.29% (16). A correlation of 4.1% with atypical forms of transposition was found with cleft lip patients (17).

Transposition is seen both in the maxillary and mandibular arches and commonly occurs in maxillary arch. It has been reported both in males and females with a higher prevalence in females (18). It occurs more commonly as a unilateral condition though it can occur bilaterally also. The left side is more commonly involved than the right side (19) with no specific etiology.

The teeth commonly involved in transposition include the the canines, first premolar, lateral and central incisors. Among these the transposition between canine and first premolar is the most commonly occurring anomaly and the canines at the position of the central incisor being the rarest (20).

Bilateral transpositions are extremely rare and very few cases have been reported. A case of bilateral transposition of maxillary canine with central incisors which were missing has been reported by Jahangiri et al (21). In concern with the mandible the mandibular canine and lateral incisor are most commonly transposed (22). Commonly transpositions not involving the canines are very rare (23).

**Etiology**

The exact etiology for transposition is not clear yet. Hence multiple factors have been associated with them. These factors include:

- Exchange of tooth germs: according to this factor exchange of tooth buds or the dental lamina cells in the initial stages of development of teeth may cause transposition (24, 25).

- Pathology: pathologies like tumour and cyst were also associated as etiological factors for transposition (26).

- Retained deciduous canine: since transposition was most commonly accompanied with retained deciduous teeth, some authors suggested it as the main etiological factor for transposition (27, 28).

- Early loss of primary teeth, or even of permanent teeth: In a dental crypt if the primary teeth undergoes resorption late, the permanent successor does not acquire a proper position (29).

- Migration of the ectopic tooth: Since the maxillary canine is the most commonly transpositioned teeth the eruptive path of maxillary canine is discussed. The permanent canine starts developing at the age of 4-5 months, its crown is completed at 6-7 years of age, it erupts at the age of 11-12 years and its root formation is complete by the age of 13-15 years. In the maxilla, at 4.5 years of age, the permanent canine lies above the first premolar, which in turn, is above the primary first molar. The eruption path is often guided by root orientation, but it may change as the erupting tooth approaches another tooth. Space conditions in the jaws, mechanical obstacles and varying rates of development may affect and modify the direction of the erupting tooth. Slow eruption, in combination with the anatomical position of the canine crypt within the jaw, may contribute to the development of canine transposition (26-30).

In addition trauma to the primary teeth, intra osseous or bony migration of canines are also suggested as an etiology (31) however the present data associates this anomaly to genetic influences with multifactorial inheritance model.

- Heredity. The DNA associated with the dental development are also responsible for proper positioning of the teeth in the dental arch. The sequence of teeth to be positioned are also genetically determined and hence any change in the sequence that is transposition was also genetically correlated. Consequently, genetic regions causing transposition must exist as a result of aberrant gene function at this region. factors substantiating this theory include the variation of transposition in various races, the high correlation of transposition with other dental anomalies like peg laterals, congenitally missing teeth, bilateral occurrence, involvement of same tooth on both halves and numerous cases within the same family tree eruption path often guided by root orientation, but it may change as the erupting tooth approaches another tooth (32, 33).

Further, space conditions in the jaws, mechanical obstacles and varying rates of development may affect and modify the direction of the erupting tooth.

**Clinical Management:**

The mesiobuccal displacement of canine between the first and second premolar can be seen when there is transposition of canine and first premolar. Yh distal
tipping of the first premolar is frequently and seen displaced in a mesiopalatal direction. Moreover, the deciduous canine is often present, yielding a temporary space restriction.\(^{(36-38)}\)

Early diagnosis of a developing transposition is extremely important and has a great influence on prognosis. Conventional panoramic radiograph can be used if diagnosed early and interceptive procedures like removal of deciduous teeth and providing eruption guidance for the permanent teeth to erupt in its proper position., thus preventing complete development of the anomaly. On the other hand, when transposition is detected at a later stage, orthodontic planning must address the indications for and against extraction and the sequence of correcting tooth positioning\(^{(36-39)}\).

When transposition is more severe and affects the crown and root, the attempt to reposition affected teeth in the dental arch is complicated and may cause damage to the supporting tissues. Thus, alignment of these teeth in their transposed positions is usually required\(^{(36-39)}\).

The decision to extract a permanent tooth, usually the premolar, is more attractive when teeth affected by transposition present carries or poor periodontal support or when there is a severe tooth-size discrepancy. When the practitioner decides to reposition the transposed teeth, care should be taken during mechanical management to avoid occlusal interference and root resorption, as well as bone loss, especially of the buccal bone plate.\(^{(36-39)}\)

Thus, the palatally displaced premolar should be initially moved to allow free movement of canine on the buccal aspect to its normal position. After repositioning of the canine, the premolar may be corrected. The disadvantage of this approach is the time required for correction, which will be compensated by the esthetic and functional outcome.\(^{(36-39)}\)

The clinical management can be summarized as

Interceptive treatment, if the transposition is detected earlier in life within 6–8 yrs\(^{(36)}\), the transposed tooth can be guided to the normal location by extracting the deciduous teeth. The space obtained can be managed with space maintainers.

Orthodontic movement can be used to bring the transposed tooth to its original position and to correct the intra arch symmetry\(^{(36)}\).

Another method is to maintain the transposed teeth in its position and reshaping the occlusal and incisal edges for restorative camouflage\(^{(36)}\).

Extraction of either one or both the teeth involved followed by orthodontic alignment\(^{(36)}\).

**Conclusion**

The prevalence and etiology of transposition were discussed along with the literature review. It was observed that the maxillary canine was the most commonly transposed teeth with the maxillary first premolar. A strong genetic predisposition was attributed to be the main etiology of transposition. Also various clinical management of transposition of teeth were described. Interceptive orthodontics to transposition can be the best way to manage it but if the early diagnosis is missed it can be managed through conventional orthodontic treatment.

Role of Thermography in Diagnosis of Patients with Temporomandibular Disorder

S.Kishore Kumar¹, E.Thulasiram², Prasanth Sreenivasan³
¹Professor, ²Senior Lecturer, ³Postgraduate, Department of Orthodontics, Sree Balaji Dental College and Hospital, BIHER.

Abstract

A temporomandibular disorder (TMD) is a very common problem affecting up to 33% of individuals within their lifetime. TMD is often viewed as a repetitive motion disorder of the masticatory structures and has many similarities to musculoskeletal disorders of other parts of the body. Treatment often involves similar principles as other regions as well.

Keywords: Temporomandibular disorder, Thermography, Myalgia, Myofascial

Introduction

Temporomandibular disorders (TMD) depend on a comprehensive history and physical examination, supplemented, when indicated, by images of hard and soft tissues. However, there are electronic diagnostic devices being marketed to acquire other measures described as relevant to TMD and to use these for diagnosis of TMD and for monitoring the effects of treatment. Changes in body temperature have long been regarded as an important diagnostic factor. Recently, rapid development in infrared radiation technology and its conversion to a visible image have given rise to a technique called thermography [1].

The undeniable advantages of thermography, such as its non-invasive evaluation approach, the absence of ionizing radiation, and the relatively low costs involved, are sufficient to recommend its inclusion among the additional tests widely employed to diagnose temporomandibular dysfunction (TMD) [2]. The validity of using thermography for dental diagnostic purposes, especially in the diagnosis of temporomandibular dysfunctions of the masticatory motor system, is still under review [3-7]. Some previous studies confirmed the diagnostic efficiency of thermography in identifying subjects with TMD [8-10]. Infrared thermography is a tool that can be applied to individuals with myogenous TMD due to the changes in the microcirculatory dynamics (i.e., there is a decrease in the skin temperature due to compression of blood vessels conditioned by muscle hyperactivity) [11,12], whereas skin temperature over the TMJ is increased in individuals with joint pain [13]. Moreover, individuals with TMD exhibit greater asymmetry in skin temperature than do those without this condition [14].

Thermography has many advantages – it is easy to use and non-invasive. However, there is a lack of standardized protocol for the temperature measurement of the masticatory muscles using infrared thermography. Gratt et al. [8] and Gratt and Sickles [14] evaluated the orofacial region by establishing 5 measurement areas: small TMJ, large TMJ, mandible, midface, and entire half-face. In another study by DibaiFilho et al. [15], the measurement of skin surface temperature was done in the muscle central point.

Materials and Method

Study Design: Case control Study

Study area: OPD, SreeBalaji Dental college and Hospital

Duration of the study: 3 months

Study Population:

Cases: cases with skeletal class – I & Angle class I malocclusion with Temporo Mandibular disorder
**Controls:** with skeletal class – I& Angle class I malocclusion without Temporo mandibular disorder

**Operational Definition of cases:**

Temporomandibular disorder (TMD) is a problem affecting the ‘chewing’ muscles and the joints between the lower jaw and the base of the skull.

**Selection Criteria:**

**Inclusion criteria:** Cases those who were coming to OPD with the symptoms of arthralgia, myalgia, local myalgia, myofascial pain, myofascial pain with referral and headache attributed to TMD

- 18 to 30 years
- Both sex were included
- Skeletal class – I
- Angle class I malocclusion

**Exclusion Criteria**

- Those who gave consent were only included
- Any chronic disorder like cancer was excluded
- HIV/AIDS cases was also excluded
- Patients undergone fixed prosthesis

**Sampling Method:**

Convenient Sampling

**Sample Size:** Those who were coming with the TMD for out patient department for a period of 3 months was enrolled

- 25 Case
- 25 Control

**Measurement:**

Temperature measurement

**Enrollment of Cases**

This diagnostic study was approved by ethical committee of SreeBalaji Dental College & Hospital, Chennai. Informed consent was signed from the patients or parents of the subjects. Patients with TMD’s who fall under the inclusion criteria were recruited for the study. Impressions & Photographic images (fig 1) were taken for all the subjects by a trained specialist in the TMD. Thermal images have been taken for all the subjects fig(2,3) involved using DITI-SCT640 Digital Infrared Thermal Camera. Patients who meet the inclusion criteria were assigned to two groups based on convenient sampling, group A (cases) and group B (Control).

**Statistical Analysis**

Statistical analysis was performed by using SPSS
software for windows (version 17) & probability value (p value) will be set as 0.05

Descriptive statistics was used to find out mean, standard deviation for demographic & outcome variable.

Paired t-test was used to find out homogeneity for baseline & demographic within the group.

Unpaired t-test was used to find out homogeneity for baseline & demographic variable between the group.

ANOVA was used to find out the significant difference between and within the groups variations

Results

In this study, a total of 25 cases (TMD) and 25 controls (without TMD) were enrolled. Of which Male was less in number than female. While comparing gender among cases there was no statistically significant association (kappa value-0.887).

Among the total recruited cases and controls, Average age group was 23 years, minimum age group was 18 years and the maximum age group was 29 years

Temperature Vs Right and Left TMD with control

Temperature with right and left and with and without TMD was compared and found that there was a highly statistically significant association as p-value 0.000.

While comparing right TMD temperature level with control group there was statistically significant difference observed as 0.000.

Table:1 Temperature in TMD

Discussion

According to the study, there was significant association between temporo mandibular disorder and temperature recording using thermography. This is in concordance with the study done by Alvir Vieira Di Bai -Filho et al who observed similar findings and established that there was greater increase in skin temperature over the right and left TMJ in cases with TMD than with control.

In the present study there was temperature difference voted between the right and the left side. Right side TMJ exhibited higher thermographic temperature recording.

This is in concordance with the study conducted by Krzysztof Wozniak et al who observed similar findings and exhibited that absolute difference in temperature between right and left TMJ has high diagnostic value.

In the present study there was temperature difference noted between the right & the left TMJ and right side TMJ exhibited higher thermography temperature recording. This is in concordance with study conducted by Krzysztof Wozniak et al who observed similar findings & exhibited through their study that the absolute difference in temperature between the right and the left TMJ has high diagnostic value.

Conclusion

According to the finding of this study

There was no association for temporomandibular disorder with gender

There was no association for temporomandibular disorder with age

There is a strong statistically significant association within and between group of right and left temporomandibular disorder with respect to temperature levels
There was a strong statistical association between cases and control with respect to temperature level.

From the above summary, since a temperature difference was noted between the right and left temporomandibular joint and a significant difference was noted between the cases and controls, we concluded that temperature change can be taken as a diagnostic criteria in Temporo Mandibular Disorder cases.

Hemangioma of Tongue – A Case Report

Hemalatha V.T¹, Guru Aribam Victoria Devi²

¹Reader, phD Research Scholar, ²Postgraduate, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Pallikaranai, Tamil Nadu, Chennai

Abstract

Vascular anomalies of the oral cavity are very rare. Hemangioma is the most common vascular anamoly. Here, we report a case of hemangioma in the Anterior two third of the tongue in a 37 year old male which appeared localized well defined, reddish pink and lobulated mass with well-defined margins on intra-oral examination. Doppler suggesting a vascular etiology. Further evaluation was done on magnetic resonance imaging, which confirms its vascular nature and diagnosed as a case of hemangioma.

Keywords: Doppler, hemangioma, tongue, ultrasonography, vascularity

Introduction

Hemangiomas are benign proliferation of dilated blood vessels & capillaries.¹,²

It is a proliferation of the endothelial cells which lines vascular channels. It is a benign developmental abnormality, characterized by onset during infancy and regresses as the patient ages. ³The term hemangioma was first coined by Sznejder et al in 1973 & was called “Haemorraghic Hemangioma”.² They are considered as benign tumors, being characterized by 3 stages: endothelial cell proliferation, rapid growth and lastly spontaneous involution. ⁴⁵ It can cause esthetic and functional impairment in the oral and perioral region depending on the location. The most common site is the lips, but other areas, such as the tongue, buccal mucosa and palate have also been reported. Clinically, they present as swellings filled with blood or as red or bluish-purple discolorations that, depending on the depth of the lesion and the localization of the affected tissue, disappear momentarily on digital compression or diascopy.⁶

Here we present a case of a 37 year old male patient who presented with a swelling in the tongue for the past 1 year which was diagnosed as hemangioma of tongue after clinical and radiographic analysis.

Case Report

A 37 year old male patient came with a chief complaint of painless swelling in the tongue for the past 1 year. There was no association of pain in the region. Patient had no difficulty in swallowing and breathing. No history of bleeding from the region of swelling. On examination of intraoral swelling, a solitary swelling was present on right dorsal surface of the anterior 2/3 of the tongue more towards the lateral border measuring approximately 2X1cm in size, dome shaped, with well-defined margins. The surface was smooth with normal papillation and it was slightly bluish in colour. On palpation, the swelling was soft, immobile, compressible, with pulsation. (figure 1,2)

Correlating the chief complaint, history of presenting illness and intra-oral examination a provisional diagnosis of benign tumour of the tongue was arrived and a differential diagnosis of fibroma of tongue, myoma of tongue and hemangioma of tongue was given.

Ultrasonography revealed a well-defined heterogenous hypoechoic lesion in the submucous plane of the tongue in the posterior right lateral border with evidence of tiny cystic components. The lesion showed high vascularity and multiple feeding vessels. (figure 3) Magnetic resonance imaging (Wide Bore 48 Channel 1.5 T High Field MRI-neck with contrast) revealed 16X15X18 mm size developmental venous malformation (hemangioma) in the right side of the anterior 2/3rd of tongue, involving the intrinsic muscles. The lesion involving on the genioglossus and hyoglossus. 42mm (AP) X 24 mm (CC) X 17mm (TRANS) size venous malformation in the floor of the mouth in the right side between anterior belly of digastric & mylohyoid and...
extending to the sublingual space along the anterior aspect of mylohyoid. Few hemangiomas noted in the tongue, right masseter, anterior to the right ramus of mandible and right side of the soft palate. On contrast administration, the lesion shows heterogenous enhancement. (figure 4,5,6) Depending on the clinical features, a diagnosis of hemangioma of the tongue was given. No surgical intervention was given as the patient had no discomfort.

Figure 1 swelling was present on right dorsal surface of the anterior 2/3 of the tongue

Figure 3 Ultrasonography showing hypoechoic lesion in the submucous plane of the tongue with high vascularity and multiple feeding vessels.

Figure 4 Sagittal view MRI showing developmental venous malformation anterior 2/3rd of tongue involving the intrinsic muscles

Figure 5 Coronal view MRI showing developmental venous malformation in ramus of mandible.

Figure 6 Axial view MRI showing developmental venous malformation in the soft palate.

Discussion

There is a complex, rich and intricate blood vessels in the oral cavity, head and neck region which makes it susceptible to a variety of vascular lesions. They may or may not be present at birth but become clinically appreciable in late infancy. Endocrinal changes, infection and trauma also affect their size and growth. The common vascular lesion affecting head and neck region is hemangiomas which are usually seen 2-4 weeks after birth, then grow rapidly till the age of 6-8 months and
further at slow rate. There is also a female predilection with a ratio of 3:1. However, the present case was observed in a 37 year old male. Around 70-80% of hemangiomas occur as a single lesion, while multiple lesions are found in 20% of affected patients with rare tongue involvement. Oral hemangiomas are most common in the regions of the lips, tongue and buccal mucosa, presenting as red, purple or violet macules or nodules of variable size, which may be well-delineated or diffuse and are relatively depressible. Hemangiomas are rarely encountered by clinicians even though they are considered one of the most common soft tissue tumors of the head and neck and it is rare in the oral cavity. Where large lesions may impinge on vital anatomical structures, such as the facial nerve or orbit, radiographic analysis is indicated. Computed tomography (CT) and magnetic resonance imaging (MRI) are also be used for volumetric analysis of hemangiomas and vascular malformations. In both diagnostic differentiation and analysis of lesion features with regard to its size, extension and location, and for follow up of lesions imaging plays a vital role.

There are several suggested pathogenesis for hemangioma. Some authors have hypothesized that angiogenesis plays a vital role in vascularexcess present. Cytokines like basic fibroblast growth factor (bFGF) & vascular endothelial growth factor (VEGF) are reported to induce the process of angiogenesis. It has been suggested that there is an imbalance in the factors that stimulates angiogenesis & the factors which control angiogenesis. The growth factors which are precisely involved in angiogenesis during the proliferation phases of haemangioma are VEGF, b-TGF, and IGF.

Treatment of hemangiomas is dependent on their location, size and nature i.e whether it is venous or arterial. For lesions which are small those which are situated in the periphery, treatment options include sclerotherapy, laser therapy, radiotherapy, conventional surgical excision, laser treatment, electrocoagulation and cryotherapy. When the lesions are large and/or intraosseous, and located in areas with esthetic impact, embolization or obliteration of the lesion and adjacent vessels should always be done. this procedure is stipulated with the intent of attaining involution of the lesion for a successive surgical procedure.

Sodium morrhuate, sodium sulphate tetradecyl, polidocanol and ethanolamine oleate, and hypertonic glucose solution are some of the sclerosing agents available and which can provide first rate results. In our case there was no surgical intervention or any kind of treatment was done as the patient had no difficulty or discomfort associated. The patient was followed up for every 6 months with no changes up till date.

**Conclusion**

Intraoral hemangioma rarely occurs on the tongue. Early detection and correct diagnosis are important steps in managing hemangiomas of the tongue. Depending on the location of the hemangioma they can cause functional and esthetic impairment. Proper clinical, radiographic and sometimes histologic analysis has to be done to come at a correct diagnosis keeping in mind the differential diagnosis & the advanced technology in diagnosis of the lesions.

Therefore, imaging modalities like ultrasound with Doppler, CT and MRI are of utmost importance. In our present case also it was arrived to a case of hemangioma of tongue after MRI and ultrasonography. A thorough knowledge about these lesions is mandatory for clinicians to avoid risk during the treatments like the flap surgery, extraction of teeth etc as they can result in profuse bleeding creating an emergency situation.

Obstructive Sleep Apnea Syndrome in Orthodontics (OSA)-
Review of the Literature

S.Kishore Kumar¹, R.Mohan Pradeep², T.shoba³
¹Professor, ²Post graduate, ³Associate Professor and Head of the Department, Department of Orthodontics,
Sree Balaji Dental College and Hospital, BIHER.

Abstract

Obstructive sleep apnea is one of the most common breathing disorder during sleep. Long term OSA may lead to depression, cardiovascular diseases, metabolic disorder, cognitive impairment. Inferior hyoid bone position in relation to line drawn from third cervical vertebra to menton is one of the important finding related to OSA pathophysiology. Orthodontist can make an important contribution to diagnosis and management of OSA.

Key words: Obstructive sleep apnea, Airway obstruction, Cephalometrics, Hyoid bone.

Introduction

Obstructive sleep apnea is characterized by collection of signs and symptoms such as arterial blood oxygen desaturation, fragmentation of sleep caused by obstruction of pharyngeal airway during sleep, reduction in intra thoracic pressure, withered executive function, central nervous system arousal and excessive daytime sleepiness. The prevalence of OSA in adults is between 14.7% to 34.2%, of which 82% women and 93% men remains undiagnosed. Cephalometrics play a major role in identifying OSA with sensitivity of 93% and specificity of 21%. Lower hyoid bone position is due to accumulation of fat in pharyngeal regions which pushes hyoid bone more anterior and inferior.

TYPES:

1. Obstructive apnea
2. Central apnea
3. Complex Mixed apnea

SUBTYPES OF OSA:

1. Severe AHI > 30
2. Moderate AHI is 15 to 30
3. Mild apnea AHI < 15

Epidemiology

OSAS is the second most common disease in order among the different respiratory disorders.

OSA affects 2-4% of the adult population. One out of every 5 adults suffers moderate OSAS, and one out of every 15 presents moderate to severe OSAS.

The syndrome is characterized by decreased oxygen levels in blood, tense breathing, and repeated arousals during sleep, excessive sleepiness during the daytime, headaches during wakingup, lack of concentration and systemic disorders.

Pathogenesis

Several factors are involved in the development of OSAS. The main causes for OSAS are reduction in expansion forces of the pharyngeal dilator muscles, as in situations of genioglossal muscle dysfunction, and lack of coordination between the inspiratory activity of the muscle and respiratory efforts, which play an important role in progression of the disease.
Other factors are increase in size or length of the soft palate, unessential pharyngeal mucosa, macroglossia, and tonsillar hypertrophy \(^{(6)}\).

Pae et al. found that the shape of tongue in patients with OSAS is different from that of normal subjects in the supine position, this being the first study to evaluate tongue shape in the supine position. Therefore, shape of tongue may play an important role in the development of OSAS \(^{(7)}\).

Increased adipose tissue in the neck region particularly in obese patients with fat infiltration and edema in the soft palate \(^{(9)}\) or altered anatomy of upper airway, as in Pierre Robin syndrome \(^{(8)}\), are also incriminated in this syndrome.

The perimeter of neck is more closely correlated to severity of the syndrome than body mass index or obesity \(^{(9)}\).

**Features of OSAS**

OSAS has distinct signs and symptoms during daytime and night time.

- **Nocturnal symptoms**

  **Snoring**

  Snoring is due to the narrowing of the upper airway and intermittent airway collapse during sleep. Generally it is observed and reported by the spouse of the patient, to the doctor. Even though snoring is the most common symptom of OSAS, it is of very little diagnostic value as snoring is also very common among the general adult population. Suspected OSA patients, apart from having a history of snoring for a long time, they are reported to have more intense and irregular snoring overtime \(^{(10)}\). This can be due to various reasons such as increased body weight, alcoholism, use of muscle relaxants or even menopause in women.

  **Observed apneas**

  Apneas are alarms to the patient and calls for an immediate consultation. They are mostly described as respiratory pauses, interrupting the snoring while the patient continuously makes efforts to breathe. observed apnea indicates high apnea/hypopnea index \(^{(5,6)}\).

  **Daytime symptoms**

  **Daytime sleepiness**

  Fragmentation of sleep in the night due to electroencephalographic awakening that terminates the apneas or hypopneas leads to Excessive daytime sleepiness, which is the most important symptom of OSAS. Various other consequence of daytime sleepiness are apathy, concentration difficulties, Depression, memory loss, morning headaches and decreased libido.

**Diagnosis**

A proper medical history, familial history and personal history (adenoidectomy, tonsillectomy, alcoholism, use of muscle relaxant drug, obesity etc.) is very essential for the proper diagnosis of OSA. Sometimes in certain profession, OSA can lead to medical emergency, so the profession of the patient is also to be noted.

Physical examination such as height, weight, BMI, CVS evaluation, exploration of upper airway is also done. It is followed by conventional lateral cephalogram which will reveal any anomaly in patients anatomy that can predispose them to OSA \(^{(11)}\).

A line drawn from third cervical vertebra to menton on lateral cephalogram serves as a guideline to diagnose OSA. In simple snorers, the hyoid bone was present in the line whereas in OSA patients the hyoid bone was present far below the line.

OSA can also be diagnosed with many tests. The most commonly used test is Polysomnography (PSG). It helps to monitor a lot of things like – respiration, sleeping state, snoring and even movements of legs. It can also record the stages of sleep, its distribution, the number of awakening, the number of apneas/hypopneas. The starting time of sleep and also the number of efficient hours of sleep is also recorded. PSG also gives the apnea/hypopnea index (AHI), according to which if AHI > 30, it is very serious apnea and need surgical intervention. If AHI is 15 to 30, it is moderate apnea and AHI < 15 it is mild apnea. PSG is expensive test and complex technique. Nowadays simple tests are developed and used in many healthcare systems which are less expensive and can be used atpatient’s home \(^{(8)}\).

Sleep fragmentation and high frequency of Respiratory effort – related auorsal (RERA) events is associated with myofacial pain in TMD.
Lavezzi et al proposed class III malocclusion children having OSA are analysed with PHOX2B gene.

When compared with healthy population, patients suffering from OSA have smaller airway size and palatal volume.

**Sleep disorders and Chronic craniofacial pain**

Improper sleep and headaches are very closely related to each other. Headaches are characterized according to frequency or proximity to sleep by most epidemiological studies. Headaches can be due to fragmented sleep, changes in sleeping position and frequent awakenings. Children with poor sleep quality and excessive daytime sleepiness, often complain of headaches. Headache clinics found that insomnia to be the most common sleep complaintin nearly two-third of patients.

In primary headaches the quality of sleep is reduced. It causes symptoms of central sensitization such as allodynia and pericranial tenderness. An average of 7-8 hours of sleep duration was associated with reduced headaches. The extreme ends of sleep durations like less than 6 hours or more than 8.5 hours were associated with increased headache intensity.

Sleep is both the cause and cure for headaches. The first symptom of sleep disorder may be headache. According to ICSD (International Classification of Sleep Disorder) Migraines, cluster headaches, hypnic headache and chronic paroxysmal hemicranias are all classified as sleep related headaches.

**Treatment options**

Behavioural modifications are vital in the treatment for patients with OSA. A regular sleep schedule, adequate sleep, using only the bed to sleep, avoiding spending too much unwanted time in bed and using the bed for other recreational activities should be avoided. Alcohol and smoking should be strictly avoided. It is because smoking causes inflammation in upper airway, thereby increasing chances of airway collapse. Alcohol exacerbates the episodes and duration of apneas. It also causes sleep fragmentation and arterial desaturation.

The American Association of Sleep Disorders has advocated the use of oral appliances to eliminate snoring or sleep apnea. It can be further classified as mandible advancement appliances, lingual retainers, appliances which act upon the soft palate and combined advancement and continuous positive airway pressure appliances.

**Mandible advancement appliances:**

The mandible advancement appliances, are constructed in such a way that they advance the mandible up to 80% of the maximum protrusion. They can be of Monoblock type or devices with two splints. There was no difference in the success rate observed between these two designs. These appliances produced a lower AHI scores as found out by PSG, thereby contributing to their success rates.

Various authors have reported pain in the incisor region, joint discomfort, facial muscle discomfort as side effects of these appliances while others authors have reported, only minimal orthopedic and dental effects.

When these appliances were compared with Continuous positive airway pressure (CPAP), they were found to be less effective in reducing AHI scores.

Sullivan introduced CPAP in 1981. The patient is made to wear a mask at night that will impel air into the upper airway. This in turn raises the air pressure in pharynx. The air forces the soft palate to move forwards, thereby allowing pressure to reach the upper airway, which prevents it from collapsing. It is effective and has shown reduced AHI score < 5 but has poor patient acceptance.

**Surgical treatments:**

It is considered after failure of non-surgical interventions.

- **Tracheotomy**

  It is the first described surgical technique. Tracheal hole is kept closed throughout the day. A plug is used to help breathe through nose/mouth. Plug is removed at night, so air can penetrate distal part of trachea.

- **Uvulopalato-pharyngoplasty (UPPP)**

  Described by Fujita et al. UPPP corrects obstruction at oropharyngeal level. Uvula is modified and the posterior and anterior pillars are closed to expand the retropalatine tract. Kamami first described laser assisted
UPPP in 1980. It was first choice of treatment, but it improved the condition by only 50% of all OSAS patients.

-Tonsillectomy

Hypertrophic tonsils can cause OSAS. In obstructive tonsils, tonsillectomy at any age, has positive impact on obstruction of upper airway. Krespi and Ling described Tonsillectomy procedures with CO$_2$ laser. Laser surgeries took less time, less bleeding and less post-op pain. Another technique is Radiofrequency ablation of tonsils. In this technique, electromagnetic rations produced heat within tissues. Trials suggest less pain than with respective surgery$^{(5)}$.

-Maxillo-Mandibular advancement by osteotomy:

The first choice of treating OSAS. Advancing the mandible, stretches anterior digastric, mylohyoid, genioglossal and geniohyoid muscles. It also stretches the tongue forwards and away from the pharynx.

Success rate is 75 to 100%. AHI scores improved long term. Results were stable over time. Lye et al in 2008 reported high success rate with bimaxillary advancement. Indications of MMA is AHI >15, low oxygen saturation and ineffectiveness of mandibular advancement, weight loss. MMA is done in patients with 

Multiple sites of obstruction

Skeletal class 2 malocclusion.

A case was reported by Coney et al, of a patient with OSAS, who underwent transverse osteogenic distraction of maxilla, combined with maxilla – mandibular advancement. There was a significant improvement of the apnoea reported. MMA surgical procedure, leads to a greater posterior and lateral airway dimensions, with minimum complications$^{(15)}$.

Conclusion

Orthodontists developed newer and simpler methods to find OSA using cephalogram, which helps to prevent OSA patients leading to metabolic disorders and systemic diseases and restores them nearer to normal lifestyle.

Temporomandibular Disorder in Pregnancy

Vikram.V1, Sanjna Nayar2, Nayan K.R Bangshiary3

1Senior Lecturer, 2Head of the Department, Department of Prosthodontics,
Sree Balaji Dental College & Hospital, BIHER

Abstract

Pregnancy is a happy stage in life of every woman, but at the same time it is a rather difficult period, since pregnancy represents a serious strain on the body. In the body of a woman during this period there are significant physiological changes that ensure the correct development of the fetus, prepare the body for the upcoming delivery. In this difficult period, the burden on all organs and systems of the woman’s body is significantly increased. Especially often suffer joints; there is a risk of permanent pain, the development of diseases or exacerbation of existing diseases. One of the most common problems is Temporomandibular Dysfunction or Disorder (TMD) which many women face, but still hasn’t been explained.

Key words – Pregnancy, TMD, Estrogen

Introduction

The term ‘temporomandibular disorder’ (TMD) embraces a number of clinical problems that involve the masticatory muscles and/or temporomandibular joints (TMJ) and associated structures. Temporomandibular disorder is the second most prevalent source of orofacial pain. A number of studies have also identified genetic (e.g., COMT, SCN1A) and inflammatory criteria of (e.g., free radicals and cytokines) risk factors that contribute to the development of TMD. According to epidemiological data, there is a strong predilection of TMD for women. The prevalence is the highest during reproductive years and the lowest before puberty and after menopause. The male to female ratio of TMD patients is estimated at around 1: 3 . It is suspected that this predisposition is related to female reproductive hormones, especially estrogen. The effects of estrogen are mediated by binding to its receptors. Three types of estrogen receptors are distinguished, two nuclear – alpha (ERα) and beta (ERβ), and one plasmatic – G-protein coupled estrogen receptor 1 (GPER1). Since 1986, when estrogen receptors were recognized for the first time in baboon temporomandibular joints, the potential influence of estrogen on TMD has become a matter of interest to many researchers. It is now known that estrogen receptors are localized in many structures of the stomatognathic organ, particularly TMJ tissues, such as chondroid tissue of condyle and retrodiscal tissues. Studies on the effect of estrogen deficiency performed on animal models revealed that estrogen depletion causes structural changes in TMJ. These include an increase in TMJ cartilage thickness, a decrease in subchondral bone volume, flattening of condyles, osteophyte formation or even serial degenerative changes.

The effect of estrogen on the development, restitution and metabolism of the temporomandibular joint and associated structures is one of the possible mechanisms in which these hormones can influence the incidence of TMD. Another probable mechanism is the modulation of the pain regulative mechanisms by estrogen. The presence of its receptors in tissues of both the peripheral and central nervous systems makes estrogen capable of modifying pain signaling . Estrogen receptors (ERα, ERβ) are found in the dorsal root ganglion (DRG) as well as in the trigeminal nerve nucleus. The influence of estrogen on pain regulatory
mechanisms seems to be very complex. Depending on the pain signaling type, estrogen may act as a pro- and anti-nociceptive. In physiological pain, estrogen seems to decrease pain while, in inflammatory pain, estrogen acts differently depending on the inflammation type. In acute inflammatory pain caused by formalin or ATP injection, estrogen has an anti-nociceptive effect. In the chronic inflammatory pain model with complete Freund’s adjuvant (CFA) or carrageen injection, the pro-nociceptive effect of this hormone is seen. It is worth noting that blocking estrogen receptors α and β diminishes sex differences in both physiologic and acute inflammatory pain. Recently, some estrogen related genetic factors predisposing to TMD have been discovered. ERα gene polymorphism causes receptor overexpression which makes certain allele carriers more susceptible to the effects of estrogen by enhancing processes associated with ERα receptor stimulation.

Etiology

Pregnancy produces dramatic changes in levels of estrogen & progesterone. Both estrogen & progesterone levels rise during pregnancy. Estrogens are known to increase joint laxity, at least during pregnancy, & laxity of temporomandibular joint is thought to play a role in development of some these disorders. Another possibility is that is that estrogens enhances a number of specific inflammatory responses in the temporomandibular joint. Another possible factor may be relaxin. Relaxin levels increase 2- to 3- fold during pregnancy. Increased systemic joint laxity in pregnant women has been linked to elevated levels of relaxin. As the levels of relaxin & estrogen increases throughout pregnancy, laxity of the temporomandibular joint may increase & there may be a tendency to TMD.

The symptoms classically associated with Temporomandibular Dysfunction (TMD) include

- Limitation of jaw range of motion
- Painful jaw range of motion
- TM joint clicking
- TM joint locking
- A sense of a bite discrepancy
- Tension in the face
- Daily headaches in the temples
- Morning headaches on arising
- Sore jaw muscles
- Jaw pain while eating
- Neck Tension

In addition, ear symptoms are rather common when a Temporomandibular Disorder is present. Ear symptoms can include pain, a sensation of stiffness or fullness, and a variety of odd sounds such as ringing, humming, buzzing, and whistling. Other less frequent symptoms include:

- Loss of balance and a sense of unsteadiness
- Tingling sensations in the face and jaw
- Some of these symptoms are directly related to the muscles of the face and/or TMJoint while others have their origins in the upper neck region.

TMJ treatment

TMJ problems are orthopaedic in nature and are the result of tired, tight, injured or sore muscles, inflamed tendons, or compromised ligaments, bone and cartilage. As a result, TMJ treatment options are similar to those offered by an Orthopaedist when managing a knee problem, for instance. The first step in TMJ treatment, of course, is to try to prevent further injury by avoiding certain foods (bagels, tough crusty breads, tough meats, uncut apples), and controlling any daytime behaviors that put strain on the jaw muscles or TMJ’s. These activities include:

- Gum chewing
- Nail and cuticle biting
- Biting on pen caps, straws, plastic items
- Teeth clenching
- Biting on your lips or cheeks
- Wide or frequent yawns
- Holding your glasses between your teeth
- Leaning your chin into your hands while at work, on the computer, or watching TV
- Phone cradling
- Ice chewing.
At times, compromise of the TMJoint and jaw muscles will require the use of an oral appliance (bite plate), which can be compared to a knee brace. These devices have different shapes and forms, can be made of variable materials and have different goals. Most importantly, they cushion the TMJs and diminish tightness in the jaw muscles. Over-The-Counter oral appliances sold in pharmacies can at times be used to protect the teeth over the short term, but remember, they are not designed to manage a jaw problem over the long term! If you’re pregnant, have had TMJ problems in the past, and suspect that they are beginning to resurface, see your dentist before it gets worse.

A custom-bitted night guard, a routine of jaw exercises, and some general relaxation techniques may just be what you need to relieve the symptoms and allow you enjoy the rest of your pregnancy.  

- Jaw exercises and physical therapy
- Medications (oral, topical, injectable)
- Massage
- Acupuncture
- Trigger point injections for pain and muscle tension in the jaw and neck muscles
- Behavior Modification strategies
- Breathing techniques

On occasion is there a need to move teeth or do other dental work to manage a jaw related problem. In some instances, changing the way teeth come together, or providing dental care to improve the efficiency of the chewing surfaces of the teeth may help jaw related problems.

Summary

The term ‘temporomandibular disorder’ (TMD) embraces a number of clinical problems that involve the masticatory muscles and/or temporomandibular joints (TMJ) and associated structures. Temporomandibular disorder is the second most prevalent source of orofacial pain. A number of studies have also identified genetic (e.g., COMT, SCN1A) and inflammatory criteria of (e.g., free radicals and cytokines) risk factors that contribute to the development of TMD. According to epidemiological data, there is a strong predilection of TMD for women. The prevalence is the highest during reproductive years and the lowest before puberty and after menopause. The male to female ratio of TMD patients is estimated at around 1: 3. It is suspected that this predisposition is related to female reproductive hormones, especially estrogen. Causes of pregnancy is due to dramatic changes in levels of estrogens and progesterone. Both estrogen and progesterone levels rise throughout pregnancy. And another hormonal factor is relaxin. Estrogens & relaxin are known to increase joint laxity. And increase in joint laxity gives rise tendency to TMD. Symptoms of TMD are painful jaw range of motions, limitation of jaw range of motion, TM joint clicking, TM joint locking, jaw pain while eating, neck tension, a sense of bite discrepancy, morning headache on arising. Ear symptoms are common in TMD. Ear symptoms can include pain, a sensation or fullness, variety of odd sounds like ringing, humming buzzing & whistling. Treatment of TMjoint & jaw muscles will require the use of oral appliance (bite plate), custom bitted night guard, a routine of jaw exercises & some general relaxation techniques.

Combination Approach of Full Mouth Rehabilitation in Partially Edentulous Patient - A Case Report

Ramyaa Dhanasekaran¹, Sanjna Nayar², Aruna U³

¹Senior Lecturer; ²Head of the Department, ³Professor, Department of Prosthodontics and Implantology, Sree Balaji Dental College and hospital, Pallikaranai, Chennai

Abstract

Restoration of a partially edentulous patient’s mouth with complete esthetic and functional reconstruction may present numerous problems to the dental professional. The severe wear and collapse of anterior & posterior teeth results in the loss of normal occlusal plane and the reduction of the vertical dimension of occlusion. The major concerns include establishing centric relation, esthetics, phonetics and vertical dimension. Taking this into consideration this case report explains in detail the step-by-step procedure in treatment planning to completely rehabilitate a 43 year-old partially edentulous patient using a combination of fixed and removable prosthesis.

Keywords: Edentulous, RPD, PFM.

Introduction

A 43 year old female patient reported to Sree Balaji Dental College and Hospital with chief complaint of multiple missing & decayed teeth. On intra oral examination Missing irt 12,16,22,23,35,36,37,44,45,46,17 (fig 1 & 2), Decayed irt 17,27,42 associated with collapsed vertical dimension and unsatisfactory occlusion. Anatomic landmarks, facial measurements and the resting positions of mandibular jaw were used to determine appropriate vertical dimension for the patient.

Fig 1: Missing teeth in maxilla

Fig 2: Missing teeth in mandible

Fig 2: OPG

OPG were taken and examined (fig 3). Intraoral & extraoral condition was analysed, then different treatment plans ranging from conventional RPD to implants were made and discussed with the patient to restore the function and aesthetics of the dentition.
Examination of radiograph and anatomical factors like maxillary sinus floor position and residual ridge resorption, patient was made aware of the steps involved before and during the surgery. Regarding treatment plan the patient was not willing for surgical procedures and was satisfied from the previous RPD. So, For these reasons, instead of implant prosthesis, combination of fixed and fixed removal prosthesis in a form of extra coronal attachment was suggested to the patient and its advantages and disadvantages were also discussed. After taking patient’s approval clinical procedures were initiated. Impressions were made with alginate and casts were poured.

Face bow transfer were done for the diagnostic mounting with anterior deprogramming done using lucia gig and Occlusal wax rims were fabricated on the diagnostic casts and later they were mounted in centric relation for prosthodontic evaluation.

After restoring the VD, crown lengthing was done using biolaseirt 14,15 to achieve optimal crown – root ratio. All the teeth were prepared. Temporary restoration was fabricated with Protemp finished and cemented with temporary cement. Try-in of temporary partial denture was also done. The patient was satisfied with the provisional restoration. Thus, it was decided to reproduce the temporary VD and centric relation (CR) state on the final restoration. Gingival displacement was done using single cord technique. Definitive impressions were made with polyvinyl siloxane impression material using putty wash technique. The preglaze trail was done for PFM crowns and precision attachments wax-up try-in were done. Temporary denture base were adjusted to accommodate the precision on attachment bilaterally with a lingual bar. Posterior teeth arrangement and PFM crowns were prepared and try-in was carried out. Clinical adjustments were done.

The glazing of PFM crowns and acrylization of attachment retained partial dentures were completed. Pink colour rubber rings were placed (as manufacture’s instruction) in the female counter part slots present in the CPD using inserting tool . These rubber rings make the CPD retentive and stable and at the same time act as stress breakers. Crown and bridges were cemented with the CPD attached (Fig 6). Extra care was taken during cementation by applying petroleum jelly to the attachments and all parts of CPD to make removal of cement easily. After the final set-up, routine check-ups...
were performed in every 3 months for one year. The final result satisfied the patient’s chief complaints with the combination fixed partial dentures and semi precision retained CPD bilaterally with a lingual bar.

**Discussion**

Full mouth rehabilitation is not only the restoration of the worn out dentition, but also maintenance of the health of the entire stomatognathic system. Full mouth rehabilitation should re-establish a state of functional as well as biological efficiency where teeth and their periodontal structures, the muscles of mastication, and the temporomandibular joint (TMJ) mechanisms all function together in synchronous harmony\(^{(1)}\). A variety of philosophies are been used in full of reconstructions, they are twin stage philosophy, Pankeymannschyularphilosophy, etc. These techniques assist in concomitant laboratory construction of the units. When all of the prepared teeth are on a single articulator, there is flexibility in developing the occlusal plane, occlusal theme, embrasures, crown contour and esthetics \(^{(2)}\). The advantages of the simultaneous and quadrant full-mouth reconstruction are combined in the present technique. The chairside disadvantages include arduous, unpredictable patient visits, full arch anesthesia, full arch chairside treatment restorations, multiple occlusal records and possible loss of the VDO. Treatment restorations also provide a stable and esthetic interim prosthesis during the fabrication of the final restoration and allow appraisal of an altered VDO.

In 1984, Turner and Missirlian classified the treatment of a severely worn dentition by the amount of the loss of VDO and available space to restore. His classification and conventional treatment, which includes raising VDO with multiple crown-lengthening procedures, have been widely used\(^{(3)}\). The occlusal splint, which is reversible and conservative in nature, has been used as a diagnostic tool to judge adaptation to the altered VDO. The waiting period to judge adaptability is between 3 weeks and 5 months for the occlusal splint and 2-6 months for the provisional prosthesis \(^{(4)}\). In this case, the patient was carefully monitored for 6 weeks to evaluate the adaptation to the removable partial denture. Furthermore, the patient’s adaptation to the provisional restoration was monitored. Discomfort, wear and muscle fatigue were not observed during this period.

The restoring of VDO was determined by standardized esthetic golden proportion of anterior teeth and also by patient’s factors like interocclusal rest space and speech. If the increase of VDO was decided arbitrarily without close evaluation, multiple complications could arise. Depending on the patient’s situation and adaptability, the interim period can be modified.

**Conclusion**

The reasons for undertaking occlusal rehabilitation may include the restoration of mutilated teeth. Increasingly, occlusal rehabilitation is also required to replace improperly designed and executed crown and bridgework. Full mouth rehabilitation involves restoring the teeth, jaw muscles and self-esteem back to a natural looking condition. Optimum oral health should be the prime objective of all rehabilitation procedures because the ultimate goal will always be to restore the mouth to health and function and preserve this status throughout the life of the patient.

Abstract

Dental implants are widely used in dentistry to replace removable dentures among edentulous and partially edentulous patients. Since the demand for dental implants, artificial tooth roots, has grown considerably. Dental implants are used to replace removable partial or full dentures in edentulous and partially edentulous patients. Implants and implant-supported prostheses offer greater stability, comfort, and aesthetics than any other removable prostheses.

Keywords: MMP8, Biomarker, GCF, PICF

Introduction

Dental implants are titanium fixtures placed into the jaw bone during surgery. Titanium is the most common biometal used in endosseus dental implants because of its excellent biocompatibility properties in physiological conditions. The term osseointegration means direct bone contact with an alloplastic metallic implant. The hard and soft tissues surrounding an osseointegrated implant show some similarities to the periodontium around natural dentition. The gingiva around dental implants is called periimplant mucosa, and consists of well-keratinised oral epithelium, sulcular epithelium, and junctional epithelium with underlying connective tissue. Between the implant surface and epithelial cells are hemidesmosomes and the basal lamina. The most significant difference between natural teeth and implants is that implants lack the periodontal ligament. The collagen fibers are unattached and parallel to the implant surface rather than in functional contact from the bone to the cementum. The titanium screw attaches directly to the alveolar bone, which is in direct and tight contact with the implant surface.

Implant Versus Natural Tooth

Peri-implantitis is an inflammatory disease that affects alveolar bone and soft tissues around implants, eventually leading to loosening of the implant. The aetiopathogenesis of peri-implantitis remains somewhat unclear, but has a similar infectious and inflammatory background to the pathogenesis of periodontitis.

Laminin-332 is a glycoprotein essential to the adhesion of epithelial cells, especially in the formation of hemidesmosomes, and is produced in the oral cavity by gingival epithelial cells. The Ln-332 molecule consists of three different polypeptide chains, of which the _2-chain is specific to Ln-332. Several matrix metalloproteinases (MMP) can cleave the Ln-332 _2-chain into smaller fragments. This cleaved Ln-332 stimulates the migration of gingival epithelial cells and is believed to play a central role in the apical migration of sulcular epithelial cells and in the formation of periodontal pockets.

MMP8 And Its Importance

MMPs are catalytic proteins, enzymes capable of cleaving almost all extracellular matrix (ECM) and basement membrane (BM) proteins. MMPs are involved in many physiological processes such as bone formation, tooth eruption, and wound healing. MMP-8 is one of the most efficient enzymes in degrading type I collagen. MMP-8 is produced by many different cells in different tissues, but is expressed most dominantly by polymorphonuclear leukocytes (PMN). During inflammation, PMN cells invade from vessels to tissues, where they release MMP-8. Many studies explain the MMP-8 levels are pathologically elevated in human periodontitis and in periimplantitis.

MMP-8 Levels And Activation In GCF And PISF

GCF can be used in the diagnostics and investigation of the severity and degree of inflammation. The enhanced expression and activation of various MMP enzymes has
been demonstrated in periodontitis as well as in peri-
implantitis, where MMPs are believed to mediate multiple
functions associated with periodontal destruction and
inflammation\(^7\). Various study found that MMP-8 activity
was, together with GCF and PISF flow, enhanced with
increased clinical severity and degree of inflammation
in CP and PI. Furthermore, MMP-8 active forms in GCF
and PISF contribute to GCF/PISF collagenase activity.
GCF has been used to evaluate the risk for an individual
to develop periodontal disease as well as to monitor the
host response to periodontal therapy. MMP-8 levels and
activation reportedly to be increase during periodontal
inflammation, and MMP-8 can serve as a diagnostic tool
to monitor periodontitis\(^8\). The present result suggests
that PISF could also serve as a diagnostic tool in the
samemanner as GCF. Furthermore, MMP-8 levels and
PISF flow in diseased PI sites were even higher than
therespective levels and flow in severe CP sites.
Because periodontal and peri-implant inflammation are
associated with the extravasation and migration of
neutrophils towards the periodontal pocket and an
increase in the amount of GCF and PISF volume, these
phenomena (increase in PISF flow and MMP-8 activity)
could be attributed to even more rapidly progressing
inflammation, increased vascular permeability, PMN
activity, and influx into the peri-implant mucosal tissues
in PI than in CP. The results make PISF interesting and
important in the future investigation of the diagnostics
of peri-implant inflammation. Elevation and activation
of multiple species of PMN- and fibroblast-type MMP-
8 reflect periodontal and peri-implant inflammation,
and that MMP-8 is more likely to be produced in many
cellular sources rather than in single cellular sources in
diseased periodontium or peri-implant mucosa\(^7\).

## Discussion

MMPs are host proteinases responsible for both
tissue degradation and remodeling. During progressive
periodontal breakdown, gingival and periodontal
ligament collagens are cleaved by host cell-derived
interstitial collagenases. One vital interstitial collagenase
capable of degrading the triple helical structures of
native types I, II, and III collagens found in alveolar
bone matrix is collagenase-2. Collagenase-2, also
referred to as MMP-8, is released during the maturation
of PMNs in the bone marrow. Once produced, it
becomes glycosylated and is prestored in the sub-
cellular-specific granules, where it is subsequently
released in large quantities as the PMNs are recruited to
a site of inflammation. Chubinskaya et al. demonstrated
the ability of non-neutrophil-lineage mesenchymal
cells, such as human gingival and periodontal ligament
fibroblasts and chondrocytes, to also be able to produce
MMP-8\(^8\). MMP-8 is the most prevalent MMP found
in diseased periodontal tissue and GCF. Nomura et al.
found no difference in MMP-8 levels from patients with
periodontal disease when compared to patients with
gingivitis. From this early investigation, it was believed
that MMP-8 may serve as a proinflammatory marker, but
not as a discriminating marker for chronic periodontitis
and gingivitis. However, Mancini and co-workers found
an 18-fold increase of MMP-8 in patients experiencing
active periodontal tissue breakdown as compared with
patients under stable conditions. Conclusions from
this investigation indicated the potential use of MMP-
8 as a screening test for detection of active disease
progression\(^9\). Elevated MMP-8 levels in active disease
progression were observed by Lee et al. in a longitudinal
study using patients with gingivitis, nonprogressive,
and progressive periodontitis. The total collagenase
activity was observed to be 50% higher in the disease
progression group. Golub et al. introduced a 20-mg
low-dose doxycycline (LDD) capsule, which preserved
its proteinase-inhibitory ability to suppress connective
tissue breakdown, but without antibiotic/ antimicrobial
capabilities. The group went on to conduct several
studies demonstrating that LDD can function as an MMP
by way of suppressing the collagenase activity in GCF
and gingival tissues of patients with adult periodontitis.
To test the hypothesis that LDD could lower GCF levels
of bone-type collagen fragments, clinical parameters
(gingival inflammation, pocket depth, and radiographic
evidence of bone loss) that predicted excessive MMP
activity in periodontal pockets of 18 adult patients were
evaluated. All patients received supragingival scaling 1
month before the baseline appointment. At the baseline
visit and at the subsequent 1- and 2-month visits, GCF
samples were collected. Conventional clinical measures
(gingival index, plaque index, probing depth, and
attachment level) were taken at each time point in the
study. Western blots analyses determined that neutrophil-
type collagenase (MMP-8) was increased in disease and
substantially reduced by approximately 60% during the
2-month protocol of LDD\(^9\). MMP-8 may have some
future value as a diagnostic marker for periodontal
disease, an indicator for disease progression, and as a
signal to determine the efficacy of treatment.
MMP-8 has also been detected in elevated amounts in peri-implant sulcular fluid (PISF) from peri-implantitis lesions. Teronen et al. identified higher collagenase-2 levels in failing dental implants compared to nonmobile implants. Ma et al. went on to explore for the presence of MMP-8 and collagenase-3, MMP-13, in peri-implant sulcus fluid. Forty-nine randomly selected dental implant sites in 13 patients were studied. Implants were categorized into three groups according to the amount of bone loss in the vertical dimension: <1 mm, from 1 to 3 mm, or >3 mm. Results from this investigation showed that both MMP-8 and MMP-13 levels were significantly higher in the >3 mm bone loss group when compared to the groups that had less bone loss11. Additional studies were conducted by Kivela-Rajamäki et al., looking at MMP-8 levels in combination with laminin-5 and, during a separate study, with MMP-7. Conclusions drawn from both investigations indicate that elevated levels of MMP-8 can be seen in diseased PISF as compared to healthy PISF12. Collectively, these findings offer hope for the use of MMP-8 as a marker for active phase of peri-implant disease. Longitudinal studies are required to evaluate MMP-8 either alone or in conjunction with other molecular biomarkers to predict the risk of future disease occurrence and to monitor treatment interventions.

**Abstract**

For the fabrication of dental inlays and crowns precise information on tooth morphology is required. Besides the conventional method, the use of digital scanners has become an central part of impression making in dentistry. Intraoral scanners (IOS) are devices for capturing direct optical impressions. The purpose of this narrative review on the use of IOS was to discuss: (1) commercially available scanners, (2) the indications and contraindication, (3) precision of the digital impression compared to the conventional methods; (4) the advantages/limitations of using optical impressions.

**Keywords**: Zirconia, Impression, CAD/CAM, Implants.

---

**Introduction**

The abbreviation “CAD/CAM” denotes computer-aided design and computer-aided manufacturing(1950). This technology enables modelling, design, and manufacture of objects. The use of CAD/CAM in dentistry has been used since the 1980s to produce inlay and onlay fillings, crowns, laminates, fixed dental prostheses (FDPs), and implants, and is increasingly used by dentists and technicians.

In the CAD/CAM system, digital impressions are recorded by intraoral scanner, which resembles an ordinary camera, collects information about projecting light. Reproducible tissues are shown on the hardware display as natural looking.

The main structures of the prosthetic design in terms of data are 3D in the prepared teeth, the adjacent teeth, and the occlusion with the opposing bite.

The intraoral scanner measures the light reflection times of the surface to be recorded. The description, based on data and calculation algorithms to copy the software, calculates and generates a computer screen image of the prepared area.

Intraoral cameras use video technique or still photo technique for scanning. Still images are based on triangulation or parallel confocal laser scanning. Systems take several still images from which a 3D image can be formed.

**CAD-CAM SYSTEMS**

LAVA C.O.S and Lava True Definition scanner use active wavefront sampling for data collection from which video image is formed.

CEREC AC Bluecam uses active triangulation and optical microscopy to produce still images.

The CEREC AC Omnicam CAD/CAM system uses video for data collection.

iTero and 3Shape Trios use the parallel confocal method to produce digital data.

**INDICATIONS**

Zirconia Coping

Single tooth restorations in lithium disilicate,
zirconia, all ceramics
Frameworks and Fixed Partial Dentures in Zirconia
Single Implant Crowns
Implant bridge
Implant-Supported bars
Digital smile design
Obturators
Guided implant surgery

CONTRAINDICATIONS
Long span fixed partial dentures and/or fixed full arches
Long span implant supported fixed partial dentures
Complete removable prosthesis

Are optical impressions as accurate as conventional impressions?

The main feature an IOS should have is accuracy: a scanner should be able to detect an accurate impression for a better treatment outcome.

In metrics and engineering, accuracy is defined as the ‘closeness of agreement between a measured quantity value and a true quantity value of a measurand’. Ultimately, accuracy is the sum of trueness and precision.

The two factors that influence the accuracy are: trueness, which describes the deviation of the impression geometry from the original geometry, and precision, which describes the deviation between repeated impressions rather than to the original geometry.

All ceramic single crowns
Zarauz et al conducted an in vivo study to evaluate the marginal fit of crowns based on conventional silicone impressions and digital iTero impressions. To evaluate the precision of crowns fabricated using conventional and digital impression systems, 26 crowns were made on each technique and cemented on their corresponding clinical preparation. Means of the internal misfit and marginal misfit were measured using stereomicroscopy of 2-mm-thick slices in a buccolingual orientation. Results of the digital impression were more accurate. Based on this, digital impression system and CAD/CAM technology can improve the marginal adaptation of all-ceramic single crowns.

FOUR UNIT FIXED ZIRCONIA FPD
Almeida e Silva et al conducted an in vitro study to evaluate the marginal and internal fit of four-unit fixed zirconia FDPs using both digital and conventional impression techniques. They found no statistical differences between the Lava C.O.S. digital impression group and the conventional impression group, using Impregum, although impressions made by the CAD/CAM system resulted in better marginal and considerable internal fit at the premolar mesial and molar distal faces.

IMPLANTED SUPPORTED CROWNS AND FPDs
An in vitro study by Abdel-Azim et al discovered the influence of computer-aided impression options on the accuracy of dental implant-based single units and complete arch frameworks. They reported that conventional impressions resulted in a smaller marginal discrepancy when compared to the digital methods for a single-implant framework. For single implants the mean marginal gap was 24.1 μm for conventional impressions compared to 61.4 μm for digital impressions.

Additionally, Lee et al conducted an in vitro study to compare the accuracy of implant impressions made with digitally manufactured models vs. gypsum models vs. CAD/CAM system models. The digital impressions were made with the iTero system and the conventional close-tray impressions with a VPS material. Gypsum models represented more details in grooves and fossae compared to CAD/CAM models. According this study, milled models based on digital impressions were comparable to gypsum models based on Conventional impression.

Full Arch FPDs
Ender and Mehl published an in vitro study on the accuracy of conventional and digital impression methods used in full-arch dental impressions. Four digital impression systems (CEREC Bluecam, CEREC AC Omnicam, iTero, Lava C.O.S.) and four conventional impression materials were used. A highly accurate reference scanner was used to evaluate the accuracy for
both full-arch conventional and digital impressions of the same dental morphology. The results showed that the highest trueness and precision was measured for CEREC Bluecam, vinylsiloxanether, and direct scannable vinylsiloxanether. The local deviations of the full arch impression were higher in digital impression when compared to the conventional methods. Ender and Mehl investigated the accuracy of the full arch impressions recorded by digital and conventional methods using a new reference scanner. In this in vitro study trueness and precision were evaluated from five conventional impressions with a vinyl siloxanether impression material and from five digital impressions of the reference model made with the CEREC AC Omnicam. The results showed that the trueness and the precision of the digital complete-arch impression were comparatively less accurate than those of the conventional impressions. The deviation patterns of conventional and digital impressions were also different.1,3,4

The advantages and limitation of optical impressions with respect to conventional physical impressions

**ADVANTAGES**

**LESS PATIENT DISCOMFORT**

The conventional method are subjected to cause momentary discomfort for the patient due to the inconvenience and hardship stemming from the materials positioned on impression trays. Some patients with strong gag reflex, children or non-cooperative individuals, find it hard to tolerate the classic procedure. For such patients, replacing conventional impression materials with light is an advantage; optical impression is therefore appreciated and encouraged.

**Time efficiency and better communication with the dental technician**

Several studies have shown that optical impressions are time-efficient, as they enable reduce the working times when compared to conventional methods. Pouring of stone cast is not need in digital methods; the recorded digital impression can be sent through an e-mail as a 3 Dimensional virtual models (proprietary or STL files) directly to the dental laboratory without the need to deliver anything via courier or regular mail. This saves considerable amount of time. Moreover, if the clinician is not satisfied with some of the details of the recorded optical impression, they can be deleted and recorded again without having to repeat the entire procedure.

**No more plaster casts**

The digital impression allows the skipping of pouring models and casts. The elimination of conventional impression materials translates into direct savings for the clinician, with reduced consumables costs.

**Better communication with patients**

Optical impression is one of the vital tool for patient communication and marketing. With optical impressions, patients feel more involved in their treatment and it is possible to establish more effective communication with them; this emotional involvement may have a positive impact on the overall treatment, for example, by improving patient compliance to oral hygiene.2,5

**Disadvantages**

**Difficulty detecting deep margin lines of prepared Teeth**

One of the most frequent problems encountered with intra oral scanner is difficulty in detecting deep marginal lines on prepared teeth or in the case of bleeding. In aesthetic areas where it is important for the clinician to place the prosthetic margins subgingivally, it may be more difficult for the light to correctly detect the entire finishing line. Unlike the conventional impression materials, light cannot physically detach the gum and therefore cannot register ‘non-visible’ areas. In the event of bleeding, as blood obscures the prosthetic margins, it is difficult to record the marginal lines. With the help of retraction cords and proper oral hygiene, it is possible for the clinician to detect a good optical impression even in difficult contexts.

**Purchasing and managing costs**

Over the last few years, manufacturers have released many new models on the market, and the growth in supply should be accompanied by a reduction in purchase costs. One important consideration is the additional managing costs related to software upgrades. Different manufacturing companies have different policies in this regard, and it is important for the clinician to be fully informed of the annual management costs and fees, where present, before purchasing an IOS. Finally, in the case of ‘closed’ systems, or with IOS that output
only proprietary file formats, an annual or monthly fee may be required to ‘unlock’ the files and render them usable by any CAD software or any laboratory. Once again, the clinician should be properly informed about these additional managing costs.\textsuperscript{2,5}

**Conclusion**

Optical impression are time-efficient, reduces patient discomfort and simplify clinical procedures for the dentist, eliminating plaster models and allowing better communication with the dental technician and with patients; however, it can be difficult to detect deep margin lines in prepared teeth and/or in case of bleeding and there are purchasing and managing costs. The current IOS are sufficiently accurate for capturing impressions for fabricating a whole series of prosthetic restorations (inlays/onlays, copings and frameworks, single crowns and fixed partial dentures) on both natural teeth and implants; in addition, they can be used for smile design, and to fabricate posts and cores, removable partial prostheses and obturators. The Digital impression techniques are a clinically acceptable alternative to conventional impression methods in fabrication of crowns and short FDPs. For fabrication of implant-supported crowns and FDPs, digital impression systems also result in clinically acceptable fit. Conventional and digital impression methods differ significantly in the complete-arch accuracy. Based on the evaluation of studies, the conventional impression technique is still recommended for full-arch impressions when compared to the digital impression technique.

Oral Lichen Planus- Treatment Planning

J. Nithya Theresa¹, Hemalatha V.T², Amudhan A³, Sankar Narayanan R⁴

¹Postgraduate, ²Reader, PhD Research Scholar; ³Reader; ⁴Senior Lecturer, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Pallikaranai, Tamil Nadu, Chennai

Abstract

Lichen planus, a chronic autoimmune disease, affects the skin and mucous membrane. It is believed to represent an abnormal immune response in which epithelial cells are recognized as foreign, secondary to changes in the antigenicity of the cell surface. It is characterized by alternating periods of symptomatic remission and exacerbation. It has various oral manifestations, the reticular form being the most common. The erosive and atrophic forms of OLP are less common, yet are most likely to cause symptoms. Different treatment modalities have been tried with limited success. Topical corticosteroids constitute the mainstay of treatment for symptomatic lesions of OLP. Recalcitrant lesions can be treated with systemic steroids or other systemic medications. However, there is only weak evidence that these treatments are superior to placebo. The main objective of this paper is to review the current literature regarding the treatment of OLP.

Keywords: OLP, Malignant transformation, Differential diagnosis, corticosteroids, Immuno-modulators, Management

Introduction

Oral lichen planus (OLP) is a chronic autoimmune, mucocutaneous disease of unknown origin. It was first described by Wilson in 1869. It can affect the oral mucosa, skin, genital mucosa, scalp, and nails. Globally, Lichen planus affects about 1-2% of population and prevalence in India ranges from 0.1% to 1.5%.[4] This disease has most often reported in middle-aged patients 30-60 years of age and is more common in females than in males (1.4:1). Rarely, OLP is seen in children.[1] Although the exact etiology of lichen planus is unknown, an immune-mediated pathogenesis is recognized.[1] A meta-analysis of primarily case-control studies conducted in multiple countries found a statistically significant association between hepatitis C virus (HCV) infection and lichen planus,[8] although there is no known explanation for this association.[2]

Corresponding Author:
Dr. Hemalatha V.T MDS.,
Reader, PhD Research Scholar, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Pallikaranai, Tamil Nadu, Chennai, Email: drhemalathamds@gmail.com

Pathophysiology

It is believed that the disease is caused by an abnormal cell-mediated immune response of both T4 and T8 lymphocytes in the basal epithelial cells.4 Autocytotoxic CD8 + T-cells activate apoptosis of oral epithelial cells. The CD8 + cytotoxic cells trigger the keratinocyte apoptosis through activation of the cells by an antigen associated with major histocompatibility Class I on basal keratinocytes.[1] The chronic course of OLP may result from the activation of the inflammatory mediator nuclear factor kappa B, and the transforming growth factor control pathway may cause keratinocyte hyper proliferation that leads to the white lesion.4 OLP may be associated with many systemic diseases, few have been confirmed, but infection with hepatitis C virus (HCV) can produce lichen planus.Carrozzo et al. have demonstrated a strong association between HCV infection and OLP. However, the association between OLP and HCV appears to be dependent on geographical heterogeneity.Moravvej et al. in 2007 found an association between Helicobacter pylori infection and lichen planus patients. However, an etiologic role of H. pylori in lichen planus is not yet properly established.[1]
CLINICAL PRESENTATION:

Six clinical forms of OLP have been described which are white forms namely reticular, papular, plaque-like and red forms namely the erosive (ulcerated), atrophic (erythematous) and bullous. Among the types, reticular and erosive are the main types.[3] Lichen planus lesions are described using the six P’s (table 1).[2]

The classic skin lesions of the cutaneous form of lichen planus can be described as purplish, polygonal, planar, pruritic papules and plaques. These skin lesions commonly involve the flexor surfaces of the legs and arms, especially the wrists. The nail beds may also be affected, with resultant ridging, thinning and subungual hyperkeratosis. Scalp involvement, if untreated, can lead to scarring and permanent hair loss.[4]

These lesions are often covered by lacy, reticular, white lines known as Wickham striae. The lesions may appear in a linear configuration, following the lines of trauma (Koebner phenomenon). It is common to see postinflammatory hyperpigmentation as the cutaneous lesions clear.[2]

OLP and may represent the gingival manifestation of many other diseases such as cicatrical pemphigoid, pemphigus vulgaris, epidermolysis bullosa acquisita, and linear IgA disease. Patients with reticular lesions are often asymptomatic, but atrophic (erythematous) or erosive (ulcerative) OLP is often associated with a burning sensation and pain. A greater malignant potential has been recognized for atrophic, erosive form of OLP and the plaques form on the back of the tongue. A regular follow-up of patients with OLP should be performed and in suspected cases, biopsy should be provided.[3]

Histopathological Features:

The classic histopathologic features of OLP include liquefactive degeneration of the basal cell accompanied by apoptosis of the keratinocytes, a dense band-like lymphocytic infiltrate [Figure 1] at the interface between the epithelium and the connective tissue, focal areas of hyperkeratinized epithelium (which give rise to the clinically apparent Wickham’s striae) and occasional areas of atrophic epithelium where the rete pegs may be shortened and pointed (a characteristic known as saw tooth rete pegs). Eosinophilic colloid bodies (Civatte bodies), which represent degenerating keratinocytes, are often visible in the lower half of the surface epithelium. [4]

Degeneration of the basal keratinocytes and disruption of the anchoring elements of the epithelial BM and basal keratinocytes (e.g. hemidesmosomes, filaments, fibrils) weaken the epithelial connective tissue interface. As a result, histologic clefts (Max-Joseph spaces) may form and blisters on the oral mucosa (bullous LP) may be seen at clinical examination. B cells and plasma cells are uncommon findings.[5]

Differential Diagnosis:

The differential diagnosis of erosive OLP includes squamous cell carcinoma, discoid lupus erythematosus, chronic candidiasis, benign mucous membrane pemphigoid, pemphigus vulgaris, chronic cheek chewing, lichenoid reaction to dental amalgam or drugs, graft-versus-host disease (GVHD), hypersensitivity mucositis and erythema multiforme. The plaque form of reticular OLP can resemble oral leukoplakia.[6]

Management:

Drug therapy is the most common method for treatment of OLP. Different drugs have been used for treatment of OLP including immunosuppressives, retinoids, and immunomodulators. Drugs are used in two

**Corticosteroids:**

Topical corticosteroids are the mainstay in treating mild to moderately symptomatic lesions. Options (presented in terms of decreasing potency) include 0.05% clobetasol propionate gel, 0.1% or 0.05% betamethasone valerate gel, 0.05% fluocinonide gel, 0.05% clobetasol butyrate ointment or cream, and 0.1% triamcinolone acetonide ointment. In patients
with widespread symptomatic lesions, in whom direct mucosal application of topical medication would be too uncomfortable, options include 1.0 mg/mL aqueous triamcinolone acetonide or 0.1 mg/mL dexamethasone elixir. IntraleSIONaL injection of corticosteroid for recalcitrant or extensive lesions involves the subcutaneous injection of 0.2–0.4 mL of a 10 mg/mL solution of triamcinolone acetonide by means of a 1.0-mL 23- or 25-gauge tuberculin syringe. The advantage of topical steroid application is that side effects are fewer than with systemic administration. Systemic corticosteroids are probably the most effective treatment modality for patients with diffuse erosive OLP doses of 1.5–2 mg/kg/daily, but adverse effects are possible even with short courses.\(^3\)

**Retinoids:**

Retinoids are metabolites of vitamin A. They have been noted to have anti-keratinizing and immunomodulating effects. Retinaldehyde 0.1\(^{36}\), isotretinoin gel 0.1% have been tried in OLP and they showed good clinical efficacy. OLP has been treated with fenretinide and tazarotene gel 0.1% successfully. These studies suggested that topical retinoid might be a suitable therapeutic agent in the treatment of hyperkeratotic OLP.\(^3\)

**Immunosuppressive Agents:**

**Azathioprine** (75–150 mg d\(^{-1}\)) may be a successful steroid-sparing adjunct to systemic prednisone therapy (Lozada, 1981) and as monotherapy may provide an alternative choice if there are risk factors against steroid use (Lear and English, 1996). However, azathioprine may induce bone marrow suppression especially in heterozygotes for high activity of the enzyme thiopurine methyltransferase (Snow and Gibson, 1995).

**Systemic cyclosporine** (6 mg/kg day) a non-myelotoxic immunosuppressant, is effective in controlling severe cutaneous LP (Ho et al, 1990). Cyclosporine induces in LP a substantial decrease of T cells and a corresponding reduction in activated CD25-positive cells and in antigen presenting cells possibly by inhibition of interferon \(\gamma\) production (Shiohara et al, 1988; Mozzanica et al, 1991). The adverse side effects of cyclosporine (most importantly, renal dysfunction) and the chronicity of the oral lesions have dissuaded clinicians from prescribing it in systemic treatment for OLP. Mouth rinses (450–1500 mg d\(^{-1}\) for 8–12 weeks) and finger applications of base solution (100 mg/day for 4 weeks) or cellulose-base preparation of cyclosporine (48 mg/day for 8 weeks) produce significant improvement in OLP, with no reliable side effects and little systemic absorption.\(^8\)

**Tacrolimus** is a macrolide immunosuppressant with a mechanism of action similar to that of cyclosporine, but is 10 to 100 times more potent and is better able to penetrate the mucosal surface. Treatment with topical tacrolimus 0.1% ointment four times daily induced a better initial therapeutic response than triamcinolone acetonide 0.1% ointment in patients with symptomatic OLP.\(^3\)

**Pimecrolimus (PI)** is a semi-synthetic product of ascomycin. Pimecrolimus has a similar mode of action to that of tacrolimus interacting with macrophilin-12 and inhibiting T-cell stimulation blocking both Th1 (IL-12, IFN-\(\gamma\), and TNF-\(\alpha\)) and Th2 cytokines (IL-4 and 10) but is more selective having no effect on Langerhans cells. PI is a weaker immunosuppressant than cyclosporine or tacrolimus, and it has lower permeation through the skin than topical corticosteroids or topical tacrolimus.\(^9\)

**Others:**

**Amphotericin** (a broad-spectrum antimycotic), when administered to patients with OLP and positive Candida cultures, resulted in a 94% clinical improvement (Lundstrom et al, 1984). A recent controlled trial suggests however that anti-Candida therapy plays a marginal role if any in the management of OLP (Carbone et al, 1999).

**Dapsone** occasionally helpful (Falk et al, 1985; Beck and Brandrup, 1986) mainly in patients with desquamative gingivitis (Matthews et al, 1989), but it has several adverse effects which may outweigh any likely moderate benefit.

**Levamisole** (150 mg d\(^{-1}\) for 6 weeks) may be best used as adjuvant medication during systemic steroid treatment (Shin-Yu et al, 1995) rather than as monotherapy (Sharps, 1978; Sun et al, 1994), and the side effects of levamisole preclude its routine use (Sharps, 1978).

**Systemic doxycycline** (200 mg d\(^{-1}\)) may improve desquamative gingivitis in OLP (Ronbeck et al, 1990) but not invariably (Eisen, 1994).
Hydroxychloroquine sulphate (an antimalarial agent) (200–400 mg d−1) has been recently reported to be useful in the treatment of OLP in a preliminary trial (Eisen, 1993), mainly in combination with topical steroids, because the effect of both agents appear to be additive.

Interferon - A pilot study had suggested that a topically applied gel preparation containing human fibroblast interferon (HuIFN-beta) may significantly improve erosive OLP (Sato et al, 1985). Systemic interferon-alpha (3–10 million IU thrice weekly) may be used to successfully treat OLP in patients with and without HCV infection (Doutre et al, 1992; Hildebrand et al, 1995). Despite these success rates, interferon has been reported to trigger or to worsen LP lesions (Protzer et al, 1993; Nagao et al, 1996a) and antibodies to interferon-gamma have been shown to abrogate experimentally-induced lichenoid reactions (Shiohara et al, 1988). Hence, there is equivocal evidence that expensive interferon therapy is a useful modality of treatment of OLP; indeed, it has been suggested that antibodies to this cytokine may be helpful (Walsh et al, 1990)

Glycyrrhizin- A recent small trial involving OLP patients with chronic HCV infection suggests than glycyrrhizin (an active component of liquorice roots) may also be useful in treating OLP (Nagao et al, 1996b).

Amitriptyline (Amy), a tricyclic antidepressant, has local anesthetic properties and seems to be more potent and safer than bupivacaine. Based on the topical anesthetic properties of Amy, a recent poor-quality randomized clinical trial compared a new mouthwash containing clobetasol, ketoconazole, and Amy with dexamethasone tablet, nystatin drop and diphenhydramine syrup. The new treatment worked better and was better accepted by the patients with OLP.

Amlexanox(C16H14N2O4) is a topical anti-inflammatory drug that has been developed as an oral paste (containing 5% amlexanox) for the treatment of patients with recurrent aphthous ulceration. Amlexanox can inhibit the formation and release of histamine, TNF-alpha, and leukotrienes from mast cells, neutrophils, and mononuclear cells, possibly through increasing intracellular cyclic adenosine monophosphate content in inflammatory cells.

Aloe vera (AV) is a cactus-like plant that belongs to the Liliaceae family. The pharmacological actions of AV include anti-inflammatory, antibacterial, antiviral and antifungal properties, and hypoglycemic effects. According to a Cochrane review, there is a weak evidence from two placebo-controlled RCTs, using different formulations, that AV may be associated with a reduction in pain in OLP. The amount of active drug substance in AV varies depending also on the age of the plant, the growing and harvesting conditions, the parts of the plant, and the extraction methods used.

Bacillus Calmette–Guerin polysaccharide nucleic acid (BCG-PSN)- A randomized comparative study employing intralesional injections of bacillus Calmette–Guerin polysaccharide nucleic acid (BCG-PSN) (0.5 ml every other day for 2 weeks) and triamcinolone acetonide (10 mg intralesional injection once a week for 2 weeks) showed similar effectiveness.

Curcuminoids have been well known as the major components in turmeric and used as the anti-inflammatory agents for a long time. Two RCTs on OLP have been published. The first study, comparing low doses of curcuminoids (2000 mg/day for 7 weeks) and prednisolone (60 mg/day for 1 week) with prednisolone alone, was withdrawn at the first interim analysis for futility. The second one employing higher doses (6000 mg/ day) showed some benefit particularly during the follow-up.

Hyaluronic acid (HA) is a linear polymer of glucuronic acid, N-acetylglucosamine disaccharide. The main function of HA appears to be in tissue healing, and a variety of mechanisms have been identified. A recent RCT evaluates the efficacy of a topical HA gel preparation (0.2%) in the management of OLP. HA (0.2%) caused just a very transient improvement in patients with OLP.

Lycopene (Ly) is a red-colored carotenoid predominantly accumulated in tomatoes as well as in other fruits and vegetables. Ly has shown some beneficial effects in the treatment of oral cancer, leukoplakia, and oral submucous fibrosis. A recent randomized, double-blind, placebo-controlled study found Ly (8 mg/day) helpful in reducing OLP symptoms.

Thalidomide has the anti-inflammatory and anti-immunologic properties of suppressing T-cell function. Because of its ability to decrease production of TNF-
alpha, thalidomide has been used in the treatment of oral disorders likely to be TNF-alpha driven such as aphthous stomatitis. Their anti-angiogenesis, anti-inflammatory, immune-modulatory properties of thalidomide could be applied in clinical use for the treatment of erosive OLP.[9]

**Surgery** - Surgical excision, cryotherapy, CO2 laser, and ND:YAG laser have all been used in the treatment of OLP. In general, surgery is reserved to remove high-risk dysplastic areas.[3]

**Conclusion**

OLP is considered a lesion with a low risk of malignant transformation to squamous cell carcinoma of the oral cavity, which rates among the ten most common cancers in the world. The five year survival rate of oral cancer is still being less than 50 %, however, oral cancer can be cured, if detected and treated early enough. Therefore, one should emphasize the importance of an early diagnosis of potentially malignant oral lesions; including OLP. A complete clinical evaluation includes a review of any medications that may be a cause of the disease. An overall assessment of the patient’s nutritional and emotional status as well as the elimination of precipitating factors, including traumatic habits and damaged dental restorations, is warranted. These may seem trivial and may rarely be relevant; however, any benefits achieved are significant when compared with a lifelong commitment to topical and systemic medications. Care should be taken when informing patients about these issues to avoid excessive worry that would only worsen the clinical picture.

Abstract

Titanium is an ideal material for use in Prosthodontics mainly due to improvement of techniques for casting titanium and its alloys. To expand the applications of Titanium alloys as dental prosthodontic materials, TiZr Alloy and TAMZ alloy are developed and to improve the physical and mechanical properties of removable partial denture castings. The purpose of this review is to prove that Titanium can be used for casting RPD frameworks because of its excellent mechanical, physical and chemical properties.

Key words – Titanium casting, RPD.

Introduction

Titanium was discovered in England by William Gregor in 1791 and is named by Martin Heinrich Klaproth for the Titans of Greek Mythology. Titanium is a chemical with the symbol “Ti” and atomic number 22. (fig.1). Titanium is a light, strong, lustrous, naturally corrosion resistant, transition metal with a grayish color. (fig.2). Many of Titanium’s physical and mechanical properties make it desirable to be used as Implants and Prostheses. Commercially pure titanium is used for dental implants, surface coating, crown, Removable Partial Denture, Complete Denture and Orthodontic wires.[¹, ²]

CASTING OF TITANIUM RPD FRAMEWORKS

Casting of Partial Denture frameworks were made using Titanium with 13%Cu and 4.5%Ni. Widely used Titanium alloy is Ti-6Al-4V alpha-beta alloy. The only Titanium alloy indicated for casting RPD frameworks is Ti-6Al-7Nb alloy which is developed by Sulzer Brothers Ltd., a Swiss Company.[³, ⁴] (fig.3 & 4)

EVOLUTION OF TITANIUM CASTING

In 1977, as suggested by Beder and Ploger, experimental castings of Titanium for removable partial denture were made by induction melting in vacuum. (fig.5) Waterstat and his associates’ casted dental prosthesis with Titanium alloy containing 13wt%Cu and 4.5wt% Ni. In 1985, Waterstat’s idea of using split chamber argon vacuum arc casting equipment for titanium casting with magnesia instrument was presented. Later, Waterstat along with Mueller et al was involved in the examination of the properties of commercially available investment materials for Titanium at American Dental Association, Chicago. In 1984, Greener and his colleagues at Northwestern University conducted a research to develop titanium alloys with corrosion resistance, biocompatibility and low fusion temperature. In 1985, Greener et al examined the capabilities of two commercial titanium casting machines acquired from Japan, the “TITANIUMER” by Ohara and the “CASTMATIC” by Iwatani. (fig.6) In 1989, Blackman et al presented 90% success rate for a cast titanium removable partial denture pattern based on observation of voids, peripheral irregularities etc., In 1990, Jelenko developed titanium casting equipment called TiCast3000 which uses a helium arc melting or centrifugal rotating system. In 1991, Tamaki
et al examined the effect of two commercial investment materials on the casting accuracy of pure titanium using different types of crucibles.

In a collaborative study at University of Texas by Sutton et al, the porosity of commercially pure titanium removable partial denture frameworks were compared among 5 different sprue designs using digital image analysis of radiographs. Watanabe et al reported on initial work using a NIOM-Baylor experimental pressure difference casting unit to find the optimal operating conditions for producing commercially pure titanium castings. Gilbert and Mante conducted a comparative electrochemical study on high purity polycrystalline and single crystal titanium. In 2001, Kyung Soo Jang and his coworkers compared the castability and surface roughness of commercially pure titanium and cobalt chromium denture framework using visual, radiographic and microscopic methods to find out that the results were qualitatively similar with surface roughness of titanium at 104.43 ± 69.24nm and cobalt-chromium at 133.91 ± 40.92nm. In 2002, Bert.T.Cecconi and Mark.L.Cecconi evaluated radiographically the castability of Titanium removable partial denture framework were technically acceptable for clinical use.

Benefits

Most of Titanium’s chemical, biological and mechanical properties make it desirable as a material for prosthesis.

- Titanium is highly biocompatible due to existence of titanium oxide layers on the metal surface.
- Titanium is relatively inert and has excellent corrosion resistance due to formation of an adherent and highly protective oxide film.
- Titanium is one of the best metals that allows for osseointegration.
- Titanium has greater flexibility and has better accuracy of fit.
- Titanium is a thermodynamically reactive metal.
- Titanium has a tensile strength of between 30,000 and 200,000 lbs. per square inch.
- Titanium alloy contains 6wt% Al and 4wt% V, which doubles its tensile strength relative to commercially pure titanium.
- Titanium has a Yield strength of 170-480MPa and Ultimate strength of 240-550MPa but it is lighter and has low density.
- Titanium is highly stable due to high strength to weight ratio.
- Titanium has a good shape memory effect as it has the ability to recover large strains and dissipate mechanical work without deformation.
- Titanium has non ferromagnetic property so that it can be safely examined with MRI.[6, 7]

Drawbacks

- Lengthy burnout
- Inferior castability and machinability
- Reaction layer formed on cast surface
- Difficulty of polishing
- High initial cost
- Discoloration of titanium surface
- Unpleasant metal taste
- Detachment of denture base resin
- Tendency of plaque adherence to titanium surface[8,9,10]

![Fig.2 – Titanium - corrosion resistant, transition metal](image2)
Fig.3 - Titanium - RPD frameworks

Fig.4 - Titanium alloy indicated for casting RPD

Fig.5 - Removable partial denture were made by induction melting in vacuum

Fig.6 - Titanium casting machines

Conclusion

Titanium and titanium alloys based on their physical, biological, mechanical properties appear to be suitable for constructing RPD frameworks. Use of titanium is ideal in patients who report a history of allergies to conventional metal alloys. With the advent of technology, it has become less cumbersome to fabricate and machine Titanium. Therefore, it can be assumed as a viable alternative to other conventional metals for casting RPD framework.

Non-Lobular Capillary Haemangioma - A Histopathological Variant of Pyogenic Granuloma

Rajesh Elumalai, K.U.Goma Kumar, Sankar Narayanan R, N.Anitha, L.Malathi

1Reader, Department of Oral Pathology & Microbiology, Sree Balaji Dental College and Hospital, BIHER, Chennai, 2Senior lecturer, Rajas Dental College and Hospital, 3Senior lecturer, Department of Oral Medicine & Radiology, Sree Balaji Dental College and Hospital, BIHER, Chennai

Abstract

Pyogenic granuloma is a non neoplastic growth which most commonly seen in the oral cavity. It is a misnomer because the lesion is unrelated to infection and in reality arises in response to various stimuli such as low-grade local irritation, traumatic injury or hormonal factors. This is predominantly seen in the second decade of life. This pyogenic granuloma is also classified under a group of vascular lesion called lobular capillary haemangioma. Here we present a case of a lingual growth from the alveolar mucosa of a young patient which has been provisionally diagnosed as pyogenic granuloma. Later diagnosed as Non lobular capillary haemangioma (LCH) and lesion was excised and follow up was done with no recurrences.

Key words: Non Lobular capillary haemangioma (NLCH) Inflammatory hyperplasia, oral cavity, pregnancy tumor, pyogenic granuloma

Introduction

Pyogenic granuloma is a misnomer, which does not produce a purulent secretion. It was described by Hullihens in 1844, and 1897 by Poncet and Dor. Initially it was called as botryomycosis hominis and latter reffered as granuloma pediculatum, benignum, benign vascular tumor, pregnancy tumor, vascular epulis, crocker hartzell’s disease. It beleived that 1903 croker and 1904 Hartzell introduced the current term and histopathologically it has been termed as haemangiomatosus granuloma by Angelopoulos and cawson suggested granuloma telangecticum due to its higher vascularity. Nowadays it has been termed as Non lobular capillary haemangima and non lobular capillary haemangioma by its varying histology [1][2]

In this article we discuss a case of unusual presentation of pyogenic granuloma histopathologically.

Case report

The young male patient of age 16 came with a complaint of a swelling in the lower left lingual region for the past few months. On intra oral examination a sessile growth of size (3x2x2) cm which increases gradually for the past few months and attained the current size (figure 1 & 2). It was painless and non tender. The surface were smooth and intendeted and non fixed with intact overlying mucosa. The growth is firm and resilient. No bleeding on provocation. The growth is non fluctuant. With a differential diagnosis of pyogenic granuloma, haemangioma, irritational fibroma, peripheral ossifying fibroma, peripheral giant cell granuloma and Epulis. After a routine hematological investigation showing normal values. The lesion was excised and processed for the histopathological diagnosis. The given Haematoxylin Eosin stained shows a para keratinised startifed squamous epithelium with a moderately collagenous connective tissue stroma (figure 3). The vascularity is high with large and varying shaped vascular channels lined by endothelial cells, the endothelium shows increased in thickness of endothelial proliferation. The stroma also shows diffuse infiltration of chronic inflammatory cells.
predominately of lymphocytes. Extravasated RBC are seen (figure 4 & 5). Suggestive of on lobular capillary haemangioma.

**Figure 1 - Intraoral swelling – sessile growth of size (3x2x2) cm in lingual aspect**

**Figure 2 - Intraoral swelling – Lingual aspect**

**Figure 3 (scanner view) - Showing parakeratinized stratified squamous epithelium with underlying connective tissue stroma.**

**Figure 4 (10x view) - Showing numerous vascular channels lined by endothelium**

**Figure 5 (High power view) - Showing increased thickness of the endothelium**

**Discussion**

The pyogenic granuloma has a higher incidence of female predilection. It is a most common gingival tumour with between 26.8% and 32% of all reactive lesions with prevalence in 5% in pregnancy. Aetiology of the pyogenic granuloma was initially assessed as a mycotic infection of horses and later as streptococci, staphylococci, hormonal, minor trauma, and irritation. But later it was suggested that they might occur as a reactive inflammatory process associated with exuberant fibro vascular proliferation of the connective tissue secondary to trauma and infection. It will occur in any age, with the peak in the second to third decade of life. The female predominance is 1.5:1 in the Female- Male occurrence ratio.[2-5]

While the capillary haemangioma it is relatively rare in the oral cavity, especially in oral soft tissues and uncommonly encountered by the dental profession. Hemangiomas are most often recognized at an early age and encountered more frequently in females than males by ratio of 3:1. Vascular malformations occur in equal incidence among females and males. The hallmark of vascular malformations is proportionate growth throughout the life of the individual. The mucous membranes are often involved contiguously with facial port wine stains. Pyogenic granulomas frequently develop within port wine stained skin; this is particularly common with intraoral stains. Physicians must distinguish these non-proliferative enlargements from the proliferating hemangiomas.[6,7]

**Pathogenesis:**

Recent studies have revealed that sex hormones manifest a variety of biological and immunological effects. Estrogen accelerates wound healing by stimulating Nerve Growth Factor (NGF) production.
in macrophages, Granulocyte- Macrophage-Colony Stimulating Factor (GM-CSF) production in keratinocytes and basic Fibroblast Growth Factor (bFGF) and Transforming Growth Factor beta1 (TGF-β1) production in fibroblasts, leading to granulation tissue formation. Estrogen enhances Vascular Endothelial Growth Factor (VEGF) production in macrophages, an effect that is antagonized by androgens and which may be related to the development of PG during pregnancy. These regulatory effects of sex steroids may be manipulated as therapeutic or prophylactic measures in PG.[8,9]

Vascular malformations are localized or diffuse errors of embryonic development. These are also classified as capillary, lymphatic, venous, arterial or a combination of these depending on the clinical and histological appearance of abnormal channels. The most common capillary malformation[6,10]

There are two kinds of PG namely lobular capillary hemangioma (LCH type) and non-LCH type, which differ in their histological features. The pyogenic lesion usually has a pedunculated shape with a tiny stalk. The pathologist often designates the lesion a “capillary hemangioma, granuloma type” or “lobular capillary hemangioma.” It may be difficult to make a light microscopic differentiation between a true hemangioma of infancy and a pyogenic granuloma. However, pyogenic granuloma exhibits immunocytochemical and ultrastructural differences. It is predominantly perithelial, rather than an endothelial tumor.[11,12]

In pyogenic granuloma the presence of blood vessels with different luminal diameter in the lobular area of LCH PG and in the central area of non-LCH PG may be because different pathogenic factors influence their development. It has been observed that foci of fibrous maturation were present in 15% of non-LCH PG but were totally absent in LCH PG. Although it is possible that PG can undergo fibrous maturation, they showed that this happened only in non-LCH PG.[11]

In our case the patient is of young age and correlate with the site of Pyogenic granuloma of provisional diagnosis with no other portwine or vascular anomalies in history. The histopathology also favors the diagnosis of Pyogenic granuloma with a histopathological variant Non Lobular capillary haemangioma

Conclusion

The term hemangioma is used inconsistently, some sources including vascular malformations, others classifying vascular malformations separately. Also, capillary hemangiomas are infrequently seen on palatal mucosa and may easily be confused with different lesions— particularly with chronic inflammatory gingival hyperplasia Dental surgeons should therefore be aware of these risks during diagnosis and management and should take necessary precautions prior to attempts at excision of apparently innocent lesions. Such situation when a clinician is in dilemma, not cognizant with the possibility of this lesion in its unusual site, can be solved by histopathological assessment which remains the most accurate and satisfactory[13-15]

Types and Classification of Nerve Injury- A Review

Jayasri Krupaa R1, Masthan K.M.K2, Aravintha Babu N3, Sona B4

1Reader, 2Professor & Head of the Department, 3Professor, 4Postgraduate, Department of Oral Pathology and Microbiology, Bharath Institute of Higher Education and Research, Sree Balaji Dental College and Hospitals

Abstract

Nerve injuries are the most common conditions with varying symptoms depending on the severity, intensity and nerves involved. Though much knowledge exists on the mechanisms of injury and regeneration, reliable treatments that ensure full functional recovery. The type of nerve injury alters the treatment and prognosis. This review article aims to summarize the various types of nerve injuries and classification.

Key Words: Axonotmesis, Neurotmesis, Neurapraxia, Wallerian degeneration.

Introduction

Nerve injuries are the most common conditions with varying symptoms depending on the severity, intensity and nerves involved. Recovery after any nerve injury is variable. Though much knowledge exists on the mechanisms of injury and regeneration, reliable treatments that ensure full functional recovery. The type of nerve injury alters the treatment and prognosis. This review article aims to summarize the various types of nerve injuries and classification of nerve injuries which is useful in understanding their pathological basis, and to evaluate the prognosis for recovery.

Understanding the basic nerve anatomy is important for the classification and also essential to evaluate the clinical prognostic value. In the CNS and PNS there are three connective tissue layers.

ENDONEURIUM- Individual nerve fibers (single axons) are covered with varying amounts of myelin and then covered by endoneurium.

PERINEURIUM-These individually wrapped nerve fibers (endoneurium) are then grouped into bundles of fibers called fascicles, which are covered by perineurium.

EPINEURIUM- Finally, groups of fascicles are bundled together to form the peripheral nerve (such as the median nerve), which is covered by epineurium.

CLASSIFICATION:

CLASSIFICATION BY TYPE OF NERVE INJURY

ANATOMICAL CLASSIFICATION OF NERVE INJURY

CLASSIFICATION BY TYPE OF NERVE INJURY

There are 3 types of nerve injuries:

1) NERVE SECTION:

Nerve section can be partial or complete, sharp or blunt. They often result from sharp wounds by glass, firearms or knives.

2) NERVE STRENGTHING

Stretching can occur in association with displaced fractures. During traction, the perineurium elongated, the axons and epineurium stretches and tears.

3) NERVE COMPRESSION:

Compression can either be extrinsic or intrinsic. Extrinsic is more common in median nerve injury in the carpal tunnel, ulnar nerve at the elbow. Intrinsic

e-mail : jayasri.krupaa@gmail.com.
compression is caused mainly by the nerve tumor.

There are 2 mechanism of peripheral nerve injury results from compression

Indirect mechanism: acute or repeated prolonged compression may cause vascular stasis with vascular permeability increased and formation of endoneural edema.

Direct mechanism: a direct mechanical damage to the myelin sheath or the axon itself, thus limiting nerve conduction.

**ANATOMICAL NERVE INJURY**

There are 2 main types of nerve injury based on the part involved and classified based on correlation with the EMG finding.

Seddon’s classification⁴

Sunderland’s classification⁵

**SEDDON’S CLASSIFICATION**

Seddon provided a basis for assessment, prognosis, and management of nerve injury. He classified nerve injuries into three categories, neurapraxia, axonotmesis, and neurotmesis.

**NEURAPRAXIA**

It is the least severe nerve injury, caused by transient compression or stretch. Conduction block results in loss of nerve function. Paralysis of muscles is innervated by the nerve. This type of injury will recover completely providing the cause, for example, ongoing compression, is removed. Recovery will take hours to months (average 6-8 weeks)

**AXONOTMESIS**

This is an anatomical interruption of the axon with no or only partial interruption of the connective tissue (endoneurium, perineurium, and epineurium). This type of nerve injury requires regeneration of about 1.5-3mm/day of the axon to the target muscle which is inhibited by scar formation. Wallerian degeneration occurs due to loss of axoplasmic flow. Patients with axonotmesis will require surgical treatment depending on the number of axons disrupted and the extent of scar formation at the site of nerve injury. Axons grow in adults at about 1 inch per month, and the recovery may take weeks- months. In infants, the axon may regenerate more rapidly, and the distance to be covered is much less. When a muscle loses its innervation, the nerve receptors will disappear over a period of 1 to 2 years. This may show neurosurgical intervention because, a repair regenerated too late will not have receptors in the muscles for the regeneration of nerves.

**NEUROTMESIS**

Here the nerve is completely disrupted or so badly disorganized. This is the most severe form of nerve injury. Along with axons all the connective tissue layers of the nerve are disrupted. There is axon degeneration distal to the injury. Neurotmesis may be caused by laceration or high energy traction injuries. In addition ischemia or injection of noxious drugs can cause nerve injury. Recovery can only occur after appropriate surgical repair of the nerve and relies on axonal regeneration. Because mixing and disruption of fibers at the site of the repair results in failure of correct distal connections. So the recovery is either imperfect or incomplete.

**LIMITATIONS OF SEDDON’S CLASSIFICATION:**

All grades of intraneural damage is not distinguished in Seddon’s classification. Lesions classified as axonotmesis have been observed to have variable recovery. This is because variable degrees of damage to the connective tissue layers of the nerve, including the endoneurium and perineurium, as well as the axons are possible without loss of continuity of the nerve trunk.

**SUNDERLAND’S CLASSIFICATION :**

Sunderland in 1951 described 5 degree of nerve injury based on the disruption of the nerve and their continuity with the connective tissue. Mckinnon and Dellonadded⁶ a 6th degree injury to Sunderland’s classification where there was variable degree of nerve injury.

1ST DEGREE - conduction block (neurapraxia)

2ND DEGREE- axonal injury (axonotmesis)

3RD DEGREE-axonal injury with endoneurium injury

4TH DEGREE- axonal injury with endoneurium injury and perineurium injury
5\textsuperscript{TH} DEGREE- axonal injury with endoneurium injury, perineurium injury and neurapraxia.

6\textsuperscript{TH} DEGREE- combination of previous injuries

Correlation between Sunderland, Seddon classification and intact connective tissue

‘+’ intact nerve; ‘-’ injured nerve (not intact)

Discussion

If there is a trauma and signs of a nerve injury then a surgery will be necessary to look at the nerve and if there it has been partly or completely disruption. If there is no wound then it is likely that a “wait & watch” policy will be adopted. Under these circumstances further investigations may be carried out to try and assess the damage to the nerve. There are various investigation method to diagnose the degree of nerve injury; this is done using neurophysiology testing\(^7\) where the nerves are stimulated with an electric current and the speed at which the nerve conducts is measured (electromyography). Neurophysiology tests can distinguish between injuries where axons have not degenerated (neurapraxia) and those where axons have degenerated distally (axonotmesis and neurotmesis). If axonotmesis has affected all the fibers in a nerve then the findings will be indistinguishable neurotmesis. However, in mixed lesion with some fibers intact detection of these will imply that there is no disruption of the nerve trunk. In addition very fine needles may be inserted into an affected muscle and recordings made of the activity in that muscle. Normal nerves can be visualized on MRI although their signal characteristics are not distinct from other tissues\(^8\). A technique called magnetic resonance neurography, which enhances neural tissue on images, was reported by Filler. Modern ultrasound scanners have improved to the extent that resolution is now greater than MRI. Ultrasound is being used increasingly to examine nerves damaged by closed trauma\(^9\). These will help to grade level of injury and can help in treatment planning and giving information on the potential outcome of the injury.

Conclusion

The result of a nerve injury depends on many variables as detailed in this article. The important thing to remember is that nerves take many months to years to repair and recovery. The final result may not be known for two years or more. The purpose of this article is to outline the main types, classification and correlating the nerve injuries to evaluate their clinical value and to improve the prognosis of nerve recovery.

Lymphangioma - A Case Report

Anitha N¹, Masthan K.M.K², L.Malathi³, N.Aravindha Babu⁴
¹Reader, ²Professor & Head of the Department, ³Reader, ⁴Professor & Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

Abstract

Lymphangioma is a benign hamartomatous neoplasm of the lymphatic system with a marked predilection for the head and neck region. Most common location is submandibular region and in oral cavity tongue is commonly affected. Around half the cases are present since birth. Herein we report a case of lymphangioma in 25 year old female. The clinical and histopathological finding of the case with possible etiology, management are discussed.

Keywords - Lymphangioma, Hamartoma, Cystic hygroma.

Introduction

Lymphangioma is a benign hamartomatous neoplasm of the lymphatic system, with a marked predilection for the head and neck region and more commonly occurs in submandibular region¹⁻². Around half the cases are present since birth³. The lesion is assessed in the line with the vessels diameter into: microcystic or capillary, macrocystic or cavernous and hygroma or cystic hygroma⁴⁻⁵. Its prevalence in mouth is rare and is more often situated at the anterior two-third of the tongue; although cases in roof of the mouth, gingiva, mucous membrane, lips and alveolar process have been represented¹⁻⁶⁻⁷. Clinically, its location is superficial, seen as clear and usually grouped vesicles, which may be red or purple because of secondary hemorrhage. The deep lesion are seen clinically as nodular masses of variable color and superficial texture⁵. There are many therapeutic modalities for the treatment of oral lymphangioma. Surgical excision is usually indicated once vital structures are not involved⁴⁻⁸.

Case Report

A 25 year old female patient reported with the complaint of pain and swelling on the right side of the tongue for the past 2 months. Intraoral clinical examination revealed the lesion was present as growth on the right lateral surface of the tongue measuring about 1x1 cm in size, erythematous and sessile in nature. There was no regional lymphadenopathy noted. Clinically such lesion was diagnosed either as hemangioma or lymphangioma. To confirm the diagnosis, an incisional biopsy was performed. The haematoxylin and eosin stained histopathological section of the given specimen showed hyperplastic parakeratinized stratified squamous epithelium with underlying connective tissue stroma (Fig-1). The connective tissue was densely collagenized with moderate cellularity with diffuse dense chronic inflammatory cell infiltrate. Numerous endothelial lined blood vessels and lymphatic channels are seen (Fig-2). Therefore, the histopathological diagnosis confirmed it as lymphangioma.

Discussion

Lymphangiomas are rare inborn malformations of the vascular system that may occur throughout the body with larger predilection for head and neck. Three theories are proposed to explain the origin of Lymphangiomas. The first theory suggests that a blockage or arrest of growth of the primitive lymph channels happens throughout embryogenesis. The second theory says that the primitive lymphatic sac doesn’t reach the blood vessel system, whereas the third theory advances the hypothesis that, throughout embryogenesis, lymphatic tissue lays within the wrong space as a result these cells don’t anastomose efficiently with larger lymphatic vessels, they then provoke areas of lymphatic blockage. Common within the neck region, the anterior triangle of the neck has been indicated because it is the commonest site, primarily bone, trapezius and sternocleidomastoid. The submandibular and salivary gland regions are the more associated areas to lymphangioma development. In oral cavity lymphangiomas occur in the anterior tongue but lip and alveolar ridge and buccal mucosa are involved.

In our case, the lesion is present in the tongue.

The incidence of lymphangiomas has been reportable to vary from 1.2 to 2.8 per thousand newborns. The foremost outstanding sign or symptom of all lymphangiomas is that the presence of a mass. In adult patients, tumor will switch to epithelial cell malignant neoplastic disease. The surface is granular as a result of clear vesicles and color is red or blue as a result of rupture of underlying blood vessels. The deeper lesion could cause higher respiratory tract disorder or incidental trauma at the location and problem in chewing, speech and deformity of the jaws.

Histologically, these lesions are composed of expanded lymphatic channels. These expanded lymphatics will vary in size, relying upon the situation and surrounding tissues and is that the basis for classification consistent with Yaita et al. Relying upon cystic area size, they’re classified as: macrocystic, microcystic and mixed.

Ultra-sonography, CT and imaging scans are often accustomed outline the link of the lesion with the neighboring structures and to assist arrange surgery. The clinical course of the pathology varies from a spontaneously regressive cyst to an aggressively invasive lesion. Spontaneous or traumatic hemorrhage of the cysts is the common complication.

While treatment of lymphangiomas includes surgical excision, cryotherapy, electro surgical procedure, sclerotherapy, steroids administration, embolization, and laser therapy. Surgical excision is the best treatment for lesions presenting localized growth.

Conclusion

Oral lymphangiomas are uncommon lesion occurring at the tongue. Superficial and localized lesion are often treated by conservative approaches like laser therapy, cryotherapy and surgical excision with less relapse rate. Therefore, proper diagnosis is important for proper therapeutic implications.

Identification Validity Early Detection of Child Development Using Indonesian Mch Handbook

Indah Lutfiya1, Irwanto2, Windhu Purnomo1

1Student of Maternal and Child Health Major, Faculty of Public Health, 2Department of Child Health, Faculty of Medicine, 3Department of Biostatistics and Demography, Faculty of Public Health, Airlangga University

ABSTRACT

Children are inevitably essential parts of Indonesian population. Prevalence of children developmental disorders in Indonesia is still pretty high, ranging from 10-18%. In fact, approximately 70% of children with developmental delays are detected without screening. Surabaya is the city with the largest number of Early Childhood Education (PAUD) institutions in East Java, Indonesia. Ministry of Health publish the latest Maternal and Child Health (MCH) Handbook containing a child development checklist. Thus, the purpose of this study is to examine the validity of MCH Handbook as a measuring tool for early detection of child development with Indonesian Pre-Screening Developmental Questionnaire (KPSP) as a gold standard among Early Childhood Education students in Surabaya city. This research was a cross sectional study using diagnostic test design. The population of the study were the children aged 3-72 months in Surabaya city. The sample were selected using multistage cluster random sampling technique, totaling of 400 children. The data were analyzed using Mc. Nemar statistic tests and Kappa Agreement tests. The results showed that there is no difference in the value of development between MCH Handbook and KPSP (p = 1,000). The MCH Handbook was valid with the sensitivity value of 84.5%, specificity value of 96.9% and has a consistency rate of 81.9%. Thus, we can conclude that MCH Handbook is said to be a valid early detection tool for children aged 3 months to 72 months with high agreement value and high sensitivity and specificity. It suggested to health workers to promote the importance of MCH Handbook utilization through social media and Primary Health Care.

Keywords: Child Development, MCH Handbook, Validity

Introduction

Indonesia is one of the countries which has the highest number of population in the world. The number of toddlers accounts for 10% of the total population in Indonesia.1 In 2015, Ministry of Health issued special regulations for health and non-health workers to monitor child growth, including monitoring of gross motor movement, fine motor movement, socialization and independence, as well as speech and language abilities. The child growth monitoring is to perform regularly from children aged 3 months to 72 months. Children with good growth and development in accordance to the age stage are expected to become healthy and productive adults as the state asset, both socially and economically.1,2

The world’s developmental delay rate is around 10%.3 In recent years, there has been about 12-16% in the United States, 24% in Thailand, 22% in Argentina and 13-18% in Indonesia. Surabaya is the city with the highest number of Early Childhood Education in Indonesia. All of them have a risk of developing developmental delay2,3.

The coverage of each Primary Health Service on children under five in Surabaya has decreased since 2015 from 83.58% to 82.54% in 2016. It is in contrast to the fact that in 2010 Ministry of Health expected that 90% of children under five and preschool children be covered by early detection activities1. The unsuccessful attempt on periodic developmental screening is attributed to lack of cross-sector coordination, funding, the provision of Educational Game Equipment (APE) and the stabilization of commitments to implement policies on Stimulation, Detection and Early Intervention of Child Growth and Development (SDIDTK)4.
Most child development disorders are unnoticed at preschool age. In fact, approximately 70% of children with developmental delays are detected without screening. This is due to the absence of obvious symptoms of child development disorders if there is no screening in accordance to standardized instruments. A good screening tool must have the validity, reliability, sensitivity, specificity and suitability to local conditions. To know the quality of the instrument, it is required to test the validity and reliability, while to test the specificity and sensitivity, it is necessary to test the comparison of measuring instruments with gold standard.

In 2015, the government published the latest Maternal Child Health/ MCH Handbook containing a child development checklist. Previously, in 2013 the government issued an Indonesian Pre-Screening Developmental Questionnaire (KPSP). KPSP should only be used by health workers. To assess KPSP, someone requires special skills, unlike the MCH Handbook which can be read and used by parents as the first known child. Parents can utilize MCH Handbook as a stimulation guide and for monitoring child development. Hence, this study aims to identify the validity of MCH Handbook as a measuring tool of early detection of child development in Indonesia.

**Materials and Method**

This is a cross-sectional study with diagnostic test design. The study was conducted in Surabaya City from March to May 2018. Research respondents were 400 PAUD children aged 3 months to 72 months obtained by multistage cluster random sampling technique.

Primary data was collected by examining the child’s development status using KPSP and MCH Handbook. The KPSP measurement tool is a translation of the Indonesian version of Pre-screening Developmental Questionnaire (PDQ) which contains 10 questions about the child’s developmental skills, which parents must answer with yes and no answers, which only takes 10-15 minutes. In this study if the answer ‘Yes’ less than 9 suspected the problem (suspect), if the answer ‘Yes’ 9-10 is considered no problem (normal). While based on MCH Handbook, children are normal if not able to answer a maximum of 1 question posed.

Diagnostic tests are carried out by researchers to obtain the sensitivity and specificity of the MCH Handbook. Processing techniques and data analysis using a computer with statistical program and Mc test. Nenar and Kappa’s Agreement.

**Findings**

Table 1 shows that the distribution of child respondents by sex is approximately the same between women (50.8%) and men (49.2%). The most frequently age that encountered during developmental examination was 72 months (25.3%) while at least was 9 months (0.5%). The children age 72-months were easy to find at the educational level such as Kindergarten.

Table 1 shows that the majority of maternal respondents are mature and productive is about 60.8% (age 25-35 years). In terms of education level, the majority of mothers have a fairly high level of education (83.5%). When viewed in terms of employment, the majority of mothers choose to work at home (54%). The choice of mothers to work at home does not indicate a low level of family income. This condition is indicated by 69.5% of families fulfilled in accordance with the Regional Minimum Wage (UMR) in force in Surabaya.

</tr>
</tbody>
</table>
Table 2 shows that the majority of children are normal based on KPSP (82.3%) and MCH Handbook (82.5%). The prevalence suspicion of developmental disturbance is 17.8% based on KPSP and 17.5% based on MCH Handbook. The sensitivity value of MCH Handbook is 84.5% while the specificity is 96.9%. Positive Predictive Value (PPV) calculation is high, 85.7% with Negative Predictive Value (NPV) which is also high (96.6%).

Mc Nemar test is used to compare MCH Handbook with gold standard (KPSP). Table 3 shows that there is no difference in the results of the examinations of the two measuring devices (sig = 1,000; p-value> 0.05). This is indicating that the MCH Handbook can be used to assess the child’s developmental status at home.

From the analysis results in table 3, we can know that the measuring tool MCH Handbook declared valid in measuring the child’s development status. To see how much the consistency of MCH Handbook assessment, Kappa’s Agreement coefficient test was performed. Table 4 shows the agreement between the two measuring devices (sig = 0,000; p value <0.05). The level of agreement on the results of the examination between the two measuring instruments is high (81.9%).

Discussion

Validity of measuring instrument test is defined as the ability of a measuring instrument to distinguish who is sick and not sick. Then this validity can be assessed with sensitivity and specificity. Based on the results of the study, the sensitivity of the MCH Handbook is seen from its ability to correctly identify children who are suspected of deviation in their development. Determination of false positive and negative will impact on health services provided.

Calculation of sensitivity value of measuring tool MCH Handbook classified as high (84.5%). This means that measurements using the MCH Handbook can represent 84.5% of cases of developmental suspicion correctly based on the gold standard. This is because the details of the questions in the MCH Handbook can represent the child’s development status before further diagnosis was made. Each of the details asked has included four aspects of development as set forth in the guidance of SDIDTK.¹

In Korea, Hyo Yun (2011) conducted a study on 226 children by comparing measurements issued in his country, Korean-Ages and Stages Questionnaire (K-ASQ) with Denver II. The result said that sensitivity of 76.3-90.2% was high. Based on the results of the study K-ASQ is feasible to be used to detect the child’s development status in Korean territory.⁸

The results of the study from Glascoe and Bryne (1992) concluded the same thing. According to him, the sensitivity value generated from Denver II is high at 83%. The study was conducted in 104 children ages 3 months to 72 months in five child care centers. Accurate screening will contribute to the necessary early intervention measures in children with suspected developmental impairment. Research in the Arab region conducted by Ansari and Bella (1998) revealed that the developmental pre-screening tool adopted from the DDST revision showed high sensitivity. Adoption is done by translating the points of development aspects that are asked in accordance with the ethnic and cultural conditions in Arabia.⁸³⁹

Dhamayanti (2006) from Bandung city, Indonesia less agree with the results of research. The sensitivity of the measuring instrument is moderate 60%. This is because the use of tools is not worth it. Similarly, Kadi (2008) who studied 85 children aged 12-14 months with a history of Low Birth Weight (LBW) in Bandung for one month in February to March 2008. The result said that sensitivity of the measuring instrument by 63%²⁰¹¹.

Calculation of specificity value of MCH Handbook measuring instrument is high (96.9%). This is due to the details of the question to assess the child’s development in the MCH Handbook according to the general condition of the child in the field so that the child is able to perform and execute the instruction easily. In addition, more or less questions asked have been based on the KPSP so that the details of the question difference are not too great. The results are supported by research of Artha (2014) on 133 toddlers aged 6-60 months in Yogyakarta, Indonesia.¹⁰¹¹,¹²

The result of research proves that MCH Handbook measuring instrument is valid with high agreement level (81.9%). The value of this high agreement is supported by the result of the assessment of normal child development status resulting from KPSP and MCH Handbook also tend to be the same i.e. 82.3% and 82.5%. The advantages of this study shows that this research was conducted on general population of children under five years’ age range 3 months to 72 months, not limited to toddlers with high risk factors such as some previous research. The selection of such research subjects is more appropriate in the context of the use of both devices as a means of screening. In addition, the location of the study does not lie in slum areas that are prone to experience developmental delays due to lack of stimulation. Field observations show the items that the MCH Handbook asks are likely to be easily answered or can be done by normal children in general, so the agreement obtained tends to be high.¹⁰¹¹,¹²

The value of the agreement of a high measuring instrument is supported by Artha, et al (2014). Furthermore, research conducted in the Tehran region by Shahshahani, et al (2010) states that the Persia version of the developmental expedition screening guidelines adopted from Denver II has good validity and reliability in detecting child development status when compared with Ages and Stages Questionnaire (ASQ). The study
was then followed up by Kazemnejad (2011) in Tehran in children aged 4-60 months. However, Marjolaine et al (2011) in his research area indicated that the agreement between ASQ and Denver II was high when compared with PEDS\textsuperscript{12,13,14}.

The results of the research in the field was less agree with Kadi (2008) which resulted in the value of a moderate agreement. This is due to the different research area conditions, the number of different research subjects and the tools used are also different. His study was conducted in one place and at one age point, thus less reflecting equality at other ages\textsuperscript{11}.

The disagreement on the results of the examination between commonly used screening tools further indicates the importance of good development surveillance processes. The role of clinician with experience and clinical skills becomes important to capture children who are likely or at risk of developing disorders. Some of the existing screening tools should be used with a good understanding of their respective advantages and disadvantages. Selection of any device should consider the things combined with the suitability of the existing clinical setting.

**Conclusion**

The MCH Handbook was valid as an early detection tool for children aged 3 months to 72 months with high agreement value (81.9\%) and high specificity sensitivity (84.5\% and 96.9\%). Most children were normal according to KPSP (82.3\%) and MCH Handbook (82.5\%). It is recommended for health workers to promote the importance of utilizing MCH Handbook through social media and Primary Health Care.

Feasibility Study of Development in Financial Aspect of Hemodialysis Service in “Y” Hospital in East Java, Indonesia

Johanes Tanzil
Faculty of Public Health, Airlangga University, Indonesia

ABSTRACT

This study aims to analyze the feasibility of development hemodialysis service in “Y” Hospital in East Java based on the financial aspect. Descriptive observational study during June-December 2017. Data collection through interviews with the chief and staff in hemodialysis installation, observation and analysis of secondary data from reports of hemodialysis installations and other data from various sources of installation such as human resources, medical records. The data obtained are then analyzed, then the preparation of the estimated needs of investment funds and funding sources, making projected service revenues, making projected fixed costs and fixed costs, making projected cash flow for the next 10 years, and projected profit and loss 10 years. The development of hemodialysis service in “Y” Hospital from financial aspect analysis is not feasible, but hemodialysis service has benefit tangible and intangible benefit, which may be further investigated if the benefit value is greater. Thus the development of hemodialysis services is still needed.

Keywords: feasibility study, financial aspect, hemodialysis services, “Y” Hospital in East Java

Introduction

Indonesia is one country with a high rate of kidney failure, according to the Indonesian Nephrology Association (PERNEFRI) in The Report of Indonesian Renal Registry, in 2012 there were 16,040 patients with renal failure. Reportedly in 2012 only 9161 patients are active in hemodialysis activities1,2.

“Y” Hospital is a hospital belonging to Government B grade Education in East Java. One of the areas in the hospital that became a priority in the effort to improve the service quality in the hospital is hemodialysis service that has been increasing the number of patients in recent years. The number of patients with kidney failure each year also increased by about 15%3,4.

At the “Y” Hospital, there are still many patients who have not been able to receive hemodialysis services, one of them due to limited number of hemodialysis machines. More than 400 patients with chronic kidney disease undergo hemodialysis in the current “Y” Hospital. Due to the large number of patients with chronic kidney disease, they have to wait a long time to get hemodialysis services, because the number of hemodialysis machines in the “Y” Hospital is very limited ie only 23 machines5,6.

In a day, the average number of hemodialysis patients reached 69-70 people. Hemodialysis patients in “Y” hospitals were largely unhealthy for hemodialysis therapy, due to the large number of patients and the limited availability of hemodialysis machines. Seeing the condition of the “Y” Hospital took the initiative to plan the construction of hemodialysis building, with the addition of hemodialysis machine reached 100 units in 20197,8.

In accordance with the need to develop a hemodialysis unit by planning the addition of a hemodialysis machine at the “Y” Hospital, it is necessary to have a thorough analysis of all matters related to conducting a feasibility study or called feasibility study. One aspect analyzed from the feasibility study is the financial aspect.

Method

Descriptive observational study during June-December 2017. Data collection through interviews with the head of the installation and executive personnel in hemodialysis services; direct observation of hemodialysis service actions, completeness of infrastructure, human resources and equipment in the hemodialysis chamber; retrieval of secondary data from reports of hemodialysis
installations and other data from various installation sources such as human resources, medical records.

The data obtained were then analyzed to see the needs of hemodialysis services in “Y” Hospital through calculation of the number of patients and the number of hemodialysis actions in 2018-2027. In addition, feasibility analysis of the needs of land for buildings, infrastructure, human resources and equipment in accordance with regulation standards of hemodialysis services. Next make an estimate of the need for investment funds and funding sources, make projected service revenues, make projected fixed costs and fixed costs, make a projection of the next 10 years cash flows, and projected profit and loss 10 years to get Net Present Value (NPV) and Internal Rate of Return (IRR). So from these results can be concluded feasibility level of development of hemodialysis service in “Y” Hospital.

**Results and Discussion**

Table 1 shows the number of hemodialysis patients of the “Y” Hospital from 2012-2027 classified as: new patients, elderly patients, stop hemodialysis (drop out) patients, as well as patients on hemodialysis (active).

Source: Data from Hemodialysis Installation in “Y” Hospital

Conducted forecasting with projected 10 years ahead of the number of patients in 2012-2017. The calculation of forecasting used using linear regression method. From the calculation of forecasting, then the data obtained the number of patients and the number of hemodialysis action in 2018-2027. In 2027 it is estimated that the number of regular active patients hemodialysis is 574 patients with an estimated action of 59.727. From the calculation it is found that hemodialysis and bed machines are needed as many as 103 units in 2027.

Machine hemodialysis and bed needed in 2027 as many as 103 units. With the addition of hemodialysis and bed machines, additional buildings for hemodialysis, additional facilities and infrastructure, additional medical and non-medical equipment, and the addition of doctors and nurses with hemodialysis competence are required. The above additions are made through calculations based on the Hemodialysis Service Guidelines.
Calculation of total income projection hemodialysis Installation in “Y” Hospital assumed 100% of patients with Board of National Health Insurance (called BPJS) financing, although in real data obtained 0.1% of hemodialysis patients are general patients. In 2018 the income received by “Y” Hospital from BPJS for one time hemodialysis service is Rp 879,100. It is assumed that there will be a 10% tariff increase every 2 years\(^1\). Then the projection of total revenue in 2018-2027 as in Table 3.

**Note:** 2018* is July until December

Estimated amount of investment cost needed for the development of hemodialysis service in “Y” Hospital is divided into: investment cost of building land, investment cost of infrastructure, and investment cost of equipment. The total cost of land and building investment in the first phase of 2017 is Rp 15,132,320,000, while the second phase of building investment cost in 2018 is Rp 17,000,000,000. The cost of infrastructure investment in 2017 is Rp 2,698,055,000. The cost of equipment investment in 2017 is Rp 4,005,783,520. So the total investment cost required is Rp 38,836,158.520.

The cost calculation in this feasibility study also includes both direct and indirect costs. Estimated direct costs in the hemodialysis installation in “Y” Hospital include: the cost of consumable hemodialysis equipment, the cost of laboratory examination (complete blood, and S/TIBC), the cost of injection erythropoietin and iron injection preparations, the cost of dialysate fluid, the cost of clean water for the hemodialysis process, as well as the cost of medical services for hemodialysis services\(^14,15\). Total direct cost of hemodialysis installation in “Y” Hospital as in Table 4, below:

While the results of financial profit and loss analysis, then obtained Net Present Value (NPV) of (-) Rp 69.002.308.249. Where the Value of Internal Rate of Return (IRR) produces a negative number so can not be calculated when the return of investment funds planned. So it can be concluded that the investment feasibility assessment is not feasible18,19.

Conclusion

The development of hemodialysis services from financial aspect analysis is not feasible, but Hemodialysis service has benefit tangible and intangible benefit, which may be further investigated if the benefit value is greater. Thus the development of hemodialysis services is still needed. In addition the function of the establishment of the Hospital is as a social function, so the development of Hemodialysis services is still needed.

Suggestions for the development of Hemodialysis services at “Y” Hospital are among others: (1) Efficiency effort is needed by negotiating consumable price to the vendor of hemodialysis machine providers, (2) Conducting KSO MOU tools with multiple vendors.
(more than 2 vendors) the opportunity to monopolize the consumable price, (3) It needs to be recounted on the distribution of medical services, so that the hospital gets a rational match between income and financing, and (4) Strives for additional government grants for the development of hemodialysis services, since development indication is a social indication.

ABSTRACT

Pulmonary tuberculosis patients lose nearly 40% of their productive time. This results in reduced productivity if he is the head of the family or productive. In addition, pulmonary tuberculosis patients become highly dangerous transmitters if they do not pay attention to handling the correct cough and being in a location with a high sexual percentage. Likewise, people who are hurt, will have great information, contracting, if any, and very experienced. This study aims to map the grouping of tuberculosis patients and who are at risk of contracting by time rather than looking at the factors that influence it by using poisson regression that address the presence of GWPR over dispersion. The results obtained there are 5 grouping of areas, with the most significant factors of the district plus the ratio of Trenggalek basic health facilities (Z2) and the percentage of school (Z4) and poor population (X1), BTA + (X2), HIV / AIDS incidence rate (X3) incidence of diabetes mellitus (X4), population density (X5) and ratio of health personnel (X6).

Keywords: TB Lungs, Poisson Regression, GWPR

Introduction

Tuberculosis sucks the attention of developing and world governments, as the treatment of pulmonary TB patients takes a lot of money, energy and time. A pulmonary tuberculosis patient requires substantial funds to complete treatment and involves field workers who monitor and take 8 (eight) months treatment even more. This has a negative impact on developing countries that should require funding to advance education, technology and community prosperity1. The economic status is very closely related to TB transmission, since small income makes people unable to live by meeting health requirements. Pulmonary tuberculosis patients with low economic levels find difficulty in meeting the requirements of healthy homes or balanced nutrition, this is in line with the Rosiana2 study, which lists 34.4% of respondents with smear + and resistant to Anti-Tuberculosis (OAT) drugs, derived from economic level below. Kizito et al (2014, p.300) in the Journal of Tuberculosis and Lung Diseases3, wrote in Kampala, Uganda, that there were 100,000 people who had been notified and waiting treatment in 2013 who all lived in slum and densely populated with bad personal hygiene, which is the source of transmission of Mycobacterium tuberculosis. People with HIV / AIDS (Human Immunodeficiency Virus / Acquired Immuno Deficiency Syndrome) are susceptible to contracting pulmonary tuberculosis, this is supported by Mesfin, et al’multi-drug resistant tuberculosis (MDR). Likewise with Diabetes Mellitus, people with DM will experience weakness of the immune system, causing the sufferer to have 3 times more likely to suffer from TB, this is written by Laurentia M, et al4, which within 10 years obtained the results of
DM screening (Diabetes Mellitus) in patients with TB showed a high prevalence of about 5.4% - 44.0%, and otherwise diabetes mellitus as a risk factor to make TB resistant (OR: 1.5 - 8.9). So people with HIV-AIDS and people with DM if they become patients with pulmonary tuberculosis, are highly infectious transmitters.

Bera, dkk\(^3\) writes with low house sanitation in a slum neighborhood in Maharashtra India, making children susceptible to contracting Mycobacterium Tuberculosis. The same thing was written in Fatimah, dkk\(^4\) on the result of his research getting the lighting (OR = 3,286), humidity (OR = 3,202), ventilation (OR = 4,144). Home sanitation contributes to the survival of the Mycobacterium Tuberculosis germ, which is then a source of contagion. Kuruc V., et al. (2014) as well as Grant M (2014) writes in The International Journal of Tuberculosis and Lung Disease\(^5\), in Cape Town South Africa the difficulty of reaching basic health facilities is one factor that makes a person slow to be detected as a tuberculosis patient.

Jacob, dkk\(^3\) writes that the most dominant risk factor is education. To support the global tuberculosis control program, early introduction of pulmonary tuberculosis in primary schools and the use of information media needs to be improved in order to decrease cases and deaths from pulmonary tuberculosis especially in the productive age.

Based on the above explanation, this research would like to see the grouping of regions around Tuberculosis sufferers in East Java Province along with predictor variables that are likely to influence and see good relationship model by using poisson regression analysis.

### Material and Method

This study uses secondary data from East Java Province Health Profile Year 2015 and P2TB Report Year 2015 East Java Provincial Health Office. The first dependent variable was the pulmonary tuberculosis sufferer who was first confirmed as the first patient \(Y_1\) with 6 predictor variables of the percentage of poor families \((X_1)\), BTA + \((X_2)\), the number of HIV / AIDS \((X_3)\), numbers Genesis Diabetes Mellitus \((X_4)\), the percentage of the population density of \((X_5)\) and the ratio of health workers \((X_6)\). \(Y_2\) is a patient with pulmonary tuberculosis determined 3 months later, with 4 predictor variables of healthy house \((Z_1)\), ratio of basic health facility \((Z_2)\), percentage of household PHBS \((Z_3)\), percentage of school population \((Z_4)\) and the layout of the latitude South \((u_i)\) and East longitude layout \((v_i)\).

Data analysis using the following steps:

1. Detecting the presence of multicollinearity on the predictor data \(Y_1\) and \(Y_2\)
2. Looking for the best model of poisson regression from transmitted and infected tuberculosis patient in East Java Province
3. Certainty of overdispersion
4. Looking for the best model from GWPR by looking at the smallest AICc number

### Results

The detection result of non-occurrence of multicollinearity in each predictor of each dependent variable can be seen in table 1

<table>
<thead>
<tr>
<th>Transmitters TB ((Y_1))</th>
<th>Infected TB ((Y_2))</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Variable</strong></td>
<td><strong>VIF</strong></td>
</tr>
<tr>
<td>Percentage of Poor Family ((X_1))</td>

<tr>
<td>Percentage of Population Density ((X_5))</td>
<td>7.721</td>
</tr>
<tr>
<td>Ratio of Health Personnel ((X_6))</td>
<td>2.112</td>
</tr>
</tbody>
</table>

The result of the parameter estimation value reach convergent after the 5th iteration. Furthermore, the simultaneous parameter testing to determine whether there is influence of independent variables to the dependent variable with the following hypothesis:

Table 1: Data Multicolastic Detection
\[ H_0 : \gamma_i^* = \gamma_1^* = \gamma_2^* = \gamma_3^* = \gamma_4^* = 0 \]
\[ H_1 : \text{most no one } \gamma_i^* \neq 0, j = 1, 2, 3, 4, 5 \]

The deviance value in this analysis is 1660.2 and \( c_\alpha((32,0,0)) = 46.1943 \), then reject \( H_0 \) because \( D(\hat{\beta}_{\text{arithmetic}}) > \chi^2(\nu;\alpha) \) so it can be concluded that there is at least one independent variable that has a significant effect on the dependent variable. Partial parameters are then tested to determine the effect of each independent variable.

\[ H_0 : \gamma_j = 0 \text{ (the i-th variable has no significant effect)} \]
\[ H_1 : \gamma_j \neq 0, \text{ (the i-th variable gives significant influence)} \ j = 1, 2, 3, 4, 5 \]

By using MLE method obtained the following parameter estimation:

**Table 2: Partial Test Parameters Poisson Regression In pulmonary tuberculosis contracted with pulmonary tuberculosis source prediction**

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Estimated</th>
<th>Standard Error</th>
<th>Z</th>
<th>P-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \gamma_0 )</td>
<td>6.05500</td>
<td>0.0425600</td>
<td>142.249</td>
<td>0.000</td>
</tr>
<tr>
<td>( \gamma_1 )</td>
<td>-0.00663</td>
<td>0.0003728</td>
<td>-17.789</td>
<td>0.000</td>
</tr>
<tr>
<td>( \gamma_2 )</td>
<td>0.00359</td>
<td>0.0003666</td>
<td>9.778</td>
<td>0.048</td>
</tr>
<tr>
<td>( \gamma_3 )</td>
<td>0.00117</td>
<td>0.0005919</td>
<td>1.975</td>
<td>0.002</td>
</tr>
<tr>
<td>( \gamma_4 )</td>
<td>-0.00131</td>
<td>0.0004171</td>
<td>-3.143</td>
<td>0.018</td>
</tr>
<tr>
<td>( \gamma_5 )</td>
<td>0.0008563</td>
<td>0.0000083</td>
<td>103.708</td>
<td>0.000</td>
</tr>
</tbody>
</table>

Table 2 shows that \( |Z_{\text{arithmetic}}| > Z_{(0.02)} \) where equal to 1.96, so at a significant level 5% reject \( H_0 \) which means variable percentage of healthy homes \( (Z_1) \), ratio of basic health facilities \( (Z_2) \), percentage of households with PHBS \( (Z_3) \), percentage of school population \( (Z_4) \) and prediction \( Y_1(\hat{Y}) \) has a significant effect on the number of people with pulmonary TB infected in 2015. So the poisson regression model obtained is as follows:

\[ \hat{\mu} = \exp(6.055 - 0.007Z_1 - 0.004Z_2 + 0.001Z_3 - 0.001Z_4 + 0.0009(\hat{Y}_1)) \]

The increase and decrease of the number of lung tuberculosis patients infected with \( Y_1 \) per district/city in East Java Year 2015 depends on the coefficient value of each influencing variable. Further examination of overdispersion cases in the Poisson regression model presented in table 3

**Table 3: Overdispersion Inspection**

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Value</th>
<th>db</th>
<th>Value/db</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deviance</td>
<td>1660.2</td>
<td>32</td>
<td>51.88</td>
</tr>
</tbody>
</table>

Table 3 shows that the deviance/db value of 51.88 is greater than 1 so it can be concluded in the poisson regression model the number of infected pulmonary tuberculosis patients with \( Y_1 \) per district/city in East Java 2015 overdispersed.

The next step to get the GPR model is to determine the point of coordinates of latitude and longitude at each location, calculate the euclidean distance, and determine the optimum bandwidth value based on Cross Validation (CV) criteria. The next step is to determine the weighting matrix with the kernel function.

The weighted matrix obtained for each location is then used to form the model, so that different models are obtained at each observation location. Estimation of GWPR model parameters is presented in table 4 below:

**Table 4: Parameter Model Estimation of GWPR**

<table>
<thead>
<tr>

</tr>
<tr>
<td>( \gamma_4 )</td>
<td>-0.16109</td>
<td>0.36839</td>
</tr>
<tr>
<td>( \gamma_5 )</td>
<td>-0.38866</td>
<td>0.48457</td>
</tr>
</tbody>
</table>

Modeling the number of pulmonary tuberculosis patients infected with in the District / City of East Java Province using the Geographically Weighted Poisson Regression (GWPR) approach is temporarily a better model when compared to the Poisson regression model.

The hypothesis testing of the GWPR model consists of two tests, namely the GWPR model conformity test and the parameter significance test of the GWPR model. Here are the results of hypothesis testing GWPR model:
H₀: \( \gamma_i(u, v) = \gamma_k; k = 1, 2, \ldots, 38 \) (There is no significant difference between the poisson regression model (global) and the GWPR model)

H₁: There is at least one \( \gamma_i(u, v) \neq \gamma_k \) (There is a significant difference between the poisson regression model (global) and the GWPR model)

Table 5: Table of Conformity Testing of GWPR Model with Adaptive Gaussian Weighing

<table>
<thead>
<tr>
<th>Source</th>
<th>Deviance</th>
<th>DOF</th>
<th>Deviance/DOF</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global model</td>
<td>1.660.164</td>
<td>32.000</td>
<td>51.880</td>
</tr>
<tr>
<td>GWR model</td>
<td>281.060</td>
<td>6.661</td>
<td>42.192</td>
</tr>
<tr>
<td>Difference</td>
<td>1.379.104</td>
<td>25.339</td>
<td>54.427</td>
</tr>
</tbody>
</table>

Table 5 shows that the deviance/dof difference of 54.427 and \( \chi^2_{(26; 0.05)} = 38.8851 \), then reject \( H_0 \) because it can be concluded that in the model the number of pulmonary tuberculosis patients is infected with \( Y_i \) per district/city East Java The year 2015 is GWPR

Next is the partial test of GWPR model parameter significance to find out which parameters significantly influence the number of infected pulmonary tuberculosis patients with \( Y_i \) in each observation location. The hypothesis used is as follows:

\( H_0: \gamma_i(u, v) = 0 \)

\( H_1: \gamma_i(u, v) \neq 0; i = 1, 2, \ldots, 38; k = 1, 2, \ldots, 5 \)

With a significance level (α) of 5%, \( t_{(0.025;26)} = 2.055 \). Predictor variables that influence significantly on each location of observation with bandwidth size = 3 can be seen that all observation locations identified variables that significantly affect all districts/municipalities in East Java Province.

Discussion

There are several variables that indicate the relationship of almost no correlation that meets the poisson regression requirements. Percentage of poor and average of school population variable in each district in East Java.

Predictor variables that significantly influence each location of observation with bandwidth size = 3, it can be seen that all observation locations significantly identify the variables that affect in all districts in East Java province grouping 5 areas. Being a reference for the treatment of pulmonary tuberculosis.

Conclusions

Based on the results of the analysis and discussion, it can be concluded that the GWPR model is more appropriate to analyze pulmonary TB patients in East Java because it has a smaller AIC value. The dominant factor in influencing pulmonary tuberculosis in all districts in East Java is the most significant factor except Trenggalek district ratio of basic health facilities and percentage of school population and poor families, BTA +, HIV/AIDS incidence rate, incidence of diabetes mellitus, population density and power ratio health. Influencing pulmonary tuberculosis patients in 5 districts/cities in East Java.

Influence of Attitude Toward Behavior and Subjective Norms in Predicting Intention to Provide Healthy Foods on Child Stunting Under Five Years Old

Muhammad Sudrajad1, Mochammad Bagus Qomaruddin1, Ira Nurmala1

1Department of Health Promotion and Behavior Sciences, Public Health Faculty, Airlangga University, Surabaya

ABSTRACT

The immediate cause of child stunting under five years old was lack of food intake and infectious disease\(^{(3)}\). Providing healthy food on child stunting has been shown to influence the growth of body height\(^{(1)}\). This study aims to determine the effect of attitudes toward behavior and subjective norms in predicting intention of caregivers to provide healthy foods on child stunting under five years old. This research was an observational analytic with cross sectional design. The study was conducted on 137 caregivers of child stunting under five years old in Tuban District. Data were collected by interviews using questionnaires.

Data analysis was using cross tabulation to know the frequency of behavioral beliefs, evaluation of behavioral outcomes, attitude toward behavior, normative beliefs, motivation to comply, subjective norms, and intention to provide healthy food on child stunting under five years old. Then data analysis using logistic regression to know the influence of attitude toward behavior and subjective norms in forming intention to give healthy feeding on child stunting under five years old.

The results obtained that most of caregivers have supportive attitude toward behavior, strong behavioral beliefs, strong evaluation of behavioral outcomes, weak subjective norms, weak normative beliefs, strong motivation to comply, and strong intention. Attitude toward behavior has strong influence on intention forming to provide healthy foods. Attitude toward behavior was the strongest predictor in forming intention to provide healthy foods on child stunting under five years old. Recommendation of this research was to provide counseling on the social environment of caregivers, especially to grandmother related to nutrition and child stunting.

Keywords: Attitude Toward Behavior, Subjective Norms, Intention, Healthy Foods.

Introduction

Malnutrition was a condition of inadequate food nutrition substances that entered to the body. Malnutrition occurs in many developing and poor countries. One of the most common forms of malnutrition was stunting. Child stunting under five years old was a long-term manifestation of malnutrition that can lead to decrease learning ability, increased risk of degenerative disease, poor health and reduced productivity.\(^{(1)}\)

Prevalence of child stunting under five years old in Indonesia in 2013 reached to 37.2%. This number was increased when compared to 2010 and 2007 prevalences. Tuban district was one of the areas in Indonesia with high prevalence of child stunting under five years old. In 2016, prevalence of child stunting under five years old in Tuban district has reached 28% of all child under five years old in Tuban district.\(^{(2)}\)

The global target of handling child stunting under five years old problem was decreased 40% prevalences of child stunting in the world. Framework for action to address this problem were by providing complementary food with high diversity in child stunting, and consumption foods from animal source. It was proven to increase linear growth in child stunting.\(^{(1)}\) The immediate cause of child stunting under five years old due to insufficient dietary intake, and infectious diseases.\(^{(3)}\) The majority of mothers in Tuban district have not provided healthy food to their child stunting, it will worsen the
nutritional status of children. This condition can be caused by food insecurity at the household level, and poor feeding practices. Children who do not get enough nutrient intake will be disturbed in growth. A girl with stunting status will grow into a mother with a short body structure, and then will increase the risk of offspring from this mother will have low birth weight that became one of the factors causing stunting problems in children. Therefore, it takes effort to break the chain of child stunting from mothers who have a history of stunting. The efforts to improve nutritional status of child stunting under five years old were by providing healthy feeding consumption to child stunting every day.

Intention was strong predictor of behavior. Intention to implementation of behavior was assumed to be a follow-up based on beliefs to carry out the behavior. Intention to carry out the behavior can be influenced by attitudes toward behavior, subjective norms, and perceptions of behavioral control. Therefore, this study aims to determine the effect of attitude toward behavior and subjective norms in predicting intention to provide healthy food on child stunting under five years old.

Materials and Method

This research was an observational analytical study with cross-sectional design. The research location was conducted in working area of Puskesmas Singgahan in Tuban District, East Java, on December 2017 until April 2018. The sample in this study was 137 caregivers of child stunting under five years old.

The independent variables in this research were subjective norms and attitudes towards behavior. Then for the dependent variable was intention to provide healthy food on child stunting under five years old. Subjective norms were measured using normative beliefs and motivation to comply indicators, then attitudes were measured using behavioral beliefs and evaluation of behavioral outcomes. All data were collected through interviews using a questionnaire guide.

Behavioral belief was a belief about the implementation of behavior associated with positive or negative feelings to execute it. Based on Table 1, it could be seen that most of caregivers have strong behavioral beliefs. It was means that the caregivers believe by providing healthy foods to child stunting under five years old was good behavior. Performing the healthy feeding behavior to child stunting can provide adequate nutrients for the child daily activities. A pregnant woman belief that eating a healthy balanced diet behavior will ensure getting all nutrients for their health, ensure have a healthy baby, because the baby getting all the nutrients it needs. The strong beliefs of caregivers were motivated by good knowledge of nutrition. Most of the caregivers of child stunting under five years old receive nutritional information through health service posts in each village at working area of Puskesmas Singgahan.

Evaluation of behavioral outcomes was assessed of the outcome of a behavior. Most of caregivers have strong evaluation of behavioral outcomes. It means, by providing healthy foods to child stunting
will be beneficial for the health of children. Adequate consumption of vegetables and fruits with high diversity were very recommended as part of healthy diet.\(^8\) The caregivers of child stunting have explained that giving healthy feeding to child stunting can improved their health status, maintain and increase the immunity of children, making the growth optimally, can be used as learning healthy food consumption early, and can increase knowledge and ability for the caregivers to process healthy food.

Attitude toward behavior was define as the degree to which a person has a support or not support evaluation or an appraisal of the behavior outcome in a question.\(^5\) The equation to measure attitude toward behavior as below:

\[ A_g = \sum b_i e_i \]

Score of attitude toward behavior was obtained from the sum of behavioral belief multiplied by evaluations of behavioral outcomes.\(^5\)

Based on table 1, most of the caregivers have support attitude to give healthy feeding behavior on child stunting under five years old. This supportive attitude suggests that the majority of caregivers have a positive perception to provide healthy feeding behavior. Providing dietary education can improve the attitudes toward healthy feeding behavior on children.\(^9\) The caregivers have a supportive attitude toward healthy feeding on child stunting, because of getting information from mother who have provided healthy feeding, and feel the benefits to the health status of her child.

Attitudes toward behavior have a significant influence (p-value 0.000 < \(\alpha\) 0.05) on the intention to provide healthy feeding on child stunting under five years old. This finding was similiar to the study by Dermot et al which aims to promote the selection of healthy food consumption for people with health problems. The results of this study indicate that attitude toward behavior was the strongest predictor affecting intention in food consumption.\(^10\) So it's necessary to designed a program that aims to improve the positive attitude toward behavior of someone to be able to carry out the behavior.

Normative Beliefs was a beliefs about whether each referent in social environment approves or disapproves to provide healthy feeding behavior on child stunting.\(^6\) Based on table 1, it could be seen that most of the caregivers have weak normative belief to provide healthy feeding. It means that the social environment of caregivers did not approve to provide healthy feeding on child stunting. The social environment of caregivers was comes from grand mother, husbands, neighbors, or health workers in health services. A child stunting that living with grandmother will experience delayed initiation of breastfeeding, discarding colostrum, and delayed introduction of complementary feeding.\(^11\) The amount and frequency of foods to be given to child stunting by grandmothers was inappropriate. Grandmothers have an important role in decision making by caregivers in feeding behavior on child stunting.

Motivation to comply was define as motivation to do what each referent or groups thinks about behavior.\(^6\) Most of caregivers have strong motivation to comply with their social environment. Caregivers will tend to follow what their social environment think or did, in this case to provide healthy feeding on child stunting. Most of caregivers will follow the grandmother’s recommendation in child feeding practice. Majority of caregivers more follow the grandmother’s opinion and suggestions in childcare activities and less in household work, like keeping the child clean, and playing with the child.\(^11\) A study in rural Gambia revealed that presence of maternal grandmother was more influential in decision making of feeding practice to child.\(^12\) Respecting and following the opinions of grandmother or older people was a culture for people living in the village. The grandmother or older person was considered to have better experience and knowledge in carrying out the feeding practice on child. So the majority of caregivers living in the village will follow what the grandmother suggested in feeding practice on a child, including child stunting.

Subjective Norms was an assessment of the extent to which important others would approve or disapprove of performing a given behavior.\(^5\) In this study, the majority of caregivers have weak subjective norms for implementing healthy feeding behaviors in child stunting under five years old. It means that most of them didn’t approve performing healthy feeding behavior on child stunting, because of the influence of their social environment factor that didn’t approve performing healthy feeding behavior on child stunting. In a study of the influence of grandmother in child care in India explained that grandparents provide an important role in feeding their grandchildren, but usually the role of
grandparents in general was provide unhealthy food for their grandchildren. Grandparents were often discussed as one of the main drivers of unhealthy child food conditions, but in some efforts to increase the consumption of healthy foods for child under five years old, the role of grandparents was often ignored. Weak of subjective norms due to influence from the opinion of grandparents who didn’t approve to provide healthy feeding on child stunting. Most of Grandparents assume that child stunting was not a nutritional problem, but it was due to heredity. So if a child stunting given healthy feeding every day, it will not affect with the nutritional status of child stunting. The equation to measure subjective norms as below:

$$SN = \sum n_i m_i$$

Based on the equation, score of subjective norm was obtained by summing the result of multiplication between normative beliefs and motivation to comply.

Based on table 2, it could be seen that subjective norms has no significant influence (p-value 0.192 > α 0.05) on intention to provide healthy feeding behavior on child stunting under five years old. The same results of a study conducted at the University of Parma, Italy which explains that subjective norms did not become a significant predictors of intention to eating novel food products containing insect flour.

Intention was the core construction in carrying out a behavior. The possibility of behavioral performing will be increased if it has a high intention to perform the behavior. Intention was assumed to be follow up based on beliefs to perform a behavior. Intention was influenced by three main components, such as attitude toward behavior, subjective norms, and perceived behavior control. Most of the caregivers have strong intention to perform healthy feeding behavior on child stunting under five years old. The intention to perform healthy feeding on child includes intention to pay attention the type of food, the frequency of eating, the suitability of child’s age with the foods, and provide high diversity foods to child stunting.

**Conclusion**

The result of the study found that most of caregivers have support attitude (61%) to give healthy feeding behavior on child stunting under five years old. But most of caregivers have weak subjective norms (81%) to give healthy feeding behavior on child stunting under five years old. Attitudes toward behavior have a significant influence (p-value 0.000 < α 0.05) on the intention to provide healthy feeding on child stunting under five years old. Then, subjective norms has no significant influence (p-value 0.192 > α 0.05) on intention to provide healthy feeding behavior on child stunting under five years old. Recommendation of this research is to provide counseling on the social environment of caregivers, especially to grandmother related to nutrition and child stunting.

Employees’s Perspective on Istawa Basic Value in Lamongan Muhammadiyah Hospital

Nuriyati
Department of Health Policy and Administration, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Human resources are the most important part of the hospital. Lamongan Muhammadiyah Hospital makes an organizational culture which called ISTAWA as the foundation of employees in serving patients. This study aims to determine the level of knowledge and understanding of employees to the ISTAWA basic value in Lamongan Muhammadiyah Hospital. This survey conducted from August to November 2016 and involved 84 employees of Lamongan Muhammadiyah Hospital. Research instrument through questionnaire. Data analysis was done descriptively. This study shows that most (67%) of employees do not know the ISTAWA basic value. Information about the value obtained by employees from direct supervisors (76%), regular unit meetings (10%), SDI 7%, and Director (7%). Understanding the meaning to the ISTAWA basic value from employees of Lamongan Muhammadiyah Hospital which is the highest lies in the aspect of sincerity. This research recommends that the management of Lamongan Muhammadiyah Hospital make socialization program and internalization of the ISTAWA basic value to all employees so that the value can be an organizational culture that is implemented in every services to patient.

Keywords: Employees’s Perspective, ISTAWA Basic Value, Organizational Culture

Introduction

Human resources becomes an important asset in an organization such as a hospital. Human resources as an actor because it plays a role in the implementation of policies and operational activities in the hospital. Effective human resource management can provide valuable capital so that patients get the best service. Each founder of the hospital must grow the basic values to all employees to form an organizational culture. Organizational culture serves as a foundation for employees in providing excellent service to all patients.

Observable organizational culture is referred to as organizational behavior. Organizational behavior affects the performance of employees in providing services to patients. If the organizational culture is successfully built, then the performance of employees in serving patients will be more optimal. Organizational culture is a strategic aspect to be studied in an effort to increase patient satisfaction.

Lamongan Muhammadiyah Hospital organizes organizational culture along with the owner of the foundation along with the manager. The values made refer to Muhammadiyah guideline and missionary journals by previous founders and aktivists of Muhammadiyah. The set base value is known as ISTAWA.

The value dissemination program has been done by Lamadah Muhammadiyah Hospital management with the hope that corporate value can serve as the principal foundation in every employee action so that organizational culture is expected to be created. Internalization effort of value of ISTAWA must be implemented comprehensively so that the implementation process can be successful. This study aims to examine the level of knowledge, understanding and implementation results of the internal effort of ISTAWA basic values in Lamongan Muhammadiyah Hospital.

Method

This research is an observational study with cross sectional design. This study lasted for 3 months, from August to September 2017 in Lamongan Muhammadiyah Hospital. This research is based on...
survey through questionnaires to 84 employees of Lamongan Muhammadiyah Hospital.

Determination of the respondents randomly or simple random sampling. The research questionnaire was also tested on the validity and reliability of the Jemursari Islamic Hospital in Surabaya due to consideration of the context and the homogeneous situation with the research location. The research variables include knowledge, understanding and result of implementation of effort of internalization of ISTAWA base value in Lamongan Muhammadiyah Hospital. The process of data analysis is done descriptively.

Results and Discussion

Overview of ISTAWA basic value: The base value is the criterion, standard, or principle used to determine behavior, reflecting the belief that determine what should and should not be done. The value formulated by Lamongan Muhammadiyah Hospital is expected to be owned by all employees. Lamongan Muhammadiyah Hospital started from the beginning of January 2013 and determined that the base value is formed from the acronym word of ISTAWA. Once the base value is selected by the managers and owners of the hospital, the Director determines the underlying value and makes a simple definition of each predefined base value. No code of conduct has been made from the base values. The basic value is taken from the acronym word ISTAWA in the form of itqon, istiqomah, ikhlas, shobru, tartibu, and waqtihi. This value has a sense that is translated again in accordance with organizational culture.

<table>
<thead>
<tr>
<th>Itqon</th>
<th>Human resources have competence according to applicable professional standard and carry out activities according to the latest science development</th>
</tr>
</thead>
<tbody>
<tr>
<td>Istiqomah</td>
<td>Health services are carried out continuously based on the worship of the teachings of Islam, always follow the progress of science and make improvements and innovation in a sustainable manner according to customer needs</td>
</tr>
<tr>
<td>Ikhlas</td>
<td>Providing safe, effective, and friendly service for pleasing Allah</td>
</tr>
</tbody>
</table>

Changes in organizational culture are necessary because of cultural adjustments to address organizational challenges, change environments and achieve organizational goals more quickly. For that to be conducted a discussion involving members of the organization especially those who bring impacts as drivers of change such as owners, directors and managers.

Relation of basic values and organizational culture: The result of survey of organizational culture of Lamongan Muhammadiyah Hospital at employee level that the culture that is currently being applied in Lamongan Muhammadiyah Hospital is hierarchical culture, whereas the culture which become the expectation of Lamongan Muhammadiyah Hospital employee is clan culture. Measurement of OCAI culture is done to determine the steps in conducting Measurement of OCAI culture is done to determine the step in doing effort of internalization of ISTAWA culture in Lamongan Muhammadiyah Hospital so that approach and program can refer to expectant culture of Lamongan Muhammadiyah Hospital, Clan.

The things needed to support the change of organizational culture type from hierarchical organizational culture to group organizational culture is a formal statement of organizational philosophy, mission, vision, values and materials in the process of recruitment, selection and socialization; role models or role models for employees, training programs, teaching, and guidance by managers and supervisors; Commitment and employee participation to seek ways of organizing and managing to gain competitive advantage.

Employee knowledge of ISTAWA basic value: Based on the results of the questionnaire about the level of knowledge of employees about the baseline value and then made a comparison of the level of knowledge about the basis of service units and non services as shown in Figure 1.

### Table 1: ISTAWA Basic Value

<table>

<td>Providing health services in accordance with professional standards or established procedures</td>
</tr>
<tr>
<td>Waqtihi</td>
<td>Providing health services in accordance with the schedule or time set</td>
</tr>
</tbody>
</table>
Figure 1: Employee Knowledge Level

Figure 1 shows the level of knowledge of Muhammadiyah Hospital Lamongan employee to the basic value ISTAWA still low. As many as 67% of employees stated not know. Based on the results of questionnaires on information sources about ISTAWA's stability can be seen in Figure 2.

Figure 2: Information Source of ISTAWA

Figure 2 shows the largest role holder in the socialization program is from the direct supervisor. This can be a capital in the effort to internalize the basic value of ISTAWA, it is expected that the boss can be a role model for the employees with the level of office below. To analyze further factors affecting the process of planting the basic value of ISTAWA in Lamongan Muhammadiyah Hospital needed analysis of each of ISTAWA's own basic values, the type of organizational culture that has been established and expected in Lamongan Muhammadiyah Hospital as well as preparing the grand design effort to build the ISTAWA culture in Muhammadiyah Hospital.

Conclusion

This study concludes that knowledge and understanding of the meaning of employees to the basic value ISTAWA not comprehensive. Therefore, the recommendation of this research is Muhammadiyah Hospital management Lamongan need to arrange socialization program and internalization of basic value of ISTAWA to all employees so that the value can become organizational culture that implemented in every service.

Determinant of Waste Causes in Outpatient and Inpatient Rooms of Surabaya Islamic Hospital

Puryanti

Master Program in Hospital Administration, Universitas Airlangga, Indonesia

ABSTRACT

Hospitals as healthcare providers are demanded more competitive in the era of national health insurance. Therefore, the hospital faces the challenges of improving the quality of health services by using available resources. The study aims to identify waste in outpatient and inpatient rooms of Surabaya Islamic Hospital. The descriptive study involved 90 patients from outpatient and inpatient rooms. The study found waste by defect category, waiting time, non-utilize talent, transportation, inventory, motion, and extra processing based on business process analysis. Category of waste over production not found. The causes of the occurrence of waste most comes from the man, material, and method factors. Program recommendations include scheduling patient-based arrival of service group, visita scheduling and polyclinic service and temporary payment method change, for inpatient program program consisting of 5R program implementation, rearranging standard operating procedure of patient’s diet information, improvement of prescribing system for patient and standard operating procedure rearrangement return of insurance patients.

Keywords: management, waste, effectivity, efficiency, health service

Introduction

In the era of National Health Insurance, competition in healthcare business is increasingly competitive so hospitals are increasingly striving to improve the quality of services through effective and efficient resource management. Hospitals in the face of competition are required to always ensure the level of effectiveness and efficiency at each stage of the service process in order to be able to produce superior service quality, ensure patient safety, and use appropriate resources by minimizing cost.

Source: medical record

During 2015-2017, the percentage of patients with BPJS increased from 63.5-81% of general patients. The challenge facing hospitals in the face of increasing BPJS patients is the efficiency in managing hospitals without necessarily reducing the quality of patient care. If the hospital does not perform efficiently well it will greatly affect the financial of the hospital. Another problem faced by Surabaya Islamic Hospital is the decline in hospital profit margin for three consecutive years, since 2015-2017.

The decline in profit margin causes hospitals to work to improve the efficiency of health services by implementing lean hospital management. Therefore, this
study was conducted to identify waste in outpatient and inpatient of Surabaya Islamic Hospital.

**Method**

Descriptive study with cross sectional design was conducted in September-October 2017 at Surabaya Islamic Hospital. 90 patients from outpatient and inpatient selected by simple random sampling, to be involved as respondents. Data obtained through in-depth interviews, observation and documentation.

**Results and Discussion**

**Business process and waste analysis in outpatient:**
The outpatient room of Surabaya Islamic Hospital is under the Head of Medical Services, included several poly such as maternal and child health, dental, early detection clinic and child growth, physiotherapy, and specialists poly

The report on service quality indicators in outpatient is well achieved. The waiting time is less than 30 minutes according to predefined standards. The waiting time calculation begins when the patient is called for an examination and action from a specialist until the patient is completed and goes to the investigation or goes to the pharmacy unit to take the drug. The wait time calculation illustrates how long the service delivery process is by doctors and nurses who are part of the processing time. Some hospitals, outpatient service waiting times are set when the patient completes the registration until he/she receives a doctor’s service\(^4,5\).

Observation of outpatients without disaggregating general patients and BPJS patients and not distinguishing patients with investigational and nonprivileged patients. Observations were performed on patients in general poly, surgical poly, interna medicine poly, poly neurons, ENT polymers and obgyn poly. Observations have been made since the patient arrives until the patient returns, starting with the patient coming in, picking up the queue number, filling out the medical record file request form, waiting for the registration, registering, waiting to get the doctor’s services, obtaining services and acting, conducting investigations in the laboratory and or radiology, make payments at the checkout and take drugs in the pharmacy unit. Activities carried out by such patients, will be described further in the value stream mapping chart in the outpatient unit\(^6\).

<td>Double drug between UDD and prescribing from doctor</td>
</tr>
<tr>
<td>Waiting time</td>
<td>Waiting for confirmation from the insurer</td>
</tr>
</tbody>
</table>

Waste motion, the movement that should not be done by the officer when looking for medical record documents, due to the arrangement of files that are not neatly arranged\(^9\). Waste inventory, ie the food of the patients presented is not eaten by the patient because the patient has gone home or out of hospital\(^7\). Waste extra processing, which is the existence of a double drug patients because doctors prescribe medication prepared by pharmacy with UDD program. Waste waiting time, which is waiting for the administrative process for patients with insurance payment guarantee, diakeranakan verifier of the insurance\(^10\).

**Business process and waste analysis in inpatient ward:** The inpatient room has 111 bed facilities with 6 units Muzdalifah room, 10 units Shofa room, 6 units of Tan’im room, 18 units of Mina room, Marwah room 9 units, Marwh room 6 units, Multazam room 12 units, Arofah 8 units, Ismail Hijr room or 21 units bnak room and Zam-Zam room or nursery 10 units.

During the study, observation of inpatient services in Marwah and Hijr Ismail rooms was conducted. Observations included patient flow, inpatient status file flows, and staff flow in the inpatient unit. Activities carried out by the patient will be described further in the value stream mapping chart in the inpatient unit. All patient service activities are presented in Table 4.

**Conclusion**

The study found waste by defect category, waiting time, non utilize talent, transportation, inventory, motion,
and extra processing based on business process analysis. Category of waste over production not found. The most likely cause of waste occurrence is due to man, material, and method factors. Recommendation programs offered in outpatient room, including scheduling patient-based arrival of service group, visite scheduling and polyclinic service and temporary payment method change, for inpatient program program consist of implementation of 5R program, re-arranging standard operating procedure of patient’s diet information, improvement of prescribing system for patients and re-arrangement of standard operating procedure for the return of insurance patients.

Satisfaction Assessment on Healthcare Service of COB Healthcare Social Security Agency Patient in Hospital X

Rike Mia Novita¹, Ernawaty, drg.¹
¹Faculty of Public Health, Universitas Airlangga, Indonesia

ABSTRACT

Background: Coordination of Benefit (COB) is a process of two or more insurers who warrant the same person for the same health insurance benefit. COB Healthcare Social Security Agency patient’s visit has been increasing in the last 3 years but the percentage of healthcare services utilization was below the normative standard (10.4%). This research aimed to assess satisfaction of COB Healthcare Social Security Agency patient in Hospital X.

Method: This research conducted on 28 respondents as the research sample which visited the outpatient unit in Hospital X. This was descriptive analytic research with cross sectional design.

Results: Research result showed that reliability and assurance indicator of COB Healthcare Social Security Agency patient in Hospital X satisfaction categorized as bad while in tangible, empathy and responsiveness indicator categorized as good or the patient satisfied.

Conclusion: Research result showed that Hospital X should increase the satisfaction of health services in reliability and assurance of COB Healthcare Social Security Agency patient. The result could be used as an evaluation related to the healthcare service utilized by the COB Healthcare Social Security Agency patient in Hospital X. Research from this research hopefully could increase the visit and utilization of healthcare services by the COB Healthcare Social Security Agency patient in Hospital X.

Keyword: Coordination of Benefit, healthcare, hospital, patient satisfaction, utilization

Introduction

Coordination of Benefit (COB) is a process of two or more insurers who warrant the same person for the same health insurance benefit(1). Healthcare Social Security Agency is an agency which managed the national health insurance in Indonesia(2). Hospital X already cooperated with the Healthcare Social Security Agency since 2014. Healthcare Social Security Agency already applied Coordination of Benefit (COB) with private health insurance (commercial insurance) since 2015. Hospital X has been cooperating with a few of company which warrant COB Healthcare Social Security Agency since 2015. COB Healthcare Social Security Agency patient’s visit has been increasing in the last 3 years from 10 visits become 95 visits. The visit increasing did not mean that the utilization of the healthcare services also increase. Percentage of COB Healthcare Social Security Agency patients showed in Table 1.

Based on Table 1, it showed that visits of patients from company with COB Healthcare Social Security Agency increased in 2017 but the utilization of healthcare services in ER, Outpatient Unit, and Inpatient Unit categorized as low. The low utilization indicator in accordance with the result of Riskesdas (Basic Health Research)(3) which showed that 10.4% Indonesian citizen in 1 month utilize outpatient service, and 2.3% utilize inpatient service. This research aimed to assess satisfaction of COB Healthcare Social Security Agency patient in Hospital X.

Method

This was descriptive analytic research with cross sectional design. This research conducted in Hospital X in January until May 2018. Sample taken was 28 respondents with purposive sampling technique. Respondent of this research was patient which have been utilize the healthcare services in Hospital X. Instrument used in this research was questionnaire. Data collected will be analysed descriptively.

Result and Discussion

Indicator of the satisfaction assessment of COB Healthcare Social Security Agency patient in Hospital X including reliability, assurance, tangibles, empathy and responsiveness. The score of each indicator shown in Table 2.

Based on Table 2, showed that 50% COB Healthcare Social Security Agency patient in Hospital X evaluate reliability and assurance indicator of the health care service provided in the hospital categorized as bad while on tangibles, empathy and responsiveness indicator categorized as good.
Result of the research showed that reliability of the healthcare service provided by the hospital categorized as low. Reliability is one of the component which influenced the achievement of patient satisfaction(4). Among all the indicators, reliability is an important indicator. The poor result of reliability assessment could be one of the factors caused the low visit of COB Healthcare Social Security Agency patient in Hospital X.

Assurance is one of manifestation of behaviour and medical ethics of healthcare workers(5). Patient who have good impression of a healthcare by the healthcare workers would make a visit to that healthcare facility. The COB Healthcare Social Security Agency patient in Hospital X mostly stated that they could not meet the doctor freely to consult on their health issues. Patient who feel their health is guaranteed and will have good services on health care have great impact towards their visit and satisfaction(6). Patient who gets more time to meet and consult with a doctor will feel more satisfied(7).

Facilities and infrastructure in a healthcare facilities affect the assessment of service quality and patient satisfaction(5). Result showed that on tangible indicator assessment which including hospital’s facilities and infrastructure categorized as good. Only a few patient rate bad in tangibles indicators, they feel that some of hospital facilities still need some improvement.

Empathy in this research defined as modesty and giving more attention from the healthcare workers and other workers in the hospital. Result from this research showed that the empathy of the healthcare workers categorized as good. However, empathy is not always directly affect the patient satisfaction(8).

Responsiveness also one of the important component which affecting service quality and patient satisfaction in healthcare services(5). Component which provide services in hospital not only healthcare workers, but also the supporting workers in hospital. In this research, supporting workers which assessed by the patient was the administration staffs. Administration staffs who were responsive and have good empathy will increase the patient satisfaction(9).

**Conclusion**

Research result showed that reliability and assurance indicator of COB Healthcare Social Security Agency patient in Hospital X satisfaction categorized as bad while in tangible, empathy and responsiveness indicator categorized as good. This result could be used as an evaluation related to the healthcare service utilized by the COB Healthcare Social Security Agency patient in Hospital X.

Need and Demand for Eye Health Services: Experience from Surabaya

Umi Nur Khasanah

Department of Health Policy and Administration, Faculty of Public Health, Universitas Airlangga

ABSTRACT

Introduction: Healthcare institutions should take into account the needs of the community for the services provided to be effective. The research aims to find out the needs and needs of the public on eye health services in Surabaya.

Method: A survey involved 59 respondents from Wonokromo, Gayungsari, Jemursari, and Darmahusada in May of 2017. The research instrument was a questionnaire. Data analysis using descriptive statistical test.

Results: The research indicates that respondents need eye health services include good and professional services (27.10%), friendly human resources (32.20%), complete laboratory (39.00%), information system (44.10%), willingness to use (79.70%), good service system (37.30%), unreliable human resources and cost and distance factors respectively 28.80%, staff counseling (54.20%), treatment (76, 30%), puskesmas (30.50%), clinics (16.90%), taking medicine (36.00%), Eye Hospital in Undaan (37.00%), close to home (20.00%).

Conclusion: The study recommends that survey results can be used as a reference for hospital management in developing eye health services in line with community expectations.

Keywords: needs, demand, eye health service

Introduction

Each individual will strive to achieve the best health status by investing and consuming a number of health goods and services. So to achieve a good health condition is needed good health facilities as well. Viewed from an economic perspective, health is a determinant factor in the low quality of human resources. The microeconomic theory of demand for health care services states that prices are inversely proportional to the number of health service requests. This theory says that if health care services are normal good, the higher the family income the greater the demand for the health services. Conversely, if these types of health services are inferior good, increased family income decreases the demand for these types of health services.

Health factors are not inferior goods, because the higher the level of wealth will increase access to health care services. Other factors that tend to increase access to health care services are the age and number of health problems suffered. Health factors are closely related to the quality of human resources itself. The high quality of human resources is determined by health status, education and income level per capita. In the economic activities, the three indicators of human resource quality indirectly will also impact on the high level of human resource productivity, in this case especially labor productivity.

Healthcare services consist of two types: modern and traditional health services. Modern health care services are services that provide health services based on modern medical science, including private and government healthcare services. Health services must be felt by all levels of society and able to improve public health status. Then health services must also meet several requirements, including in accordance with the needs of users of the service and assured quality (accessibility, affordability, quality assurance).

Ronald Andersen et al. divide the factors that determine the utilization of health services into three predisposing factors, namely the tendency of individuals in using health services that are determined by a set of variables such as demographic conditions (age, gender, marital status), social circumstances (education,
race, family number, religion, ethnicity, occupation), emerging attitudes/beliefs (towards health services, labor, community behavior on health and ill health); supporting factors are factors that indicate an individual’s ability to use health services, as indicated by variables of family income sources (family income and savings, insurance or other sources of income, types of health services available and affordability of health services in terms of distance or service prices) the existing power in the community as reflected in the availability of health including the type and ratio of each service and its health personnel to the population, then the price of adequate health services and in accordance with their ability; the need factor is a factor that indicates an individual’s ability to use health services as indicated by the need for strong reasons such as the approach to perceived illness and the answer to the disease by seeking health services. Service to a disease is part of the need.

Laksono mentioned that there are several factors that influence the demand for health services, namely physiological needs, personal health status, tariff economic variables, community income, health insurance and health insurance, demographic and age variables, and gender. Surveys of needs based on needs and demand for eye health services in communities in the city of Surabaya were conducted to determine the needs and needs of the public on eye health services in the city of Surabaya.

Method

A survey involved 59 respondents with the criteria of living in the city of Surabaya and a minimum age of 17 years. Research respondents came from Wonokromo, Gayungsari, Jemursari, and Darmahusada areas. The survey was conducted in May of 2017. The research instrument was questionnaire and asked on the respondent. Data analysis using descriptive statistic test through frequency distribution table to know the need and demand of eye health service for Surabaya city population.

Results and Discussion

Characteristics of respondents: A detailed description of the sociodemographic picture of respondents can be seen in Table 1.

Table 1 shows that most of the respondents were female (69.50%), worked as private employees (49.20%), had recent education from undergraduate (45.80%), earned 1-5 million in a month (57.60%), have insurance (76.30%), type of insurance from health insurance (97.77%).

Needs Analysis: The respondent’s need for eye health services is assessed based on several indicators, consisting of the need for services, human resources, completeness, facilities and infrastructure, the willingness to use the service, the reason for trust, the reason for mistrust, the type of information, the first action at the time of illness,
selected referral sites, first-time eye acts, ophthalmological services, and reasons for the selection of eye health services, are presented in Table 2.

</tbody>
</table>

Table 2 explains that the majority of respondents expect to receive good and professional services (27.10%), friendly human resources (32.20%), complete laboratory (39.00%), information systems (44.10%), willingness to use health services eye (79.70%), good service system (37.30%), unreliable human resources, cost and distance factor (28.80%), counseling officer (54.20%), treatment (76.30%), public health center (30.50%), clinics (16.90%), taking medication (36.00%), Undaan Eye Hospital (37.00%), close to home (20.00%).

Based on the results of the survey can be concluded that the need for eye health services vary. The condition is influenced by several factors. Previous studies explain the factors that affect the needs of a society is the geographical conditions, the needs of people living in the village is different from the needs of people living in the city; civilization, the higher the civilization the higher the quality of goods needed; customs, community traditions affect the needs of society.

**Demand Analysis:** Respondent’s demand for eye health services is assessed based on several indicators, consisting of morbidity, general illness category, illness, history of healing, willingness to move to another health service, symptoms of eye diseases.

Table 3: Description of Respondent’s Demand

<td>23</td>
<td>39.00</td>
</tr>
</tbody>
</table>

Table 3 shows that most of the respondents were ill (93.20%), flu and dementia category (47.00%), illness in the last 3 months (47.50%), choosing a doctor (33.90%), (83.10%), had a desire to move to another health facility (78.00%), had symptoms of red and itchy eyes (39.00%).

Similarly to demand, demand is also influenced by various factors such as consumer income, the intensity of consumer needs, tastes or habits, the price and availability of related products, the price of the goods themselves; total population; future price forecasts; income distribution; producer efforts to increase sales.

**Conclusion**

The tendency to seek health care solutions for the first time by visiting general practitioners. Tariff is a major consideration in determining the choice of health services. The first health-care institution is the Undaan Eye Hospital. Easy access to information is a top priority for non-medical services. The services of specialist doctors are a major requirement in hospitals. Expected tariff is reasonable tariff in accordance with the services provided from the respondents who had undergone inpatient treatment, choose a local hospital as an option in health services. Distance is the dominant factor in determining the choice of health services. The results of the previously described survey are part of the initial assessment activities that can be used as a reference for hospital management in developing eye health services in accordance with community expectations.

An Approach of Predisposing Factor to Increase Immunization Coverage

Viko Darma Permana¹, Ilham Akhsanu Ridlo¹, Munif Arifin²

¹Public Health Faculty, Airlangga University, Surabaya, Indonesia; ²District Surveillance Officer, Lumajang District Health Office, East Java, Indonesia

ABSTRACT

Background: Immunization for infants is a national program that should be given to all infants under 1 year of age. However in the last 3 years, coverage of basic infant immunization in Lumajang District still has not reached the target or below than 91.5%. This could be a potential outbreak of the vaccine preventable disease such as diphtheria and measles. Parents as a determinant of health decisions for children are the main actors to be approached by health workers.

Purpose: This study aims to identify predisposing factors that affect mother’s health behavior about immunization and the correlation with completeness of basic immunization.

Method: This is observational analytic study with cross sectional design. The sample was taken by proportionate stratified random sampling method with the sample size is 188 mothers. Predisposing factors in this study are age, number of children, education, knowledge, employment status and children parenting. Data collected using structured questionnaire.

Results: There are 122 children with complete basic immunization and 66 children was incomplete. There are significant correlations between education (P Value = 0.010) and mother’s knowledge (P Value = 0.000) with completeness of basic immunization. There aren’t any correlations between mother’s age, number of children, employment and children parenting with completeness of basic immunization.

Conclusion: Mother’s knowledge is predisposing factors that affect immunization behavior. To elevate achievement completeness of basic immunization, health worker must give enough information about benefit and also risk about immunization with social cultural approach in promoting immunization programs.

Keywords: Predisposing Factor, Knowledge, Immunization

Introduction

Almost all developing countries around the world have to face triple burden disease that is contagious diseases, non-communicable diseases and new emerging disease. Indonesia is also has some health problem to solve. Vaccine preventable disease such as diphtheria, pertussis and measles are still common happened in community. This is because the immunity is not yet established in the community.

Immunity is obtained from vaccination to some or all communities. Immunizations begin from infancy to adulthood to prevent people get ill from some vaccine preventable disease. The 0-1 year period is a period in which infants should be given 9 kinds of vaccine at certain intervals in accordance with the national program later called as basic immunization.

In the last three years, Lumajang district didn’t reach their target to make herd immunity in all villages. Immunization withdrawal are still occurs. Some issues were emerged such as health worker performance, stakeholder support and parents decision about
immunization. Parents are the ultimate decision makers and they responsible for all of their child’s health efforts.

Mother as a person closest to her child becomes an important factor in efforts to improve the completeness of basic immunization of infants. According to Green (1999) there are 3 factors that can affect people’s health behavior that is predisposing, enabling and reinforcing factor. Predisposing factors are internal factors of a person such as age, gender, education, knowledge, attitudes and values that can cause a behavior to occur.

The purpose of this study is to determine the predisposing factors that cause mother’s behavior in giving immunization to their children. Ages, number of children, education, knowledge, employment status, and baby care are the factors to be studied.

**Materials and Method**

This is observational analytic study with cross sectional design in Lumajang district of East Java, Indonesia. The sample is a mother with at least has one child younger than 3 years old. The sample was taken with stratified random sampling method. A total of 188 mothers became respondents.

Data were obtained from the interviews using a questionnaire. The data were processed using chi-square test SPSS 23.0 to see the frequency and correlation between predisposing factors consisting of age, education, knowledge, employment and parenting status with completeness of basic immunization.

### Results

The result shows that 122 children complete following immunization programs which get 9 type vaccines. 5 children didn’t get any vaccinations because refusal from their parents. Vaccination refusal was found to rely on multiple factors including cultural, emotional, religious, and social issues.[2]

Most immunization withdrawal occurs after the baby gets first, second or third stage DPT-HB-HiB vaccination. This is because some children have a fever after getting the vaccine so the mother decides not to follow the next vaccination interval. There are some mild problems (common) such as fever, redness and soreness where the shot was given. The risk of DPT vaccine causing serious harm or death is extremely small.[2]

Mother didn’t want their children became sick or weak after getting vaccination. Some parents who refuse or delay vaccines worried that their decisions may be putting their child at risk for infection.[4]

**Discussion**

From the table we can conclude that mostly mother is at their adult age to have married and children. In general, woman can think more wisely when they are at adult stage. It’s also show that mostly of them only has 1 or 2 child. They think have less children are good in social and economic. Because if they have more than 2 children, they have to give more attention and also have to spend more money for their daily need. The result shows there are no correlation between ages P value 0.630 (>0.050) and number of children that mothers have P Value 0.463 (>0.050) with completeness of basic immunization.

In education, mostly mother had get a 9 year basic education which is at least they graduate from junior high school. There are correlation between education and completeness of basic immunization with P Value 0.010 (<0.05). Higher their degrees in education, the chance of their children completeness of immunization are increase too. In line with others study, the association was significant and strongest among children of mothers with the lowest education level and may reflect the challenge of keeping accurate vaccination records when multiple providers are involved. [3]

When mother have enough education, they consider that giving basic immunization as a right choice in maintain and increasing children health. Education about herd immunity and local vaccination coverage could be a useful tool for increasing willingness to vaccinate. [9]

The result show that mostly mother’s knowledge is at intermediate and good level. There is correlation between mother’s knowledge levels with completeness of basic immunization P Value 0.000 (<0.050). These result has the same result with past study that there is a correlation between mother’s knowledge with complete basic immunization in infants. [8][11] Mother’s knowledge about immunization can change their behavior about giving immunization for their children.

Mother gets their knowledge about immunization mostly from health worker such as midwife in village or public health center. Health worker must give information equally between benefit and risk of immunization. Parents need information about risks of vaccination as well as the components and effectiveness of the vaccines, and that they would like to receive more detailed scientific information. [7]

Most mothers do not have a job with a percentage of 75.53%. They spend their entire time in home while caring their children. This is in line with the result that most mothers take care of their own children (82.97%) and the rest of mothers who have jobs entrust their children to parents or in-laws to care for their children during their work.

There is no correlation between employment status P Value 0.631 (>0.50) and parenting status P Value 0.266 (>0.050) with completeness of basic immunization. Others study state that there is few associations were found between parental employment and up to date vaccination status. [3] Even mother has a plenty time with children, it doesn’t change the behavior of mother about giving immunization to their children. Children who are cared by their own mother have an almost equal opportunity to get complete basic immunization or not.

**Conclusion**

Education that has been taken by the mother became one of the primary factors on how mother’s thinking. The more complex something like immunization, they will try to get more information and knowledge about it before they make a decision. Health worker must provide the right information to them about benefit and risk of immunization so that it can increase the chance completeness of basic immunization.
In the other hand, mother’s knowledge should be improved through health promotion efforts with a more personal approach so that knowledge of mothers increases and also can improve the positive attitude of mothers against immunization.

The Application of Lesson Study in Education of Stunting Prevention

Kasmita1, Nur Indrawaty Lipoeto2, Ali Khomsan3, Mudjiran4, Hardisman5
1Student of Doctoral Program of Public Health Sciences, Faculty of Medicine, University of Andalas, Padang; 2Public Health Faculty of Andalas University Padang, Indonesia; 3Bogor Agricultural Institute, Indonesia; 4State University Padang, Indonesia; 5Faculty of Medicine Andalas University of Padang

ABSTRACT

Background: The concept of Lesson Study (LS) has been used in the field of educational science. In the time being, Lesson Study is a concern in the health sector, due to health problems, especially stunting, which enable it to be prevented through education, especially education for mothers of toddler. This is an important factor to educate mothers of toddler with good use of lesson study. The purpose of this article is to summarize previous studies of the literature on Lesson Study, which is based on learning education for adults with applications that might be applied in educating these adults. It is hoped that the education provided through lesson study may help in improving the knowledge and attitudes of mothers of toddler in the purpose of stunting prevention efforts.

Method: The method used is by finding the keywords likes: education, andragogy, Lesson Study application techniques, health promotion, and media and adult learning methods.

Finding: 128 articles are reviewed and then the data extracted to: (1) reveal reasons for implementing Lesson Study, (2) identify the benefits of Lesson Study, (3) describe facilitators and obstacles to implementing Lesson Study.

Conclusion: Lesson Study includes: analyzing community needs about what they need to know, planning learning, community training/education sessions, communication technology, process mapping and reflection. So from that the health sector in the application of Lesson Study with the opportunity to analyze their needs for learning, designing the strategies used, implement and evaluate the Lesson Study system needs to be conducted. While further research needs to be done about the best way to do this lesson study so that it is applied to the health sector, especially in educating the public so as to provide a basis for preventing stunting.

Keyword: Lesson Study, Education, stunting.

Introduction

Health problems that have not been resolved until now one of them is stunting. The National Team for the Acceleration of Poverty Alleviation noted that there were several obstacles in the implementation of stunting prevention, including: the limited capacity and quality of program organizers, the limited number of health workers and the lack of competency in implementing programs1. In addition, there is still a lack of advocacy, campaign, and dissemination related to stunting and prevention efforts.

In general, people do not realize the importance of nutrition during pregnancy and the first two years of life. The Minister of Health, Antara (2017) explained that: “Women must increase their knowledge about nutrition, so that they can prevent cases of stunting in children or stunting. The nutrition education program that has been carried out in the form of counseling and counseling is felt to be ineffective. This happens because learning/counseling is done on a monologue basis. Monologue learning has not involved students directly in the learning process it self2.
Education for adults (toddlers' mothers) is very important. This is very possible, because adults are part of the community who will take strategic decisions in the family. Education carried out aims to change the mindset of society towards nutrition and health, so as to be able to change people’s attitudes in preventing stunting.

Education or learning in adults is a specific one. According to Makarao (2009) and Kartono (1992), adult learning is assumed that, the more mature students are, then: 1) self-directed behavior and mutual learning, 2) their learning orientation changes from mastery of material to problem solving abilities, 3) mastering ability in carrying out real life tasks, 4) requires self involvement in planning, implementing and evaluating learning (problem centered-orientation)²³.

The activity of planning the learning process, one of which can be done with lesson study. Lesson studies have developed in Japan since the early 1900s. In the 1970s the Japanese government benefited from konaikenshu and since then the Japanese government has encouraged schools to implement konaikenshu by providing cost support and incentives for schools that implement konaikenshu. The reason why lesson study in Japan is popular is because lesson study is very helpful for teachers. Although lesson study takes time, the teachers benefit greatly from valuable information to improve their teaching skills.

Lesson study not only helps students find their problems in learning, but also finds problems faced by the teacher in delivering material⁴. The advantages of applying study lessons in improving the quality of learning are: 1) Can be applied to all classes both schools and communities, 2) Encourage and assist in overcoming problems in learning, 3) encourage students to be more active in a pleasant learning atmosphere, 4) Participants students help each other in understanding the material, 5) encourage students to think and work as well as possible.

Lesson studies have long been developed in Japan and have been proven to improve the quality of learning. In addition, lesson study can improve communication and teacher competence⁵. Through the application of lesson study in adult learning, especially for mothers of children under five, it is assumed to have a positive effect not only for mothers of children under five, but also for instructors (health workers and cadres). The purpose of this study is to implement effective nutrition education for the community with the lesson study approach to stunting prevention, test the effectiveness of application of Lesson Study (ALS) in educating the public to prevent stunting and to find nutritional education programs to prevent stunting for the community.

Method

Literature Review: Lesson Study is identified by using electronic databases or browsing articles, journals, theses, dissertations and other research related to community health, andragogy, and health promotion. The searches were limited to English and Indonesian articles published from 1970 to 2019. In the literature search, the author read, summarized and summarized the contents of articles or journals independently, to identify themes to fit the theme written. Most articles are presented in the form of research, case studies, grounded theory or research methodology. Articles that have been collected, identified, and used to support the basic ideas of this study.

Result

Through 128 articles collected, after identification, 32 articles were obtained that did not meet the criteria, leaving 67 articles used in expressing, (1) reasons for implementing Lesson Study in the community, (2) identifying the benefits of Lesson Study, (3) describing the facilitator and obstacles to implementing Lesson Study.

Reasons for applying Lesson Study: Health efforts sourced from the community cannot be separated from public education. Low parental education has a greater risk of malnutrition status compared to highly educated parents⁶. The nutrition education program that has been carried out in the form of counseling and counseling is felt to be ineffective. This happened because learning/counseling carried out by health workers was carried out on a monologue basis. Monologue learning has not directly involved the community in the learning process itself. It is necesssurytano to find a solution in the process of nutrition education to the community. Behavioral problems that often arise in adult education programs, namely, get new things, arise incompatibility (feeling bored), grandiose theory (difficult to practice), new recipes/instructions (independent), not specific and difficult to accept changes ⁷.
Adults have a tendency to orient themselves toward solving life problems. Because learning for adults is a need to face problems in life. Before learning to the community begins, it must be planned in advance. Planning is an effort to involve the community in the learning process. The activity of planning the learning process, one of which can be done with lesson study. Lesson study not only helps students find their problems in learning, but also finds problems faced by the teacher in delivering material. The advantages of applying study lessons in improving the quality of learning are: 1) Can be applied to all classes both schools and communities, 2) Encourage and help in overcoming problems in learning, 3) encourage students to be more active in a pleasant learning atmosphere, 4) Participants students help each other in understanding the material, 5) encourage students to think and work as well as possible.

The community needs to be empowered in teaching the community itself. This is in accordance with the concept of lesson study, where learning is done by including from planning to evaluating the effectiveness of the learning provided. Lesson study carried out has a cycle that includes planning (plan), implementation (do) and reflection (see). The success of lesson study is not a person’s achievement in a moment, but is a result of the collaboration of many parties. This means that lesson study applied in the nutrition education process is a collaborative effort between health workers, cadres and the community, with the aim of improving the quality of nutrition education, which is carried out on an ongoing basis.

Lesson study applied in adult learning has a positive impact, because collaborative learning fosters enthusiasm for learning because there is involvement of participants in the learning process. Teachers can always conduct evaluations on each process that has been carried out. This can improve teacher competency. In addition, by implementing lesson study in learning provides a positive effect for teachers and students.

Lesson study can help improve the quality of learning. In this dissertation concept, the principles of lesson study are used to find the problems faced in providing nutritional learning to the community, help find solutions to those problems, plan how best to implement the solution and evaluate the implementation of learning that has been planned together between the community, staff health and cadres. Combining learning models and lesson study in nutritional learning in the community, is expected to be able to concretize effective learning/prevention of stunting.

Through the stages in lesson study, the community together finds what material they need so that they know about nutrition, parenting and healthy living habits. While health workers and cadres were helped to find out what material should be given, how the strategy for delivering the material, so that collaboration between the community, health workers and cadres was formed. A distinctive feature of learning in adults is learning together with colleagues, finding problems faced and solving problems together. Learning that is based on needs will foster interest in knowing about nutrition, parenting and healthy living habits. If community interest has grown, it is expected that there will be an increase in nutritional knowledge, changes in attitudes and healthy behavior in the community.

**Solution and Strategy: Implementation of Lesson Study in Formal Classes**

Lesson study is a process of learning implementation which consists of several stages in Mulyana, mentioning there are four stages in doing lesson learning, namely: 1) Analysis Phase (identification), 2) Planning Stage, 3) Implementation Phase, 4) Reflection Stage.

**Picture 1: The Lesson study Cycle**

1. **Analysis Phase (identification):** Planning begins with setting learning objectives, analyzing the needs and problems faced in providing education.
2. **Planning Phase:** Get around the lack of learning facilities, and collaboratively find solutions in solving problems faced by teachers in providing education in the classroom.
3. **Implementation Phase:** At this stage there are two activities, namely the implementation of
Learning activities carried out by one of the agreed instructors or at one’s own request to practice the learning plan that has been compiled together and observation activities carried out by other instructors acting as observers or observers.

4. Reflection Phase: This stage was carried out in the form of a discussion attended by all observers in the lesson study implementation activities guided by a facilitator. The discussion starts from conveying the impressions felt during practicing learning. Furthermore, all observers submit comments or suggestions wisely on the learning process that has been carried out supported by evidence obtained from observations, not based on their own opinions. This is done as an effort to improve the learning process going forward.

Application of Lesson Study in Non Formal Classes: In this informal class, it is conducted on very heterogeneous communities. Learning or education is based on the theory of learning in adults (Andragogy). According to Lunandi (1987) and Knowles (1970), the teacher’s own abilities must also be improved, because teaching adults requires strategies and methods tailored to the abilities of adults\textsuperscript{15,16}. Besides the limitations possessed by adults such as the ability to understand a material, feeling bored faster, the limited time available, should be the attention of the teacher in choosing the methods, strategies and media used\textsuperscript{17}.

The application of lesson study to stunting prevention education is oriented towards improving the quality of non-formal learning. Modified the application of lesson study to this educational process. Modifications include the place of study, time of study/duration, participants and instructors as well as the learning environment. The process carried out at each stage of lesson study also undergoes modification, but it is still implemented using the lesson study cycle. If in the implementation of lesson study in class, the more instrumental is the teaching community, namely the teacher lecturer, but in the Lesson Study Application (ALS) the teacher and participants collaborate to achieve the learning objectives that have been set together. In ALS, students are mothers who have stunting toddlers and mothers who have children under five with normal nutritional status. This is intended to fulfill the characteristics of adult learning, which tends to study with peers. In ALS teaching is not a teacher or lecturer, but health workers (health workers) are in charge of providing counseling to the community and posyandu cadres. This is done because health workers and cadres in the health education and promotion program carried out by the government are nutrition counseling staff and have close relations with the community, especially mothers of children under five.

Study of Limitations: The main limitation of this review is that most of the research in English has been included in databases of the social sciences and humanities. There is also another disadvantage is the consistency of research design included in the review using different methodologies.

Conclusion

There are several obstacles in the implementation of the acceleration of stunting prevention, including: Limited capacity and quality of program organizers, limited number of health workers who provide counseling to the community. Besides the limited number of health workers, the government is also faced with the problem of lack of competency of officers in carrying out the program (WHO, 2018)\textsuperscript{1}. 5) Still lack of advocacy, campaigning and dissemination related to stunting, and various prevention efforts. The limitation of organizing nutrition intervention programs, has not shown a significant impact in preventing stunting and improving child nutrition. Several studies have been conducted in countries with high prevalence of stunting, such as Peru, Vietnam, Indonesia and Bangladesh, recommending that the importance of a national campaign to encourage public awareness about stunting.

Prevention of stunting itself must get the right response, concrete evidence found the importance of implementing lesson study to educate the public. The advantages of implementing lesson study in improving the quality of learning are: 1) Can be applied to all classes both schools and communities, 2) Encourage and assist in overcoming problems in learning, 3) encourage students to be more active in a pleasant learning atmosphere, 4) Participants students help each other in understanding the material, 5) encourage students to think and work as well as possible.

Lesson study applied in the nutrition education process is a collaborative effort between health workers, cadres and the community, with the aim of improving the quality of nutrition education, which is carried out on
an ongoing basis. In addition, lesson study is a transition and if possible further research must apply this education to make changes in public education.

**Author Contributions:** K leads at the beginning of article search, identification, writing and review analysis. NI leads in the identification of additional articles, analysis, weighting of articles and writing. I give ideas for research, and help compile research designs, revisions and finalizations. M assists in the supervision and revision of research, especially regarding research methodology. H helps in revisions, identification of additional articles, evaluation of articles and rearranged until the end of article writing.

ABSTRACT

Ebola epidemic model threshold value indicates whether the disease will continue to spread in a population or not. However, the accurate value of this threshold is influenced by uncertainty in its parameters’ values which are marred by parameter estimation errors due to procedure, errors in data collection and underlying model assumptions. Understanding the implication of changes in parameters values is necessary in order to guide outbreak control decision. Next generation matrix approach was used to determine the basic reproduction number of SVEQHIFR Ebola epidemic model. In assessing the influence, direction, and strength of relationship parameters to Ebola basic reproduction number, 1000 simulations run for LHS/PRCC procedure was used. Positive or negative sensitivity indices of the threshold value to parameter changes indicate that control measure should be intensified in reversing or enhancing these indices. This information can gauge implementation of interventions strategies in the attempt to decelerate Ebola disease transmission.

Keywords: Ebola, uncertainty analysis, sensitivity analysis, basic reproduction number

Introduction

Ebola outbreak infected over 28,000 and killing nearly half the number infected in West African region. It spread to more than 5 countries (Guinea, Liberia, Sierra Leone, Nigeria Mali and Senegal) in the region, adversely affecting Guinea, Sierra-Leone, and Liberia¹. Epidemic models’ parameters are more-or-less uncertain and outcomes of model fits are themselves uncertain as due to several factors. An important static parameter value that shows if a disease outbreak will stop or not, is the basic reproduction number. It is defined as average number of secondary infections caused by a single infectious individual during its entire infectious lifetime in a fully susceptible. As different diseases have different values, so do different methods are used to determine this parameter². Though there are alternatives to this parameter³-⁵, the basic reproduction number has been widely used to analyze its sensitivity to changes in its parameter changes to interpret growth of epidemic in order to gauge prevention and control. Ebola is known to have threshold value ranging from 1.2 to 2.8 in the affected countries⁶-¹⁰. Performing uncertainty and sensitivity analysis upon this model threshold is important for determining influential parameters of Ebola virus disease transmission. Sensitivity indexes will help identify whether a small change in any of the model parameters will lead to a greater or lesser effect in the increase or decrease in Ebola transmission or prevalence.

This study is divided into four sections, section one provided the review and background of the problem. Section two considered the Ebola transmission model used to determine the threshold parameter, the basic reproduction number. The third section performed local and global uncertainty and sensitivity analysis of Ebola basic reproduction number to its parameters, finally the conclusion.

Ebola Transmission Model: The model considered for this investigation is a nine compartmental deterministic epidemic model, intended to model Ebola disease,
following which has caused at least 14 confirmed outbreaks in Africa between 1976 and 2006. Using data from two epidemics in Democratic Republic of Congo (DRC) we developed SVEQIHFR for Ebola epidemic, in which the population is divided into susceptible, susceptible-quarantined, vaccine, asymptomatic exposed and quarantined, nonisolated and isolated symptomatic infectious, safely removed dead and recovered individuals. The model is depicted in Figure 1.

The ordinary differential equations of the Ebola growth model is

\[
\begin{align*}
\frac{dS}{dt} &= -(1-\gamma)\lambda S - \gamma L S - \lambda S - \xi S \\
\frac{dV}{dt} &= \lambda S - (1-\eta)\lambda V \\
\frac{dE}{dt} &= (1-\gamma)\lambda S + (1-\eta)\lambda V - (\chi + \alpha_1)E \\
\frac{dQ}{dt} &= \gamma_1L + \chi E - \alpha_2 Q \\
\frac{dI}{dt} &= \alpha_1 E - (\theta_1 + (1-\theta_1)\delta_1 + (1 - \delta_1)\gamma_1) I \\
\frac{dH}{dt} &= \alpha_2 Q + \theta_1 - (\delta_2 + (1 - \delta_2)\gamma_2) H \\
\frac{dF}{dt} &= -(1-\theta)\delta_1 I + \delta_1 I, F \\
\frac{dR}{dt} &= (1-\theta)(1-\delta_1)\gamma_1 I + (1-\delta_1)\gamma_2 H + \gamma_2 F \\
\end{align*}
\]

The process of disease transmission and transition among compartments starts with a susceptible individual becoming infected through contact with infectious individuals. Susceptible individual enters into the latent class at a rate \(\lambda S\). Among the infected individuals (\(S\)) a fraction \(\gamma\) will be quarantined (Q) at the early stage of infection. A fraction of exposed individuals (1 - \(\gamma\)) who are not quarantined at the beginning of infection will be quarantined at a constant rate \(\chi\) throughout the latent period. Susceptible individuals are vaccinated at a rate \(\xi\). Effectiveness of immunization is assumed to be \(\eta\) where 0 \(\leq\) \(\eta\) \(\leq\) 1 that is vaccine effectiveness ranges from imperfect to perfectly effective vaccination. Proportion of susceptible individuals upon whom vaccine is not effective is exposed to infection at a rate \(\lambda(1 - \eta)\). Non-quarantined and quarantined individual progresses to infectious stage at constant rates \(\alpha_1\) and \(\alpha_2\) respectively. Proportion of infectious individuals \(\theta\) will be isolated at a rate \(\gamma_1\), non-isolated infectious individuals die and are removed through safe burial at a rate \(\delta_1(1 - \theta)\gamma_1\). The non-isolated infectious survivors are removed at a rate \((1 - \theta)(1 - \delta_1)\gamma_1\). Hospitalized individual die and are safely buried at a rate \(\delta_2(1 - \delta_2)\gamma_2\) but they recover at a rate \((1 - \delta_2)\gamma_2\). Cadavers from community and isolated centers are safely buried or removed at a rate \(\gamma_2\).

With the force of infection defined as, 
\[
\lambda = \frac{\beta_1 I + (1 - \rho)\beta_2 H + (1 - \Psi)\beta_3 F}{N} 
\]

Where \(\beta\) (relative to infectious individuals in community, hospital and funeral) the transmission coefficient, \(\rho \in [0, 1]\) is the fraction of reduction in the transmission rate of isolated with \(\rho = 1\), \(\rho = 0\) and \(0 < \rho < 1\) denotes a completely effective, completely ineffective and partially effective isolation. Fraction of reduction in transmission during safe burial is \(\Psi \in [0, 1]\) with \(\Psi = 1\), \(\Psi = 0\) and \(0 < \Psi < 1\) denoting completely effective, completely ineffective and partially effective safe burial respectively.

\textbf{Ebola Reproduction number (R\(_9\))}: Basic reproduction number (usually denoted as \(R_0\)) is the average number of secondary infections caused by a single Ebola infectious individual during the entire infectious lifetime. Epidemiologists make use of \(R_0\) to gauge control requirement. Since the model SVEQIHFR consists of multiple infective classes, we used the next generation matrix approach, developed by specifically for the most frequently used so-called compartmental models. We present a detailed easy recipe for the construction of the NGM from basic ingredients derived directly from the specifications of the model. We show that two related matrices exist which we define to be the NGM with large domain and the NGM with small domain. The three matrices together reflect the range of possibilities encountered in the literature for the characterization of \(0\), to determine the reproduction number of the Ebola epidemic model. The reproduction number is the dominant eigenvalue (spectral radius) of \((FV^{-1})\) as \(R_0 = \rho(FV^{-1})\). Hence

\[FV^{-1}\]
R₀ = \frac{β₁α₁}{(χ + α₁)(γ₁ + γ + (1 - θ)(1 - δ₁) + γ₂ + (1 - θ)δ₁)}
+ \frac{β₂}{γ₁ + γ₂ + γ₃(1 - δ₂)} + \frac{β₁(1 - ρ)}{(χ + α₁)(γ₁ + γ₂ + γ₃(1 - θ)(1 - δ₂) + γ₄ + (1 - θ)δ₂)}
+ \frac{β₃}{γ₃ + (χ + α₁)(γ₁ + γ₂ + γ₃(1 - θ)(1 - δ₁) + γ₄ + (1 - θ)δ₁)}
+ \frac{β₄(1 - r)}{γ₄ + (χ + α₁)(γ₁ + γ₂ + γ₃(1 - θ)(1 - δ₁) + γ₄ + (1 - θ)δ₁)}
+ \frac{β₅}{γ₅ + (χ + α₁)(γ₁ + γ₂ + γ₃(1 - θ)(1 - δ₁) + γ₄ + (1 - θ)δ₁)}

\text{Sensitivity index of Ebola Transmission Threshold (R₀):} \text{ Performing a sensitivity index will help identify parameters of significant influence on the disease transmission and prevalence. Therefore the normalized sensitivity index of each parameter is evaluated using}

\frac{∂R₀}{∂y_j} = \frac{y_j}{R₀} \frac{∂R₀}{∂y_j}

\text{Using the parameter in values indicated in related study, we determine the sensitivity index of } R₀ \text{ with respect to the model parameters of each country and is provided in Table 2}

\text{Sensitivity Index of Ebola transmission in Guinea:} \text{ The most sensitive parameters of Ebola transmission rate in the Liberian outbreak are the transmission coefficients in the community } β₁, \text{ fatality rate of Ebola in the community } δ₁, \text{ proportion of hospitalized individuals } θ \text{ and hospitalization rate } γ_{IH}, \text{ followed by the average incubation of individuals in the community } α₁, \text{ transmission coefficient in the hospital } β_{IH}, \text{ fatality rate in hospital } δ₂, \text{ transmission coefficient during burial } β₇, \text{ efficiency of isolation } ρ \text{, quarantining of exposed } χ \text{ asymptomatic individuals, rate infectious non isolated or isolated individuals survive } γ₇, \text{ rate non-isolated individuals die and are given safe burial } γ_{IH}, \text{ rate of safe burial } γ₈ \text{ and finally rate isolated individuals die and that are given safe burial } γ_{IH}.

A desired percentage reduction in the Ebola transmission rate in the Liberia population will demand
intervention strategies that reduce the transmission coefficients. Since $\beta_1$, $\delta_1$, $\gamma_{HF}$, $\theta$ have high sensitivity index, a percentage change in control strategies that minimizes or maximize these parameters will equivalently influence Ebola transmission rate in Liberia. Intensive efforts to enhance the hospitalization rate coupled with effective isolation and reduction in fatality rate in the community through effective contact tracing and identification of exposed asymptomatic individuals will largely decelerate Ebola transmission in Liberia. A 10% reduction in transmission coefficient in the community and an increase in hospitalization will result in an 8.72% and 4.55% reduction in transmission rate.

**Sensitivity index of Ebola transmission in Sierra Leone:** Parameters that have high sensitivity index in the transmission of Ebola in Sierra Leone are transmission coefficient in the community $\beta_1$, rate of non-isolated individuals die in the community that are safely buried, $\gamma_{IF}$ hospitalization rate of symptomatic individuals $\gamma_{II}$ and proportion of individuals that are isolated $\theta$, these are followed by $\alpha_1$, $\beta_{HF}$, $\delta_1$, $\beta_r$, $\psi$, $\chi$, $\rho$, $\gamma_r$, $\gamma_I$, $\gamma_{HF}$, $\gamma_b$, $\gamma_f$. With high isolation and safe burial efficacy, the transmission rates in hospital and during burial will be reduced, hence a decrease in the transmission of the virus in Sierra Leone population. Equivalent percentage change in $R_0$ due to changes in parameters, will empirically explain the Ebola transmission minimization objective. A 10% change in reduction in the Ebola virus transmission in the community $\beta_1$, increase in hospitalized individuals $\theta$, reduction in death rate of non-isolated individuals from the community $\gamma_{IF}$ and increased rate of hospitalization $\gamma_{II}$ will result into 8.4%, 4.9%, 7.2% and 27.0% a decline in disease transmission in Sierra Leone population.

**Uncertainty analysis of Ebola Transmission:** There are different methods for carrying out a uncertainty analysis on static or functional epidemic quantities. In this study, we carried out uncertainty analysis of the reproduction number using sample-based Latin Hypercube Sampling/Partial Rank Correlation Coefficient. Using PRCC we can rank the effect that each parameter has on $R_0$ while other parameters simultaneously vary within their ranges. With sample runs of 1000 simulations, transmission rate of Ebola in each country was determined to be 2.076 with confidence interval [1.9764, 2.1749] for Guinea, 2.0242 with CI of [1.9316, 2.1168] for Liberia, and 2.0282 with CI of [1.9351, 2.1213] for Sierra Leone. This is within range, as determined by other studies. Uncertainty analysis showed that transmission coefficients in the community $\beta_1$ and hospitals $\beta_2$, and effective safe burial rate $\psi$ have higher correlation to the disease transmission, as is established. This is followed by transmission coefficient at funeral $\beta_f$ and effective contact tracing and quarantining of exposed individuals $\chi$, while death rates in hospital $\delta_1$ and proportion of hospitalized individuals $\theta$ also have moderately lower correlations along with average periods of recovery from community $\gamma_f$ and hospital $\gamma_{HF}$ or removal of deaths from isolation centers $\gamma_{HF}$ and non isolated victim $\gamma_{IF}$. Average period from onset to hospitalization $\gamma_{II}$ and average period of safe burial of victims $\gamma_{IF}$, this findings concurs with . Qualitative information showing the correlation coefficients of parameters changes to Ebola transmissions are provided in Figures 1, 2 and 3 for respective countries’ outbreaks. Preventive measures like limiting contact rate, restriction of movement, closure of public places and borders across countries and communities, enhanced public and personal hygiene will reverse the positive influence of these parameters to Ebola transmission. On the other hand safe burial rate having negative correlation coefficient thus requires quick and safe burial practices involving trained teams, sterilization of fomites from victims, and cordon sanitaire of premises in improved upon. To control the high chances of Ebola virus transmission in the hospital, intensive support and barrier nursing practices will curb the increase in transmission.

![Figure 1: PRCC showing the influence of parameter changes on the transmission rate ($R_0$) of Ebola in Guinea](image-url)
Figure 2: PRCC showing the influence of parameter changes on the transmission rate ($R_0$) of Ebola in Liberia

Figure 3: PRCC showing the influence of parameter changes on the transmission rate ($R_0$) of Ebola in Sierra Leone

Conclusion

Assessing the epidemic threshold’s change to parameter can help gauges deployment of preventive and control measures to stall the rising transmission rate of Ebola in the populations. Based on these findings it is recommendable that concerted efforts in controlling the epidemic should involve reducing contact rate among the susceptible population by identifying and tracking exposed (both symptomatic and asymptomatic) individuals that will be promptly moved to safe isolation centers. Victims’ relatives and medical personnel should make use of personal protective equipment and barrier nursing to limit contact with victim’s body fluid. Prompt and effective safe burial protocols should be adhered to so that dead victims from the community should be handed over to the trained teams for effective safe burial. For high impact of preventive and control interventions upon Ebola transmission in these countries, contact tracing and safe burials, restricted movement across borders and the provision of diagnostic and support facilities in isolation centers should be enhanced.

The Influence of Topical Propolis Administration Against the Number of Macrophag Cell Migration in Mice Wounds

Sherly Horax¹, Harun Achmad¹, Mirdawati K²
¹Department of Pedodontic, ²Student, Faculty of Dentistry, Hasanuddin University, Makassar South Sulawesi, Indonesia

ABSTRACT

Background: Wounds are lost or damaged body tissue integrity due to trauma experienced such as sharp objects trauma. The initial occurrence of the wound will trigger the body’s response to inflammation which is a complex biological response and the body’s immune system to dangerous stimuli. Clinically the inflammatory phase is characterized by symptoms around the tissue such as increased heat, redness (rubor), pain (dolor), swelling (tumor), and loss of function. Excessive trade processes can be suppressed by giving anti-inflammatory ingredients such as propolis. Propolis is a natural material from bees that has anti-inflammatory properties that can be an alternative ingredient in suppressing inflammation that occurs to reduce the clinical symptoms that appear.

Objective: To know the potential for topical administration of propolis to the migration of macrophages to wounds in mice.

Method: This study was a pure laboratory experiment with a post-test only control group design. The subjects of this study were 24 mice divided into 12 treatment groups which were given topical propolis and a control group of 12 who were not given propolis. An incision with a wound of 2 mm and a length of 15 mm was carried out on the back of the mice then the wound was smeared with 80% propolis extract twice a day for the treatment group. Three mice were sacrificed for each observation day, namely days 1, 3, 5, 7 and then made tissue preparations, then macrophages were observed using a microscope.

Results: There were significant differences between the treatment and control groups using the Mann Whitney test statistical analysis.

Conclusion: There is the influence of topical propolis administration in mice wounds against macrophage cell migration as an anti-inflammatory effect of propolis.

Keywords: propolis, wounds, inflammation and, macrophages

Introduction

Wounds are lost or damaged body tissue integrity due to trauma experienced such as trauma by sharp objects or blunt, changes in temperature, chemicals, explosions, electric shock or animal bites that can cause a total injury which will then trigger a reaction from the body to hold healing process.¹ The wound healing process will involve a complicated relationship between cellular, humoral factors and connective tissue elements. Host responses to wound healing are generally divided into several phases, each of which overlap, namely the inflammatory phase, proliferation, and maturation.²,³ The first phase of the inflammatory phase is a complex biological response of vascular tissue and immune cells to dangerous stimuli, characterized by phagocyte migration, accumulation of neutrophils, monocytes, macrophages and loss of tissue function. During the inflammatory process, some release of pro-inflammatory cytokines are activated by macrophages, causing more severe symptoms of inflammation.⁴
Macrophage is one of the most leukocyte cells that play a role in the inflammatory phase. Generally macrophages appear first 48-96 hours after injury and reach a peak on the third day until the healing process runs perfectly. Macrophages play an active role as phagocytes that are capable of affixing and digesting agents, macrophages also play a role in producing various types of mediators that regulate various biological activities such as arachidonic acid metabolism which will produce pathways of cyclooxygenase and lipoxygenase pathways which trigger the appearance of inflammatory symptoms. The best results from inflammatory reactions can be achieved if there is little or no tissue damage below. Therefore the excessive inflammatory process must be suppressed by giving anti-inflammatory drugs.

Propolis is a resin material that is attached to flowers, shoots and bark. It is concentrated, gummy, blackish brown, with a distinctive odor, and bitter taste. Propolis is obtained from various types of plants, especially from buds and leaves which are often used as traditional medicines that have various beneficial effects such as anti-bacterial, anti-fungal, anti-inflammatory, anti-viral, immunostimulator, and anti-cancer.

Propolis has anti-inflammatory activities that can increase the body’s immune system because it contains CAPE (Caffeic Acid Phenethyl Ester) in it. CAPE is a chemical compound in propolis which can inhibit inflammation (anti-inflammatory), because CAPE is able to enter the cell and it can inhibit lipoxigenase or LOX and cyclooxygenase or COX enzymes involved in the arachidonic acid metabolic pathway and also inhibit the release of proinflammatory cytokines and increase the production of anti-inflammatory cytokines. In addition CAPE can also reduce inflammatory cell neutrophils and monocytes infiltration.

Method

This type of research is an experimental (true experiment) laboratory with a post test only with control group design research.

Propolis used is propolis from Trigona Spp bee, which is widely found in South Sulawesi’s North Luwu Regency. What is applied to the wound is mice twice a day.

The mice used was Mus Musculus with ages 2-3 months and weighing 20-30 gr. The next one will be wound with a length of 15 mm and a depth of 2 mm (full thickness).

The results of the calculation of the number of macrophage cells per field of view in the control group showed the average number of macrophage cells on the first day after the wound was 56.66 and then increased on the third day 106 cells, then observations on the fifth day showed a decrease in the number of cells, 51 cells and continued to decline until the seventh day, which were 38 cells.

The results of the calculation of the number of macrophage cells per field of view in the treatment group or by giving propolis showed the average number of macrophage cells on the first day after the wound was 35 cells and then increased on the third day 50.3333 cells, then observations on the fifth day showed a decrease in the number of cells, 32 cells and continued to decline until the seventh day, which were 29 cells.
From the results of observations in both groups, namely the control and treatment groups, it can be concluded that the average number of macrophage cells is higher in the control group compared to the treatment group or those given propolis.

From the above data it can be visualized the number of polymorphonuclear in the graph below:

![Figure 1: Graph of average polymorphonuclear quantities](image)

Based on the graph above it can be seen that macrophages began to appear on the first day then increased on the third day and then decreased on the fifth day and seventh day and the average number of macrophages in the group given propolis extract was lower compared to groups not given propolis.

Statistical analysis with the Whitney mann test showed a significant difference between the control group and the treatment group.

The description of the results of observations of macrophage cells as follows:

1. First Day (Control)

![Figure 2: First day of control](image)

2. First day (Treatment)

![Figure 3: First day of treatment](image)

3. Seventh day (treatment)

![Figure 4: Seventh day of treatment](image)

**Discussion**

Based on observations and calculations of the number of cells per field of view it was found that the number of macrophages in the treatment group given propolis was lower than the group not given propolis. The highest number of macrophages was on the third day in the control and treatment groups and there was a significant difference between the two groups on the third day, according to the literature which said that the peak migration of macrophages would occur on day 3 to day 5 after injured.

Inflammatory process is a complex biological response from vascular tissue and the body’s immune system against harmful substances such as irritation, damaged cells, pathogens. The presence of wound stimulation will trigger cellular activity such as phagocyte migration, accumulation of neutrophils, monocytes and macrophages. During trade macrophages will activate some release of pro-inflammatory cytokines so that it will cause more severe symptoms of inflammation.

Clinically inflammation will cause symptoms of inflammation such as heat, redness, swelling, pain.
and even cause loss of function.\textsuperscript{11} Symptoms of severe inflammation must be suppressed by giving anti-inflammatory drugs.\textsuperscript{6}

Propolis is a natural ingredient derived from bees, has various health benefits, one of which is to provide an anti-inflammatory effect, this has been proven based on the results of research that show that the average number of macrophages in groups with topical propolis is lower than those who do not given propolis and in the treatment group (given propolis) on the third day it has shown that there is a process of reepithelialization on the surface of the wound until the 7th day epithelialization of the wound surface begins to form well and begins the formation of connective tissue which indicates the wound healing process is going well.

The ingredients contained in propolis will inhibit the metabolism of arachidonic acid thus it suppresses the cyclooxygenase (COX) and lypoxygenase (LOX) enzymes during the inflammatory process. COX is inhibited by flavonoids which suppress prostaglandins while LOX is inhibited by a component of quercetin propolis. flavonoids also inhibit the accumulation of mast cells. Caffeic phenetyl ester (CAPE) in propolis into the cell inhibits the release of proinflammatory cytokines and increases anti-inflammatory cytokines such as IL-4 and IL-10.\textsuperscript{10,15}

IL-10 will suppress TNF-α and IL-1.\textsuperscript{13,14} Reduction in TNF-α and IL-1 influences eukocyte rolling and adhesion, especially elephant macrophages from blood vessels, this causes a decrease in the number of macrophage cell migration in the wound, in this case if the macrophage migration to the inflammatory area decreases it will reduce inflammation symptoms that arises because macrophages also have a role in activating the release of pro-inflammatory cytokines which will cause more amount of tissue to be destroyed thus the clinical symptoms of inflammation will be more severe. However, with a decrease in macrophage migration to the injured area, it will reduce the trading signals that occur.\textsuperscript{16,17}

\textbf{Conclusion}

The conclusion of this study is that there are significant differences between the control and treatment groups. macrophages begin to migrate on the first day after a wound and reaches its peak on the third day then decreases again on the fifth day to the seventh day. Propolis extract given topically to the wound in mice can reduce the number of macrophage cell migration to the inflammatory area.

Update on Ethanol Induced Oxidative Stress in Liver Toxicity and the Effects of Pregnancy

Vetriselvan Subramaniyan¹, Ravindran Jegasothy²

¹Associate Professor, Department of Pharmacology, ²Dean, Department of Gynecology and Obstetrics, Faculty of Medicine, MAHSA University, Malaysia

ABSTRACT

Background: Ethanol induced hepatotoxicity is one of the major problems worldwide and especially in developing countries. Alcohol is the most abused substance and affects the normal defense mechanisms. Methodology: Chronic consumption of alcohol can cause behavioral changes, oxidative stress and elevation of liver enzymes due to imbalance between the antioxidant and pro-oxidant systems. Continuous oxidative stress results in accumulation of fat in the liver, which can lead to fibrosis, cirrhosis and liver cancer. Pathogenesis of alcoholic liver disease has several mechanisms and progression not fully understood. Results: Prognosis of alcohol induced liver disease depends on the period of alcohol consumption, percentage and volume of alcohol, inflammatory effects, dietary habits and genetic linkage among others. Conclusion: This review mainly focuses on updates on alcohol induced oxidative stress, liver toxicity and the effects of pregnancy.

Keywords: Alcohol, oxidative stress, liver toxicity, pregnancy

Introduction

Alcohol consumption is a significant contributor to the burden of metabolic diseases and is a major public health concern. Generally, most of the population surveys showed that alcoholics have a high prevalence of anxiety disorders, schizophrenia, affective disorders and other psychological effects. The condition of alcoholic liver disease ranges from steatosis to fibrosis and ultimately the patients develop cirrhosis. Previous studies reported that around 80% of heavy drinkers have chances to develop steatosis, 35% develop hepatitis and another 10% get cirrhosis. Experimental studies showed that chronic intake of alcohol induces severe oxidative stress and damage normal functions of the liver and develop the condition of apoptosis. Recent research studies showed that alcohol sensitizes the hepatocytes and leads to lipopolysaccharide mediated cytotoxicity. Intake of alcohol during pregnancy results in fetal alcohol spectrum disorders which includes fetal alcohol effects and fetal alcohol syndrome.

Development of oxidative stress and liver disease: Long term consumption of ethanol results in sensitization of inflammatory mediator’s response such as ROS, nitrogen species and cytokines that characterized the development of hepatic steatosis. Figure 1 demonstrated that oxidative stress is a common denominator in pathogenesis of liver disease. Injury of adipose and liver tissue cause an expression of inflammatory mediators and increase the infiltration of macrophages. The condition of steatosis, hepatic fibrosis and cirrhosis developed by chronic ingestion and continues to represent a major health issues. Chronic intake of alcohol increases the response of kupffer cells and activation of inflammatory mediators and ROS. It is also associated with vascular diseases and other risk factors. Regular use of ethanol is associated with inadequate control of blood pressure in treating hypertensive patients.

DOI Number: 10.5958/0976-5506.2019.02124.7
Chronic ethanol intake → increase toxic metabolites in the liver (CYP 2PE1) ↓ (Iron overload) → Proliferative cytokines (IL-1β, TNF-α) ↓ Induction and increase of GGT ↓ Production of ROS/RNS ↓ Increase MDA and consumption of GSH ↓ Decrease GSH and sustained oxidative stress ↓ Membrane damage, enzyme leakage ↓ Alcohol liver disease

**Figure 1: Schematic representation of oxidative stress and liver disease**

Several clinical studies show that chronic intake of alcohol has a higher risk of brain ischemia, stroke and increased blood pressure. The modulation of kupffer cell activation and liver enzymes elevation appears in chronic alcoholic individuals. Moreover, the kupffer cell activation is a major contributory factor of liver carcinogenesis. There is hyper-excitability of the central nervous system. Many of the alcohol dependent individuals try to quit but few of them succeed. The development of apoptosis can induced via extrinsic or intrinsic pathway such as death receptor and mitochondria.

In experimental animals including rats and mice, the decrease in the concentration of serum adiponectin after chronic exposure of ethanol has been demonstrated. Long term use of ethanol impairs the normal regulation of insulin and changes of hormonal regulations.

**Inflammatory mediators and response on liver:** It is well documented that chronic ethanol consumption inhibits mitochondrial electron transport, increases ROS production and impaired synthesis if adenosine triphosphate. Numerous studies reflected that reactive oxygen species to develop lipid peroxidation of liver cell membranes and this leads to tissue damage. Chronic ethanol consumption causes a number of health issues, including incoordination of motor function, blurring vision, sedation and hypnosis. Continued use of ethanol results in the elevation of endotoxin levels and the stimulation of Kupffer cells to generate free radicals via NADPH oxidase. Further there is activation of NF-kB and damage of tissues.

**Alcohol consumption and alters the metabolism:** Alcohol induced hepatic damage leads to elevation of liver enzymes such as aspartate amino transferase and alanine amino transferase and this ratio is greater than 1. This is the specific marker of liver toxicity. Regular use of ethanol is associated with inadequate control of blood pressure in treated hypertensive patients. Long term intake of ethanol is associated with uncontrolled blood pressure in cardiovascular disease patients and accumulation of proteins in the liver due to decreased rate of protein catabolism.

Long term use of ethanol reveals damage of mitochondrial structure and elevation of ROS and cytotoxicity. Additionally, ethanol-fed rats show increased hydroxyl radical production and protein carbonyl groups when compared with cytosolic proteins. Table 1 showed that several metabolic pathways have been playing a vital role in liver pathogenesis. Chronic intake of ethanol increases the production of hydrogen peroxide and superoxide by CYP450.

When increasing of hydroxyl radical factors to develop the damage of normal metabolic functions. In ethanol metabolism, increase oxidative stress, such as malondialdehyde, acetaldehyde and 4-hydroxy-2-nonenal (HNE). Lipid Peroxidation of 4-Hydroxy-2-Nonenal (4-HNE) induces the insulin resistance in skeletal muscle through carbonyl and oxidative stress.

In addition, oxygen demand and nitrosative stress play a key role of initiating fatty liver and cirrhosis. There are some specific factors involved in liver pathogenesis such as generation of NADH, triglyceride synthesis, inhibition of mitochondrial β-oxidation of fatty acids and activation of NF-kB.
The following metabolic disorder found in alcoholics such as,

- Fatty liver and excessive level of lipids in the blood
- Accumulation of lactic acid in the body fluids
- Excessive production of ketones in the body
- Elevated levels of uric acid in the blood

A number of behavioral effects influenced by ethanol and it’s referred at the action of GABAA receptors. Some toxicological compounds more affinity to the subtype of CYP2E1 enzyme such as acetaminophen, ethanol, benzene, carbon tetrachloride and other halogenated substrates. Injury of liver, that leads to oxygen demand in centrilobular and sensitivity increased in inflammatory mediators. Several studies evidenced that chronic ethanol intake abnormalities of cardiovascular functions and effects on alpha α1-induced contraction.

**Effect of alcohol in pregnancy:** Alcohol usage in women varies from country to country depending on cultural and social variations. Even those women who drink will modify their behaviour once it is known that they are pregnant. In a national survey of more than 300000 records, it was found that 87% of women who drank alcohol before pregnancy stopped drinking during pregnancy, 6.6% reduced their intake and another 6.4% carried on at previous levels. Women have to be informed that there is NO safe level of drinking in pregnancy. Alcohol is considered a teratogen that impacts fetal growth and development at all stages of pregnancy. Women would do well to remember that the major part of organogenesis occurs in the first trimester (first 12 weeks) of pregnancy. All international guidelines from professional bodies advocate complete abstinence in pregnancy. No half measures are safe as far as alcohol is concerned. Abstaining from alcohol while pregnant eliminates the risk of alcohol-related birth defects and developmental disabilities, including resultant neurocognitive and behavioral problems. It must be remembered that alcohol will pass through the transplacental circulation into the fetus. Once circulating in the fetus, elimination occurs at 3-4% compared to that of the maternal circulation. Alcohol that is secreted into the amniotic fluid is swallowed again by the fetus and be excreted back into the amniotic fluid by fetal urination.

Alcohol has the potential to cause harmful internal or somatic effects at all stages of gestation. During first trimester, significant intake of alcohol is associated with facial anomalies and major structural anomalies, including brain anomalies; exposure in the second trimester increases the risk of spontaneous abortion; exposure in the third trimester predominantly affects weight, length, and brain growth. However, neurobehavioral effects may occur with a range of exposures throughout gestation, even in the absence of facial or structural brain anomalies. Neuroimaging and pathologic studies in humans and animal models of prenatal alcohol exposure demonstrate abnormal brain structure and function following prenatal alcohol exposure. Influence of ethanol that changes in normal functions of memory, coordination, perception, judgement and ability work. In addition, alcohol-induced epigenetic alterations may disrupt normal developmental gene expression. The fetus with fetal alcohol syndrome is typically described as having a facies with short palpebral fissures, thin vermillion border and short philtrum, central nervous system abnormalities and growth retardation. Laboratory testing in patients with suspected alcoholic liver disease includes testing for evidence of hepatitis and liver synthetic dysfunction.

Identification and counselling of women who use alcohol can decrease intake during pregnancy. A number of screening tools are available to screen pregnant women. Clinicians should use one that is appropriate for their setting and population. Intervention sessions with counselling can be done for those who are not heavy drinkers. For those who are, professional help should be sought.

**Conclusion**

Alcohol remains a major cause of social ills and health burden. Many studies have confirmed that alcohol induced oxidative stress leads to mortality such as liver toxicity, renal failure, cardiovascular diseases and adverse effects of pregnancy. Preventive aspects are critical in the effort to reduce this burden. Getting a history of the level of alcohol intake in every patient irrespective of social class or gender is an important first step in this effort. Counselling and professional help are the next steps depending on the level of alcohol intake.
Competing Interest: The authors declare no competing interest

What is known about this topic?

- Chronic consumption of alcohol can cause oxidative stress and pathogenesis of disease.
- Alcoholic liver disease ranges from steatosis to fibrosis and ultimately the patients develop cirrhosis
- Intake of alcohol during pregnancy results in fetal alcohol effects and fetal alcohol syndrome

What is this study adds?

- Reactive oxygen species to develop lipid peroxidation of liver cell membranes and this leads to tissue damage
- Chronic intake of ethanol accelerates hepatic viral infections

ABSTRACT

The exclusive breastfeeding percentage given to a baby in Indonesia in 2018 was 37%. It was still far away from the WHO’s target that is 50%. The successful breastfeeding does not only belong to a wife’s responsibility but it belongs to husband. This research is aimed at knowing the effect of a husband’s bonding behavior model on the knowledge improvement, the husband’s attitude and bonding behavior to the successful exclusive breastfeeding.

This research used an experimental quasi design and was conducted from February up to March 2019. Its samples comprises of 31 respondents in intervening group and 31 respondents in controlling one. The respondents are the husbands having wives whose pregnancy ages range ≥36 weeks in the Regency of Bungo. The data analysis used is the test of McNemar and Chi Square. The intervening is done with husband’s bonding behavior module for the successful exclusive breastfeeding as long as 8 days.

The research result showed that the husband’s bonding behavior model is able to significantly improve the knowledge (p<0,0001), attitude (p<0,0001), and husband’s bonding behavior (p<0,0001). There is a meaningful difference found in knowledge, attitude, and behavior of husband’s bonding between kelompok controlling group and intervening one.

The husband’s good bonding behavior is meaningfully influential to the successful exclusive breastfeeding.

Keywords: exclusive breastfeeding, husband’s bonding behavior

Introduction

The breastfeeding is the best food for a baby since the exclusive breastfeeding given to the baby could maximize the baby’s growth, to improve the development of the baby’s intelligence, to minimize the baby’s morbidity and mortality as well as to distance the pregnant frequency¹,². WHO intended to promote the exclusive breastfeeding given given to the baby, at least, 50% in 2025³. Based upon the WHO’s data in 2016, the coverage level of exclusive breastfeeding given across the world is still below the target approximately 38%³.

In Indonesia, in 2018, the coverage level of exclusive breastfeeding given did not achieve the target of 37% either⁴. In Jambi Province, the coverage of baby milking the exclusive breastfeeding until six months old merely 27.2% whereas in the Regency of Bungo just reach 21% lower than the target or national achievement⁵.

Majorly, the wives come across a difficulty practicing to give exclusive breastfeeding within the community, health care experience, place and job type, and even their own families. everybody plays a role in helping a wife to surmount the hindrance from being successful to give the exclusive breastfeeding. The husband, particularly, could be one of the important roles and source of the strongest support in helping the wife to manage in giving the exclusive breastfeeding⁷. Based upon the previous study and field experience it showed that the failure of asking the husband to participate and to empower

DOI Number: 10.5958/0976-5506.2019.02125.9
him in intervening the behavior change could inhibit both the efficacy and the effectiveness of program. The promotional effort to give an exclusive breastfeeding has set up a target to the wife but the husband seems to be out of participation\textsuperscript{8}.

Research Abbass-Dick, showed that the husband informed and supported the exclusive breastfeeding given\textsuperscript{9}. This research suggests that the successful exclusive breastfeeding given does not only belong to the responsible of a wife. The husbands are considered the part of co-parenting team that is to collaborate with the wife to achieve the purpose of exclusive breastfeeding commonly intended and he does not only function as to support the wife\textsuperscript{10}. Moreover, significantly, more wives in intervening group were satisfied with their couple’s involvement in the breastfeeding practice as many as 89\% compared to the one of control as many as 78,1\% under $p=0,04$\textsuperscript{11}.

The husband’s involvement is influenced by knowledge, attitude and behavior of the husband. The Februhartanty’s research on husband’s role in optimizing the practice of breastfeeding in Wilsuami, Urban of Jakarta showed that the husband having a good knowledge of breastfeeding preserves good and harmonious relationship between both wife and baby\textsuperscript{12}.

The husband’s positive attitude is supported by a good knowledge of breastfeeding. Without sufficient knowledge of exclusive breastfeeding given, the husband will tend to behave negatively to the practice of breastfeeding given and a plan to give a formulated milk to the baby.\textsuperscript{13} The attitude represents the specific reliability of implementing a behavior including the experience attitude (emotional response toward the idea of practicing behavior) and instrumental attitude (reliability on the possibility or the potential result of behavior)\textsuperscript{14}.

The husbands said that they appreciate if they are specifically informed what role to play. This showed that the particular information is to target the husbands that they are not only well accepted by their wives but are also effective in promoting their involvements\textsuperscript{15}. This research is the quantitative research of the continuity titled Model of Husband’s Bonding Behavior (HBB) for The Success Of Exclusive Breastfeeding In Rural Sumatra.\textsuperscript{9} This research intends to re-evaluate the HBB model over the promotion of knowledge, the change of both husband’s bonding attitude and behavior to the successful exclusive breastfeeding.

\section*{Method}

This research made use of experimental quasi design done from February to March 2019. The research sample comprised from 31 respondents in intervening group and 31 respondents in controlling group. The respondents were the husbands having wives whose pregnancy age are $\geq$36 weeks in the area of Bungo Marketplace and District of Pelepat, Regency of Bungo. This research made use of multistage random sampling technique. The data analysis implemented McNemar and Chi Square test with the reliable degree 95\%.

Educational Module of husband’s bonding behavior as a media in defining model of husband’s bonding behavior. The interning would be done under the educational module for 8 days. The monitoring in the husband’s change bonding behavior was conducted during 66 days. The education was done by the ways of 1) Education I: explanation of intention and learning material based upon the module; 2) Education II: individual learning with various modules for each participant and is asked to learn at home at least10 minutes per day during six days.

\section*{Result and Discussion}

Respondents characteristic was intended to see the husband’s characteristic frequency. The husband’s characteristic in this research was based upon education, age group, and wife’s job.

\begin{table}[h]

Table 2 showed that the husband’s knowledge in the controlling group increased up to 9.7% meanwhile it increased up to 0% in intervening group. Statistically, there was a meaningful difference in the knowledge increase between the controlling group and the intervening one (p < 0.0001).

Table 2 showed that the husband’s bonding behavior in a good controlling group is as as many as 51.6% whereas the good intervening one is as many as 96.8%. Statistically, there is a meaningful difference of husband’s bonding behavior between the controlling group and the intervening one (p < 0.0001).

The effect of husband’s bonding behavior model for a successful exclusive breastfeeding given could be seen on the following table:

Table 3: Husband’s Bonding Behavior For Successful Exclusive Breastfeeding

</table>

Table 3 showed that the percentage of the exclusive breastfeeding given is higher than in the good husband’s bonding behavior compared to the one of bad husband’s bonding behavior that is as as many as 83.9% to 36.7%. Statistically, there is a meaningful difference (p<0.0001). It meant that the husband’s bonding behavior model is meaningfully influential to the successful practice of exclusive breastfeeding given.

Discussion

A better part of respondents in this research at the intervening group are educated up to senior high school whereas the one at the controlling one are educated up to junior high school. The result of this research is in line with Abera’s et al., showing that almost a half as many as 42% out of husbands taking the senior high school course up to the college one. However, the majority as many as 54.7% out of the husbands only took the education up to elementary school. The husbands taking education up to senior high school are 4.9 times more possible to get involved well in the practice of giving the exclusive breastfeeding rather than those only taking education up to elementary school (AOR = 4.961, 95% CI = 2.483, 9.91).

Respondent’s average age, either in intervening group or in the controlling one, mostly are in the age group <35 years. The result of this research does not
come along together with Abera’s *et al.*, showing that the husband’s average age is 35.64 (SD + 6.023) years. Approximately a half 209 (50.1%), the husbands are over 35 years old whereas 176 (42.2%) in the range of 25 years up to 35 years old and the rest is 32 (7.7%) are under 25 years old.\(^6\)

In this research, the husbands having good perceptions to their husband’s involvement in milking practice tend to be involved more in breastfeeding given. This finding is in line with the one conducted by Abbas-Dick *et al.*, in which the husband is ignored during the pregnancy - baby birth cycle as they are prohibited by their wives from participating in the breastfeeding process\(^{6,17}\).

The research result showed that there is a difference found among the respondents found during both pretest and post-test in the intervening group but there is no difference found among the controlling one. It also showed the respondent’s interaction between the controlling group and the intervening one. Based upon the theory of behavioral change elaborating it that could happen through a learning process such as information given through a counseling or an education. The learning process could bring about the visible change and it take a long time.

Based on the result of analysis, it showed that the good husband’s bonding behavior preserved a significant relationship to the successful exclusive breastfeeding given. Roesli said that the husband is an important part in defining either success or failure of exclusive breastfeeding given so that the husband could play an active role for the successful exclusive breastfeeding given by the behavior emotionally or passionately and gave other practical helps such as replace the diaper or pick up the baby. This important role is the first step for the husbands to support their wives in order to manage giving the exclusive breastfeeding\(^18\).

The exclusive breastfeeding could be beneficial for it is able to improve the child’s life quality. However, there are many conditions that are not understood by the husbands. Husbands play roles to create a comfortable environment for their wives so that their both physical and psychological conditions always fit. The husband’s support could be in form of his ability described as the husband’s knowledge, practical help, and information related to the exclusive breastfeeding given. The knowledge possessed by a husband would influence the supporting and and parenting as well as influencing the wife to feel more optimistic and more confident to exclusively breastfeeding\(^19\).

**Conclusion**

The husband’s bonding behavior model is able to meaningfully promote knowledge, behavior, and husband’s bonding behavior. There is a meaningful difference of knowledge, attitude, and bonding behavior of the husband between the controlling group and the intervening one. The good husband’s bonding behavior is meaningfully influential to the successful breastfeeding given.

Reduction Turbidity of Water in Tikrit Drinking Water Treatment Plant by Using Alum Which was Quantified by a Jar Test Apparatus, with limnological Study of Treated and Raw Water

Bashar Tareq AL-Shandah¹, Shaimaa Fatih Ali¹
¹Department of Biology, College of Science, University of Tikrit

ABSTRACT

Tigris river is a major source of water for drinking, agricultural and industrial desires in Iraq. The quality of drinking water is very important because it is related to the health of people. For this purpose, we assess the quality of drinking water in the city of Tikrit with some physical-chemical parameters which have a significant role in determining the potability of drinking water. The obtained results were compared with the permissible limits for universal standards of drinking water such as Environment Protection Agency (EPA), World Health Organization (WHO), etc.

In this study, two samples of water within Tikrit drinking water treatment plant were taken, the first sample was the raw water (Tigris River) which is a water source project, and the second sample represents treated water in the Tikrit drinking water project.

All the physical and chemical parameters (Conductivity, pH, Chloride and Total Alkalinity) were found to be within the safe limit values except turbidity and aluminum levels of treated water in some months.

Turbidity is a principle physical characteristic of water, excessive turbidity in drinking water is aesthetically unappealing and may also represent a health concern.

Generally, alum is the first coagulant of choice because of its lower cost and its widespread availability. The coagulation performance of alum, an inorganic chemical coagulant was used to remove the turbidity of raw water, but the problem with the use of alum as a coagulant for water treatment often leads to higher concentrations of aluminum in the treated water than in the raw water itself.

Jar tests were carried out to optimize alum dose in most months of the current study. Results showed that the efficiency of alum has been high in reducing values, but it is necessary to choose the lowest doses of alum and appropriate in reducing the values of turbidity to be within the permissible limits to avoid increasing the concentration of aluminum in treated water, especially that increasing the concentration of aluminum in drinking water has a risk to human health.

Results showed an increase in concentrations of aluminum in treated water in some months through recording values exceeded the permissible limits (Maximum Permitted Level 0.2 mg/L) according to the universal standards of drinking water due to excessive doses of alum added to sedimentation basins at Tikrit drinking water treatment plant.

Keywords: Drinking water, Jar test apparatus, alum dosage, turbidity removal, aluminum concentration.

Introduction

The population growth and lack of infrastructure had made it a serious problem to get safe drinking water for people in developing countries, such as Iraq.¹ Water from all sources must have some form of purification before consumption. Various methods are used to make water safe and attractive to the consumer. One of the problems with treatment of surface water is the large seasonal variation in turbidity.²⁺³
Turbidity may contain many contaminants like pathogenic organisms. Thus, effective turbidity elimination is necessary to ensure removal of many health-related contaminants. Alum and Ferric Chloride are the most commonly used chemical coagulants worldwide in the water treatment plants for over a hundred years all over the world.

In this study Alum was used as a chemical coagulant in the Tikrit drinking water treatment plant. The removal of turbidity from water is important because colloids may directly or indirectly threaten the human health.4

The use of alum as a coagulant for water treatment often leads to higher concentrations of aluminum in the treated water than in the raw water itself.5

Water that contains more than 0.2 mg aluminum per liter should not be used for drinking water or to prepare beverages or infant formula. It is safe to use this water for other purposes such as bathing, showering and household chores.6

**Studying Area:** The study area is located in district of Tikrit in the province of Salah Al-Din which is located in the north of Baghdad, the capital of Iraq, between latitude (77.37’34 N) and longitude (24.20’4339 E) (Figure 1)

The study area included taking two samples of water within Tikrit drinking water treatment plant. The first sample was raw water (Tigris River) (one of the most important sources of fresh water in Iraq), which is the source of feed for Tikrit drinking water project, which is pulled into the project by pumps, and the second sample represents treated water in the Tikrit drinking water treatment plant, which is pumped to consumers.

**Description of Tikrit drinking water treatment plant:** This project is located in the center of Tikrit district away 1 km from the Tigris River on the left side of the river. It consists of 4 large sedimentation basins and also contains 14 sand filters. The operational capacity of the project is estimated at about 49000 cubic meters per day, which feeds the people of the area with drinking water after the disinfection of water by chlorination process. The source of this project is Tigris river.

![Figure 1: Maps of Iraq, including the distract of Tikrit and location of the Tikrit Drinking Water Project](image)

**Materials and Method**

**Samples Collection:** Samples were collected, on a monthly basis for a period of eight months from February to the end of December 2018.

Water samples were taken for physical and chemical analysis, using poly-ethylene bottle which had been washed twice with water sample before filling it.7

**Studying Stations**

**First Station:** The sample of water in this station was taken from water entering to the Tikrit drinking water project, which is water from the Tigris River.

**Second Station:** The sample of water in this station was taken from treated water in the Tikrit drinking water project, which is pumped to consumers.
Physical and chemical analysis

The parameters were checked in laboratory of Tikrit drinking water treatment plant. The methods for analyzing these parameters are shown in Table (1).

Jar Testing Procedures: In Jar test procedure was used alum (aluminum sulfate Al\(_2\) (SO\(_4\))\(_3\).18H\(_2\)O) a chemical for coagulation/flocculation in Tikrit drinking water Project, and a typical six-gang jar tester. The results of this device are used to improve the performance of water projects to supply low turbidity water, the procedures of Jar test were as following:

1. Was used a 1000 mL graduated cylinder, then has been added 1000 mL of raw water (Tigris river) to each of the jar test beakers. Were recorded turbidity of the raw water before beginning.

2. Prepared a stock solution by dissolving 1 grams of alum into 1000 mL distilled water. Each 1 mL of this stock solution will equal 1 mg/L (ppm) when added to 1000 mL of water to be tested.

3. Was Used the prepared stock solution of alum, dose each beaker with increased amounts of the solution. Table (2) shows the additions and doses of alum used in the study.

4. After dosing each beaker, were turned on the stirrers. This part of the procedure should reflect the actual conditions of the plant as much as possible. Meaning, if the plant has a static mixer following chemical addition, followed by 30 minutes in a flocculator, then 1.5 hours of settling time before the filters, then the test also should have these steps. The jar test device was operated as follows: Operated the stirrers at a high RPM for 1 minute to simulate the static mixer. Then reduced the speed of the stirrers to match the conditions in the flocculator and allow them to operate for 30 minutes. Observed the floc formation periodically during the 30 minutes. At the end of the 30 minutes turned off the stirrers and allowed settling. Most of the settling was completed after one hour. \(^{10}\)

Statistical Analysis: The results of this study were analyzed statistically using analysis of variance test (F test), and has been compared the means by a polynomial Duncan test in level of 0.05 and 0.01. \(^{11}\)

Results

Water Temperature: The results revealed that temperature of water values were ranged between (10–30.5 °C) during the study period. The highest value was in June at raw water (Tigris River), while the lowest value was recorded at same location in February (Figure 2).
The statistical analysis according to the analysis of variance for water temperature showed no significant differences between the raw and treated water stations, with a significant difference at (P≤0.01) between some months of the study (as shown in table 3).

**pH and Total alkalinity:** The results revealed that pH values of water were ranged between (7.47 - 8.53) during the study period. The highest value was in April at raw water (Tigris River), while the lowest value was recorded at water project in February (Figure 2).

The values of total alkalinity were ranged between (83-128) mg/L expressed as CaCO$_3$. The highest value was in July at raw water (Tigris River), while the lowest value was recorded at water project in August (Figure 2).

**Chloride:** In the present study the results of chloride concentrations were ranged between minimum value 12 mg/L and maximum value 51.94 mg/L (Figure 2).

The statistical analysis according to the analysis of variance for water temperature showed no significant differences between the raw and treated water stations, with a significant difference at (P≤0.01) between months of the study (as shown in table 3).

**Electrical Conductivity (EC):** The maximum value (493.02 µS/cm) was recorded at water project in May and the minimum value (370 µs/cm)) was recorded at raw water (Tigris river) in February (Figure 2).

The statistical analysis according to the analysis of variance for electrical conductivity showed a significant differences at (P≤0.01) between some months of the study, while there are no significant differences between the raw and treated water stations (as shown in table 3).

**Turbidity, Aluminum and Jar test results:** In the present study water turbidity values at raw water (Tigris River) ranged between (7.1 - 153) NTU, the highest value at raw water was in April, and the lowest value was recorded in August as shown in Figure 2. While water turbidity values at treated water (water project) ranged from 3.75 to 7.6 NTU, the highest value was recorded in June, and the lowest value was in May.

As illustrated in Figure (2) the results revealed that the aluminum values at raw water (Tigris river) ranged between (0.014 - 0.078 mg/L), the highest value was recorded in June, while the lowest value was in July.

At treated water (water project) the concentration of aluminum was recorded ranged from 0.014 to 2.68 mg/L, the highest value was recorded in April, and the lowest value was in September.

Through the Figure (2), a correspond was observed in the rise and decline in the values of both turbidity and the concentration of aluminum in the raw water during the months of April, May and June, this increase and decrease in turbidity reflected its effect on aluminum concentrations in the treated water (water project).

Figure 3 (a - f) presents the results obtained for Jar test study performed on raw water (Tigris river) samples using alum (Aluminum sulfate) tested within (5 - 25 mg/L) dose range. The red dots in the figure 3 (a-f) refer to the concentrations of the selected alum dosage used in sediment basins in the water project.
Figure 2: Monthly variations of parameters in the studied stations

Discussions

**Water Temperature:** The results of the current study showed clear monthly variations in the temperature of the water and these differences back to the climate differentiation through the seasons of the year. Temperature values for this present study showed marked seasonal variation. Higher water temperature values recorded in the dry season months in the present study are expected since temperature from sunlight increases temperature of surface water.

**pH and Total alkalinity:** The recorded values of pH in this study for both locations were within the standard limits for drinking water recommended by the World Health Organization (6.5 - 8.5) and (6.5 - 9.5) respectively. The desirable limit for total alkalinity is 200 mg/L expressed as CaCO$_3$. The results of the present study, as in Figure (2), show that the pH values and alkalinity values of the raw water (Tigris river) are higher than the water of the Tikrit project in most months of the study, these results were confirmed by statistical analysis with a significant difference at (P<0.01) between the two stations for pH parameter (as shown in table 3), that may be because when alum is added to a water containing alkalinity, the following reaction occurs:

\[
\text{Al}_2(\text{SO}_4)_3\cdot18\text{H}_2\text{O}+6\text{HCO}_3^- \leftrightarrow 2\text{Al(OH)}_3 + 6\text{CO}_2 + 18\text{H}_2\text{O} + 3\text{SO}_4^{2-}
\]

Such that each mole of alum added uses six moles of alkalinity and produces six moles of carbon dioxide. The above reaction shifts the carbonate equilibrium and decrease the pH. However, as long as sufficient alkalinity is present and CO$_2$ is allowed to evolve, the pH is not drastically reduced and is generally not an operational problem. When sufficient alkalinity is not present to neutralize the sulfuric acid production, the pH may be greatly reduced: \[
\text{Al}_2(\text{SO}_4)_3\cdot18\text{H}_2\text{O} \leftrightarrow 2\text{Al(OH)}_3 + 12\text{H}_2\text{O} + 3\text{H}_2\text{SO}_4.
\]

**Chloride:** In the present study chloride concentrations in both locations were within the standard limits for drinking water recommended by the (ODWS; WHO and EPA) Maximum Permitted (250 mg/L).

Chloride is considered to be pollution indicating parameter and it is responsible for the salty taste of water, chloride present in water originates from both natural and anthropogenic sources.

**Electrical Conductivity (EC):** The values obtained in all sampling sites were within the standard value of (SON) drinking water quality which is 1000 μs/cm and within the standard value of (EPA) drinking water quality which is 2500 μs/cm so they are good for use.

Figure (2) shows that all electrical conductivity values of the water project were relatively higher than the conductivity values of the raw water (Tigris River), this may be due to daily additions of alum in the water project which are used as a chemical coagulant to reduce water turbidity, especially that conductivity of water depends upon the concentration of ions and its nutrient status and variation in dissolve solid content. Seasonal variation in the conductivity is mostly due to increased concentration of salt because of evaporation.

**Turbidity, Aluminum and Jar test results:** Through the results all of the observed values of turbidity at raw water (Tigris river) were high (more than the permissible level 5 NTU recommended by the ODWS, SON, WHO, EPA etc. for drinking water) therefore, this elevation in turbidity must be treated through the water project by using alum in settling basins before it reaches to consumers, these fluctuating values of turbidity at raw water (Tigris river) were natural result, due to the turbidity affected by the natural components present in water bodies like as silts, clay, silica component and other as well as may be it is affected by human activity.

Turbidity should ideally be below 5 NTU, the main reasons for the determination of drinking water with the values of turbidity less than 5 NTU that is the microorganisms (bacteria, viruses and protozoa) are typically attached to particulates, furthermore, high levels of turbidity can interfere with disinfection and protect microorganisms from the effects of disinfection. In addition to the effect of turbidity resulting from sand, silts or clay on the health of body organs as kidneys.

Therefore alum was used to reduce the water turbidity values to the permissible limits but, the use of alum as a coagulant for water treatment often leads to higher concentrations of aluminum in the treated water than in the raw water itself, typically, a portion of the alum added to the raw water is not removed during treatment and remains as residual aluminum in the treated water.

As illustrated in Figure (2), the proportions of aluminum concentrations are normal in raw water because of that aluminum (Al$^{3+}$) is the third-most-
common element in the earth’s crust and is present in all natural waters.\textsuperscript{21}

Aluminum determination at low level is of particular interest in potable water units because this metallic ion is commonly used as reactant for coagulation–flocculation in the treatment of raw waters to remove colloidal or suspended particles or to eliminate organic matter.\textsuperscript{22} At the outlet of these units, maximum tolerable level of this cation has been fixed for drinking water to (200 µg/L equal 0.2 mg/L) by the ODWS\textsuperscript{14}, SON\textsuperscript{16}, WHO\textsuperscript{12}, EPA\textsuperscript{13} etc.

The obvious increase of turbidity values in months (April, May and June) at raw water (Figure 2) coincided with the high level of the Tigris river and heavy rain, especially in April leading to the erosion of soil, sand, inorganic fertilizers on farmlands and plankton during the flow of the river.\textsuperscript{23} To remove this increase of turbidity, larger amounts of alum were used in drinking water treatment plant.

Through the results were recorded in the current study of aluminum concentration in treated water as shown in Figure (2) were observed that the values exceeded the permissible limits (0.2 mg/L) in the months April, May, June and July with values 2.68, 0.285, 0.31 and 0.268 respectively.

High concentrations of residual dissolved aluminum indicate incorrect coagulant dosing were added to raw water in sedimentation basins at drinking water treatment plant.\textsuperscript{24} Residual aluminum concentration was affected by concentration of coagulant dosage, the relationship between aluminum concentration and turbidity of water in treated water confirmed by statistical analysis which showed a negative correlation between alum dosage and turbidity in all months of the study.

Residual aluminum concentration after sedimentation and filtration in the effluent must be taken into consideration because of the health effects of aluminum. The studies on health effects of aluminum in drinking water showed that high consumption of aluminum from drinking water may be a risk factor for Alzheimer’s disease.\textsuperscript{25}

Aluminum accumulation in the brain is proposed to be associated with neurodegenerative diseases, including Alzheimer’s dementia, Parkinson’s disease, amyotrophic lateral sclerosis, and dialysis encephalopathy.\textsuperscript{26}

The laboratory staff in Tikrit drinking water treatment plant chose the alum dosages depending on the results of Jar test apparatus to ensure getting values of turbidity less than 5 NTU according to the universal standards of drinking water.

Alum dosages selected (as shown in Figure 3) in the months in which high concentration of aluminum was observed, as shown in Figure (2), was the main reason for this elevation in aluminum concentration in treated water. Therefore, it was better for the health side to select less alum dosages than those chosen, especially in months (April, May, June and July) to avoid the increase of aluminum values in the treated water, especially that the Iraqi standards of drinking water allowed the turbidity values of drinking water to reach 10 NTU.

The highest value of aluminum (a value inconsistent with other values were recorded during the current study period) was in April recorded because of the project staff didn’t rely on the Jar test apparatus in estimating the amount of alum that should be added to the sedimentation basins, but they added alum randomly, this is one of the problems that lead to a defect in the quality of drinking water.

In the last two months of the current study (August and September) no amount of alum has been added because the turbidity of raw water was under 10 NTU, after the river returned to normal level.

**Conclusion**

Coagulation-flocculation using alum (aluminum sulfate Al$_2$(SO$_4$)$_3$.18H$_2$O) is a suitable process for the removal of turbidity at drinking water treatment plant but, alum dosage which added to removal turbidity of water in water projects plays a major role in increasing the concentration of aluminum in the treated water, this increase has an impact on consumer health. Therefore, alum should be added according to the results of Jar test apparatus.

All the physical and chemical parameters were studied in this study (Conductivity, pH, Chloride and Total Alkalinity) were within the national standards such as WHO, EPA,SON, ODWS except turbidity and aluminum levels of water for Tikrit drinking water treatment plant in some months.

Effects of the Climacteric Symptoms, Social Support and Couple Intimacy on the Health-related Quality of Life of Married Middle-aged Women

Hyea-Kyung Lee¹, Hee-Kyung Kim²

¹Professor, Department of Nursing, Jungwon University, Goesaneup, South Korea; ²Professor, Department of Nursing, Kongju National University, Gongju, South Korea

ABSTRACT

Purpose: The purpose of this study was to analyze the effect that climacteric symptoms, social support and couple intimacy of married middle-aged women have on the quality of their health life.

Method: The subjects of this study were 131 married middle-aged women aged between 40 and 65. The data were analyzed using descriptive statistics, t-test, ANOVA, Pearson’s correlation coefficient and stepwise multiple regression using the SPSS 22.0 program.

Results: The climacteric symptoms of subjects had a negative correlation (r=-.31, p<.001), while social support had a positive correlation (r=.38, p<.001). Couple intimacy had a positive correlation (r=.35, p<.001). The social support of married middle-aged women (β=.251, p=.005), climacteric symptoms (β=-.215, p=.009), and satisfaction with married life (β=-.193, p=.035) were found to be significant variables affecting health related quality of life. The explanatory power was 13.6% for social support, 5.6% for climacteric symptoms, 2.2% for satisfaction with married life and 21.4% for these factors altogether in explaining health-related quality of life.

Conclusion: The researchers hope that through the development of various nursing intervention programs and application of such programs to improve couple intimacy and satisfaction with married life, health related quality of life for married middle-aged women will improve.

Keywords: Married middle-aged women, Climacteric symptoms, Social support, Couple intimacy, Health-related quality of life

Introduction

The trends in female population in the past several years show that those in their 40s account for 16.2%, those in their 50s account for 16.4%, and those in their 60s account for 11.4%. This indicates that middle-aged women in their 40s to 60s take up a total of 44.0%. In terms of female employment, those in their late 40s account for the highest share of 69.7%. While up to 2011 the majority of divorces were of couples married for 4 years or less, since then the largest number of divorces occurred in couples who have been married for 20 years or longer.¹

Couple intimacy is a concept referring to emotional interaction and emphasizes non-verbal feelings or thoughts. It is the process of making efforts to feel closer with the other person in both positive and stressful situations.² Couple intimacy is an important factor in marital relations and is the main reason for marriage.³ ⁴ Lack of intimacy is a leading indicator of divorce.⁵ Factors affecting the subjective happiness of middle-aged women are sexual intimacy of the couple and communication.⁶ Recent studies show that marriage and co-habitation were correlated with positive health status.⁷ In particular, emotional support from the spouse had the most direct impact on how middle-aged
women overcame challenges, and the more positive the couple’s relationship the higher the well-being of the individual. As such, ultimately couple intimacy needs to be identified as a major factor in the healthy life of middle-aged women.

One’s middle age is when one moves on from being an adult to an elderly person. With the aging of cells, the immune system is undermined and resistance to diseases or external stress decreases, leading to higher likelihood of chronic diseases. Climacteric symptoms cause various health issues which can serve to undermine health-related quality of life. Ware and Sherbourne defined health-related quality of life as a more comprehensive concept than an individual’s health status, which covers overall health, physical function, physical role, pain, vitality, social function, and subjective evaluation in the emotional role.

Factors that affect the quality of life associated with health in middle-aged women are self-efficacy, number of chronic diseases, social support, symptoms, status of physical functions, and perceived health status. Most of the studies on health-related quality of life in middle-aged people to date have been focused on middle-aged women, but those on married middle-aged women are lacking. This study seeks to analyze the effect of climacteric symptoms, social support and couple intimacy of married middle-aged women on their health related quality of life.

Method

Subjects: Subjects of this study were sampled among married middle-aged women between age 40 and 65. Only those who voluntarily gave their consent to participation in the study were selected as study subjects. To verify the fitness of the sample size, the G*Power 3.0 program was used and a significance level of 0.05, effect size of 0.15, verification power of 0.90 and six predictive factors were applied to the regression analysis to acquire the final number of 123 subjects. A total of 131 copies were used in the final analysis.

Instruments

Climacteric Symptoms: In this study, the 20 questions from Menopause Symptom Index developed by Sarrel and revised by Jo & Lee were used, and were revised by Han. For each response, 0 point was given for ‘no’ and 2 points for ‘frequently’. A higher score indicates worse climacteric symptoms. In this study Cronbach’s α was 0.87.

Social Support: Developed by Park, the tool consists of a total of 25 questions. One point is given to ‘not at all’ and 5 points given to ‘very much so’, using a 5 point Likert scale. A higher score indicates higher social support. In this study Cronbach’s α=.90.

Couple Intimacy: The tool developed by Lee was used. For responses given to statements on couple intimacy, one point was given for ‘not at all’ and 5 points given for ‘very much so’ on a 5 point Likert scale. A higher score indicates higher couple intimacy. In this study Cronbach’s α=.94.

Health-related Quality of Life: The tool developed by Dunbar et al. and revised by Yoon et al. to fit the Korean standard was used. There are a total of 23 questions. Each question has a statements presenting two polar opposites and measured on a scale of 1-10 points. A higher score indicates a higher health-related quality of life. In this study Cronbach’s α=0.88.

Data Collection: Data were collected from November 1 to December 10, 2018. Married middle-aged women of age 40 to 65 who participate in religious groups, volunteer organizations, cultural centers and private institutions in three cities of Chungcheong region were conveniently sampled the researcher and three research assistants.

Ethical Consideration: Approval was acquired by the ethics committee of K University on the objective, methodology and protection of rights of study participants (KNU_IRB_2019_17). During the study period the guidelines on ethical studies were observed.

Data Analysis: Using the SPSS/WIN 21.0 program, the general characteristics and variables were analyzed for frequency, percentage, mean and standard deviation. The correlation between the subjects’ variables was analyzed using Pearson’s correlation coefficients. The difference in health-related quality of life across different general characteristics was analyzed using a t-test, ANOVA and Scheffe test. Multiple regression analysis was conducted to analyze the factors affecting the subjects’ health-related quality of life.
Results

General Characteristics of Subjects: The average age of subjects was 51.3 years, with those aged 50–59 accounting for the largest share of 47.3%. The majority of the subjects at 49.6% had high school as their final education. Those married for 20-29 years accounted for the largest share at 49.6%. Those satisfied with their marriage accounted for the largest share of 45.8%, and in terms of monthly periods, those who had a regular period accounted for the largest share at 46.6%. Those who did not have a hobby that they enjoyed as a couple accounted for 73.3%, and those who were not on any medication took up 71%.

Climacteric symptoms, social support, couple intimacy and health-related quality of life in subjects

The subjects’ climacteric symptoms scored .59 points out of 2 points, and social support scored 3.79 points out of 5 points. Couple intimacy scored 3.39 points out of 5 points and health-related quality of life scored 7.03 points out of 10 points (Table 1).

Factors affecting health-related quality of life: Health-related quality of life was set as a dependent variable for a multiple regression analysis. The self-correlation coefficient of Durbin-Watson was 2.043, and VIF value was 1.074~1.350 which is smaller than 10, indicating that there were no issues of multi-linearity. The analysis showed that social support (β=.251, p=.005), climacteric symptoms (β=-.215, p=.009), and satisfaction with married life (β=-.193, p=.035) had a significant effect on health-related quality of life. The regression analysis was statistically significant (F=12.68, p<.001), with the combined explanatory power of social support, climacteric symptoms and satisfaction with marriage being 21.4% (Table 4).

Discussion

The health-related quality of life in married middle-aged women was 7.03 points on a scale of 1 to 10, which was higher than average. This was lower than in a study conducted on middle-aged women where it was 6.73 points. In a study on both middle-aged men and women the score was 79.5 points (on a scale of 1 to 100 points) which was higher than in this study. As such, while a nursing intervention method must take into account whether the subject has a partner and which gender they are, an iteration of the study also seems necessary with a wider array of subjects as the findings differ across different studies.

A review of the correlation between the health-related quality of life and other variables showed that climacteric symptoms had a negative correlation, while social support and couple intimacy had a positive correlation. Fewer climacteric symptoms, higher social support and higher couple intimacy were correlated with higher health-related quality of life. This is similar to the study results where climacteric symptoms had a negative correlation with health-related quality of life. In addition, there was a net correlation between couple intimacy and quality of life, which is a similar result to that of this study. As in this study, climacteric symptoms and social support were identified as factors affecting health-related quality of life, and social support affected not only health-related quality of life but also health behaviors and symptoms. Moss and Schwebel noted that couple intimacy, compared to satisfaction with marriage, takes the aspect of mutual emotional, cognitive, physical closeness and dedication more seriously. Programs to help improve couple intimacy in middle-aged couples would need to be operated in local communities.

Factors affecting the health-related quality of life in married middle-aged women were social support, climacteric symptoms and satisfaction with married life. In preceding studies, social support was found to have a direct effect on climacteric symptoms to ease the symptoms and depression, and greater family support was correlated with improved quality of life. In a study conducted on middle-aged women, social support was found to mitigate climacteric symptoms through direct effect on quality of life, with higher perceived support from family or friends associated with lower degrees of climacteric symptoms. More severe climacteric symptoms were associated with lower quality of life, indicating that climacteric symptoms affect health-related quality of life.
Moreover, the level of satisfaction with married life was also found to be a factor affecting health-related quality of life in married middle-aged women. This is similar to the conclusion of a preceding study where those who enjoyed hobbies with their spouse had a higher couple intimacy and those with higher family support had higher couple intimacy. In other words, those receiving higher family support and higher support from their spouse in particular, had a higher couple intimacy and higher satisfaction level with their marriage. This indicates that higher satisfaction with married life and greater support from the spouse and family would ease climacteric symptoms and improve health-related quality of life in middle-aged women. As such, an effective nursing intervention measure must be developed by taking into account the fact that social support, climacteric symptoms and satisfaction with married life are factors affecting health-related quality of life in middle-aged women.

Conclusions

The findings of this study suggest that social support, climacteric symptoms, and satisfaction with marriage affect health-related quality of life in such women. This researcher hopes that the findings of this study will serve as a basis for developing and applying various nursing intervention programs in local communities to boost couple intimacy and satisfaction with marriage, to ultimately improve health-related quality of life in married middle-aged women. As this study conducted a survey on married middle-aged women in only a certain region of Korea, the findings cannot be generalized. It is suggested that a wider base of subjects be used for a follow-up study that can help identify additional factors that affect the health-related quality of life of married middle-aged women.

ABSTRACT

Currently, a very common variant of carbohydrate metabolism in the modern world is type I diabetes. Of the diseases associated with lipid disorders, obesity is the most common on the planet. The most effective means of physical rehabilitation in the combination of diabetes mellitus and obesity is the muscular load of moderate intensity, which involves medium and large muscles with a significant number of repetitions. During such work, per unit of time, the body energy expenditure is small, however, due to the long exercise time, the total energy consumption is significant. Aerobic mode of work contributes to the adequate absorption of glucose from the blood and its complete combustion in the muscles with a decrease in the sugar content in the blood. In addition, against the background of regular physical exertion in the body of patients, the activity of mobilization and utilization of lipid sources for energy supply of the contractile function of muscles increases. With mild and moderate severity of the disease, regular endurance training increases the overall effectiveness of the treatment of diabetes and obesity, stabilizes blood glucose and body weight, which results in a reduction in the dose of insulin injected.

Keywords: physical activity, physiology, lipid metabolism, carbohydrate metabolism, diabetes, obesity.

Introduction

The regular development of any living organism is associated with the consistent implementation of the program of hereditary information¹,². Its deployment is closely related to the influence on the body of environmental factors³,⁴. The formation of the general functional status of the organism largely depends on their positive or negative character⁵,⁶. For this reason, accurately predicting the further state of his health is quite difficult⁷,⁸. In addition, the ontogeny of the body is always accompanied by numerous age-related changes that are not always functionally beneficial⁹,¹⁰. All this determines the violation of the optimum activity of the body at any age with the development of various dysfunctions and diseases¹¹,¹². Their presence weakens the vitality of the body and the work of all internal organs. Very common among them in humans in modern society are various disorders of carbohydrate and fat metabolism¹³,¹⁴.

The most frequent variant of the disturbance of carbohydrate metabolism in the modern world is diabetes mellitus type I. According to the World Health Organization on the planet, the number of people suffering from diabetes type I increased from 108 million in 1980 to 422 million in 2014.

Of the diseases associated with lipid disorders, obesity is the most common on the planet. It is noticed that excess fat deposition in itself can worsen carbohydrate metabolism. When diabetes is combined with obesity, metabolic disorders are greatly aggravated. This significantly weakens the body and leads to the
development of numerous complications. In this regard, the aim of the paper is to consider the basics of the use of physical activity in patients with a combination of type I diabetes and obesity.

**Material and Research Method**

The study was approved by the local ethics committee of the Russian State Social University on September 15, 2017 (protocol №11).

The material of the study served 43 literary sources. As methods of the study, methods of analysis and synthesis, methods of induction and deduction, and a method of generalization were used.

**Research Results**

Type I diabetes is a disease that is characterized by chronic hyperglycemia, polyuria, thirst, weight loss, a decrease or, conversely, an increase in appetite and general asthenia. Currently, there are two types of insulin-dependent diabetes: immuno-dependent and idiopathic. In immunodependent diabetes, low insulin levels are associated with the destruction of specific pancreatic cells due to an autoimmune reaction in the body. Insulin autoantibodies and pancreatic cells are detected in the patient’s blood. These antibodies disappear after the complete destruction of pancreatic cells.

In the case of idiopathic diabetes, autoantibodies are not detected. At this time, the reason for the weakening of the pancreas in this form of pathology has not been determined.

Especially often diabetes is combined with obesity, as well as increased cholesterol in the blood, lowering thyroid and adrenal gland functions, heart dysfunction, gout, osteochondrosis, inflammatory and obstructive processes in the respiratory system.

Often, obese diabetics accelerate vascular atherosclerosis, painful itching of the skin and poorly treatable skin purulent processes (boils) appear. Such patients develop diabetic changes in the kidneys, leading to hypertension, proteinuria and edema. The consequence of a metabolic disorder is a general functional weakness of the organs with its progression up to a fatal outcome.

Obesity is a disease that is characterized by metabolic disorders with excessive deposition of fat in the human body. Like diabetes, obesity is considered an epidemic of the 21st century. According to the World Health Organization, since 1975, the number of obese people in the world has more than tripled. Already in 2016, more than 1.9 billion people on the planet over 18 years old were overweight, and over 650 million of them were obese. Today, almost every second inhabitant of the planet is obese 1 degree. It is considered that overweight is a condition in which a significant amount of fat and its ratio to muscle tissue accumulates in the body. Normally, the regulator of this ratio in the body is the correspondence between anabolism and catabolism, and if a person moves little, then a certain part of the nutrients consumed with food is converted into fat.

A particular health hazard in diabetes mellitus type I is abdominal (android) obesity. In the case of the android type of obesity, an increase in blood pressure occurs most often, shortness of breath with minimal exertion, the functioning of the digestive system and the menstrual cycle is disturbed. In itself, abdominal obesity is often the impetus for the development of diabetes, atherosclerosis and hypertension.

The appearance and progression of these diseases is directly related to the adverse effect of excess fat on the internal organs. Most of it accumulates in the subcutaneous tissue and on the abdominal organs (in the omentum, on the stomach and intestines). As a result, the work of these organs deteriorates.

It is customary to distinguish four degrees of obesity. The degree of this disease can be determined using special tables that help calculate the ideal body weight, taking into account the patient’s sex, height and age, as well as body mass index. Grade 1 obesity is diagnosed when the patient’s body weight is above normal by 20-29%. Grade 2 obesity is considered when the patient’s body weight exceeds the norm by 39-49%. Grade 3 obesity is a condition where body weight is 59-99% higher than ideal. With 4 degrees of obesity, the patient’s body weight exceeds the ideal mass by 100 percent or more. Previously, it was believed that this disease predominantly affects women, but according to statistics, both sexes are affected almost equally. It is clear that diabetes mellitus type I and abdominal obesity are very dangerous diseases of modern man. Their combination dramatically worsens the state of health and forms a very negative prognosis. Their presence closes the vicious circle - one pathology burdens another. Regular exercise
increases the sensitivity of insulin receptors and thereby reduces the level of glucose and lipids in the blood. This often allows patients to reduce the dose of insulin injected and significantly reduce body weight\textsuperscript{22}.

The most effective means of physical rehabilitation in the combination of diabetes mellitus and obesity is the muscular load of moderate intensity, which involves medium and large muscles with a significant number of repetitions. During such work, per unit of time, the body energy expenditure is small, however, due to the long exercise time, the total energy consumption is significant. Aerobic mode of work contributes to the adequate absorption of glucose from the blood and its complete combustion in the muscles with a decrease in the sugar content in the blood\textsuperscript{23}. In the introductory period of aerobic exercise, such patients should be advised to use walking and, if the patient’s condition permits, to run. It should be performed at such a pace that the pulse is kept within 110 - 140 per minute. It is not necessary to significantly increase the speed of running in such patients - it is dangerous. In this category of patients it is rational to gradually increase the load by increasing the duration of walking or running. The main criterion for the adequacy of the load performed should be considered patient well-being. We must strive to gradually bring the duration of training up to 40 - 60 minutes\textsuperscript{24}.

In addition to aerobic exercises with a combination of diabetes and obesity, gymnastic exercises should be used in combination with breathing exercises, which helps to activate fat burning and normalize their metabolism in the body. The specific selection of exercises and the mode of their implementation should be determined by the initial degree of fitness of the patient, his general condition, the available clinical picture and the severity of insulin deficiency\textsuperscript{25}.

Regular physical exercises stimulate protein metabolism, contributing to overall recovery, minimize the manifestations of the pathology of the gastrointestinal tract, musculoskeletal system, respiratory system, liver, reproductive system. As with taking medications, when applying physical activity, you must follow a number of simple rules. During the load, it is necessary to consume 1 XU (apple) every 30 minutes in order not to get hypoglycemia. With high-intensity training should reduce the dose of insulin by 20-50\%\textsuperscript{26}.

### Discussion

The great benefit of reduced muscle activity in patients with diabetes mellitus type I and obesity is associated with the mobilization of the utilization of carbohydrates and fats in the body against its background. The main consumer of glucose and lipids from the blood during work is brain tissue. A significant part of them also absorbs the heart muscle and skeletal muscle\textsuperscript{27}.

The relationship between carbohydrate and lipid metabolism depends on the intensity and duration of muscle activity. With short-term physical exertion, when predominantly anaerobic splitting of the glycogen of the muscles is observed, the accumulation of lactate inhibits lipolysis in adipose tissue and skeletal muscles, inhibiting harmoniously sensitive lipase. At the same time, prolonged physical exertion causes a decrease in the concentration of free fat in the blood and an increase in the blood flow to the working muscles leads to a decrease in their utilization during prolonged physical exertion, which is very physiologically beneficial for disorders of carbohydrate and fat metabolism\textsuperscript{28}.

Against the background of physical exertion, the glucose level in the blood of such patients is often normalized and then can be maintained for some time within the normal range. This occurs due to a decrease in the glycogen content in the muscles and the liver, which inevitably leads to a drop in the glucose concentration in the blood. At the same time, it is lipid sources that are important energy substrates for the metabolism of skeletal muscles when performing regular feasible physical exertion.

Mobilization and utilization of carbohydrate and lipid sources for energy supply of the contractile function of muscles during physical exertion is controlled by epinephrine, norepinephrine, insulin, cartosol. Their number in the course of regular muscle activity, even with obesity and diabetes mellitus, increases significantly. This hormonal response to physical work favors successful hepatic glycogenolysis, as well as lipolysis\textsuperscript{29}.

Prolonged physical activity in such patients at the level of 30\% of the maximum oxygen consumption is
accompanied by a significant contribution of free fatty acids of the blood plasma to its energy supply. At the same time, an increase in the intensity and a decrease in the duration of muscle activity leads to an increasing use of carbohydrates as the main energy sources.

**Conclusion**

The most frequent variant of the disturbance of carbohydrate metabolism in the modern world is diabetes mellitus type I. Of the diseases associated with lipid disorders, obesity is the most common on the planet. Their combination dramatically worsens the state of health and forms a very negative prognosis. The most effective means of physical rehabilitation in the combination of diabetes mellitus and obesity is the muscular load of moderate intensity, which involves medium and large muscles with a significant number of repetitions. During such work, per unit of time, the body energy expenditure is small, however, due to the long exercise time, the total energy consumption is significant. Aerobic mode of work contributes to the adequate absorption of glucose from the blood and its complete combustion in the muscles with a decrease in the sugar content in the blood. With mild and moderate disease, regular endurance training increases the overall effectiveness of treating diabetes and obesity, stabilizes blood glucose and body weight, resulting in a reduction (on average by 25%) the dose of insulin injected.

ABSTRACT

Currently, bronchial asthma is one of the most common diseases in childhood and adolescence, capable of consistently worsening the quality of life of patients, and in severe cases it leads to disability. Despite the fairly widespread prevalence of bronchial asthma in adolescents, the specifics of disorders in them in the external respiration system require clarification. For this reason, an additional examination of patients in this category was conducted. The aim of the work is to assess the impairment of the functional state of the respiratory system in adolescents suffering from bronchial asthma. The study involved 38 adolescents aged 13–14 years suffering from at least 5 years of moderate bronchial asthma without signs of respiratory failure. At the time of the examination, the disease in the examined adolescents was in a state of unstable remission. The control group consisted of 20 adolescents of the same age, clinically completely healthy. For adolescents with asthma is characterized by a decrease in lung capacity and bronchial diameter of any caliber. This inevitably leads even in adolescents suffering from at least 5 years of bronchial asthma, to a marked decrease in the functional capabilities of the respiratory apparatus. It became clear that early in this disease, resistance of the respiratory center to hypoxia and weakening of the adaptive capacity of the entire respiratory system occurs. In adolescents with bronchial asthma, all the identified disorders lead to an increase in the functional weakness of their respiratory and circulatory systems, and, consequently, they form a low resistance to hypoxia even at a young age.

Keywords: respiratory system, bronchi, lungs, bronchial asthma, adolescents.

Introduction

The course of ontogeny of any organism implies its continuous interaction with the environment, which does not always have a beneficial effect. All external influences on the organism cause in it sometimes a whole series of genetically determined reactions aimed at adapting to the current conditions of existence. Due to the severity of adverse environmental effects and the presence in some cases of imperfect adaptation mechanisms and responses in the body, various dysfunctions can occur, and sometimes pathological processes.

Observations show that the cardiovascular system, the blood system and the respiratory system are very vulnerable in the human body. Being life support systems, they largely support the overall viability of the mammalian organism. At the same time, in recent years there has been a marked increase in the number of various lung diseases, especially at young and young age.

Bronchial asthma is currently one of the most common diseases in childhood and adolescence, capable of consistently worsening the quality of life of patients and their families, and in severe pathology leading to disability. It is precisely established that bronchial asthma is a chronic disease of predominantly inflammatory and allergic etiology. It often develops against the background of a hereditary predisposition to allergic processes.

The total number of patients with bronchial asthma in the modern world is more than 150 million people. In
Russia now there are about 8 million people (about 9% among children and adolescents and about 5% among adults), and 1 million of them have a severe course of the disease. However, there is reason to believe that the true prevalence of bronchial asthma is several times higher, since it is officially registered only in 1 out of 4-5 patients.\(^{15}\)

Despite the fairly widespread prevalence of bronchial asthma in adolescents, the specifics of disorders in them in the external respiration system require clarification. For this reason, it was necessary to conduct additional examinations of patients in this category.

The purpose of the study is to assess the impairment of the functional state of the respiratory system in adolescents suffering from bronchial asthma.

**Materials and Research Method**

The study was approved by the local ethics committee of the Russian State Social University on September 15, 2017 (protocol №11). The study was conducted on the basis of the Moscow Children’s City Polyclinic No. 38 and the Russian State Social University, Moscow, Russia. The study involved 38 adolescents aged 13–14 years suffering from at least 5 years of moderate bronchial asthma without signs of respiratory failure. At the time of the examination, the disease was in all adolescents in a state of unstable remission. The control group consisted of 20 adolescents of the same age, clinically completely healthy.

Studies were conducted on the spirograph SMP-21/01-“P-D” produced by the Scientific-Production Enterprise “Monitor” (Russia). According to the spirogram, a number of indicators were evaluated: minute respiratory volume, lung capacity, maximum lung ventilation, inspiratory reserve volume, expiratory reserve volume, forced vital capacity, forced expiratory volume in 1 second, peak volume rate, maximum volume rate at 25%, 50% and 75% of the forced vital capacity.

All examined were subjected to a functional test of the Post by determining the maximum possible breath-holding time after a deep breath. It was performed in all cases after resting in a sitting position. The subject took a full breath and then exhale, and then again inhale (80-90% of the maximum) and held his breath for the maximum time possible for him.\(^{16}\)

Also, all Genchi’s functional tests were carried out to all those taken under observation, determining the maximum possible breath-hold time on exhalation. After 3-5 minutes of rest in the sitting position, the patient was asked to take a full exhalation and inhale, and then exhale again and hold the breath.\(^{16}\)

For a holistic and objective assessment of the functional state of the cardiorespiratory system in the examined, the Skibinsky index was calculated. This indicator characterizes the overall functional state of the respiratory system and its resistance to hypoxia. The calculation of the Skibinsky index was carried out in the following way: vital capacity of the lungs/100 × barbell test, s/heart rate. The results obtained during the calculation were evaluated on the following scale: less than 5 - very bad; 5-10 - unsatisfactory; 10-30 - satisfactory; 30-60 - good; 60 or more - very good.

The size of the chest excursion was measured with a centimeter tape, which was applied to the back at the corners of the shoulder blades and in front over the mammary glands (in girls), then the difference between the maximum inhalation and exhalation was calculated.\(^{16}\)

The obtained results were processed by the methods of mathematical statistics using the statistical software packages Microsoft Excel.

**Research Results and Discussion**

In adolescents suffering from bronchial asthma, there was a significant violation of indicators of respiratory function (Table 1).

**Table 1: Indicators of respiratory function in adolescents with bronchial asthma**

Legend: p-confidence of differences in performance between patients and the control group.

It was found that the values of lung capacity in adolescents with asthma were lower than the control group by 20.0%. The magnitude of the forced vital capacity of the lungs was below the control level by 27.0%. At the same time, in terms of the forced expiratory volume in 1 second, the control group exceeded the same indicator in sick adolescents by 29.4%.

When comparing the indices of the minute volume of respiration, it was possible to establish its increase in adolescents with asthma compared with the control group by 23.8%. In addition, in the group of patients, the maximum ventilation rate was reduced by 18.4%.

In the group of adolescents with asthma, the peak volume rate was reduced by 73.1%. This was accompanied by their reduction by 34.4% of the average value of the maximum volumetric flow rate at 25% of the value of the forced vital capacity of the lungs. Their maximum space velocity, at the level of 50% and 75% of the forced vital capacity, was reduced by 30.4% and 20.0%, respectively. In addition, in adolescents with bronchial asthma, the indices of hypoxic samples and the level of chest excursion were significantly lower than those in the control group. The average Skibinsky index in adolescent patients was significantly lower than in the control group (2.3 times).

Discussion

Currently, asthma in adolescents is a very common pathology. Often, it manifests itself already in childhood and progresses rapidly, sometimes leading to disability in young and mature age17,18.

It was shown that a significant decrease in lung capacity is characteristic of this group of patients19,20. In addition, they have an average indicator of forced vital capacity of the lungs also significantly inferior to the level of control. Increasing their bronchial obstruction inevitably leads to a decrease in the forced expiratory volume in 1 second. This was confirmed by the study. The authors found a decrease in the maximum ventilation index in adolescents with asthma21,22. These changes should be considered as evidence of the low functional capacity of the respiratory apparatus in adolescents suffering from bronchial asthma, as well as in their ability to mobilize reserves of respiratory function23,24,25.

A comparison of the indices of the minute volume of respiration in both groups of observations showed an increase in adolescents with bronchial asthma26,27. At the same time, the found decrease in peak volumetric rate in the group with bronchial asthma proved for them the presence of low functionality of the respiratory muscles and reduced patency of large-caliber bronchi. The reduced values of the maximal volumetric rate at 25% of the forced vital capacity of the lungs confirmed the development in adolescents with bronchial asthma and the progressive deterioration in patency at the level of the large bronchi28,29. The found decrease in bronchial asthma of the average values of the maximum volumetric rate at 50% and 75% of the forced vital capacity of the lungs also proved in patients with adolescents a decrease in the patency of their bronchi of medium and small caliber. Negative changes in their indices of hypoxic tests and a reduction in the volume of the chest excursion proved the possibility of developing already in adolescence with this pathology of a pronounced resistance of the respiratory center to hypoxia and weakening the adaptive capacity of the entire respiratory system30,31,32. The decrease in the Skibinsky index found in the observation group should be regarded as a manifestation of functional weakness of the respiratory and circulatory organs against the background of bronchial asthma, and, consequently, their body’s low resistance to any hypoxic conditions33,34,35.
Conclusion

Currently, asthma remains one of the most common diseases of the respiratory system. The presence in this pathology of changes in the sensitivity of the walls of the bronchi to external influences and the development of their hyperresponsiveness creates the basis for respiratory dysfunction. These disorders occur already in adolescence and sometimes manifest significant impaired respiratory function. These patients are characterized by a decrease in lung capacity and bronchial diameter of any caliber. Already in adolescents suffering from bronchial asthma, this leads to a marked decrease in the functional capabilities of the respiratory apparatus, as well as to a weakening of the ability to mobilize the reserves of the respiratory apparatus.

ABSTRACT

The aim of the work is to assess the impairment of the functional state of the respiratory system in adolescents suffering from bronchial asthma. The study involved 38 adolescents aged 13–14 years suffering from at least 5 years of moderate bronchial asthma without signs of respiratory failure. At the time of the examination, the disease in the examined adolescents was in a state of unstable remission. The control group consisted of 20 adolescents of the same age, clinically completely healthy. For adolescents with asthma is characterized by a decrease in lung capacity and bronchial diameter of any caliber. This inevitably leads even in adolescents suffering from at least 5 years of bronchial asthma, to a marked decrease in the functional capabilities of the respiratory apparatus. It became clear that early in this disease, resistance of the respiratory center to hypoxia and weakening of the adaptive capacity of the entire respiratory system occurs. In adolescents with bronchial asthma, all the identified disorders lead to an increase in the functional weakness of their respiratory and circulatory systems, and, consequently, they form a low resistance to hypoxia even at a young age.

Keywords: rehabilitation, respiratory system, lungs, bronchial asthma, adolescents.

Introduction

The individual development of a living organism is associated with its constant interaction with the environment, which often has an adverse effect on it. All effects on the organism from the environment form in it a whole series of regular reactions aimed at adaptation to the existing conditions of life activity. Due to the severity of adverse environmental effects and, in some cases, imperfect adaptation reactions in the body, various dysfunctions sometimes develop, and sometimes obvious pathology.

The cardiovascular system, the blood system and the respiratory system are highly susceptible to pathological processes in the human body. They are life support systems and, as a result, largely support the overall viability of the mammalian organism. However, it is in them that the appearance of various pathologies is realized. At the same time, there is an increase in lung diseases, especially at an early age. One of these diseases is bronchial asthma. Currently, it is one of the most common diseases in adolescence, which greatly deteriorates the quality of life and often leads to disability.

The number of patients with bronchial asthma in the world reaches 150 million. In Russia now there are about 8 million people (about 9% among children and adolescents and about 5% among adults), and 1 million of them have a severe course of the disease. There is reason to believe that the true prevalence of bronchial asthma is several times higher, since it is officially registered only in 1 out of 4-5 patients.

The prevalence of asthma and its sometimes severe course is currently creating an urgent need to improve the approaches to the rehabilitation of this cohort of patients, using a wide range of health effects.

To date, developed many methods of medical treatment of bronchial asthma. However, their frequent and long-term use has a number of side effects and does not provide in all cases stabilization of the patient’s
Especially not studied modern medicine the possibility of exercise based on the elements of yoga.

The purpose of the study is to assess the rehabilitation capabilities of the asanas complex in terms of correction of the functional state of the respiratory system in adolescents suffering from bronchial asthma.

**Materials and Research Method**

The study was approved by the local ethics committee of the Russian State Social University on September 15, 2017 (protocol №11). The study was conducted on 38 adolescents aged 13-14 years suffering from at least 5 years of moderate bronchial asthma without signs of respiratory failure. At the time of the first survey, the disease was in all adolescents in a state of unstable remission. The control group consisted of 20 adolescents of the same age, clinically completely healthy.

All adolescents with asthma underwent physical rehabilitation for 3 months according to the scheme below. The applied rehabilitation included the daily performance of the following asanas, developed and tested by thousands of years of practice of Indian medicine:

1. Asana “Cobra”. Starting position - lie down on your stomach, with your palms on both sides of your chest, bending your elbows. Legs straight, pulled together, socks stretched. During inhalation, leaning on the arms, gently lift the upper half of the body and head upwards, and deflect them as far back as possible. Asana is performed 8-10 times per exercise.

2. Asana “Locust”. Starting position - lie on the stomach so that the chin touches the floor. Hands lie along the body, fingers clenched into fists, socks stretched. Inhale deeply and simultaneously raise your right leg as high as possible. When holding your breath while inhaling, keep your leg as high as possible and then lower your leg to the starting position. Asana is performed 8-10 times.

3. Asana “Bow”. Starting position - lie on your stomach, lift your legs bent at the knees, hold your ankles with your hands. Inhale deeply and pull both legs up, bending the back. Stay in that position, hold your breath, then as you exhale, slowly lower your legs. Asana is repeated 10-12 times.

4. Asana “Folding knife”. Starting position - lie on your back, stretch your legs. Inhale deeply and as you exhale, raise the bent right leg. With both hands, press the knee firmly against the stomach, holding the breath. Put your hands on the sides of the torso. Extend the leg and as you exhale slowly lower it to its original position. Make a similar movement with the other leg, and then with both feet together. Asana is repeated 8-10 times.

5. Asana “Birch”. Starting position - lying on your back, arms along the body, palms down. With an exhalation, bend the legs at the knees and pull them up to the stomach. Then, rest your hands on your back, lift the torso vertically upwards. Asana is repeated 8-10 times.

6. Asana “Cleansing Breath”. Starting position - standing. After the maximum exhalation, inhale through the nose, as with full breathing. After that, immediately begin to exhale through the mouth: press the lips tightly to the teeth, leave only a narrow gap between them, through which to produce a forced exhalation with several pushes, to strain the abdominal muscles and intercostal muscles. Asana perform 6-8 times.

7. Asana “Blacksmith”. Starting position - sitting in the lotus position. After a full exhalation, quickly inhale and exhale through the nose - 10 times, then exhale, hold the breath for 7-10 seconds, inhale, followed by a breath hold for 10-15 seconds. Gradually bring the number of breaths in one cycle to 25-30. Asana is repeated 5 times.

The study used the spiograph SMP-21/01-“P-D” produced by the Scientific-Production Enterprise “Monitor” (Russia). With it, a spirogram was recorded, which was used to evaluate the minute respiration volume, lung capacity, maximum lung ventilation, inspiratory reserve volume, expiratory reserve volume, forced lung capacity, forced expiratory volume in 1 second, peak volume velocity, maximum volume velocity at the level 25%, 50% and 75% of the value of the forced vital capacity of the lungs.

In the work, all the examined were subjected to a functional Stanbe test by determining the maximum possible breath-holding time after a deep breath. It was performed in all cases after resting in a sitting position.
All taken under the supervision of a functional test performed Genchi, determining the maximum possible breath-hold time on the exhale\textsuperscript{18}.

For a complete and objective assessment of the functional state of the cardiorespiratory system in the subjects, the Skibinsky index was calculated.

The activity of the chest excursion was measured using a measuring tape, which was applied to the back at the corners of the shoulder blades and in front over the mammary glands (in girls), then the difference between the maximum inhalation and exhalation was calculated\textsuperscript{18}.

The results of the study were processed by the methods of mathematical statistics using the statistical software packages Microsoft Excel.

**Research Results and Discussion**

In adolescents suffering from bronchial asthma, there was a significant violation of indicators of respiratory function (Table 1).

**Legend:** \(p\) - reliability of differences in indicators between patients and the control group, \(p_1\) - reliability of the dynamics of indicators against the background of rehabilitation.

As a result of rehabilitation activities carried out for 3 months in adolescents with asthma, an increase in lung capacity was achieved to the level of the control group (by 15.0%). At the same time, the value of the forced vital capacity of the lungs in them also reached the level of control, having increased by 22.2%. By the end of the observation, in terms of the forced expiratory volume in 1 second, the control group was equal to the same indicator in adolescent patients due to its growth by 23.5%.

During physical rehabilitation in adolescents with bronchial asthma, normalization of the minute volume of respiration was achieved due to its decrease by 46.8% and the maximum ventilation rate as a result of its increase by 14.9%.

Rehabilitation of adolescents with asthma provided an increase in peak volume rate of 53.8%. In these adolescents, by the end of the observation, the maximum volumetric rate, which is at 50% and 75% of the forced vital capacity, increased by 26.1% and 13.3%, respectively. In addition, in adolescents with asthma against the background of the rehabilitation, the indices of hypoxic samples and the level of the chest excursion increased significantly and approached those in the control group. At the same time, the average value of the Skibinsky index in adolescent patients increased significantly and by the end of the observation corresponded to the level of the control group.
Discusson

In the modern world, asthma is a very common pathology in adolescents. Often it manifests itself already in childhood and progresses very quickly\(^{19,20,21}\).

It was found that the applied asan complex provided in adolescent patients an increase to the level of the lung capacity\(^{22,23}\). In addition, they managed to significantly increase their average forced vital capacity\(^{24,25}\).

Rehabilitation provided adolescents with a decrease in the minute volume of respiration, which was accompanied by an increase in peak volume velocity, proving the development of an increase in the functionality of the respiratory muscles and optimization of the large-caliber bronchi\(^{26,27}\). The found changes on the background of the rehabilitation of the maximum volumetric rate indicator at the level of 25% of the forced vital capacity of the lungs indicated a significant increase in the patency of the large bronchi in the treated adolescents\(^{28}\). Achieved during the rehabilitation of adolescents with bronchial asthma, the growth of average values of the maximum volumetric rate at 50% and 75% of the forced vital capacity of the lungs proved the optimization of the passability of the bronchi of medium and small caliber in them\(^{29}\). Positive changes in them during the rehabilitation of the indices of hypoxic samples and the volume of the chest excursion proved the possibility of normalization in adolescence with this pathology of the sensitivity of the respiratory center to hypoxia and the adaptive capacity of the entire respiratory system.

Conclusion

The development of asthma changes the sensitivity of the walls of the bronchi to external influences and leads to their hyperresponsiveness. Early in this disease, resistance of the respiratory center to hypoxia and weakening of the adaptive capacity of the entire respiratory system occurs. This leads to an increase in the functional weakness of the respiratory system and circulatory system, forming a low resistance of the young organism to hypoxia. The system of asanas, tested in adolescents with asthma, helped to gradually eliminate disturbances in the system of external respiration, establishing a normal relationship between the cerebral cortex and internal organs.

ABSTRACT

The Aim: to evaluate the developmental changes in the hemostatic properties of platelets in outbred rats aged between 3 and 24 months of ontogenesis.

Materials and Method: The study included 156 outbred healthy male rats, including 28 heads at 3 months of age, 31 rats aged 6 months, 33 heads aged 12 months, 34 animals aged 18 months and 30 rats aged 24 months. Used biochemical, hematological and statistical research methods.

Results: The amount of lipid peroxidation products in rat platelets remained stably normal for up to 12 months, subsequently progressively increasing until the end of observation. This was due to the change in their physiological properties of catalase and platelet superoxide dismutase. Their activity in rats remained stably large until 12 months, and subsequently gradually decreased until the end of the observation. The found changes were accompanied in rats by an increase in the platelets of self-assembly of the actin-myosin complex, as well as the level of content in them and the degree of secretion from them of the ADP and ATP molecules after 12 months of age. In animals older than 1 year, an increase in the ability of platelets to aggregate was observed, which indicated an increase in their primary hemostasis.

Conclusions: The found gradual increase in the level of platelet activity in rats during the second year of their life indicates an increase with age of expression of fibrinogen receptor on the surface of platelets to various inducers of platelet aggregation and an increase in the activity of intra-platelet hemostatic processes.

Keywords: ontogenesis, rats, platelets, aggregation, secretion, lipid peroxidation.

Introduction

Recently, the greater physiological significance of platelet activity in providing the necessary adaptive manifestations of the body has become increasingly clear. It has been found that platelets have a serious regulatory role in ensuring the optimum microcirculation, which are required for the development and maximum realization in the phenotype of all genetically determined traits. They are very sensitive to all impacts from the external environment can be activated in response to a large number of environmental factors of different nature. As a result of changes in the ability of the aggregation process, platelets regulate hemocirculation processes and, thus, trophism of tissues.

For the successful implementation of many studies, it is of great scientific and practical interest to determine the ontogenetic changes in the hemostatic properties of platelets, which are very important during the process of thrombus formation. This information is very relevant for successful research in various models of cardiovascular disorders.

It has been observed that during an increase in chronological age, platelet activity in a person changes. For this reason, the assessment of the age dynamics of platelet functions throughout ontogenesis in rats, which are very often used in laboratory animals in studies, is very relevant. This information can be very useful for an experimental search for corrective effects on platelet function at different ages and in many pathological
processes\textsuperscript{15,16}, which are very common in humans. In this regard, the purpose of this study was to assess the developmental changes in the hemostatic properties of platelets in outbred rats aged between 3 and 24 months of ontogenesis.

**Materials and Research Method**

This study was carried out in full compliance with the norms of ethics defined by the European Convention for the Protection of Vertebrate Animals used for experimental and other scientific purposes (adopted in Strasbourg on 03.18.1986 and confirmed in Strasbourg on 15.06.2006). The study took outbred healthy male rats (n = 156), which were obtained at the age of 2 months from the nursery of laboratory animals of the Branch of the Institute of Bioorganic Chemistry (Moscow Region, Pushchino). The rats stayed in the quarantine zone for 14 days, and subsequently were kept in standard vivarium conditions in fairly spacious cages (the surface area of the bottom of the cage per 1 rat was 200 cm\(^2\)). In one cage were placed no more than 8 animals. Replacement of cells was carried out 2 times during the week. Before placing the animals in them, the cells were disinfected. Dry litter was located in the cells, having a thickness of 5-10 mm (sawdust, dry peat, wood chips), previously autoclaved at a temperature of 150-180°C. In all cells, the litter was replaced once a day. Natural lighting was used, the temperature was maintained at 18-22°C, relative humidity was maintained at 50-65\%, the level of ammonia in the air was not more than 0.01 mg/l, the amount of carbon dioxide in the air by volume was not more than 0.15\%, the multiplicity indicator air exchange (volumes per hour) was 8 by exhaust, 10 by inflow. Before being included in the study, rats did not participate in other experiments. All animals received high-grade compound feed intended for laboratory animals (produced by Laboratorykorm, Moscow) of brand PK-120. In rats, water was available in unlimited access.

Blood from rats was taken from the tail vein once, including 28 heads at 3 months of age, 31 rats aged 6 months, 33 heads aged 12 months, 34 animals aged 18 months and 30 rats age 24 months.

In rats, the general state and results of biochemical and hematological blood parameters were determined. Blood plates were obtained from them during washing and resuspension for further evaluation of the amount of malondialdehyde (MDA) in them, using the reduction reaction of thioarbituric acid and recording the amount of acylhydroperoxides (AHP)\textsuperscript{17}. The activity of intrathrombocyte enzymes with the antioxidant activity of catalase and superoxide dismutase (SOD) has been elucidated\textsuperscript{18}. The levels of adenosine triphosphate (ATP) and adenosine diphosphate (ADP), the activity of their secretion in response to the action of collagen, were also determined in platelets. The composition of the protein platelet cytoskeleton consisting of actin and myosin was determined in the case of activation and in the case of platelet aggregation in response to ADP and thrombin\textsuperscript{19}. The number of platelets in the blood was detected using the camera Goryaeva. The expression of platelet aggregation (AP) was detected by standard micromethod\textsuperscript{20}, using a number of agonists: ADP (0.5 (10\(^{-4}\) M), collagen (dilution 1: 2 of the main suspension), ristomycin (0.8 mg/ml), H\(_2\)O\(_2\) (7.3×10\(^{-3}\) M), thrombin (0.125 units/ml), adrenaline (5×10\(^{-6}\) M). The state of intravascular platelet activity (IPA) was assessed by microscopy using a phase-contrast nozzle\textsuperscript{21}. The obtained digital results were processed by the Student’s criterion, using the program StatSoft STATISTICA for Windows 6.0.

**Research Results and Discussion**

The overall functional status of the rats in all their observation groups was normal. The parameters of platelets in rats during ontogenesis were stable between 3 and 12 months of their life. The number of AGP in their platelets at the age of 3 months it turned out to be 2.38 ± 0.15 D\(_{235}\)/10\(^9\) platelets, not changing up to 12 months 2.40 ± 0.12 D\(_{235}\)/10\(^9\) platelets and increasing by 18 months to a level of 2.66 ± 0.19 D\(_{235}\)/10\(^9\) platelets and then increasing by the 24 months to 2.86 ± 0.29 D\(_{235}\)/10\(^9\) platelets. The MDA level in platelets in rats aged 3 months was 0.68 ± 0.11 mmol/10\(^9\) platelets, remaining unchanged for up to 12 months of life (0.70 ± 0.09 mmol/10\(^9\) platelets), rising to 18 months to 0.87 ± 0.18 mmol/10\(^9\) platelets and by 24 months to 0.95 ± 0.14 mmol/10\(^9\) platelets. The physiological properties of catalase and SOD of platelets in rats were stable up to 12 months (9920.0 ± 14.07 IU/10\(^9\) platelets and 1860.2 ± 17.06 IU/10\(^9\) platelets), and subsequently decreased and reached in 24 month-old rats 8610.0 ± 12.07 IU/10\(^9\) platelets and 1640.0 ± 3.52 IU/10\(^9\) platelets, respectively. The found dynamics of peroxidation processes during ontogenesis in rats significantly ensured the features of functional mechanisms involved in platelet hemostasis.
found in them, including the course of self-assembly of the actin-myosin complex, as well as the presence of ADP and ATP molecules in platelets. Thus, over the course of the observation, the amounts of ATP and ADP in the animal platelets \((5.56 \pm 0.18 \mu\text{mol/10}^9 \text{ platelets and } 3.32 \pm 0.10 \mu\text{mol/10}^9 \text{ platelets})\) persistently increased to 12 months gradually increasing, reaching at the age of 24 months to \(5.88 \pm 0.26 \mu\text{mol/10}^9 \text{ platelets and } 3.82 \pm 0.23 \mu\text{mol/10}^9 \text{ platelets},\) respectively. The activity of secretion from platelets of rats ATP and ADP under the action of collagen with increasing age increased in total by 13.4% and 14.2%, respectively.

The content of actin in the platelets of rats between the ages of 3 and 12 months turned out to be fairly stable and small, but increased at an older age, reaching by 2 years \(39.8 \pm 0.20\%\) of the total protein in the platelet. The level of additional assembly of actin in rats against the background of platelet activation by a strong or weak inducer and during platelet aggregation also increased after 12 months of ontogenesis. A similar pattern of activity in animal platelets was also found for myosin. It was revealed that in the discoid blood plates of one-year-old rats, the content of myosin was \(16.3 \pm 0.22\%\) of the total amount of protein in the platelet. In older rats, this indicator was higher and reached 24.4 months of life \(18.4 \pm 0.23\%\). In the case of activation and development of platelet aggregation, either by strong or weak inducers in rats older than 12 months, the degree of additional myosin self-assembly gradually increased (table).

In the examined rats, already from 12 months, a gradual decrease in the period of occurrence of antibodies was found in response to all inductors used (table). The earliest AP was collagen, occurring in 24 month-old rats for 29.8 ± 0.10 s. Underwent a comparable age dynamics of AP activity in response to ADP and ristomycin occurred in the examined rats a little later. Later, AP developed under the action of H$_2$O$_2$, thrombin and adrenaline, the time of its occurrence with which also decreased in rats older than a year. The marked acceleration of AP in the observed animals agreed with the established fact of IPA enhancement. The found parameters of antibodies with individual inductors made it possible to find out in rats over the age of 1 year the increase in the ability to aggregate their blood platelets. Acceleration of the onset of platelet aggregation in response to strong aggregation inducers (collagen and thrombin) indicated the activation of the enzyme phospholipase C, which implements the phosphoinositol pathway of platelet activation. This happened when the level of diacylglycerol and protein kinase C increased in platelets and with the simultaneous intensification of the assembly of actin and myosin macromolecules in them. Acceleration of AP in response to weak inducers of aggregation, including ADP, indicated an increase in the availability of receptors to it on the platelet surface and at the same time an increase in the expression of fibrinogen receptors, as well as an increase in the activity of phospholipase A$_2$, which releases arachidonic acid from the phospholipids of blood plasmid membranes further synthesis of thromboxane A$_2$. In the blood of rats in the first year of life, the number of small and large platelet aggregates circulating in the blood was also stable and subsequently increased from 3.3 ± 0.06 and 0.12 ± 0.007 per 100 free-lying platelets at the age of 12 months to 5.5 ± 0.08 and 0.35 ± 0.004 per 100 free platelets at 24 months of ontogenesis. The number of platelets involved in the aggregates in rats between 12 and 24 months increased by 34.9%. The established increase in IPA in rats during the second year of their life indicated an increase in the density of receptor on their platelet membranes, which can interact with fibrin and physiological inducers of platelet aggregation while enhancing the functioning of intraplatelet mechanisms for implementing their hemostatic processes.

Conclusion

At the age of 12 months in rats, there is a consistently low platelet aggregation. Subsequently, before the age of 2 years, they have a significant increase in it, manifested by an increase in the number of activated platelets in their blood and their freely moving aggregates. The found gradual increase in the level of platelet activity in rats during the second year of their life indicates an increase with age of the expression level on their surface fibrinogen receptors to various inducers of platelet aggregation against the background of the activation of intra-platelet hemostatic mechanisms.

ABSTRACT

Introduction: One of the main infectious diseases in pre-school children (4-6 years) is Early Childhood Caries (ECC). Parents, especially mothers, play a central role in encouraging children to have good and sustainable habits in maintaining the health of their teeth and mouth. In this era, parents get to know a lot of informations about dental health through the internet.

Objective: This study aimed to analyze the behavior of mothers of pre-school age (4-6 years) children in accessing dental and oral health information.

Method: The population of this study were mothers and children from 10 preschool in the Mojo Health Center area, Surabaya. 228 pairs of mothers and children in kindergarten were selected by simple random sampling as respondents. Data collected by conducting intra oral examination in children with def-t index and questionnaire.

Results: Probability values (P-value) and Prevalence Ratio were obtained using Chi-square Test with categories of intention, attitude, subjective norms, and behavioral control that were perceived towards the behavior of mothers accessing dental and oral health information. The intention, attitude, subjective norms, and perceived behavioral control significantly influenced the behavior of mothers accessing dental and oral health information (P-value <0.05).

Conclusion: The behavior of mothers in accessing dental and oral health information is influenced by intentions, attitudes, subjective norms, perceived behavioral control. However, mother’s intention is only influenced by subjective attitudes and norms.

Keywords: dental caries, health behavior, information seeking behavior, internet access

Introduction

Oral and dental health of pre-school age children highly influences the health of the teeth and mouth when they are adult. Pre-school age children have not been able to think critically about information so that their behavior is based on the behavior of people they consider important. Children will imitate parents as the person closest to them. Therefore, parents have a central role in encouraging children to have good and sustainable habits to maintain dental and oral health¹.

A person’s behavior is based on three aspects, i.e. knowledge, attitudes, and actions². Of the three, the knowledge aspect becomes the most important one as the basis for the formation of behavior. Therefore, a poor knowledge of a mother about dental and oral health can be reflected in her behavior which will be imitated by her child. This shows that maternal knowledge is closely related to children’s behavior.

One of the main infectious diseases in pre-school children is dental caries (early childhood caries). The caries prevalence of pre-school age children in Surabaya in 2017 was high, which was 67.5% with a high degree of severity (def: 7.0)³. This is also based on the mother’s knowledge of the pre-school child respondents surveyed as low (49.1%)⁴.
In preventing dental caries problems in Surabaya, health centers are the leading agents for conducting preventative efforts through health education and promotion to reduce the high rates of dental caries in pre-school age children. Mojo Health Center is a health center in the Surabaya area that houses three villages, i.e. Mojo, Gubeng, and Airlangga sub-districts with a total number of children aged 1-4 as many as 4798 in 2017. Based on preliminary research conducted on 72 children aged 4-6 years in the working area of Mojo Health Center, the prevalence of dental caries obtained reached 87.5% with high severity (def: 6.7).

Based on the description above, it is necessary to examine the level of knowledge of mothers on dental and oral health as well as the behavior of accessing information, in order to obtain a clear and specific picture of the causes of high rates of caries in pre-school children in Mojo Health Center working area.

**Subjects and Method**

This study used observational analytical method with cross sectional approach to the relationship of maternal behavior in kindergarten children in accessing dental and oral health information for preschool children aged 4-6 years in the Mojo Surabaya Health Center area, aiming to analyze the behavior of mothers in accessing dental and oral health information. The sampling technique used was cluster sampling.

Respondents of this study were 228 pairs of mothers and children from 10 kindergartens in the Mojo Health Center area, Surabaya, i.e. Nabawi Islamic Preschool, Fajar Jaya Preschool, Candra Negara Preschool, Hapsari Preschool, Anak Ceria Preschool, Aisyiyah Preschool, PKK V Preschool, Bina Prestasi Preschool, Putra Airlangga Preschool, and Dian Surabaya Preschool.

Mothers as respondents were asked to fill out questionnaires in the form of questions that could provide an overview of the characteristics of parents, parents’ knowledge of dental and oral health, intentions, attitudes, subjective norms, and behavioral controls perceived by mothers towards the behavior of mothers accessing dental and oral health information. In the respondents of children, dental caries examination using WHO was carried out.

The data obtained were processed and cross tabulated using IBM SPSS 20 applications. Correlation between intention, attitude, behavior control perceived by the behavior of mothers accessing dental and oral health information was analyzed using cross tabulation.

**Findings**

The total sample was 228 pairs of mothers and children. However, researchers spread 500 questionnaires and received answers from respondents of 253 questionnaires. Based on this, the calculation was done with a total of 253 results of the questionnaire.

In this study, 86.6% of the respondents had good intentions to access dental and oral health information. This was also reflected in most attitudes (93.7%), subjective norms (69.3%), and perceived behavioral control (96.1%) towards the behavior of mothers in accessing dental and oral health information. The four categories also showed a significant P-value (ρ < 0.05). It means that intentions, attitudes, subjective norms, and perceived control affected the behavior of mothers in accessing dental and oral health information. Whereas, mothers’ knowledge of dental and oral health showed poor results (72.7%) with non-significant P-values (p>0.05).

The mothers’ belief regarding accessing dental and oral health information was good to do showed good results. It can be seen from the behavioral belief value of 93.7%, normative belief of 92.1%, and belief control of 94.1% with a significant P-value (p<0.05). However, the high prevalence of caries (84.7%) and caries severity (def: 6.9) were not in harmony with the results obtained by the researchers.

Table 1 shows that the incidence of poor intentions in mothers with poor attitudes is 100%, while for mothers with a good attitude is 0%. It was found that attitudes were significant (ρ <0.05) on the intention of mothers to access dental and oral health information. Then, poor intention for mothers with poor subjective norm was 15.6% while that in mothers with good subjective norms was 2.3%. It was found that subjective norm was significant (ρ<0.05) with the intention of mothers to access dental and oral health information.

The probability value (P-value) and Prevalence Ratio were obtained using Chi-square tests with the category of mothers’ age variables on the knowledge of mothers accessing dental and oral health information. From Table 2, it can be seen that poor knowledge at the age of <35 years old mothers was 69.8%, while at mothers aged ≥ 35 years was 75.8%. Mothers’ age was not significant (p = 0.28) to the knowledge of mothers in accessing dental and oral health information.

</tbody>
</table>
The caries rate in pre-school age children (4-6 years) in the Mojo Health Center working area obtained very high prevalence rate, i.e. 84.7% with a very high severity (def: 6.9). The high incidence of caries was influenced by children’s behavior in maintaining dental and oral health. According to Bozorgmehr (2013)\(^5\), children’s behavior in maintaining dental and oral health is closely related to the behavior of the surrounding people, especially mother. Pre-school children tend to not be able to decide something by themselves, but are more likely to imitate the people around them, especially mothers\(^1\). This causes the mother’s role to be needed at this stage because the mother is the closest person to the child to provide examples, education, advice, and advice on dental health\(^1\).

Knowledge of parents, especially mothers, in terms of dental and oral health will provide an important role in the education process for children. Mothers with few knowledge tend to not pay attention to the health of their children’s teeth and mouth\(^6\). Knowledge of mothers in dental and oral health can be influenced by several factors, including, education, employment/income, age, and socio-cultural environment. Mother’s education will provide a role in the process of obtaining and processing dental health information and knowledge. Mothers with low education level tend to have an impact on low knowledge too.

In this study, low mother’s knowledge can be influenced by a lack of access to information regarding oral and dental health\(^7\). In this study, mothers’ behavior in accessing information about dental and oral health was analyzed. The intended behavior included taking time and energy to find information, reading and understanding information about children’s dental and oral health.

Based on the Theory of Planned Behavior, the behavior of mothers in accessing children’s dental and oral health information is influenced by the intention of the mothers. Mother’s intention in behaving is influenced by the presence of mother’s attitude, subjective norms, and perceptions of behavior control. These three aspects are influenced by the presence of several beliefs, namely behavioral, control, and normative beliefs\(^8\).

From the model analysis carried out in this study, it was found that perceived behavioral control to directly influence the behavior of mothers accessing dental and oral health information without affecting intention first. Mother’s intention is only influenced by subjective attitudes and norms. With these results, it can be said that this research was more in accordance with the Theory of Reasoned Action (TRA). It means that mothers do not carry out long-term and mature planning to conduct behaviors to access dental and oral health information. Mothers prioritize strong motives or reasons to eventually emerge behavior in accessing dental and oral health information.

Based on the results of statistical test analysis illustrated by p value and prevalence ratio, the most influential variables on mothers’ behavior in accessing dental and oral health information, from the most significant, were (1) mothers’ intentions, maternal behavioral beliefs, (3) mothers’ control beliefs, (4) mothers’ attitudes, (5) mothers’ subjective norms, (6) mothers’ normative beliefs, and (7) perceptions of mothers’ behavior control. It shows that intention is a major risk factor in influencing poor mothers’ behavior in accessing children’s dental and oral health information.\(^9\)

**Conclusion**

Mothers’ behavior in accessing dental and oral health information is influenced by intentions, attitudes, subjective norms, and perceived behavioral control.

ABSTRACT

Aging is recognized as an inevitable biological process. He proved the presence of the genetic component and the environmental component. The aging process affects all organs, gradually weakening their viability and making the death of the body more and more likely. The hemostasis system, including platelets, is also involved in the implementation of the aging process. They also show signs of aging, which play an important role in the development of various pathologies with age. In the experiment in aging rats, a gradual increase in platelet aggregation properties was observed. This leads to an increase in the number of activated blood platelets in their blood and an excess of their aggregates of any size. These changes make a serious contribution to the development with age of a decrease in the reactivity and resistance of the organism, making many of the negative effects from the environment very dangerous for an aging animal. An increase in the intravascular activity of platelets in aging rats indicated an increase in the number of inducers of their aggregation in their blood and an increase in the sensitivity of platelets to them. In rats in the late stages of ontogenesis, this is accompanied by a gradual decrease in the number of inactive discoid platelet varieties in the blood. The increase in the blood of old rats of the number of different active forms of blood platelets is a consequence of the enhancement of their aggregation properties and causes the development of thrombophilia during the progression of aging.

Keywords: aging, rats, aggregation, platelets, intravascular platelet activity.

Introduction

Aging is a very complex biological process. It has a very strong genetic component 1 and a significant environmental component 2. The aging process always affects all organs of the body, gradually weakening their viability and making it more and more likely to die 3. In the hemostasis system, including in platelets, signs of aging are also noted 4, which play an important role in the development of various pathologies with age 5. Particularly significant aspects of platelet function in the clinic of internal diseases 6,7.

Timely and accurate identification of the level of platelet activity 8 and its early and effective correction is in many cases the basis for successful therapy of existing diseases 9,10 and their complications, largely determining the prognosis for life and health 11,12,13. At the same time, in the search for effective therapeutic effects 14,15 with very many diseases in humans 16,17 it is difficult to do without research in the conditions of experimental models in rodents, including outbred rats.

Due to the importance of platelet hemostasis in the formation of age-related pathology and the need to improve the approaches to its treatment, it is important to continue to determine the level of platelet activity in aging outbred rats under normal environmental conditions 18. This information can serve as a basis for understanding the role of platelets in the pathogenesis of age-related pathology and the success of further research in the experiment of secretion options by influencing hemostasis during late ages 19,20.
In this regard, the goal of the work is to find out the peculiarities of age-related changes in platelet activity in outbred rats in the late stages of their ontogenesis.

Materials and Method

The study was conducted in strict accordance with the ethical principles established by the European Convention for the Protection of Vertebrate Animals used for experimental and other scientific purposes (adopted in Strasbourg on March 18, 1986 and confirmed in Strasbourg on June 15, 2006).

The work was performed on 96 healthy outbred male rats. They were kept during their life on the usual diet of the vivarium: 34 heads at the age of 18 months, 30 rats having the age of 24 months and 32 heads at the age of 30 months. Before being included in the study group, all rats did not participate in other experiments and did not have any pathological processes in the body. The control group consisted of outbred healthy male rats at the age of 6 months, a total of 31 animals.

In rats taken in the study, plasma lipid peroxidation activity was determined by recording the level of thiobarbituric acid-active products in it, using the kit manufactured by Agat-Med (Russia), and by the concentration of acylhydroperoxide in their plasma. In the plasma of animals, the level of its antioxidant potential was evaluated. The quantitative content of platelets in the composition of the capillary blood was carried out using the camera Goryaeva. The expression of platelet aggregation was ascertained in the course of using a visual micromethod in response to the use of ADP (0.5 × 10⁻⁴ M), thrombin (0.125 U/ml), collagen (dilution 1: 2 of the main suspension), ristomycin (0.8 mg/ml), hydrogen peroxide (7.3 × 10⁻³ M) and adrenaline (5 × 10⁻⁶ M). The expression of intravascular platelet activity was determined by phase contrast microscopy. The results obtained in the work were subjected to statistical processing using Student’s t-test.

Research Results

In animals, pallor of mucous membranes, dullness of hair, its significant thinning, decrease in general physical activity, weakening of appetite, as well as a low level of interest in everything around, appeared.

In the examined rats, with increasing age, an increase in the plasma concentration of lipid peroxidation products was found (at 18 months acylhydroperoxides 1.62 ± 0.026 D₂₃₃/1 ml., Thiobarbituric acid-active products 3.85 ± 0.019 μmol/l, at 2.5 years 1.93 ± 0.064 D₂₃₃/1 ml and 4.37 ± 0.046 μmol/l against the background of a decrease in the activity of antioxidants from 30.9 ± 0.37% in 18 months to 25.0 ± 0.31% in 30 months). The level of these indicators in the control was respectively 1.43 ± 0.008 D₂₃₃/1 ml, 3.44 ± 0.018 μmol/l and 34.9 ± 0.014%.

The concentration of platelets in the blood of rats of all the observed groups corresponded to the norm. The severity of platelet aggregation in rats during aging gradually increased. It first occurred at the age of 30 months in response to collagen (26.1 ± 0.12 s), a little later on ADP and ristomycin, and even later on H₂O₂ (34.6 ± 0.16 s) and thrombin (45.5 ± 0.17 s). The most delayed platelet aggregation occurred in rats aged 30 months in the case of adrenaline (80.2 ± 0.23 s) (table).

The blood levels of aging rats platelet-dysocytes decreased as they grew in chronological age and was minimal at 30 months of age - 68.0 ± 0.20% (in the control - 78.8 ± 0.12%). Against this background, animals showed an increase in the total number of active platelet species, reaching 32.0 ± 0.25% at the age of 30 months (in the control 21.2 ± 0.12%). At the same time, the level of disco-echinocytes in them was increased to 17.8 ± 0.18%. They combined this with high blood levels of spherocytes, sphericulo-echinocytes and bipolar forms, which were 7.9 ± 0.14%, 5.1 ± 0.08% and 1.2 ± 0.03% in the oldest group of rats, respectively. Levels of small and large platelet aggregates in the blood of aging animals gradually reached levels of 7.4 ± 0.06 and 0.52 ± 0.003 free-lying platelets at 30 months. At the same time, their platelet count in the composition of the aggregates increased from 4.7 ± 0.08% at the age of 18 months to 6.9 ± 0.08% in 30 months of ontogenesis (table).

Discussion

The functioning of the whole organism is very closely connected with the work of all its life support systems and the response to any environmental factors\(^2^3\). A very significant role in this process is played by the functioning of the mechanisms of hemostasis and the characteristics of the rheological parameters of the blood\(^2^4\). Their condition greatly limits the level of oxygen and nutrients in the tissue, which is especially important with age to maintain optimum homeostasis\(^2^5\). The activity of blood platelets, which is very clearly controlled by the vessels\(^5\) and the level of lipid peroxidation in plasma and platelet membranes\(^1^3,2^6\), is of great importance for the circulation processes in the capillaries.

During aging in rats, an increase in the activity of their platelets is observed, which reaches a maximum by 30 months. Apparently, this is caused by an increase in the sensitivity of their platelet receptors to any external influences. These include an increase in the amount of von Willebrand factor in the plasma, which is an obligate cofactor of the platelet adhesion process. This is compounded by the increase in the number of receptors to it on their membranes. The onset in the rats with age, the enhancement of the processes of reception on the surface of the blood plates should be associated with the development during aging of complex adaptive processes in the membranes of platelets\(^9,2^6\).

The detected increase in platelet aggregation activity in response to different inducers in rats aged between 18 and 30 months of age showed an age-related development of the activity of the aggregative properties of their platelets. The accelerated development of platelet aggregation in these conditions in response to strong aggregation inducers (collagen and thrombin) seems to be associated with the activation of platelet phospholipase C and the process of phosphorylation of contractile platelet proteins. This is largely due to an increase in the amount of inositol trisphosphate in them, which leads to the stimulation of the release of Ca\(^2+\) from its depot and to an increase in its level inside the platelets\(^2^7\). Activation of these mechanisms inevitably leads to an intensification in platelets of actomyosin contraction processes. In addition, the increasing
potential of platelet thromboxane-forming enzymes with age also plays a significant role in enhancing platelet aggregation with age. The acceleration of platelet aggregation found in rats with age in response to weak agonists of aggregation, in particular to ADP and adrenaline, indicated an increase in the number of receptors for them on the surface of platelets and an increase in the expression of fibrinogen receptors on them. This was accompanied by an increase in the level of phospholipase A2 activity in them, which determined the growth as the arachidonic acid output from the membranes ages and the activation of thromboxane A2 synthesis from it.

The increase in intravascular platelet activity detected in aging rats indirectly indicated an increase in the number of inducers of their aggregation in their blood and an increase in the sensitivity of platelets to them. At the same time, in the blood of rats that are in the late stages of ontogenesis, a gradual decrease in the number of inactive discoid platelet species is observed, which also confirms the growth of activity of their receptor apparatus. The increase in the blood of old rats of the number of different active forms of blood platelets is a consequence of the enhancement of their aggregation properties and causes the development of thrombophilia during the progression of aging.

**Conclusion**

In healthy aging rats, a gradual increase in platelet aggregation properties is normal. This leads to an increase in the number of activated blood platelets in their blood and an excess of their aggregates of any size. These changes make a serious contribution to the development with age of a decrease in the reactivity and resistance of the organism, making many of the negative effects from the environment very dangerous for an aging animal.

Effect of Adding Different Levels of Anise, Fenugreek, Anise and Fenugreek Mixture and Sage to the Diet on the Total Bacterial Count and Colonic Bacteria in the Intestines of Broilers

A. A. Majid1, M. A. Al- Noori2, Ibrahim A. Al- Anai2

1Faculty of Agriculture, University of Anbar; 2Faculty of Veterinary Medicine, University of Fallujah

ABSTRACT

The present study included two experiments. The first experiment was carried out to investigate the effect of adding different levels of anise, fenugreek and their mixture powder, to the diet and the second experiment was conducted to determine the effect of adding different levels of sage powder to the diet on the preparation of total bacteria count and coliform bacteria in the intestines of the broilers. In the two experiments, 390 one-day-old Ross 308 hybrid broilers were used with an average weight of 41g. At the first experiment, 270 one-day-old broiler chicks were randomly divided into 9 dietary treatments with 3 replicates per treatment and 10 chicks per replicate (30 chicks per treatment). The dietary treatments involved T1: Control treatment was basal diet (without supplementation), T2, T3, T4, T5, T6, T7, T8 and T9 were basal diet with 0.5 % of anise, 1% of anise, 0.5% of fenugreek, 1% of fenugreek, 0.5:0.5% anise:fenugreek, 1.0:0.5% anise:fenugreek, 0.5:1.0% anise:fenugreek and 1.0:1.0% anise:fenugreek powders respectively. As for the second experiment, 120 one-day-old broiler chicks were randomly divided into four treatment with three replicates (each replicate 10 chicks). The dietary treatments included T1: control treatment (basal diet), T2, T3, T4 were basal diet supplemented with 0.5, 1.0 and 1.5% of sage powder respectively. The results showed a significant decrease (P<0.05) in the total bacterial count and coliform bacteria in the intestines of the broiler chickens for all addition treatments and both experiments compared to control treatment. The results also showed a significant (P<0.05) decrease in the total aerobic bacteria and coliform bacteria count in broiler intestine at high levels of herbs and their mixture added to the diet compared with control treatment. Significantly, the interaction treatments between anise and fenugreek, reduced the number of bacteria compared to T1, T2, T3, T4 and T5. It can be concluded that the addition of anise, fenugreek and sage to the broiler diets led to a significant reduction in the numbers of total bacteria and colon bacteria in the intestines which improves health situation that reflected positively on productive performance of broilers.

Keyword: Anise, Fenugreek, Total Bacterial Count, Colonic Bacteria, Broilers

Introduction

The researchers drew attention to the use of medicinal plants, herbs and their extracts as feed additives in poultry diets for their content of active substances and volatile oils1 their effects on productive and physiological traits, and the immunity of the body against microbes as well as their stimulating effect on the digestive system2. Anise (pimpinella anisum) is an herb known to have been used since the time of the Pharaohs and Greeks in the field of feed additives as a kind of spices3. Anise seeds have many properties such as, antiviral, antibacterial, antifungal, diuretic and antioxidant. Most of these properties are due to the presence of anethole, the active compound in anise4. Anise seeds can be effective growth promoters of anise because of their catalytic role in the production of gastric juices and their antimicrobial effects2. Anise seed oil has antifungal and antimicrobial properties and anti-parasites5,6.7 found that the use of anise in the diet of quail bird for six weeks resulted in a significant decrease in the number of pathogens and an increase in the number of non-harmful microorganisms in anise treatments compared with the

control treatment. A reported a decrease in E. coli and Staphylococci in the small intestine, colon of laying chickens and broilers when adding anise to the diet. The seeds of fenugreek (trigonella foenum graecum) have been used since ancient times because of their medicinal effectiveness against many diseases as well as their lack of deposition in the tissues. The results of 11 indicated the natural antioxidant activity of fenugreek seed compared to industrial antioxidants, which contain a good proportion of the compounds of saponins, alkaloids and flavonoids that play an important role in lowering the level of glucose, cholesterol and triglycerides in animal blood. The essential oils of the sage have a positive effect on pathogenic microorganisms that feeding rabbits and broilers with sage extracts led to anti-bacterial and fungal efficacy as well as the essential oils of sage and its oil are alpha-thujone and beta-thujone, Camphor and Cineole as well as the essential oils of sage have anti-bacterial and fungal efficacy pointed out that feeding rabbits and broilers with sage extracts led to increased cellular impotence activity (phagocytosis) in the blood. The essential oils of the sage have a positive effect on pathogenic microorganisms.

Materials and Method

This study was conducted in the poultry field of the Faculty of Veterinary Medicine, University of Fallujah for 42 days, which lasted from 13 October to 23 November 2017. It included two experiments: At the first experiment, 270 one-day-old broiler chicks were randomly divided into 9 dietary treatments with 3 replicates per treatment and 10 chicks per replicate (30 chicks per treatment). The dietary treatments involved:

T1: Control treatment was basal diet (without supplementation), T2, T3, T4, T5, T6, T7, T8 and T9 were basal diet with 0.5% of anise, 1% of anise, 0.5% of fenugreek, 1% of fenugreek, 0.5:0.5% anise:fenugreek, 1.0:0.5% anise:fenugreek, 0.5:1.0% anise:fenugreek and 1.0:1.0% anise:fenugreek powders respectively.

Second Experiment: In this experiment, 120 one-day-old unsexed broiler (Ross) from Turkish origin obtained from kebisa hatchery in Anbar province with an average weight of 41 g, broiler breeds were distributed at one day on 4 treatments with 3 replicates per treatment and 10 chicks (30 chick per transaction). The dietary treatments included T1: control treatment (basal diet), T2, T3, T4 were basal diet supplemented with 0.5, 1.0 and 1.5% of sage powder respectively. A continuous lighting program (24 hours/day) for the duration of the experiment and the protective program according to the conditions of the area were used in this study. As for nutrition, the chicks were fed ad libitum on two diets: starter diet from 1 day to 21 days and grower diet from 22 days to 42 days (Table 1) while the medicinal plants have been obtained from the local market.

Microbial Study: The contents of the small intestine were collected in the two-decimal area for three birds per replicate (9 birds/treatment) at 42 days of the first and second experiments. The standard method was used in total bacterial count and total coliform count. Use MacConkey broth agar media, MacConkey agar N. broth, N. agar and incubation at 37 °C. The total number of species was calculated according to 19.

Statistical Analysis: Experimental data were analyzed using Complete Randomized Design (CRD) to determine the effect of treatments on the studied traits and the smallest significant difference between the mean of different treatments was used to determine the differences based on what was stated 20.

**Results and Discussion**

The effect of the addition of anise, fenugreek and the interaction between them on the number of total bacteria and coliform bacteria in the intestine of broilers was noted (Table 3). The table indicates significant differences (P <0.05) between the different treatments where a significant decrease in the preparation of total bacteria and coliform bacteria for the supplemented treatments compared to control treatment. As shown in the same table, an increase in the addition level of anise and fenugreek to the diet resulted in a significant decrease (P <0.5) in the number of bacteria in the intestines of chicken as is observed in T3 (1% of anise) and T5 (1% of fenugreek) compared to T2 (0.5% of Anise) and T4 (0.5% of fenugreek). The table also showed that the interaction between the two herbs significantly (P <0.5) reduced the number of bacteria compared with the T1, T2, T3, T4 and T5. As for anise treatments, the results are consistent with**

</tbody>
</table>

The different letters indicate significant differences below (P <0.05).
The effect of the addition of sage on the total number of bacteria and coliform bacteria in broilers was detected (Table 3). The result indicates significant (P<0.5) differences between the different treatments where a significant decrease was found in the preparation of total bacteria and colonic bacteria for the supplemented treatments compared to T1. Furthermore, the results indicated significant differences between the addition of sage (T2, T3, and T4) where the higher addition level of the sage to the diet, the lower number of bacteria in the chicken intestines. The obtained results were consistent with finding of who demonstrated that the addition of medicinal plants (thyme, sage and rosemary) to the white chickens diet significantly reduced (P<0.05) the total number of coliform bacteria and the number of E. coli bacteria in the feces as well as the essential oils of the sage have a positive effect on pathogenic microorganisms.

Conclusions

It can be concluded that the addition of anise, fenugreek and sage to the broiler diets led to a significant reduction in the numbers of total bacteria and colon bacteria in the intestines which improves health situation that reflected positively on productive performance of broilers.

**Effect of Knowledge and Attitude Factors on Tuberculosis Incidents in Mandar Ethnic in The District of Majene West Sulawesi**

Abdul Madjid¹, Syafar Muhammad¹, Arsunan Arsin Andi¹, Ida Leida Maria¹, Thahir Abdullah¹, Burbahar¹, Rustia Russeng¹

¹Faculty of Public Health, Hasanuddin University, Makassar, Indonesia

Abstract

Tuberculosis is still one of the diseases that cause health problems in the community. Tuberculosis (TB) is an infectious disease caused by the bacterium Mycobacterium tuberculosis. Indonesia is ranked third in the world with the highest burden in the world for TB cases, this can be influenced by several factors. This study aims to determine the factors that influence the level of knowledge and attitudes regarding the prevention and spread of TB in the ethnic Mandar of the Rangas village, Banggai District, Majene Regency, West Sulawesi. This study used an observational analytic design. 200 respondents were selected by purposive sampling. Data collected included gender, age, family income, education, knowledge about TB, and the attitude of respondents. Data was processed using SPSS for univariate analysis and path analysis to understand the relationship of variables. The results showed that there was a significant relationship between the knowledge and attitudes of respondents with a value of 2,521.

**Keywords:** Tuberculosis, Incidents, Path Analysis, Knowledge, Attitude

Introduction

Tuberculosis (TBC) is a direct infectious disease caused by Mycobacterium Tuberkulosi. Until recently, TB is still a worldwide health problem where WHO reports in 2017 there are 14 countries in the world that experience a double burden of TB such as TB sensitive, MDR TB and TB/HIV, this condition is worse than the previous years globally estimated estimates > 300/100,000 residents of new TB cases occur in developing countries such as southern Africa in Indonesia and India¹.

The incidence of TB cases in Indonesia varies according to numbers and absolute if seen from the figures, Java is recorded as <400/100,000 population but if based on absolute numbers the highest incidence of TB cases is> 100,000 cases occur on the Java island and in the next report shows a map of TB cases based on the Province differ from one another².

West Sulawesi Province, implemented the DOTS strategy as an WHO recommended strategy that is believed to be effective in stopping the spread of TB, but the results have not been able to reduce the incidence of TB. Early case discoveries such as pulmonary tuberculosis can prevent and break the chain of transmission by making early detection and immediate treatment is prevention and treatment efforts that must be carried out simultaneously (parallel) and are simultaneous³.

West Sulawesi currently has a high incidence rate of 395 per 100,000 inhabitants. The description of the high incidence that has not been matched by high findings demands to find the right case finding method and scientifically accountable the idea of case finding that connects social determinants with the TB incident flow in tune with the recommendations of the 2016-2020 RAN TB Research²,⁴.

The research location is Majene Regency where this district is the center of the Royal Mandar ethnic and this district has a high incidence based on data obtained at Totoli puskesmas for three years showing a increasing trend of incidents from 2016 recorded 43 new cases, in 2017 there were 56 new cases and in 2018 there were 62 new cases in this district for 3 years TB control always showed that low case discovery rates never reached the target, reflected in the 2015 target is set at 80 % but only...
case discovery is 67% in 2016 the target was set at 90% but coverage was only 72%, so in 2017 the target was set at 90% and achievement was only 75%.

A high incidence rate should be followed by high discovery rates as well, based on the concept of social determinants that illustrate how to understand the factors that determine the incidence of TB disease. As explained earlier in this paper that the determinant of tuberculosis is mycobacterium tuberculosis but it is not the only one caused someone to become sick with TB, but it is still necessary to know the determinants outside themselves which are also called risk factors for TB disease known as determinants social TB. Based on the concept above, the researcher tried to describe the condition of the mandar ethnic real in the Rangas sub-district by age, sex, and level of education, and income towards knowledge and attitudes regarding the prevention and spread of TB in the community.

Materials and Method

Location and Research Design: This study was carried out in the Rangas village, Banggai District, Majene Regency, West Sulawesi in January - November 2018. The type of research used was operational research, with a quasi experimental design.

Population and Sample: The population in this study were all residents residing in the health center area of Rangas Village, Banggae Sub-District, Majene Regency, West Sulawesi. Sampling technic using selected purposive cluster sampling with number sample size of 258 people, from the selected sample size refers to 10% of opinions and also refers to SEM modeling, an analysis tool that requires a minimum of 100-200 samples, so that 200 samples were taken in this study. Residing in Rangas Village, and is willing to take part in this research as a respondent.

Data Collection Method: Data collection was conducted by researchers using questionnaires (age, sex, education, family income, knowledge and attitudes) of respondents about TB. The results of this study are presented in the form of tables and narratives and applied path analysis.

Results

Characteristics of the Sample: Table 1 shows the results of the univariate analysis, by sex showed most respondents were female that equal to 58.5%. age showed most respondents in the age group 31-40 was 62.5%. the level of education showed most respondents at the elementary school level that is equal to 62.5%. Based on the work the most respondents work as housewives who sell their husband’s catch which was equal to 31.5%. Family income per month the most respondents were in the group of Rp.500,001-Rp.1,000,000 which was by 43.0%

Based on the research variable, the respondent distribution n based on the level of knowledge and attitudes of respondents regarding TB, it shows that there were 58.5% of respondents who have sufficient level of knowledge about TB, and based on the variable attitude of respondents regarding TB there are 75.5% of respondents who have a fairly good attitude.

Path Analysis: In picture 1 the results of path analysis variable have a significant correlation between the knowledge and attitudes of the respondents (2.512) and there is no significant association between age, sex, family income, recent education with the respondents’ knowledge and attitudes to tuberculosis prevention.

Discussion

This study used a questionnaire as a measure of the level of knowledge about tuberculosis prevention and the attitude of respondents to TB patients in the community of Rangas, Banggai District, Majene Regency, West Sulawesi. Basically the level of public knowledge about TB disease in the research location is quite good. Even some people who became respondents already knew about the TB treatment procedure which requires a long time which is around 6 months. However, people’s knowledge about the causes of TB is still high, because there are still people who think that TB is caused by viruses or magical powers.

The path analysis results showed that there was a significant relationship between the level of knowledge about TB and the respondent’s attitude towards TB with a score of 2.512. The results of this study were also supported by the study of Daniel Tolossa which suggests that the low level of knowledge about TB can affect behavior in seeking health care and maintaining transmission of disease in the community. Similar results were also found in studies conducted in Bangladesh, which suggested that the main reason for the poor early
The high level of knowledge a person can cause changes in one’s perceptions and habits, behavior based on knowledge will last longer than those not based on knowledge. However, there are also studies that are not in tune with those conducted by Mohammad RN who say that there was no significant relationship between knowledge and attitudes towards the prevention and spread of TB in the community.

Path analysis result also showed that there was no correlation between age and level of knowledge and attitudes regarding the prevention and spread of TB. The results of this study were in tune with research conducted by Hilma P. Lubis et al which states that there was no relationship between age and duration of work with the level of knowledge and attitudes of midwives at community health centre in Medan (p = 0.191; p = 0.478 and p = 0.22; p = 0.649). The result happen because the knowledge was come from prior knowledge, personal experience, and other people and several other factors that can shape a person’s knowledge for a long time and knowledge will last until old. But this was different from the research of Urasa et al. who said that there was a significant relationship between the age of nurses and knowledge (p = 0.027) where nurses’ knowledge was better at a young age of 87.5%.

In his theory, age influences the development of capture power and one’s mindset, the older a person is, the better the processes of mental development, but at a certain age, the increase in mental development process is not as fast as when he was a teenager. Increasing one’s age can influence the increase in knowledge gained by Ar-Rasily and Puspita.

The results of path analysis showed that there was no relationship between the level of knowledge and attitudes with education (p = 1.586 and p = 0.497). This result, similar to the results of a study conducted by Urasa et al. and Hilma P. Lubis et al which showed that there was no significant relationship between knowledge and attitudes regarding the causes of cervical cancer with education level. This can happen because knowledge was not absolutely obtained from formal education, but can also be obtained from non-formal education. In fact, a person with a high level of education does not mean having a good level of knowledge, and vice versa. As with one’s attitude, a low level of education does not mean having a bad attitude.

The results of the path analysis conducted also showed that there was no significant relationship between sex with the level of knowledge and attitudes (p = 0.644 and p = 1.146). This research was in tune with the research conducted by ERWandwalo and O. Morve where he said that knowledge was not significantly affected by gender or place of residence.

In this study also found that there was no association between income per month and the level of knowledge and attitudes towards the prevention and spread of TB. In tune with this, Portero Navio J., L et al stated that respondents who did not seek health services in TB cases were significantly correlated with low family monthly income. This can happen because not everyone with low income cannot provide special facilities to obtain knowledge and information regarding the prevention and spread of TB. In addition, knowledge and examples of attitudes can also be obtained from anywhere.

However, this study was not in tune with previous studies conducted in Nigeria by KE Agho et al which showed that the probability of having bad knowledge and negative attitudes towards TB was consistently significant with the poorest households in the region. This finding was also in tune with the national household survey conducted in the Philippines, Pakistan, and India, which shows that higher knowledge of TB was present among urban residents. This might reflect the fact that respondents who live in rural areas and come from low socioeconomic backgrounds may feel embarrassed and stigmatized because they suffer from tuberculosis.

Conclusions and Suggestions

This study concludes that based on path analysis conducted the knowledge level variable has a meaningful relationship with the attitude of the respondents, while the variables of age, sex, education, and income do not have a meaningful relationship with the level of education and attitudes about the prevention and spread of tuberculosis. Therefore, the local government can intervene as counseling on the prevention and spread of TB in the community, so that people can be consistent in the prevention of tuberculosis.

The Relationship between Psychoeducation and the Decrease in Family Burden of Diabetes Mellitus Patients, Magelang, Indonesia

Adi Isworo¹, Suharsono¹, Frans Yosep Sitepu²

¹Health Polytechnic of Semarang, Indonesia; ²Provincial Health Office of North Sumatera, Indonesia

ABSTRACT

Diabetes Mellitus (DM) is a chronic disease that is frightening because a lifelong disease and can not be cured. Diabetics should pay attention to their blood sugar levels to improve their quality of life and can be a burden not only for the patient’s but also their family. One of the interventions to overcome this problem is psychoeducation. It is a therapy to provide information to individuals who are experiencing distress, providing education to improve skills and be able to understand and have coping due to illness that causes problems in family relationships. The study objective was to determine the effect of psychoeducation on the family and DM patients at the clinic of Prof. Dr Soerojo Magelang. It was an experimental design with pretest and post test. Intervention group will be given psychoeducation both patient and family while control group without psychoeducation. Respondents were patients and family with random allocation sampling. Before and after psychoeducation will be measured to the family about family burden, control regularly and family support. The result showed that variable of psychoeducation was realted to family burden (p <0.01). It was concluded that psychoeducation was significant to decrease family burden on family who had DM patient. Psychoeducation may help to minimize or prevent the effects of burden on family caregivers responsible for patients’ of DM.

Keywords: psychoeducation, diabetes mellitus, decrease family burden, Indonesia

Introduction

DM is a chronic disease that is frightening because its a lifelong disease and can not be cured(1,2) In 2013 based on Indonesia basic health research reported that an increase in prevalence of people with DM from 1.1% in 2007 to 1.5%.(3) Lifestyle of patients with DM need on planning meal (diet), exercise, blood glucose monitoring, therapy (if needed) and health education. Therefore, the role and support of sustainable family groups, relatives, health workers, nurses and extension is highly recommended.(4,5)

A baseline survey at the DM clinic at Prof. Dr Soerojo Magelang Hospital resulted that DM patients will obey regularly control and adhere to take medication when their blood sugar level arise. This proves that patients have less adherence on therapeutic management for DM due to lack of support from those around them, whereas to achieve therapeutic success desperately needs a lot of support and help from others around them.(6,7)

Therefore, the objective of this study was to determine the relationship between psychoeducation and the decrease in family burden of DM patients

Method

Study Design and Setting: This was an experimental design using pretest-posttest with comparation group. Population was all DM patients and family at clinic DM RSUP Prof DR. Soerojo Magelang. Sampling technique was random allocation. The total number of respondents was 36 people, 18 as intervention group and 18 as control group. The independent variable was psychoeducation, and the dependent variables were family burden, family support, and control regularly. Psychoeducation is a
therapy used to provide information to families and patients who experience distress, provide education to improve skills and be able to understand and have coping due to illnesses experienced by one family member which results in problems with family relationships.

**Data Collection**

Psychoeducation will be conducted in 8 sessions, each session will last for 60 minutes. Family burden will be measured using a questionnaire consisting of 12 statements related to family burden due to family members suffering from DM. Family support will be measured using a questionnaire of 12 questions. Control regularly will be measured using a questionnaire of The Summary of Diabates Self Care Activities (SDSCA). Drug and dietary compliance was measured by HbA1C examination.

**Statistical Analysis**

Data analysis by using univariate and bivariate with parametric test by using pair t-test, if the data is not normally distributed then non parametric test will be employed to know the difference of psychoeducation effect on intervention group and control group.

**Ethical Consideration**

The study protocol was approved by the Institutional Review Board of the Semarang Health Polytechnic of Ministry of Health of Republic of Indonesia. The aims, risks, and benefits of the study were explained to each participant, and they were asked to sign a consent form prior to enrolment in the study. Participants were also informed that they could quit at anytime during the interview session. After informed consent was obtained, the interviewers conducted the structured interviews.

**Result**

The total number of respondents in the intervention and control group was 36 people, 50% was male. Most respondents were at vulnerable aged (61-70 years) as many as 15 people (42%), with the highest age was 77 years and the lowest was 42 years (Table 1).

<table>

</tbody>
</table>

The statistical analysis resulted that the family burden variable in the intervention group decreased, while the variable of control regularly and family support increased. The level of HbA1C in the intervention group decreased (Table 2).

**Discussion**

There was a decrease in family burden in the control group and intervention group, indicating that the effect of psychoeducation was significant on the decrease of family burden of DM patient. The decrease in family burden on the intervention group can occur due to the empowerment of family caregiver and in the control group due to awareness within the self caregiver family.\(^{(5,9,10)}\) Psychoeducation is a process of behavior modification and behavior directly through the client’s total involvement in an intervention education program.\(^{(5)}\) The process not only provides cognitive information, but also experimentally gives participants the chance to experience their own changing attitudes and behaviors through the presence and assistance of others in a group activity.\(^{(11–13)}\)

Family support is the most important factor in the compliance of chronic disease management that given by family members that will provide physical and psychological comfort\(^{(9,14)}\). It will be more effective if given in accordance with what is wanted by the needy.\(^{(13,15,16)}\) DM management should be discussed as individualized therapeutic between patients and their families, and patients should receive coordinated medical care and integration of the health team.\(^{(11,12,14,17)}\)

Control regularly is the measurement of blood glucose levels performed in accordance with predetermined time intervals. DM treatment has the main goal to try to normalize insulin activity and blood glucose levels in an effort to reduce the occurrence of vascular and neuropathic complications.\(^{(9,18,19)}\) DM can cause chronic complications. Therefore, to avoid the occurrence of complications it must be managed to normalize insulin level.\(^{(11,19,20)}\)

The decrease of family burden on intervention group can occur because of family caregiver empowerment and giving intervention to family caregiver in taking care of DM patient. The provision of this intervention aims to increase knowledge about DM patient care such as health counseling by bringing in experts, asking family members about the burden felt by the family as a result of DM family members, and praising the participation of family members. The psychological burden experienced by family caregiver is due to their assessing the duties and situations of treatment encountered beyond their coping skills.\(^{(10,16,21)}\)

The results of the study showed an increase in the score of HbA1C examination from both control and the intervention group. The examination of HbA1C is one of the most important blood tests to evaluate blood sugar control. HbA1C levels will reflect the average blood sugar levels within 2-3 months before the examination.\(^{(19,20)}\) The higher the HbA1C level the higher the risk of complications, and vice versa. Psychoeducation is the provision of direct intervention to family members and DM respondents who have checked HbA1C levels.\(^{(22)}\)

**Conclusion**

Psychoeducation is significant to decrease family burden on family having DM patient. In addition, family caregivers should be taken into account by health professionals. They are an important part of the mental-health field, providing home care to patients with DM.

The Effectiveness of Fluoride on Zam Zam Water on Inhibition of Bacterial Growth Causes of Dental Plaques

1Medical Laboratory Technology Poltekkes Kemenkes Banjarmasin, Mistar Cokrokusumo Street 4a Banjarbaru Indonesia; 2South Kalimantan Provincial Health Office, Banjarmasin Indonesia; 3Medical Laboratory Technology Poltekkes Kemenkes Banjarmasin, Mistar Cokrokusumo Street 4a Banjarbaru Indonesia

ABSTRACT

One of the good waters on this earth is Zam Zam water. Springs that are in the area of the Grand Mosque are not only clean but also have considerable benefits for health. The uniqueness of this spring also never runs out or is dry. Although every year millions of pilgrims take water from the Zam Zam well, the water continues to flow profusely. Zam Zam water is sterile because it has a high content of calcium, magnesium and fluoride minerals which are capable of functioning as an antimicrobial in a proportional amount and do not have the effect of poisoning the human body. The content of fluoride compounds in Zam Zam water has an antibiotic role. The purpose of this study was to determine the effectiveness of Zam Zam water fluoride in reducing the growth of Streptococcus sp and lactobacillus sp bacteria as a determinant of the causes of dental plaque. The method in this study was an experiment with design post-test with control group design. The results showed that Zamzam water fluoride was able to inhibit the growth of Streptococcus sp and Lactobacillus bacteria with water fluoride concentrations of Zam Zam 20% (0.12 ppm), 40% (0.22ppm), 60% (0.35 ppm), 80% (0.52ppm) and 100 % (0.68ppm). The decrease in the number of germ numbers occurred 100% in both Streptococcus sp and Lactobacillus sp at a concentration of 100% fluoride (0.68ppm). It is recommended as a basis for further research to compile and develop a model of Zam Zam water use as a mouthwash ingredient.

Keywords: Zam Zam water, Fluoride concentration, Streptococcus sp, and Lactobacillus.

Introduction

One of the good waters on this earth is Zam Zam water. Based on the results of the European laboratory tests on Zam Zam water samples showed that Zam Zam water has special physical properties that make it has many benefits and advantages. The main difference is Zam Zam, and other water is sterile Zam Zam water has a high content of calcium, magnesium and fluoride minerals so that it can function as an antimicrobial in a proportional amount and does not have poisoning effects on the human body.1,2,3

The content of the fluoride compound in Zam Zam water is one of the important ions which have the role of antibiotics. Therefore most toothpaste products prioritize the presence of fluoride content in their packaging which is used to fend off the accumulation of bacteria causing dental plaque. Flouride is a chemical compound that naturally exists in Zam Zam water at various concentrations. Proportional concentration is very beneficial for health, especially dental health because it can prevent tooth decay.4 Fluoride compounds serve to strengthen enamel by making it resistant to acids and inhibiting bacteria from producing acid. Fluorine is antibacterial, but its weakness can make gray stein in teeth.4,5

Dental plaque is one of the problems in dental and oral health, which is a soft deposit that is firmly attached to the teeth, consisting of microorganisms that multiply if someone neglects the cleanliness of their teeth and mouth. In plaque there are various kinds of bacteria and their metabolism, for example, the results

DOI Number: 10.5958/0976-5506.2019.02137.5
of carbohydrate metabolism by acidogenic bacteria will result in the formation and accumulation of acid which results in decalcification and destruction of tooth surfaces resulting in carries.\textsuperscript{6,7}

The classic research of Keyes (1960) shows that plaque which is dominated by the bacteria \textit{Streptococcus mutan} and \textit{Lactobacillus} causes caries to form. \textit{Streptococcus mutan} and \textit{Lactobacillus} are cariogenic germs because they can form acid from carbohydrates that can be distributed immediately. These germs can thrive in an acidic atmosphere and can stick to the surface of the teeth because of their ability to make extra cell polysaccharides. These extra cell polysaccharides consist mainly of glucose polymers which cause the plaque matrix to have a consistency like gelatin. As a result, the helpful bacteria attach to the teeth and stick together. Plaque is getting thicker, so it will inhibit the function of saliva from carrying out its antibacterial activity.\textsuperscript{8}

Zam Zam water composition which contains high fluoride is thought to be able to suppress the growth of bacteria causing plaque. On herbal toothpaste containing fluoride can stimulate early caries remineralization and reduce the ability of bacteria to produce acid and fluoride-containing toothpaste to show antibacterial activity.\textsuperscript{9}

Method and Materials

Type of research is experimental with a \textit{pretest and posttest design with control group design}, which measures the effect of Zam Zam water on the inhibitory forces of \textit{Streptococcus sp} and \textit{Lactobacillus sp} in vitro. The research sample was Zam Zam water made with a concentration variation of 20\%, 40\%, 60\%, 80\%, 100\%. Preparation of bacterial stock; cultures of \textit{Streptococcus sp} and \textit{Lactobacillus sp} were scratched on blood agar media, incubated for 18-24 hours at 37 °C, and stored in the refrigerator. Preparation of bacterial suspension; inoculation of 1 colony of \textit{Streptococcus sp} and \textit{Lactobacillus sp} bacteria from bacterial stock and dipped in 10 ml 0.9% sterile NaCl solution, equated with turbidity with standard \textit{Mc. Farlan} 0.5 (estimated cell number 108), carried out repeatedly until the turbidity is the same.

The Minimum Inhibition Concentration (MIC) measurement was determined qualitatively based on whether or not each sample in the test tube was cloudy compared to the control. If clear, bacterial growth is inhibited and if cloudy, bacterial growth is not inhibited. Determination of Minimum Bactericidal Concentration (MBC) carried out the distribution of TSB suspension as a result of the MIC test on Nutrient Agar media, then incubated at 37 °C for 24 hours. It is viewed whether or not bacterial growth (qualitative) and the number of colonies (quantitative) were calculated. The lowest concentration/level that is not overgrown with bacteria is MBC.\textsuperscript{10}

Figure 1: Increased Germicidal Power Based on Fluoride Concentration
Zamzam used in this study is 5000 Zam of Zam Zam pack water with 0.68 ppm fluoride content. In a previous study conducted by Muhlisin found a fluoride content of 0.7 ppm\(^\text{1,3}\).

In the variation of the concentration of fluoride content in Zam Zam water which was used to inhibit the growth of \textit{Streptococcus sp} and \textit{Lactobacillus sp}, MIC was obtained at a concentration of 40\% (0.22 ppm). The decrease in the number of bacteria \textit{Streptococcus sp} and \textit{Lactobacillus sp} occurs at the time Fluoride concentration in Zam Zam water is increasing. This condition shows the influence of fluoride in inhibiting the growth of \textit{Streptococcus sp} and \textit{Lactobacillus sp}. Fluoride plays a role in inhibiting the growth of \textit{Streptococcus sp}. High concentrations of fluoride in the oral cavity can inhibit acid production by bacteria and can reduce the number of certain bacterial species\(^\text{11}\).

The Zam Zam water fluoride concentration has a significant effect on the germ numbers of both bacteria \textit{Streptococcus sp} and \textit{Lactobacillus sp} (\(P<0.05\)). Fluoride is one of the substances that can provide pressure on environmental factors that have an impact on the oral bacterial community, besides providing beneficial effects on caries prevention, it also affects the enamel and demineralization\(^\text{12}\). Fluoride inhibits bacterial metabolism so that it affects the rate of catabolism of carbohydrates which can be fermented into acid. The acid pH produced from carbohydrate fermentation leads to an increase in oral microbial communities in dental plaque-causing bacteria\(^\text{1,12}\).

The mechanism of action of fluoride on bacteria \textit{Streptococcus sp} and \textit{Lactobacillus sp} can inhibit the enzyme \textit{enolase} which plays a role in bacterial metabolism so that it cannot form plaques\(^\text{13}\). \textit{Enolase} catalyzes glycercate-2-phosphate to phosphoenolpyruvate. Phosphoenolpyruvate is further metabolized into acids such as lactic acid, formic acid, pyruvic acid which can cause demineralization of tooth enamel. Phosphoenolpyruvate is also an essential substrate for the phosphotransferase sugar transport system that is dependent on phosphoenolpyruvate and is found in many bacteria, including \textit{Streptococcus} and \textit{Lactobacillus}\(^\text{11,14}\).

In addition to containing fluoride, Zam Zam also contains bicarbonate, which can neutralize acids produced by bacteria that cause dental plaque (\textit{Streptococcus} and \textit{Lactobacillus}) and with hypertonic properties can cause hypotonic components of bacterial cells to lose water. The loss of water causes bacteria to dehydrate and die. Bicarbonate compounds can damage the bacterial matrix structure and weaken the bond between bacteria and tooth surfaces\(^\text{2}\).

The bacteria that can cause dental plaque, in general, are mutant \textit{Streptococcus} and \textit{Lactobacillus}. The two bacteria will then be able to cause caries formation. Interactions between bacterial plaque, food, and teeth can cause dental caries\(^\text{15}\). Fluoride can inhibit the activity of bacterial plaque enzymes including \textit{enolase}, \textit{phosphatase}, \textit{proton extruding ATPase}, and \textit{pyrophosphatase}; this activity will inhibit the process \textit{glycotransferase} that forms \textit{extracellular polysaccharides} plaque and interferes with plaque attachment\(^\text{6,17}\). Therefore the results of this study which show the ability of fluoride Zam Zam-containing water to dental plaque bacteria have the potential to be used as a mouthwash to prevent the development and decrease bacteria in the mouth that cause dental plaque. Sterile Zam Zam water contains high fluoride which has proportional antimicrobial properties and does not give poison to the body.

### Conclusion

Inhibitory effectiveness of the growth of \textit{Streptococcus sp} and \textit{Lactobacillus} begins at dilution of water fluoride Zam Zam 40\% (0.22 ppm). The ability of fluoride in Zam Zam water to inhibit the growth of \textit{Streptococcus sp} and \textit{Lactobacillus sp} respectively 0.12 ppm (30\%); (45\%), 0.22 ppm (63\%); (71\%), 0.35 ppm (86\%); (81\%), 0.52 ppm (94\%); (91\%) and 0.68 ppm (100\%).

Maternal Attitude Toward Formula Feeding among Sample of Iraqi Mothers

Ali Abdul-Razak Obaid1, Ban Abdul-Hameed M.1, Zena Khalid Mahdi2, Mohammed J. Hussein1, Isam AL-Zwaini1

1Department of Pediatrics, AL-Kindy Medical College, University of Baghdad; 2Elwyia Pediatrics Hospital

ABSTRACT

Background: There is a well-documented decline of breast feeding rate especially in the developing world. Artificial feeding carries high risks of diarrhea, malnutrition, and death especially in a crisis situation in which there is poor water supply and poor sanitation.

Objectives: To assess maternal attitude and practices toward formula feeding regarding proper handling, sterilization, preparation and amount given.

Patients and Method: A cross sectional study done from the first November 2017 to the 30th of May 2018, in outpatient department of AL-Elwyia pediatric hospital. Mothers were interviewed and were asked some questions regarding sociodemographic criteria and their knowledge and practices toward formula feeding their children.

Results: Eighty two percent of mothers had less than five feeding bottles, 73.55% had improper sterilization, 80.3% had proper reconstitution of their infant formula, 54.7% of infants has improper caloric intake during the day and 51.9% only feed their infants in a proper technique.

Conclusion: The study concluded that there is low level of mother’s knowledge about formula-feeding handling in which the majority uses unsafe practices of feeding. The maternal knowledge is greatly influenced by culture and community beliefs rather than seeking a health professional advice.

Keywords: Attitude, formula feeding, practices, Mothers

Introduction

Breastfed infants are protected against many health problems such as gastrointestinal, respiratory infections and allergies1. Worldwide, only 40% of infants under six months of age are exclusively breastfed2. Despite the WHO recommendations and many health benefits of breast feeding, there is a well-documented decline of breast feeding rate especially in the developing world. Many factors have influenced infant feeding practices including social background of the mothers, mother’s fear of inadequacy of breast milk, their lack of awareness of the benefits of breast feeding and employment3. In Iraq still there is a low rate of early initiation of breastfeeding at 2012 (42.8%), exclusive breastfeeding under 6 months (19.6%) and breastfeeding at 2 years (22.7%), while there is a high rate of bottle feeding in Northern Iraq (64%) 4. A study done in Erbil showed that even with baby friendly hospital initiative there is a low rate of early initiation of breast feeding (38.1%) and exclusive breast feeding (15.4%) 5. Moreover, such rates are also the result of the wide distribution of infant formula to Iraq’s markets by many commercial formula companies has led many mothers to shift to bottle feeding. Nutrition program leaders consisting of UN agencies, nongovernmental organizations and government of Iraq today strongly urge those involved in the response to the Iraq crisis to avoid unnecessary illness and death in
children which can be achieved by protecting, promoting and supporting breast feeding and strongly discouraging the uncontrolled distribution of and use of breast-milk substitutes (including infant formula). Artificial feeding carries high risks of diarrhea, malnutrition, and death especially in situations in which there is poor water supply and poor sanitation and is a last resort only when other safer options have cannot be fully provided. There are remarkable economic disadvantage of using bottle or formula feeding especially in developing countries, a study done in Iraq 2016 showed that the mean cost of formula milk consumption for each infant who was exclusively bottle fed was (1584) Iraqi Dinars per day which equal to 1.2 dollars.

Powdered infant formula carries risk of contamination with E. sakazaki and salmonella which are the main pathogen that may cause serious illness and sometimes death in infants, this risk is increased with poor handling and preparation of infant formula.

**Patients and Method**

A cross-sectional study carried out at Al-Elwyia Pediatric Teaching Hospital, Baghdad, from first of November 2017-to 30th of May 2018.

Participants were mothers of exclusively formula fed infants; the sample size consists (422) mothers and their one day-12 months old infants who attend the outpatient clinic using a convenience sampling. All participants provided informed consent before inclusion in the study. Infants with chronic illness and congenital malformations were excluded from the study.

Eligible mothers were interviewed and asked a semi structured questionnaire formed by the researchers according to guidelines on formula feeding. The questionnaire consists of two parts:

A. Demographic characteristic (mother age, education, occupation, age and sex of infant)

B. Feeding practices: Number of bottles, way of sterilization, way of preparation, water used, number of feeding during the day, any change in milk formula, and the technique of feeding.

C. Ethical approvals were taken from Al-Elwyia Pediatric teaching hospital and from the ethical committee of Al-Kindi College of Medicine.

Standards for powdered infant formula preparation:

- Number of bottles five or more considered adequate
- Way of sterilization: considered appropriate if the mother wash her hand thoroughly with soap and water before preparation, brushes the bottles and teats thoroughly with soaped water and sterilize them with boiling for at least 10 minutes, or by using steam sterilization or sterilising liquid or tablets.
- Water used: boiled water should be used before preparation; bottled water is not usually sterile and must be boiled before use.
- Milk preparation: Preparation considered optimal if one level scoop of milk powder to one ounce of water or according to the manufacturer’s instructions.
- Technique of feeding considered appropriate if the baby in upright position with their head supported.
- Intervals between feeding is 2-4 hours in the first 6 months of life and more than that after introduction of solid food (Table 1)

**Table 1: Average daily fluid intake of infants during the first year of life**

### Discussion

In fact there are a few studies in Iraq and developed countries had assessed maternal practices toward formula feeding especially with the widespread use of formula and aggressive marketing of powdered milk.

The study showed the majority of mothers in our sample were a housewife (91%) which is comparable to a study done by Mohammed-Hossein that showed 96.6% of mothers were housewives. The study showed the majority of mothers in our sample were a housewife (91%) which is comparable to a study done by Mohammed-Hossein that showed 96.6% of mothers were housewives. The current study showed that majority of mothers had poor experience with formula feeding practices regarding sterilization of bottles, milk preparation and the frequency of feeding; this finding is similar to other studies. Lack of mother’s knowledge regarding formula feeding recommendations, traditional beliefs and practices by the family and lack of health workers advice might be the most evident explanation of barriers to proper handling of infant formula.

The study showed that there is significant correlation between maternal education and bottle sterilization (P value 0.008) and daily caloric intake (0.012) while there is no significant correlation with other practices. A study done by Mohammad-Hossein revealed that there was a significant relationship between mothers level of education and the number of children they had with proper feeding practices. This finding explores the impact of education on increasing maternal knowledge and may change their behavior toward proper feeding practices.

Majority of mothers in this study had less than five feeding bottles and follow non-safe handling recommendations including washing their hands before formula preparation and bad sterilization technique of the bottles and teats (73.5%). A previous study demonstrated that 55% of mothers wash their hands with soap before preparing formula while another study done by Kassier et al showed that only 41.8% of mothers wash their hands with soap and water and 65.1% of them sterilize bottles with boiled water and that 84.6% of the bottle tested were contaminated. ON the other hand a study done by Lokare et al showed that bottles were washed in boiled water for hygiene purpose by 88.8% of participants mothers. Faulty sterilization technique and non-hygienic bottle handling carries a high risk of contamination that will further increase incidence of food borne infection and diarrhea especially among poor and low educated families.

This study revealed that 80.3% of mothers correctly reconstitute the infant formula milk while 19.7% giving dilute formula for better digestion and for prevention of vomiting as they believe. Similar to this finding, MacInture et al found that 82% of mothers correctly prepare infant formula. A systematic review of studies about mother experiences of bottle-feeding done by Rajalakshmi et al showed that 11 studies reported reconstitution errors (over and under concentration), while another study showed that the majority of mothers (87.5%) dilute the milk. The practices of infant feeding trends in a community play an important role in deciding the health and nutrition status of infants, giving dilute or concentrated milk by mothers or care givers carry a risk of under nutrition or obesity later in life. On the other hand the amount and the frequency of milk given per
day may be affected by cultural beliefs and practices that do not match the biological needs of the infant. Our study revealed that only 45.3% of mothers giving proper amount of milk per day and 65.2% of them giving average number of feeds per day. A study done by Tarrant RC et al showed that many infants consumed a considerably greater than recommended formula volume per kg/day\textsuperscript{13}. This may be explained that majority of mothers didn’t follow a proper schedule of feeding and they feed their infant when he cries, or they think that when a baby gets heavier is better.

The WHO recommends using boiled water in formula preparation\textsuperscript{9}. This study showed that only 22% of mothers used boiled tap water in preparing infant formula while 78% used non boiled bottled water. This finding is similar to another study that found mothers did not boil tap water (70%) or bottled water (83%) used to reconstitute formula\textsuperscript{12}. Another study showed that 72% of participants prepare formula with boiled water\textsuperscript{11}. This difference may reflect the underlying socioeconomic and educational status of the parents among a community.

An interesting finding in this study is the frequent change of formula feeding in 41% of the studied sample, in which 56% has been changed by doctors and 44% by mothers. Tarrant RC et al showed that there is a high frequency of formula type/brand changing evident among the study participant (49.2%)\textsuperscript{13}. Lakshman et al found that seven studies reported that mothers made frequent change to the type of formula feeds\textsuperscript{16}. Excessive formula marketing had led the health professionals, the non-baby friendly hospitals and mothers to frequently change formula type for various reasons like crying, regurgitation, and inadequate weight gain.

Limitation of this study is that our sample is hospital based, and there is a need for community based study for a better representation of feeding practices in the community.

**Conclusion**

The study concluded that there is low level of mother’s knowledge about formula-feeding in which the majority uses unsafe practices of feeding. The maternal knowledge is greatly influenced by culture and community beliefs rather than seeking a health professional advice.

**Recommendation**

It is important that every opportunity of contact of health personnel with care-givers be taken to counsel on infant feeding. Ensure all parents who have chosen to bottle-feed are shown how to sterilise bottle feeding equipment and ensure that they make up formula feeds safely before they leave hospital in line with national standards.

ABSTRACT

In this article, the concentrations of radon gas (²²²Rn) in some houses were measured at 10 sites in Al-Najaf city, using RAD-7 radon monitoring system. The effective doses for all samples were estimated using Monte Carlo method. The Visual Monte Carlo code was used to simulate the transport of the radiation as emitted from the ²²²Rn through the human voxel model. Room geometry of 3×3×4 m³ was designed to estimate the people radiation dose due to the exposure to the indoor radon. The latter doses were estimated for each of male and female people individually. It is found that the radon concentrations varied from (8.75 ± 1.1 Bq/m³) to (32.32 ± 4.0 Bq/m³) with an average (20.57 ± 2.90 Bq/m³). The resulted data of the Monte Carlo calculations for male reveal that the effective dose was ranged from 2.91E-05 to 1.07E-04 μSv/h while the female effective dose was noticed to range from 2.87875E-05 to 1.06333 E-04 μSv/h.

Keyword: ²²²Rn, Monte Carlo, effective dose, Al-Najaf city and RAD-7.

Introduction

Radon gas is a natural radioactive source and is chemically considered as an inert element. It originates from the natural decay of uranium 238 series, with atomic number 86 and mass number 222(1). The major contribution of radon exposure is attributed to indoor or household air(2). In this regards, many houses and buildings are built on top of radon emitting rocks. It should be noted that radon daughters are likely to attach to dust which would result in that people are exposed to them via breathing. However, the radon level in outdoor air is, to large extent, low at about 0.003 to 2.6 picocuries/liter of air. When considering the indoor exposure, such that at homes, schools, or offices buildings, the levels of radon and its daughters are generally higher than that of outdoor levels. Cracks exist in the foundation or basement of the homes can increase the level of the radon. This happens when the radon gas move through these cracks into home. In this context, at some areas of the country the amount of uranium and radium in rocks of different kinds, such as phosphate rock or granite, is high. In areas like these the radon levels in indoor air is generally expected to be high(3). The radon gas enters the houses from the ground via cracks present in concrete of the floors and walls, then through the gaps between floor and slab, around drains and pipes, and small pores of hollow-block walls. It is important to mention that radon levels usually high in places such as basements, cellars and ground floors. Based on certain factors, the concentration of radon in indoors changes considerably throughout the time of the year, from day to day, and from hour to hour(4,5). As reported in many countries, the radon is taking the second order of being the most important cause of lung cancer after smoking(6). Nevertheless, relevant studies in Europe, North America and China have also confirmed that even at lower concentrations of radon – such as those live in homes – also include health risks and contribute markedly to the occurrence of lung cancers worldwide(7,8). It has been reported that probability of lung cancer incidence can increases by 16% per 100 Bq/m³ of radon concentration increment. In this regards, the dose-response relation appears to be linear, this means that the lung cancer risk

DOI Number: 10.5958/0976-5506.2019.02139.9
increases proportionally with increasing radon exposure. The level of the environmental radon is a function of time and climatic conditions. So, on order to monitor the radon level, active and passive techniques can be used. Active method often used for short-term measurements of radon. By contrast, passive method could be suitable for the assessment of radon exposure over long period of time. This enables it to be used for large-scale surveys at a low cost\(^9\). In active measurement, in general, radon and its decay products are brought either into the vicinity of a detector or into a collector device via forced pumping, while in passive measurements, radon and its decay products are collected through their natural diffusion (or permeation) into the device, containing a detector. The terms active and passive are also used to differentiate those radiation detectors that operate with and without power supply. However, estimation of the amount of dose received by tissues/organs of the body that exposed to radiation source in an environmental medium is an extremely difficult computational task\(^{10}\). Therefore, Visual Monte Carlo (VMC) is computerized software that simulates the human body irradiation by an external source of radiation. It uses a voxel phantom designed at Yale University and the Monte Carlo method to simulate the emission of photons by a point, ground, cloud source as well as X-ray source. It therefore simulates the transportation of the photons through the phantom of the human body and estimates the dose to all body regions\(^{11}\). Consequently, this permits the estimation of the effective dose. The aim of the present work is to measure the radon concentrations in some houses of Al-Najaf area. Also by using Monte Carlo method the estimates for the effective dose can be provided for both male and female voxel phantoms/models.

**Materials and Method**

Najaf city situated between coordinates of latitudes of 32°21’N and 29°50’N, coordinates of longitudes of 44°44’E and 42°50’E with a total area of 28,824 km\(^2\) (6.6% of Iraq whole area)\(^{12}\). Al-Najaf city, considering the administrative side, includes three qadhas (administrative units consisting of the governorate, Al-Manatheria, Al-Kufa and Al-Najaf Qadhas). In the current study, ten sites were selected as fair distribution in Al-Najaf city.

The RAD-7 is a device that provides a real-time and continuous monitoring for radon. The latter would help in observing the variations occur within the radon concentration levels during the measurement period. This might be effective, in turn; in the case that one can check the factors that impacting the radon levels throughout time. To illustrate, these factors may include temperature variation, wind speed, humidity (relative). This could give an insight into movements of the air inside a room\(^{13}\). The RAD-7 includes an internal standard sample cell at around 0.7 liter and has a hemispherical shape as can be observed in Figure (1). The inner side of the hemisphere is coated with an electrical conductor that can be changed, with a high power supply, to a potential difference range of about 2000-2500 Volts relative to the detector. This in turn creates an electrical field across the cell. The latter electric field drives the positively charged particles into the detector in the periodic-fill cell.

![Fig. 1: Schematic diagram of the RAD-7 detector\(^{14}\)](image)

The method which was adopted to collect the samples can be described as follows: Four samples for the house air were taken from each region. The number of air samples that considered in this work was forty. The sniff mode and circle time was set at 1 hour in accordance with running time of each path of the valve. In order to investigate the amount of radon released from the sample to air, the samples were enclosed into a column, and an airborne radon/thoron was measured with a continuous monitor of electrostatic type (RAD-7, Durridge Company, and USA). The flow rate of the air was 0.7 L min\(^{-1}\). The air of the room was drawn from the, and the radon generated in the air flow system was measured using the RAD-7 device.

The concentration of radon in the inside cell of RAD7 is calculated by the following equation\(^{15}\):

\[
\frac{dU(t)}{dt} = -\lambda U(t)
\]
\[
\frac{d\lambda_{Po}}{dt} = \lambda_{Po} U(t) - \lambda_{Po} U_{Po}(t) \quad \ldots 2
\]

where \( U(t) \) represents the concentration of radon in the RAD7 internal cell, \( \lambda \) is the radon decay constant, \( U_{Po}(t) \) is a concentration of \(^{218}\)Po, and \( \lambda_{Po} \) is decay constant of \(^{218}\)Po and equals to 0.0037s\(^{-1}\).

Once the pumping time has elapsed, the concentration of radon in the inside cell of RAD7 equals that of the environment Co. Equation 2 can be rewritten as

\[
\frac{dU_{Po}}{dt} = \lambda_{Po} U_{o} - \lambda_{Po} U_{Po}(t) \quad \ldots 3
\]

The initial condition is \( U_{Po}(0) = 0 \) \ldots 4

The solution of Eq. (4) is

\[
U_{Po}(t) = U_{o}(1 - e^{-\lambda_{Po}t}) \quad \ldots 5
\]

When the time is much longer than that of the half-life of \(^{218}\)Po, Equation 5 then can be rewritten as (3).

\[
U_{Po}(t) = U_{o} \quad \ldots 6
\]

The concentration of radon can be calculated using Equation 6, and this is the measurement principle of RAD-7. The RAD-7 utilizes a high electric field over a silicon semiconductor at a ground potential to catch the heavy charged of the polonium daughters, \(^{218}\)Po (\( t_{1/2} = 3.1 \text{ min; } = 6.00 \text{ MeV} \)) and \(^{214}\)Po (\( t_{1/2} = 164 \text{ ms; } = E_{a} \text{ 7.67 MeV} \)), which are estimated in sample as a measure of \(^{222}\)Rn activity concentration., the RAD7 prints out a summary of the average radon reading at the end of each run (about 30 min for each run). The time required for the process of collecting and analyzing the sample is corrected using equation (3):

\[
U = U_{o}e^{-\lambda t} \quad \ldots 7
\]

where \( U \) is the recorded concentration, \( U_{o} \) calculates primary concentration next to the decay corrections and \( t \) is the elapsed time until collection in day unit, \( \lambda = 0.181, \ t_{1/2} = 3.83 \text{ days.} \)

**VMC Validation:** This VMC program was written in the Instituto de Radioproteção e Dosimetria for simulating the radiation transport via specific voxel model. Basically, this program was written using visual basic, and can be applied to both internal and external dose calculations resulted from photons\(^{(16)}\). The program was later extended to include alpha particle, electron and proton transport through a specified voxel structure. To investigate the validity of this software, it has previously been benchmarked via comparisons with many other models and Monte Carlo software\(^{(17)}\). The results of these validation attempts show a good agreement for the effective dose due to cloud immersion obtained using VMC and Federal Guidance Report No.12. In this paper, the program provides coefficients that based on the Monte Carlo simulation to calculate both the organ and effective dose as a result of radiation exposure.

**Results and Discussion**

The resulted data concerning the level of radon concentrations in houses air and for the 10 sires at Al-Najaf are presented in Table (1). According to Table (1), it can be seen that radon concentrations were varied from (8.75 ± 1.1 Bq/m\(^3\)) in location (N10 sample) to (32.32 ± 4.0 Bq/m\(^3\)) in location (N1 sample) with an average value (20.57 ± 2.90 Bq/m\(^3\)). The variations of radon concentrations which were seen among different regions can be caused by a number of factors. These include things like the geological structure of the sites, different kinds of building materials that used to construct houses, the heating systems together with ventilation level, the aging effect on the building and the social habits of the dwellers. The maximum value of \(^{222}\)Rn concentrations in present study is which is much lower than the recommended ICRP indoor of (200-400) Bq/m\(^3\). Comparing these results with those of the Arabic countries it was found that the range of average radon concentration in Jordan (west of Iraq) building measured is (9.95 – 68.15) Bq/m\(^3\) and in Egypt particularly in some region, the average radon concentration in air of buildings was reported to be about 79.505 Bq/m\(^3\) in range from (38.62-120.39)Bq/m\(^3\).

</table>

According to the above Tables (2 and 3), it is clear that for male the highest effective dose was noticed to be at Missan site with a value of 1.07E-04 μSv/h whereas the lowest was found to be at Milad site with an effective dose of 2.91E-05 μSv/h. By contrast, when considering the female effective dose, the highest was 0.000106333 at Miasan site and the lowest was at Milad with an effective dose of 2.87875E-05 μSv/h. The reasons behind the above fluctuations in the value of dose can be attributed to the level of radon detected in these sites (see Table 1). Also, it should be mentioned that Missan site as a one of the new neighborhoods in Najaf city is undergoing a marked wave and building using different materials that could arise the level of radon. The rest of the sites reveal different levels of radon and therefore exhibit different radiation absorbed dose.

Conclusions

According the results of the current work, the following conclusions can attained: all the findings of radon concentrations were obtained in this study were less than the allowed level. The highest people effective dose whether for male or female was found to be at Missan Neighborhood of Al Najaf city.

Conflict of Interest: There are no conflict interest.

Source of Funding: The authors declare that they have no competing interests.

Ethical Clearance: All authors are in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national) and with the Helsinki Declaration of 1975, as revised in 2000 (5).

Detection of Dioxin in the Packed Tea Bags that Available in the Local Markets

Aliaa Saadoon Abdul-Razaq Al-Faraji
Department of Commodity Evaluation and Service Performance, Market Research and Consumer Protection Center, University of Baghdad, Iraq.

ABSTRACT
This study was performed to examine the existence of Dioxin in packed black and green tea bags, that being imported from Arabic and international manufacturers available in the local Markets, (10) kinds of tea bag from (UAE, Syria, Sri Lanka) were bought randomly from Baghdad city markets, The results showed that all samples doesn’t include within it Dioxin, so we insure their safety for consumption and these tea bags specifications are satisfied the standard specifications and technical regulations, and accordingly we deny the rumors that say the tea bags are one of the important causes of cancer.

Keywords: Dioxin, packed tea bag, GC-mass.

Introduction
Dioxin is considered the troublemaker companion in all chemical processing and industries. It is found in the Herbal Pesticides, plastic industry, paper industry, in the furnaces that process the plastic garbage chlorinated in hospitals and all the traditional usage of the chlorine such as: Operations for bleaching and sterilization. Dioxin is considered to be an organic matter of hydrocarbons which is of many chemical derivatives up to 420 organics known as Isomers and they are all similar in effect, it includes: dioxin, Furans and PCBs. The worst kind of which is 2,3,7,8- tetrachlorobenzo (TCDD) P-dioxin. This kind characterized by receptors within the cell in the nucleus of animals, humans and the food chain, that it is found in water, air, soil, and food. Finally, it gets into the muscles easily where it centralizes in the cells of DNA and begin to destroy, if it damages DNA, it may so cause cancer or deform the fetus. It may also change the DNA directions to build enzymes, natural hormones and other proteins that can lead to many sicknesses which harm the health and has massive risks. Recently, such a kind of compound was common in the tea bags and it causes cancer and infertility, so, the study aimed to reveal the dioxin in tea bags to investigate it and determine its suitability for consumption.

Materials and Method
Gathering the Samples: Ten 10 samples of tea bags from different local markets in Baghdad as shown in table 1.

Tea solution was prepared by emptying the tea bags and boiling them with non ionic distilled water in a beaker and filter it and prepare it for measurement.

Detecting Dioxin: The devices: GC-Mass Agilent 5977 E.MSD and GC (oven) were used by using different temperatures and a line type (HP5MS 30 µm*250 µm*0.5 µm) and flow rate 1.1ml/min and injecting a model of the sample 2.5µl, then measurements were taken.
### Results and Discussion

The table no. 2 results showed that all tea bags samples were free of dioxin and it contains only caffeine and the natural components of tea. And so it is fit for human consumption and removes the doubt of not using them and Denies that it causes cancer and infertility, because dioxin is considered an element that exists in the human food and the food chain and it exists in the food chain, it exists in the water and air and soil and helps to connect with the DNA causing damage of the natural enzymes and hormones and proteins and increase above the natural limits causes different diseases and cancers.

Effect of High Intensity Training on Blood Measurements for Young Volleyball Players

Amal Sabeeh Salman Al-Tamimi
Department of Physical Education and Sports Sciences, Faculty of Basic Education, University of Diyala, Iraq, Diyala

ABSTRACT
The importance of the research is to improve the functional aspect of volleyball players through the use of appropriate training method, which works to build and adapt the appropriate function, including blood components, in addition to the receipt of scientific information for trainers about the role of this training, the high severity on the components of blood has applied in a manner that suits the privacy of the game of the ball of the plane.

The objectives of this research are to prepare of high-intensity training on some blood measurements for young volleyball players, identification of the effect of high intensity training on some blood measurements for young volleyball players.

This study concluded that, training of high-intensity fetus is of high significance in increasing blood components under the study (number of red blood cells (million/mm 3), Percentage of hemoglobin in mg (%), Number of white blood cells (Thousand/mm3), Number of thrombocytopenia (Thousand/mm 3)). Also, high physical load of severity gives great benefits in the components of blood, which is the most important functional component of the body functions to transfer energy and waste to and from the working muscles.

Keywords: Volleyball players High-intensity training Blood measurements

Introduction
This scientific output is adopted by the scientific scholars of the country, in all its various fields, including sports. Therefore, the developed countries are the owners of high athletic achievements and prosperity in sports on all their needs from the infrastructure to establish the stadiums and in terms of health interest of citizens and sports as well as building the base of heroes from the National teams of specialized schools.

Therefore, the training of the fetus, especially the high intensity has a direct impact of the high stress it affects the adaptation of the functional body of the player if treated with the correct scientific method.

The first effect is on the blood and its components as the first functional factor, which stimulates the rest of the functions of work and adaptation of the transport of food and oxidation and irregularities within the body.

Hence, the importance of research is to improve the functional aspect of volleyball players through the use of the appropriate training method, which works on building and adapting the appropriate function, including blood components, in addition to the delivery of scientific information to trainers about the role of this high frequency training on the blood components has to be applied in a manner that suits the privacy of the Volleyball game.

Blood and its components have a direct effect in giving an indication of the adaptation of the functional player, especially when developing for the better being the main factor for the transfer of nutrients to the working muscles and the transfer of waste from outside the body.

Therefore, the use of appropriate scientific training will be a crucial component for upgrading the player and for achieving good results.
Thus, the researcher decided to study this problem by identifying the effect of high intensity training on some blood measurements for young volleyball players. (9, 10, 11).

**Materials and Method**

**A. Research Hypothesis**

1. There are significant differences between the results of tests tribal and remote and in favor of remote tests on some blood measurements of young volleyball players.

2. There are significant differences between the control groups and the experimental groups and for the benefits of the experimental group on some blood measurements for young volleyball players.

**B. Research Areas:**

1. **Human Field:** Players of the advanced volleyball team/Faculty of Basic Education/University of Diyala.

2. **Spatial Field:** The Faculty of Basic Education/University of Diyala and the Shams Laboratory for Pathological Analysis in Baquba Al-Jadida Al-Tabu Street.

3. **Time Zone:** Duration from 2/12/2018 to 12/2/2019.

**C. Theoretical Studies:**

1. **Periodic Training:** The periodic training is characterized by regular exchange between pregnancy and the rest is incomplete and takes into account the use of this method to start the recurrence of pregnancy after the rest period when the arrival of the pulse is to the limits of (120-130) bpm, the range of comfort is incomplete. To the interval between each exercise and the next exercise. In this way, the exercise time, duration, rest shape is used, and number of repetitions are considered. Based on the specifications of these variables, the reaction level is determined for the internal devices.

**D. This method has been divided into two types:**

1. Low-intensity periodic training.

2. High-intensity periodic training.

**High-Intensity Periodic Training:** In this way, that the training is carried out in such a way which is characterized by high intensity and little repetition. The muscles of the body perform with insufficient oxygen due to the intensity of pregnancy, i.e. the occurrence of so-called (oxygen debt). The aim of using this method is to improve the level of anaerobic tolerance (The adaptation of the devices) under the conditions of effort with the debt of oxygen”2”. The characteristics of training in this way that the intensity of exercise goes to high ranges between (80-90%) of the maximum level of the individual, and exercise with additional weights reach about 75% of the maximum capacity of the individual. This is confirmed by Mufti Ibrahim (3).

As for size, Mohammed Othman (7) and Abdullah Al-Lami “5” mentioned that the exercise is repeated 10-12 times and can be repeated in 3-4 groups. The Interval periods are enhanced by increased intensity of exercise and incomplete rest periods to allow the heart to return to normal part of the body. Mohammed Hassan Allawi mentioned it (15). The rest period ranges between 90-180 seconds for advanced players, with no heart rate falling to 110-120 bpm. The use of the principle of positive rest in the interstellar rest periods, such as; walking and relaxation exercises.

**E. Procedures:**

1. **Design:** The researcher used the experimental method with the sample of the controlled groups and the experimental groups to suit the solution of the research problem and achieve its objectives.

2. **Sampling:** The research community defines in a deliberate way for players of the volleyball team of applicants in the College of Basic Education/University of Diyala and the number of (20) players. After that, 12 players were selected from the main team, who continued the training and their participation in the tournaments. The sample was randomly divided into two controlled and experimental groups, so that the number of each group was 6 players and the sample formed 60% of the original society.

The sample was homogenized within the group using the difference of coefficient and the equivalence of the two groups using the (t) test as in Table (1).

The Schedule (t) Value at the Freedom Level (10) and the Level (0.05) = 1.812

### F. Information gathering Methods:

#### 1 Means of Data Collection:

1. Arabic references.
2. Exploration experience.
3. Measurements used.

#### 2. Instruments and Tools used:

1. Needle to draw blood samples.
2. Bottles to save blood samples.
3. Centrifuge
4. Cool Box to save blood samples with all requirements for obtaining ratios.
5. Six (6) Volleyballs.
7. Regulated volleyball playground.
8. Metric tape measure.

#### 3. Procedures

#### 1. Determining Research Variables: Based on the modest experience of the researchers and review of sources and references, the blood variables and their components were determined by the researcher as necessary:

- Number of red blood cells (million/mm³)
- Hemoglobin ratio (mg%)
- Number of white blood cells (thousand/mm³)
- Number of thrombocytopenia (thousand/mm³)

#### G. Exploration Experience: The researcher conducted an exploration experiment on 2/12/2018 on the same research samples. The required training was applied for the purpose of rationing the training load used according to the high periodic training method and preparing the measurements required for measurement, and the purpose of the experiment was to:

1. Know the required tools.
2. Know the right time.
3. Know the obstacles facing the researcher in the future.
4. The regulation of exercises and the calculation of the appropriate size by the quality of training high intensity and low intensity.

#### H. Measurements Used:

1. Anthropometric measurements (length - weight).
2. Measurements of blood components (number of red blood cells million/mm³, hemoglobin ratio mg%, number of white blood cells thousand/mm³, number of thrombocytopenia thousand/mm³).
1. Method of Measurements: The pre-measurements of the blood parameters and their components were performed inside the playground and transferred to a laboratory. The blood sample was withdrawn by 5cc after sitting the testers for 5 minutes. After the procedure, the blood was drawn into a glass box that placed the blood in a special box called cool box and then transferred to a laboratory to obtain the results for the variables. The two-stage blood draw was included:

First: During the Rest:
1. Measurement of the pulse rate and blood pressure measurement for the research sample at the time of rest.
2. (5cc) Blood was drawn to the sample of the research for each player.

Second: during During the Effort:
1. Application of a specialized training unit.
2. Increase the load after one minute by repetition and difficulty exercises.
3. Continue to increase the load until the intensity of (100%) by measuring the maximum pulse (180-190 bpm).

I. Field Experience:

Pre-measurement: The pre-measurement was performed on 16/12/2018.

Main Experience and Training: The exercises were implemented in the main section of the trainer’s training units during the special number period at a rate of (3) units per week and for two months (24) training units.

The size of the load was determined according to the intensity set. The rest was based on pulse return (120-130 bpm) and time was calculated to rest during the pulse. The application of the exercises was for the period from 17/12/2018 to 11/2/2019.

Post-measurement: The post-measurement was performed on 12/2/2019.

J. Statistical Methods: Using the (SPSS) system in statistical treatments and to find the following:
1. Arithmetic mean.
2. Standard deviation.
3. The difference coefficient.
4. Test (T) for interrelated samples.
5. Test (T) for independent samples.
6. Percentage.

Results and Discussion

By noting Table (2) and Table (3), it was found that there are significant differences in the controlled groups and the experimental groups in pre and post measurements. This is an evidence of improvement in the physiological variables under the study, including blood and its components, which is due to the training used and have positive impact as a result of the regularity of the sample training and the use of additional loads of the set and this is consistent with the statement of Karima Ahmed Fattouh, (5) “The regularity in the training program lead to the creation of some physiological variables of the body as a manifestation of adaptation to the nature of that activity” (1, 10, 11, 18, 19).

Regardless of the type of training used by the control or the experimental group, adaptations occur for all components of the body, including blood. “It is the process of adaptation of the system that begins with physical pregnancy leading to internal imbalance by depleting energy and increasing capacity and function” (16, 17, 18).

Table 4 showed differences between the controlled and the experimental groups and for the benefit of the experimental group, which the researcher considered to be due to the high-intensity infant training used as a high-load method that interacts with the exchange between pregnancy and rest. In a previous study, rest and regular exercise have health benefits and stress the balance between oxidative stress and antioxidant enzymes“3”.

As for the effect of training on blood components, it is natural that there is a significant impact on blood training, as Kamal Abdul Hamid (4) contended that, “physical exertion increases the number of red blood cells.. As the researcher saw that, the increase in blood components, including red blood cells and hemoglobin to the size of the pregnancy used and affecting the body and adapting, as Qassem Hassan Hussein (2) stated that “The practice of sports training for a certain period leads to the adaptation of blood for the performance of physical training, in blood volume and hemoglobin and erythrocyte volumes” (11, 12, 13).

The Schedule (t) Value at the Freedom Level (10) and under the Level (0.05) = 1.812

Our study concluded that, the periodic training of the high-intensity is of high significance in increasing blood components under the study (number of red blood cells million/mm³, hemoglobin ratio mg%, number of white blood cells thousand/mm³, number of thrombocytopenia thousand/mm³). Also, high-intensity physical loads give great benefits to the blood components, which is the most important functional component in the body’s functions to transfer energy and waste to and from the working muscles.

Also, our study recommended that, relying on the periodic training of the high-intensity, as it is especially important in increasing blood components.
under the study (number of red blood cells million/mm³, hemoglobin ratio mg%, number of white blood cells thousand/mm³, number of thrombocytopenia thousand/mm³). Also, the need to emphasize the use of high loads of physical strength because it provides great efficiencies in the blood components, which is the most important functional component of the functions of the body to transfer energy and waste to and from the working muscles. Also, conducting periodic laboratory tests at various levels for their benefits to their health and to continue to develop their levels.

Use of Anti-Dyslipidemia in Type 2 Diabetes Mellitus

Amalia Irza Maharani¹, Didik Hasmono¹, Muhammad Noor Diansyah²

¹Departement of Pharmacy, Faculty of Pharmacy, Universitas Airlangga; ²Department of Internal Medicine, Airlangga University Hospital, Surabaya, Indonesia, Jl. Airlangga No.4-6, Airlangga, Gubeng, Kota SBY, JawaTimur 60115

ABSTRACT

Background: Dyslipidemia is one of the most common conditions in type 2 diabetes mellitus patients. Use of anti-dyslipidemia needs to be studied because it can cause improper therapy and drug-related problems that affect patient management.

Objective: To study the use of anti-dyslipidemia in type 2 diabetes mellitus

Method: The study was descriptive retrospective study with medical record of type 2 DM patients with dyslipidemia. Inclusion criteria were patient who was diagnosed with type 2 DM with dyslipidemia; received anti-dyslipidemia therapy; ≥20-year old male or female; and had a complete medical record. Sampling used time-limited sampling method. Data were analyzed descriptively.

Result: Patients who met inclusion criteria were 390 people. The most commonly found laboratory data was LDL value (96.41%). The mostly used anti-dyslipidemia therapy was HMG-CoA reductase inhibitors and fibrate. This study found potential DRP (drug interaction, drug reaction, and therapy suitability) and actual DRP (drug side effects). In therapeutic response, there were still many patients who did not reach the expected lipid level. This showed that controlling lipid levels in patients with type 2 DM is difficult. Management of anti-dyslipidemia was not only pharmacological therapy but could also be balanced with non-pharmacological therapy to prevent other risk factors development.

Conclusion: Use of anti-dyslipidemia therapy in type 2 DM patients in outpatient care unit was in accordance with existing guidelines, but the therapeutic response was not in accordance with the goals of therapy.

Keywords: Type 2 diabetes mellitus, dyslipidemia, anti-dyslipidemia drug

Introduction

Diabetes Mellitus (DM) is a metabolic disorder illness characterized by hyperglycemia. Metabolic disorder in DM patient that causes hyperglycemia is caused by insulin secretion disorder, insulin sensitivity, or both that can relate to many organ disfunction. ¹ ² Classifications of DM according to American Diabetes Association are type 1 diabetes mellitus, type 2 diabetes mellitus, gestational diabetes mellitus, and specific types of diabetes due to other causes. People with DM increase each year; mainly type 2 DM. Based on WHO¹ diabetes global prevalence has increased from 4.7% in 1980 to 8.5% in 2014. Over the past decade, prevalence has increased more in low and middle-income countries than high-income countries. Proportion of undiagnosed type 2 DM varies greatly; a recent review of data from seven countries has found that between 24% and 62% of people with diabetes are undiagnosed and untreated.

Characteristics of type 2 DM are insulin resistance and reduced insulin secretion. Both of these can be caused by age factors, dyslipidemia, hypertension and genetics. Dyslipidemia is one condition that always accompanies type 2 DM patients. Dyslipidemia is defined as an abnormal lipid level. Diabetic dyslipidemia is characterized by decreased levels of high-density lipoprotein (HDL), increased low-density lipoprotein

DOI Number: 10.5958/0976-5506.2019.02141.7
(LDL) and triglycerides (TG). Dyslipidemia in type 2 DM patient is caused by insulin resistance causing an increased plasma insulin and β cell depletion which results in circulatory disorders of lipoprotein and glucose so it causes abnormal plasma lipids.\textsuperscript{1,2,4,5}

Complications that can occur in type 2 DM patients with dyslipidemia are cardiovascular disease, cerebrovascular disease, Cerebro Vascular Disease (CVD), peripheral vascular disease, atherosclerosis, and death. Controlling lipid level in type 2 DM patient can be done with lifestyle interventions. Along with many failures of lifestyle interventions therapy, pharmacological therapy is used to achieve therapy target. The drugs used in therapy to reduce lipid level are HMG CoA reductase inhibitors (statins), bile acid sequestrans resins/BAR (cholestiramine and cholestipol), nicotinic acid (niacin), fibrates (gemfibrozil, fenofibrate), and absorption inhibitors bowel cholesterol (ezetimibe).\textsuperscript{1,6–9} Giving anti-dyslipidemia therapy in type 2 DM patient must be accurate by paying attention to the patient’s condition based on clinical and laboratory data and treatment options.

The use of anti-dyslipidemia needs to be studied because it can lead to improper therapy and potential drug-related problems that affect patient management, so an observational study is conducted to examine the use of anti-dislipidemia in type 2 DM patients.

**Method**

This research was descriptive retrospective study. Research data used medical record of type 2 DM patient with dyslipidemia who received anti-dyslipidemia therapy in outpatient care unit of Airlangga University Hospital (RSUA) Indonesia. Inclusion criteria of sample were patient who was diagnosed with type 2 DM with dyslipidemia; received anti-dyslipidemia therapy; ≥20-year old male or female; and had a complete medical record. Then, exclusion criterion of sample was patient who visited <2 times. Sampling used time-limited sampling method. Sampling was carried out in January 2014 - June 2016. Observed variables were age, gender, clinical symptoms, comorbid diseases and complications, type of anti-dyslipidemia, dose, route of administration, frequency of administration, laboratory data, and therapeutic response. Data were analyzed based on patient’s medical record. Data that were obtained from data collection sheet were entered into parent table then they were processed and analyzed descriptively into tables and narratives.

**Results**

Research resulted 390 patients who met the inclusion criteria and were dominated by female (58.46%). Patients were dominated by the age group 45-64 years old (68.97%). The three highest clinical symptoms experienced by type 2 DM patients with dyslipidemia were whole body pain (5.90%), tingling (2.82%) and headache (2.82%). The rest of clinical symptoms were thick extremity, airway disorders, knee pain, swollen feet, polyuria, and nausea and vomiting.

**Comorbid Profile:** The most common comorbid disease can be seen in the table below:

**Table 1: Comorbid disease and complication in Type 2 DM Patient with Dyslipidemia**

</tbody>
</table>
Discussion

From the data, it can be seen that the most distributed patients who were hospitalized in the hospital are female. This is because women have estrogen which has a function in regulation of lipids. In lipid regulation, estrogen plays a role in increasing HDL and decreasing LDL. Estrogen will decrease with increasing age in women with menopause so women will be more susceptible to interference with lipid regulation\textsuperscript{10}. The number of type 2 DM patient with dyslipidemia mostly occurs in the age range of 45-64 and it will increase at age $>$41 years old. These results are in accordance with the literature that men over 40 years old and women over 50 years old are one of the risk factors of dyslipidemia.\textsuperscript{11,12}

The comorbid disease and complications can be seen that diabetic hypertension and nephropathy were the most common comorbid disease accompanying type 2 DM patients with dyslipidemia. Hypertension is one of the risk factors of complications that increases the incidence and mortality because insulin resistance enhances the process of lipolysis which causes disruption of lipid metabolism or dyslipidemia. High lipid levels cause atherosclerosis so it causes stiffness in arteries due to the accumulation of plaque so it can be experience cardiovascular complications such as stroke, coronary heart disease, retinopathy, neuropathy and nephropathy\textsuperscript{13-15}. Changes in lipid metabolism can be shown by an increasing LDL, increasing TG, and decreasing HDL. The highest obtained lipid profile was triglyceride laboratory data. Most patients still did not reach the desired and normal lipid target. HDL levels were rarely tested in laboratory lipid profiles of patients obtained in this study.\textsuperscript{2}

Type of HMG CoA reductase inhibitors that was given is simvastatin. Simvastatin is lipophilic. The absorption process is fast and the maximum level in plasma can be reached within 4 hours. Simvastatin elimination half-life (t$\textsuperscript{1/2}$) is short which is 2 hours so that simvastatin was given only once in the afternoon or evening. The timing of this administration is associated with high cholesterol synthesis at night. Another type of HMG CoA reductase inhibitor that was given is atorvastatin. Half-life (t$\textsuperscript{1/2}$) elimination of atorvastatin long is 14 hours. Simvastatin and atorvastatin had no differences in significantly reducing lipid profiles\textsuperscript{20-22}. Another anti-dyslipidemia that was given to patients is the fibrate which are fenofibrate and gemfibrozil. Fibrate is more effective for patients with hypertriglyceridemia and low HDL. Fenofibrate is also more effective in decreasing LDL in patients with hypercholesterolemia and mixed hyperlipidemia than gemfibrozil\textsuperscript{10,23,24}. The frequency of drug use must also be appropriate so that the therapy runs more optimally and get the desired therapeutic response. In this study, the regimentation of anti-dyslipidemia doses received by patients varied but was still in accordance with the range of uses in the literature.

DRP found during the study includes potential DRP which are drug interactions, ADR and DRP suitability therapy. The interaction between amlodipine with simvastatin and simvastatin with diltiazem occurs. The interaction of simvastatin with other drugs is based on the pharmacokinetic mechanism. This drug interaction can affect several pharmacokinetic parameters of simvastatin, that is increasing or decreasing maximal concentration (C$\text{max}$) and AUC of simvastatin. The use of simvastatin with amlodipin and simvastatin with diltiazem can cause decreasing simvastatin metabolism. Decreasing the metabolic process of simvastatin causes increasing concentration of simvastatin in the serum. Increased simvastatin concentration in serum potentially increase the side effects of simvastatin. Side effect that can occur is myopathy\textsuperscript{27,28}

The actual DRP that was listed is allergic to fenofibrate, a skin rash. However, other allergic reactions were not recorded in the patient’s medical record. In the therapeutic response, assessment of the achievement of plasma lipid targets is a method for evaluating the response to anti-dyslipidemia therapy and determining whether therapeutic modification or replacement therapy is necessary or not. Based on the results, there were still quite number of patients who did not achieve the predetermined lipid levels. This showed that controlling plasma lipid levels in patients with type 2 diabetes both high and very high risk is difficult, so it requires special attention in therapy. In the management of dyslipidemia therapy in type 2 DM, the main focus is not only pharmacological therapy to reduce lipid levels in the blood, but also can be balanced with modifications to non-pharmacological therapy to prevent the development of risk factors\textsuperscript{10}.

Conclusion

Most of the use of anti-dyslipidemia therapy in type 2 DM patients was in accordance with existing guidelines but the therapeutic response obtained was not as expected in this study.

Improving Response Units Integration a Related Factor to Total Prehospital Time (TPT) on Patients of Public Safety Center (PSC) 119 in Purworejo Regency, Indonesia

Anggun Setyarini1, Respati S Dradjat2, Heni Dwi Windarwati2

1Nursing Postgraduate Program, 2School of Nursing, Faculty of Medicine, Universitas Brawijaya

ABSTRACT

Background: Rapid response and appropriate management of Public Safety Center (PSC) 119 team is very necessary for patients who experienced trauma or serious illness in prehospital area. The aim of this study was to identify the response units integration as related factors with total prehospital time (TPT) of PSC 119 in Purworejo Regency.

Material and Method: This research was conducted by Retrospective Chart Review (RCR) design on 105 patients who treated by PSC 119 in Purworejo Regency. Bivariate test was conducted by using Spearman correlation test to investigate the correlation with response unit integration.

Results: The majority of patients were trauma by traffic accident (57.1%). The fastest TPT was 9 minutes and the longest was 105 minutes with an average of 30.85 minutes. Bivariate test results demonstrate that response units integration had a value of p=0.000 (r=0.387). It meant that there was significant correlation between response units integration with TPT.

Conclusion: This study suggests the PSC leaders to improve the integration between the call center unit with response units. The improvement of nurses’ capacity through nursing specialist education and advanced level training of prehospital emergency were very important for optimizing the quality of prehospital intervention. The result of this study was useful in the future as the basic information for research, education and service of prehospital emergency.

Keywords: Public Safety Center, Total Prehospital Time, Indonesia Prehospital Management

Introduction

Trauma contributed for 12% of disease burden in the world, with the number of patients reach up to 5 million (1). Most of trauma patients dead in prehospital phase (2). Data of medical case shows more than 356,000 patients who suffered out-of-hospital cardiac arrest (OHCA) annually in the US (3). Coronary heart disease and stroke are expected to increase up to 23.3 million in 2030 (4). Trauma due to traffic accidents (TA) in Indonesia during 2016 reached 108,696 cases, 31,195 people died, 35,285 inhabitants got severe injured, and 108,945 inhabitants got mild injuries (5). Data of medical case shows the number of diagnosed patients with coronary heart disease at the age ≥ 15 years old is estimated at 2,650,340 million people (4). The patients with hypertension that are not diagnosed in society totaled 63.2% of total existing prevalence (25.8%) (6). People who are diagnosed with diabetes mellitus (DM) totaled 2.1%, increase from the data in 2007. This indicated that the risk of cardiac emergency due to hypertension and diabetes also increase.

The potential for emergencies due to trauma or serious illness in prehospital area increase the community’s need for Emergency Medical Services (EMS) system. The EMS service starts from the call center officer that receives emergency call, then conduct dispatch the Emergency Medical Technician (EMT), paramedic or nurses who has been trained to intervene in Basic Life Support (BLS) or Advanced Life Support...
(ALS), then transfer the patient to the appropriate health care facility \(^\text{7, 8}\). Indonesia is currently implementing the EMS system called the Sistem Pelayanan Gawat Darurat Terpadu (SPGDT) \(^\text{9}\). PSC is part of SPGDT that organize and conduct a rapid response in each regency in all region of Indonesia. The system that has been implemented is important to be assessed, thus it can be determined about the service provided is good or not. One aspect that can be used as indicators of EMS service is the response time \(^{10-14}\). For example, response time achieve in 8 minute in UK, 10-15 minute in Netherland \(^7\). The other research has shown that an assessment of total prehospital time (TPT) of patients is more significant for patient’s clinical condition than the assessment of the response time \(^\text{15}\). PSC team can ideally achieve TPT <60 minutes as “golden hour” for trauma patients, or <3 hours after onset of stroke patients that required thrombolytic therapy.

Research about TPT of EMS and affected factors has been conducted in other countries. PSC 119 in Purworejo Regency, Central Java, has not been analyzed completely about the achievement of TPT and related factors. Identification of the TPT achievements is important because it may be related with prehospital service outcomes and useful to understand the level of personnel skills and support systems against the PSC operational. The purpose of this study was to identify response units integration related to TPT on patients treated by PSC 119 in Purworejo Regency.

Material and Method

This study was conducted by retrospective chart review (RCR) method. This method was design using patient data to answer research questions by using several types of data including electronic data base, the results of diagnostic tests, and records of health workers \(^\text{16, 17}\). This research had been conducted in PSC 119 Purworejo Regency, Central Java, Indonesia during January-February 2019. The population of this study was all of the patients record that treated by PSC 119 from January to December 2018. One hundred and five patiens record selected based on two inclusion criteria: (1) records of emergency patients with trauma and medical cases handled by the call center unit and response units of PSC 119 Purworejo Regency, (2) records of emergency patients who are transported to definitive care. The records which excluded were (1) records of patients with phsyciatric and obstetric emergency, (2) records of trauma and medical emergency patients who needs to be referred to the hospital, but not complete in documenting the prehospital time intervals. Data was collected by observation sheet to investigate TPT and response units integration as related factor. Univariate test was conducted to analyze the characteristics of respondents including gender, age, Mechanism of Injury (MOI)/Natur of Illness (NOI), response units integration and TPT. Bivariate analysis by Spearman correlation test used for analyzed the correlation of TPT with the response units integration.

Findings

Setting: Purworejo Regency is one of thirty-five regencies/cities in Central Java Province, Indonesia. The area of Purworejo Regency is ± 1034.82 km². Morphologically consists of lowland areas. The total population of this regency is 708,038 consist of 349,237 male and 358,801 female. Based on population density, it is divided into areas with high and low population densities. PSC 119 Purworejo started since the ratification of the Regent Regulation (Perbup) Purworejo No. 48 of 2016 on 28 October 2016. This PSC is domiciled in the Purworejo Regency Health Office. The Organizational Structure of the PSC 119 consists of the Head of the PSC 119, the secretariat team, 119 call center units, counseling units and response units. The PSC Secretariat Team is assigned to administration and information systems. The call center unit is the central unit that receives each emergency call from the patient, then dispatch the ambulances team. Personnel entitled to the call center unit currently receive 12 people consisting of 10 nurses and 2 ambulance drivers, they are supported by 146 respons units officer. All of employees both nurses and ambulance drivers have received basic emergency training. They work in three service time shifts, namely morning (07.00-14.00), afternoon (14.01-20.00) and night (21.00-07.00). Each shift consists of one operator, 1 nurse and 1 driver. The counseling unit consists of physicians who have the function of receiving and answering consultations from nurses.

Univariate and Bivariate Analysis: According to Table 1, the majority of patients were male, totaling 61 people (58.1%). The majority of patients were trauma by traffic accident, totaling 60 (57.1%). Response units integration was concluded into good category 61 (58.1%).

Table 3 shows that the response units integration had a value of p=0.000. This meant that there was significant correlation between the response units integration with TPT on patients that treated by PSC 119 in Purworejo Regency (r = 0.387).

Discussion

Correlation Response Units Integration with TPT:
The statistical test result shows there was significant correlation between response units integration with TPT. The result of this study was in line with the other research (18) on the first responder community, followed by 20 medical students in the UK named Community First Responder (CFR), proven that the average response time of CFR from 89 calls were 3-8 minutes faster than the response time of ambulance. Criteria of calls received by the CFR was the location of call should be closer to the CFR as compared with the nearest ambulance; CFR was within a 5 mile of the location of the call; CFR might call central dispatch and request a higher priority call. Qualitative evaluation of this study shown that student who was trained and involved in first-responder program had the better confidence and readiness in conducting prehospital relief in patients with severe acute conditions. The univariate results of this study shown the integration of call center units and response units in PSC 119 Purworejo Regency included into category of good with percentage of 66%. This means that there was already a synergy with the response units for calls that were far from the call center unit. Unfortunately, there were still 44% which shown that the integration included into category of poor. This indicated that there were some calls that in the radius more than >5 km were not responded by the response units, thus, the ambulance from the call center unit should reach a further location.

SPGDT was a form of emergency services that integrate the PSC as a call center with its response unit. The other literature mentioned that the EMS service system operated by the operator/dispatcher, first responder, and EMT or paramedic (19). The network of first responder was the first link in chain of survival. Cooperation between call center unit in Purworejo Regency with response units in 27 primary health care called “puskesmas” as the closest first responder to the patient had been implemented since the issue of Decree of Head of Health Office No.188/27/2017. There was a collective agreement if the distance calls >5 km, the operator would dispatch response units. Good integration between the call center unit with response units were expected to be able to provide fast service. The result of this study was consistent with the recommendations of the National Highway Traffic Safety Administratiion (NHTSA) in United State, entitled “EMS Agenda For The Future “ (20). One of the 14 things that were...
recommended by the NHTSA for the functioning of EMS system was the integration of health services. The presence of ambulance officers from the nearby response unit as the first responder to the scene could shorten the response time and TPT.

This study was different with the previous research (21), which was conducted by using Delphi method to develop EMS design in UK. The consensus result agreed on the importance of system integration development with a first responder by involving police, firefighters and commoner who were trained. Police or firefighters who were trained in prehospital emergency could be involved in handling prehospital cases (8). PSC 119 in Purworejo Regency utilized the puskesmas which were spread in 27 points. Empowering health care worker such as the nurses or physicians who already have basic knowledge about health and emergencies, deemed more likely than with the involvement of police or firefighters who had not been trained.

Currently, PSC in Purworejo Regency has not yet involve other agencies such as the police and firefighter as the first responder. This could be considered by the policy makers for the implementation of emergency services to be more integrated in the future. Community volunteers in Purworejo also can be involved. As the consequences, this step needed to be prepared with socialization and training of those who would be involved as first responders. In the future, conducting preceptorship programs and training for ambulance first responder for the nurse or medical student could create a good symbiotic mutualism between students, the PSC and the community. Students could be more prepared for managing prehospital cases, the PSC could achieve the target of short TPT, and community get the prehospital service more quickly.

Conclusion and Recommendation

There was significant correlation between response units integration factors and TPT. It was expected that in the future integration with response units would be better, thus the services provided would be more optimal. It was recommended that expanding networks of first responder was not only involve the response units of 27 puskesmas but also other parties such as police, fire fighters and trained community. Policies to supervise the complete TPT documentation, distance and integration between call center unit and reponse unit is useful for evaluation of PSC’s performance. Developing manual standard about prehospital documentation including TPT and its related factors is needed in the future.

Climate Change: An Overview of the Prevalence of Dengue Hemorrhagic Fever in The South Sulawesi Province of Indonesia

Ashari Rasjid¹, Ririh Yudhastuti², Hari Basuki Notobroto³, Rudy Hartono⁴

¹Department of Environmental Health, Makassar of Health Polytechnic, Indonesia; ²Department of Environmental, ³Department of Biostatistic, Faculty of Public Health, Airlangga of University; ⁴Makassar of Health Polytechnic, Indonesia

Abstract

Makassar City, Maros Regency and Tana Toraja Regency in South Sulawesi Province are regions with varying topography. Makassar City is a lowland area (1-19 DPAL), Maros Regency is a middle-land region with variations in height of 15-700 DPAL and Tana Toraja Regency located in the Toraja highland region 700 - 820 DPAL which is ideal for the breeding of Aedes aegypti mosquitoes as a vector which is dominant to the incidence of dengue hemorrhagic fever, because it has a temperature between 19,00° - 31,00° C (Central Meteorology Climatology and Geophysics Council region IV Makassar), with humidity between 63-94%. Between temperature and humidity affect each other for the breeding of Aedes aegypti, climate conditions (temperature and humidity) will support the increase in mosquito population density and subsequently have an impact on the transmission and spread of dengue hemorrhagic fever. Temperature between 20° C - 30° C with a humidity range of 60% - 90% is the optimum moisture for growth and development of the Aedes aegypti mosquito⁴. The aim of the study was to determine the effect of climate conditions on the transmission and spread of dengue hemorrhagic fever in South Sulawesi Province. This type of research is cross-sectional by measuring all variables at the same time. The research sites were Makassar City, Barru Regency and Tana Toraja Regency. Analysis using Spearman Correlation. The results showed that there was a significant relationship between air temperature and duration of solar radiation on the number of cases of dengue hemorrhagic fever (rs = 0.281 and 0.265 p <0.000), while also having a significant relationship but with negative rs (p = 0.001).

Conclusion climate factors are related to the incidence of ddb in the province of South Sulawesi. Prevention of ddb should be by anticipating environmental improvements to eliminate climate factors in order to suppress cases of dengue hemorrhagic fever.

Keywords: climate, dengue hemorrhagic fever.

Introduction

In 2014 there were 139 cases of dengue fever in all Puskesmas areas in Makassar City with rates of illness/IR = 10.15 per 100,000 population of whom there were 2 deaths due to DHF. Cases in 2014 declined compared to 2013 with the number of cases 265 with rates of illness/IR = 19.6 per 100,000 population of whom there were 11 cases of deaths due to dengue, the number of 2012 was 86 cases with a rate of illness/IR = 6.3 per 100,000 population and there are 2 deaths¹,⁵,⁷. In addition to Makassar City, Maros Regency is also an endemic area of DHF, from 14 Subdistricts in Turikalle District, the highest incidence of DHF. While in Tana Toraja Regency, it is also prone to dengue attacks, especially in Makale District²,³,⁴.

Makassar City, Maros Regency and Tana Toraja Regency in South Sulawesi Province are regions with varying topography. Makassar City is a lowland area (1-
Based on the description above, the relationship between average temperature for mosquito growth is 25º - 27ºC. The optimum temperature for the breeding of Aedes aegypti mosquitoes as a vector dominant to the incidence of DHF, because it has a temperature between 19.00ºC - 31.00ºC (Central BMKG region IV Makassar), with humidity between 63-94%\(^8,10,15\). Between temperature and humidity affect each other for the breeding of Aedes aegypti, climate conditions (temperature and humidity) will support the increase in mosquito population density and subsequently have an impact on the transmission and spread of dengue disease. Temperatures between 20ºC - 30ºC with a humidity range of 60% - 90% is the optimum moisture for growth and development of the Aedes aegypti mosquito\(^9,11,12\). DHF is one of the public health problems in Indonesia where the number of sufferers tends to increase as well as the wider area of spread. DHF is affected by dengue virus which is transmitted by Ae. aegypti and Aedes albopictus\(^4\).

Disease transmission is strongly influenced by climate factors in a region. Parasites and vectors of disease are very sensitive to climate factors, especially air temperature, rainfall, humidity and wind. DHF needs to be watched out because transmission of this disease will increase with climate change\(^13,14,20\). Climate is related to the breeding habitat of Aedes aegypti mosquitoes. The conditions of rain and heat alternating at the turn of the season are more positive for the mosquito population because rainwater does not flow and stagnate in several places\(^16,17,19\). The climate of South Sulawesi Province varies as in Maros Regency which is a lowland area, namely 26.0 ºC to 28.8 ºC, Makassar City 25.5 ºC to 29.0 ºC, and Tana Toraja District which is a plateau ranging from 21.1 ºC to 29.0 ºC\(^18,21\).

Mosquitoes are cold-blooded animals so that the metabolic processes and life cycles depend on the temperature of the environment, unable to regulate their own body temperature against changes outside their body. Mosquitoes can survive at low temperatures but the metabolic process decreases and even stops when the temperature drops to a critical temperature. At temperatures higher than 35ºC, also experience limitations in physiological processes. The optimum average temperature for mosquito growth is 25º - 27ºC\(^9\). Based on the description above, the relationship between air temperature, humidity, rainfall, duration of solar radiation, and rainy days has been investigated with an increase in the incidence of dengue hemorrhagic fever in South Sulawesi Province.

Material and Method

This type of research is quantitative and is an analytical study to analyze the relationship of climate with the incidence of dengue hemorrhagic fever. This design aims to reveal correlative relationships between variables. The location of the study was carried out in South Sulawesi Province in three regions, namely Makassar City, Maros Regency and Tana Toraja Regency. The selection of this location is based on the consideration that the three regions are endemic areas of DHF with different social demographics as well as the topography. Time of research for 1 year starting June 2015 until May 2016.

The population and sample in this study were purposive sampling by directly assigning 250 people each study area who had symptoms of endemic DHF. So the sample size in this study was 750 respondents.

The independent variables are climate (air temperature, humidity, rainfall and duration of sun and rainy days) obtained from the data of the Meteorology and Geophysics Agency of Makassar City, Barru Regency and Tator in 2011-2015, while the dependent variable is dengue hemorrhagic fever using data the number of cases of dengue hemorrhagic fever in 2011-2015 was obtained from the Makassar City Health Office, Barru Regency and Tator. Data analysis using the Spearman correlation test.

Findings

The duration of solar radiation for the Makassar region tends to be higher than that of Maros and Tana Toraja. The highest Makassar irradiation rate occurred in 2015, the Maros region had the highest sun exposure rate in 2015, and Tana Toraja the highest rate of solar radiation occurred in 2013. The high level of solar radiation in a the area will have an impact on the breeding and spread of mosquitoes.

The relation between rainy days and the spread of dengue disease is determined by the presence of wind speeds that influence the flight and spread of mosquitoes,
if the wind speed is 11-14 m/sec or 25 - 31 miles/hour it will inhibit mosquito flight. Wind speed on rainy days is when mosquitoes fly into or out of the house, and this is one of the factors that determine the amount of contact between humans and mosquitoes.

Table 1: Climate Relationship with 2011-2015 Dengue Fever Events

<table>
<thead>
<tr>
<th>Relationship</th>
<th>$r_s$ (Spearman Correlation)</th>
<th>$p$</th>

</tr>
</tbody>
</table>

Climate relations which include air temperature, humidity, rainfall, and duration of solar radiation with the number of DHF cases show a probability value of <0.05, which means there is a significant relationship of climate to DHF cases.

Discussion

Climate change can affect the ecosystem of animal habitats that transmit disease, even natural growth of colonies of germs. Climate can affect the pattern of infectious diseases because vectors and viruses are sensitive to changing climate$^9,10$.

The incidence and spread of dengue hemorrhagic fever in South Sulawesi Province cannot be separated from the existence of climate as a cause of the proliferation of various types of parasites and vectors of diseases that are very sensitive to climate. In relation to the incidence and spread of dengue fever, the existence of climate, especially temperature, humidity, rainfall, rainy days according to wind speed, and solar radiation is a climate that directly affects the occurrence of various distributions and densities of vector organisms and intermediate hosts. Vector-borne diseases such as malaria and dengue fever need to be watched out for because transmission of such diseases will increase in accordance with climate change. As in South Sulawesi Province, where in the three regions observed, Makassar City, Maros and Tana Toraja Regency are tropical regions whose climate supports the proliferation of disease vectors.

Climatic conditions in the three regions observed showed that rainfall, humidity, temperature and sun exposure throughout the year greatly supported the proliferation of dengue fever disease vectors which greatly affected the vector life cycle of Aedes, especially in breeding from eggs, larvae, larvae and mosquitoes adult. Therefore, to anticipate climate support that affects the proliferation of Aedes aegypti vectors, efforts are needed to improve the environmental system.

The air temperature is a state of heat or cold air. The temperature of the air due to climate change causes the mosquito incubation period to be shorter. As a result, mosquitoes will breed faster. The increasing population of mosquito vectors will increase the chances of disease agents to infect humans.

Air humidity has an indirect influence on the metabolic process and the development of mosquitoes. When low humidity causes evaporation of water from the body which causes dryness of body fluids. One of the enemies of mosquitoes is evaporation because low humidity shortens the life of mosquitoes, although it does not affect parasites. The humidity level of 60% is the lowest limit to allow mosquitoes to live. Humidity also affects the ability to fly mosquitoes. Small mosquitoes have a large surface because of the respiratory system with the trachea. At the time of flight, mosquitoes need more oxygen so that the trachea is opened. Thus evaporation of water from the mosquito’s body becomes larger. in the body from evaporation, the flight distance of mosquitoes is limited.

Rainfall variability can have direct consequences for infectious diseases. Increased rainfall can increase the presence of disease vectors by expanding the size of existing larval habitats and creating new mosquito breeding grounds. Rain is an important factor in influencing vectors, such as mosquitoes.

The presence of rainfall affects the humidity of the air and the breeding places of mosquitoes also breeding places the incidence of diseases transmitted by mosquitoes usually increases some time before the heavy rainy season or after heavy rains that can leave inundation where mosquitoes are favored. Mosquitoes carrying Dengue Fever are at tropical and subtropical regions, which are dominated by high rainfall$^{21}$. 
There are several results of previous studies that showed that the climate greatly determines the incidence of Dengue Hemorrhagic Fever. The results of the study show the results of the study based on the results of observations revealed that climate factors have a close relationship with the incidence of DHF\(^6\). The results of this study observe that there are influences of temperature, humidity, rainfall, and solar radiation that are positive and significant for the incidence or incidence of DHF. In addition, the climate can affect the pattern of infectious diseases because agents of disease in the form of viruses, bacteria, or parasites and disease vectors are sensitive to the presence of temperature, humidity, rainfall, wind speed, and solar radiation in the environment. WHO also states that mosquito-borne diseases such as dengue are highly associated with very bad climatic conditions.

**Conclusion**

Climate factors in the form of temperature, humidity, rainfall, duration of solar radiation and the number of rainy days are determinants of mosquito breeding as disease vectors that can cause Dengue Hemorrhagic Fever. Bad climate factors support mosquito breeding compared to stable climate factors.

Sensory Evaluation of Jam Produced from Hearts of Palm Kestawee Varieties of Phoenix Dactylifera, L

Ashraq Monir Mahmed1, Baidaa Hahidh1, Alaa Aid1, Hadeel Yosef1, Humam Safaa1
1Department of Food Science, College of Agricultural Engineering Sciences, University of Baghdad, Iraq

ABSTRACT

As the chemical composition of heart palm the main components of moisture contents were 87.1, and the proteins contents were 2.11. Either carbohydrates amounted to 7.12, either in fat models were the 1.30. estimated the percentage of ash in the models were 1.28. The work evaluated the sensory quality of jam produced from hearts of palm Kestawee varieties of Phoenix dactylifera, L. Pulp was extracted from hearts obtained from new market. The pulp produced was mixed with prepared and standardized citric acid-sugar syrup, allowed to cook on constant boiling/stirring and the gelatinization temperature and the time were taken and recorded. The prepared jam was carefully poured in steam/ethanol sterilized jam bottles and cocked immediately the jam was allowed to cool. The cooled jam was served to panelist to compare sensory acceptability of the heart palm jam alongside apple jam. Sensory evaluation revealed significant difference (P>0.05) in colour and aroma of the samples while there was no significant difference (P<0.05) in the texture and sweetness of samples tested. The study concludes that hearts of palm Kestawee varieties of Phoenix dactylifera, L. is a promising source of pectin which can be successfully applied in food gel system such as fruit jams.

Keyword: hearts of palm, Jam Produced.

Introduction

The heart of Palm is characterized by a very high nutritional value1 which makes it an effective treatment for many health problems that negatively affect the stability of human life2, thanks to its unique natural structure rich in essential elements needed by the body in specific quantities per day. This type of vegetable is derived from the perennial palm tree. Brazil is home to it3. It is used in many fields, especially the food field4. He is anemic because he is rich in iron, helping to raise the hemoglobin level in the blood. It also contains vitamin A which is very useful for the strength of eyesight, and for the health of pregnant women specifically, as it protects against congenital malformations affecting the fetus, and ensures proper growth of the nervous system. Contains calcium, which ensures the building of bones, nails, muscles, teeth, and protects the fragility and bone lobe that affects the elderly greatly4. Contains improved fiber to work the digestive system, which protects against constipation and indigestion, and helps to put toxins out of the body. It contains the hormone, which is very useful for ovarian stimulation in women. It also protects against depression, as it reduces nervous tension. It contains vitamin C anti-inflammatory and allergy6.

Jam is an example of fruit preserve usually made from pulp and juice of one fruit whole fruit7. It can be defined as cooked and gelled fruit purses packaged for long term storage which is normally used as bread spread, fillings and food jellies. The preparation of fruit jam traditionally involves the use of pectin as a gelling agent, although sugar or honey and citric acid may be added as well8. Good jam has a soft even consistency without distinct pieces of fruit, a bright colour, good flavour and a semi-jelled texture that is easy to spread but has no free liquid9.

Pectin refers to a group of diverse complex polysaccharides found in the primary cell wall and intercellular space (middle lamella) of plants cells. It is

DOI Number: 10.5958/0976-5506.2019.02144.2
most abundant in young tissues and are the characteristic constituents of fruits (Ihekoronye and Ngoddy, 1985). Pectin is a high molecular polymeric carbohydrate which is present in all plants\textsuperscript{10}. It is a purified carbohydrate product generally obtained from the acid extraction of the inner portion of the citrus fruit peels and apple pomace\textsuperscript{11}. Pectin is mainly used in food as a gelling of boiled fruits preparations. Today, it is used in fillings, sweets, and as a source of dietary fiber in food.

Materials and Method

The heart palm powder was analyzed for moisture, protein, fat, ash and carbohydrate contents\textsuperscript{12}. Carbohydrate content of samples was determined as total carbohydrate by difference method. All determinations were done in triplicate and the results were expressed as the average value.

Production of Heart Palm Jam: The of heart palm used for the work were purchased from New Market Iraq, Baghdad. The of heart palm were washed thoroughly with clean water and cut into small sizes. The seeds were carefully removed using knife, and the jackfruit peeled then blended using Kenwood blender Model 5024ID. The juices from the fruits were sieved with muslin cloth and the fruit pulp kept in clean bowl. 300ml of water to 250g of sugar was used to prepare sugar syrup. The syrup was boiled at 100°C and 4g of citric acid was added, and allowed to boil again until a slippery feel to gel was formed, it was placed acid to cool. 200g of the fruit pulp was concentrated and the prepared syrup added on boiling, it was allowed to cook on constant boiling/stirring and the gelatinization temperature and the time were taken and recorded. At the end, the prepared jam was carefully poured in steam/ethanol sterilized jam bottles and cooked immediately the jam was allowed to cool\textsuperscript{12,13}.

Determination of Total Dissolved Solids (TDS): The total dissolved solids of the samples were determined using a total dissolved solids meter (ATP Instrumentation –TDS- 5031- Meter High range. ATP Instrumentation, UK.). The instrument probe was inserted into a beaker containing the sample and allowed for a few minutes until the reading equilibrated.

Sensory Evaluation: Sensory evaluation of the jam samples were conducted as described\textsuperscript{14} using 10-members panel randomly selected from the university community. The samples were packaged in a transparent jam bottles and presented in a coded manner. The sensory quality attributes of the samples were color, taste, aroma and sweetness\textsuperscript{15}.

In the questionnaire presented to the panelists, they were requested to observe and taste each sample as coded with bread provided and grade them based on a 4-point hedonic scale showing least acceptable to most acceptable in all attributes.

Results and Discussion

Composition of Heart Palm: The heart palm (Fig. 1) heart palm powder were analyzed for moisture, protein, fat, ash and total carbohydrate contents. The results are presented in Table 1. The fresh heart palm contained moisture 87.01%, protein 2.11%, fat 1.30%, ash 1.82% and total carbohydrate 7.12 %. The composition of heart under study was more or less similar to those reported by\textsuperscript{16}. They reported the nutrient content of fresh heart palm as follows: Moisture 84.20%, protein 4.22-5.89%, carbohydrate 9.24%, fat 1.7%, ash1.65%.\textsuperscript{17}\textsuperscript{also found that heart palm contained water 81.55-82.82%, protein 2.78%, fat 0.32%, and ash 0.97%.

The table 2 showed average sensitivity of palm heart, apple jam, color analyzer, odor, texture, and tissue analysis. The results obtained from the analysis showed that sample B contains the best acceptable color at an average of 9.5, while sample A contains the lowest color (7.5). However, there was no significant difference between B and A.

For the odor sample B, the highest value is 9.5, while sample A has the lowest value (8.0). Results showed that there was no significant difference between B and A.

In texture, sample B contains the highest value of (8.0), but there is no significant difference in sample A and B,

In the sweet B sample, the highest value is (9.0) while sample A has the lowest value of (7.5), but there is no significant difference in sample A, B in terms of sweetness.

The result of the sensory evaluation shows that the sample B (apple) is more acceptable followed by A (Heart of palm).

Conclusion and Recommendation

The results obtained from the study showed that heart of palm is a promising source of pectin which can be successfully applied in food gel system such as fruit jams jellies and fillers etc. However, this tropical fruits wastes a lot due to underutilization. If optimally utilized for pectin and jam production could significantly reduce the present wastage and waste disposal problems encountered while handling heart of palm, thereby reducing post-harvest losses. From the results obtained, it showed that heart of palm can be industrial source pectin. This lower pH tends to create more preserved and stable jam which is less prone to microbial spoilage. It is therefore recommend that detailed and improved research should be done on the pectin from these lesser known sources to produce better jam with improved sensory attributes\(^{18}\).

**ABSTRACT**

This study was carried out at the farm of the Animal Resources Dept., College of Agriculture, University of Tikrit during the period from 15/2/2017 to 15/6/2017. Twelve Awassi lambs at the age of 4-5 months of age with an average weight of 24.65 ± 2.49 kg, were distributed into 3 groups (4 lamb/group) to study the effect of replacement of soybean meal (SM) with *Lupinus albus* L. (LA) at levels of 0, 6 and 12% for the T1 (control), T2 and T3 respectively and its effect on some hormones growth hormone, thyronine, thyroxine, testosterone, interstitial cell stimulating hormone ICSH and Follicle stimulating hormone FSH levels for four age periods, 4-5, 5-6, 6-7 and 7-8 month for 1st, 2nd, 3rd and 4th periods respectively. A significant increase (P≤0.01) in lambs weight in T3 at the 2nd and 4th periods. Also, substituting with LA in proportion 6 and 12% showed a significant increase (P≤0.01) in the levels of thyroxine, testosterone, ICSH and FSH. In addition. This study concludes that it is possible to substitute soybean meal with *Lupinus albus* L. for in lambs’ provender which raises the level of certain hormones.

**Keywords:** Soybean meal, *Lupinus albus* L., hormones, Awassi lambs

**Introduction**

Physiological changes associated with sexual maturity in different types of animals provided evidence of the importance of nutrition in puberty. Hafez and Hafez¹ have expressed the term threshold body weight for the weight at which an animal reaches sexuality and does not reach sexuality below it. Puberty is reached by an increased frequency of GnRH hormone secretion pulses from the hypothalamus, leading to increased frequency of the FSH and LH hormones produced from the pituitary at high and sufficient levels, which is responsible for increasing the stimulation of the offspring. Centralized mechanisms which time puberty are sensitive to the critical levels of metabolic signals². Repeated LH hormone secretion as a reflection of GnRH hormone secretion is more correlated with body size compared to age in growing lambs, as it can increase significantly and rapidly by increasing the level of nutrition³. The free fed lambs with high levels of energy and protein showed a very higher GnRH hormone pulse rate than that of lambs fed on low energy and protein content. In response to this hormonal action, the testis secretes the testosterone hormone from the interstitial cells called Leydig cells responsible for showing secondary male traits as well as sexual activity or desire to mate⁴.⁵. One of the crops used to strengthen the body structure of animals and have a positive effect is the use of lupine seeds, which gave a positive role and an effective alternative to soybean meal⁶. Lupine seeds and soybean meal are considered reliable food supplements which can be depended on in feeding ruminants⁷,⁸. Purroy⁹ did not find any significant differences in the replacement of lupine seeds by soybean meal in the lamb’s provender in the digestion rate of dry material, organic matter, raw protein, and raw fiber. Kung¹⁰ and Tracy¹¹ noted decrease in growth rates of lambs fed on lupine seeds in substitution to soybean meal as a protein source. This

is because there is a proportion of indivisible proteins in the soybean meal which is not digested in the rumen and, therefore, passes into the small intestine, which is considered an economic loss, while feeding on the lupine seeds reduces the amount of non-digestible acids. Thus, the aim of our study was to detect the biological effect of substituting soybean meal with white lupine seeds at the level of certain body and sexual hormones from weaning to puberty in Awassi lambs.

Materials and Method

The study was conducted from 15/2/2017 to 15/6/2017 in Constantine region at the location of the animal production farm of the College of Agriculture/University of Tikrit. A total of Twelve Awassi lambs were divided into three groups (each group consisted of 4 lambs), aged between 4 - 5 months with an average control body weight of 24.65 ± 2.49 kgs. The control group (T1) was fed on a diet* containing 12% soybean and 0% *Lupinus albus*, the 2nd group (T2) was fed with a diet containing 6% soybean and 6% *Lupinus albus*, and the 3rd group (T3) was fed on 0% Soybean and 12% *Lupinus albus*.

*The chemical analysis has been calculated as the ratio of crude protein to all components of the chemical analysis tables of the Iraqi feed material.

Animals were housed in an individual cage 1.35m², supplied with a container for diets, minerals, salt, and water. Blood was collected once every 15 days from a jugular vine. Samples were collected into a 10 ml serum clot tube from each lamb in the morning before feeding, and blood samples were centrifuged at 3000 rpm for 10 minutes, for separation of serum. The serum samples were stored at -20°C before analysis. Then, they were performed according to the manufacturers’ instructions as follows. Serum tests were performed according to the manufacturers’ instructions for the work kit. A veterinary preventive system was followed that included dosing and vaccination against internal and external worms and smallpox. The method of Danzer to determine the ICSH mlu/ml concentration and the applied method of Odell to determine the concentration of FSH mlu/ml and testosterone ng/ml concentration was determined by measured of Moltz. The method for the detection of thyronin (nmol/L) and thyroxine (nmol/L) was adopted from Dunn. The concentration of growth hormone (ng/ml) concentrations was determined by according to Henry.

Statistical Analysis

All data were expressed as means ± standard error (SE). Differences between group means were estimated using a one-way analysis of variance (ANOVA) and a Duncan using the software SAS. Data from the experiment were analyzed according to the following model: Yij = μ + Ti + eij

Where: Yij = the dependent variable, μ = mean, Ti = effect of the treatment (i = control, 6% *Lupinus albus*, 12% *Lupinus albus*), eij = random residual error.

Results and Discussion

Table (2) showed the third treatment were significant increased (P ≤ 0.01) in lamb weights during the second and fourth period 29.63 and 35.70 kg, respectively, compared with control 25.79 and 32.65 kg respectively. This finding agreed with Alkhatib in the absence of significant differences in the weights of the uterine lambs fed on the lupine seeds by 4% and 8%, but there was an improvement in the daily growth rate of the lambs using lupine seeds as an alternative to fenugreek in nutrition. Kung also recommended the use of lupine seeds as an alternative to soybeans in feeding lambs because there were no negative effects on lamb weights. While Tefera found a significant superiority of the Washera lamb, which was fed 300 gm of white lupine in its provender.

*a,b* means in the same column, with different subscripts indicate a significant difference (P < 0.01)

-T1: control 0% LA 12% SB
-T2: 6% LA 6% SB
-T3: 12% LA 0% SB

In 4th, the significant increase (P ≤ 0.01) in the T2 87.872 (nmol/L) compared to the T3 and control 76.642 and 70.950 (nmol/L), soybeans contain the elements of isoflavones in large amounts compared to lupine. These elements affect the ability of the thyroid gland to produce threonine and thyroxin, as well as the more the elements of isoflavones are increased in the content of the lamb provender it leads to the weakening of the thyroid gland tissue and the size of its follicles20. In the table, the results showed the lack of significant differences between the treatments in the concentration of the growth hormone during the four periods of breeding. The possibility of partially replacing the lupine seeds in place of the soybean meal in the provender of the Awassi lambs has a positive effect on the body development of the animals, live weight and other body measurements21. In addition, lupine seeds and soybean meal are considered food supplements that can be reliable for feeding ruminants. The lack of differences between the treatments can also be attributed to the equilibrium of the provender in terms of its energy and protein content, which attributes the possibility of replacing the lupine seeds with the soybean meal19.

The high level of energy and protein has a vital effect on the GnRH hormone pulse rate, which in turn has increased the concentration of (ICSH and FSH) hormone pulses produced by the pituitary gland that affects the stimulation of the gonads22. The animals
over 90 days of balanced nutrition were able to reach the threshold of weight at the age of puberty in an early age\(^1\). The reaching of Awassi lambs to a weight of 34-35 kg at an age of 212 days is considered a good indicator of balanced nutrition that is rich in energy and protein, which in turn has had a positive effect on increasing the size of the body and the growth of the genitals. The complete growth of the body contributed to the reaching of the animals to the desired body weight at the age of early sexual maturity. The weight of lambs reached 35.0 kg for the Awassi strain and at the age of 212 days. This is an indicator of early puberty due to balanced nutrition since weight increase is considered important for the growth of the genitals\(^2\).

\(^{a,b}\) means in the same column, with different subscripts indicate a significant difference (P < 0.01)

- T1: control 0% LA 12% SB.; -T2: 6% LA 6% SB.; -T3: 12% LA 0% SB.

Table 4 shows that the levels of the testosterone (2.348 ngm/ml) and ICSH 0.155 mIU/ml respectively increased significantly (P ≤ 0.01) in the T3 during the 2\(^{nd}\) compared to the T2 1.610 (ngm/ml) and 0.113 mIU/ml respectively and control 1.323 ngm/ml and 0.098 mIU/ml respectively; while at the 3\(^{rd}\) the level of testosterone decreased significantly (P ≤ 0.01) in the T3 1.733 compared to the T2 4.788. As for the level of the follicle stimulating hormone, it had significantly decreased in the T2 0.308 mIU/ml and T3 0.343 mIU/ml compared with the control 0.148 mIU/ml. In the 4\(^{th}\), the T3 was reintroduced 4.013 ngm/ml by increasing significantly (P ≤ 0.01) in the testosterone level compared to the T2 1.743 ngm/ml. The control (3.288 ngm/ml) was not significantly different from the two treatments in this period. This was found by\(^23\) when he used two levels of lupine and found its direct effect in stimulating the secretion of the hormone GnRH, because it has a strong correlation between the level of nutrition and reproductive efficiency and the acceleration in reaching puberty in male lambs\(^24\).

**Conclusion**

Based on the obtained results, it is possible to substitute soybean meal whit *Lupinus albus* L. for in lambs’ provender which raises the level of certain hormones.

Evaluation Factors for Non Medical Treatment Failure Patients
Tuberculosis Lung Health in Children on Makassar City

Baharuddin K.1, Bahtiar1, Harliani1, Muh Basri1, Muh Yusuf M1, Sitti Rahmatia1, Rudy Hartono2

1Department of Nursing, 2Department of Nutrition, Makassar Health Polytechnic, Indonesia

ABSTRACT

The purpose of the study, known factors associated with treatment failure patients Tuberculosis in children. The method used is an observational design, cross-sectional study intended to determine the factors associated between the independent variables (independent) and dependent variable (dependent) with the identification of all the variables. Both of these variables can be seen at the time of execution simultaneously. The findings in this study found that low education, low knowledge and disobedience taking drugs is a factor that has a strong risk of treatment failure patients with pulmonary tuberculosis in children, while family support only protective factor (prevention) and not a risk factor for treatment failure patients with TB in children, The conclusion showed that the variables influencing the failure of treatment of TB patients is variable education and knowledge has a value of OR unchanged at 22.752 in CI 95% to the value of the lower limit (LL) = 1.032 and Upper limit (UL) = 501.786 with a significance level of 0.048 <0.05.

Keywords: pulmonary tuberculosis, failure, treatment, children.

Introduction

In 1993 the WHO to declare TB as a global health emergency, because it is a major health problem worldwide cause of morbidity in millions of people each year and recommends the DOTS strategy as a strategy to control TB. TB is regarded as a community health problem of the world despite efforts to control the DOTS strategy has been implemented since 1995 by the WHO report in 2015, in 2014 there were 9.6 million cases of pulmonary tuberculosis in the world, 58% of TB cases are in Southeast Asia and the Western Pacific Region and 28% of cases are African. In 2014, 1.5 million people worldwide die from TB. Tuberculosis is second only to Human immunodeficiency virus (HIV) as an infectious disease that causes most deaths in the world’s population. Indonesia is a country located in Southeast Asia with the second largest number of TB cases in the world after India14. In 2014 TB cases in India and Indonesia, respectively, are 23% and 10% of cases. Based on the WHO report in 2015, the prevalence of TB cases in Indonesia in 2014, including HIV, 647 per 100,000 population1,3.

According to the Global Tuberculosis Report WHO14, estimated the incidence of tuberculosis in Indonesia in 2015 amounted to 395 cases/100,000 population and a mortality rate of 40/100,000 population (of HIV patients with TB are not counted) and 10/100,000 population in HIV patients with tuberculosis.models, according to calculations Prediction based on data tuberculosis prevalence survey 2013-2014. Estimates of the prevalence of tuberculosis in 2015 amounted to 643 per 100,000 population in 2016 and estimates as high as 628 per 100,000 populations3,5.

The incidence of pulmonary tuberculosis is still very high and difficult lowered, this was due to issues non-medical such as; poverty, poor nutritional state, hygiene, low low purchasing power, low education cause failures and delays in getting a diagnosis8.

Although widely available in TB treatment, but current TB treatment failure remains a major health problem worldwide. Therefore, the objective of this study was to evaluate the non-medical factors that influence the rate of treatment failure patients with tuberculosis (TB) in children Lung Health Center.
Material and Method

This study is a quantitative research with cross sectional approach which has been conducted on June-September 2017 in four health centers in the region of Makassar. The population in this study was all mothers of children (aged 5-18 years) who received treatment of pulmonary tuberculosis at the sites. The samples of this study were all patients within 4-6 months of treatment. Our inclusion criteria are Sementra Tuberculosis patients in treatment, willing to become respondents and the age of 5 -18 years, so that a sample size of 42 respondents, taken by total sampling technique.

Data collection instrument was a questionnaire for respondents observe TB treatment failure. Questioners made by researchers and have tested the validity and reliability using the values of r and α values obtained chronbach of 0.824. The method of data collection in this study with a total sampling where the entire population of the research sample4. Data analysis was performed with the statistical test Ratio Prevalence (RP). RP is characterized by a value of the confidence interval (confidence interval) which will determine whether the ratio of the prevalence of significant or not with the parameters: if the confidence interval passes (not including) the number 1 on the starting point, then the risk factors are meaningfully and if the confidence interval below (cover) number 1 at the starting point, it is not a significant risk factor5. Interpretation of the results of the ratio of prevalence at a value confidence interval (CI) is also based on the value ratio Prevalence (RP) with the parameters: if RP = 1, meaning that the independent variable is not a risk factor, if RP>1 and CI does not include numbers 1, meaning that the independent variable is a risk factor and if RP <1, CI no caps a numeral 1, which means that the independent variable is a protective factor or a deterrent. Data processing was performed using SPSS for Windows.

Findings

This study aimed to evaluate the role of non-medical factors against TB treatment failure in Makassar City Regional Health Center. Of the 42 respondents, the majority were in the age group 16 to 18 years (40.5%).

Discussion

Data analysis of the 42 respondents obtained through data collection in the health center: Minasa, Batua, Antang and Housing Antang Makassar, the results are as follows:

a. Education Level: Table 3.9. Shows Bivariate analysis of test results that the value of OR = 39,000 with CI = 95%, P-Value = 0.001 < 0.05, and UL LL = 4.116 = 369.510. The value of RR = 16,200, LL = 2.266 and the value UL = 115.841 does not include the value of 1, then it is said to be meaningful and Ho rejected. Results of multivariate analysis showed the educational value of 22.752 with a level of 95% (P = 0.048 < 0.05) value LL = 1.032 and the value UL = 501.786 does not include the number 1. The test results of bivariate and multivariate test results both showed that education has an influence very strong against pulmonary TB treatment failure in children.

Research explains that the duration of TB treatment should be carried out for 6-8 months. Duration of time can cause the patient to become bored and impatient and cause undisciplined and disorganized to take medication that failed in the treatment, but for patients who have a good knowledge will continue to take medication appropriate treatment program. Further explains that the failure of the treatment and cure TB patients contribute directly to the knowledge acquired through education. Education can influence attitudes and behavior of someone who is a product of a learning process carried out consciously. Higher education for someone to be able to change the mindset formed a unified awareness in order to change a healthier lifestyle in everyday life. Although the level of education does not always directly Luru with TB disease yng enough education means not always a determinant of treatment success absoluteness of someone who is suffering from tuberculosis disease or illness

b. Level of knowledge: Shows the results of analysis test Bivariat that the value of OR = 39,000 with CI = 95%, P-Value = 0.001 > 0.05, the value LL = 4.116 and the value UL = 369.510, the value of RR = 16,200, the value LL = 2.266 and the value UL = 115.841 not mencup value of 1, then it is said to be meaningful and Ho rejected. Multiavriat test results show the value of the knowledge of 22.752 with a level of 95% (P = 0.048 < 0.05), values LL = 1.032 and the value UL = 501.786 does not include the number 1. Thus
both bivariate and multivariate testing both show that the level of knowledge has a very strong influence of treatment failure.

Knowledge is the result of the know and this occurred after people perform sensing on a particular object\textsuperscript{9,11}. Knowledge is very important in shaping the mindset, attitudes and behavior and actions of a person. Health knowledge can help individuals to adapt to the disease, preventing complications and learn to solve problems when faced with a new situation.

Knowledge of TB patients about the disease are factors that affect the incidence of TB suffered by a patient, therefore, a good knowledge of the illness will make the patient aware and determined to do what should be done and so is what should not be done so as to maintain and avoid events worse, and when not protecting and maintaining health, in line with the research. Instead minimal knowledge about the illness, can not in itself raises awareness for the need for regular medical treatment. Within their health development goals to improve public health\textsuperscript{5,7,8}.

c. Noncompliance Drink Drugs: Results show that the value of OR = 27,000 with 95% CI, 0.004 P-Value, the value LL = 2.946 and the value UL = 247.487. The value of RR = 13.235, value LL = 1.842, the value UL = 95.093 does not include the value of 1, then it is said to be meaningful and Ho rejected. Results of multivariate analysis showed noncompliance value of 18.538 with a level of 95\% (P = 0.049 <0.05) value LL = 1.007 and the value UL = 341.215 does not include the number 1. Both bivariate test results multivariate testing results show that the non-compliance has to take medicine strong influence on lung TB treatment failure in children while suffering from tuberculosis.

Compliance TB patients take medication regularly and on time is a crucial factor in the healing process Tuberculosis\textsuperscript{13}. Compliance includes: schedule time to take medication, taking medications according to the number, type of drug, the dosage is in etiquette drug, drug spending, came to the health center regularly taking medication before the medicine runs out and always remember the advice of health officials. In line with the research that has been done by Muniroh et al that the results show the value of P-Value = 0.001 (P <0.05).

The high rates of treatment compliance due to the high level of motivation, education and knowledge, and understand the importance of health; it is also inseparable from the patient’s awareness of the importance of healthy living which says that the use of Anti-Tuberculosis Drugs (OAT) improper/irregular or interrupted treatment can lead to drug resistance of Mycobacterium tuberculosis\textsuperscript{3,5,8,10}. The other variable factors cause patients do not regularly seek treatment even stopped the treatment prematurely, namely the emergence of drug side-effects such as vertigo, nausea, vomiting and headache, which eventually gives rise to non-compliance, trust factor, factor bustle and lacking/not understand the reaction of the drug in the body. TB treatment takes a long time (4-6 months) to achieve healing and with a guide (a combination of) several kinds of drugs, so it is not uncommon patients stop taking medication before the treatment is completed which resulted in treatment failure\textsuperscript{1,6,10,12}.

**Conclusion**

There is a relationship with the education level of TB disease treatment failure in bivariate and multivariate analysis at 95\% confidence showing OR value and the value of LL and UL > 1 so that the level of education is a risk factor for TB disease treatment failure in children.

There is a relationship with the knowledge level of TB disease treatment failure in bivariate and multivariate analysis at 95\% confidence showing OR value and the value of LL and UL > 1 so that a low level of knowledge of a risk factor for TB disease treatment failure in children.

There is a relationship Take medication adherence with treatment failure of TB disease, the bivariate and multivariate analysis at 95\% confidence showing OR value and the value of LL and UL > 1 so that non-compliance with taking medication is a risk factor for TB disease treatment failure in children.

There is no family support relationship with TB disease treatment failure, the multivariate analysis showed 95\% CI indicates the value of OR and LL and UL < 1 so that family support is a protective factor rather than as a risk factor for TB disease treatment failure in children.
Conflict of Interest Statement: This study there was no conflict of interest between the researcher and the subject.

Source of Funding: This research was funded independently by researchers, because they did not get sponsorship from other institutions.

Maternal and Fetal Outcomes of Labor in Grand-Multipara Women

Baidaa Abdulkareem Alwan1, Areej Sabah Abdulridha1

1MBChB, DOG, FICOG, Lectures in Gynecology and Obstetrics Department, College of Medicine, Wasit University, Iraq

ABSTRACT

Grand multiparity represented a big challenge facing health institutes and obstetricians especially in developing and poor communities due to accompanying hazards on mothers and fetuses. This study aimed to identify the risk factors and outcomes of grand multiparity among group of Iraqi women. Hence, a prospective clinical study was conducted at labor rooms of Alzahraa Teaching Hospital, Alkut Teaching Hospital and Alshaheed Fairose Hospital in Al-Kut governorate in Iraq during January, 1, 2018 to January, 31, 2019. A total of 1000 pregnant women; 500 pregnant women with grand multiparity (parity ≥ 5) and 500 pregnant women with multiparity history of (2-4). Data were collected through direct interview and examination of the participated women or from their medical records and then followed for 10 days after labor to assess the maternal and neonatal outcomes. Findings revealed adverse neonatal outcomes in 3.6% of women with grand multiparity which was significantly higher than other ones (p=0.02). The neonatal complications of grand multipara women were intrapartum stillbirth, early neonatal death, birth injury and admission to NICU. A significant association was found between incidence of maternal adverse outcomes and women with grand multiparity (p<0.001). The maternal complications in grand multiparity women were perineal tear, hysterectomy, intrapartum hemorrhage and cord prolapsed. Grand multiparity of pregnant women was significantly related to increased age, unemployment and low educational level. The main obstetrical complications were high rates of cesarean sections and oligohydraminosus. In conclusion, grand multiparity was associated with adverse maternal and neonatal outcomes.

Keywords: Grand multiparity, Multiparous, Maternal outcomes, Neonatal outcomes.

Introduction

Grand multiparity represented a big challenge facing the health institutes in developing countries which is accompanied by high rates of obstetrical and neonatal complications1. Grand multiparity is defined as giving birth of more than five times; live births or stillbirths of more than 20 weeks gestation, while the multiparity is birth of 2-4 times and primiparity is birth of one time in addition to nulliparity of no birth2. The grand multiparity is always related to bad family planning with big burden on family and society3. Nowadays, strict antenatal care and regular checking with advancing of delivery care techniques have been associated with better outcomes of grand multiparity 4,5. Many authors clarified the medical and obstetrical difficulties of grand multiparity among Iraqi women and detected the weakness of Iraqi family planning and antenatal programs in limiting and caring of women with grand multiparity 4,5. The family planning system in developed countries was the main cause of decreasing rates of grand multiparity to reach an incidence of 3-4% while in developing countries, the incidence of grand multiparity reached about 10-30% 8-10. Increased parity among families in these poor communities is related to bad outcomes for fetuses, mothers and the family specifically if accompanied with bad antenatal care1-11. The grand multiparity is associated with gestational and delivery complications especially when accompanied with poor or absent antenatal care,
short intervals between subsequent pregnancies, no contraceptive methods, older age of mother and bad quality of health system. The grand multiparity is more prevalent with higher morbidity and mortality rates in rural areas of developing countries. The main complications of grandmultiparity are either systemic like anemia, obesity, diabetes mellitus and hypertension or obstetrical like perineal tear, obstructed labor, malpresentation, placenta previa, placental abruption high rate of cesarean sections, retained placenta, hysterectomy, ruptured uterus and postpartum hemorrhage. Variances in death rates for fetuses and mothers are commonly related to bad health services especially for women with grand multiparity. Unfortunately, there was a predisposition of women with grand multiparity for lower utilization of medical services with increasing number of pregnancies specifically for delivery in hospitals or assisted delivery. Cultural, social and economic changes in Iraq in last years are associated with increase rates of grand multiparity that is accompanied with high morbidity and mortality rates in addition to economic burden on families and national health system.

Methodology

This was prospective clinical follow up study which conducted at the labor rooms of Alzahraa Teaching Hospital, Alkut Teaching Hospital and Alshaheed Fairrose Hospital in Al-Kut governorate in Iraq during the period from 1st of January, 2018 to 31st of January, 2019. The study included 1000 singleton pregnant women at labor aged (20-45 years). Women who was Primigravidity (nulliparity history), primiparity, had previous cesarean section, preexisting medical diseases and current smoking history were excluded.

Participants women assigned into two groups with 500 women in each group, group 1 included women with grand multiparity (para≥5) and group 2 included the remaining 500 pregnant women with multiparity of (2-4). Data were collected through full history and complete clinical examination of participant women. The baseline data collected either directly from pregnant women or from their records. Data were gathered in a pre-constructed data collection sheet (questionnaire) included the demographic and clinical information. The neonatal and maternal outcomes of pregnant women were reported.

The participant pregnant women were admitted to labor rooms after reporting signs of labor like. The obstructed labor was referred by the responsible Gynecologist to surgical operation room for cesarean section.

Post-delivery maternal assessment was done by researcher and gynecologists in the hospital, while neonatal assessment was performed by pediatricians in the hospital. Radiological imaging and laboratory investigations were performed in the hospital.

Maternal complications and outcomes were reported and medications were prescribed accordingly. Sometimes, perineal tear was sutured in the labor room under local anesthesia, but in some cases it needed surgical intervention in operation room. Neonatal outcomes and admission to neonatal care unit were documented under supervision of a pediatrician. Follow up was continued for 10 days after labor. Statistical analysis was performed using the statistical package for social sciences (SPSS) version 22, IBM, US software for windows and appropriate statistical tests and procedures applied accordingly at a level of significance of 0.05 or less to be significant.

Results

The mean age of the 500 grand multipara pregnant women of group 1 was significantly higher than that of multiparity women in group 2; 27.7 ± 5.4 years vs. 25.5 ± 4.4 years respectively, (P<0.001). Vast majority of participant women in both groups were housewives. A significantly higher employment rate for multiparous women (p<0.001). The educational level of grand multipara women was distributed as followings; low (24%), intermediate (75.8%) and high (0.2%) and for multiparous women, it was low in (13.8%) intermediate in (78.4%) and high in (7.8%) with a significant difference between both groups (p<0.001). Grand multipara women with low socioeconomic status (SES) were 61 (12.2%) women, with intermediate SES were 430 (86%) women and those with high SES were 9 (1.8%) women, with no significant difference in SES between both groups, (P>0.05), (Table 1).

No significant differences were observed between both studied groups regarding gestational age (p=0.2), fetus lie (p=0.1), spontaneous labor (p=0.06) and presentation (p=0.1). Grand multipara women had significantly higher cesarean sections rate compared to those in group 2, 26% vs. 18.5%, respectively, (p=0.01). A significant association was observed between grand multiparity and oligohydraminos (p<0.001) where oligohydraminos reported in 11.8% of grand multipara group compared to only 3% of multiparous women (Table 2). In grand multiparity group, 3.6% of women
developed adverse which was significantly higher than multiparous group (p=0.02). The neonatal complications recorded for grand multipara women were intrapartum stillbirth (55.6%), early neonatal death (33.2%), birth injury (5.6%) and admission to NICU (5.6%); there was a significant association between intrapartum stillbirth and grand multiparity (p=0.007). A highly significant association was observed between high maternal adverse outcomes and women with grand multiparity (p<0.001); 17.6% of women with grand multiparity had adverse maternal outcomes in comparison to 6.6% of multiparous women. The complications of women with grand multiparity were perineal tear (90.9%), hysterectomy (5.7%), intrapartum hemorrhage (2.3%) and cord prolapse (1.1%); the perineal tear was significantly more frequent in grand multipara women (p<0.001). (Table 3)

![Figure 2: Proportional distribution of overall Maternal complications among the studied groups](image2.png)

Discussion

The parity history was regarded by many authors as an independent risk factor for gestational complications and still becomes as a challenge for obstetricians in management of deliveries. Grand multiparity pregnancy has been associated with many gestational, labour and puerperium complications for both mother and fetuses since many years ago. Present study showed significantly higher adverse neonatal outcomes for women with grand multiparity in comparison to multiparous women (p=0.02). This finding is consistent with results of Abbas et al study in Iraq and Qamar et al study in Pakistan which reported poor neonatal outcomes for women with grand multiparity in comparison to multiparous women. The intrapartum stillbirth and early neonatal death were significantly the common adverse neonatal outcomes of women with grand multiparity (p=0.007). Similarly, Al-Rubae study in Iraq revealed that rate of stillbirth was significantly higher for women with grand multiparity. Kc et al study in Nepal found that multiple birth history is one of common risk factors for intrapartum stillbirth. Our study showed a highly significant association between high maternal adverse outcomes and women with grand multiparity (p<0.001). This finding is consistent with results of many literatures like Ahmed and Al-Saffar study in Iraq, Alhainiah et al study in Saudi Arabia and Bezircioğlu et al study in Turkey which all proved that grand multiparity had a significant role in development of adverse maternal complications like perineal tear, antepartum hemorrhage and hysterectomy. In current study, the perineal tear was the significant adverse maternal outcome for women with grand multiparity (p<0.001). Consistently, previous Pakistani study documented that genital tract trauma specifically perineal tear is commonly related to grand multiparity and lead to infection, hemorrhage and shock. Inconsistent with our findings, Al-Shaikh et al found that Saudi women with grand multiparity had the pregnancy risks and outcomes of women with low parity and they stated that advanced age play role in risks related to grand multiparity. However, many literatures stated that grand multiparity in low socioeconomic countries are related poor antenatal care, anemia, pregnancy, labour and postpartum complications in addition to its effect on neonatal outcomes. In this study, grand multiparity was significantly associated with increased age of women, unemployment and low educational level (p<0.001). These finding coincide with results of Severinski et al study in Croatia which revealed that women with grand multiparity were significantly characterized by advanced age, unemployment, low educational level and unmarried or divorced than multiparous women. All these sociodemographic characteristics are the results of multiple pregnancies of women in developing or poor countries. Our study showed a significantly higher cesarean section rates for women with grand multiparity (p=0.01). This finding is considered as one
of adverse obstetrical outcomes for women with grand multiparity which is similar to results of Al-Sammani and Ahmed study in Sudan⁴ which reported high rates of cesarean section among women with grand multiparity in comparison to multiparous women due to prevalent fetal macrosomia. Current study showed also a highly significant association between oligohydraminos and women with grand multiparity (p<0.001). This finding is in agreement with results of Ahmed study in Sudan²⁵. The oligohydraminos is regarded as common obstetrical complication of women with grand multiparity²⁰.

**Conclusions**

Grand multiparity of women is accompanied by adverse maternal and neonatal outcomes. The main obstetrical complications were high rates of cesarean sections and oligohydraminos. The main risk factors related to grand multiparity of women were advanced age, unemployment and low educational level. Special efforts are needed to strengthening the national antenatal care system in Iraq in addition to social, cultural and health sectors re-enforcement in facing the grand-multiparity with strengthening of national family planning program.

ABSTRACT

Used in this study, 21 local Awassi lambs age 3-4 months and primary weight of 21.5 kg were period the experiment 3 months to study the effect of chromium in the blood biochemical properties (cholesterol, triglycerides, total protein, glucose, low-density lipoprotein (LDL), high-density lipoprotein (HDL) and very low-density lipoprotein (VLDL), The study showed a significant difference (P <0.05) for the treatment of 600 μg Chromium Yeast on control treatment and the other of the treatments for the total protein trait for the first period of the experiment. In the second period of the experiment, the added treatments did not have a significant effect on the studied traits, except the low-density lipoprotein (LDL), where all the added treatments of low-density lipoproteins compared to control. While triglycerides, total protein, glucose and very low-density lipoproteins (VLDL) to 300 μg Chromium Chloride compared with control for the third period. Low-density lipoproteins (LDL) were decreased in all additive treatments compared to control and high-density lipoproteins (HDL) increased with 300 μg Chromium picolinate compared to other treatments for the same period.

Keywords: lambs, chromium, biochemical blood traits.

Introduction

Chromium is a component of the periodic table, which is a transition metal and its atomic number. 24, the word chrome came from the Greek and pronounced chroma in the sense of color due to the color of its compounds, which is one of the most common elements in the crust and sea water1. There are two types of chromium triple as a result of its association with other compounds, inorganic chromium such as chromium chloride (CrCl3) and organic chromium such as chromium picolinat (CrPic) and chromium yeast (Cr-yeast) 2. There is a discrepancy in the information available regarding levels of chromium in animal feed, In general, the concentrations of chromium identified in traditional ruminants feed are between 0.3-1.6 mg/ kg as the feed material is generally poor in chromium3. Chromium is incorporated into a compound formula called glucose balancing agent (GTF), which is the link of chromium (the most influential compound) with some acids namely clotamic asid, niacin, claysin and systeine. GTF is an essential nutrient that increases the action of insulin and thus regulates the metabolism of protein, fat and carbohydrates2. Many studies have indicated the role of triple chromium (III) in decreased harmful cholesterol (LDL) (low-density lipoprotein cholesterol) And increased the useful cholesterol (HDL) high density lipoprotein cholesterol) in blood4,5. There was a relationship between chromium decreased, indicated blood insulin levels and indicated cholesterol levels. high cholesterol level was observed in mice exposed to chromium decreased. When chromium was added to the interest, a decrease in cholesterol levels in blood. 5reported that of chromium decreased leads to an increased incidence of heart disease, high levels of insulin and blood glucose in addition to high cholesterol, low HDL and immune degradation.

The objective of the study was to investigate the effect of adding various sources and levels of organic and inorganic chromium to feed as feed additives in the performance of the Awassi lambs and their effect on the biochemical traits of blood.
Materials and Method

In this study, 21 local lamb were used, ranging age 3 to 4 months, at a weight of primary 21.5 kg. The homogeneity of animals was observed and the experiment lasted for 3 months. Lambs were randomly assigned to seven treatments and 3 lambs per treatment. A fixed feed was provided concentration for all experimental animals. The sources and concentrations of the different chromium were added to the treatments as follows:

**T1**: Treatment control (without addition).

**T2**: added 300 μg of Chromium Yeast/kg of concentration feed.

**T3**: added 600 μg of Chromium Yeast/kg of concentration feed.

**T4**: added 300 μg of Chromium Picolinate/kg of concentration feed.

**T5**: added 600 μg of Chromium Picolinate/kg of concentration feed.

**T6**: added 300 μg of Chromium Chloride/kg of concentration feed.

**T7**: added 600 μg of Chromium Chloride/kg of concentration feed.

The lambs were randomly distributed to individual pens with dimensions of 1.75 m x 1.25 m. Each pen contained a plastic feeder for concentration feed, another for rough feed and a 5 liter plastic water purifier. Chromium samples were prepared for each type of experiment using a by taking weight Each type is Enough for 50 kg of concentrated feed and according to the concentration used in each treatment. This quantity was powder with a small electric mill and then mixed with 50 kg of concentrated feed by a micro mixture.

All lambs were fed on a basic diet of concentrated fodder (55% grated barley, 22% bran, 15% grated wheat, 7% soya, food salt) Feeding 3% of live body weight, wheat straw was provided as raw feed and free to all lambs throughout the experiment.

Blood was withdrawn from the jugular vein in three periods (the first period of 30 days from the start of the experiment, the second period 60 days from the start of the experiment, the third period 90 days from the beginning of the experiment). Place in clean, sterile 10 ml plastic tubes and leave for 1 hour under temperature The laboratory was then kept under 4° C in the refrigerator. The tubes were arranged in a 45 ° angle for 24 hours. The centrifuge was then placed at 3000 ° C/min for 20 minutes to separate the serum from the rest of the ingredients. Closed under temperature - 20°C serum until biochemical tests I ran the blood serum tests as per the manufacturer’s instructions for the kit.

The data were statistically analyzed using the General Linear Model (GLM) within8 for the following mathematical model: Yil = μ + Ci + eil

The differences between the averages were compared with9 polynomial test

Results and Discussion

Table (1) shows that the difference chromium sources added to all the treatment did not significantly affect blood cholesterol in all periods. This is agree with (10;11;12), Triglycerides were not affected by the added treatments in the first and second periods and 300 μg Chromium Chloride increased triglycerides in the third period significantly (P <0.05) compared with control (39.33, 26.0) mg/100 ml and this result is agree with (11) and differs with (10;13), Table (1) shows that the total protein was significantly increased in the first phase of the experiment at P <0.05. The treatment was 600 μg Chromium Yeast compared with control (7.93, 6.66) g/100 ml Was not affected by the second period and also increased in the third period where the treatment of 300 μg Chromium Chloride significantly (P <0.05) compared to control (13.53, 8.66) g/100 ml The result is that the chromosome has an anabolic agent rather than destruction and therefore regulates protein synthesis and controls the increase in muscle weight in the body14. This result is agree with10,13, While blood glucose was not affected in the first and second period treatments added, but increased in the treatment of 300 μg Chromium Chloride in the third period significantly compared to control ((64.33, 49.0 mg/100 ml and the reason for high glucose that chromium is associated with insulin and insulin receptors in insulin sensitive cells and increases the action of insulin hormone and thus improves metabolism of carbohydrates8 and this study agrees with11 no agrees with13,15.

Table 2 shows that high-density lipoproteins (HDL) were not affected by the first and second period
treatments added but increased in the 300 μg treatment of Chromium picolinate for the third period compared to control (63.66, 59.33) mg/100 ml. This result is agrees with\(^1\) no agrees with\(^4\), whereas low-density lipoproteins (LDL) were not affected in the first period but decreased in all added treatments in the second and third period compared to control (23.80, 7.60, 12.46, 6.20, 11.06, 16.26 8.20) mg/100 ml respectively for the second period and (15.16, 6.70, 10.40, 6.03, 11.80, 11.90, 7.93) mg/100 ml respectively. This result is agrees with (13) and no agrees with\(^4\), Table 2 also shows that very low density lipoproteins (VLDL) were not affected by the added treatments in the first and second periods. In the third period, however, the treatment was significantly increased to 300 μg (P <0.05) compared to control (7.86, 5.20) mg/100 ml.

**Conclusion**

Chromium addition with different sources (Chromium Yeast, Chromiumpicolinate, Chromium Chloride) and different concentrations 300, 600mg diet lambs Awassi effect significant in:

1. Increased concentration of triglycerides, glucose and total protein at the end of the experiment (90 days after addition.
2. Decrease concentration of low-density lipoproteins at the center and end of the experiment (60 and 90 days after addition.
3. Increased concentration of high-density lipoproteins at the end of the experiment (90 days after addition.

ABSTRACT

Background: Pudendal nerve block (PNB) provides anesthesia and analgesia for minor gynecological surgeries.

Aim: To determine the effectiveness of PNB in providing postoperative analgesia for patients undergoing anterior and posterior vaginal wall repair (APR) under spinal anesthesia.

Materials and Method: When 50 adult patients, aged 25-50 years, ASA physical status I and II were scheduled for Anterior and posterior vaginal repair and involved in this study. Spinal anesthesia was performed and at the end of surgery, patients were divided randomly into two equal groups. In bupivacaine group (group B), local anesthetics (0.5 ml/kg bupivacaine 2.5%) had been given in three equal divided volumes for an ultrasound guided pudendal nerve block, skin infiltration to the vulva and deep infiltration to the perineum. In control group (group C), the same volume of normal saline had been given. Pain was assessed by using the visual analogue score (VAS).

Results: Prolonged duration of postoperative analgesia and reduced total analgesic dose in Bupivacaine group than control group were observed.

Conclusion: PNB provides a satisfactory postoperative analgesic effects and reduces the need for opioid consumption.

Keywords: Bupivacaine, Pudendal nerve block, Anterior and posterior vaginal wall repair, Postoperative analgesia.

Introduction

Anterior and posterior vaginal repair (APR) is a surgical procedure that had been used for the treatment of pelvic organs prolapse [(1,2)]. Pudendal nerve (PN) block is one of several techniques used to provide anesthesia and analgesia to the genital area and reduces the need for opioid consumption postoperatively with their associated side effects.

PN originated from 2nd, 3rd and 4th sacral rami and pass through the lesser sciatic foramen between two ligaments and then directed into the pudendal canal near the ischial tuberosity (3). Within the pudendal canal the nerve divides into:

1. Inferior rectal nerve (inferior haemorrhoidal nerve): In about fifty percent of cases, it is arise directly from the 4th anterior sacral primary ramus and supplies the anal mucosa and perianal region.

2. Dorsal nerve of penis or clitoris

3. Perineal nerve that supplying vulva and perineum⁴⁻¹¹. Apart from the branches of pudendal nerve, the ilioinguinal nerve also send branches to the mons pubis and labia majora¹².
Therefore, the ideal method to produce a complete nerve block for APR surgeries should include the blocking of the areas that supplied directly inferior rectal and ilioinguinal nerves together with PNB \(^{12}\).

The objective of the current study is to evaluate the postoperative analgesic effect of intraoperative pudendal block for patient undergoing Anterior and posterior vaginal repair.

**Materials and Method**

This study was applied from 1\(^{st}\) of February 2018 to 1\(^{st}\) of March 2019 when 50 adult patients, aged 25-50 years, ASA physical status I and II were scheduled for Anterior and posterior vaginal repair and involved in this study.

Exclusion criteria from this study include: Patients with ASA physical status > II, patients receiving analgesics, allergy to local anesthetics, refusal of the patient, history of bleeding tendency, neuropathies, diabetes mellitus, hypertension, pregnant women, infection at the site of infection and immune compromised patients.

Informed consent was taken from all the patients who were divided into two groups randomly.

An Intravenous (IV) access was inserted in both groups and received 10 ml/kg ringer lactate solution immediately prior to spinal anesthesia. Standard monitoring include lead II electrocardiogram, pulse oximetry and non-invasive blood pressure monitor. Spinal anesthesia was performed using gauge 25 spinal needle at L\(_3\)-L\(_4\) interspace with patients in the sitting position and using 2.5% bupivacaine 0.5%. Patients remained in the sitting position for 4 minutes then placed in lithotomy position and surgery (APR) was done. Vital sign was monitored and recorded at 0, 15, 30 and 60, 90, 120 and minutes following spinal anesthesia. At the end of surgery, patient were divided randomly into two equal groups. In bupivacaine group (group B), local anesthetics (0.5 ml/kg bupivacaine 2.5%) had been given in three equal divided volumes for an ultrasound guided pudendal nerve block, skin infiltration to the vulva and deep infiltration to the perineum. In control group (group C), the same volume of normal saline had been given. Pain was assessed by using the visual analogue score (VAS) \(^{13}\) in which a score of 0 indicates no pain and a score of 10 worst pain. The VAS measurements were obtained every three hours post-operatively at 3, 6, 9, 12, 15, 18, 21 and 24 hours. Rescue analgesic in the form of slow IV bolus of 50 mg of tramadol was administered at the VAS score of 4. Time of first rescue analgesic and the total analgesic during the first 24 hours post-operative period were recorded.

**Statistical Analysis:** The analysis was carried out with the SPSS program; version 23. The qualitative data had been analyzed by using of Chi - square. The quantitative data had been analyzed by using student’s paired t-test was used. VAS were analyzed by the Friedman test.

**Results**

Demographic parameters (age and sex) revealed that there was no significant difference in both groups. The mean duration of surgery was 79.55 ± 19.58 minutes in Group C while it was 75.22 ± 21.33 minutes in Group B which is statically not significant (table 1).

**Table 2: Heart rate and mean arterial blood pressure in both groups during 0, 15, 30, 90, 120 and 180 minutes following spinal anesthesia (C = control group, B = Bupivacaine group)**
Regarding the onset of pain, was much earlier in Group C. Mean of VAS was higher in group C > B. There was no significant difference between the two group regarding VAS at 3rd postoperative hour. The maximum mean of VAS score occur at 6th in control group, while it occurs at 12th in bupivacaine group. There was significant difference between the two group regarding VAS at 6th, 9th and 12th postoperative hours (table 3 and figure 1). Total dose of analgesic (tramadol in mgs in 24 hours) was very significantly lower in group B than group C. (table 4).

Discussion

This study is focused on the impact of pudendal nerve block on the outcome of pain control after APR surgeries. There was significant difference between the two group regarding VAS at 6th, 9th and 12th postoperative hours with prolonged duration of postoperative analgesia and reduced total analgesic dose in Bupivacaine group than control group. O’Neal et al (14) supported our study although their study focused on paracervical block. Aissaoui (15) and his colleague agree with the current study. They found that intraoperative pudendal nerve block can reduce post-operative pain intensity and their required analgesic doses. Ismail and his colleagues found that bilateral injection of local anesthetics by using nerve stimulator result in a reduction in the post-operative visual analogue score and rapid return to normal activity(16).

ABSTRACT

Nosocomial infection or currently better known as Health-Care Associated Infections (HAIs) is the most important cause of hospitalized mortality and morbidity. The hands of health workers are the most common carriers of microorganisms from one patient to another and from the contaminated environment to the patient. Hand hygiene is the most important measure in preventive measures because it is more effective and has low cost. The purpose of this research was to analyze the correlation of behavior determinant with compliance of nurse hand hygiene at Ward Room of Undata Palu Hospital, Indonesia. This research used cross sectional design study with observational method, interview, and questionnaires. Data on compliance of hand hygiene obtained through direct observation with questionnaires and interviews to nurses at ward room of Undata Palu General Hospital. This research conducted from July to August 2017 at ward room of Undata Palu Hospital, City of Palu, Central Sulawesi, Indonesia. There was a significant correlation between high predisposing factors, enabling factors, and reinforcing factors for implementation of hand hygiene (p < 0.05). Continued efforts to understand and improve hand hygiene compliance among hospital workers, including monitoring success after implementation of identified initiatives to promote recommended practice are essential to help reduce the impact of the spread of hospital infections particularly beneficial to the health of patients in the hospital who are at high risk.

Keywords: determinants of behavior, nurses, compliance, hospitals

Introduction

There are five important issues related to hospital safety: patient safety, worker safety or health care workers, building safety and hospital equipment that may impact on patient safety and personnel impacting on environmental pollution and associated hospital safety with the survival of the hospital. Patient safety is a top priority to implemented and related to quality issues and hospitalization image (1). Therefore, related to patient safety, the World Health Organization (WHO) has campaigned for patient safety programs one of them is by lowering the risk of nosocomial infections (2,3).

According to Regulation of the Minister of Health of the Republic of Indonesia No. 1691/MENKES/PER/VIII/2011 on patient safety, there are 6 patient safety goals. One of them is the reduction of risk of infection related to health services. Infection is common in all forms of health services including urinary tract infections, infections of the bloodstream, and pneumonia (4).

According to WHO, nosocomial infection is the presence of invisible infections in patients while in hospital or other health facilities (5). Those currently known as Health-Care Associated Infections (HAIs) are the most important causes of infection rates, but it can be reduced by nearly 32% in hospitals that have infection prevention and control programs, such as professional
behavior involved. The hands of health workers are the most common carriers of microorganisms from one patient to another and from the contaminated environment to the patient with the impact of reduction on HAIs reaches 50% (6).

In Indonesia, HAIs reached 15.7%, well above developed countries ranging from 4.8 to 15.5% (7). At the Yogyakarta hospital, the incidence of HAIs in general was 5.9% (8). Study on the Efficacy of Nosocomial Infection Control (SENIC) conducted at hospitals in the United States to calculate infection rates, it found that hospitals with strong surveillance and prevention/control programs showed the lowest rates of nosocomial infections (9,10).

WHO states that the nosocomial infection rate will decrease by 24% if hand washing compliance from bad behavior (60%) to be better (90%) (11). According to data of HAIs surveillance by the Committee for Prevention of Infection Control of Undata Hospital of Central Sulawesi Province from January to December of 2016, the incidence of Regional Infection Operation in the 1st Quarter was 2.8% (13 events), in 2nd Quarter of 14.2% (64 events) and in the 3rd Quarter of 6.2% (22 events).

The purpose of this research was to analyze the correlation of behavior determinant with compliance of nurse hand hygiene implementation at ward room of Undata Palu Hospital, City of Palu, Indonesia. Therefore, the researcher interested to examine about “Correlation of Nurse Compliance to the Implementation of Hand Hygiene at Undata General Hospital, City of Palu, Indonesia”.

Materials and Method

This research used cross sectional design study with observational method, interview, and questionnaires. Data on compliance of hand hygiene obtained through direct observation with questionnaires and interviews. This research conducted from July to August 2017 at ward room of Undata Palu Hospital, City of Palu, Central Sulawesi, Indonesia. The population in this study was all the nurses. The sample used nurses in Lotus Room (30 respondents). The research sampling technique used total sampling. The behavioral determinant data consisted of predisposing factor data, enabling factors, and boosting factors (include answers strongly agree, agree, disagree, and strongly disagree with the statement that has provided).

Data on hand hygiene implementation of respondents used the parameters of “Five Moments of Hand Hygiene” consisted of questions that must answered ‘yes’ or ‘no’.

The categories of behavioral determinants included predisposing factors, enabling factors, and reinforcing factors with their respective categories (high : score ≥ 62.5% and low : score < 62.5%). Coagulation test used was chi square correlation test to know the relationship between variables.

Results

Table 1 based on gender characteristics indicating that almost (90%) of respondents were female and almost 70% of respondents have recent education 3-year diploma.

Table 2 shows the frequency distribution based on the determinants of behavior. In the table shows that from 30 respondents, more than most (83.3%) of respondents had high predisposing factors in the implementation of hand hygiene. Likewise with the enabling factors where more than most (83.3%) of respondents had a high enabling factors in the implementation of hand hygiene. However, the lower figure appeared to be reinforcing factors, but it is not significant that 80% of respondents had high reinforcing factors in the implementation of hand hygiene.

**Discussion**

The results showed that there was a significant relationship between high predisposing factors to compliance to the implementation of hand hygiene with \( p < 0.05 \). This is because respondents understand the importance of hand hygiene implementation which is one of the main key in prevention and control program of nosocomial infection. In accordance of the research in M.H. Thamrin Salemba Hospital in Indonesia is a factor of lack of knowledge of nurses about technique and five times of hand hygiene implementation, higher workload while less human resources, still lack of sink count, and long distance \( (16) \). The nurses are placed at appropriate level in terms of knowledge, attitude, and performance but to increase their knowledge by holding training classes and courses, especially for hand hygiene in which nurses had less knowledge \( (12) \).

Respondents who have low predisposing factors are disobedient in the implementation of hand hygiene due to the time of education nurse/midwife has not got the concept of theory and how to prevent nosocomial infection correctly consequently they has not been able to prevent that infection to the maximum when it starts working. In fact the lack of awareness of hand washing
is the high mobility of nurses and physicians because it is practically easier to wear gloves, however they are negligent to wash hands before and after use\textsuperscript{(13)}.

The result of statistical test proved that there was a significant correlation between enabling factors and the implementation of hand hygiene with $p < 0.05$. Based on the observation of the researcher, respondents who had high enabling factors to be obedient in the implementation of hand hygiene. This was due to the availability of handrub in each treatment room to make the respondent obedient in the implementation of hand hygiene and the nurses will also report to the procurement department if handrub in one of the empty/unfilled space, while the respondent had low enabling factors so it was disobedient in the implementation of hand hygiene caused respondents feel unsuited to the handrub available due to a pure alcohol-based antiseptic mixture that created a stinging smell and feels hot in the hand and sticky.

Based on the research\textsuperscript{(13,14)}, one factor, which allows nurses to comply with handwashing policies, includes availability and accessibility of resources to perform hand hygiene procedures. ICU of Port of Spain General Hospital has nine beds with one isolation room that has its own washtafel; eight other beds in open units with four washtafels, giving 2:1 bed and sink ratios. There are also six automatic hand sanitizers mounted on the wall placed inside the open unit and one in the isolation room.

The result of the research there was a relationship between reinforcing factor with the implementation of hand hygiene with $p < 0.05$. ICU of Eric Williams Medical Sciences Complex (EWMSC) is a five bed unit that has a ratio with a washtafel of 5: 2. The availability of washtafel for nursing staff is a good motivation for hand washing as it allows them to perform tasks as often as they need them. Another results showed that nurses in medical ICUs had 1: 1 beds with a washtafel ratio for a higher hand washing percentage of 76%, than those in surgical ICU who had a bed-to-bed ratio 4:1 washtafel which the percentage was 51\%\textsuperscript{(13,14)}.

The result of the research showed there was a relationship between reinforcing factor with the implementation of hand hygiene with $p < 0.05$. All of respondents who had high reinforcing factors were obedient in the implementation of hand hygiene. This was due to the hospital conduct supervision related to the implementation of hand hygiene compliance to the nurses and also gives sanctions to the nurse who was caught not running hand hygiene procedure when contact with the patient. In addition, the hospital also always reminds the nurse through loudspeakers to perform hand hygiene before contact with patients. Meanwhile, respondents who had low reinforcing factors were disobedient in the implementation of hand hygiene caused when handling emergency conditions, nurses feel the procedure hand hygiene troublesome, lazy factors, dead water or damaged tap.

This is in line with previous research that states all health workers should have been able to apply hand hygiene in five moments\textsuperscript{(16)}. Administrative orders, continuous observation, performance feedback, increasing the supplies necessary for health workers and institutional support can improve hand washing practices\textsuperscript{(15),(16)}.

**Conclusion**

Continued efforts to understand and improve hand hygiene compliance among hospital workers, including monitoring success after implementation of identified initiatives to promote recommended practice are essential to help reduce the impact of the spread of hospital infections particularly beneficial to the health of patients in risky hospitals high.

Parenthood Experiences of Immigrant Women Married to Korean Men: A Qualitative Study

Bo Young Kim
Assistant Professor, College of Nursing, Gyeongsang National University, South Korea

ABSTRACT
Immigrant women married to Korean men experience a lot of conflict and confusion while raising their children due to differences in values and cultures. This study takes a qualitative approach, seeking to examine the parenthood experiences of the subjects. The study involved a total of eight participants, from age 23 to 46. The data were collected through a focus group interview after the participants underwent the Parent Education Program for Married Immigrant Women (PEMI). Four categories were derived after an analysis of the results: “wounds from parenting stress”, “gaining confidence in child rearing”, “a hidden barrier: it power”, and “communication among family members”. Married immigrant women saw themselves as competent beings as parents, learned more knowledge on child-rearing and gained confidence in performing a parent’s role. This led to an improvement in awareness and a desirable change in their child-rearing attitude, while their families experienced a positive transfer.

Keywords: Immigrant, Women, Parenthood, Experiences, Qualitative

Introduction
Demographic diversity has been growing significantly in Korean society as marriage- and labor-related immigration to Korea increases rapidly. The 2016 foreign residents survey found that there were a total of 932,235 immigrant women married to Korean men, and over 90% of them were Asians. An increase in international marriage-related immigration leads to an increase in the number of children born to multicultural families. According to Korean statistics from 2016, children of multicultural families made up 4.5% of the total number of children born in 2016. The number of multicultural children is expected to rise as there is an increasing number of foreign residents in Korea. Multicultural children experience a lot of conflict and confusion due to the differences in their parents’ values and cultures, and their linguistic development can be slowed by their parents’ different languages and child-rearing practices.Externally, they may experience being ridiculed and ostracized due to prejudice against them, or experience inequality and feelings of alienation. For this reason, it is significantly meaningful to take an interest in how immigrant women married to Korean men raise their children, as it can help raise healthy future generations of Korean society.

Immigrant women married to Korean men may not understand their children’s behavior or may have conflicts with them because they are raising children in a completely different environment from what they grew up in. In this condition, they experience parenting stress, which can affect their interactions with their children because it undermines the functions of parents and families and increases their children’s problematic behaviors. A child’s problem behavior affect the mother’s stress level, which in turn, makes the mother have a negative parenting attitude. This negative parenting attitude causes further problem behaviors from the child, forming a vicious cycle. For this reason, immigrant women married to Korean men...
desperately need to establish their roles as mothers in Korean society, which is becoming more diverse and is changing rapidly.

Immigrant women married to Korean men experience a parent role in Korea through the parenting experience they have in the Korean society. As strong models for children and adolescents, parents not only determine their children’s personality formation and the quality of their interpersonal relationships but also affect their socialization process in which they obtain the behavior rules, values and morality required by society. In particular, a parent’s role is important in defining the relationship between parents and children in order for immigrant women married to Korean men to overcome their special conditions, adapt to a new environment and take care of their families as the mother. Therefore, this study intends to conduct a qualitative analysis on their social and child-rearing experiences after having participated in a parent education program.

Method

Study Participants and Data Collection: Study participants were collected from among immigrant women married to Korean men who were residing in Korea through marriage, who wanted to participate in the Parent Education Program for Married Immigrant Women (PEMI), could communicate in Korean and understand and answer the survey questions, and had lived in Korea for four years or longer. They were collected through a convenience sampling method for qualitative research with the help of a multicultural family support center. The PEMI is a revised and supplemented version of the “Parent Empowerment Program for Married Immigrant Women,” developed by Kim (2013). There were a total of six sessions, each lasting 120 minutes. There were a total of eight female participants aged 23 to 46. Five were in their 30s, two were in their 40s and one was in her 20s. As for their nationalities, there were two Japanese participants, one Chinese, three Filipinos and two Vietnamese. The questions for the focus group interview included the following: “How do you raise your children?”; “What difficulties did you have when raising your children?”; “In what particular area did your family members have different opinions?”. Participants indicated their voluntary participation in this study and submitted their written consent. All participants were given a small amount of money as an honorarium ($30).

Data Analysis

The participants’ adaptation to parenthood was analyzed by following Downe-Wamboldt (1992) steps for content analysis research: deciding the unit of analysis, deriving categories and definitions, and defining categories and modifying rules. This researcher transcribed the interview and a research assistant edited the transcription. The interview was transcribed by both this researcher and the research assistant, and the conformity was checked in order to increase the accuracy of the transcription.

Results

1. Wounds from Parenting Stress

   1. Insufficient preparation to become a mother:
      Participants had double difficulties: child-rearing and education difficulties. In particular, when they were not prepared for motherhood, their negative experience as children affected their parenting attitudes. This, in turn, caused problem behaviors from their children, forming a vicious circle.

      “It’s been over four years since I came to Korea. My husband has a child already, an elementary school student. I don’t have much experience. It is somewhat difficult. I can’t even manage my life there well. I have to know many things to raise children. I sometimes meet other mothers at the center. I cannot meet them often. When the child throws a tantrum and is stubborn, I just keep screaming, like own my parents did...” (Participant 4)

   2. A sense of being dispirited by a different language and culture:
      Participants worried a lot that their children might not be able to adapt to school life because they were different from Korean children. Participants also felt dispirited because their Korean was not fluent. They found themselves withdrawing when trying to help children with homework and schoolwork. This prevented some of them from forming a bond and properly communicating with their children. They felt guilty for not being able to assist in their children’s schoolwork and education due to their poor Korean language ability. They also said that they had difficulty because their husbands did not cooperate in their children’s education.
“I want to be the best mother in the world. I wish I could speak good Korean and cook well, but it wasn’t easy. My husband does not help me. I am from a foreign country so my children may appear a little different from their classmates. It is not so obvious but their appearance can be a bit different. So they may be socially ostracized by their friends. As a parent, I am worried a lot about their relationships with their friends.” (Participant 5)

2. Gaining Confidence about Child-Rearing

1. Learning new child-rearing information:
   Married immigrant women with preschool children had difficulty dealing with their children’s distraction and stubbornness, while those with school-aged children had difficulties related to conversation, computer use and their children being truthful. Although they learned that their children had their unique characteristics in the parent participation program, they still had no idea how to raise children according to their characteristics. But they said that they became more confident about child-rearing after learning about children’s developmental stages and emotional and behavior problems.

“I watched a TV program about spoiled children who would not listen to their parents but changed little by little. I want to learn how to do that. So I eagerly watch the program. I’d like to know what kind of hobbies will fit my children at their ages. But when my children keep fighting each other, it just gives me a headache and I feel stressed. I don’t know if I should scold my children when they lie to me. I don’t know what to do, so I ask other mothers participating in the program. These days, my children are curious about sex, so I often talk about this with other mothers.” (Participant 1)

2. Seeing children positively: Participants did not speak fluent Korean and had communication problems with their children, which made them withdrawn. But they learned that not only communication but also having an interest in and caring about children’s needs can be a good approach. This helped them build an improved relationship with their children, they said. They also said that they felt less anxious about their children’s problem behaviors and that they could accept their children as they were instead of trying to raise children in their ways. They attempted to solve problems through conversation according to their children’s situation, and could see the positive sides of their children.

“My son was losing things and did not pack things he should bring to school. This gave me a hard time, and I even wished that I did not have a son. When I got angry, I yelled at him, scolded him and slapped him with hands. I talked a lot with him. And I tried to find good things about my children. When my children bring their friends home, I make them sweet and sour pork and other snacks. My children eagerly eat the food I make and brag about it to their friends. My children like their mother and compliment my cooking, which I don’t realize before.” (Participant 2)

3. A Hidden Barrier: IT Power: It has been reported that in Korea, married immigrant women have difficulty guiding their children’s studies, and this researcher could not agree more with this statement. But in particular, information technology education was a more threatening element to the participants than linguistic and cultural differences. Korea has one of the highest levels of access to multimedia of any country in the world, and Korean children and mothers are often adept at using computers and software systems. And at school, classes continue to utilize computers and students are required to perform assignments by using a computer. Information technology education has emerged as another obstacle that threatens the child-rearing of married immigrant women, who begin at a different ‘starting line,’ so to speak, than Korean mothers.

“Immigrant mothers have to be adept at using computers in order to take care of their children’s studies. Teachers post notices on the bulletin board. Those mothers who do not know about this miss things that their children need.” (Participant 6)

4. Communication among Family Members:
   Participants all shared the characteristic of having gone through marriage-related immigration.
Although there were small personal differences, they all experienced the social isolation and difficulties caused by linguistic barriers. In particular, many of the participants felt withdrawn when they tried to communicate due to their pronunciation and spelling errors, and their inability to properly use connective suffixes. This enabled them to experience a change in the relationship with their children at home.

“I tried to nag less, made concessions to my children, thought a lot about my family and talked a lot with them. I hope I can talk better, but after learning that good listening is an important part of conversation, I often would initiate a conversation with my children and listen to them. There is more conversation and laughter in my family now, and there’s much less quarreling.” (Participant 8)

**Discussion & Conclusion**

Just as each country has different practices and culture, each married immigrant woman will have different convictions about the parent’s role. This means that the parent’s role for married immigrant women needs to be newly established in the fast-changing Korean society. “A parent’s role” has had various meanings in previous studies, but the “parenthood” of married immigrant women has not been correctly defined.

Parenthood is a process that requires ceaseless efforts to maintain a good relationship with children by learning information and knowledge on children’s growth, while developing a sense of responsibility to raise children. When a parent performs this process well, the parent can develop confidence about performing a parent’s role, have a more comfortable relationship with the children and feel higher satisfaction with their role. A parent is indispensable to his or her children’s growth and development. Behind competent children, there is a parent who works for the child’s intellectual development, and seeks to satisfy the child’s social needs.

However, married immigrant women have difficulty raising their children due to differences in child-rearing practices and culture. These difficulties were highlighted in Obounou and Mpelega’s study, which studied 16 reviews about immigrant women married to Korean men. Married immigrant women experience not only linguistic communication difficulties but also difficulties in guiding their children’s studies. They pay a lot of attention to child-rearing, which is helpful, but they still find it difficult to guide their children’s studies at an advanced level. And it is considered that Korea’s overheated environment of early and private education adds to their confusion regarding a parent’s role.

Married immigrant women’s husbands do not have a particular interest or get directly involved in their children’s education. In this poor environment, the weight on married immigrant women in playing the role of parent is heavy. Previous studies show that this heavily weighted role causes difficulties to married immigrant women because they arrive in Korea without sufficient education on Korean culture, and thus have to raise their children before they have established values about a desirable role for a parent, or prepared related knowledge or skills. They also have limited authority to play their role as a parent and to express their thoughts and convictions as a decision maker in the family.

Parenthood should be seen as not a static state, but a process of continuous expansion. There are limitations encountered when we attempt to understand the parenting role played by married immigrant women from a traditional Korean perspective. Married immigrant women have to raise and educate their children in a culture that is different from the one in which they grew up, and in a multicultural environment that does not offer their native language education or child-rearing practices. This requires more expert resources in communities who can help them change for themselves and develop as parents, and most of all, who can give them clear answers when they are confused as they try to set a standard point for their children’s role in child-rearing.

This study has some limitations. The changes in the participants’ child-rearing occurred within Korean society, and thus the results of this study are confined to Korea geographically. Because married immigrant women in other countries do not have the same experiences, it is difficult to generalize the results of this study. This difficulty exists because the parenthood process continues while parents are engaged in a learning process. However, the efforts of this study are expected to provide a foundation for understanding the parenthood of married immigrant women, as there are a growing number of married immigrant women and their children are growing into members of Korean society.
Further studies on the parenthood adaptation model of married immigrant women should be conducted in the future, and related theories may be formed based on the data of this study.

ABSTRACT

This study aimed to develop the Green Consumerism E-Book for Undergraduate Students (GC-EBUS). The novelty offered in this study is the development of a book specifically discussing green consumerism for undergraduate students, which has never been developed before. This research was conducted in November 2018 - March 2019. The research method used is the research and development method development model Borg and Gall which consists of conducting needs analysis, designing media, developing media, and conducting media validation, in this study not yet tested try the effectiveness of the media in the field. GC-EBUS was develop in Indonesian language. The average total validation score obtained is 3.33 which is very valid. This showed that GC-EBUS is suitable for use in classroom learning. The conclusion of this study is that green consumerism books for undergraduate students developed are suitable for use in learning.

Keywords: e-book, green consumerism, learning environment, learning media, research and development, undergraduate students

Introduction

One of the concepts that put forward the concept of consuming environmentally friendly materials is what is called green consumerism. In principle, green consumerism is an understanding where one must prioritize various environmental interests in terms of what he consumes¹–³. Examples of cases, for example in terms of shopping, for people with high green consumerism will put forward to buy goods that are more environmentally friendly. Even though the price to be paid is higher, he will still try to buy it, to maintain the environment for the better.

The understanding of people about green consumerism is still not deep, especially for people who live in developing countries like Indonesia. Green consumerism concepts are also very minimal understood by students who already have a high level of thinking. This is because when they go to school, they are not given enough knowledge about this. This resulted in their low pro-environmental behavior⁴–⁶.

As an effort to improve the understanding of undergraduate students on green consumerism, learning materials need to be provided. This learning material can be delivered through learning media. This is very helpful, especially to convey environmental material to undergraduate students from various majors both from natural sciences or social sciences⁷,⁸.

Previous research related to learning media and the environment usually directed the media to improve Biology learning outcomes. Researchers usually only focus on improving learning outcomes⁹,¹⁰. Also, previous research usually carried out action research based on what cases were in the class. In this case, for example, student learning outcomes in environmental pollution material are low. Then the teacher conducts
action research and uses existing learning media such as video, chart, and power point as an effort to improve student learning outcomes\textsuperscript{11,12}.

In this research the novelty offered is the development of the Green Consumerism E-Book for Undergraduate Students (GC-EBUS). Books like this are classified as products that are rarely developed because most people only develop media that contain material on environmental pollution in general. In this book, special content is only discussed about green consumerism in more detail. Besides that, another novelty offered is in this book also given environmentally friendly aspects, this is a novelty of this research.

Based on these problems it is necessary to develop learning media in the form of e-books to help provide knowledge to students from various walks of life. The book developed must also have characteristics that can facilitate the various backgrounds of students who study the book\textsuperscript{13-15}. This study aimed to develop the Green Consumerism E-Book for Undergraduate Students (GC-EBUS) for students in Social science and natural science.

Method

The research was conducted in November 2018 - March 2019. The research method carried out in this study was the media development method of Borg and Gall models with modification stages. The stages are (1) conducting a needs analysis (2) Designing media (3) developing GC-EBUS Media (4) Doing expert validation. In this study, only the development process was carried out, and it has not been continued to test the effectiveness of learning media (16). Experts involved in this study are lecturers, teachers and undergraduate students as users. The validation categories used are as stated by Ratumanan & Laurens (2006) as follows in table 1.

<table>
<thead>

</tbody>
</table>

At the stage of the needs analysis, a study was conducted through literature and direct observation, and it was found that the learning media in the form of e-books had never been developed before. At the stage of media design, a media design was started which consisted of storyboards and design layouts of the products. GC-EBUS was develop in Indonesian language. During the development phase, it was carried out for two months and obtained a GC-EBUS product which was then validated to media and material experts and undergraduate students.

Findings and Discussion

Based on the results of the research that has been done, the results of the validation show that the developed GC-EBUS has a valid category and gets positive values from experts. This category shows that the media developed is suitable for use in classroom learning. As for more details can be seen in table 2.

The results of the media that have been validated and developed are then made an improvement process based on input from various experts. Repairs were carried out for two weeks. The results of the improvement and development of the book can be seen in Figure 1 and Figure 2.

Figure 1: Front cover view and introduction page of GC-EBUS

Figure 2: GC-EBUS content page
Based on products that have been developed, there are several advantages of GC-EBUS which are the hallmarks of other learning books. In this book, there are various drawings that are interesting and support an explanation of various concepts regarding the environment. This interesting image can make undergraduate students more enthusiastic in learning it\textsuperscript{18,19}. Another advantage is that the size of the book is relatively small, just the size of an A5 paper, which makes the book easy to use and lightweight. GC-EBUS also has advantages because it can be used in various devices such as smartphones, laptops and tablets. This is very in line with the development of the age where learning is no longer dependent on distance, because learning can be anywhere\textsuperscript{20–22}.

The material presented in GC-EBUS is also relatively easy to understand. In GC-EBUS, the material developed consisted of 6 aspects namely Energy Conservation, Transportation, Waste Avoidance, Consumerism, Recycling, Vicarious, Social Behavior\textsuperscript{23}. In the aspect of using language, there is no confusing vocabulary in this book. This is so that readers who come from various departments can read it. The sentence delivered is also directly in essence and not convoluted. of course, this will make it easier for undergraduate students to understand environmental learning material\textsuperscript{24,25}.

The development of GC-EBUS is very useful in learning, especially for wide spreads. Environmental learning gained in the classroom when at school is felt to be insufficient so that additional material is needed for undergraduate students so that they better understand the material available. Especially for undergraduate students from social sciences programs where they are not too deep in the concepts of nature. Book development is also felt to increase knowledge of student behavior. Student’s environmentally friendly behavior can be improved by using various learning media\textsuperscript{26–28}. Undergraduate students who read this book are invited to preserve nature and protect nature. Although indeed other treatments need to be given, not only this book. This book also provides various facts about the environment, this makes people more rational in taking action and protecting their environment\textsuperscript{4,5}.

GC-EBUS in learning is one form of innovation in learning media. That is because all this time the textbook has a rigid, boring, and rather difficult to understand. This book is different from books that are already on the market. GC-EBUS will make undergraduate students more enthusiastic in learning. Undergraduate students will also be more active in learning, this will have a good impact on learning. The activities of undergraduate students in the classroom using this book will change their knowledge in understanding the environment towards a better direction\textsuperscript{29,30}.

Besides using GC-EBUS, this is for undergraduate students in the class. We can also combine this media with other learning media such as videos. This is because the video is sufficiently proven to be able to improve student learning outcomes and also can improve various student abilities needed in 21st-century learning\textsuperscript{31–33}. Videos combined and can also be taken from various sources such as the internet. This is because in the digital era like now using the internet is a habit of undergraduate students\textsuperscript{34–36}.

Conclusion

Based on the results of the study, it can be concluded that GC-EBUS has a valid category and is suitable for use in classroom learning. This book has various advantages, such as the information delivered is brief but clear so that it is easy to understand. This is very suitable for the characteristics of readers, namely undergraduate students from various majors in science and social science undergraduate students.

Acknowledgements

Thank you to the validators, media experts, and material experts who have been involved in this research. Thanks also to the Indonesian Ministry of Research, Technology and Higher Education (Kemenristekdikti) for helping with funding from this research. Without support from various parties, this research will not work well.

Chemical Contaminants of Water Resources to Neurological Symptoms of Population around Cipayung Landfill Depok, West Java

Fajaria Nurcandra¹, Terry Yuliana Rahadian Pristya¹, Azizah Musliha Fitri¹
¹Public Health, Faculty of Health Science, Universitas Pembangunan Nasional Veteran Jakarta, UPNVJ Kampus Limo Depok 16514, Indonesia

ABSTRACT

Introduction: There was a report of increase in the levels of heavy metals (Ag, Pb, Cd, Cu, Fe and Zn) between 214% and 2040% in the soil around the landfill. Long-term disposal of municipal waste can affect the nature and productivity of land around municipal waste disposal sites. This study aimed to analyze the relationship of lead and mercury levels in water sources to complaints of neurological abnormalities of residents around Cipayung landfill.

Method: A cross sectional study was conducted between September-October 2018 with a sample of 88 people. Data were collected by interview using questionnaire and water samples were tested in Indonesian Center for Biodiversity and Biotechnology (ICBB). Data were analyzed using logistic regression to achieve the fit model.

Results: Logistic regression showed a weak relationship between mercury levels and complaints of neurological symptoms with POR = 1.422 (95% CI 0.328-6.159). While all water source samples contained lead levels around 0.08 mg/L which was likely to have been contaminated.

Discussion: The effect of mercury levels on water sources to complaints of neurological disorders symptoms was found to be weak and the possibility of lead levels has exceeded TLV. Residents around Cipayung landfill are suggested to not using ground water as their drinking water.

Keywords: lead, landfill, neurological symptoms, mercury, environment

Introduction

Indonesia’s population growth will also increases consumption which generate to increasing in the amount of solid waste generated from activities so that effective waste disposal is needed. The open dumping method and the accumulation of waste used in Indonesia at the landfill has resulted in a decrease in the quality of the environment due to air pollution which are resulted to the burning of solid waste and groundwater pollution which endangers communities around the landfill ¹².

Indonesia is the second place as a contributor to plastic waste and produces tens of millions of tons annually. In 2015, Indonesia produced garbage 0.7 kilograms/person/day. With 250 million people, 175,000 tons of waste produced are produced every day, reaching 64 million tons/year. The Cipeucang landfill covering an area of 2.5 hectares was expected to run out of space in the end of 2016, while the Bantar Gebang landfill receives 6,700 tons of waste per day each year ³.

Groundwater contamination by landfill is known. There was an increase in the levels of heavy metals (Ag, Pb, Cd, Cu, Fe and Zn) between 214% and 2040% in the soil around the landfill. Long-term disposal of municipal waste can affect the nature and productivity of land around municipal waste disposal sites ⁴５.

Heavy metals have adverse effects on soil, agriculture, and human health\(^1\). Solid waste from landfill can also increase nitrogen levels, pH, cation exchange capacity, percentage of base saturation, and organic matter\(^1\). Long-term disposal of municipal waste can affect the nature and productivity of land but can still be used for agriculture because the eco-toxic risks associated with its use continue to be assessed and controlled.

Heavy metal in the soil due to contaminated landfill waste causes chronic cancer, decreased nerve function, bone abnormalities, and infertility. Whereas in children pollutant particles from landfill enter through breathing and digestion. The impact of lead on drinking water causes depression, decreased appetite, gastric complaints, muscle pain, weakness, dizziness, abdominal cramps, fertility, miscarriage, nervous system damage\(^{16}\). The impact of contaminants is very influential on vulnerable populations such as infants, children, pregnant women, parents, individuals with a history of serious illness, or other subpopulations at greater risk than the general population\(^7\).

The problem of waste management, especially in areas that are for final disposal sites, has not found effective management in several countries. Organic material contributes a volume of 50-90% including kitchen scraps and food (food scraps, rotten fruit, vegetables, leaves, crop residues, animal excretion, and bone). Organic waste can rot and become fertilizer. However, the problem is, it is still rare for countries to effectively manage organic waste. For inorganic waste, reuse efforts are preferred in waste management avoiding water and soil pollution\(^5\).

The existence of landfill greatly affects the quality of groundwater of the surrounding population. Studies in Cameroon show cadmium concentrations in water sources 0.48-7.64 mg/kg, Cu range 38.3-236 mg/kg, nickel 44.06-58.03 mg/kg, lead 117-528 mg/kg, zinc 270-2110 mg/kg\(^5\). Contamination of water by metals or heavy metals was also found in Nigeria around open dumping indicated containing Cd between 0.65–0.80 mg/kg, besides SO4\(^8\). Short-term exposure to high concentrations of metal or long-term accumulation of metal contamination in water can cause symptoms of poisoning in humans such as increased blood pressure, headaches, impaired memory and concentration and fertility problems.

Increasing the volume of solid waste at Cipayung Landfill from 2004 to 2018 has experienced a significant increase. The waste has reached 30 meters in height. While the distance between the landfill and the residents’ housing is around <500 meters. This condition is very possible to affect the quality of drinking water from local residents, which in the long term can reduce the quality of health. Based on informal interviews with residents around the landfill, the ground water sources have experienced changes in color, smell, and taste during the rainy season. Since the establishment of the Cipayung Landfill until 2018 there have been no studies that measure the water quality of residents around 1 kilometer in radius and assess the quality of their health through symptoms of neurological disorders in residents due to water pollution.

Cipayung landfill is operated with an open dumping system in an area of 2.5 ha. The expansion of the 10.6 ha Cipayung landfill was due to an increase in volume. The waste disposal system is upgraded to a controlled landfill. There is a settlement of Kampung Bulak, Cipayung Village, with a distance of about <500 meters from the TPA center. Residents use ground water for washing activity, cooking and drinking water. However, many complain about the well water experiencing changes in taste, color and smell, especially in the rainy season. Research conducted at other landfills has proven that most of the residents’ wells have been contaminated\(^1\). Therefore, the community around the Cipayung landfill are high risk in health problems mainly due to groundwater pollution from landfill leachate. Measurements of cadmium, chromium, lead, and mercury from water sources around other landfills have been carried out, but there has never been a study linking the water quality of the local residents in the landfill with the health of its residents. Furthermore, this study aimed to analyze the levels of lead and mercury in the water sources of residents around Cipayung TPA against complaints of neurological disorders.

**Method**

A cross sectional study was performed between August and October 2018 for residents living in a radius of 1 km from TPA Cipayung, Depok. The closest house is at a distance of <500 meters. This location was chosen because the volume of solid waste is increasing every year. There is a possibility that local residents have experienced water pollution from physical, chemical, and inorganic pollutants due to the large volume of waste.

The eligible population of study were residents aged >17 years and a maximum of 60 years who lived around the Cipayung landfill within a radius of 1 km for...
at least 6 months when data were collected. Proportional sampling was used to collect 88 residents who lived in a radius of 500 meters, 600 meters, 700 meters, 800 meters, 900 meters and 1 kilometers. Data were analyzed using logistic regression.

The concentration of lead (total) in well water samples was analyzed at the Indonesian Center for Biodiversity and Biotechnology (ICBB). The number of samples for each radius is determined proportionally. Distance of wells with landfill was measured by the global positioning system (GPS). Well water samples were collected from a depth of 20 cm from the surface of the water and packaged in a 1 liter acidified plastic bottle with two drops of concentrated HNO3. The water samples were then analyzed by inductively coupled plasma atomic emission spectroscopy. The cut-off point is used to categorize the independent variables based on the threshold value (NAB) of the Minister of Health Regulation of the Republic of Indonesia Number 492/Per/IV/2010 concerning drinking water quality requirements.

Ethical Clearance: The Health Research Ethics Committee Universitas Pembangunan Nasional Veteran Jakarta approved the study protocol (No. B/1617/X/2018/KEPK). Before interviewing, the researcher explained the purpose of the study to each of the participants. Written informed consent was obtained from all participants on a voluntary basis.

Result

The levels of heavy metals tested in this study were lead and mercury. The test results for all water samples showed that it contained lead around 0.08 mg/L. While the results of mercury test of all samples varied and were categorized based on the threshold value (NAB) of 0.001 mg/L. The prevalence of complaints of neurological disorder symptoms in Cipayung Village was 23.86%, while the lead levels of all samples were still below the NAB of 76.14%.

The majority of residents did not have any history of neurological diseases (96.59%), the type of drinking water did not meet the requirements (52.27%) so they has the potential to be contaminated with heavy metals from landfill protection, the type of clean water resource did not meet the requirements (62.50%). The highest proportion of demographics aspects showed that occupation was not risk of neurological symptoms (87.50%), occupational history was not risk factor (60.23%), mild smokers (88.64%), monthly income was no differences between both categories, normal BMI (52.27%), education did not graduate until junior high school (63.64%), length of employment <5 years (76.14%), and age <36.5 years (51.14%).

Based on crude results obtained from 21 subjects who suffered from neurological complaints, there were 28.57% whose the mercury levels in the water resource exceeded TLV (POR = 0.562; 95% CI 0.372-4.652). Only the drinking water, water resource, and the occupation showed a significant in the level significance at 0.05 in crude to the complaints of neurological disorders with each POR were 0.940, 5.686, and 0.738. Body mass index (BMI) found to be an increase a risk in people under the category of underweight, overweight, and obesity in complaints of neurological disorders. While other variables did not found as a risk for complaints of neurological disorders.

The effect of mercury exposure in water resources on complaints of neurological disorder symptoms in Cipayung Village population needs to be controlled by confounding variables statistically like work history and BMI, but drinking water and water resource remain included in the model because it is considered to have substantial effect. The magnitude of the effect of mercury in residents’ water resources on neurological symptoms after being controlled by those confounding variables was 1.422 (95% CI 0.328-6.159). Based on those result, the effect of mercury on water resources into complaints of neurological symptoms was not very clear.

Discussion

Lead levels of all samples probably have exceeded the TLV because they showed lead content around 0.08 mg/L. This number has exceeded the TLV stipulated in the Regulation of the Minister of Health of the Republic of Indonesia No 32 of 2017 which is 0.05 mg/L. The result was different from the study at the Namobintang landfill which showed the lead content was still below TLV. The mercury threshold value was 0.001 mg/L and there were several samples that passed this value. Mercury and lead in contaminated food and beverages will be accumulates in several body parts such as hair and can be used as biomarkers.

Results of the lead test for all samples were homogeneous so it could not be analyzed. Whereas the results of the analysis of mercury level to neurological symptoms were found to be 1,422 (95% CI 0.328-6,159) which showed a weak effect after being controlled by work history, BMI, drinking water, water resource, and house distance to landfill. In addition, 95% CI passed the null value so that the possibility of results was influenced by chance. There were also possibilities that these results are underestimated caused by non-differential misclassification.

In accordance with the theory and results of several studies, chronic exposure of mercury can cause abnormalities in the central nervous system (such as mental retardation, deafness, blindness, speech disorders) and kidney damage. The most frequently reported exposure to mercury is long-term exposure with low level exposure.

House distance to the landfill was one of the factors that influenced the mercury level of water resource. Our result showed that the closer to the landfill, the smaller the risk for complaints of neurological disorders. This was probably due to the behavior of most subjects and population there who feel that their water resources are not appropriate for drinking or sanitation, so they use water sources from other locations (piped water systems) or refill water. The distance of 0-500 meters should be a buffer zone for protection for residents who carry out daily activities around the landfill and prevent the impact of leachate on the population. Whereas a radius of <100 meters from the outermost site boundary of the landfill must be a green belt, a space with many trees so that it should not be used as a water source for any purpose.

The use of ground water in radius between 0-800 meters to the landfill is not permitted.

The limitations of this study were the number of samples. It is recommended for further research to increase the number of samples and increase power statistics. If there was information bias, there tends to be non-differential misclassification because there was no difference in treatment between groups.

Conclusion

The prevalence of complaints of neurological symptoms in population of Cipayung Village was still low at 23.86%. The results of testing the levels of lead in the water source of the residents of all samples may exceed the threshold limit value which were around 0.08 mg/L. The range of mercury levels in the water sources of population of Cipayung Village is <0.0001 – 0.0011 mg/L. The relationship of lead levels in water sources to complaints of neurological disorders in residents around Cipayung landfill could not be analyzed because all samples contain the same lead levels. The relationship between mercury levels and complaints of neurological abnormalities in residents around Cipayung landfill was weak (POR = 1.422; 95% CI 0.328-6.159)

Conflict of Interest: There no conflict of interests of this study.

Comparison of Simulation Method and Animation Video on Knowledge Related to Preparedness of Elementary School Students in Ternate, Indonesia

Fitriyanti N Idrus¹, Lilik Zuhriyah², Tony Suharsono³
¹Postgraduate Program of Nursing, School of Nursing, ²Department of Public Health, Medical Faculty, ³Department of Basic Nursing, School of Nursing, Universitas Brawijaya

ABSTRACT

Ternate location which passed by Pacific Ring of Fire made the area of Ternate have a high risk of experiencing volcanic eruptions. School as one of the stakeholders is responsible for improving the preparedness of students. Students are the most group vulnerable to disasters. Preparedness in reducing disaster risk that possessed by students is still relatively low, thus requires training for students to deal with disasters that cannot be predicted when it occurs. This study aimed to analyze the effectiveness of simulation and animation video methods in improving the knowledge related to preparedness among students. This study used pre-test posttest with control group design. The population in this study were fifth and sixth-grade students from four different schools which in the disaster-prone area in Ternate, North Maluku. Total respondent in this study was 90 respondents that were selected using purposive sampling technique, then divided into two groups: simulation and animation video methods. Data of knowledge and attitude variables were collected before and after training using a questionnaire. Data collected from this study were analyzed using the Wilcoxon and Mann Whitney tests (α=0.05) with SPSS 20. The result of this study was shown that there was a significant difference in knowledge between the two groups before and after an intervention. Both groups shown an improvement mean score in knowledge (from 5.02 to 7.38) Similarly, the video group (5.27 to 6.67, p=0.000). Comparison between the two methods shown that the simulation method obtained higher knowledge than the video method with a mean rank of 55.44 vs. 35.56 (p=0.000).

Keywords: knowledge, preparedness, simulation, animation video

Introduction

Geographically, Indonesia is a region that has the largest number of volcanoes in the world. Geologically, Indonesia is among the three world’s plates, those are Eurasian, Indo Austria, and Pacific Ocean Plate¹. This condition causes the tectonic and volcanic activity is very high and have active faults which are mostly found under the sea, thus potentially resulting in a volcanic eruption².

Ternate is one of the areas in Indonesia which has active volcanoes. This is because Ternate is included in The Ring of Fire Area¹. This condition indicates that Ternate has a high risk of experiencing the effects of volcanic eruptions³. Volcanic eruptions have occurred in Ternate in 2012 which caused 7 people dead, 10 lose, and 284 people displaced, but it also, there is damage in residential areas and public facilities such as roads, bridges, and schools. The incident has rightly become a lesson for the whole of society and government⁴.

Several schools in Ternate located in disaster-prone areas with a radius of ± 4km from the mountain ⁴. This condition indicates the location of the school is very risky to the threat of volcanic eruption. Children are one of the most vulnerable populations during disasters, especially if they are in school⁴. Therefore, the safety of children in schools became the focus of attention of
global security efforts. The Hyogo Framework for Action 2005-2015\(^6\) and The Sendai Framework for Disaster Risk Reduction 2015-2030\(^7\) has prioritized safety and security in a comprehensive school consisting of three pillars, namely; safe learning facilities, school disaster management, and DRR and resilience education.

The low preparedness of students in terms of disaster risk reduction both in terms of knowledge, attitudes, and actions make preparedness as an important element for disaster risk reduction that is pro-active \(^8,9\). Efforts should be made towards disaster risk reduction is to increase preparedness someone who is part of the disaster management\(^10\). To build such a culture requires innovative interventions, economic, logical, human-oriented and demand-oriented\(^11,12\).

One of the stakeholders who are responsible for building this culture is school because of its strategic role in building the preparedness in facing disaster, especially for students\(^13\). The Student is a strategic objective to disseminate information among the public and the sources of knowledge in improving preparedness\(^14\) Indonesia, in terms of safety of school location, disaster management and disaster education. The findings indicate that 56\% of public elementary schools in Banda Aceh City are exposed to high tsunami risk, and most externally driven school disaster preparedness activities were not continued by the schools due to lack of ownership, institutional arrangement and funding. The study proposes the minimum essentials to reactivate school disaster preparedness activities and strongly recommends the local government’s policy support for ensuring a city-wide, all-schools implementation. These essentials should include an annual school plan that involves conducting a tsunami evacuation drill at least once per year and a school budget for conducting disaster preparedness activities. To ensure smooth implementation, the Education Agency Circular Letter should provide justification for all headmasters to include these components in the schools’ annual plans. It also recommends that external parties who donate or provide physical equipment (e.g., tsunami evacuation routes or maps. The purpose of this study was to compare the methods to improve the preparedness of students’ knowledge among methods of simulation and animation video.

**Method and Material**

The method used in this study was quasi-experimental with a pretest-posttest control group approach. This research was conducted in January and February 2019 at Public Elementary School of 61, Public Elementary School of 62, Public Elementary School of 64 and Public Elementary School of 70 Ternate, North Maluku, Indonesia. The population in this study were 127 students and 90 respondents were selected using purposive sampling technique with inclusion criteria: fifth and sixth-grade students, had never participated in disaster preparedness training of volcanoes, then respondents were divided into two groups: groups of simulation and animation video.

Each group has a different treatment. The simulation group was facilitated by trained personnel of the Regional Disaster Management Agency (BPBD) of Ternate with applying the method of role-playing with the scenario of an event when the volcano erupted at the school. Actions taken included: how to recognize the warning signs of volcano erupted, the action is taken when a disaster
occurs while in school, evacuation drills, and toward the interim blunt point. All circuit simulation needed 45 minutes. In the video group of students invited to watch a video animation “disaster preparedness volcanoes” that lasted ± 7 minutes, which included images, text and an explanation of the formation of a volcano, volcanic eruptions, and preparedness to face eruptions. Informed consent was given to all participants prior to the study. This data acquisition phase was divided into two phases. First, pretest conducted for both groups, second, intervention phase and posttest.

This study used a questionnaire as an instrument of knowledge that consisted of 9 questions. Validity and reliability of the questionnaire were performed by involving 20 respondents with the same characteristics as the subject of research. Validity and reliability revealed that correlation of corrected item total for all items of questions was > r table (0.444) and Cronbach’s alpha value of 0.84. Data were tested by Friedman with Post Hoc Wilcoxon and Mann Whitney. Statistical analysis was performed using SPSS 20.

### Results

According to Table 1, could be seen that most of the gender of primary school students in the simulation group was male with total students of 24 and animation video, group was female with total students of 23. The most dominant age of primary school students in the simulation group was 12 years old with a total number of 23 people and in the video group was 11 years old with a total number of 25 people. The most dominant of primary school students in a group of simulation and video was sixth-grade students with a total number of 32 and 37, respectively. The most of intervention group (24 people) had 1 time joining the simulation conducted by parties from outside of school, whereas in the control group the majority of students (41 people) had never participated in simulation training.

</tbody>
</table>

Table 3 was shown the difference in the improvement of knowledge between the groups of simulation and video. Mann Whitney Test resulted in the p-value of (p = <0.005), explained simulation group was higher.

Finding

Statistical analysis was shown a significant improvement of knowledge in both groups, before and after the disaster preparedness education. This was shown that the method of simulation and video could be useful in improving the knowledge related to preparedness for fifth and sixth-grade students of elementary school. Then, based on the average of difference test in improving the knowledge score between methods of simulation and video, there was a significant difference between the two methods in which the average score of simulation group was higher than video group. This indicated that knowledge related to preparedness given to fifth and sixth-grade students using simulation method was better in improving knowledge than video.

The results were consistent with Unver et al., (2018) which stated that the use of simulation training for disaster preparedness incorporating the knowledge and skills to provide direct experience of the response when disaster strikes as though. These results were consistent with research conducted by Kalanlar, (2018) involving 75 nursing students who demonstrated that increased knowledge and preparedness of disaster-related student in the simulation group compared with the control group.

The simulation method used in this study could be used as one method of effective disaster preparedness training at elementary school students because it could provide a better level of knowledge compared to the video method. This was possible due to the use of video, respondents focused only on impressions that displayed in the LCD (Liquid-Crystal Display). Instead, disaster preparedness training using simulation method of role-playing was providing a direct experience of the trainees in improving preparedness. This process provided convenience to participants in improving the knowledge.

A simulation was a learning experience strategy using mock situations that could provide opportunities for students to practice, develop knowledge and skills in a real disaster situation but still performed in a safe environment. Health care staff and institutions should be prepared to manage these events. The aim of study is to analyze the effects of high-fidelity simulation on the perceptions of senior nursing students regarding their preparedness for disasters. Methods: This study used a pretest-posttest design and was conducted as a quasi-experimental investigation. Results: Slightly less than the half of the students (42.5%). This was in line with the research of Steward & Wan (2010) which stated that simulation in disaster management could measure a person’s readiness to deal with disasters. According to Olson et al., (2014) in his research also stated that education about disaster preparedness using simulations could provide better results than not using simulation. Thus, disaster preparedness training using simulation method was recommended as an effective method to improve the preparedness of elementary school students.

Conclusion

There was a significant difference in the improvement of preparedness-related knowledge among fifth and sixth-grade students in elementary school after receiving disaster preparedness education using simulation and video animation. The result was shown that simulation method was better in improving knowledge compared to the method of animation video. These findings proved that simulation method could be used as an effective method in improving the preparedness-related knowledge in elementary school students. Researchers suggested conducting further research to determine the retention of knowledge with a follow-up period of 30 or 60 days. For nurses could research to improve knowledge as first aid knowledge that could be conducted by students when the disaster occurred.

Low Self-Esteem of Women Suffering *Mayer Rokitansky Kuster Hauser Syndrome*

Gardha Rias Arsy¹, Retty Ratnawati², Septi Dewi Rachmawati³
¹Master Degree Program for Nursing, Faculty of Medicine; ²Physiology Department, Faculty of Medicine & Master Degree Program of Woman Studies; ³Paediatric Nursing Department, School of Nursing, Universitas Brawijaya

**ABSTRACT**

*Mayer Rokitansky Kuster Hauser Syndrome* is a rare disorder suffered by females. Women suffering MRKH cannot have menstruation cycle, cannot have intercourse with her husband, and cannot pregnant, even cannot give a birth to children. This condition puts the women to have lower confidence, to feel inferior, to close and attract themselves from environment because of shame, useless, and feeling to be bad fortune for their family. There are participants in this research got shocked and depressed after realizing their condition. Their low self-esteem is an unappreciated feeling, feeling useless and having low self-esteem due to negative evaluation upon themselves and their abilities. The purpose of this research is to explore self-esteem of those women. The method of this research is qualitative by using interpretative-phenomenology approach. The participants are aged between 19-30 years old. While collecting the data, the researcher used in-depth interview by using structural interview by involving seven participants suffering MRKH. The findings describe the meaning of the participants’ experiences in which they feel inferior, cannot socialize with their friends nor people around them.

**Keywords:** Low Self-esteem, Women, Mayer Rokitansky Kuster Hauser Syndrome

**Introduction**

*Mayer Rokitansky Kuster Hauser Syndrome* or known as MRKH is an inherited disorder occurred on early mature female indicated by the absence of tubes, vagina, and uterus normally¹. The condition is known when a woman is in her early teenager age and does not experience menstruation (amenorrhea primer)². The syndrome is a rare disease with occurring ration 1 to 5000 female baby births around the world. Where they will experience a very burdening condition for a woman to have problems with menstruation, to get involved in intercourse and to give a birth¹. The data gained from Indonesia MRKH community whose 33 members around the world, consisting not only Indonesian citizen but also foreign citizen.

The occurrence of reproduction organ problem of woman can influence the woman’s life because the health of woman’s organ is assumed as completeness identity of a woman⁴. It influences psychological aspect of a woman because the condition of woman suffering MRKH has psychological or emotional trauma and existences of changes toward her self-esteem³.

Low self-esteem is describes as negative feeling toward an individual’s self, included losing confidence and self-esteem². Low self-esteem is unworthy feeling, useless and being inferior due to negative evaluation upon their own self and their abilities. It is also indicated by poor self-treatment, untidy clothing, appetite regression, feeling afraid to face while talking, seeming gloomy, slower and weak speaking⁶. Low self-esteem is included in mental problems.

*World Health Organization* predicts 450 million people around the world suffering mental problems.
There are 10% of adult people suffering mental problems now and 25% of them are predicted to have this problems in certain age during their life. Meanwhile, according to Indonesian Republic Health Department, mental problem reaches 13% of whole disease and is possible to grow into 25% in the end of 2030. In Indonesia, in 2007, the prevalence of the case is 4.6 per mile. It means from 1000 people of Indonesia there are four to five to have mental disorder.

Experiencing low self-esteem is a condition which mental problem occurs on an individual. Mental health is a psychologically and emotionally condition health, related to satisfied interpersonal relationship, behaviors, and effective copes, positive self-esteem and emotional stability. According to Prabowo, mental health is various positive characters to describe harmony and mental balance to reflect an individual’s matureness. Mental problem is a set of interruption on functions, thoughts, emotions, behaviors, and socializations to surrounding people.

**Methodology**

The design of the research is qualitative with interpretative phenomenological approach. The participants are seven persons, adjusted by inclusion criteria determined through purposive sampling. The data collection is done by in-depth interview by using semi-structure guided interview. During interview, the researcher uses field note. After collecting all data, the researcher continues to analyse the data using Interpretative Phenomenological Analysis (IPA). This research was done at Regional Hospital dr. Loekmonohadi, Kudus in January-February 2019

**Findings**

The gained data of this research findings are questions expressed by participants. The expressions are coded and looked based on the arranged keywords and then are grouped based on similar meaning categories. Then, the categories are arranged to get subthemes which later are arranged into themes of research findings. This research describes the meaning that the participants experience confidence regression to cause low self-esteem in which they do not want to communicate to surrounding people.

In this research, several themes are self-seceding, being introvert, feeling inferior, and feeling not to be able to make parents happy. Here are the explanations.

**Self-Seeding:** This sub-theme is taken from social relationship interruption experience theme. It means the participants do not want to interact with their friends due to insecurity upon his or her disease. Here is the excerpt stated by one of the participants:

“I am feeling insecure after realizing what happens to me. When I am at school, I often spend my time to alone, to go canteen alone, to go everywhere alone. Sometime I go to library for reading” (P1)

The statement describes the meaning of the participant’s experience in which he felt insecure, did not feel like to interact with their friends or anyone around him.

**Being Introvert:** This sub theme defines that the participant do not have intention to be with anyone, do not want to be opened upon her condition even to her brothers or friends. Here is the excerpt of the participants’ statement:

“...I occasionally ever felt less confident. Even I did not want to meet my brothers nor family. I just wanted to keep myself locked in the bedroom. I was crying more than 2 weeks” (P2)

“What woman wants to be like this, like my condition? What did I wrong? Until I get this life test? I directly closed myself from boys” (P7)

The statement from some participants describe that the participant was being introvert to her friends, her close friends, her brothers, until her family.

**Feeling Inferior:** This sub-theme is participant’s feeling where she does not feel confident anymore due to her disease. Here is the excerpt:

“Sometimes I feel incomplete and less confident” (P2)

Statement of the participants describes that the participants feel inferior because she does not feel complete anymore after realizing her disease.

**Feeling not to be able to Make Parents Happy:** This feeling is sub-theme of social relationship interruption experience. This sub-theme explains that participants feel incomplete and cannot make her parents happy. It causes herself to be pessimistic and insecure so she limits herself to her surrounding people. Here is the excerpt:
“But sometimes my parents seem crying while praying. It makes me think. Ya Allah, how useless I am (while crying) ....” (P1)

“...sometimes my parents in law asked: ‘Why have not you pregnant?’ They already wanted grandchildren. You know? My husband is the single child. Yaaa.... It is normal if my parents in law wanted to have grandchild. But, what can I do with my current condition?” (P5)

The statement describes the participants do not feel useful because she cannot do anything while looking at her parents sad. It makes her thinking about her parents.

Discussion

Low self-esteem is negative feeling toward an individual self, causing to lost confidence, to be pessimist, and to feel unworthy. Low self-esteem is negative evaluation toward an individual self and her ability followed by poor self-treatment, being afraid to face while speaking, slowly and weakly speaking.

The explanation above is in line with research on women suffering MRKH in which the participants felt lonely, denied, rarely communicate, lack of eye contact, lazy, not have eager to get activity, unsafe and uncomfortable with the existence of surrounding people. However, when the condition is not handled soon, it may cause to have risk of perception sensory changes, such as hallucination in which it is as uncontrollable negative symptom with high risk of committing suicide.

Various special therapies given to patients with low chronic self-esteem covers three categories for: individuals, families, and groups. Therapy of special individual which is able to be given to patients with low chronic self-esteem is Cognitive Behaviour Therapy (CBT) and Logo Therapy. A group therapy which is implementable to patients with low chronic self-esteem is Supportive Therapy and Self-Help Group (SHG).

Some researches about treatments to clients suffering low self-esteem uses method to improve interaction ability of the patients by using Social Skill Therapy. Based on the research, it is gained that cognitive ability and behaviour of the clients intervened by such therapy are improved. The findings show that after the intervention, there was improvement of social skill with average score 65.26 before treatment and became 65.68 after the treatment.

The implementation of Social Therapy Skill done by Harkoma et al with characteristics of the client aged 31 years old for intervention group and 34 year old for control group, having primary school education 65.8%, unemployment 63.2%, unmarried 57.9. The absence of social skill differences of intervention group and control group after being intervened has p-value 0.694. The result of the therapy is 13% not completely done and 87% completely done. From 4 sessions of supportive therapy with 3 sessions done and 100% completely done.

According to Calafell in his research, it states that provisions of SST therapy, clients with social interruption can provide Cognitive Behavioural Therapy (CBT). CBT therapy is effectively proven to improve life quality of young clients but the therapy is not purposed and not suggested for middle age or above. CBT is a basic psychotherapy based on theory of how an individual maintains structure of himself or experience in which majorly determines how an individual feels and acts.

CBT is effective to improve self-esteem and independency of patients suffering breast cancer at Cancer Hospital, Darmais, Jakarta. Kristiyaningsih in her research shows CBT can improve self-esteem of chronic kidney-failure patients whom get haemodialysis therapy at Fatmawati Hospital, Jakarta.

Besides providing therapy to clients with low self-esteem done by medical team, family supports will maximize results of therapy. Family is the closest environment and is always together with the patient. Family is main supporter to recover and cure patients’ low self-esteem.

Conclusion

The role of nurses in giving full guidance and counselling for participants, women suffering MRKH to give morale supports and to recover and develop self-confidence of their own selves is needed. The role of more communicative and friendly nurses in giving treatment to the participants will help them to achieve their self-esteem positively to reach adaptive coping mechanism so it will reach active situation between nurses to constructive participants.

Major Influencing Factors on Infants Feeding Pattern of Hospitalized Children Under 2 Years, Najaf Governorate-Iraq, 2017

Hadi Jebur Suhail1, Riyadh Kareem Abbood2

1MD, PhD (CM), Assistant Professor, Al-Qadisia Medical college, Department of Family and Community Medicine; 2MBch B, DCM-FRSPH, Specialist Doctor (Community Medicine), Faculty of Nursing, University of Kufa

ABSTRACT

Infant feeding practices are based on many factors; socio demographic factors are the most critical one. To investigate socio demographic factors that influence the infant feeding practices of mothers in Najaf Governorate/Iraq. A cross-sectional study was employed. Mothers who have under two years child participated in the study.

A tested questionnaire of twenty six inquiries was completed and chi-square test was used to associate feeding practices with different socio- demographic characteristics.

Among the mothers, the majority were between the ages of 19-35 years, unemployed, primary educated, and from low socioeconomic status. Mothers who reported having primary education were significantly more likely to exclusively breastfeed than those with higher levels of education. Mother’s socioeconomic statuses, employment status, were also influential in infant feeding practices.

Aim of the Study: To describe the feeding practices of infants below two years of age and determine maternal socio-demographic factors that influences these practices among mothers in Najaf Governorate.

Method: A cross-sectional study involving three hundred ninety five mother- under two years infant pairs hospitalized at Al-Zahraa teaching hospital for maternity and children, Najaf Governorate, during 2016 – 2017 were consecutively recruited after meeting the study inclusion criteria.

Data on breastfeeding were based on infant feeding practice in the previous 24 hours. Exclusive breastfeeding was defined as infant feeding with only breast milk.

Pretested questionnaire is comprised of 26 items include social demographic domain (11 items) Delivery details domain (3 items) , Feeding pattern domain (12 items).

Results: The findings of present study presented that the majority of sample was breast fed (44.3%) , formula feeding (21.8%) and mixed feeding pattern (33.9%). High significant association between mother age and feeding pattern, the frequency of feeding pattern in age group (19-24) P-value 0.002.

Also significant association between mother educational level and feeding pattern P-value 0.018, also it was noticed that there is significant association between mother occupation with feeding pattern P value 0.043.

The study conclude that infant feeding pattern was significantly associated with mother education, income and occupation, mode of delivery and by person who advice to specific pattern of feeding.

Keywords : Breastfeeding, formula, Najaf, infant feeding practices.

Introduction

The World Health Organization recommends “infants should be exclusively breastfed for the first six months of life followed by breastfeeding along with complementary foods for up to two years of age or beyond to achieve optimal growth, development and
According to the WHO recommendations, the appropriate age at which semisolids should be introduced is after 6 months of age while continue breast feeding to meet the increased physiological requirements of growing infant (9) owing to the immaturity of the gastrointestinal tract and the renal system as well as on the neurophysiologic status of the infant (9).

Some of the major factors that affect exclusivity and duration of breastfeeding include breast problems such as sore nipples or mother’s perceptions that she is producing inadequate milk (4), and problem which is affect infant feeding such as refusal to eat, colic, and vomiting. Societal barriers such as employment and length of maternity leave (7), inadequate breastfeeding knowledge, lack of familial and societal support; lack of guidance and encouragement from health care Predictors of breastfeeding (9).

When breast milk or infant formula no longer supplies infants with required energy and nutrients to sustain normal growth and optimal health and development, complementary feeding should be introduced (11) which is both breast milk and other foods or drinks defined as mixed feeding (1). It has been recognized worldwide that breastfeeding is beneficial for both the mother and child, as breast milk is considered the best source of nutrition for an infant (7).

Objectives of the study:

To study feeding practices among hospitalized children under 2 years

Methodology

A cross-sectional descriptive and analytical study carried out over a 10 months period involved all infants under-two years with their mother who admitted to Al-Zahraa teaching hospital for maternity and children in Najaf from 1st of December 2016 to 30th of September 2017.

Three hundred ninety five mother-infant pairs hospitalized in Al-Zahraa Teaching hospital for maternity and children during 2016 – 2017 were consecutively recruited after meeting the study inclusion criteria. Data on breastfeeding were based on infant feeding practice in the previous 24 hours. Exclusive breastfeeding was defined as infant feeding with only breast milk.

The hospital serves the entire Government and also the neighboring communities from the surrounding Governments. It also provides mainly free routine immunization services. Other services rendered include growth monitoring, and counseling in diverse aspects of child survival strategies.

The Inclusion Criteria Includes: All hospitalized children under 2 years of age whose mothers have given informed written consent.

Exclusion Criteria:

(i) All infants delivered prematurely.

(ii) Low birth weight infants.

Data Collection

Data collection was done by the two researchers and two research assistants who often randomly went back to interview the mothers for quality control checks. These were all geared towards ensuring that study criteria were well applied. Before data collection mothers were assured that refusal to participate in the study will in no way affect the welfare services for their infants.

The data collection tool was a pre-tested interviewer administered questionnaire which was completed by questioning the mother and taking measurements of the infants’ weight, length and head circumference. Information was collected regarding parental residence, maternal age, marital status, educational attainment and occupation.

The categorization of the specific infant feeding option practiced by the mother was based on mothers’ past 24 hour dietary recall. Baby’s first feed, everything baby took in the previous 24 hours, reason for stopping breastfeeding etc. were documented. There was also a section that sought to find out whether the mothers ever heard of exclusive breastfeeding, mothers’ knowledge of the weaning, willingness to practice it if given the opportunity and reason for rejecting exclusive breastfeeding.

Statistical Analysis: Percentage, Chi square test, Correlation analysis was conducted to quantify the strength of association among feeding pattern and social demographic variables.
Results

Factors influencing infant feeding practices in the first six months of life: This section looks at the influence of mothers’ characteristics, method of delivery whether spontaneous vaginal delivery, assisted delivery, or caesarean section. Also look for any maternal complications, and looking for newborn baby history on feeding practices.

Table 1, presents data on how these variables of mothers influence infant feeding practices. The percentage of breast feeding practice is found in 53.4% of mothers with spontaneous vaginal delivery. According to maternal complications, respondents with maternal psychosis or post-partum hemorrhage will be less for breast feeding (3% & 2.3%) respectively.

For newborn baby history, it was found that 78.5% of full term babies were breast fed while in preterm or post term it was low (15.4% and 6.1%) respectively.

Current Infant Feeding Patterns of the Mothers Interviewed: Mothers interviewed breastfed for varied periods. Meanwhile, other foods (formula, juice, porridge etc.) were introduced at varied times in the first six months of the child’s life.

Table (2) , shows the infant feeding practices of mothers who participated in the study. As shown, the proportion of women who practiced exclusive breastfeeding and formula feeding were 34.0% and 21.8% respectively. The proportion of women who practiced mixed feeding within the first six months of life was 33.9%.

When mothers were asked what food they introduced to their infants in the first six months of life majority were quick to respond that they give water. Their responses are summarized in Table 2.

</table>
The majority (228 of 395) of respondents give water in addition to breast milk to their infants. As mentioned earlier 50 respondents were exclusively breast feeding, however 56 were giving their babies formula and other home prepared foods. respondents who introduced their infants to water, 36.2% gave their infants water in their first six months of life. Another 30% were still receiving water and breast milk at the ages of 7-12 months (Table 3). Mothers in this category explained that water has been part of our culture as a welcoming drink and as part of our food. Their responses emphasize the importance of water in infant feeding practices.

Discussion

It was evident from this study that awareness and knowledge do not equate to practice. Inferentially, our mothers, probably, have not come to accept or understand the critical vital benefit of breast feeding or that the challenges to its practice are deemed insurmountable for now. To overcome this, emphasis should be shifted from mere dissemination of information on breast feeding to empirically helping mothers resolve potential challenges highlighted in this study.

On average only about 34% of the babies were on breast feeding and this proportion was seen to rapidly decline from about 64% at 1–2 month to around 34% at the 5–6 months. As much as this trend has been variously reported, the rate was much lower than in Port Harcourt Southern Nigeria and Sokoto in Northern Nigeria which were 58% and approximately 41% respectively at 6 months(13).

Differences in study design might have accounted for this wide variation in rates. The Port Harcourt and
Sokoto studies were both longitudinal and interventional studies and since active mobilization and monitoring have been documented to positively impact EBF practices, the reported higher rates in these locations could be attributed to these interventions(13).

Complementary breastfeeding which involves use of both breast milk, infant formula and other non-milk feeds was practiced by significantly more (39%) mothers surveyed compared to breast feeding (34%) and predominant breastfeeding (28%). Not surprisingly stratification analysis showed that mothers whose infants were older and mothers with lower education attainment practiced complementary breastfeeding than other infant feeding option.

The reason for these findings is easily explained. Most mothers usually start introducing other types of feeds as child gets older and able to tolerate these feeds in order to give them (mothers) time to attend to other activities. Likewise mothers with higher education will more likely understand and be better informed of the benefits of EBF thus delay introduction of other feeds compared to mothers with lower educational attainment. This study clearly showed that mothers with tertiary education were more likely to practice EBF compared to those with secondary and primary education. This was similar to the findings of other study done by Cheizman and his group (14).

Findings in the tables (1,2,3,) refer to relationship between mother age group, level education, Mother’s occupation, whether employed or un-employed, and income, and infant feeding patterns. receive education/counseling about infant feeding choice from mother, decision about infant feeding method was by mothers themselves, previous children was (1-3,less than 5 years), notice in household use the same infant feeding method.

This result of our research agreed with what the researcher pointed(15) which is said successful breastfeeding promotion program depends on the understanding of the factors that influence perception, Maternal socio demographic characteristic like age, education, parity, and employment may influence breastfeeding.

Other factors include, antenatal attendance, multiple births, type of delivery, previous breastfeeding experience, breastfeeding support It is the following table (3) which is refer to relationship between marriage, residence, number member in the house show no significant association with feeding pattern, these result was non consistent with the result researcher (15)

**Conclusion**

Exclusive breastfeeding practice is poor from this study but the awareness is remarkably high depicting significant knowledge-practice discordance. Factors such as low maternal education, higher socioeconomic status, non vaginal birth and use of pre lacteal feeds were significant predictors of lower EBF practice.

This study is one of the important studies related to infant and child health issues, It identified major influencing factors on infant feeding patterns and explore significance association between infant feeding patterns and mothers age, education, occupation and family income, and on other hand the study didn’t find any association between infant feeding pattern with number of household members and residence.

**Recommendations**

1. Promotion of early starting breastfeeding during the first hour of life with establishment of consultancy clinic about infant feeding problems.

2. Follow up implementation of (Ten steps) of successful breast feeding and further studies about breastfeeding practice and problems are highly indicated.

**Ethical Clearance:** Taken from the (Health Directorate of Najaf).

**Source of Funding:** It was self-funding.

The Biosynthesis of Silver Nanoparticles by *Moringa Oleifera* and its Antibacterial Activity

Hajir Ali Shareef¹, Nehan Bahaaldden Jafar¹, Rosure Borhanalden Abdulrahman²

¹Department of Biology, ²Department of Physics, College of Science, University of Kirkuk, Iraq

**ABSTRACT**

The study was aimed to synthesized and characterization of silver Nanoparticles (AgNPs) from *Moringa oleifera* (*M. oleifera*) leaves and seeds extract, and to investigate the antibacterial activity against gram-positive (*Staph.aureus* and *Enterococcus faecalis*) and gram-negative (*Pseudomonas aeruginosa, Acinetobacter lwoffii, Shigella spp, Citrobacter spp, Alcaligenes spp, and E.coli*). The synthesized nanoparticles was characterized by UV-visible and Fourier transform infrared (FTIR) spectroscopy. The result of UV-visible reveals broadband absorption for both leaf and seed extract. The FTIR analysis showed that AgNPs contains the functional groups. The antibacterial activities against mentioned pathogens were done by using agar well diffusion method, the considerable inhibitory action for both leaf and seed extract were observed both in gram-positive and gram-negative bacterial isolates.

**Keyword:** AgNPs, Antibacterial activity, *Moringa oleifera*

**Introduction**

Bulk silver has been known for antibacterial activity since ancient times, where it used to maintain food and water fresh¹. As a result of reducing the size of bulk material to the nanoscale, the continuous energy levels are changed to discrete energy levels consequently nanomaterials may present unusual properties². Thereafter, the discrete energy levels in metal nanoparticles may develop a novel optical response due to collective oscillations of free electrons which are called surface plasmon resonance (SPR). Moreover, metal nanoparticles show remarkable shape dependent physical properties³ thus nanotechnology plays a prominent role in the evolution of many fields. Silver nano particles (AgNPs) show extraordinary response in many important applications such as drug delivery to inhibit cancer tumor growth⁴, the incorporation of AgNPs in the filter layer can deactivate *Escherichia coli* and *Enterococcus faecalis* bacteria in water treatment systems⁵, Localized surface plasmon resonance (LSPR) property can increase the enhancement of light absorption in solar cell devise about 65% for different shape nanoparticles compared to spherical AgNPs(3). AgNPs have been synthesized by several techniques such as chemical and biological reduction⁶, photo-mediated⁷, microwave⁴, laser ablation⁸ and gamma irradiation⁹. These methods have successful productions of AgNPs, but there are some undesirable synthesize steps for instance use of toxic chemicals and high fabrication cost. Green chemistry is an efficient alternative eco-friendly and cost-effective biosynthesis method of AgNPs fabrication by using plant extract¹⁰ as a reducing agent. Consequently, we describe the formation of AgNPs using aqueous extract of *M. oleifera* leaves and seeds as a reducing agent.

**Materials and Method**

Fin powder of leaf and seeds of *M. oleifera* were purchased from the commercial market. The selection of plants was based on its content of important antioxidants that act against free radicals in the human body. The plant powdered were sterilized in an autoclave at 121°C for 15 min. For the preparation of the aqueous leaf extract, 10 grams of leaf powder were mixed with 100 ml of sterile double distilled water (DDW) then boiled in a water bath at 50°C for 20 min. Using sterile filter paper (Whatman No. 1) the obtained leaf extract
was filtered into a clean conical flask then centrifuged at 6000 rpm for 20 min. The supernatant of solution samples was stored at 4°C for further studies. The same method was followed to prepare seed extract. To prepare 1mM of silver nitrate (AgNO₃) solution 16.987mg of AgNO₃ powder was added to 100ml DDW and mixed thoroughly, the solution stored in a dark bottle. For biosynthesis of Ag NPs, 90ml of 1mM AgNO₃ solution was taken in 250ml Erlenmeyer conical flask and 10ml of the aqueous extract of leaf was added to it, the solution was mixed well and incubated in a rotating shaker set at 200 rpm for overnight at room temperature in dark condition, visual observation was conducted, forming of brown to black color solution indicating the formation of Ag NPs. The same method was followed to synthesize AgNPs from seed extract. The solutions used for further characterization and antibacterial studies.

Characterization of Silver Nanoparticles

UV-VIS Spectra Analysis: The formations of AgNPs were monitored to investigate the performance of the bio-reduction of silver nitrate by leaves and seeds extract of M. oleifera plant carried out using a double beam ultraviolet-visible spectrophotometer (T92+ UV Spectrophotometer, PG INSTRUMENTS). Specimens were loaded into a 1cm path length cuvette for analysis. The UV–Vis spectrophotometric readings were recorded at a scanning speed of 2 nm intervals were scanned from 190 to 900 nm. UV–Vis analysis of two months old samples was furthermore carried out to check the immutability of AgNPs. Fourier Transforms Infrared Spectroscopy (FTIR)

Fourier transforms infrared analysis (NICOLET IR 100 FT-IR) spectrophotometer was measured for M. oleifera leaf and seed extract silver nanoparticles were dried and mixed with Potassium Bromide and pressed using hydraulic press to form pellets.

Evaluation the Antibacterial Activity of Biosynthesized AgNPs: The effectiveness of synthesized AgNPs against bacteria was investigated using agar well diffusion assay eight pathogenic bacteria, two gram-positive bacteria (Staphylococcus aureus and Enterococcus fecalis) and six gram-negative bacteria (Pseudomonas aeruginosa, Acinetobacter lwoffii, Shigella spp, Citrobactor spp, Alcaligenes spp. and E.coli) were isolated from food and different clinical specimens and identified by recommended conventional, biochemical tests and API systems. By using pour plate method, 1ml of fresh overnight culture of each isolate was placed uniformly into in the center of sterile Petri dish using a sterile pipette, then 20ml of Muller-Hinton agar was poured in each plates containing the inoculum and blended well, after the solidification, the plates were bored utilizing cork borer (6mm) to create four wells on each plate, then silver nanoparticles (20µl, 15µl, 10µl, and 5µl) aliquots were placed into each well on all plates and allowed to diffuse at room temperature for 15-20 min. The previous procedures followed by incubation of the plates at 37°C for 24 hours. The assessment of antibacterial activity was done via determining the diameter of the growth inhibition zone formed against the target bacteria. Aqueous plant extract and the aqueous solution of AgNO₃ were considered as comparative controls.

Results and Discussions

Synthesis of Silver Nanoparticles Using M. Oleifera: Primarily identification of silver nanoparticles synthesis was done by visual observation, an appearance of brown to black color in the reaction mixture denote the formation of nanoparticles. The leaf extract shows light brown color while seed extract shows yellow color before the addition of silver nitrate and these changed after 24 hours of incubation into black color indicating the completion of reaction as shown in fig 1.

![Figure 1](image-url)

**Figure 1:** (a) The aqueous extract of leaf and seed without silver nitrate, (b) The aqueous extract of leaf and seed with silver nitrate before incubation and (c) Visual observation of biosynthesis of silver nanoparticles using M.oleifera after 24 hours incubation
The formation of black color in plant extract indicates the silver nanoparticles formation. Previously it has been reported that the aqueous solution of AgNPs display a brown color as a result of the excitation of surface plasmon phenomenon\textsuperscript{11}. The color change of *Hemidesmus indicus* leaf extract from light brown to dark black was observed\textsuperscript{12}. Complete bio-reduction of Ag\textsuperscript{+} from *Aloe vera* leaf extracts happened within 24 h\textsuperscript{13}. At a reaction temperature between 60℃- 80℃ stated a rapid synthesis (within 10 min) for AgNPs by using *M. oleifera* leaf powder\textsuperscript{10}. In the presence of direct sunlight immediate reduction of Ag\textsuperscript{+} by *M. oleifera* leaf extracts occurred, while a complete reduction happened after 1h, which was indicated by the color change of the reaction solutions to dark brown\textsuperscript{14}. In the present study the complete reduction occurred after 24 h at room temperature, this appears to propose that the time desired for nanoparticle formation alter depending on the nature of reducing agent.

**UV-VIS Spectroscopy:** In the wavelength region 190-900 nm, the absorbance is enlarged as shown in fig.2. The presence of AgNPs results in a large and very broad absorbance enhancement cover the entire ultraviolet and visible spectral range moreover some parts of near IR range for both *M. oleifera* leaves and seeds extract. According to the Mie scattering theory, a broadening suggests an increase in nanoparticle size, where for particles above 30 nm Multipolar modes can emerge in the extinction spectrum due to the retardation effect as well as to the red shift in the spectrum\textsuperscript{15}. Figure 2 revealed that leaves extract produced the largest absorbance intensity between 520-830 nm compare to seed extract which is attributed to the formation of polydisperse AgNPs\textsuperscript{3}. The maximum absorption peaks of nanoparticles and nanoprisms have been reported about 400 and 600 nm, respectively, which originate from the LPRs of two various shapes of NPs. After mixing nanoparticles and nanoprisms Ag NPs, a broadband spectrum (covering the range 400-600 nm) is obtained\textsuperscript{16}. The formation of stable nanoparticles through the reduction of silver ions occurred rapidly, thus making it one of the fastest eco-friendly bio-reducing methods to produce silver nanoparticles. Moodley and his co-worker reported a maximum peak of spherical shape AgNPs at 450nm for *M.oleifera* fresh leaf extract and 440nm for *M.oleifera* freeze-dried leaf extract\textsuperscript{11}.

![Figure 2: UV–VIS spectra of AgNPs obtained using leaf and seed of *M. oleifera* extract](image)

**FTIR:** The FTIR analysis showed that Ag NPs contains the functional groups at 3538.03 cm\textsuperscript{-1} which is characteristic of hydroxyl stretching vibrations group in alcohols or phenolic compounds, 3444.81 cm\textsuperscript{-1}, 3398.79 cm\textsuperscript{-1}, 3352.68 cm\textsuperscript{-1}, 3323.06 cm\textsuperscript{-1} correspond to alkyne stretch group, 2656.53 cm\textsuperscript{-1} correspond to alkyl stretch group, 1837.48 cm\textsuperscript{-1} correspond to carbonyl stretch group for leaf extract as shown in fig. 3(a). Seed extract reveals a functional group at 3416.49 cm\textsuperscript{-1} which is characteristic of hydroxyl stretching group and 1640.34 cm\textsuperscript{-1} correspond to carbonyl stretch group as shown in fig. 3(b). These indicated that proteins and phenolic compounds were the capping and stabilization molecules in the biosynthesis of Ag NPs. Noteworthily, *M. oleifera* leaves are recognized to be an excellent source of many important nutrients including proteins, riboflavin, iron and is rich in various antioxidant phenolic compounds such as chlorogenic acid and quercetin that belong to flavonoid group which has been previously shown to have the robust chelating ability, this proposed that the reduction of Ag ions by quercetin might reduce the cytotoxic effects of silver nanoparticles(11).
Antibacterial Activity of Silver Nanoparticles: Antibacterial efficiency of silver nanoparticles against gram-positive bacteria (*Staphylococcus aureus* and *Enterococcus feacalis*) and gram-negative (*Pseudomonas aeruginosa, Acinetobacter lwoffii, Shigella spp, Citrobactor spp, Alcaligenes spp, and E.coli*) isolates performed by agar well diffusion assay and the activity was specified on the basis of the zone of inhibition. The results revealed that *M.oleifera* leaf and seed extract showed strong inhibition of gram-positive and gram-negative bacteria fig.4 and fig.5. Table1 summarizes the zone of inhibition measured, between all isolates tested the broadest inhibition zone was found to be for *Staphylococcus aureus*.

Owing to the broad-spectrum antibacterial activity of AgNPs which deduced from *M.oleifera* leaf and seed extracts AgNPs can be considered to have an effective inhibition action on both gram-positive and gram-negative bacteria. Seeing that gram-positive bacteria composed of thick peptidoglycan layer adjacent the cells plasma membrane while gram-negative bacteria contain a solid outer membrane structure which is consist of lipid bilayer and lipoproteins, this difference in the cell wall structure and membrane stability will not affect the mode of AgNPs inhibition. Many researchers investigated the antibacterial effect of biogenic silver nanoparticles solution against several pathogenic bacteria they reported different data in diameter of zone inhibition which might be because of the variation in AgNPs concentration furthermore, change in diffusion effects produced by agar medium composition.

**Conclusion**

An eco-friendly and one step cost effective green synthesis of AgNPs using *M. oleifera* leaf and seed extracts as an successful reducing agent was presented in this study. The synthesized AgNPs showed considerable antimicrobial activities against gram-positive and gram-negative bacteria. This biosynthesis clean, nontoxic and eco-friendly method could be a better substitution to the conventional AgNPs synthesis method and thus it has a prospective use in biomedical applications.

The Outcomes of Infants with HIV Infected Mother in a Tertiary Hospital in Indonesia

Hapsari Widya Ningtiar¹, Leny Kartina¹, Dwiyanti Puspitasari¹, Dominicus Husada¹, Parwati Setiono Basuki¹, Ismoedijanto¹

¹Department of Child Health Faculty of Medicine, Dr. Soetomo General Hospital Surabaya, Universitas Airlangga, Indonesia

ABSTRACT

Background: Infant from HIV mother face the risk of HIV infection. Effective prevention on mother-to-child transmission (PMTCT) program increasing the number of uninfected infants in East Java Indonesia. This study describes the outcomes of infants with HIV mother in Dr. Soetomo Hospital, a tertiary referral hospital in East Java, related to outcome (infectious morbidity, nutritional status, immunodeficiency status, growth/development, and incidence of anemia).

Method: This cross-sectional study analyzed 0-18 months infant and HIV mother pairs at HIV outpatient clinic Dr. Soetomo General Hospital from January to April 2017. The data were collected and analyzed using Fisher’s exact test and chi-square test with P<0.05.

Results: Fourty HIV-infected mothers and infants pairs were analyzed, separated into two groups positive (3 infants) and negative (37 infants) Anti HIV PCR. There were 19 male. Age distribution (6 weeks-5 months 40%; 6-11 months 47.5%; 12-18 months 12.5%). Five percent were born prematurely, 77.5% infant has normal birth-weight. Only 2.5% were fed breast milk, AZT-cotrimoxazole were given to 87.5% infant while the rest received AZT/3TC/NVP. Immunizations of the infants were mostly (60%) up to date. Infectious morbidity (P=0.433), WAZ-score (P=0.666), LAZ-score (P=0.973), WLZ-score (P=0.219) and incidence of anemia (P=0.548) were not significant differences between groups. The development test using DDST II (P=0.001), as well as immunodeficiency status [presence of immunodeficiency (P<0.001)] was significantly different between groups.

Conclusion: There were significant effects of HIV exposed on the development and immunodeficiency status in 0-18 months infant.

Keywords: HIV-exposed infants, outcomes, Prevention on mother-to-child transmission/PMTCT.

Introduction

HIV infection in children has become a major problem in family, community, and health care throughout the world. Most of the causes of HIV-exposed-infected (HEI) children are a vertical transmission from mother to infant. HIV infection progression occurs very quickly in the first few months after birth. It often leads to death.¹ HIV-exposed-infected infants are infants born to mother possessing HIV positive and/or positive antibody results. HIV-exposed-uninfected (HEU) infants are infants with negative PCR DNA results.²

Vertical HIV transmission was first reported in 1983.³ It was estimated that 1.8 million children under 15 were HIV infected in 2017. About 180.000 children were newly infected with HIV, mainly through transmission of the virus from their mother during pregnancy, delivery, or breastfeeding.⁴ An estimated 110.000 children died of AIDS-related causes globally. HIV-infected infants through mother-infant transmission...
significantly increase the risk of death, in which 20% of them who do not receive therapy during the perinatal period will die within 1 year.\textsuperscript{3}

HIV related to infant mortality increases in 2-3 months of age and can only be addressed with Prevention of Mother to Child Transmission (PMTCT) by limiting the vertical transmission and providing initial therapy for HEI infants. A study in health outcomes of HEU infants has increased in the past decade. Several studies suggested that these infants have increased mortality rates, infectious morbidity, and impaired growth compared with HEU infants. However heterogeneous results might reflect the inherent challenges in the study of HEU infants.\textsuperscript{3} This research evaluates the outcome of HIV-exposed infants from infected mother in Dr. Soetomo Hospital related to infectious morbidity, nutritional status, immunological status, growth and development, as well as incidence of anemia.

Method

This research was a prospective cohort, conducted at Child Health Department, Dr. Soetomo General Hospital Surabaya within January 1\textsuperscript{st}-April 30\textsuperscript{th}, 2017. Data were taken through history-taking, physical, and supporting examination. The research subjects were all 0-18 months infant with HIV-infected mother in Dr. Soetomo General Hospital since January 1\textsuperscript{st}-April 30\textsuperscript{th}, 2017. The status of HIV infection determined by the Anti HIV PCR DNA or RNA test. The inclusion criteria are 0-18 months infant with HIV-infected mother diagnosed either before or during pregnancy, during or after the delivery and infants whose parents have agreed to participate as research sample and have signed informed consent. Parents who withdraw participation were excluded. Data collected were age, gender, nutritional status, gestational age, birth-weight, birth history, breastfeeding history, immunization status, mother’s and infant’s ARV, and infant condition (infectious morbidity, incidence of anemia, immunodeficiency status, growth and development). Infectious morbidity recorded as present if there were diarrhea, fever or cough more than three times all their life. Definition of anemia was according to WHO (Hb<13.5g/dL). Descriptive analysis were performed using Fisher’s exact test, chi-square test with significant value when P<0.05.

Results

A total of 40 infants with HIV-infected-mother were analyzed and divided into 2 groups positive (3 infants) and negative (37 infant) Anti HIV PCR DNA or RNA. No patients were excluded. Characteristics of research subjects are listed in table 1. In this study there were 3 infants infected of HIV infection, 2 infants with no PMTCT (spontaneous delivery, mother with no ARV, breastfeed) and 1 infant with PMTCT after-delivery (no ARV before and during pregnancy). Infection morbidity occurred in 18 infants were 4(10%) diarrhea infection, 14(35%) cough, 7(17.5%) fever.

Discussion

This research described the outcomes of 40 infants born from HIV-infected mothers, 3 infants-infected with HIV and 37 infants were not infected. Two of HEI infants with no PMTCT program and 1 infant with PMTCT program after birth. One of HIV infected infant use only 1 type of ARV, while recommendations from ARV treatment in developing country recommend giving 3 types of antiretroviral drugs, for infants who have never received ARV during pregnancy. This is in accordance with the previous research in which HEU infants population will increase.\(^5\) It is said that an effective intervention PMTCT has decreased the HIV antenatal prevalence.\(^6\)

Infectious Morbidity: In the recent study found the prevalence of infectious morbidity possesses no significant difference in both groups. This result differs from Venkatesh study of HEI infant had over twice at risk of morbidity and over four-times at risk of death compared to HEU infants.\(^9\) Mofenson in 1999 founded that maternal PVL was not only a major predictor of the risk of perinatal HIV transmission,\(^10\) but may also closely predict viral levels in maternal breast milk and the health of both HIV-infected and HIV-uninfected infants.\(^11,12,13\) The risk of hospitalization due to diarrhea and pneumonia was close to four times greater among HEI than HEU infants. The most common cause of infant pneumonia requiring hospitalization in Rufini study population exhibited PCP.\(^14\) The source of data in this study comes from recalling interviews with parents so that there is a high probability of bias recalling.

Incidence of Anemia: Anemia has been recognized as an important clinical problem in HIV-infected patients\(^15,16\) with an estimated prevalence ranging from 10% in asymptomatic HIV-infected patients to 92% in patients with AIDS.\(^17\) This study exhibited no significant difference between HEI infants compared to HEU infants. History of administration of antiretroviral drugs and cotrimoxazole in HIV exposed infants did not result in an increased incidence of anemia. The high number of anemia in this study caused by high incidence of anemia in Indonesia. The 2001 Household Health Survey showed the prevalence of ADB in infants 0-6 months, infants 6-12 months, and children under five respectively at 61.3%, 64.8% and 48.1%.\(^18\) About 66.7% anemia occurred in HEI infants in this study. Anemia could be correlated with several factors as described in several previous studies such as advanced clinical and immunological HIV disease stage\(^19,20\), breastfeeding period\(^21\), highly active antiretroviral therapy (HAART), and cotrimoxazole.\(^7\) Further research is needed to determine the cause of anemia in this group.

Growth and Development: Research results exhibited that the effects of ARV regimens may cause deficits of height and abnormality of body composition. Treatment with ARV containing protease inhibitors had a significant impact on body weight and weight to height ratio and the limit of height. This is in line with research conducted by Kerr in 2014. It stated that growth failure is a sensitive indicator of HIV disease.\(^22\) In addition, the research of potential effects of the ARV regimen category leads to a deficit in body height and abnormality of the body composition. Treatment with an ARV regimen containing protease inhibitors has a significant impact on body weight and weight-to-height ratios as well as borderline effects on height.\(^9\) However, no significant differences in growth between HIV-exposed-infected infants compared with HIV-exposed-uninfected infants in this study.

The growth failure occurs in mother with antiretrovirals. As a result of the use of nevirapine in mothers, in this study the results were not statistically significant. According to Ram (2012) studies Infants who were HIV-infected and breastfed notes were higher risk of being stunted and underweight, but not wasted, and two variables were not statistically significant. Maternal anemia has significantly increased the risk of stunting but not underweight. Infant morbidity, increased risk of underweight and wasting, but not stunting. In this study maternal education data is absent so that it cannot be assessed, while breastfeeding history, birth weight, gestational age and delivery method have no significant relationship to the incidence of stunted, underweight and wasted.
Delayed development was assessed by the Denver Developmental Screening Test and the result was a significant difference between HEI and HEU infants in this study. These results are consistent with recent findings from a trial in South Africa, in which HIV infected infants randomized to deferred ART had lower locomotors scores at 11 months of age compared with HIV-uninfected infants. Another study in South Africa found differences in language and motor scores among HIV-infected-infants who had initiated ART at a mean age of approximately 5 months. They were observed for six-months and compared with HEU infants. The study showed significant differences between the two groups. About 5 infants in HEU and 2 infants in HEI. In HEU there is a high possibility that a developmental disorder will occur so that it needs longer observation.

**Immunodeficiency:** Recent studies revealed significant differences in immunological status between two groups according to CD4%. Two-infants with HEI suffers from severe immunodeficiency and 1 infant suffers from moderate-immunodeficiency. Infants with uninfected HIV infection, 3 suffers moderate-immunodeficiency, and 5 suffers from mild-immunodeficiency.

CD4 is the parameter to measure immunodeficiency in HIV infection. It was used in conjunction with clinical criteria, therefore CD4 can be used as an early indication of disease progression because it will decrease compared to clinical condition. Infants under 18 months require assessment on two important parameters (HIV-infection and %CD4) prior to initiating HAART. Infants who are positively identified as HIV-infected and meet clinical criteria are likely to benefit from HAART. In this study accordance with the course of the HIV, in HIV-infected patients the value of CD4 is much lower than that of those infected.

**Conclusion**

In conclusion, outcome evaluation of the presence of 0-18 months HIV exposed infants have determined significant value on immunological status and growth.

ABSTRACT

A landfill can have an impact on environmental quality such as air pollution from dust and gas produced from the anaerobic decomposition process, especially if waste disposal uses an open dumping system¹. The results of the preliminary study showed that scavengers in the final processing of garbage had not used PPE (Personal Protective Equipment) such as masks and did not use hand protectors. Many health complaints felt by them are low back pain and headache. This research was observational, the study design used was a cross-sectional study design. The location of the study was carried out at the Surabaya Benowo waste landfill, the sample in the study was scavengers of women who worked at the Surabaya Benowo waste landfill aged 15-64 years. The method of measuring TSP (Total Suspended Particulate) dust using laboratory tests with gravimetric methods, data on the use of PPE mask and respiratory complaints were obtained through questionnaires. Statistical tests were used to see strong relationships using Kendall’s tau-b with a significance value of α = 0.05. The results of the air quality test in the form of TSP dust content at the work site of the scavengers showed the results of 0.0972 mg/Nm³ which meant that TSP dust levels did not exceed environmental quality standards. Of the 37 scavenger respondents, 13 people (24%) experienced moderate respiratory complaints and 24 people (65%) experienced mild respiratory complaints. Characteristics of individual scavengers associated with respiratory complaints were cigarette exposure (Sig = 0.025) and disease history (Sig = 0.00). There was no significant relationship between the use of PPE with respiratory complaints suffered by scavengers at Benowo landfill Surabaya.

Keywords: TSP Dust, Respiratory Complaints, Individual Characteristics.

Introduction

The landfill is a place where waste reaches the last stage in its management from the start in the source, collection, transfer or transportation, processing to disposal.

Open dumping landfill will be a source of income for local residents, especially for people who do not have jobs and choose to become scavengers at the final processing of garbage.

The landfill can have an impact on environmental quality and scavenger such as air pollution from dust and gas produced from the anaerobic decomposition process, especially if waste disposal uses an open dumping system¹.

Air pollution is pollution inside and outside the room either by chemical agents, physics, or biology that changes the natural characteristics of an environment².
The results of a preliminary study conducted on December 23, 2015, showed that scavengers at Benowo landfill Surabaya did not use PPE such as masks and hand protectors. Many health complaints felt by them are back pain and headache. Low back pain and fatigue occur because their work is not ergonomic, such as constantly looking down to pick up garbage long time, and dizziness can be caused by sun exposure from morning to evening when they work.

**Material and Method**

Judging from the data collection method, this research is observational. The study design used in this study was a cross-sectional study design.

The location of the study was carried out at Benowo landfill Surabaya, precisely at the South IIB waste point. The sample in the study was scavengers of women who worked at Benowo landfill Surabaya 15-64 years old. The determine sample to be carried out during this research is by using Simple Random Sampling.

The variables in this study consist of independent variables and dependent variables. The independent variable in this study is TSP (Total Suspended Particulate) Dust, while the dependent variable is respiratory complaints.

How to measure the independent variables and dependent variables in this study include TSP Dust Based on East Java Governor Regulation No. 10 of 2009 using laboratory tests with Gravimetric, PPE (Self-Protective) mask methods through questionnaires and respiratory complaints through questionnaires. Statistical tests using Kendall’s tau-b with a significance value of $\alpha = 0.05$.

**Findings**

Benowo Surabaya landfill is located on Jl. Romokalisari Romokalisari Village, District Benowo Surabaya. has an area of 38.7 hectares, 24 of which are used for sanitary landfills consisting of 5 terminals and the rest are used for public facilities, there are green beams which are used as odor catchers around the landfill site and along to the terminal.

Every month there are only 2 terminals that are used for loading and unloading garbage, 3 are carried out by fireplaces and backfillers use the land. Garbage that is in Benowo landfill comes from all over the Surabaya area, the volume of waste that comes in a landfill is around 1,200 tons/day.

The results of the measurement of ambient air quality at Benowo Surabaya landfill show that the dust parameters are 0.0972 mg/Nm³ where the results are still below the quality standards set by Rule. Gub. East Java No. 10 the year 2009. Coarse dust particles can be filtered by a hair in the nostrils, while fine dust particles will become entangled in the mucus layer. In addition, high levels of TSP dust can endanger health because it can cause obstruction and restriction from the airways.

Respiratory complaints in this study diseases that have been or are being experienced by scavengers during the last three months, including coughing, phlegm, wheezing, shortness of breath, flu and chest pain.

Mild respiratory complaints in this study included mild coughing less than 4-6 times a day, flu for <3 weeks, and coughing up phlegm <3 months. While moderate respiratory complaints in this study include mild coughing up to 4-6 times a day, wheezing or wheezing, experiencing shortness of breath so difficult to walk, flu>3 weeks, coughing with phlegm for>3 months and chest pain.

**Table 1: Scavengers Mild And Moderate Respiratory Complain**

<table>
<thead>
<tr>

<td>35</td>
</tr>
<tr>
<td>Weight</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Total</td>
<td>37</td>
<td>100</td>
</tr>
</tbody>
</table>

From the table above it can be seen that scavengers who experienced mild respiratory complaints were 24 people (65%), while scavengers with moderate respiratory complaints were 13 people (35%).

Coughing is the most common symptom of respiratory problems. Stimulations that usually cause coughing are mechanical and chemical stimulation, dust inhalation, smoke, and small foreign objects are the most common causes of coughing.

The relationship of scavenger characteristics in the form of using PPE with respiratory complaints in this study showed that scavengers, using PPE experienced mild respiratory complaints of 13 people (65%) and severe respiratory complaints of 7 people (35%). Whereas with scavengers who did not use PPE...
experienced respiratory complaints as many as 11 people (65%) and experienced moderate respiratory complaints as many as 6 people (35%). The results of statistical tests obtained Sig=0.985, it can be interpreted that there is no relationship between the use of PPE with complaints of respiratory scavengers landfill Benowo Surabaya.

This is because the masks used by scavengers are masks that are specifically not intended to prevent exposure to harmful gases or dust, scavengers only use ordinary cloth or their veils for women to use to cover their noses, this is not the same as having no effect on exposure to incoming gas in the respiratory tract.

### Table 2: Age Of Cavengers Mild And Moderate Respiratory Complain

<table>
<thead>
<tr>
<th>Age (th)</th>
<th>Mild</th>
<th>Medium</th>
<th>Total</th>
<th>Sig</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-24th</td>
<td>2</td>
<td>33</td>
<td>6</td>
<td>100</td>
</tr>
<tr>
<td>25-34th</td>
<td>9</td>
<td>75</td>
<td>3</td>
<td>25</td>
</tr>
<tr>
<td>35-44th</td>
<td>9</td>

<td>2</td>
<td>40</td>
</tr>
<tr>
<td>55-64th</td>
<td>1</td>
<td>100</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

From the table, it can be seen that the scavengers mild respiratory complaints are the highest in the 25-34 age group of (75%). Whereas the biggest scavengers who experience moderate respiratory complaints are in the age group 15-24 by 67%.

Jatibarang landfill in Semarang, the results showed that complaints of health problems were more experienced by 43.3% female scavengers aged less than 39 years (young age) compared to aged female scavengers ≥ 39 years old (old age).

Based on the results of the research, the results of statistical tests using Kendall’s tau-b obtained Sig = 0.000 so that it can be interpreted that there is a relationship between the history of the disease

<table>
<thead>
<tr>
<th>Working Time</th>
<th>Respiratory complaints</th>
<th>Total</th>
<th>Sig</th>

<td>9</td>
<td>60</td>
<td>6</td>
</tr>
<tr>
<td>&gt;5 tahun</td>
<td>15</td>
<td>68</td>
<td>7</td>
</tr>
</tbody>
</table>

Most scavengers who experience mild breathing complaints are > 8 hours of exposure, which is 21 people (68%), while most scavengers with moderate respiratory complaints at exposure to ≤ 8 hours are 50%.

The longer a person’s exposure is likely the greater the risk of lung disease. This shows that the longer a person’s work will be the longer the time for exposure to the pollutant occurs.

Based on the questionnaire results related to individual characteristics that have been distributed to scavengers, it was found that was a significant relationship between exposure to cigarettes and respiratory complaints with a Sig value=0.025. From the results of the study, it can also be seen that 100% of active smokers experience moderate respiratory complaints and 40% of passive smokers experience moderate breathing complaints and 60% of passive smokers experience mild breathing complaints.

This is consistent with the research that cigarette exposure is a protective factor for pulmonary dysfunction in employees. Besides that, there is a significant relationship between smoking habits and respiratory disorders.

Based on the results of the research, the results of statistical tests using Kendall’s tau-b obtained Sig = 0.000 so that it can be interpreted that there is a relationship between the history of the disease.
and complaints of scavenger breathing at Benowo Surabaya landfill. In addition, the results of the study also showed that scavengers with a history of 71% had moderate respiratory complaints and 29% of scavengers experienced mild respiratory complaints.

The results of this study are in line with the research conducted that workers who have had lung disease are significantly associated with lung function disorders7. Likewise with research workers who have a history of pulmonary disease will find it easier to get pulmonary function disorders compared to workers who do not have a history of pulmonary disease8.

Conclusion

1. The results of testing the air quality in the form of TSP dust content at the work site of waste collectors showed the results of 0.0972 mg/Nm3 that TSP Dust levels did not exceed environmental quality standards according to the East Java Governor Regulation No. 10 of 20099.

2. Of the 37 scavenger respondents, 13 people (24%) experienced moderate respiratory complaints and 24 people (65%) experienced mild respiratory complaints.

3. Characteristics of scavenger individuals associated with scavenger lung physiological disorders, namely cigarette exposure (Sig=0.030) and disease history (Sig=0.00). While the characteristics of individual scavengers associated with respiratory complaints were cigarette exposure (Sig=0.025) and disease history (Sig=0.00).

4. There was no significant relationship between the use of PPE (Personal Protective Equipment) with respiratory complaints suffered by scavengers in the garbage dump in Benowo Surabaya.

Determinants of Breast Cancer in Eastern North Baghdad

Hiba D. Al-Ameri, Hayder K. Hanash Al-Jaberi, Mohammed Al-Hilli, Jawad K. Al-Diwan

1Early Detection Clinic of Breast Cancer, 2Head of Radiology Department, Al-Imamein al Kadhimaein Medical City; 3Chairman of Scientific Council of Radio-diagnosis and Medical Imaging, Medical City Complex-Baghdad; 4Dept. of Family and Community Medicine, College of Medicine, Baghdad University

ABSTRACT

Background: Breast cancer is the most common cancer affecting women all over the world. Breast cancer is the most frequent cancer among women in Iraq, it is account for approximately one third of the registered female cancers in Iraq. The age adjusted rate of breast cancer is 31.5 per 100000. Young women are at relatively higher risk for developing breast cancer than that in Western countries.

Method: A total of 300 case records of attendees to the early detection clinic of breast cancer in Al-Imamain al Kadhimaein Medical City. The sample was selected in systematic random sampling.

Results: Out of the total, 101(33.7%) were with malignant tumor. Age of menarche 12 ± 1 year was significantly earlier in malignant cases p<0.05. Breast cancer was significantly increased with age p=0.00. breast ca was significantly varied between marital status p=0.04. positive history of contraceptive use was significantly associated with breast cancer p=0.001. positive family history, positive lactating history and positive smoking history were not significantly associated with breast cancer p> 0.05.

Conclusions: Early onset of ca breast in Iraq. There is an urgent need for screening program.

Keywords: Breast cancer, Determinants, Baghdad, Iraq, risk factors.

Background

Breast cancer is the number one cancer in women across the world. It makes up 16% of all female cancers and accounts for 16% of cancer deaths globally.

Breast cancer is the most frequent cancer among women in Iraq, it is account for approximately one third of the registered female cancers in Iraq. The age adjusted rate of breast cancer is 31.5 per 100000. Young women are at relatively higher risk for developing breast cancer than that in Western counterparts.

Geographical variations in incidence and mortality rates of breast cancer suggest that the known risk factors for breast cancer may vary in different parts of the world and environmental factors are of greater importance than genetic factors.

The population, cultures, religious, habits, and knowledge of women in eastern Mediterranean region (EMR) is different from the women lived in developed countries. Majority of women in this region knows little about screening methods of breast cancer. Differences in cultures, habits, and ethnicity. Differences in marital age, pregnancy features, age of menarche, and other important variations in risk factors of breast cancer in this region. In many countries such as Iran, Tunisia, Pakistan of this region the breast cancer diagnosis age is younger than other parts of the world.

Although more than half of all new cases of breast cancer in the world were diagnosed in the industrialized countries (i.e. North America excluding Mexico and Western Europe), more than three quarters of breast cancer related deaths occur in the developing countries. This discordance in incidence and survival is largely related to the lack of organized mammographic screening.

in developing countries, the advanced stage at diagnosis (>60% of patients are diagnosed with stage III/IV breast cancer in the developing countries), poor access to care, and substandard treatment regimens\(^7\)\(^-\)\(^9\).

The known most important determinant factors for breast cancer included: age, family history, genetics, personal history of breast cancer, radiation to chest/face before age 30, race/ethnicity, being overweight, pregnancy/breast feeding and menstrual history, using hormone replacement therapy (HRT), drinking alcohol, having dense breast, lack of exercise, and smoking\(^10\),\(^11\).

Identification of risk factors of breast cancer is essential for policy makers to plan preventive strategies.

**Objectives**

The goal of this study to identify the determinants of breast cancer in Iraq for future applying in screening program.

**Material and Method**

A total of 300 case records of attendees to the early detection clinic of breast cancer in Al-Imamain al Kadhimaein Medical City. The sample was selected in systematic random sampling. The required information was demographic data, age at menarche, family history of breast cancer, use of contraception, history of smoking, history of lactation and type of tumor (benign or malignant).

Chi square test was carried out to examine the association of studied factors on the malignancy. \(p\leq\)0.05 was considered significant.

Student’s \(t\) test was done to examine the difference in means of age and age of menarche.

**Results**

Out of the total, 101(33.7%) were with malignant tumor. In 271(90%) the mass was self-detected and 22(7.3%) were detected in clinical breast examinations.

In malignant cases the age at menarche was 12±1 year and in benign cases was 13±1 year. The age of menarche was significant lower in malignant cases than that in benign cases (\(t=4.6, df=298, p=0.000\)).

The age of women with malignant cases was 5(15%) in the 2nd decades, 21(24.7%), 34(31.5%), 30(58.8%) and 11(73.3%) in the 3rd, 4th, 5th, 6th, and 7th decades respectively. It was shown that the breast cancer increased with age (\(\chi^2 = 36.2, df=4, p=0.000\)).

Breast cancer was noticed in 10(23.3%), 74(33.2%) and 17(50.0%) in the unmarried, married, and divorced, widow & separated, respectively. The breast cancer was significantly varied between the marital status (\(\chi^2= 6.17, df=2, p=0.04\)).

A mass was the main presenting symptoms in 73(54.1%), pain in 12(18.5%) and mass with pain in 13(15.3%). Mass was significantly the dominant presenting symptoms (\(\chi^2= 51.5, df=6, p=0.000\)).

Positive family history was noticed in 25(35.7%) of women with breast cancer. The positive family history was not significant associated with breast cancer (\(\chi^2=0.17, df=1, p=0.6\)).

Positive history of contraceptive use was observed in 39(48.8%). It was significantly associated with breast cancer (\(\chi^2=11.1, df=1, p=0.001\)).

Sixty seven (33%) of women with breast cancer gave a history of lactation. It was not significant associated with breast cancer (\(\chi^2=0.12, df=1, p=0.7\)).

Positive smoking history was noticed in 9(52.9%) of breast cancer. No significant association between breast cancer and smoking (\(\chi^2=2.99, df=1, p=0.08\)).

**Discussion**

This study revealed that 90% of cases detected the mass by self-examination. In the absence of developed screening program for breast ca in health service, Iraq depends on breast self-examination as a screening method. In the last 2 decades, early detection centers were developed. Deterioration of health system in Iraq due to wars and widespread violence lead to neglecting screening program for breast ca.

The clinical breast examination revealed a mass in breast in 7.3%. A finding reflects a failure of health...
A mass in breast was a presenting symptom in 45% of patients (benign and malignant). This finding reflects the activity of Ministry of Health to create the early detection clinics.

The age of women with malignant tumor was 48 ± 10.7 years. It is almost similar to that reported in Iraq, Saudi Arabia (47-48.6) year and Iran (43.4-49.3) year. The observed figure (48 ± 10.7 year) is lower than that reported in Australia, Denmark, Sweden and UK 62.5 years range (60.6-63.9) years. The difference might be explained by the difference in life expectancy.

The highest frequency 33.7% of malignant cases were at age group (41-50). The observed figure is similar to that in other studies in Iraq and that in the region (Bahrain and Oman). It is higher than those reported in USA and France. This difference might be attributed to the higher proportion of women aged < 50 years old in Iraq and generally in developing countries. The proportion of women < 50 years old in Iraq has 82%. It might be due to genetic, contraception use, westernization lifestyle including late marriage, late age at first birth, less number of pregnancies, less breast feeding duration and westernization of diet.

The mean age of menarche in malignant cases were 12 ± 1 year. It is significantly earlier than that in benign cases 13 ± 1 year. Early menarche ≤13 are well documented as a risk factor of breast cancer.

High frequency of malignant cases with positive family history of breast cancer (35.7%) is similar to that documented in Iraq. Low frequency of positive family history in Japan and Nigeria. It might be explained by the fact customary consanguineous marriages. This phenomenon may be due to tribal factors in Iraq.

Age of malignant cases with positive family history (46 ± 10 year) was lower than that of malignant cases with negative family history (48.6 ± 11 year). Similarly it was reported in Morocco.

Contraception was significantly associated with cancer breast (p=0.001). Similar finding was reported in Iraq. Contraception users constitute 48.8% from those with breast cancer. This proportion is higher than that in Iran and lower than this study in Bangkok. This difference might be explained by memory biased. Several brands with different concentrations are available in the Iraqi market might be interfered with this finding.

Smoking and breast cancer were not significantly associated. Inconsistent with that in literature. This finding might be explained by the fact that smoking is a stigma to female, so that they hide that in history taking.

The proportion of breast cancer was high among widow, divorced and separated than that among married and unmarried (p=0.04) similar finding was reported in Iraq.

Breastfeeding is of particular interest as a modifiable risk factor for breast cancer. No significant association of negative lactation history with breast cancer was observed (p=0.7). It is in contrast with that in this meta-analysis. This finding might be explained by the insufficient information in the case records. This lack of information explained by deterioration of health system in Iraq.

Conclusion

Early onset of breast cancer in Iraq. There is an urgent need for screening program of breast cancer. To establish guideline for screening of breast cancer.

Influence the Awarding of a Purple Sweet Potato Snack (Ipomoea Batatas Poiret) and Flour Anchovies (Stolephorus) in Toddlers Stunting in The Region of Clinics Paccerakang Makassar

Hikmawati Mas’ud1, Siti Nur Rochimiwati1, Zaki Irwan2, Rudy Hartono1
1Department of Nutrition, Makassar of Health Polytechnic, Indonesia; 2Mamuju of Health Polytechnic, Indonesia

ABSTRACT

An increase in the incidence of disease caused by stunting along with the occurrence of degenerative diseases. Directly caused less intake of less and the presence of infectious diseases. Indirectly, such as the environment, social cultural and economic. One of the alternative treatment with primary food intake increases and the granting of a snack. This research aims to know the influence of awarding the purple sweet potato and snack flour anchovies on childhood stunting. Quasi experimental design research approach pre test post test with the control. Samples taken toddlers suffering from stunting. The location was done in Makassar and Mamuju. Snack made from purple sweet potato and flour anchovy designed with value energy 160 calories and protein 3.5 to 5 grams its serving a day given once. The results obtained occurs gaining weight and height on both treatment and control means both before and after the intervention. But if the comparison group treatment and control are not meaningful. Nutritional status before treatment index TB/U short and very short 26 (86%) on the Group’s treatment and 26 (86%) on the group control and after treatment in the treatment group 26 (86%) and group control 15 (50%). Index BB/TB before treatment thin and very thin on treatment group 4 (13.3%) and on the group control 11 (36.6%) after treatment group treatment 26 (86%) and group control 22 (73%). Conclusion change of nutritional status improved in smaller treatment group. An increase in weight and height but have not yet reached the standard. Suggestion allotment of purple sweet potato and snack flour anchovy can proceed given to toddlers.

Keywords: snack, purple sweet potato, flour anchovy, toddler stunting.

Introduction

Less nutritional problems and malnutrition to date this has not been resolved completely. The results of the monitoring of the nutritional status of infants (0-59 months) years 2016 nationally with the index BB/U the malnutrition 3.4% and 14.4% less nutrition1,2,6. According to index TB/U children extremely short 7.5% and 19.1% short. While according to index BB/TB and the very thin 7.5% and the skinny3,4,5. Picture in South Sulawesi as follows based on the index BB/U children suffer malnutrition 4.4% and 16.5% less nutrition. For index TB/U children extremely short 7.5% and 19.1% short3,8,15. According to index BB/TB and the very thin 7.5% and the skinny8,10,14.

The cause of the problem of malnutrition is a factor. Factor in the risk of children suffering from nutritional problems is less intake, presence of infectious diseases such as ISPA, measles, diarrhoea, intestinal worms. Other factors such as the environment (means, clean water), social culture and economy. Short term relief is correct the child’s diet and intake, cure a variety of ailments suffered companion infection or disease. For the long term is to improve income levels (economic) family12,13,17.
The impact of this nutritional problem in the long term would interfere with growth and development and child health. This will cover the impact of cognitive and skills to work. This will result in the generation of low-quality, not being able to compete globally\textsuperscript{18}. One of the programs the Government in solving the main nutritional problems prevent a high number of stunting is additional feeding. Food additives can be a snack such as a purple sweet potato and snack flour anchovy.

Anchovy is a local food with a variety of advantages, can be consumed fresh or processed into flour. Benefits for the growth and development of brain function in children as well as the health as prevention of heart disease. This is supported by the high protein content, fatty acid omega three levels as well as vitamins and minerals\textsuperscript{7}.

Purple sweet potato is a local food with a variety of advantages and beneficial to health. High fiber, low carb, rich in antioxidants and vitamins and minerals. The disadvantage is its low protein content\textsuperscript{18,19}. To make the purple sweet potato processed can be enhanced with the addition of flour protein value of anchovy. New food produced like a snack have a better nutritional value and can be consumed by people including children are toddlers.

Still high toddlers suffering from stunting his food intake needs to be increased. One of the ways that can be done is by the giving of snack made from purple sweet potato ingredients flour and anchovy\textsuperscript{19}. Awarding of purple sweet potato and snack flour anchovy is expected to be beneficial in increasing weight and height child stunting. The purpose of the study is to know the influence of awarding the purple sweet potato and snack flour anchovy against stunting toddler nutrition status.

### Material and Method

The research method used was quasi experiment pretest and posttest control group. Before given a snack both groups rated the status of its nutrition value. Next to the Group’s treatment was given a snack for one month (30 days) while the control group not given the treatment. After the intervention of two groups finished re-assessed the status of its nutrition value\textsuperscript{10,15}. The results were analyzed in descriptive and statistical test using paired T-test.

The population is all of the toddlers who experience stunting work area clinics Paccerak kang in Makassar and the toddler in the working area clinics Kaluku Mamuju.

Sample treatment is a toddler who suffered stunting a work area clinics Paccerak kang selected random simple. Sample control is a toddler who suffered in the region a stunting clinics Kaluku Mamuju. The respondent was the mother of a toddler sample. Great sample treatment and control groups each of 30 children. Sample criteria is age 11-60 years and healthy time of data collection. The measured variable is the status of child nutrition toddler and children’s food intake. Data on nutritional status in Anthropometry with index BB/U, TB/U and BB/TB. Measured parameters gender, age, weight and height. Book Anthropometry used WHO antro 2005. Food intake was measured by the method of the 24-hour food recall when, then analyzed the value of its nutrition value using DKBM. Analysis of the research done on variable descriptive statistics and analysis. To know of any changes before and after intervention with the test paired T-test

### Findings

Formulation of draft refers to the proportion of the nutritional value of snacks in the amount of 10% of the adequacy of energy and protein. The adequacy of the energy group 6-59 months of 1125-1600 kcal protein and 26-35 grams everyday. Therefore this snack designed 10% of adequacy of energy and protein so energy made 16 kcal and 3.5 to 5 grams of protein its portion is big and it is hoped children could spend. Snack purple sweet potato and anchovy flour that is made is:

1. Cake/bolu purple sweet potato and flour anchovies (163.8 energy kcal, protein 3.3 g/porsi)
2. The purple sweet potato Croquette mix and flour anchovy (161.8 6.0 energy grams protein and/porsi)
3. The purple sweet potato mud cake and flour anchovies (166.5 kcal of energy and protein 4.2 grams)
4. The purple sweet potato and Nugget flour anchovies (163.7 Kcal energy and protein 7.0 g/porsi)
5. The ball is the ball of purple sweet potato and flour taste salty anchovy (159.4 energy and protein 7.5 g)
6. The ball is the ball of purple sweet potato and flour anchovies (sweet) (163.0 energy and protein 7.5 g/porsi)
7. Prol the purple sweet potato and flour anchovies (153.1 Kcal of energy and protein 4.8 g/porsi)
8. Tarajong (156.0 kcal of energy and protein 3.6 g/porsi)
9. Talam Cake the purple sweet potato and flour anchovies (153.2 kcal of energy and protein 3.2 g/porsi).

**Research Variables**

**Changes in body weight, height, the intake of energy and protein:** Very stable weight influenced daily food intake and the conditions of measurement. When the officer less when weighing more can occur due to an attribute that is used the child forget the minimized state of the tool and weigh whether new or already measure or not for a long time. Children’s health conditions such as diarrhea, heat or fevers, vomiting cough long will have an impact on the child less appetite and cause weight loss.

The increase in weight occurred in both groups, the Group of treatment going on average increased weight of 0.5833 kg while in control group of 0.1300 kg. The larger increase in the Group’s treatment.

Height is more stable and the parameters that describe what happened in the past. Height children can’t go down. If the current high less than his normal reflects his past is indeed short at the time were born or mother suffering from malnutrition when she was pregnant. After birth the baby is not getting enough nutrient intake to catch up growth in the womb\textsuperscript{12,14,17}.

Child nutrition intake method using 24-hour food recall describing what is consumed over the past 24 hours ago are starting to wake up until the night before going to bed. Recall when at the beginning of the study and research on the end just gave an overview of the time and not give an actual description of what is consumed during one month. If linked with other parameters such as gaining weight then this intake has been giving the effect of a particular time subs. These changes can be seen in diagrams 1 to 4.

Discussion

Nutritional status is a reflection of the intake of nutrients and the body’s ability to use and exploit it are reflected in body size and proportions of the body. Parameter commonly used height, weight against age, the proportion of weight against height and other nutritional status according to the distribution of the index weight according to age (BB/U), height according to age (TB/U) and weight according to height Agency (BB/TB).

Nutritional status with weight loss index according to age (BB/U) gives an overview of the current state. In table 3 above seen less status and very less dominating group treatment and control group before the intervention. There is an increasing change after intervention of nutritional status is very less is becoming less good nutritional status on treatment group or the control group. This condition can be affected by intake and State of health of the child. The passive consumer is a toddler treatment where the intake is still very dependent on the mother or his running mate. On the other hand if the mother thinks her son can already self-sufficient so that it becomes less attention plus the children getting to know food courts. The consumption of snacks such as crackers, assorted biscuits and milk packaging is often given after the midmorning meal at lunch time and would not eat or given drink milk 2 cups of morning, noon and night. This can affect children’s food intake. Weight loss is a labile parameters are easy to change. This time the intervention assumption is only 30 days and at the time of research there were child illness (fever, flu and cough). It is like declaring the results of the research there is 2016 Siska relationship knowledge of pregnant women and the intake of nutrients with a baby born short in Karanganyar Regency and Ernawati 2013 also stated there is the influence of protein intake of pregnant women and the length of the body. In this study the increase relative height is small and this state of Affairs indicates that at this age children are indeed slow than the age of the baby.

Nutritional status with the index BB/TB provides an overview of the current state and past. On the Group’s treatment before the intervention there are 13 (43.44%) normal children and 14 (46.6%) children are thin and very thin 3 (3.3% 0 changed after the intervention of a normal kid into 16 (53.4%), skinny kid that 12 children (40%) the family and the very thin 2 children (6.6%), on the group control and the very thin 1 children (3.3%) a child has not changed, the skinny 6 children (20%) unchanged and the normal of the 23 children (76.7%) do not change. The increase of the very thin on the Group’s treatment caused the end of intervention child illness (fever, cough, flu). The same thing also happened in the control group that is a sick child but did not decrease the weight of the child. This situation can be seen in table 4.

Stunting has not yet reached normal levels. The granting of this snack can proceed as a healthy snack of the child and the family.

Conclusion

The conclusion of the Formula of purple sweet potato snack and anchovy flour to increase the intake of energy and protein toddler stunting. It has been created
by as much as 9 items snack for toddlers stunting but have yet to achieve adequacy nutritional stunting toddler. An increase in weight and height but not yet reached normal nutritional status.

ABSTRACT

The definition of the Newcastle disease (ND) under the World Organization for Animal Health strategy is that chicken which infected with ND virulent (NDV) strains of avian paramyxovirus (APM). The current work included the identification of pathogenic properties (PPs) of serotype 1 belongs to AP that was detected in samples collected from severe-ND-affected chickens. The detection was performed measuring heamaglutination inhibition (HI), intracerebral pathogenicity index (ICPI), and mean death time (MDT) for in vivo exploration and real time-quantitative polymerase chain reaction (RT-qPCR), restriction enzyme analysis (REA), and DNA sequencing of the F2/F1 cleavage site for the in vitro investigation. This study is the first genetic-based analysis of the ND virus in Iraq. Complete correlation between the in vivo and in vitro results was recognized. The findings of the in vivo investigation showed that the strain was pathogenic and at the same time the structural patterns of the restriction plus the sequence of the amino acids were typical for virulent strain which resemble with 99% Iranian strain.

This study adds new information about the pathology and antigen distribution of this novel virus in Iraq and additional work is needed to get a complete data base of viral diversity and procedure for vaccinating and eliminating from this disease in our country.

Keywords: New Castle Disease, phylogeny, RT-qPCR, sequencing

Introduction

Newcastle disease can induce serious production losses in poultry industries for the occurrence of mortalities in high rates1,2. The etiological factor responsible of causing the ND is a virulent strain, APMV-1. The virus is categorized under the Paramyxoviridae family, the Mononegavirales order, and the Avulavirus genus. The disease is widespread in Iraq encouraging for continuous surveillance regarding identifying newly emerged strains of the ND virus. For the viral structure, the genome is presented in a single-stranded RNA that shows six-modular-protein-coding genes, 30-NP-P-M-F-HN-L 5'. Moreover, the ribonucleoprotein complex of the virus is made from a nucleoprotein, a phosphoprotein, and a large protein. The complex play important roles in replication of the genome plus expression of mRNA4. Intracerebral pathogenicity index (ICPI) can categorize the APMV-1 into certain pathotypes classifying the viruses into genotypes that can be further explored using the phylogenetic analysis. Using the ICPI, APMV-1 can be sorted into three pathotype strains: lentogenic, mesogenic, and velogenic. Using the metric provided by the (OIE), An ICPI of 0.7 indicates lentogenic typed strains, an ICPI range of (0.7-1.5) suggests mesogenic
An outbreak
All layers have pathological samples and tissue homogenates and stored allantoic fluid were collected, clinical and pathological samples, and then the collected and stored allantoic fluid were collected, clinical and pathological samples and tissue homogenates when flock suffered from signs of Newcastle Disease and the mortality rate reached 78% for about 10 days with the following symptoms:

The isolating of the NDV: Isolation was done in embryos of chicken eggs aged 9-11 days which inoculated with clinical and pathological samples, and then the collected and stored allantoic fluid were collected, clinical and pathological samples and tissue homogenates.

Materials and Method

Poultry Farms and Classical Tests: An outbreak occurred during March 2018, in Baghdad, Capital of Iraq. The farm composed from five caged houses 18 week layers with total number of 100,000 hens. The symptoms recorded were signs of respiratory involvement showing gasping, different degrees of coughing, rales, pronounced nasal discharge with dyspnea, recumbency, head tremors, decreased awareness, blood-stained diarrhea, head and throat-based swollen, and conjunctivitis. According to the presence of those signs, ND was immediately suspected, so that swabs of oropharyngeal and cloacal contents were collected from infected live and dead birds.

The isolating of the NDV: Isolation was done in embryos of chicken eggs aged 9-11 days which inoculated with clinical and pathological samples, and then the collected and stored allantoic fluid were collected, clinical and pathological samples and tissue homogenates on as micro-plate well as slide haemagglutination (HA) test with 0.1% and cRBC suspension that was prepared as described by\textsuperscript{11}. NDV identification applied haemagglutination inhibition (HI) test by employing HA positive samples with NDV hyperimmune sera elevated in chickens. Assessment of pathogenicity by ten samples were confirmed NDV out of 30. The pathogenicity was measured on basis of the highest mortality. In vivo depend on MDT in chicken embryos and the ICPI in day-old chicks. The MDT and ICPI tests were induced using a standard procedure revealed by\textsuperscript{12}.

Serological Diagnosis: Sixty swabs were used for serological diagnosis of ND virus antigen using Lilitest (Lillidale Diagnostics, England) Rapid ND Ag Test Kit to qualitatively detect of avian-secretion-based ND viral antigen (NDV Ag).

RNA Extraction: All samples were pooled on FTA spots (Whatman\textsuperscript{®} FTA\textsuperscript{®} card technology), each card contains four areas of samples, up to 100μl of homogenized plant/ per card. Four samples were pooled for each area. The compositions of FTA cards include some chemicals that act on lysing the cells, denaturing proteins, and protecting nucleic acids against the activities of nucleases, the oxidizing and UV-based damaging effects. The benefit is that nucleic acids are entrapped in the matrix fibers preventing transport-based damages, allowing immediate processing, or enhancing long-term ambient storage.

four cards were shipped to AniCon Labor GmbH I Muehlenstraße 13a I 49685 Hoeltinghausen I Germany, then viral RNA was extracted with the manufacturer’s instructions of Kyli\textsuperscript{®} RNA/DNA Purification kit.

Realtime-PCR: The real-time PCR reactions were run by AniCon Labor GmbH, Germany. Briefly, species-specific and variant-specific RT-qPCR method was utilized to identify APM-1, specific RT-qPCR Hybridization probe-based chemistry was used with the primers: (Kyli\textsuperscript{®} Paramyxovirus 1) (a).

Results

Clinical signs and postmortem exam: All layers have been vaccinated against Newcastle Disease many times, but the last vaccination was at 15 weeks old. At 18 weeks, the disaster started with infection of about 100,000 hens
Sudden onset with depression & prostration, decreased feed and water consumption. Signs of respiratory involvement showing gasping, different degrees of coughing, the presences of rales, and pronounced nasal discharge were noticed that were directly followed by CNS signs. Less than 22% have CNS signs - opisthotonus. The post mortem examination revealed inflammation with high severity of the tracheal inner surface and the air sacs, Mucosal presence of foci representing hemorrhages or necrosis in the intestines especially cecal tonsils. The proventricular and the gizzard isthmus mucosae showed severe hemorrhages with hemorrhagic spots present in the cloacae. The classical tests showed that the virus was velogenic strain as in table (1).

Serological Diagnosis: Results of rapid ND Ag Test Kit showed that Fifty-four swabs out of sixty positive results for diagnosis of ND virus antigen.

Real-time PCR: The viral RNA from FTA card (4 spots pooled) showed positive results for Avian Paramyxovirus serotype 1 (Newcastle Disease Virus, aPMV-1) with a method of serotype-specific Real-Time RT-PCR (Kylt® Paramyxovirus 1) (a).

A 360 bp fragment of the fusion protein coding gene of Paramyxovirus-1 (PMV-1) has been sequenced and a conceptual translation was generated. Based on the F2/ F1 cleavage site the pathogenicity of the analyzed PMV-1 strains was classified.

Sequencing of HA gene products and phylogenetic analysis: Based on certain amino acids in the fusion protein gene the sequenced strain carries amino acids typical for velogenic strains. The isolated RNA from sample show 99% identity to strain Newcastle Disease virus (Acc.No MG871466.1) that isolated in Iran as in figure-1.

Gene bank accession number: The fusion protein (F) of the NDVs were submitted to NCBI geneBank data base. The GenBank accession number was MK034858.1 under the name Avian avulavirus 1 fusion protein (F).

Figure 1: Phylogenic tree of Newcastle disease virus Iraqi isolates using MEGA X program software.
Discussion

In spite of heavy vaccination program submitted in Iraqi farms for NDV, the last 15 years, has been recorded major economic crisis in poultry production lines in different Iraqi provinces.

This study characterizes the clinical signs, gross lesions, and antigen distribution that resulted in a commercial hen flock after infection with NDV. According to symptoms, gross lesion, high morbidity and mortality rate (78%), The suspected diagnosis was that the infection is Newcastle Disease, but unfortunately, we don’t have all the facilities in our country to make genetic diagnosis. So, the aim of this study was focused on the detection and genetic characterization of the NDV after preliminary determination of infection with rapid ND kit detection.

All the positive results of the rapid kit test, HI, MDT and ICPI confirm the diagnosis of infection with velogenic strain of NDV. However, the current work gives genetic information of the NDVs circulating in poultry farms in Iraq and we precisely detected the presence of the virus that resembling with 99% with the Iranian ND strain in cooperation with AniCon Labor GmbH, Germany.

Poultry-based commercial and backyard rearing in countries of southeast Asia is the hugest in the world with the capabilities of inducing new emergent viruses especially those of virulent sub-genotypic strains of NDV. Informational reports from neighboring countries of Iraq showed the presence of various strain-based infections in those countries; however, factors stand behind the induction of a panzootic types of infections are yet not recognized plus the availability of adequate epidemiological or retrospective information required for understanding this induction is not present.

According to the presence of ND virulent strains, variation of the pathotypic, virulence evaluation (VE) of the isolated strains must be performed after routine viral identification. ICPI, in vivo, related techniques alone can be of a limited support in the VE of the strains; however, we used all the techniques (in vivo and in vitro) that confirm the accurate diagnosis for infection.

The F-protein-360-bp-fragment-related gene of the PMV-1 has been sequenced and a conceptual translation was generated. According to the cleavage site of the F1/F2, the pathogenicity of the analyzed PMV-1 strains was classified.

Based on the presence of certain amino acids in the sequence of the fusion protein gene, the sequenced strain was assigned to the velogenic PMV-1 strains. The isolated RNA from samples show 99% identity to strain NDV isolated in Iran, the neighbor of Iraq, and that may refer to the origin of infection and to the virus that circulated in the area.

Several countries of the Asia and middle east have large population and large backyard based raised of birds with uncontrolled market selling of backyard poultry and live birds leading to enhance the virulent NDV persistence presence and evolution as sometimes due to the lack of vaccination programs that target newly hatched chicks belong to the backyard birds. The poultry ND epizootics are persisted in Asia, Africa, Central and South America; however, sporadic epizootics are reported to occur in Europe. Consistent occurrence of ND infection is found in all the globe countries. The poultry mortality rate of the ND is considered among the highest. Millions of dollars estimated annually for the losses induced by ND worldwide. The genetic similarity between Iraqi virus and Iranian virus with a 99% may be due to legal and illegal transportation of chickens between Iraq and Iran. Frequently, the NDV studies regarding the evolution of the outbreak-diagnosed viruses have been performed between time and time. However, these studies were immunogenic-based but not genomic-based investigations to understand the viral properties. In addition, the vaccine-uncontrolled use has led to risk increases in the pathogenic alterations of the NDV. According to these, it has been become as an international important interest to launch research aiming at resolving these problems using methods such as NDV-based isolation and molecular characterization, genome sequencing, partial or complete, analyses for epidemiological, immunogenic, and evolutionary based characterization, and RT-qPCR assays that should be studied for its validity to increase protection and control awareness of the ND in future.

Although this study adds new information about the pathology and antigen distribution of this novel virus, additional work is likely needed to characterize this pathogen further and make a complete procedure for vaccinating and eliminating from this disease.
Conclusion

Our findings of the in vivo and in vitro showed that the strain was pathogenic and the sequence of the amino acids were typical for virulent strain which resemble with 99% Iranian strain.

This research adds new information about the pathology and antigen distribution of this novel virus in Iraq and additional work must be done to get a complete data of viral diversity and procedure for eliminating from this disease in future.

The Determinant Factors of Child’s Immunization Status: A Cross Sectional Study on the Dayak Pitap Tribe in the District of Balangan Indonesia

Ida Hastutiningsih1, Oedojo Soedirham2, M. Bagus Qomaruddin2, Boerhan Hidayat3
1Doctoral Student of Public Health Program, 2Lecturer, Department of Health Promotion and Behavior Science, Faculty of Public Health, 1Professor of Medicine, Department of Pediatric, Faculty of Medicine, Airlangga University, Surabaya, Indonesia

ABSTRACT

Background: Even if the immunization coverage in a region is high, but the unimmunized child gathered in one location, then the benefit from herd immunity developed will not be gained by the child in that location so the risk for outbreak vaccine preventable diseases is high. So in order to solve this problem, it is important to reach this under vaccinated population and increase the child’s immunization status of the population. The aims of this research were to describe the immunization status and its determinant factors that influenced the child’s immunization status of Dayak Pitap tribe in the district of Balangan Indonesia.

Method: A cross sectional study conducted in May to June 2018 which included the interview using a questionnaire with the mother of 12 – 35 month old child in all house hold in Dayak Pitap tribe. The independent variables were the mother’s education level, the mother knowledge about immunization, the history of mother immunization status during pregnancy and the childbirth attendant and the cultural determinant namely the aruh ritual, the papantang and the use of the samban, whereas dependent variable was the child’s basic immunization status. The uni-variable analysis and logistic regression analysis employed as the research analysis method.

Result: The complete child’s immunization status coverage was 48%. The determinant factors that significantly influenced on the child’s immunization status were the mother immunization knowledge level (p=0.000), the history of mother immunization during pregnancy (p=0.033), the history of birth attendant (p=0.000) and the using of samban by the children (p=0.012).

Conclusion: In order to gain the better child’s immunization status coverage of the Dayak Pitap tribe, it is important to develop combination interventions to give better knowledge about immunization to the mother with the tailor made material, promote birth attendant labor and reach the pregnant mother for immunization.

Keywords: Child immunization, indigenous tribe, cultural determinant.

Introduction

One of the purposes of immunization is to develop herd immunity in the community that can make all the children get benefit from the protection, including not immunized children and children who had already immunized but failure in developing antibody that can be caused by the child condition such as virus and bacterial infection(1), the nature and condition of the vaccine itself (2)(3) and the abnormalities of the immune system such as the hypogammaglobulinemia, other genetic factors and other causes that still poorly understood (4). In order to develop the herd immunity, high uptake of fully immunized children must be obtained. The problem is every country has population groups that are not fully immunized that have a consequence in the risk of vaccine-preventable disease outbreak.
Actually, in case there is a child, who is getting an infection of vaccine preventable diseases, but the high uptake of immunization has been obtained and the herd immunity has been developed, the other children will be protected because the spread of the infection had already blocked. However, this only works if unvaccinated child is scattered across geographical areas. If the unvaccinated child is gathered in one location, such as in the Dayak Pitap tribe, diseases can cause large outbreaks—even if the region or province or national vaccination coverage is high.

In this purpose, it is important to make sure that the immunization coverage in the remote areas is also high. However, based on the preliminary study that conducted in Dayak Pitap on January to March 2017, the fully immunized children coverage of the Dayak Pitap tribe was only 34.3% and from the in depth interview conducted with the traditional leaders, the balian (the traditional spiritual leader/traditional healers) and other community members, the reason for this low uptake of fully immunized children was probably because of the community belief about the causes of illnesses which are natural causes (heat, cold, rain), spirit of ancestor causes, shamanism causes, breaking taboos causes and other supra natural causes. This belief, therefore has an implication on the initiatives that they use to prevent illness, namely always conducted aruh ritual, not violate papantang and the use of a samban for their children. So besides the factors that have commonly stated as the determinant factors of the immunization coverage, in the Dayak Pitap tribe, the cultural factor such as the aruh ritual, the papantang and the samban probably also has a contribution in determining the child immunization coverage.

The aruh ritual is a ritual that conducted regularly by the Dayak Pitap tribe across the human life cycle and the rise cultivation cycle. The ritual filled with many kinds of sacred activities and materials, offerings and also rhythm that accompany the spell of the mantra and dance of the balian as the traditional spiritual leader. The absence of conducting the aruh ritual believed by the community can cause misfortunes and illnesses. The papantang or taboo is a form of oral prohibition to do something because it’s against the culture and community tradition, although there was no legal or customary sanction for the violator. The violation of papantang also believed by the community can cause misfortunes and illnesses. A samban is a kind of amulet that worn as a necklace by the child after conducting a sacred ritual and believed can protect children from illnesses.

This research conducted in the Dayak Pitap tribe that settles in the slope of Meratus highlands in Tebing Tinggi sub districts of Balangan, South Kalimantan Province, Indonesia. Although this tribe registered as Hinduism which is called Hindu Kaharingan, very little aspect of Hinduism exists in their everyday lives. They still maintain their belief and culture as animism and dynamism tribe.

Hence, the aim of this paper is to describe the immunization status and its determinant factors that influenced the child’s immunization status of Dayak Pitap tribe in the district of Balangan Indonesia.

Material and Method

This analytic observational quantitative research employed by a cross sectional design. The analysis unit was the household of Dayak Pitap tribe that had a 12 – 35 month old child. Data collected from all households that had a 12 – 35 month old child in May to June 2018 using a questionnaire. The respondent was the mother of 12 – 35 month old child.

The independent variables were the mother’s education level, the mother knowledge about immunization, the history of mother immunization status during pregnancy and the childbirth attendant and the cultural determinant namely the aruh ritual, the papantang and the use of samban, whereas dependent variable was the child’s basic immunization status.

Data analysis using the univariable analysis to describe the distribution of frequency and proportion of independent and dependent variables and logistic regression analysis to analyze the influence of independent variables toward the dependent variable.

Results

1. Socio-demographic characteristics of respondent and children of Dayak Pitap tribe: The majority of mother in Dayak Pitap were in 20 – 29 years old interval (60%) and had primary educational level (42%) and 90% were farmer. Their immunization knowledge level mostly was low (68%). Most of the mother had only one child (44%) with higher
female distribution (54%). 66% of the mother did not complete their immunization during pregnancy and 46% assisted by the traditional birth attendant when delivered their babies.

2. Immunization Status of 12 – 35 month old child of Dayak Pitap tribe

|        | birthattendant | -19.405 | -14.361 | 1 | 0.000 |
|        | arun | -12.810 | 1.172 | 1 | 0.279 |
|        | samban | -15.306 | 6.163 | 1 | 0.013 |

| Step 4 | knowledgelevel | -19.340 | -13.060 | 1 | 0.000 |
|        | historyofmotherimmunization | -15.070 | 4.520 | 1 | 0.033 |
|        | birthattendant | -19.405 | -13.189 | 1 | 0.000 |
|        | samban | -16.003 | 6.386 | 1 | 0.012 |

Based on the table above, the dependent variables that significantly influenced the independent variables were the mother immunization knowledge level (p=0.000), the history of mother immunization during pregnancy (p=0.033), the history of birth attendant (p=0.00) and the using of samban by the children (p=0.012).
Discussion

The complete child immunization coverage in the Dayak Pitap tribe was 48%, still far from the Indonesian Health Ministry target i.e. 92.5%. The highest coverage was in Kambiyain village i.e. 88.9% and the lowest was in Iyam village i.e. 20%. The highest immunization dose coverage was Polio1 i.e. 48% and the lowest dose coverage was DPT-HiB-HB3 i.e. 29%.

Based on the data analysis conducted, the independent variables that significantly had influenced on the child immunization status of Dayak Pitap tribe were the mother immunization knowledge level, the history of mother immunization during pregnancy, the history of birth attendant and the cultural determinant namely the use of samban. Whereas the mother education level and the cultural determinant namely the aruh ritual and the papantang were not significantly influenced the child immunization status.

Many research have shown that the mother immunization knowledge correlated with the child immunization status (8)(9)(10) and influenced the child immunization. Other research also shown that the mother with good immunization knowledge has 2.21 probability to fully immunized their children compare with the mother with poor immunization knowledge (10).

In this case, develop an intervention to increase the mother immunization knowledge with the combination with the other interventions still promising in order to increase the fully immunized child coverage.

The other determinant factor that significantly influenced the child immunization status in the Dayak Pitap tribe was the use of samban. Using some kind of amulet both for protection and curing not only known in Dayak Pitap tribe but also widely known in many traditional cultures such as in Narsinghdi district in Bangladesh (11), in Bedouin tribes of the Negev Southern Israel, Middle East (12), in Gaddis of Bharmour Himachal Pradesh, India (13) and most of tribal communities worldwide especially for the children (14).

Even if the using of samban significantly influenced the child’s immunization status, the intervention of this cultural variable is not easily formulated and need further research. Intervention with poor knowledge about the culture itself can result in negative consequences and can lead to worse health outcome. However, based on this research, health professional known that the using of samban was significantly influenced the child’s immunization status of the Dayak Pitap tribe.

The history of mother immunization during pregnancy and birth attendant also significantly influenced the child’s immunization status. These two variables actually correlated with the present of the care for pregnant women and labor that usually provided by the midwife.

As states by the WHO and other references, immunization is one of the most successful and cost effective health intervention achievement, has saved countless of children’s lives and increased health status in the world (15)(16). However, virus and bacteria do not respect border, if the disease still circulate in any part of the world the risk of outbreak still remained. In order to give all protection to all children the high uptake of fully immunized children must be obtained all over the world and to reach the under vaccinated, immunization programs need to develop tailored intervention to overcome the existing barriers.

Conclusions

The child immunization coverage of the Dayak Pitap tribe was 48%, lower than the Indonesian health ministry target i.e. 92.5%. The determinant factor that significantly influenced the child’s immunization status of the Dayak Pitap tribe were the mother immunization knowledge level, the history of mother immunization during pregnancy, the history of birth attendant and the cultural determinant namely the use of samban.

Hence, in order to gain the better child’s immunization status coverage of the Dayak Pitap tribe, it is important to develop combination interventions to give better knowledge about immunization to the mother with the tailor made material, promote birth attendant labor and reach the pregnant mother for immunization.

Study Immune Response and Serum Proteins for Scabies of Sheep in Middle of Iraq

Inam A. Nayyef

Department of Animal Production, College of Agricultural Engineering Sciences, University of Baghdad, Iraq

Abstract

Current study was detected on native Awassi sheep which devided into two groups included healthy and infected animals to highlight on relationship between scabies disease and interleukin 12 (IL – 12) Concentration also relation with serum proteins and leukocytes. The research demonstrated that infection influenced significantly (P<0.05) on globulin while total proteins albumin, globulin/albumin (glo/alb) not affected by incidence, there is no importance for scabies on neutrophils, lymphocyte, monocyte and basophils in serum which were 46.6%, 45%, 6.61% and 0.30% respectively and these rates reduced in healthy animals whereas eosinophils was 1.42% (P<0.01) for infested animals, correlation coefficient between scabies and each of IL – 12 was -0.176 (P<0.05) and highly significant reached to -0.350 with eosinophils but insignificant association found for lymphocyte, monocyte, basophils with infestation and these cells negatively linked with IL-12 were 0.118, 0.225 and 0.121 also lower with eosinophils was 0.097, on contrast side, positive relation with neutrophils become 0.188.

Keyword: Leukocyte, proteins, serum, correlation, IL – 12.

Introduction

Ectoparasites diseases have a negative role in livestock progression and one of them is scabies disease which occurred because of mites types inter stratum corunea, infection still unclear until wool shedding in most of infected animals which considered as indicator for infection spreading to reflect its negative effect on skin and wool damages in addition genetic material also immune cells1, productivity reduction and toxaemia thus, constraining herds breeding development hence, regression of health status for animal which depending upon body resistance to parasites presence and their residues, infections varied among small ruminants that received to 0.88% in Nigeria, most of infections related to Psoroptic was 7.46% among Iraqi sheep2 while wide spreading to 58.3% in Basrah3. Immune response to scabies is complex, mediator cells stimulated for disease causes in skin which surrounding with pre immflamatory cells that recognized and perform to cytokines secretion which responsible for immune effect in skin4. As a result of T cells, lymphocyte, neutrophils attendance which dominated kill burdern parasite therefore, immunity for unreplicated infection with scabies due to those mediators that produce pathogens to T memory cells5.

Cytokines various markedly and their response is normal and necessary in mast circumstances also secreted with limited concentrations in blood and damaged skin in addition pro infection inhibit phagocytes ability to grow and reproduction in inflammable area6. Various proteins found in blood widely different in function which concentrate in total protein thus, abnormal value for it determine health status of animal for that this study quested relation between scabies disease and serum protein also immune cells with IL – 12

Material and Method

The research done in animal farm which found at college of Agriculture, University of Baghdad for period from 1st July to 1st October 2018 on national sheep that had bred in open door pens and demonstrated drugs for anti endo parasites also strewing with anti-parasites to avoid and reduce infections as well as ocular diagnosis with scabies was considered to ensure happening of infections among animals

Blood samples collected from jagular vein in tubs without anti agglutination then clotted for ten minutes and centrifuged at 3000 r.p.m for five minutes to get pure serum which frozen at -20°C until analysis time
Serological Analysis: Total protein was estimated by biuret method\(^7\). For having albumin concentration in serum, Bromocresol green method used\(^8\). However, by adding the quantity of non-albumin proteins, globulin concentration was calculated, alb/glo ratio was determined manually. 1L – 12 levels in serum evaluated by using E11SA Kit. Blood put in vacutainers with anti agglutination EDTA and immediately translated to laboratory for counting differential leukocytes by covering glass slide with smears of fresh blood leishaman checking through microscope

Statistical Analysis: Mean square for serum proteins: total protein, albumin globulin, alb/glo, were recorded by using General Linear Model within statistical analysis system\(^9\) depending upon breeding records for parents whom have more than five offsprings, variance was estimated by Type 1 method to determine correlation coefficient between serum proteins and immune cells with both of scabies disease and concentration of 1L – 12\(^10\).

Results and Discussion

Association between scabies and serum proteins

Total protein: Total protein not affected by scabies which was 6.49 g/dl in infected and higher to 6.64 g/dl for healthy animals (table 1), this result agree with 24 who membered that reduction of serum proteins in case of infection due to hemorrhage because of homo dilution for velonis while total protein was higher for infected Desi sheep in South of Africa\(^11\) also received to 10 g/dl and 7 g/dl for infested and healthy animals which impacted significantly in Dera sheep in Pakistan\(^12\), less values of total protein were 4.75 and 5.42 g/dl for infected and healthier respectively in west Africa Dwarf sheep\(^13\).

Albumin: Infection not influence on serum albumin which declined to 3.67 g/dl for infection whereas it rised to 4.05 g/dl with those not infested (table 1), this result came at the same direction with findings of 16 on West African Dwarf sheep about insignificantly impact. Reduction of albumin production may be refer to acut phase response which associated with globulin yield so, albumin considered negative acut phase for protein so that, changes happen at conformation of amino acids and proteins in liver and that perform to change their concentration in blood docilely hence, reduce response for inflammation because of cutaneous infection\(^11\).

Globulin: Ecto parasitological infection has significant effect (P<0.05) on globulin concentration which increased to 4.43 g/dl at infestation and lower in healthy status was 3.08 gm/dl (table 1). Reason for raising globulin levels in serum with infection may be due to globulins that mediated immune response to protect host against parasites feedings on blood, these globulins produced from mast cells as a result of monocye and T lymphocyte action which contributed to TGF production that yield globulin A in addition increasing of globulin E which response to parasite infection\(^8\).

Albumin/globulin: Values of the ratio of glo/alb was high received to 1.80 and 1.65 respectively in each of sick and healthy animals, there is no effect of the disease on this ratio (table 1), this result dealing with study of 16 about non-significant effect. High values of this ratio probably back to increasing of immune globulins in serum

Relationship between leukocytes and scabies

Neutrophils: Scabies has not influence on neutrophils which was at higher percentage reached to 49.8% Vs 46.6% for both of infection and non-infection correspondingly (table 2), contrary to this finding affected animals have less rate of neutrophils was 23.3% and raised to 30% for healthier with high significant\(^13\). Increasing percentage of neutrophils at infested cases may be come from immune mediators production which stimulated by parasites in pre infection period that inhibit ability of phagocytes to migrate to dramatic inflammation locus so, these cells act as effective factors by phagocytosis and antigen representing also implicated as means to destroy tissues by filtering cells by phagocytosis\(^14\).

Lymphocyte: These cells still within normal values out of infection effect and received to 45% for infected and 41.46% for control group (table 2). Disagree with this result those indicated that lymphocyte impacted by incidence significantly and was 55% for sick while up to 60% for healthy subjects\(^11\). Normal values of lymphocyte in serum may be translocation higher numbers of these cytes to damaged skin area more than those in blood\(^15\).

Monophils: Monophils increased to 6.61% for infestation and declined to 5.20% for healthier also these rates not affected by incidence (table 2), while this rate dipped to 20% for both of healthy and unhealthy conditions\(^11\), monocyte increased in blood and represent pathogens to T cells to form anti bodies as well as for
memory after that leave blood to convert to phagocytes which remove destructions of mortile cells with attack pathogens agents

**Eosinophils:** These cells various significantly (P<0.01) by dermatic infection which reduced to 1.42% for infections whereas raised to 3.20% for healthy animals (table 2). 16 observed that higher rate of eosinophils in skin was 7.3% for incidence while declined to 4% for control significantly. Reduction of eosinophils in serum probably go to that monocyte transfer to damaged area in skin and little of them stay in blood and recruited to Th2 expression therefore, higher number of these cells in dermatic infection as local reaction because of parasites presence and residues, mast cells estimated by complement throughout releasing mediators such as heparin and histamine which eradicate eosinophils to inflammation site16.

**Basophils:** Scabies is not effect on basophils which were 0.30% and 0.26% for incidence and healthy animals respectively (table 2), this result coupled with conclusion of 16 for non-significant of infection in basophils rate which increased to 0.67% to illness and lower to 0.33% for healthy subjects. Monocyte affected mainly by skin sensitive as response secret heparin and histamine which extended blood vessels to be more permeability to pass blood to damaged tissues also neutrophils with angulation proteins then basophils release chemical signals to bring these cells in addition to eosinophils17.

| Table 1: Means of proteins concentration ± standard error for infected and health animals |

Relation between IL – 12 with leukocytes:
Lymphocyte and neutrophils in two opposite directions while monocyte coupled with lymphocyte when IL-12 concentration 0.13 – 0.17 mg/dl, monocyte trend to top and reached to 10% with reducing neutrophils to 47% and raised lymphocyte to 45% maximum to 64% while IL – 12 received to 0.21 – 0.25 mg/dl, rate of monophils, neutrophils, lymphocyte still steady at 5%, 45% and 50% respectively, eosinophils tend up to 6% and 10% with increasing of IL – 12 concentration to 0.25 mg/dl. According to basophils, rate grow with eosinophils but not coupled with IL – 12 concentration (fig 1). Monocyte, macro phagocyte, natural kill cells control on activity of immune cells that balance function of immunity and formation immune response so, expression changes of these cells perform to infection, in the same way, lymphocyte stimulate oxidants aspects of immune mechanisms that contribute in defence against infection and regulated it by cytokins which protect immune response in resistance genetically20. Eosinophils implicated as a result for parasites and sensitive induction then secret IL – 10 and IL – 12 which influence on persistency for wide range of parasites and other pathogens21.

![Figure 1](image)

**Figure 1: about relationship between scabies disease and IL – 12 with leukocyte**

Conclusions

Present study concludes that immune globulins affected by scabies disease which has a positive relation with eosinophils and negative with IL – 12 that not associated with leukocytes in serum so that, to increasing body immunity must be providing animals with a sufficient feeding and detection more studies about genes which controlled on this disease and immunity.

Trauma Mechanism, Length of Prehospital Time and Survival Rate of Head Trauma Patient

Irine Yunila Prastyawati, Teguh Wahju Sardjono, Setyoadi

1Emergency Nursing Master Program, 2Medical Program, 3Nursing Master Program, Faculty of Medicine, Universitas Brawijaya, Indonesia

ABSTRACT

Background: Trauma patient’s survival rate is influenced by trauma mechanism and prehospital length time. Trauma mechanism that often happens in head trauma is caused by traffic accident and falling incident. The period between the trauma and the arrival in Emergency Department can also determine the secondary head trauma and the survival of the patient.

Aims: The aim of the study was to analyze correlation between trauma mechanism and the length of prehospital time toward the survival rate of head trauma patient.

Method: Design of the study used was a cross sectional and retrospective approach. The sample was medical record of patients with moderate and severe head trauma from January 2017 to December 2018.

Findings: The total sample was 180 medical records data. Most patients were male with total of 129 patients (71.7%) and the average age is 43.63 years old. The chi square test found that trauma mechanism and survival rate showed the value of p=0.783 while spearman rank test result between the length of prehospital time and survival rate was p=0.000.

Conclusion: Trauma mechanism has no correlation with the survival rate of head trauma, whereas the length of prehospital time has negative correlation with survival rate of head trauma.

Keywords: trauma mechanism, length of prehospital time, head trauma, survival rate

Introduction

Head trauma is a global phenomenon in the world. The prevalence of head trauma rate is increasing. There are 67 to 317 of head trauma cases per 100,000 accident cases each year(1). The average head trauma rate in Indonesia is 8.2% and East Java is in the seventh rank with 9.3%(2).

The criteria of survival rate are categorized into each death time, namely immediate death, early death, and late death(3). Meanwhile, the survival rate of patients with head trauma is influenced by trauma mechanism and prehospital time. There are 90.3% of the patients survive and 9.7% non-survive due to trauma(4). There are 243 head trauma patients in the Emergency Department (ED) only 80% survived(5).

Trauma mechanism can take form in transfer of kinetic energy such as blunt or sharp trauma. In the case of head trauma, trauma mechanism is often related to linier acceleration and rotation. Linier acceleration is linked to changes of gradient pressure in the cranial whereas rotation is related to the pressure that can change the brain position. Each head trauma mechanism has impact to influence the direction and the degree of the head trauma(6).

Trauma mechanism has direct impact on survival rate of patients with head trauma. Indonesia is the third country in Asia with 38,279 death casualty due to traffic accident(7). Traffic accident accounted for 59.6%, and 47.5% of the casualty experienced head trauma(8).

DOI Number: 10.5958/0976-5506.2019.02164.8
The most common trauma mechanism is motor vehicle accident with the percentage of 81.7%\(^9\).

Trauma mechanism due to falling is the main cause of head trauma for adult (51%), with accident due to traffic accident comes second (9%)\(^{10}\). Head trauma mechanism encompassed 56.1% of traffic accident, 18.4% precipitation and 11% falling\(^{11}\). Head trauma patients due to speeding motored vehicle accident tend to experience diffuse axonal injury, and in crush injury cases the survival rate are low.

The length of prehospital time provides significant influence for survival rate of patients with head trauma. Late intervention on the head trauma can cause further damaging impact on patient who have short time to get medical attention.

The period between trauma incident and the arrival in ED can become a determinant for a secondary head trauma and survival rate\(^{12}\). The output of the head trauma patient can degrade the survival rate when the patient receive medical treatment more than 60 minutes following the incident\(^{13}\).

There are 458 patients with head trauma, 50% are dead in the first two hours following the head trauma incident\(^{14}\). This condition is due to the lack of prehospital treatment on patients with head trauma. The large proportion of head trauma patients’ death (66%) happen in the first minute and in the incident scene\(^9\).

The objective of this study was to analyze the correlation between trauma mechanism and the length of prehospital time toward the survival rate of patients with head trauma.

**Method**

This study was a cross sectional retrospective study. The sample was the medical record of patients with moderate and severe head trauma from January 2017 to December 2018. The data was taken from ED of the regional public hospital Madiun, Indonesia. The sampling technique used purposive sampling. The inclusion criteria were medical record of patients with moderate and severe head trauma aged 18 years old above. The medical record of head trauma patients’ with open cranial fracture, multiple trauma, alcohol intoxication was included to exclusion criteria.

The data was taken using observation sheet, which consists of sex, education, job, age, diagnose, means of arrival, trauma mechanism, length of prehospital time, survival rate category: immediate death, early death, late death and alive.

Out of 494 medical records analyzed, there were 180 medical records that met the inclusion criteria. Table 1 showed the general characteristics, most respondents were male 129 patients (71.7%) and the education level of the patients was mostly Senior High School with total of 79 patients (43.9%). There were 136 patients (75.6%) who was working. Table 2 showed that respondents with severe head trauma were 98 people (54.5%). Ninety one people (50.65%) were taken to ED by their family. Head trauma mechanism that often experienced by 155 cases (85.2%) was due to traffic accident. There were 92 cases (51.1%) of head trauma patients with survive category, 69 cases (38.3%) categorized into late death and 19 cases (10.6%) categorized into early death. There were no patients of head trauma who experienced immediate death or unable to survive 60 minutes following the accident. Based on Table 3, it obtained that the average prehospital time was 33.14 minutes. The average respondent’s age was 43.63 years. The chi square test between trauma mechanism and survival rate showed p=0.783 (p>0.05), thus, there was no correlation between the trauma mechanism and survival rate of head trauma patient. Spearman rank test between the length of prehospital time survival rate was p=0.000 (p<0.05), thus, there was a correlation between the length of prehospital time and survival rate of head trauma patient. The r=-0.312 showed a negative weak correlation. It means the longer the prehospital time, the lower the survival rate of the head trauma patient.

Discussion

Trauma mechanism brings different impact on head trauma patient. Traffic accident dominates the cause of head trauma in Madiun. National data shows that 65.6% of traffic accident is caused by crash(15). Traffic accident that causes head trauma in Madiun are mostly due to two-wheeled vehicle accidents. National data shows that the number of two-wheeled vehicle in Indonesia is about 113 million(16). In Madiun, the number of two wheeled vehicle accounted for 94% of the total vehicles, and it becomes the main cause of traffic accidents(17).

Another main cause of head trauma in Madiun is falling from height. This type of falling is falling from trees, cliffs, and roofs. The average height that causes head trauma patients to be admitted to the ED is 2 – 5 meter. The falling contributes 21% to the head trauma case, in which 12% of them are due to the falling from the height of > 3 meter, and 9% are due to the falling from the height of <3 meter(18).

The analysis between trauma mechanism and survival rate showed that there was no correlation between trauma mechanism and survival rate. The head trauma mechanism is influenced by several factors that contribute to the different degree of severity among patients in anatomically and reconstructive way. Anatomic study investigates the brain network of the head trauma patient, whereas reconstructive study investigates the process of head trauma up to the impact, which aims to find the correlation between acceleration, pressure, and tension with the impact in head trauma(19). The other factors that can influence trauma mechanism are environmental condition, clinical condition, mechanical responses, also level of physical tolerance and biological factor of individuals(20).

Each head trauma mechanism has impact that influences the direction and degree of the head trauma impact(6). Brain trauma can occur post head traumatic incident due to acceleration deceleration and rotation of the head that produces kinetic power and manifested on the disturbance of neurons mechanism and axonal diffuse disorder. Trauma mechanism based on the linear acceleration is linked to the changes of gradient pressure within the cranial. Rotation mechanism is related to the pressure which can changes the position of brain networks. Trauma mechanism due to the blast and non-blast injury can cause different complication due to the primary and secondary exposures(21).

The average length of time from the accident scene to the ED is 33.14 minutes. The average prehospital time is 37 minutes and the most prominent one is in the first 30 minutes(22). The total prehospital time needed is 45 minutes, principally patient will have better survival rate when arrived in the hospital within the first 60 minutes(23).

Head trauma is a time sensitive condition due to pathological process of the head trauma. Head trauma patients spent much time in prehospital without receiving any definitive medical treatment due to many factors(24).
The principle of head trauma destruction is based on primary and secondary time. Primary head trauma is the initial destruction of brain following the trauma incident. This damage causes brain edema or laceration of brain network and its surrounding area\(^{(25)}\). Secondary head trauma evolves for several hours and days following the initial trauma incident. Secondary head trauma causes complex pathological process and complication of primary brain trauma. Time is considered as important factor for the head trauma patient. The principle underlying the trauma care is golden hour, with the treatment following the head trauma incident consists of resuscitation, stabilization, and transportation\(^{(26)}\).

The arrival of patient at ED of the regional public hospital Madiun is classified into two types, taken by the family and police. The average prehospital time taken by family is 26.4 minutes and 39.8 minutes taken by police. The Emergency Medical Service (EMS) in Indonesia is currently developing. Most areas in Indonesia are immediate assistance to patients with head trauma on a highway managed by family or police. The head trauma patients' arrival in ED who are taken by the patient's family is faster than those taken by the police, as it is easier for the family to reach the head trauma patient at the incident spot and immediately take patient the head trauma patient to the ED compared to waiting for the police or medical officers, which cannot be ensure their arrival time.

The length of prehospital time needed to take head trauma patient to the medical center with personal transportation and EMS\(^{(27)}\). The result showed that private transportation takes 46 minutes and EMS takes 59 minutes. Private transportation is faster so it can shorten the prehospital time, thus, it brings benefit to accelerate the head trauma patient’s arrival at the ED and can increase the survival rate. However, private transportation can also slow down the medical intervention that should be immediately provided for patients with head trauma. Based on the findings of this study, the average time suggested for good survival rate of the head trauma patient is 27.67 minutes with the maximum of 30 minutes.

**Conclusion**

In general, this findings outlines that trauma mechanism has no correlation with the survival rate of head trauma patient, whereas the length of prehospital time has negative correlation with survival rate of the patient with head trauma.

ABSTRACT

Objective: verify the utility of measuring prostate cancer antigen 3 (PCA3) and serum PSA levels in the diagnosis of prostate cancer.

Method: This case-control study conducted from March 2017 to November 2018. It consisted of 140 men subjects with age range (40-85 years); 70 prostate cancer patients group included (35 patients with newly diagnosed Pca and 35 prostate cancer patients under hormonal therapy treatment (HT-Pca) and 35 patients with benign prostate hyperplasia (BPH) and 35 healthy men age matched normal control.

Results: The PCA3 and serum total and free PSA were measurement by using ELISA technique in patients and healthy controls. The results revealed that the mean values of PCA3, serum total and free PSA and the prostate Specific antigen density (PSAD) of prostate cancer patients and hormonal therapy group were significantly higher compared with healthy controls (all p-value <0.001) the mean of the percentage free/total PSA Ratio were significantly lower than those of benign prostate hyperplasia and healthy controls.

Conclusion: The diagnostic value of PCA3 is relatively higher, as it of both sensitivity and specificity; increased serum PCA3 values cannot be detected in presence of other cancers. PCA3 level in serum can discriminate early Pca from healthy controls, indicating its diagnostic value for the early-stage Pca.

Keywords: prostate cancer antigen, prostate cancer, marker, benign prostate hyperplasia, stage

Introduction

Prostate cancer is a testosterone–driven cancer that typically present in men over 40 years also is the second most common solid tumor, in men worldwide and, is also one of the leading cancer deaths in developed countries throughout the world, with about with about 1 in 8 developing despite significant advances in early diagnosis and management, remains a leading cause of cancer related death in men. Almost all prostate cancers are adenocarcinomas. Other types of prostate cancer include: Sarcomas, Small cell carcinomas, neuroendocrine tumors and transitional cell carcinomas and other types are rare. The benign prostatic hyperplasia also called benign enlargement of the prostate is noncancerous increase in the size of the prostate. In this disease the prostate gland enlarges beyond the normal volume of 20 – 30 mL as part of the aging process, thus it is common among older men.

Prostate specific antigen (PSA) is serine proteases produced by epithelial cells in the prostate encoded by the kallikrein-related peptidase 3 (KLK3) gene located in the long arm of chromosome-19 within the region the spanning q13.2 – q13.4. The circulating levels of PSA increase in the presence of cancer, this latter association led to the development of PSA as a screening biomarker and an indicator of the disease progression. However, PSA is also influenced by age, prostate size, inflammation
and infection\textsuperscript{4,5}. The PSAD is described as the ratio of total PSA concentration to the prostate volume (PV), (tPSA/PV), it requires the transrectal ultrasound (TRUS) or magnetic resonance imaging (MRI) to assess the prostate volume. The PSAD is describes as the difference in mean PSAD between men with Pca and men with BPH. This measurement could be used to predict the clinical pathological features of disease\textsuperscript{6}.

Prostate cancer antigen 3 PCA3 (previously referred as DD3) is a gene composed of 4 exons and 3 introns and is located on the chromosome 9q21-22 in antisense orientation within intron 6 of the prune homolog 2 gene or BMCCI. The PCA3 gene is transcribes a long non-coding mRNA that is overexpressed in the prostate cancer tissue\textsuperscript{7}. The PCA3 mRNA is a highly overexpressed in 95% of Pca as compared to BPH or normal prostatic tissue\textsuperscript{8-10}. The PCA3 is useful in the detection of early prostate cancer, especially for patients with previous negative biopsy. And the FDA has recommended using a cut off value of 25 for the PCA3 test to indicate the repetition of biopsy\textsuperscript{9,10}. The purpose of this study was to verify the utility of measuring prostate cancer antigen 3 (PCA3) and serum PSA levels in the diagnosis of prostate cancer.

Method

Setting: This case- control study was achieved at the Department of Uro-surgery at Al-Imamain Al-Kadhumain Medical City and Baghdad Medical City Hospital (Gazi Al-Harery) and Al-imam Aljwad Medical Center in Baghdad, Iraq, from March 2017 to November 2018.

Subjects: It consisted of 140 men subjects with age rang (40- 85 years); 70 prostate cancer patients group included (35 patients with newly diagnosed Pca and the 35 prostate cancer patients under hormonal therapy) and 35 patients with benign prostate hyperplasia (BPH) and 35 healthy men age matched normal control

Exclusion Criteria: Patients with previous diagnosis of Pca or a family history record of Pca were excluded. Patients with symptoms of urinary tract infection, immunodeficiency disorders, patients under medical treatment for prostate hyperplasia, were also excluded.

Laboratory Analysis: The whole blood samples was taken prior to surgery for prostatectomy or fine needle aspirate or TURP biopsy 5 milliliters (ml) of venous blood samples were aspirate from all patients and control group. The aspirated blood sample allows clotting and centrifuged at 3500 rpm to 5 minutes, the sera was transferred to divided into two partitions: the first partitions contains 3 mls which were immediately stored at -70°C to be used for the measurement of serum prostate cancer antigen 3(PCA3) and the second partitions contains 3 mls to be used for the measurement of serum total and free PSA.

Statistical Analysis: A statistical study using SPSS version 21 statistical software (SPSS Inc., Chicago IL, USA) was performed to indicate the presence of significant difference and correlation between the studied parameters, with the p- value of less than 0.05 was considered significant. The diagnostic accuracy of the biochemical were performed by the Receiver operating characteristic curve analysis (ROC).

As shown in table 3, the optimal cutoff value for positive serum PCA3 when used as a test to diagnose prostate cancer was set at 45 at this cutoff value the test sensitivity, specificity and accurate was (80 %, 78 %, 93%) respectively. The testing positive at this cutoff value (having as serum PCA3 more than 45 would establish the diagnosis of prostate cancer with 98.5 confidence (PPV=98.5). the optimal cutoff value for positive serum PSA when used as a test to diagnose prostate cancer was set at 5.6 at this cutoff value the test sensitivity, specificity and accurate was (82 %, 68 %, 78 % respectively) associated with diagnosing prostate cancer.

Discussion

Serum level concentration of TPSA was significantly higher in Pca patients and Pca patients under hormonal therapy (HT-Pca) as compared with BPH patient groups and normal control (p-value<0.001). Serum level concentration of fPSA were significantly higher in Pca patients and Pca (HT-Pca) patients as compared to BPH patient groups and normal control (p<0.0001). During prostate cancer progression, excess amounts of PSA are leaked into the blood dramatically elevating both tPSA and fPSA levels this may occur because PSA molecules (34 kDa glycoproteins) in prostate adenocarcinoma cells more readily cross the multiple barriers between the prostate and blood vessel. It has been suggested that Pca cells produce more PSA than normal cells. It is proposed that poorly differentiated Pca cells may secrete and release greater amounts of PSA than well-differentiated ones11. This observation agrees with other study12, 13 and contrast with other study14. Significant positive correlation was found between the age of the patients, Gleason grade, pT staging, with PSA values and fPSA values. This finding is agreements with15, 16, and different from results of Djavan et al17.

The mean PSAD was significantly higher in Pca and HT-Pca as compared to BPH group and healthy control group (p<0.001). The ROC curve analysis revealed that PSAD was a better predictor of prostate cancer. When PSAD value increased the sensitivity and specificity to detection of prostate cancer increased (80% and 75% respectively). Our results are found significant correlation between PSA, %fPSA and PSAD to diagnostic the prostate cancer. This was agreements with other18. Our results indicated that PCA3 value is not affected by patients’ age, the size of prostate. These finding are also confirmed by other19, 20.

Our results found that the values of PCA3 test a significantly highly in the two group the Pca patients and HT-Pca patients as compared to BPH patient group and normal control (p<0.001). Also a significant positive correlation was found between PCA3 values with increasing GS (G.S ≥ 7) and TNM staging. The sensitivity and specificity (80% and 87 %) of PCA3 were a significantly highly in Pca patients and HT- Pca patients (86 % and 85 %) as compared to BPH patient groups and normal control. This was agreements with other15, 21, 22. While other study showed that there was no significant relationship between PCA3 with any Pca prognostic parameter including Gleason Score, tumor volume or stage23, 24.

Conclusion

The summation of PCA3, PSA, f/tPSA and PSAD with other clinical information increase the diagnostic precision of prostate cancer detection. PCA3 is a new biomarker that could be improve the accuracy of Pca diagnosis due to its fairly high specificity and sensitivity and the most promising due to its great role in distinctive of Pca from other prostate benign conditions. Also could be applied for early diagnosis of Pca, patient follow-up, prognosis prediction, and targeted therapy. The PCA3 value correlates with the chance of a positive biopsy. Addition to better detection, using this parameters may prevent invasive diagnostic procedures such as prostate biopsy

Conflict of Interest: None

Ethical Clearance: Informed written consent was obtained from all the participants in the study, and the study and all its procedure were done in accordance with the Helsinki Declaration of 1975, as revised in 2000. Staphylococcus Aureus and Bacillus Cereus in Yellow Rice

Leka lutpiatina1, Nudia Kurniati1, Ratih Dewi Dwiyanti1, Wahdah Norsiah1
1Medical Laboratory Technology Poltekkes, Kemenkes Banjarmasin, Mistar Cokrokusumo Street 4a Banjarbaru Indonesia

ABSTRACT

Yellow rice is one type of food made from rice cooked together with coconut milk and spices. This food is very popular with Indonesian people at breakfast. Carbohydrates contained in rice are the body’s provisions for activities until lunchtime arrives, but if food sanitation factors such as human factors, equipment factors, and environmental factors are not considered it will cause yellow rice vulnerable to contamination with pathogenic bacteria. One of the pathogenic bacteria that often contaminate food and beverages is Staphylococcus aureus and Bacillus cereus. This study aims to determine whether or not there is contamination of Staphylococcus aureus and Bacillus cereus bacteria in yellow rice sold in Sekumpul Martapura Village. The type of research used is a descriptive survey. Samples were taken in total sampling, 15 samples of yellow rice from different sellers. The results showed that 1 sample (7%) contaminated with Staphylococcus aureus, and as many as three samples (21%) contaminated with Bacillus cereus. The conclusion of the study was that there was contamination of Staphylococcus aureus and Bacillus cereus in yellow rice which were sold in the Sekumpul Village of Martapura Indonesia. Based on these studies it is recommended for sellers to always pay attention to food sanitation, especially in terms of processing to serving so that quality food obtained.

Keywords: yellow rice, Staphylococcus aureus

Introduction

Food is a source of energy for the human body, with good food intake we can do all activities. Food and drink can act as agents of transmission of disease from bacteria to humans. There are so many ways to spread pollutants in food processing. Therefore food processing and packaging plays a vital role in efforts to improve food health. A useful method of processing is that there is no food damage due to improper handling, and the packaging and presentation of food needs to consider so that the food is protected from contamination by bacteria. Bacteria that are proven to cause Extraordinary Events are Salmonella, Staphylococcus aureus, Clostridium perfringens, Clostridium botulinum, Bacillus cereus, Vibrio parahaemolyticus, Escherichia coli, Campylobacter jejuni.

Staphylococcus aureus is the species that most often causes poisoning and produces enterotoxin. The resulting enterotoxin causes food poisoning with a period of shoots between 2-6 hours. Sudden symptoms that arise are nausea, vomiting, and diarrhea.

The results of the Maulida study found the presence of Salmonella sp in 4 samples from 16 samples of yellow rice sold in Kelurahan Sungai Besar Banjarbaru. Salmonella sp can also contaminate siomay.

The case of mass poisoning that occurred in the area behind the Jami mosque of Teluk Dalam Banjarmasin, where as many as 92 residents experienced food poisoning after eating nasi bungkus (yellow rice), according to the results of a health laboratory examination of food samples and vomiting of victims, Staphylococcus aureus. A case of poisoning that occurred at the State Islamic University of Antasari Banjarmasin, as many as 21 students experienced poisoning after eating food in the form of chicken side dishes and eggs and beans, from the results of tests conducted by the Banjarmasin Health Service, Staphylococcus.
Foods that we often consume are rice; various rice processing is done to reduce boredom towards the types of food wasted every day, one of which is yellow rice. Yellow rice consumed as breakfast, there are many traders who sell yellow rice, one of which is in the Sekumpul Martapura village which is a densely populated area. Food consumed should be free from pollution caused by processing and serving which does not pay attention to hygiene and environmental cleanliness.

This study aims to determine the contamination of Staphylococcus aureus and Bacillus cereus bacteria in yellow rice which are processed and sold at the regional food stalls at Sekumpul Martapura.

Method and Materials

The type of research used in this study is the representative survey, which is a research method with the primary aim to make a description or descriptive of the presence or absence of Staphylococcus aureus in yellow rice which is processed and sold alone in food stalls in Sekumpul Martapura Village.

The design of the study in this study was cross-sectional. Namely, researchers conducted observations or measurements of variables at one particular time. The population in this study were all yellow rice sellers who processed and sold themselves at food stalls in Sekumpul Martapura Village. The sample in this study were 15 sellers who prepared and sold at food stalls in Sekumpul Martapura Village. Sampling uses total sampling technique. The research variables used in this study were independent variables, namely the bacteria Staphylococcus aureus in yellow rice.

Samples in the form of yellow rice sold at Sekumpul Village, Martapura, and only yellow rice is taken on the same day for inspection, coded for each sample and immediately taken to the laboratory for examination. Yellow rice samples crushed with mortars and stampers which sterilized with 70% alcohol, the samples were weighed as much as 10 grams and then put into enrichment media, TSB, then incubated at 37°C for 1 x 24 hours.

From TSB enrichment media using sterile swabs inoculated on MSA (Merck) and agar chocolate (Merck) media then using the ose to be pulled by zigzagging. Incubate at 37°C for 1 x 24 hours. Observations were made after 1 x 24 hours by observing S.aureus and Bacillus cereus colonies. The colonies examined with Gram staining. Suspected colonies of Staphylococcus aureus then identified by coagulase test, catalase test, biochemical test (glucose and mannose), D-Nase test, novobiocin sensitivity test. Alleged colonies of Bacillus cereus identified by biochemical tests (glucose, lactose, mannose, maltose, saccharose, indole, motility, citrate).

Result and Discussion

Based on the results of the examination of yellow rice sold in Sekumpul Martapura Sub-District from 15 identified samples, one sample (7%) contaminated with Staphylococcus aureus. And three samples (21%) infected with Bacillus cereus.

Based on the results of observations of respondents it is known that almost all yellow rice sellers pay less attention to food sanitation either from food factors, the presentation of the food itself or the equipment used. Observation data is that all yellow rice sellers (100%) use well water sources. Selling yellow rice where it trades close to public roads, there are 14 sellers (93%), where there are lots of flying flies, there is one seller (7%). Yellow rice sellers who washed their hands before serving food had six sellers (40%), while those who did not remove their hands before serving the food were nine sellers (60%). Yellow rice sellers (100%) use oil paper as a yellow rice wrapper. Yellow rice sellers who wash their hands before milking the coconut milk have 12 sellers (80%), while those who don’t wash their hands because of using instant coconut milk there are three sellers (20%).

Based on the results of examination of yellow rice samples, there was a positive result of 7% contamination of Staphylococcus aureus and 21% Bacillus cereus (figure 1). Contamination of yellow rice depends on food sanitation in terms of environmental conditions, cleanliness of the equipment used, personal hygiene and the state of raw materials.
At the time of processing until the presentation stage, it is necessary to pay attention to the cleanliness of the cooking utensils used and the food containers and wrappers used. Of the 15 sellers who use oil paper wrappers, there are six sellers (40%) who do not clean food wrappers or who clean there are nine sellers (60%). One positive result of Staphylococcus aureus obtained on samples whose packaging not cleaned and 14 other samples contaminated with other bacteria. Based on the research of Maulida (2013) there were 3 positive samples of Salmonella and 17 other bacterial samples in the yellow rice sample. Microbial contamination can be through cooking utensils and food wrappers and food storage containers that not cleaned when they want to use, even though re-cleaning of equipment used is an action to avoid contamination during processing, serving and storing.

The condition of the raw material for coconut milk and water sources used to milk coconut milk plays an essential role in the food processing process. The results of the examination showed that using well water sources for processing yellow rice obtained the results of all samples contaminated by bacteria, and there was one positive sample infected with Staphylococcus aureus. The cause of contaminants for microorganisms for groundwater can come from domestic wastewater, either in the form of leach or leakage from septic tanks. Roebikato’s research shows a bacteriological quality of fresh water is not good.

Processing yellow rice using milk coconut is one source of contamination by bacteria because sanitation is in the process of milking and the environment for processing yellow rice and the method of cooking food that does not mature properly, cooking food until it is fully cooked can kill most bacteria. Staphylococcus aureus is a bacterium that is not heat resistant (100°C) and is inhibited by growth in high salt-containing media. Staphylococcus aureus frustrated by an increase with propolis and honey. The presence of Staphylococcus aureus in yellow rice may not originate from raw materials and the processing process because the cooking process of yellow rice reaches temperatures (100°C) for 25 minutes. Unlike the case with Bacillus cereus which is resistant to high heating. Yellow rice contamination of these bacteria is likely to come from raw materials. Bacillus sp is a spore-forming bacterium that spread in the environment including laboratory air. Food poisoning can be caused by Bacillus cereus with types of diarrhea poisoning and emetic syndrome. Foods that often contaminated with bacteria include rice cooked and honey.

Personal hygiene of sellers is seen from the habit of washing hands before serving food and the presence of festering wounds especially in the hands of sellers. Staphylococcus aureus in humans can found in the perianal, inguinal, axillary and nasal areas. In career, individuals have a higher risk of transmitting this bacterium, in diabetic or paramedic nose ulcers. Staphylococcus aureus can be contagious as long as there is pus coming out of the lesion or nose. Sellers who washed or cleaned their hands before serving the food had 6 sellers (40%) the results of the study did not find Staphylococcus aureus but found other bacteria and those who did not wash their hands were 9 sellers (60%), one of the sellers who did not wash their hands got a positive staphylococcus result aureus and 8 contaminated with other bacteria. Based on Ratih’s research, Staphylococcus aureus has infected sauces. Rahayu’s study (2014) found that from 24 sausage samples there were 12 samples contaminated with Staphylococcus aureus, this might be due to contamination originating from the soil when cutting, skin, tools or air and traders handling food. Individual hygiene is essential because it is one of the factors in serving food that must meet requirements such as the health and cleanliness of the seller.

The environment around the place of sale significantly affects yellow rice pollution by bacteria. As many as 14 yellow rice sellers sell near public roads, and one seller (7%) whose selling environment is flying flies. Yellow rice sellers pay less attention to environmental hygiene, as evidenced by the garbage around the selling place that can invite flies. Flies or insects can carry microorganisms on the rice that are not tightly closed. Contamination can also come from dust in flying air. Staphylococcus aureus and Bacillus cereus can be transmitted through the air and contaminate yellow rice.

Conclusion

The yellow rice samples examined found 1 sample (7%) contaminated with Staphylococcus aureus and three samples (21%) infected with Bacillus cereus.

ABSTRACT

The study was carried out in animal feeding laboratory/Department of Animal Production the college of Agriculture, University of Baghdad for the period from 2016/11/1 to 2017/4/1. Peppermint oil was added by 0, 70, 140 and 280 μl/kg dry matter mixture ration (concentrated 20% and alfalfa hay 80%), to study the effect on total gas, methane production and invitro digestibility. The results as follows: A significant decreased (p<0.01) was found in total gas production, which was lower after 12 hr. were 26.55 ml/200 gm dry matter in T4 compared to T1 (control), while methane production were significantly decreased (p<0.01) in T2, T3 and T4, respectively, with adding 70, 140 and 280 μl/kg dry matter compared with T1. After 24 and 48 hr. of incubation, T4 recorded the lowest volume of total gas while methane production was a significant decreased (p<0.01) in the T3 and T4, for both periods compared to T1 treatment, after 72 hr. of incubation period treatment T4 recorded is lost significant decreased (p<0.01) in methane gas production compared to the treatment T1.

The results showed increased significantly (p<0.01) in the invitro digestibility of dry matter and of metabolizable energy in T2 and T3 except T4 and increased (p<0.01) in the T2 treatment in the invitro digestibility of organic matter except T4. We conclude that addition of peppermint oil to the ration diet has given better results in reducing the production of total and methane gas and led to a significant improvement in invitro digestibility of dry matter, organic matter and of metabolizable energy.

Keywords: Total gas, methane production, alfalfa hay, invitro digestibility

Introduction

The production of methane gas is an effective mechanism to reduce the amount of carbon dioxide and to dispose of the hydrogen gas formed in the rumen. The amount of gas produced is the result of the process of fermentation of various organic materials. These gases include hydrogen gas, hydrogen sulfide, methane and carbon dioxide. In the ruminants varies depending on several factors: animal type, strain, rumen pH, estic acid ratio, propionic, ration composition, and animal fodder quantity\textsuperscript{1}. The production of methane in ruminants is similar to that of organic fertilizer\textsuperscript{2}. Methane is hotter than carbon dioxide 23 once\textsuperscript{3}. The production of laboratory gas gives an indication of the quality of rumen fermentation, which is a fast and inexpensive way to estimate the nutritional value of fodder. It was therefore important to conserve feed capacity by reducing the composition of methane by using some plant-based feed additives that could modify the internal environment of microscopic rumen\textsuperscript{4}. These dietary alternatives are plant extracts and essential oils, essential oils that are antimicrobial as an alternative to the chemical and antibiotic preparations used to treat the microbial activity within the rumen\textsuperscript{5}. Over the past few years, there have been several studies on the use of vegetable oils and their active constituents on microbial fermentation in the rumen\textsuperscript{6}. Microbial fermentation in the rumen is also a major source of methane production, which is called greenhouse gas. The use of vegetable oils and their components reduces the production of methane 9 and reduces its emissions at high rates of the ruminant gastrointestinal tract. There are several different types of vegetable oils, including peppermint oil, which is the most versatile vegetable oil. Its unique chemical composition makes it useful in a large number of industries and applications of use, including in the pharmaceutical industries such as tooth soap and mouth washes. It is used as an appetizer, Mint
oil mainly contains menthol, which is considered as one of the oil compounds, which helps to alleviate some cases of back pain and nasal congestion. The aim of this study is to add peppermint oil with different proportions to the ruminants’ diet consisting of 80% drys with 20% concentrated feed and to study their effect on the total gas and methane production in the laboratory and measure the invitro digestion after different laboratory incubation periods.

**Material and Method**

**Experiment Aim:** To determine the effect of using different levels of peppermint oil in the diet was added by 0, 70, 140 and 280 μl/kg dry matter mixture with (concentrated 20% and alfalfa hay 80%), to study the effect on total gas, methane production and invitro digestibility.

**Experiment Plan:** The study was conducted in the Nutrition Laboratory of the Faculty of Agriculture/University of Baghdad to study the effect of adding different levels of peppermint oil in percentages 0, 70, 140 and 280 μl/kg dry matter, into a ration mixture with concentrated feed and alfalfa hay in effect to some rumen fermentation, total gas, methane production and invitro digestion of dry matter, organic matter and metabolizable energy. Tables 1 and 2 show the chemical composition of concentrates and alfalfa hay.

T1:control(Without adding), T2:diyet adding peppermint oil 70 μl/kg dry matter, T3:diyet adding peppermint oil 140 μl/kg dry matter, T4:diyet adding peppermint oil 280 μl/kg dry matter,** indicates significant differences at the probability level (P <0.01).

**Estimation of total gas and methane production in the laboratory:** The total gas production in the laboratory was estimated by taking 4 replicates per sample according to method. 200 mg of experimental feed was weighed and 20 ml of industrial saliva and 10 ml of filtered rumen were added. The syringe was closed with a plastic seal to prevent the fluid from flowing from the syringe at the incubation and then the injection was incubated in a water basin at 39 °C for periods 24, 48, 72 and 96 hours With Planck work for each period of incubation (4 replicates), then the injection was withdrawn to calculate the total gas production was added 4 ml of sodium hydroxide concentration of 4% to 2 samples only to calculate the production of methane gas by method. The metabolizable energy(ME) of the organic matter (IVOMD), the short-chain fatty acids (SCFA) and the net production of milk (NEL) of the total gas production were calculated (ME) After a period of 24 hours using the following equations:

ME (MJ/kgDM) = 1.06 + 0.157GV + 0.084CP + 0.22CF –0.081A(Ash)

By method (13)

IVOMD(%)= 14.88 +0.889 GV + 0.45CP +0.651 x A(ASH)

SCFA(mmol/Later) = 0.0239 GV – 0.061

By method
NEL (MJ/Kg DM)=0.096xGV +0.0038xCP+0.000173x EE²+0.54

By method\textsuperscript{10}

Whereas:

ME= metabolizable energy (MJ/kg dry matter)
GV= Total gas production (ML)
CP=Protein Fiber %
CF= Crude Fiber %
A=Ash %
SCFA= short-chain fatty acids (MMOL/L)
IVOMD= \textit{in vitro} the organic matter %
NEL= net production of milk (MJ/kg dry matter)

\textbf{Measuring in vitro digestion dry matter and organic matter coefficient:} Both were estimated \textit{in vitro} digestion dry matter and organic matter coefficient by method\textsuperscript{11}.

\textbf{Chemical analysis:} Samples were analyzed to determination dry matter, organic matter, ash, ether extract, crude protein, and crude fiber by method\textsuperscript{12}.

\textbf{Statistical analysis:} The data were analyzed statistically complete randomized design treatments means were separated using Duncan\textsuperscript{9}, multiple range test, level of probability using the\textsuperscript{10}.

\textbf{Results and Discussion}
