Jane Brockett, an acclaimed wine taster and author of “The Gentle Art of Domesticity” ranked the Enid Blyton Picnic as her favourite “food scene” in Children’s Literature only behind the tea party in Elizabeth Gouge’s The Little White House. The very fact that a critic had to resort to multiple occasions rather than a standalone one to describe the sheer delicacy of her writing—if I may put it so-vindicated her standing as a harbinger of infectious happiness in children’s literature. Brockett writes “Tomato sandwiches, lemonade, tinned sardines, melt-in-the-mouth shortbread, lettuces, radishes, Nestlé milk, ginger beer, tins of pineapple chunks, squares of chocolate. The Famous Five set a standard in picnics that has never been equalled”.

In that first book, a simple spread of cold ham, salad, bacon and eggs, plums and a ginger cake fuelled the discovery of gold ingots on Kirrin Island. But over the years, as the five go off in a caravan, or camping on Billycock Hill, the author has discovered the importance of food in recounting a good yarn. The Blyton Menu is never complicated. Blyton, the crafty camouflager mixes food just the right amount. She starts her acclaimed St. Clare’s series like this: “One sunny summer afternoon four girls sat on the grass by a tenths-court, drinking lemonade.” This gives a refreshing imagery as opposed to the tiredness after the game. This is where Blyton sells her food. She uses something as simple as lemonade to make summer and games look fresh.

Blyton is an imaginative dramatic realist. She does not bring in the supernatural in all her stories and yet sends the children on unrealistic adventurous trips. Yet, in the end she preaches the values of friendship, sharing and humility. All good characters get together and share food in her stories, be it the sharing the food trunk in St Clare’s and Malory Towers or the picnic lunches in the Adventure series. We often see snobbish characters refusing to share their food but reforming themselves in the end by sharing their portion rather generously. The secret meetings of the ‘Secret Seven’ is never complete without their secret password and delicious home-made snacks.

In this passage from the fifth book of the Famous Five series, *Five go off in a caravan* the blend of food with her writing is clear. Soon they were all sitting on the rocky ledge, which was still warm, watching the sun go down into the lake. It was the most beautiful evening, with the lake as blue as a cornflower and the sky flecked with rosy clouds. They held their hard-boiled eggs in one hand and a piece of bread and butter in the other, munching happily. There was a dish of salt for everyone to dip their eggs into. Wordsworthian nature is infused with the Blytonic food making it a perfect sensory delight. The elaborate descriptions of nature require food to sell it to the children.

In Lewis Carroll’s *Alice’s Adventures in Wonderland*, C.S. Lewis’ *The Lion, the Witch, and the Wardrobe*, Roald Dahl’s *Charlie and the Chocolate Factory*, and Neil Gaiman’s *Coraline* food is used as temptation for child protagonists, a tool to lure them into doing evil deeds or being generally mischievous. In fact, even the most ancient of literature texts-The Book of Genesis-describes food and the underlying, impending danger lurking beneath the aftermath of its consumption, through the narrative on the Forbidden Fruit. While they use food as modes of temptation, Blyton uses it to normalize and humanize her stories. Even though Blyton herself is no stranger to deploying food as a prescient indicator of mischief or adventure (Sly and Gobbo, the goblins from her hugely popular Noddy stories are repeatedly guilty of stealing ice creams), the overriding joy, innocence and constant whetting of reader appetites mean that they’re mere trivialities in the grand scheme of things as far as her culinary recitals are concerned.

Enid Blyton has made her own lexicography in literature, enjoyed by adults and children alike. She made her own dictionary of the commonest of terms and used her books to define them. Unsurprisingly, food glossary stands out from those pages. She painted her own version of the dream holiday, the perfect school, the happiest families and the exciting adventures and her versions soon became every child’s dream and her, the dream weaver. Action and fighting crimes were no longer restricted to the adult world. Children were invited to be heroes in her world. The refrain “you are too small for this” is non-existent in the Blytonic universe.

Daniel points out that it established in the study of children’s literature that food is a central component in this body of writing as a whole. The boarding schools
like the St Clare’s series and the Malory Tower series has a midnight feast in almost every book. It is shown as a means of bonding among the girls. The Blyton characters are never seen to eat food by themselves. Refusing to share food is looked down upon in schools. The first thought that food brings is sharing. Values are thus transmitted into children through food. Elaborate midnight feasts attended by the whole class is the perfect example of sharing among children. Everyone contributes and has an excellent feast. “I don’t know why food tastes so much nicer in the middle of the night than in the daytime, but it does!...Golly! Pork-pie and chocolate cake, sardines and Nestlé’s milk, chocolate and peppermint creams, tinned pineapple and ginger-beer!” Jammy buns and lemons during match day half times at St Clare’s and Malory Towers paint an image of serenity and delight even amidst the intensity of competition, much like how the elaborate descriptions of culinary delights always juxtapose themselves happily next to hair raising moments of adventure and maddening moments of mystery.

Blyton’s healthy diet: Josh Sutton in a Guardian article5 points out that the characters eat a balanced diet. Despite an abundance of humbugs, toffees and ginger pop, when grouped into the five main food categories (fruit and vegetable; meat and fish; dairy; starchy foods; high fat/sugar foods), no one group outweighs another. This comes naturally to the children rather than by diktat. Sweets are eaten sparingly; hunks of crusty bread are accompanied by handfuls of radishes or fresh fruit.

The elaborate descriptions along with the excitement of the characters increase the appeal of the food much more. The temptation in Blyton is very different from that in Dahl. Blyton offers a healthier and a more positive food image. Food fantasies are seen in realistic fiction, but they are most effective, perhaps, in fantasy literature, where all sorts of foods can be enjoyed, even ones that don’t exist in reality. I argue that food can be enjoyed as much in realistic fiction as in fantasy. While fantasy literature may allow the reader to enjoy even the nonexistent food item, the realistic fiction gives an authenticity to the same making the readers connect to the experience. In Five Go To Billycock Hill, Blyton writes “A large ham sat on the table, and there were crusty loaves of new bread. Crisp lettuces, dewy and cool, and red radishes were side by side in a big glass dish. Great slabs of butter and jugs of creamy milk were there, too, with honey and home-made jam.”10 Carolyn Daniels11 argues that Blyton’s fictional feasts directly reflect the adult Edwardian extravagant cholesterol-laden diet. But, these feasts do not happen every day. While we see children sneaking out and having extravagant food once a term, the food is mostly kept simple and healthy. She also argues that the food fantasies reflect a longing for her mother’s love and emotional satisfaction that was absent during her childhood. She points out that Blyton’s most prolific period of writing took place during the war era when food rationing meant that the majority of the people in England were eating less. Following the outbreak of the World War II, food rationing went on from 1940 to 1954. He argues this as an unrealistic portrayal of the period. But, I argue that realism was not her aim. Blyton was more of an optimist. In between the bleak realities of war she managed to keep her spirits unmarred and always presented a happy story for her devoted young readers.

Influence on India: Food transcends its traditional roles to stand for emotions and adventures that triggers a child’s fascination thus shaping the image of the West both to the Occident and the Orient. For a post-colonial child, Blyton is the window to the world of the west. She shapes the image of the ‘other’ for them. Calling her writing deliberate colonial propaganda would be doing a disservice to the oft overlooked quality that Enid Blyton stories had in oodles-simplicity, joy and refreshing innocence. Take this quote from The Enchanted Wood (The Faraway Tree) for instance. Well, come back and have tea with us,” said Moon-Face. “Silky’s got some Pop Biscuits—and I’ve made some Google Buns. I don’t often make them—and I tell you they’re a treat! Superle12 points out that Blyton’s books have been extremely popular in India. Thus the Indian authors have felt the need to replicate that charm and induce the Indianness into the Blyton loving audience. Food in children’s fiction caters to a feeling of ‘otherness’ in the post-colonial world, leading to creations of Indianized epigones. Michelle Superle calls this phenomena the Indian-“Blytonnade” in her book Contemporary English-Language Indian Children’s Literature. She claims that the Indianness is infused by including Indian settings, names and by the centrality of Indian food. It has been noted that they are worthy replacements of Blyton to the Indian audience but I argue that the Indian audience need to read the original books instead of colonial imitations. Swapna Dutta’s Juneli at St Avila’s is identified as a Malory Towers clone, but starring the Indian characters of Poonam and Harbinder. The kids brought up in India do not need an introduction to India but they will benefit more by an
introduction to a new culture through the simple lens of Blyton. Favouring the books merely because of the overt Indianess will not wave the patriotic banner higher, rather it restricts the comfort zone of a child to a region. Familiarizing the child to both the worlds, I argue, is the best answer to the two choices.

**Conclusion**

Books leave a lasting impression on its readers, especially on young readers. Promoting a healthier lifestyle through books like the way Blyton does may provide effective results. The Blyton characters have a healthy diet despite their abundance. It is to be noted that the characters are never forced to eat. They enjoy the food thus sending across a positive message to the children. Unattainable luxuries like chocolate were rarely part of her menu or kept only during special occasions. Thus, the popularity of these books among generations of readers urges us to look deeper into the appeal offered by these works and the need for interdisciplinary research among various fields like literature and public health. These interdisciplinary aspects which can be used to influence a child’s healthy habits often provide a much wider positive impact.

Magnitude of Coexisting Cognitive Impairment and Depression among Elderly in Urban Field Practice Area of Mysuru City, Karnataka

Renuka M.¹, Meghana Narendran², Narayana Murthy M.R.³

¹Professor, ²Junior Resident, ³Professor and Head of Department, Department of Community Medicine, JSS Medical College, Mysuru

Abstract

Background: Cognitive impairment (CI) is an important clinical issue among elderly patients with depression and has a more complex etiology. The objective of the present study was to screen a representative sample of adults aged ≥60 years for the prevalence of Cognitive Impairment and Depression.

Method: A Community based Cross-sectional study done among 290 elderly in a declared slum area, Medar’s block, Mysuru city, Karnataka. Standard tools like Mini-Cog questionnaire was used to assess Cognitive Impairment and Geriatric Depression Scale (GDS) to estimate the prevalence of depression.

Results: Among the study participants, 201 (69.3%) belonged to the age group of 60-69 years and most of them belonged to medium Standard of living Index (SLI) 201 (69%). The prevalence of cognitive impairment was 132 (45.5%) and suggestive depression was seen in 141 (48.6%) of the elderly.

Conclusion: There was an association between cognitive impairment and depression which in turn had a significant impact on activities of daily living. Early diagnosis of these problems with appropriate intervention can bring about significant change in the quality of life among the elderly.

Keywords: Cognitive Impairment, Activities of daily living, Depression, Functional Status, Mental health, Elderly.

Introduction

Ageing is a universal process. The demographic transition is attributed to the decreasing fertility and mortality rates due to the availability of better health care services.¹ India’s elderly population in 2011 census contributed to 8.2% of the total population. The proportion of the population aged 60 years and above was 6.7 percent in 1991 and is projected to increase to 20 percent in 2050.² Various dimensions of the health of elderly persons include physical, mental and socio-economic, which at times are interlinked and often one affecting the other.

Improved healthcare promises longevity but social and economic conditions, such as poverty, break up of joint families, and poor services to the elderly, pose a psychiatric threat to them.³ Cognitive impairment mainly affects older people and about two percent of cases start before the age of 65 years. After this, the prevalence doubles every five years.

Dementia is one of the major causes of disability in later life.⁴ Prevalence rates of Mild Cognitive Impairment vary from 3% to 59% with approximately 8–15% cases converting into dementia;⁵ Indian studies have reported the relative proportion of Alzheimer’s disease between 41% and 65% and the proportion of vascular dementia between 22% and 58%.⁶-⁷

Depression is a common cause of disability in older adults. Among its consequences are reduced life satisfaction and quality, social deprivation, loneliness, increased use of health and home care services, cognitive decline, ADL limitations. In the age group of 60 years and above, residing in various parts of the world revealed that the median prevalence rate of depressive disorders in the world was determined to be 10.3% and among the Indian elderly population was found to be 21.9%. The feeling of loneliness along with the natural age-related decline in the physical and physiological functioning make the elderly more prone to psychological disturbances. Functional dependency is common among elderly people and many will need assistance in their activities of daily living. The physical illnesses have a role of causal or association with psychiatric illness especially with depression and significant or non-significant association with cognitive impairment and depression. Of all the problems associated with an ageing population, health care demands top priority.

Therefore, screening of mental health conditions become necessary in the community which at the next level can be confirmed and managed at Primary Health Care level and/or beyond. Keeping this background in mind, the study was planned to assess Cognition, depression and Activities of daily living (ADL) among elderly persons.

Materials and Method

A Community based cross sectional Study was done over a period of one year. The sample size was calculated based on the Prevalence of Geriatric Depression in urban India of 21.9% and was worked out to be 290. Inclusion criteria were individuals aged 60 yrs and above residing in the study area for more than one year. Exclusion criteria was persons with Stroke and Aphasia, Loss of Hearing and those who were affected by loss of memory. Data collected using Semi-structured Proforma, Socio-demographic information, history of existing Medical Illness. Anthropometric measurements like height, weight were recorded. Blood Pressure recording was done using calibrated digital BP apparatus. Standard tools like Mini-Cog questionnaire, Barthel Index questionnaire and Geriatric Depression Scale (Short Form) used to assess Cognitive Impairment, Activities of daily living and Depression.

The data obtained were analyzed with SPSS 22. The prevalence of cognitive impairment and depression was calculated in percentage. Chi-square test and Independent T-test were applied. Analyses were conducted to look for differences between groups and were expressed as statistically significant at P < 0.05.

Results

In the present study, 201 (69.3%) individuals belonged to the age group of 60-69 years, with Mean±SD of 69.2±6.98 years and 170 (59%) were females, with Mean±SD of 69.25±6.99 years in females. About 152 (52.4%) of them belonged to three generation family. About 208 (71.7%) were currently married, and 29 (10%) were widow/widower, among whom 27 (93%) were widow and 2 (7%) were widower. Hypertension was seen in 205 (70.3%) of individuals, and 126 (43.6%) were known case of Diabetes Mellitus.

Based on word recall test, two-word recall was seen among 111 (34.8%) and 75 (25.8%) had one-word recall. On the basis of clock drawing test, about 109 (37.5%) were unable to or refused to draw. Cognitive Impairment was seen in 132 (45.5%) individuals. Among the study participants, 57 (19.6%) had urinary incontinence or occasional incontinence, 53 (18.2%) were immobile, or using wheelchair or needed help, 31 (10.6%) needed minor help for transfer from bed to chair and back (verbal or physical), 25 (17.9%) needed help to climb stairs (verbal, physical, carrying aid), 10 (3.4%) had occasional accidents of incontinence, 5 (1.72%) needed help cutting, spreading butter, etc., or required modified diet and other 5 (1.73%) needed assistance for bathing, grooming and 3 (1.03%) for dressing. Among the study population, 58 (20%) have disability. It was seen that there was a statistically significant difference in weight (p value 0.004), BMI (p value 0.006) and Cognitive Impairment (p value 0.001) with functional dependency.

Among the study population, 141 (48.6%) were of suggestive Depression and seen more among females (young old) about 135 (67%). The average diastolic blood pressure among individuals with suggestive Depression was comparatively lower with respect to people who did not have Depression which showed statistically significant difference (p value 0.039). There was a statistically significant association between ADL, Medical illness and Cognitive Impairment.

Discussion

Cognitive Impairment (CI) was assessed based on two categories. In word recall test, two words delayed recall was seen among 34.8% of elderly and 25.8% had one word delayed recall. On the basis of clock drawing test, about 37.5% were unable to or refused to draw. The reasons for refusal to draw were first due to lack of interest to draw and secondly due to instability in hands to hold a pen and further due to their low literacy level they could not write what they knew. Prevalence of cognitive impairment in our study was 45.5%. The results were similar to a study done which revealed 55% of elderly had cognitive impairment. Another study which was done among older cancer patients showed the overall prevalence of CI was approximately 35% which showed that the presence of a chronic disease may have baseline CI of upto 20%. In the present study, marital status was significantly associated with cognitive impairment, those who were widow were affected more which was similar to a study done at ludhiana.

Cognitive impairment and Depression: Those cognitively impaired were also found to be more than three times at risk of depression in the present study. Depression is associated with cognitive impairment in older adults, and a meta-analysis of case-control and prospective studies of the association between depression and dementia conducted in 2001 concluded that history of depression approximately doubled the risk for dementia. The prevalence of depression in dementia has been reported to be between 9% and 68%, and it has been proposed to be both a risk factor for as well as a prodrome of dementia. People with mild cognitive impairment and dementia exhibit greater rates of depression than age-matched cognitively intact individuals.

Activities of Daily Living and Cognitive Impairment: In the present study it was found that there is a significant decline in functional ability with an increase in cognitive impairment. A study done by Andreas E Stuck et al, revealed the highest strength of evidence for an increased risk in functional status decline was found for cognitive impairment and depression. Cross sectional studies have consistently reported that dementia is a powerful contributor for functional disability in the elderly. This has also been studied in a longitudinal study, which indicate that dementia is the strongest determinant for developing functional disability and functional decline, independent of the presence of other chronic diseases using Katz index tool which has similar domains of that of our present study tool.

Activities of Daily Living and Depression: The relationship between depression symptom and functional status is often complex, and there may be several plausible explanations for a weakened association between depression and functional challenges with age progression. Changes in coping strategies to overcome challenges, and the onset of new physical illness are strong correlates with depression which was explained by Kukull et al, in 1986 in his study. Approximately 60% of the participants reported at least one type of functional difficulty, with about 40% reporting at least one functional dependency, and more than half have some form of physical functioning and mobility difficulty.

Depression: Prevalence of suggestive depression was 48.6% in the present study. Few studies have revealed that the prevalence rates for depression in community samples of elderly in India vary from 6 to 50%. The prevalence has been reported to be 45.9%
in the urban slums of Mumbai,28 29.36% in the urban slums of Dharwad district, Karnataka,29 However, a high prevalence of depressive disorders of 52.2% among the elderly ≥ 60 years was observed in the study conducted by Nandi PS et al in the rural areas of West Bengal.30

Significant predictors for depression found among the elderly in our study were the urban residence, female sex, increasing age, nuclear family, illiteracy, and poverty.15 The elderly living in a nuclear family was more than three times likely to suffer from depression than those living in a joint family. Urbanization leads to households becoming less extended and more nuclear. Data from household surveys conducted suggest a trend toward convergence to predominantly nuclear households.31 A significant association was found between co-morbidities and depression. These co-morbidities along with depression increases physical disability, poor compliance and increased health care utilization leading to poor quality-of-life and further complicating the treatment of depression.31 (Table 2).

All these evidence strengthen the fact that depression in elderly is emerging as an important public health concern due to age-related decline in the physical and physiological functioning, urbanization, changing family structure leading to poor quality-of-life, increased disability, and morbidity.

Conclusion

The health problems identified in this study were physical as well as mental. The prevalence of CI, functional disability and Suggestive Depression was 45.5%, 19.7% and 48.6% respectively in elderly participants. There was also statistical significance between CI, Depression and ADL. Through outreach services by clinical psychologists and therapeutic interventions by psychiatrist through Medical Officer of Urban health care, can bring about the much needed solace to the existing problem.

Strengths and Limitations: Standard tools used for assessment of Cognition, ADL and Depression. Limitations were Inability to draw or refuse to draw Clock drawing Test were categorized into Cognitive Impairment based on Mini-Cog tool, which might also include few normal participants who might not be truly having cognitive impairment simply by refusal. The present study undertaken was a screening test and therefore cannot be generalized to the population and needs confirmation at the next level by the specialists.

Neuro Degenerative Diseases Classification Using Triplelayer Feature Extraction

A. Athisakthi\textsuperscript{1}, M. Pushpa Rani\textsuperscript{2}

\textsuperscript{1}Department of Computer Science, \textsuperscript{2}Proff & Head, Deapartment of Computer Science, Mother Teresa Women’ s University, Kodaikanal, India.

Abstract

Neuro Degenerative Diseases include Parkinson Diseases, Huntington Diseases, Ataxia, Myoclonus and Amyotrophic Lateral Sclerosis are medically, Hereditarily, pathologically fluctuated and are described by its symp-toms and execution of motor impairment. In this study, the data samples are of 15 subjects with PD, 20 subjects with HDdisease, 13 subjects with ALS and 16 subjects of healthy or fit persons. The database is composed a one minute recording of Force Sensitive Resistor (FSR) Signal. For feature deduction 2 – level wavelet Decomposition is done using Discrete Wavelet Transform (DWT). The acquired features were evaluated using the means of 10-trials for fivefold cross-validation (FFCV) in LDA with a Random Forest classifier (RFC). For NDD localization. The Random Forest Classifier gives the better outcome contrast with SVM and QB ordinary classifiers. The experimental proves that the accuracy, sensitivity and the Specificity of the proposed system is highly accurate and efficient than the previous method. The percentage of the proposed method is 98.24%, 97.92% and 96.78% as each.

Keywords: Neuro Degenerative Diseases (NDD), Amyotrophic Lateral Sclerosis (ALS), Parkinson Disease (PD), Support Vector Machine (SVM), Huntington Disease (HD), Random Forest classifier (RFC), Discrete Wavelet Transform (DWT).

Introduction

Neuro degenerative diseases are debilitating of neurons that result in accelerating degeneration. This causes problems with motor impairment. Now a day’ s predictable people are affected by some form of neurodegenerative diseases such as Parkinson’s disease (PD), Prion Disease, Amyotrophic lateral sclerosis (ALS), Huntington disease (HD), and Spinal Muscular Atrophy (SMA). In early phases of the disease, it is more difficult to distinguish the atypical variants. The early detection and stratification of neuro-degenerative disease is important and efficient for general practitionerwhich reduces the time and cost of the diagnosis process.

Gait recognition is one of a fascinated technique for suc-cessive people recognition. Even though this technology is not only limited with this function, it can be used in the clinical side to distinguish the motor disability using gait samples. Haeri.M.\textsuperscript{3} et.al told, The Gait signal may be a fine parameter for classifying the NDD’s that is caused by some demise of neurons in the human brain. In this work a hybrid method on triple layered feature extraction technique is urged to detect the neurodegenerative diseases from control and morbid signal of Parkinson Disease (PD), Huntington Disease (HD), and Amyotrophic Lateral Sclerosis (ALS).

In the Human nervous system, Parkinson Disease (PD) is one of a brain condition, which leads to tremoring and complexity with walking in movement progress, and management skill. The human muscle movements are controlled by nerve cells, these cells uses one of a chemical called dopamine. When dopamine content was getting destroyed in the nerve cells, the Parkinson disease will occur. The brain nerve cells cannot properly propel the command without dopamine. So the muscle functions are slowly losing its ability. Rigid or stiff muscles, problem with balance and walking, Stooped position, difficulty continuing to move are some most common symptoms of Parkinson diseases J. M. Hausdorff\textsuperscript{9} explained. The National Parkinson foundationsurvey shows, in worldwide there were 1% of older adults affected by this disease.Huntington Disease (HD) is a degenerative disorder which is inherited from upper generations. In this disorder, there was a hereditary defect on chromosome 4. CAG is one of a DNA part of the brain cell. It is repeated many more times than it is...
supposed to. The CAG gene portion was repeated 10 to 28 times in normal person, but in the HD gene it was repeated in 36 to 120 times. The counting of repeats tends to increase by as the gene inherited through the families. The greater chances of developing earlier symptoms are depending upon the repeats of chromosome. Slow uncontrolled actions, trembling gait, Facial movements including frowns, judgment deflection, Head turning to shift eye position are some of the symptoms of ALSJ.

M. Hausdorff\textsuperscript{9}, Amyotrophic Lateral Sclerosis (ALS) is an accelerating Neuro degenerative disease, which affect the brain and spinal cord nerve cells of the human body In ALS, because of accelerating degeneration in a nerve cell, the motor neurons are dying and losses its ability to control the muscle movements.Huang, Chenn-Jung and et al.,\textsuperscript{7} explained, the basic muscle movements of speaking, eating, moving and breathing are affected by the loss of motor neurons. Figure 1 shows the gait signal of PD, HD and ALS subjects.

Figure 1: Gait Signal of PD, HD, ALS Subjects

### Background Study:
The researcher named M.P.Murray et.al.\textsuperscript{5} demonstrated identifying gait is the best theory of recurrent development in medicinal tests, and the Peak examination can be useful in the comprehension of the diseases propelling state which is valuable data for the medicines.

The author Simon.S.R.\textsuperscript{2} proves the examinations of gait in persons are characterized as the better investigation of strolling people. In his paper, J.M.Hausdorff\textsuperscript{10} clears that Clinicians as well as specialists are requiring much of the time for gait ex-amination framework.\textsuperscript{11}

The researchers Haeri et.al.\textsuperscript{3} implemented their work as the change of gait flag might be a decent technique in separating-development issue which is due to the breaking down of some neurons in the part of brain.

### Methodology:
These medical conditions were picked in light of the fact that they are known to have related causes that may make troublesome finding of them. In this examination, we have utilized an open database from Physionet. 15 subjects with PD, 20 subjects with HD disease, 13 subjects with ALS and 16 subjects of healthy or fit person’s signals are incorporated from the benchmark database. The natural information was procured utilizing Force Sensitive resistors, with the yield roughly in respect to the power under the foot. Each file comprises two signs and it is analyzed using FSR of each foot’s Stride-to-stroll proportions with respect to footfall touch instances. In this paper, the time arrangement of flag was categorized as six intervals. The intervals are given as Right Stride interval, Left Stride interval, Left Swing interval, Right Swing interval, Left Stance interval, Right Stance interval and Double support period in-between and follow measurable, energy estimations of wavelet decay and pinnacle exam systems for spotlight extraction.

Figure 2: Movement Disorder detection and classification
The repetitive pattern of human motion is called a gait cycle. It includes steps and strides. One single step is called as a step; whole gait cycle is called as a stride. The stance and swing phases are incorporated in every gait cycle. In a verbose gait cycle the stance phase occupies 60% of the gait cycle and it can be part into the double support and single-leg support.

**Statistical Analysis:** The statistical gait analysis helps mainly in depicting the gait. In this research for each time arrangement of a single subject, the parameters such as Energy, Standard Deviation, Mean, Variance and Co Variance of a similar walk are considered. The “statistical gait analysis” approach helps to find the repetitions and exact results.

(a) **Energy**

The continuous time complex signal’s energy and it is represented as \( x(t) \) is calculated as

\[
E_x = \int_{-\infty}^{\infty} |X(t)|^2 \, dt
\]

(b) **Mean**

The mean is always calculated to know the average rate of the signal or the preferred sample. The calculation of mean value is done using the below formula.

\[
\mu = \frac{1}{N} \sum_{i=0}^{N-1} X_i
\]

(c) **Standard Deviation**

The computation of Standard deviation is the diffusion set of records from its mean. It measures the complete variability of a distribution. The mathematical representation of standard deviation is as follows.

\[
\sigma = \sqrt{\frac{1}{N-1} \sum_{i=0}^{N-1} (X_i - \mu)^2}
\]

(d) **Variance**

The Variance calculation is done using the below representation.

\[
Var(X) = E[(X - \mu)^2]
\]

(e) **Co Variance**

The covariance of data sample of X and Y is calculated as follows.

\[
COV = \sum_{i=1}^{n} (X_i - \bar{x})(Y_i - \bar{y})
\]

**Discrete Wavelet Transform:**

**a) Decomposition of Wavelet Signals:** The decomposition of wavelet is one of the best approaches to identify signals in the field of signal processing.

The utilization of wavelet decomposition is to break down the signals into its appropriate segments for testing purpose.

The proposed method handles two phases of decomposition of wavelet which is mainly used for feature extraction. The process of signal decomposition resulted in approximation and detailed set of three. Basically, a wavelet is a function \( \varphi \in L^2(R) \) with a zero \( \int_{-\infty}^{\infty} \varphi(t) dt = 0 \).

The continuous Wavelet Transformation (CWT) of a signal \( x(t) \) is then defined as:

\[
CWT_\varphi x(a,b) = \frac{1}{\sqrt{|a|}} \int_{-\infty}^{\infty} x(t) \varphi^* \left[ \frac{t-b}{a} \right] dt
\]

where,

\( \gamma(t) \) represents the ancestor of wavelet,

\* is defined as complex conjugate,

Scaling parameters are \( a \) and \( b \).

The recurrence of the oscillation and the wavelet length is defined by the scaling parameter \( a \). The scaling parameter \( b \) defines the position of moving of wavelet. The capacity of scaling and function of wavelet is addressed to Low-Pass Filters (LPF) and High-Pass Filters (HPF).

The process of decomposition of signal starts by transiting through these filters. The low-frequency parts of the time arrangement is considered as approximation and the high-frequency segments are computed by points of interest. The signal processing passes through the low-pass filters and high-pass filters. To get the detail coefficients and the approximation coefficients \( A1 \) and \( D1 \) at first level, the yielded signals from the filters are crushed. The approximation, coefficients are obtained and passed to the next phase, which is to rehash the technique. The signal is deteriorated at the normal level in the last phase of decomposition process.

The energy of a vague signal can be separated at different resolution levels. Mathematically, this can be presented at
\[ ED_i = \sum_{j=1}^{N} |D_{ij}|^2, i = 1, \ldots, I \]

\[ EA_l = \sum_{j=1}^{N} |A_{ij}|^2 \]

Where \( i = 1, \ldots, l \) is the wavelet decomposition level from level 1 to level \( l \). \( N \) is the number of the coefficients of detail or approximate at each decomposition level. \( ED_i \) is the energy of the detail at decomposition level \( i \) and \( EA_l \) is the energy of the approximate at decomposition level \( l \).

**Peak Analysis:** For analyzing signals, peaks are considered to be the most important thing. In identifying the signals, the peaks are categorized within the signal’s series of time. Using the six intervals, the interims and histogram of normal peak is calculated.

**a. Classification**

The proposed theory is carried out with the help of three different classifiers which are random Forest Classifier (RFC), Quadratic Bayes (QB) and Support Vector Machine (SVM). It helps mainly in the identification and characterization of signals. The chosen classifiers in the proposed work is considered to be learning classifiers and they mainly supports in the categorization of various levels of class in the test vector. Leo Breiman\[^8\] explained among the three classifiers, the SVM belongs to two class classifier category. It is used in the process of augmenting the hyper-plane with the choice limit comparison. The arrangement of work is done by SVM and the preparation of group vectors \( x \) as per the accompanying condition:

\[ c = \sum_{k} a_{k(x_i, x)} + b \]

Where, Support Vector is represented as \( S_{k,x} \) is used to define the weight, bias is represented as \( b \), and \( k \) is to represent the kernel function. \( k \) is considered to be the dot product, when the process is of a linear kernel. In the case of \( c > = 0 \), the member of group 1 is categorized by \( x \), or else it is categorized as a member group 2.

The next classifier is Random Forest Classifier which is a combination of predictors of tree. In that each predictor of tree is individually dependent on the sampled random vector values like the distribution as same in all the trees of forest. The algorithm for random forests applies the general technique of bagging, to tree learners. A training set is denoted as \( X = x_1, \ldots, x_n \) with responses \( Y = y_1, \ldots, y_n \), bagging repeatedly \( (B \) times \) selects a random sample with replacement of the training set and fits trees to these samples for \( b = 1, \ldots, B \). Sample, with replacement, \( n \) training examples from \( X, Y \); call these \( X_{b}, Y_{b} \). Train a decision or regression tree \( f_{b} \) on \( X_{b}, Y_{b} \). After training, predictions for unseen samples \( x' \) can be made by averaging the predictions from all the individual regression trees on \( x' \):

\[ \hat{f} = \frac{1}{B} \sum_{b=1}^{B} f_{b}(x') \]

Another classifier Quadratic Bayes normal classifier, in this classifier, the pattern-generating mechanism is represented in a probabilistic framework. A Bayes classifier is a pattern classifier based on two fundamentals: (1) When an object is injured or loss its value by the incorrect classification it can be quantified as a cost. (2) The anticipation of the cost is acceptable as an optimization criterion.

**Performance Measures:** The classifiers performance is calculated in the terms of sensitivity, accuracy and specificity. The terms are presented based on the comparison of actual and predicted output. The confusion matrix is used to predict the count of True positives, False positives, False negatives and True negatives of each classifier.

The ability of trained method to identify the positivity of NDDs is done using the sensitivity rate calculation. The Sensitivity (SE) calculation is as below.

\[ SE = \frac{TP}{TP + FN} \]

The specificity rate (SP) is calculated to review the result of negativity with respect to healthy subjects or non-infracted and it is evaluated as below.

\[ SP = \frac{TN}{TN + FP} \]

Accuracy is basically a measurement system which helps in the computation of degree of closeness of a quantity to its actual or true value. The formulaic of computation is as follows.

\[ Acc = \frac{TP + TN}{TP + TN + FP + FN} \]

**Results and Discussion**

For the proposed method, the data samples are collected from the online database Physionet.
In this paper, the proposed method based on the analysis of statistical, energy and peak is discussed. The parameters like energy, standard deviation, mean, variance and co-variance are evaluated with respect to 6 intervals in statistical analysis. The six intervals are Left Stride Interval, Right Stride Interval, Left Swing Interval, Right Swing Interval, Left Stance Interval, Right Stance Interval and Double support interval signals.

The energy space is calculated from the signal decomposition using Discrete Wavelet Transformation in the phase of energy analysis.

Average peak interval and Histogram is computed in the last phase peak analysis.

For better performance and high accuracy result, the three different analysis method are combined. The tabular view of performance, classification, specificity and sensitivity of all the three classifiers SVM, QB and RFC comparison is presented in the following section.

Conclusion

In this paper, the Neuro Degenerative Diseases are successfully detected by the proposed method. This is achieved using force sensitive resistor signals. The proposed method is based on the single method and it comprised the three different sets of analysis. This type of proposing resulted in the high rate of accuracy percentage in early analysis of disease. The accuracy 85.743% is considered as reasonable of proposed method based on Random Forest Classifier (RFC). The discussion of comparison is also presented in this paper and the effectiveness of proposed method is explained.

A Comparative Study on Effectiveness of Craniosacral Therapy Versus Self Sustained Natural Apophyseal Glide (SNAG) in the management of Cervicogenic Headache

A. Pahinian¹, M. Manikumar², R. Monisha³, D. Devaki⁴

¹Professor, Sri Venkateshwara College of Physiotherapy, Puducherry; ²Professor, Saveetha College of Physiotherapy, Chennai; ³Assistant Professor, SRM College of Physiotherapy; ⁴Assistant Professor and Director of Physical Education, Chennai

Abstract

Background: Headache that is caused by the structures of the upper neck is called cervicogenic headache. It usually starts on one or both sides of the upper neck area and then spreads to different area in forehead and face, there is a continuous need for some non-pharmacological intervention in the management of headache.

Objective: The aim of the study is to find the effectiveness of Craniosacral therapy and SNAG in cervicogenic headache patients to reduce the headache symptoms and improve the quality of life.

Methodology: Total number of participants in this study in 30 subjects and randomly allocated to two groups, 15 patients with cervico-genic headache in group A receives Cranio-sacral therapy and 15 in group B receives SNAG. The period of intervention for each participant was 3 weeks alternative days and total study duration was 3 months.

Discussion: From the statistical tool it has been analyzed the group A shows significant reduction of headache symptoms and the level of pain than compared with group B.

Conclusion: It has been concluded that craniosacral therapy shows that more significant reduction of headache symptoms and pain in cervicogenic headache patients than compared with SNAG group.

Keywords: Craniosacral therapy, cervicogenic headache, SNAG.

Background

Cervicogenic headache is a chronic, hemicranial pain syndrome in which the sensation of pain originates in the cervical spine or soft tissues of the neck and is referred to the head. Primary headache disorder may present with coexisting neck pain and tenderness(2).

Headache that is caused by the structures of the upper neck is called cervicogenic headache. It usually starts on one or both sides of the upper neck area and then spreads to different area in forehead and face. Specific neck movements or keeping the neck in one position or longer time aggravate the increasing of headache symptoms(1).

Cervicogenic headache have an average of 17° less rotation toward the headache side in the FRT, in contrast to those with no headache or migraine with aura. The incidence of an cervicogenic headache has been estimated to be 14 to 18% through in a recent population. Other treatment for cervicogenic headache includes cervical spine manipulation, strengthenening exercise, thoracic spine thrust manipulation.(3-5)

In addition these individuals report lower quality of life than healthy individuals. Manual therapy is advocated for managing cervicogenic headache .Trial studies shows that mulligan manual therapy was beneficial the reduction of cervicogenic headache. There is a increased demand for a non pharmacological approach in the management of patient with cervicogenic headache. Craniosacral therapy is a
Mulligan has described a novel approach for the self management of articular dysfunction in cervicogenic headache. The c1-c2 self SNAG targets c1-c2 dysfunction by emphasizing c1-c2 rotation using cervical self SNAG strap although the Mulligan concept is frequently used in clinical practice.

Craniosacral therapy is a light touch modality when we have to apply gentle manual force to the somatic dysfunction of the head and mobilize the cranial sutures which is leading to loss of normal physiological function. It actually mobilize the surrounding peripheral tissues and fascia that might produce the restriction in the movement of the body.

CST helps to prevent and abort headaches primarily by releasing tensions throughout the meninges by removing restrictions from meningeal and cranial bone structures, pressure is taken off the nervous system and the entire craniosacral system can open up. This also allows fluid to drain, so back pressure does not build up.

It causes tightening and loss of mobility of the dural tube related to the facilitated vertebral segments with increased nerve pressure from a contracted dural tube sleeve resulting in continual neuronal firing.

Also, the nerves in the area go to the intervertebral muscle, causing them to contract and cause fixation and subluxation. If a peripheral restriction is released but the dural tube restriction and facilitated spinal cord segments are not, the peripheral problem usually re-occurs. So a peripheral problem can translate through the facilitated segments up into the cranium and cause the meninges to contract in the same way an intracranial meningeal problem can translate down the dural tube and cause facilitation.

**Objective:** The aim of the study is to find the effectiveness of Craniosacral therapy and SNAG in cervicogenic headache patients to reduce the headache symptoms and improve the quality of life.(6-12)

**Methodology:** Total number of participants in this study in 30 subjects and randomly allocated to two groups, 15 patients with cervico-genic headache in group A receives Craniosacral therapy and 15 in group B receives SNAG, The study design employed here is comparative design and the population selected for this trial includes both male and female age group above 18 and the period of intervention for each participant was 3 weeks alternative days and total study duration was 3 months.

**Selection Criteria:** Patients with Unilateral Headache with neck stiffness or side dominant headache with the duration of 3 months and those having Positive flexion rotation test and restriction < 10 degree were included and the participants having onset of headache following cranial tumors and meningitis and with Sudden onset of new severe headache and history of cancer and HIV were excluded out of the study.

**Outcome Measures:** Outcome measures used in this trail is NPRS (numerical pain rating scale) and HIT-6 (headache impact test).
**Procedure:** The subjects those who fulfill the inclusion criteria were included in this study will be explained about the study and a written consent were taken and the participants are will be divided into group A and group B.

**GROUP A (Recevied SNAG)**

Self sustained natural apophyseal glide (SNAG) group. Patient in this group will be mobilized with a c1-c2 self SNAG using the thin, rubber-covered strap, position on the posterior arch of c1 and drawn horizontally forward across the face. The subjects will apply forward pressure on the strap and turn the head toward the restricted side of rotation, sustaining end for 3 seconds. Subjects will ask to perform 10 repetitions of the self mobilizations SNAG during every treatment sessions\(^\text{15}\).

**GROUP B (Received Cranio-sacral therapy)**

In Stage 1, the patient has been positioned in supine lying and they were given instructions to take deep breath and the therapist flexes the neck in 10 to 15 degree and maintains this position for 2 minutes.

In Stage 2, the patient has been positioned in supine lying and they were instructed to take deep breath and therapist lateral flexes the trunk on right side and lower limbs passively and maintain this position for 2 minutes.

In Stage 3, the patient has been positioned in supine lying and instructions were given to take deep breath and lateral flexes the trunk on left side passively and maintain this position for 2 minutes.

In Stage 4, supine lying was adapted by the patient and they were instructed to take deep breath and hip and knee flexed 90 degree passively and maintain this position for 2 minutes.

**Data Analysis and Representation**

**Statistical Analysis:** Baseline characteristics of all the subjects were given as Mean ± SD.

The outcomes values obtained were manually tabulate in Microsoft Excel '07 spreadsheet, and were exported to “Graph pad prism 5” for Windows version 5.03 for statistical analysis.

Statistical comparisons within the group and between the groups for post traumatic stiffness, NPRS and ROM were analyzed using paired ‘t’ test and unpaired ‘t’ test respectively.

The paired “t” test is formulated as:

\[
t = \frac{\bar{d}}{s / \sqrt{n}}
\]

Where, \( \bar{d} \) = mean difference
\( d \) = mean,
\( n \) = total no. of sample.

The unpaired “t” test is formulated as:

\[
t = \frac{x_1 - x_2}{s \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}
\]

\[
S = \sqrt{\frac{n_1 S_1^2 + n_2 S_2^2}{n_1 + n_2 - 2}}
\]

Where, \( X_1 \) & \( X_2 \) are means of group A & B;
\( N_1 \) and \( n_2 \) are sample sizes of two groups. Variance of sample 1 \((s_1^2) = \frac{\Sigma (x_i - \bar{x}_1)^2}{n_1 - 1}\)

Variance of sample 2 \((s_2^2) = \frac{\Sigma (x_i - \bar{x}_2)^2}{n_2 - 1}\)

The p-value was chosen as per the description given by “Graph pad prism 5” for Windows version 5.03.

**Description of p- value:**

<table>
<thead>
<tr>
<th>P- value</th>
<th>Level of significance</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;0.0001</td>
<td>★★★</td>
<td>Extremely significant</td>
</tr>
<tr>
<td>0.001 to 0.01</td>
<td>★★</td>
<td>Very significant</td>
</tr>
<tr>
<td>0.01 to 0.05</td>
<td>★</td>
<td>Significant</td>
</tr>
<tr>
<td>&gt;0.05</td>
<td>NS</td>
<td>Not significant</td>
</tr>
</tbody>
</table>

All data analysis were done using presented as mean value ± SD. For using the above said outcome measures, data were collected regarding the pretest and posttest values. The related paired ‘t’ test was performed to find the significant changes after treatment using the formula.

**Result**

The collected data was analysed using the graph pad prism 3.

The mean and standard deviation of pre and post value of NPRS for GROUP A with Pre test(8.06) Post test(3.93) and GROUP B with Pre test (7.93) Post test(5.93)

The mean and standard deviation of Pre and Post value of HIT-6 for GROUP A with Pre test(59.4) Post test(41.3) and GROUP B with Pre test(56.3) Post test(49.2)
Within the group analysis it have been shown that the Pre and Post values of NPRS & HIT 6 shows significant in Group A than the Group B and the Between Group analysis the pre test and post test values of both groups shows NPRS Group A(18.42), Group B(7.72), HIT-6 Group A(9.99), Group B(5.60)

Between group analysis the post test values shows that Group A is more significant than Group B. After statistically analyzed, it have been seen that there is high reduction of pain in craniosacral therapy group than SNAG group. The post test values (between group analyzes) of both group were analysed with the mean differences of NPRS and HIT-6.NPRS Group A(4.1) & Group B(2.1). HIT-6 Group A(18) & Group B(7.1) Which shows that Group A shows much significant than Group B. It have been concluded that Group A shows high reduction of pain than Group B.

Discussion

From the statistical tool it has been analyzed the group A shows significant reduction of headache symptoms and the level of pain than compared with group B.Januz Kojan et al., (2015) they have performed a study to effect of a c1-c2 muligan sustained natural apophyseal glide (SNAG) in the treatment of cervicogenic headache .the result of this study shows significant reduction of pain and improvement of ROM in upper cervical region use of muligan technique.(28) cervicogenic headache and improving cervical range of motion more related with neurophysiological changes in pain modulation.(28)

Jull et aevaluated mobilization and specific exercise for the management of patients with cervicogenic headache. Combined interventions did not produce a significantly better effect than the single therapies across all outcomes. Nevertheless, there was a 10% better response for the participants who received the combined therapy, which was thought to be clinically relevant.(30)

In that study there was a 50% reduction in headache frequency in 71% of subjects receiving manual therapy alone. The results of both studies suggest a significant benefit of manual therapy in the management of patients with cervicogenic headache.

A number of studies have shown manual therapy to be effective in the management of cervicogenic headache. The majority have investigated a combination of manual therapy with exercise, as cervicogenic headache is a disorder of cervical muscular impairment as much as cervical joint dysfunction.(31-32)

From thus study it has been seen that SNAG reduced the symptoms of headache disorders because it stimulate the mechanoreceptors of the joint capsule and surrounding tissues which inhibit the pain at the spinal cord. SNAG is also improving the cervical ROM which likely reduced the joint stiffness and breakdown the adhesions of soft tissue structures in the vice versa it improving joint ROM which further decrease the symptoms of head ache disorders.

SNAG usually workout for upper cervical joint segments which reduce the pain radiating area for cervicogenic headache subjects.

In subjects with craniosacral therapy shows that reduction of pain sensitive tissues in the brain. This relates to pain gate theory in which pain supports in the upper cervical segments tensions thoughtout the meninges which might open the entire craniosacral system. It will be releasing the tightening and loss of mobility of the dural tube which further release the dural tube restrictionsin order to normalize the ability of facilitated spinal cord segments.

Craniosacral therapy is difficult to perform due to changing posture and variations as to be done but result benefits to subjects with cervicogenic headache disorder usually SNAG workout on the part of upper cervical segments but CST shows benefits of entire mobilization of vertebral body segments.

Conclusion

It has been concluded that craniosacral therapy shows that more significant reduction of headache symptoms and pain in cervicogenic headache patients than compared with SNAG group

Limitations of the Study: Further study should be conducted in longer duration with large sample size and more than two outcome tools should be used for further research.

Conflict of Interest: There has been no conflict of interest for the authors.

External Funding: No funding has been needed for this study.

Assessment of Knowledge, Attitude and Practices Regarding Breastfeeding among Primiparas Mothers in Kanchipuram District, Tamilnadu

Adithi K.1, N.Vinodh2

1Project Technical Officer, Bengaluru, 2Scientist B, ICMR-NCDIR, Bengaluru,

Abstract

Background: Breastfeeding is the fundamental component of the child-survival strategy. Lack of breastfeeding – especially exclusive breastfeeding during first few months of life is important as it reduces the risk factors for the infant mortality and the morbidity rate. Limited studies have attempted to understand the knowledge on benefits of breastfeeding among mothers which affect breastfeeding pattern in urban areas.

Objective: To find out the association of socio demographic factors and breastfeeding knowledge among Primiparas. To understand the current practices of breastfeeding among Primiparas.

Method: A quantitative, institutional based cross sectional study was conducted in a PG Medical college. Convenient Sampling was used to collect data from 216 Primiparas in the age group of 18-49 years having a child up to 12 months of age for a period of one month. Their knowledge and practice with regard to prelacteal feeds, initiation of breastfeeding, feeding colostrum, and exclusive breastfeeding were assessed.

Results: Various demographic factors like the Maternal age, Maternal age at marriage, Maternal education, type of delivery, and religion had a direct association on Breastfeeding knowledge. Statistically significant difference was also found in the prevalence of knowledge about advantages of breast feeding with respect to education trend (p<0.005). The main reason cited for incorrect practices was shortage of breastmilk which led to mixed feed and discontinuation of Exclusive breastfeeding.

Conclusion: Increased Involvement of the Heath care personnel’s in imparting knowledge on breastfeeding benefits to both mother and the baby would encourage and counsel the mothers for proper breastfeeding practices.

Keywords: Breast feeding, Knowledge and Practices, Advantages, Colostrum, Exclusive Breast feeding.

Introduction

Breastfeeding is the fundamental component of the child-survival strategy. It provides all the energy and nutrients that the infant needs for the first months of life. It continues to provide up to half or more of a children nutritional needs during the second half of the first year, and up to one third during the second year of life.1 WHO recommends Exclusive breastfeeding for the first six months of life. Breastfeeding also benefits mothers. Exclusive breastfeeding is associated with a natural (though not fail-safe) method of birth control (98% protection in the first six months after birth).2 Breastfeeding technique is a learned skill for both mother and new-born. Breastfeeding techniques comprises of commencement of breast feeding, breastfeeding positioning, latching on, taking your baby off the breast and burping.3

Study Design: A quantitative, institutional based cross sectional study was conducted in a PG Medical college, Kanchipuram district. Multipara mothers, Primi mothers with post-natal complications, Primi mothers who are not willing to participate in the study were excluded from the study. The study was approved by Institutional Review Board of the School of Public Health, SRM University and IEC PG Medical college, Kanchipuram district.

Data Collection: The data was collected from Primi mothers in the age group of 18-49 years having a child up to 12 months of age. Since it was knowledge based study the literacy level was taken for calculating the sample size. With prevalence of 85.6% literacy level among urban women (NFHS-4) in Chennai, Tamil Nadu with marginal error of 5% for 95% Confidence interval.
and oversampling of 10% the sample size calculated was 216. The respondents were selected using convenient sampling. The data collection was conducted for one month through semi structured questionnaire and with informed consent printed in English.

Statistical Analysis: Data was analyzed through Statistical package for social sciences version 20. Descriptive statistics were used to present the level of knowledge and practices of breastfeeding among Primipara mothers. Chi square was used to find out the association between the socio demographic variables and Knowledge and Practice scores.

Results: It was seen that majority of the primipara mothers were in the age group 24-28 years with mean age of 25.37 years. Around 47.7% of the mothers were married in the age group of 22-26 years. 64% of the Primipara mothers have undergone C-Section delivery while remaining 36% primiparas delivered normally. Most of the mothers were Graduates (52.8%) with most of them studied till high school (45.4%) followed by primary school.

Table-1: Knowledge of primi mothers towards breastfeeding.

Table-1 reveals the Knowledge among Primiparas towards the benefits of breastfeeding. Most of the Primipara mothers knew the importance of Breastfeed. 94% agreed that breast milk is nutritious and protective in nature compared to bottle milk. It was seen that only 31% of were aware that prolonged breastfeeding prevents Dental Caries, Diabetes and other Non-Communicable disease among babies in future. The knowledge on benefits of breastfeeding among Primipara mothers was noted to be moderate. Around 51.9% agreed that breastfeeding helps to lose weight Post pregnancy. 42.6% of mothers knew that prolonged breastfeeding acts as a natural contraception. It was seen that effect of Breastfeeding on Post-Partum Depression to be very low (10.6%) among Primiparas.

</tbody>
</table>

Table 4-shows that 88.4% of the mothers knew how to make the child burp post feed. Baby getting. Wet burp, falling asleep, getting relaxed, stop crying were few signs of fully fed baby according to mothers.

Discussion

The main rationale behind the study was to understand the level of knowledge and breastfeeding practices among Primi mothers with child under one year. Although, most of the women were literate, it was seen that they possessed moderate knowledge on breastfeeding (57.87%).

Attitude of mothers towards breastfeeding revealed that majority of mothers had favorable attitude towards breastfeeding. 94% of mothers agreed that breast milk is nutritious and protective for the baby and 81.9% felt that it strengthens the immune system. According to study by Naseem et al. 67.5% of mothers agreed that breast milk is the best milk. Half of the mothers knew that Breastfeeding helped to lose weight post pregnancy and acts as a natural contraception. Only one tenth of the mothers knew that breastfeeding prevents postpartum depression.

In our study it is seen that the main sources of information about breastfeeding were Elders (56%), whereas only 32.5% received information from the Health care providers. In a similar study conducted by M. Ekambaram et al it was seen that 17% received help from health care workers. It was noted that mothers who delivered normally, the level of knowledge (63.6%) and practice (68.8%) on initiation of breastfeeding were nearly the same. In a study conducted at Bengaluru, few issues like, baby shifted to NICU for observation (38.5%), mother seriously ill (requiring ICU care-2.5%) were cited as the main reasons for delay in initiation of breastfeed.

Surprisingly, it was seen that only 24.5% of the mothers were aware about initiation of breastfeeding after C-section but nearly three fourth started breastfeeding within 4 hours. The prime reason behind this may be the support and counseling provided by Health care workers on the importance of breastfeeding. Various Indian studies have noted higher knowledge about early initiation of breastfeeding ranging from 87-92% but breastfeeding initiation varied from a low 6% to 36%.

According to WHO, Exclusive Breastfeeding should be practised for 6 months. In our study around 83.8% of the mothers knew the importance of EBF but 71.8% practiced it. In a study conducted at Mangalore 71.6% of the mothers practiced Exclusive Breast feeding. Mixed
Feed was practiced by 28.2% of the Primi mothers. Poor health of lactating mother, Insufficient milk Production, depending on infant formula for ease and lack of guidance were few reasons cited for discontinuing Exclusive Breast Feeding.

Nearly 88% of the mothers fed colostrum to their babies and 12% discarded as advised by elders owing to their cultural beliefs. This runs parallel to a study at Telangana, where 88% of the children were given Colostrum\textsuperscript{4}. The prevalence of prelacteal feed was lower in studies done by Madhu et al.\textsuperscript{11} (19%) and S. Jain\textsuperscript{5} (4.7%) whereas it was higher in studies done by Abhay Bagul et al.\textsuperscript{12} (78.6%), than the present study (8.3%) and was practiced mostly by Hindus.

In the present study 34.7% mothers practiced demand feeding whereas in studies done by Srivastava A et al.\textsuperscript{10} (32.5%) were practicing demand feeding. Post burp feeding was found to be practiced by 88.4% but Srivastava et al\textsuperscript{10} in their study found that only 40.3% mothers practiced post feeding burping. In the present study 62.7% were aware of the different breastfeeding techniques. The knowledge regarding techniques of breast feeding was noted to be 35% in a study done by Premlata Mittal et al\textsuperscript{13} in their study in Rajasthan.

According to our study, higher breastfeeding scores shows association with higher maternal age(p<0.005). Similar findings have been reported in study done by Narayan et al\textsuperscript{14} and Scott J. A.\textsuperscript{15}. An association was seen between breastfeeding scores and maternal education status which similar to a few other studies\textsuperscript{16,17}. Young and less educated Primiparas should be given support and counselling. Other than age, and educational status, maternal age at marriage, type of delivery, place of delivery and religion were positively associated with better breastfeeding scores.

**Conclusion**

Majority of Primi mothers had knowledge about the benefits of breastfeeding to the child, but nearly half of them were still unaware about the long and short term benefits of breastfeeding to mothers. Health care personnel’s can emphasize primi mothers on the health benefits of exclusive breastfeeding and colostrum feed, educate them during ante-natal period, support at the time of birth to help them initiate breastfeeding and ensure that breastfeeding is fully established in the post-natal period. Measures should be taken to educate the mother on dietary habits after delivery to ensure sufficient milk production which will help them to breastfeed exclusively. Doctors can play a proactive role by motivating and keeping the mother under supervision until they acquire proper skills of breastfeeding like attachment, positioning and demand feeding. Efforts should be taken to disseminate and promote breastfeeding which supports and encourages young primi mothers.

Chromosomal Aberrations in Breast Cancer Females

N. Ganesh¹, Alibha Rawat¹

¹Jawaharlal Nehru Cancer Hospital and Research Centre, Idgah Hills, Bhopal

Abstract

Breast cancer is one of the most prevalent cancers in women and accounts for nearly 23% of all cancers worldwide. It has been increasing at an alarming speed and there is a need to search for new and better diagnostic tools for its early and effective diagnosis. The current diagnostic tools include mammography, MRI, and FNAC. In this regard, cytogenetic analysis of breast cancer using standard Lymphocyte Culture Technique ¹ can be proved as a powerful and cost-effective tool to identify women with high risk of developing Breast Cancer. The technique can be used to study the altered chromosomal pattern in terms of its number or structure owing to its diseased condition that might be specific to Breast Cancer. In the present study, peripheral blood from breast cancer as well as healthy females were taken and subjected to cytogenetic analysis and studying their structural and numerical aberrations. The breast cancer patients were found to be having higher frequency of aberrations than healthy control.

Introduction

Chromosomal instability is a known feature of cancer and a number of aberrations, both numerical and structural are found in all types of cancer. The majority of cancer cells represent dynamic karyotypic changes, including chromosomal rearrangements². A positive association between the frequency of chromosomal aberrations in peripheral blood lymphocytes (PBLs) and the risk of cancer at different sites has been supported by numerous clinical observations³. Different case-control studies have also reported a significant increase in the frequency of aberrant cells in PBLs of cancer patients⁴. The discovery of Philadelphia chromosome (9; 22 translocation) was a breakthrough discovery in the field of cytogenetics which led to the development of cytogenetic analysis as a powerful tool for the diagnosis of some type of cancer. In case of Breast Cancer also chromosomal aberrations play a very important role and hence cytogenetic marker of breast cancer can be a very powerful diagnostic tool for this dreaded disease.

In this regard, it can also be useful in the study of Breast Cancer and if any specific chromosomal aberration pattern is indeed found, it can be used for screening females who are at high risk to develop this deadly disease and also for monitoring the prognosis and treatment response of Breast Cancer patients. Therefore, it is essential to assign role of cytogenetic endpoints such as chromosomal aberrations for the diagnosis and treatment of breast cancer.

Material and Method

Collection of Sample: Peripheral blood samples were collected from 50 registered Breast Cancer patients of age 18-65 years from the ward and Pathology Department of Jawaharlal Nehru Cancer Hospital & Research Centre after obtaining patient informed consent and other details such as Medical History, Family History, Ob/Gyn History and the samples were processed for cytogenetic analysis. Blood samples were also collected and analyzed from age-matched 50 healthy females for control study. For cytogenetic analysis, blood samples were cultured by following standard Lymphocyte Culture protocol of Moorehead et al., (1964) and Karyotype were prepared to look for any chromosomal aberrations that might be identified in breast cancer patients.

Lymphocyte Culture: Lymphocyte cultures were set up by Moorhead et al., protocol. Heparinized whole blood (1 ml) was added to a mixture containing 5 ml of culture medium RPMI 1640 and 300 ul of phytohemagglutinin (PHA). Then the culture vials were kept in HERA cell CO₂ incubator for 72 hrs, at 37 °C with 5 % CO₂. Then 0.02% of Colchicine solution was added at 70th hour of incubation period to arrest cells at metaphase. The cells were collected by centrifugation, resuspended in a prewarmed hypotonic solution (KCL,
0.075 M) for 17 minutes and fixed in chilled methanol/acetic acid (3:1 v/v) solution (Carnoy’s fixative). Then drops of cell suspension were allowed to fall from at least 6 inches height on pre chilled and chemically cleaned slides. These slides were air dried on a hot plate at 50-60 °C. All slides were labelled and stained with Giemsa stain and observed under microscope to look for well spread chromosome. The slides showing best metaphase plates were then selected for GTG Banding to prepare karyotype and study chromosomal aberrations. Slides were GTG banded according to the Benn and Perle method. Banded slides were scanned for numerical and structural aberrations. For each subject, 50 clear metaphases were assessed for CAs. Of these, 10 metaphases were karyotyped.

**Results**

The Chromosomal Assay showed higher frequency of abnormal metaphases with numerical as well as structural chromosomal aberrations observed in 50 Breast Cancer patients as compared to equal number of age-matched Healthy Controls. Most of the Breast Cancer patients showed Hypoaneuploidy, Fragments, Breaks, Acrocentric Association, Rings, PCD and ICD etc. (p value 0.0001***, highly significant) as shown in Table 1 and 2 and Figure 1 to 4, whereas Healthy Control females showed normal karyotype. However, very few subjects were presented with minimal chromosomal aberration pattern. The p value was calculated by Two Sample t test using OriginPro 8 Software.

**Figures showing structural and numerical chromosomal aberrations in Breast Cancer Females**

![](image1)  
**Fig. 1: Break**  
![](image2)  
**Fig. 2: Fragment.**
Genetic instability is a defining feature of human cancer. In the present study, breast cancer patients had a significantly higher percentage of aberrant metaphases as compared with controls. There was a high frequency of numerical as well as structural abnormalities in the cultured lymphocytes of patients. Thus, determination of the genomic instability level by chromosomal analysis which is a very cost effective technique can be used as a diagnostic tool for identifying females with high risk of developing Breast Cancer and also in monitoring disease progression and prognosis.

Conclusion

It can be concluded from this study that chromosomal assay is a very effective and cost effective tool to look for tumor markers in breast cancer patients and for screening high-risk categories as the constitutional chromosomal aberrations indicate towards a genetic damage that can lead to cancer. It has the potential to be used as a routine screening diagnostic marker in breast cancer. The non-invasive nature of the test requiring just 2 ml of peripheral blood and cost-effectiveness is an added advantage in a developing country like us where costly molecular tests are not affordable to everyone. More large scale cytogenetic studies needs to be done in this area to establish this as a potential tumor marker.

Study of Factors Affecting Low Birth Weight of Newborn in Uttar Pradesh

Ambri Agarwal¹, Prashant Tomar¹

¹Assistant Professor, Department of Obstetrics and Gynecology G.S. Medical College, NH24, Near Doohri Petrol Pump, Peeplabandapur, Pilkhuwa (UP), 2Department of Paediatrics G.S. Medical College, NH24, Near Doohri Petrol Pump, Peeplabandapur, Pilkhuwa (UP)

Abstract

82 (Eighty two) pregnant ladies aged between 16-30 years were studied. The maternal history was—qualification, 38(46.3%) were illiterate, 28(34%) were primary school educated, 16(19.5%) were secondary schooleducated. The habits were, 4(4.87%) were smokers, 36(43.9%) were passive smokers, 42(51.2%) were Tobacco chewers. Socio-economic status was 12(14.6%) were house wives, 17(20.7) were shop keepers, 53(64.3%) were laborer. The material age was, 38(46.3%) were aged between 16-19 were, 29(35.3%), were aged between 20-25, 15(18.2%) were aged between26-30. The clinical manifestation during pregnancy was—14(17%) had PIH, 4(4.87%) had pre-eclampsia, 2(2.43%) had eclampsia, 6(7.31%) had gestational diabetes, 24(29.2%) had APH, 32(30%) had PROM. The obstetric factors were 30(36.5%) were prim bares, 52(63.4%) were multiparous, 62(75.6%) had history of LBW, 38(46.3%) had history of miscarriage, the period of amenorrhea was—22,(26.8%) had 28 to 37 weeks, 53(64.3%) had 38-40 weeks 7(8.53%) had above 40 week 5(6.09%) had multiple pregnancy. This pragmatic approach study of LBW will be quite helpful to obstetricians and gynecologists, pediatricians, physicians to treat such patients actively to prevent morbidity and mortality of low birth newborn which is a great threat and challenge to the medical fraternity globally.

Keywords: PIH- pregnancy Induced Hypertension APH= Ante partum Hemorrhage PROM= premature rapture of membrane LBW= Low Birth weight.

Introduction

LBW (low birth weight) defined as weight at birth which is less than 2500gm usually measured in the first hour of life irrespective of the gestation age(¹). LBW is the major cause and contributes to about 60% to 80% of all neonatal deaths(²). Based on epidemiological studies, infants weighing less than 2500 gm, are more, likely to, die than normal weight babies. Global occurrence of LBW is 15.5% which amounts to about 20 million low birth weight infants each year. 96.5% of them in developing countries(³). Many of the LBW newborn become the victims of protein energy malnutrition (PEM) and infection. The causes of LBW are socio-economic status, poor nutrition during pregnancy, education level, and awareness of health condition. LBW is one of the most serious challenges for mother and child health. It has number of public health consequences such as mental retardation, congenital anomalies, morbidity and mortality. Moreover very high cost of special care and intensive care unit(⁴). Hence attempt was made to study the different causes of LBW because there is increase of neonatal death every year globally.

Material and Method

82 (Eighty two) pregnant ladies aged between 16-30 years, regularly visiting to obstetrics and gynecology department of G.S medical college hospital NH24 near Dhoori petrol pump, Peeplabandpur, Pilkhuwa-245204 (U.P.), were selected for study. They were admitted as per their expected delivery date (EDD). History of every patients was noted individually. The history

clinical manifestations of pregnancy and obstetrics problems were noted and classified with percentage. The LBW babies were referred to neo-natal department for further investigation. The patients having neurological complications, HIV, HbSAG and mothers having still born babies were excluded from the study.

The duration of the study was about 2 years (from September-2016 to December-2018).

**Observation and Results**

**Table 1: Maternal history in LBW fetal study.**

1. Qualification study: 38(46.3%) were illiterate, 28(34%) were qualified upto primary school, 16 (19.5%) up to high school. (Secondary school)
2. Habit study: 4(4.87%) were smokers, 36(43.9%) were passive smokers, 42(5.2%) were Tobacco chewers.
3. Socio-economic status: 12(14.6%) were house wives, 17(20.7%) were shop keepers, 53(64.3%) were laborer.
4. Age of maternal: 38(46.3%) were between 16-19 years, 29(35.3%) were between 20-25 years, 15(18.2%) were aged between 26-30 years.

**Table 2: Study of clinical manifestation during pregnancy.**

14(17%) had PIH (Pregnancy Induces Hyper tension), 4(4.87%) had Pre-eclampsia, 6(7.31%) had gestational Diabetes mellitus, 24(29.2%) had APH (Antepartum hemorrhage), 32(39%) had PROM (Premature Rupture of Membrane).

**Table 3: Obstetric factors affecting LBW.**

30(36.5%) were primiparous, 52(63.4%) were multiparous, 62 (75.6%) had previous history of LBW, 38(46.3%) had history of miscarriage.

The period of amenorrhea at delivery, 22(26.8%) had 28-37 weeks, 53(64.6%) had 38-40 weeks, 7(8.53%) had above 40 weeks, 5(6%) mothers had multiple pregnancies.

**Discussion**

In the present study of factors, affecting LBW of newborn in Uttar Pradesh. The maternal history was qualification 38(46.3%) were illiterate, 28(34%) were studied till primary school. 16(19.5%) were educated till secondary school. The habits were 4(4.8%) were smoker, 36(43.9%) were passive smokers, 42(51.2%) were Tobacco chewer (like Gutaka). The Socio-economic status was 12(14.6%) were house wife, 17(20.7%) were shop keepers, 53(64.3%) were laborer. The age of pregnant mothers was 38(46.3%) were between 16-19 years, 29(35.3%) were aged between 20-25, 15(18.2%) were 26-30 years old. (Table-1). The clinical manifestation of pregnant mother was 14(17%)PIH (Pregnancy induced Hyper tension HTN), 4(4.87%) had pre-eclampsia, 2(2.43%) had eclampsia, 6(7.3%) had gestational diabetes, 24(29.2%) APH (Antepartum hemorrhage), 32(39%) had PROM (Premature Rupture of Membrane) (Table-2). The obstetric factors were –In parity study 30(36.5%) were primiparous, 52(63.4%) were multiparous, 62(75.6%) mothers had previous history of LBW, 38(46.3%) mother had history of miscarriage. The period of amenorrhea was 22(26.8%) had 28-37 weeks, 53(64.6%) had 38-40 weeks, 7(8.53%), had above 40 weeks, 5(6%) mothers had multiple pregnancies. This finding were more or less in agreement with previous studies. The socio-economic conditions such as poverty, education level, violence during pregnancy, passive smoking (because her husband or father in law, family members could be smokers) early marriages are also contributing factors for LBW. Infectious agents have potential to penetrate through uterus in lesser immunity females and cause inflammation in uterus and placenta. Cytokines are released in response to the inflammation by the body immune system resulting in preterm initiation of labor which results in LBW. Adolescent when become pregnant before their own growth is completed faces difficulty in fulfilling their own and nutritional requirement. It has been also reported that passive smokers exposure to beedi or cigarettes smoking contains a complex mixture of various mutagenic which endogenous to growing fetus.

LBW individuals experience many health complication throughout their life which can cause long and short terms consequences including hypothermia, perinatal asphyxia respiratory problems, Hyperbilirubinemia, anemia, infection, neurological problems, ophthalmic complications, hearing defects, sudden infant death syndrome, coronary artery disease, immune-system problems. LBW could be due to serious placental problems leading to insufficient transport of nutrient and oxygen to fetus. Hence expecting mothers should have proper nutritional intake and regular medical check-up moreover expecting mothers should
not take self-medicine without advice of physician or obstetrician and gynecologist

Sometimes premature LBW babies need to be born to save mothers life due to other complications like anomalies of placenta, severe bleeding etc. It is also hypothesized that, violence during pregnancy leads to stress and strain on growing fetus may impair or retard the growth of fetus lead to LBW with de-arrangements of cardio-vascular and central nervous system. The LBW babies suffer with this de-arrangement in their future life, such children will be burden to whole family and society as well.

During pregnancy, apart from proper nutrition, regular medical check-up, expecting mothers should be treated, sympathetically and amicably for healthy growth of fetus.

Summary and Conclusion

The present study of factors affecting LBW of newborn in Uttar Pradesh will be quite useful to obstetric and gynecologist, physician pediatrician to avoid the morbidity and mortality of newborn. It is necessary improve the maternal health through nutrition and education because maternal malnutrition and anemia have significant association with LBW but this study further demands genetic, immunological, nutritional and embryological study because exact function of placental barrier and duration of formation of germ layers is still un-clear.

This research paper was approved by ethical committee of G.S. Medical College, NH24, Near Petrol Pump, Peelabandapur, Pilkhuwa-245304(UP).

Abstract

Background: “Demographic transition” has affected the health-care needs of the world’s population. The epidemiological transition from communicable diseases to Non-communicable diseases (NCDs) and Cardiovascular diseases (CVDs) being a leading cause of death calls for prevention of CVDs which will be the essential step to control the epidemic of NCDs. The aim of this study is to estimate the cardiovascular risk among adults aged ≥40 years, utilizing WHO/ISH risk charts.

Method: A community based cross-sectional study conducted among 250 individuals aged ≥40 years residing in urban area of Mysuru, Karnataka. Study participants were personally interviewed using a semi-structured questionnaire. Information regarding anthropometric measurements and laboratory investigations were also collected. The 10-year risk for cardiovascular events was estimated using the WHO/ISH risk prediction charts.

Results: Among 250 study participants, the mean age was 52.7 (+9.5) years and majority were females (69.6%). 25.6% had very high (≥40%) risk, 18% had 10–<20% risk, 23.2% had 20–<30% risk and 8% had 30–<40% estimated risk of developing fatal and non-fatal CVD event in next 10 years. The prevalence of risk factors like Hypertension, Diabetes, Hypercholesterolemia, Moderate Stress and Physical Inactivity were 49.2%, 28.8%, 24.4%, 45.6% and 8.8% respectively. Over-nutrition was more prevalent where 34.4% and 27.2% had class I obesity and class II obesity respectively.

Conclusion: There was a high prevalence of CVD risk factors and estimated risk of CVD are significantly prevalent in the urban population. Simple tool like WHO/ISH risk prediction charts can be used as a screening tool to estimate the CVD risk occurrence in next 10 years, in a low resource country like India, even at a community level.

Keywords: CVDs, CVD risk factors, Estimated 10 year CVD risk, WHO/ISH risk prediction charts, Urban population.

Background

Cardiovascular Diseases (CVDs) comprises a group of diseases of the heart and the vascular system.[¹] CVDs are the leading cause of death globally with 17.5 million annual deaths which is more in Low- and middle-income countries (LMICs).[²] By 2030, almost 23.6 million people will die from CVDs, mainly from heart disease and stroke.[³]

There has been a paradigm shift in the focus from communicable diseases to a new epidemic of NCDs and their sequelae. CVD, cancer, and diabetes mellitus (DM) have become the major causes of morbidity and mortality worldwide, but particularly in Southeast Asia region where they contribute to 52% of deaths and 38% of disease burden.[⁴]

Currently, India is facing a rapid health transition from Communicable disease to NCDs which account for
around 60% of all deaths causing a considerable loss in productive years of life. These losses due to premature deaths are projected to increase over the coming years.\[^5\] Compared with other countries, India suffers the highest loss in potentially productive years of life, due to deaths from CVD in people aged 35-64 years.\[^1\]

The prevalence of CVD reported to be 2-3 times higher in urban population.\[^1\] Over the past four decades, the prevalence of IHD in India has raised twofold in rural areas and sixfold in urban areas. At present, estimated prevalence of CHD is 7-13% in urban and 2-7% in rural areas.\[^2\] This higher incidence of CVD in urban areas reflects the acquisition of several risk factors such as tobacco consumption, lack of physical activity, unhealthy diet etc.

As CVDs are eminently preventable, Investment in prevention is the most sustainable solution. Over the last two decades, CVD mortality has declined in developed countries due to a combination of prevention and control measures.\[^6\] LMICs can be benefitted from the strategy of primary prevention.\[^1\] Research from several countries has consistently shown that treatments of established CVD explain less of the decline than reductions in risk factors to prevent development of CVDs.\[^7\] Therefore, Established tool like WHO/ISH risk prediction charts is used to estimate the total CVD risk.\[^8\]

In this context, present study was conducted with the objective of evaluating cardiovascular diseases risk utilizing WHO/ISH risk prediction charts among urban population in Mysuru, Karnataka.

**Methodology**

A community based cross-sectional study was conducted from January 2017-December 2017 among urban population residing in Mysuru, Karnataka. The required sample size was calculated using the prevalence of diabetes, 17% (CVD risk factors with highest prevalence)\[^8\] with 5% absolute precision, confidence level of 95% and non-response rate of 10%, the required sample size was 239 which was rounded off to 250. Study participants were selected using simple random sampling method. Individuals who were ≥40 years and residing for at least past one year were included. Individuals who were unavailable for two consecutive visits to the houses and those with confirmed CHD, stroke or other atherosclerotic diseases were excluded.

After obtaining clearance from institutional Ethics committee, study participants were personally interviewed using semi-structured questionnaire. Information about socio-demographic profile, family history, diet, personal habits, physical activity (GPAQ), and stress (DASS 21) was collected. BP (Prehypertension: BP 120-139/80-89 mmHg; Hypertension: BP ≥140/90 mmHg), anthropometric measurements, obesity (according to WHO-Asia-Pacific perspective BMI), total cholesterol (≥200 mg/dl) and random capillary blood glucose levels (Impaired glucose tolerance: ≥140-<200 mg/dl; Diabetes mellitus: ≥200mg/dl) were measured.

Estimation of CVD risk was done using SEAR-D specific WHO/ISH Risk prediction charts,\[^9\] according to gender, age, systolic blood pressure, total cholesterol, smoking status and presence or absence of DM. The risk was classified into five levels as <10%; 10% to <20%; 20% to <30%; 30% to <40%; and ≥40% and were depicted with green, yellow, orange, red and deep red colours respectively.

Data thus obtained was coded and entered in Microsoft Excel 2010 and analyzed using SPSS software version 22. Descriptive statistics such as frequencies, percentages, mean and standard deviation were calculated. Data was represented as tables and graphs as relevant.

**Results**

The Mean (SD) age was 52.7 (±9.5) years and majority (70%) belonged to age groups of 40-49 and 50-59 years with nearly equal representation from both the groups. Higher proportion of study individuals were females (69.6%), non-literates (53.2%) and homemaker (52.4%). According to modified Kuppuswamy scale for Socioeconomic status classification, 63.2% of them belonged to Upper Lower class.

In the present study, Family history of CVD was reported in 5.6% of study individuals. 15.2% were smokers and 9.2% had habit of tobacco chewing. Alcohol consumption was noted in 15.6%. 89.6% were consuming mixed diet.

History of hypertension (who were either diagnosed previously as hypertensive and/or was taking treatment) was noted in 28%, 21.2% were newly diagnosed as hypertensive and 15.6% as pre-hypertensive. The overall prevalence of hypertension was 49.2%. Similarly, 23.6% gave history of DM (who were either diagnosed previously as Diabetic and/or was taking treatment). 5.2% were newly diagnosed as diabetics and 13.6% as pre-diabetics during the study. Overall, 8.8% of the study participants had DM. Only 2.8% were aware
about their hypercholesterolemia status and 21.6% were newly diagnosed during the study. The prevalence of hypercholesterolemia was 24.4%.

It was observed that, 79.6% had substantially increased risk based on Waist-Hip Ratio. 61.6% were Obese and 16% had At risk Obesity. Underweight was noted among 5.6% of the study individuals. Mild to moderate stress (total score between 15-25) was noted in 55.2% and 28% had severe/extremely severe stress (total score ≥26) according to DASS-21. Majority, 91.2% were physically active and were meeting the WHO recommended metabolic equivalents of >600 minutes per week. Those who did not meet the criteria and belonged to sedentary group contributed only to 8.8%.

From the Figure 1 it was observed that, 25.6% of the study individuals had very high (≥40%) risk of developing fatal or non-fatal CVD event in next 10 years. 18% had 10%–<20% risk, 23.2% had 20% – <30% risk and 8% had 30%– <40% risk.

The estimated overall CVD risk was more in females than in males. Females were having more risk in all the levels of risk except for very high risk (≥40%) where males had 38.2% chance and females had 20.1% chances of having CVD occurrence in next 10 years, but statistically association was not noted between males and females with respect to estimated CVD risk (p value: 0.053). (Figure 2)

In present study, family history of CVD was reported among 5.6% of study individuals. Other studies conducted in central India and in Urban population also reported low prevalence of family history of CVD as 4.1% and 4.6% respectively.[4,10] Prevalence of tobacco consumption was noted among 24.4% of the study individuals whereas Global Adult Tobacco Survey 2 (GATS 2) done in India reported 28.6% of tobacco use in adults in any form.[11] Our findings are in accordance with this findings. Alcohol consumption was noted only in males (15.6%). Study done by Junapudi SS and Rao BB reported high prevalence (30.7%) than our study. This could be due to more sample size in their study.[12] Study by Ghorpade AG in South India also reported high prevalence of alcohol as 53%.[8]

Present study reports hypertension in 49.2%. Prevalence of hypertension was 18.7% and 21% in study done by Junapudi SS and Sekri T respectively which is in contrast with our study.[10,12] High prevalence of hypertension is noted in study done in Kathmandu, Nepal (53.6%) and study by Satyanarayana PT(41.9%).[13,14] In our study, prevalence of DM was 28.8%. Similar result was found in study conducted in Tamil Nadu, where DM in urban area was 23.6%.[15] However, contrast result was noted in study conducted in rural Indian population (16%) by Sekhri T et al.[10] The CARRS (Center for Cardio-metabolic Risk Reduction in South Asia) Study has shown that overall prevalence of diabetes in 3 major cities of South Asia was Chennai (South India): 22.8% (21.5-24.1%); Delhi (North India): 25.2% (23.6-26.8%); and Karachi (Pakistan): 16.3% (15.2-17.3%).[16] There is marked heterogeneity in prevalence of diabetes based on residence. Prevalence of hypercholesterolemia in our study was 24.4%, whereas, it was contrasting in study by Oommen AM et al where prevalence of total cholesterol was 44.3%.[15] This could be due to lower cut off value of total cholesterol than our study (total cholesterol >200 mg/dl) which led to inclusion of more individuals. Along with epidemiological transition, developing countries are also undergoing nutritional transition from an earlier high prevalence of under-nutrition to now facing a burden over nutrition both in urban and rural areas. Our study also revealed over-nutrition with the prevalence of 5.6% underweight (BMI<18.5), 16% at risk obesity (BMI 23 to 24.9) and 34.4% obesity class I (BMI 25 – 29.9) and 27.2% obesity class II (BMI > 30). According to the nationwide, population-based Indian Council of Medical Research-India Diabetes (ICMR-INDIAB)
In our study, prevalence of generalized obesity, varied from 11.8% in Jharkhand to 31.3% in Chandigarh.\textsuperscript{[17]}

In our study, 45.6% had moderate stress and 6.8% had extremely severe stress. Physical inactivity was seen in 8.8%. Study conducted in Nepal showed physical inactivity among 18.7%.\textsuperscript{[13]} and study by Junapudi SS, reported, sedentary life in 13.7% in urban population\textsuperscript{[12]}

In our study, WHO/ISH risk prediction chart reported that, 25.6% had very high (> 40%) risk, 8% had 30-<40% risk, 23.2% had 20-<30% risk, 18% had 10-<20% risk, 25.2% had low (<10%) estimated risk of developing fatal or non-fatal CVD event in next 10 years. It was found that the estimated overall CVD risk was more in females than males. However, the very high (> 40%) risk was more among males (38.2%) than females (20.1%). Study done in rural India utilizing WHO/ISH risk prediction chart reports 86% subjects to have a low risk (<10%) of the CVD event and only 7 people to have a risk of >30%.\textsuperscript{[9]} Our results are in contrast with these results and this could be due to low prevalence of hypertension and diabetes in their study compared to ours. Another study done among supporting staff of tertiary care hospital predicted, 1.7% had >10% of CVD risk and 98.3% had less than 10% risk\textsuperscript{[18]} and in Bansal Pet al\textsuperscript{[19]}, risk of CVD was assessed to be ≥10% in 44.4% of subjects, while 55.6% subjects were predicted to have <10% risk of CVD in 10 year duration. Low risk (<10%) is noted in these study and this could be due to non-consideration of another important risk factor i.e, Total Cholesterol while using WHO/ISH risk prediction chart and this might have led more members to fall in low risk (<10%) category.

**Conclusion**

Significant portion of study participants with higher prevalence of CVD risk factors and very high CVD risk in next 10 years calls for preventive measures by investing in primary and secondary prevention of CVD risk factors which will be the sustainable solution for CVD epidemic. Simple tool like WHO/ISH risk prediction charts which is graphical and easy to understand by general population, can be used as a screening tool to estimate the CVD risk occurrence in next 10 years, in a low resource country like India, even at a community level.

**Conflict of Interest:** Non declared

**Source of Funding:** Self

**Ethical Clearance:** Ethical clearance was obtained from JSS Medical College Institutional Ethics Committee before start of the study. Written informed consent was obtained from all the study individuals before interviewing them and at most care was taken to maintain privacy and confidentiality.

Health Care in Andaman, Lakshadweep and Puducherry: A Comparative Study

Anita Banerjee
Assistant Professor (in Economics), Andaman Law College, Port Blair

Abstract

Given the growing importance of health care in the present day world, The present study attempts to draw a comparison between supply of health care (infrastructure) and the demand for health care (in terms of health outcomes) in the three Union territories of Andaman, Lakshadweep and Puducherry, in the backdrop of the recently published report on “healthy states” published by the government of India. The study points out through health outcomes, the lacunae in certain areas which needs to be corrected.

Keywords: Infrastructure, Birth Rates, IMR, U5 mortality rates.

Introduction

To begin with what is health care? Well broadly defined health care implies providing individuals as well as the community adequate medical care. More specifically health care would mean monitoring of health through prevention, diagnosis, treatment of diseases, and injury besides other ailments. Health care is provided by health professionals through private or public health care institutions. In India health care services has gradually evolved over the years, starting from the Bhore Committee report in 1946, which gave an outline of the health systems and policies for betterment, yet a lot has to be done towards this direction. Even in the constitution, health care is a subject which has been mentioned right from the time it was implemented. There is a mention of social justice and health care and the principle of justice in the matter of equal access to health care is tacitly mentioned in the constitution. The subject of health is also referred to under fundamental rights. In recent times concerns of health has been gaining importance. In the recently published report by the central government on the performance of health outcomes of states and union territories under the title “Healthy States, Progressives India” ranked states, and union territories based on certain indicators. The present study seeks to draw a comparison between the three union territories based on supply side factors (health infrastructure) and the demand side health outcomes (indicators), in the process pin-point the areas which need special attention.

Methodology: The study is based on secondary data collected from the various Government departments and websites. For the purpose of comparison a method of percentage analysis was adopted.

Earlier studies on health care: Studies based on comparison of health care facilities and health indicators have been undertaken with respect to interstate comparisons among populous states such as Uttar Pradesh and Bihar where it was found that there existed a poor and insignificant correlation between infrastructure and outcome. In a somewhat different study based on health care needs and accessibility to health care in a county in Romania it was revealed that there existed inequalities in people’s access to health care services. It also showed that there existed an inverse relationship between higher health care needs and poor health care services. In yet another study on health infrastructure and health indicators in Andhra Pradesh it was found that 70% of the variation in all health indicators is explained by health infrastructure. Similarly in a study based on a comparative evaluation of Public health services with private health centres using Data Envelopment Analysis (DEA) technique in Uttar Pradesh found that the primary health care services were far more efficient than the private health facilities with better efficiency.
scores. A description of public health infrastructure was also attempted in an article on public health systems with focus on new born. It also emphasizes that health infrastructure and health systems have a bearing on health outcomes. Most studies on health systems have highlighted the structural constraints in providing health care services in government health care facilities.

Thus from the various studies it can be inferred that there does exist a relation between health infrastructure and health indicators.

The present study seeks to study the status of health care facilities and health indicators in the three union territories in the peninsular India. First a brief overview about these union territories: the three union territories are located in the Indian peninsula. Two of them that are Lakshadweep and Andaman & Nicobar are islands and Puducherry is a land locked area.

For the purpose of drawing a comparison between the three union territories two major variables have been taken into account they are the health infrastructure and the health outcomes that is stated in other terms on the supply side are the health infrastructure provided by the government and on the other hand is the health outcomes in terms of infant mortality rate (IMR), Birth Rates and Under Five Mortality Rate (U5). First a comparative study of the health facilities in the three union territories under study. To begin with the union territory of Andaman and Nicobar Islands has a population of 3.85 lakhs, with literacy rate of 86.63% and a sex ratio of 876 females per thousand males. It has a total of 31 rural hospitals and 1 urban hospital with a total of 1075 number of beds. The average number of population served per hospital is 16642 and average number of population served per hospital bed is 495. Puducherry has population of 12.4 Lakhs. Sex ratio is 1037, literacy rate at 85.85%. This union territory has nearly equally distributed number of hospitals in rural and urban areas. A total of 27 rural hospitals and 26 hospitals in urban areas, total number of beds in the hospitals are 3271. The average population served per Government hospital is 29677 and the average population served per government hospital bed is 481. Location of this union territory Puducherry is such that it attracts people from nearby districts of Tamil Nadu. Lakshadweep an island in the Arabian Sea has a population of only 64673 but has a better literacy rate than the other two union territories under study (92%) and a better sex ratio than Andaman and Nicobar Islands with 946 females per thousand males. Total number of hospitals in Lakshadweep islands is 9, the reason is that it is by and large a rural island with no hospitals in urban areas, the total number of hospital beds is 300 and average population served per hospital is 8698, whereas average population served per hospital bed is 261.

Health Indicators: Though there are several indicators of health to assess, for the present study only three have been chosen for comparison. The birth rate for Lakshadweep has remained constant in the three year period at 14.8% whereas in the other two union territories of Puducherry and Andaman and Nicobar Islands have registered a decline during the period. Infant mortality Rate that is per thousand live births is identical for both the island union territories of Andaman & Nicobar and Lakshadweep whereas for Puducherry its much lower at 17 per thousand live births though it has a larger population than both Lakshadweep and A & N Islands. In terms of children who die before attaining the age of five, Andaman Nicobar Islands recorded the lowest deaths at 13 per thousand live births, indicating that child and mother care health are better looked after than in Lakshadweep which had registered a higher under five mortality rate at 23 per thousand live birth followed by Puducherry with 16 death for every thousand live births.

*Based on three year period 2010-2012 (from National Health Profile 2015).

Other significant indicators which are considered relevant for assessing the health status of the people of a state are maternal and child health. In this respect also a comparison is made between the three union territories.

Maternal and Child Health Care Services: One of the key areas where the National Rural Health Mission (NRHM) has been very successful in delivering the services to a large extent is in the matter of maternal and child health care services. One of the primary needs when a woman is pregnant is that she should goes for checkups initially in the first trimester, the union territory of Lakshadweep had the highest percentage
of women (91.9 %) who had the antenatal check up in the first trimester which was followed by Puducherry with 80.6% of women who had registered for antenatal check ups and Andaman & Nicobar Islands registering the lowest percentage at 68.4%. But again in case of the four antenatal visits as stipulated by WHO, the islands of Andaman and Nicobar were highest with 92.1 % coverage of women, in contrast Puducherry had 87.7% and Lakshadweep had 82.8%. In most of the indicators of maternal health it is observed that Lakshadweep is ahead of the other two union territories in terms of percentage of coverage that is mothers who consumed iron folic tablets during pregnancies is highest in Lakshadweep (82% as against 66% in Puducherry and 58 % in A & N Islands as well as in getting post natal care within two days of delivery). However when it comes to the question of mothers who received financial benefits for institutional delivery under the JananiSurakshaYojana it is observed that Puducherry though has a larger population than the other two union territories under the present study, happened to have a larger percentage of women who could avail this benefit (21%) as against just 1.4% in Andaman and Nicobar Islands, whereas it was only 17.5 % in Lakshadweep, this could be due to lack of awareness among people. In terms of nutritional status of children Puducherry stands ahead of the other union territories on most of the indicators used to assess the health status of children in the initial years after their birth.

</table>
The table on number and percentage of people living below poverty line it can be inferred that among the three union territories Andaman and Nicobar has the lowest number of persons living below the poverty line (1%), interestingly it is also the union territory with the lowest number of under five mortality rate registered in the period 2010-2013, with low birth rates too among the other three union territories indicating thereby that health indicators have a direct bearing upon the poverty lines. Studies in the past have also indicated that poverty and health are intertwined; there exists a vicious link between poverty and ill health 8, 9, 10. Looking at union territory of Puducherry, it becomes evident that with a higher percentage of people living under poverty line (9.69%), its health indicators such as birth rate and infant mortality rate are on the higher side as compared to Andaman and Nicobar islands. Lakshadweep Islands exhibit a drastic fall in percentage of people living below poverty line from 6.80% in 2009 to 2.7% people below poverty line in 2011-12, but with a comparatively higher under five (U5) mortality rate during the said period when compared to the other two union territories even though it has a very high percentage of overall literacy at 91.85%. Thus, it can be said that poverty line and health indicators are related though; there are other factors which needs to be considered as well.

Monthly per capita out – of- pocket expenditure is lowest in Andaman and Nicobar islands. Even looking at the table on monthly per-capita out of pocket expenditure what becomes clear is that over all whether it is institutional expenditure as a share of total non – food consumption expenditure or medical expenditure as a share of total consumption expenditure, Lakshadweep spends the most. Therefore, these anomalies among the union territories needs to be investigated because if population is taken to be the factor into consideration for the high out –of –pocket expenditure then, Pondicherry ought to have higher expenditure than the other two islands under study, but as is evident from the table, this is not the case, Lakshadweep has the lowest population when compared to the other two.

Conclusion

The report of the government of India assigning ranks to the states/ Union territories based on the health indicators have placed Lakshadweep among the best performing union territories, yet based on the data in the study it has come to light that on certain indicators such as under five mortality rate, Andaman and Nicobar Islands and Puducherry are ahead in the sense that these UTs have registered a lower mortality rate when compared to Lakshadweep. When it comes to benefit received under JananiSurakshaYojana, it is observed that in union Territory of Puducherry larger percentage of mothers were covered under this scheme when compared to Lakshadweep, even though the percentage of people living below poverty line is larger in Lakshadweep than in Puducherry. Whereas on the other hand Lakshadweep exhibits higher literacy rates and better sex ratio. Thus it can be said that on certain parameters Lakshadweep seems to be ahead of the other two Union territories. Therefore it can be concluded that there is some policy lapses in implementing health programmes.

Sree Balaji Dental College and Hospital.

Abstract

Lymphangioma is a benign hamartomatous neoplasm of the lymphatic system with a marked predilection for the head and neck region. Most common location is submandibular region and in oral cavity tongue is commonly affected. Around half the cases are present since birth. Herein we report a case of lymphangioma in 25 year old female. The clinical and histopathological finding of the case with possible etiology, management are discussed.

Keywords: Lymphangioma, Hamartoma, Cystic hygroma.

Introduction

Lymphangioma is a benign hamartomatous neoplasm of the lymphatic system, with a marked predilection for the head and neck region and more commonly occurs in submandibular region1,2. Around half the cases are present since birth3. The lesion is assessed in the line with the vessels diameter into: microcystic or capillary, macrocystic or cavernous and hygroma or cystic hygroma4,5. Its prevalence in mouth is rare and is more often situated at the anterior two-third of the tongue; although cases in roof of the mouth, gingiva, mucous membrane, lips and alveolar process have been represented1,6,7. Clinically, its location is superficial, seen as clear and usually grouped vesicles, which may be red or purple because of secondary hemorrhage. The deep lesion are seen clinically as nodular masses of variable color and superficial texture5. There are many therapeutic modalities for the treatment of oral lymphangioma. Surgical excision is usually indicated once vital structures are not involved4,8.

Case Report: A 25 year old female patient reported with the complaint of pain and swelling on the right side of the tongue for the past 2 months. Intraoral clinical examination revealed the lesion was present as growth on the right lateral surface of the tongue measuring about 1 × 1 cm in size, erythematous and sessile in nature. There was no regional lymphadenopathy noted. Clinically such lesion was diagnosed either as hemangioma or lymphangioma. To confirm the diagnosis, an incisional biopsy was performed. The haematoxylin and eosin stained histopathogical section of the given specimen showed hyperplastic parakeratinized stratified squamous epithelium with underlying connective tissue stroma (Fig-1). The connective tissue was densely collagenized with moderate cellularity with diffuse dense chronic inflammatory cell infiltrate. Numerous endothelial lined blood vessels and lymphatic channels are seen (Fig-2). Therefore, the histopathological diagnosis confirmed it as lymphangioma.

Fig 1: Histopathology image shows Parakeratinized Stratified squamous epithelium and underlying connective tissue stroma.
Discussion

Lymphangiomas are rare inborn malformations of the vascular system that may occur throughout the body with larger predilection for head and neck. Three theories are proposed to explain the origin of Lymphangiomas. The first theory suggests that a blockage or arrest of growth of the primitive lymph channels happens throughout embryogenesis. The second theory says that the primitive lymphatic sac doesn’t reach the blood vessel system, whereas the third theory advances the hypothesis that, throughout embryogenesis, lymphatic tissue lays within the wrong space as a result these cells don’t anastomose efficiently with larger lymphatic vessels, they then provoke areas of lymphatic blockage. Common within the neck region, the anterior triangle of the neck has been indicated because it is the commonest site, primarily bone, trapezius and sternocleidomastoid. The submandibular and salivary gland regions are the more associated areas to lymphangioma development. In oral cavity lymphangiomas occur in the anterior tongue but lip and alveolar ridge and buccal mucosa are involved. In our case, the lesion is present in the tongue.

The incidence of lymphangiomas has been reportable to vary from 1.2 to 2.8 per thousand newborns. The foremost outstanding sign or symptom of all lymphangiomas is the presence of a mass. In adult patients, tumor will switch to epithelial cell malignant neoplastic disease. The surface is granular as a result of clear vesicles and color is red or blue as a result of rupture of underlying blood vessels. The deeper lesion could cause higher respiratory tract disorder or incidental trauma at the location and problem in chewing, speech and deformity of the jaws.

Histologically, these lesions are composed of expanded lymphatic channels. These expanded lymphatics will vary in size, relying upon the situation and surrounding tissues and is that the basis for classification consistent with Yaita et al. Relying upon cystic area size, they’re classified as: macrocystic, microcystic and mixed.

Ultra-sonography, CT and imaging scans are often accustomed outline the link of the lesion with the neighboring structures and to assist arrange surgery. The clinical course of the pathology varies from a spontaneously regressive cyst to an aggressively invasive lesion. Spontaneous or traumatic hemorrhage of the cysts is the common complication.

While treatment of lymphangiomas includes surgical excision, cryotherapy, electro surgical procedure, sclerotherapy, steroids administration, embolization, and laser therapy. Surgical excision is the best treatment for lesions presenting localized growth.

Conclusion

Oral lymphangiomas are uncommon lesion occurring at the tongue. Superficial and localized lesion are often treated by conservative approaches like laser therapy, cryotherapy and surgical excision with less relapse rate. Therefore, proper diagnosis is important for proper therapeutic implications.

Prevalence of Musculoskeletal Problems in Untrained Exercising Individuals

Ankita A. Patil1, Trupti S. Yadav2, Amrutkuvar Jadhav2, Vaishali Jagtap2

1Department of Physiotherapy, 2Assistant Professor, Department of Physiotherapy
Krishna Institute of Medical Sciences Deemed to be University, Karad.

Abstract

Objective: To find untrained exercising individuals and to find out which all musculoskeletal problems arises due to untrained exercising individuals.

Method: A total 100 subjects were included both males and females between age group 20 to 40 among which 51 were males and 49 were females. The subjects were explained about Mc. Gill questionnaire and were asked to rate the pain according to VAS in reference to before practising unsupervised exercise and after practising un supervised exercising.

Results: The prevalence rate of musculoskeletal problem in untrained exercising individuals is 84 %.

Conclusion: It is found that musculoskeletal problem increased after practicing untrained exercises and pain was increased in the individuals and the most affected area was low back area, type of pain found to be more was sensory and intermittent type in relation to time.

Keywords: musculoskeletal problems, untrained exercises.

Introduction

Musculoskeletal disorders are defined as musculoskeletal symptoms, musculoskeletal complaints or musculoskeletal pain that arises due to many conditions such as back pain, shoulder pain, neck pain, pain in limbs, myofascial dysfunction syndrome, carpal tunnel syndrome, atypical facial pain etc. In past few decades musculoskeletal disorders are found to be commonly increasing.

Common mechanism for musculoskeletal disorders is overuse of certain muscles which may be attributed to any of the factors like performing repetitive action with or without required located efforts, postures during work, short rest interval and stress imposed. Therefore, it must be aimed to verify influence of type of exercise, intensity, frequency, duration of training in reducing MSD.

Exercises are performed for various reasons, like for growth and development, preventing aging, strengthening muscles and cardiovascular system, honing athletics skills, weight loss and maintenance of health. They are also found to be effective in improving the mental well-being of general Public.

Exercises also help to improve neuromuscular control/coordination, balance/postural equilibrium, muscle performance, mobility/flexibility, stability, cardiopulmonary/endurance. Weight management is improved by performing regular exercise and also lowers blood pressure, improves c-reactive protein and CHD biomarkers, improve lipoprotein and enhance insulin sensitivity. Exercise also promotes strength and improve bone mass and therefore helps to prevent and slow down the loss of bone mass thus decreasing the risk of osteoporosis. The muscle weakness is proved factor for increasing risk of osteoarthritis and therefore the various resistance training exercises can be a useful to reduce it.

As the ultimate objective is improvement and maintenance of physical fitness, it should be planned and structured with desired repetition. Parameter such as power, endurance, strength should be added in graded manner as per required goals of the individual, even the frequency, intensity and rest interval should be properly looked for whether the exercise are performed under

the guidance of therapists or self-practised, safety should be considered as fundamental aspect of programme. The patient who is not familiar with physical exertion may be at risk of developing adverse effect due to exercise.\textsuperscript{5} The safety is affected by performance of an individual in performing exercise, the body alignment and the posture of the body is also included, the speed of performance, and duration. Signs of fatigue should be informed to the individual, risk of injury and its relationship with fatigue. The rest importance during recovery and after an routine of exercise. Under guidance therapist can control these variable, but when exercise program independently are carried out by patient at home or at a community fitness facility, safety is enhanced of an individual and patient is at risk of injury or re-injury.\textsuperscript{5} The multiple factors are associated with variation in training like characteristic of training regimen environmental and individual factor habit for physical activity fitness level physiological and genetic variability social and psychological factors.\textsuperscript{6} Today’s society has enormous impact from Social media. survey showed that people’s lifestyle and as they compare themselves on social media is influenced by fitness related content on social media. The most common Sources from which people are influenced are newspaper, magazines, media and person to person communication but nowadays more negative body image is found in women as they compare themselves on social media. Even body image issues are experienced by men and feel social media pressure. Workouts are encouraged by Online communities.\textsuperscript{8}

**Materials and Method**

**Inclusion criteria:**
- Young individuals between age group 20 to 40.
- Individuals practicing untrained exercise.
- Individuals with or without existing musculoskeletal problem.
- Individuals practicing exercises form more than 15 days.

**Exclusion criteria:**
- Individuals practicing exercises under advice.
- Any pain due to secondary to pathology.

**Materials used**
- Data Collection sheet
- Consent form
- Pen
- Pencil

**Study Procedure:** An approval for the study was obtained from the protocol committee and institutional Ethical Committee of Krishna Institute of medical Sciences Deemed To be University. The study was conducted in Krishna Hospital campus to study prevalence of musculoskeletal problems in untrained exercising individuals. Both the males and females subjects were included between age group 20 to 40. The subjects were selected according to the inclusion and exclusion criteria. Prior consent was taken. They were explained with the necessary information before handing them with forms. Subjects were told about the McGill questionnaire and they were explained that the description fall into four major groups sensory(s) 1-10; affective (A), 11-15; evaluative (E)16; and miscellaneous (M), 17-20. The sum of the rank value is the pain rating index (PRI). The present pain intensity (PPI) is based on a scale of 0-5 and were asked to rate the pain according to VAS in reference to before exercising and after exercising. Survey was done according to the results obtained. Conclusion was made according to the results obtained.

**Description of outcome measures**
- McGill pain questionnaire.
- Visual Analogue scale.

**Statistics:** Statistical analysis was done manually and by using the statistics software INSTAT so as to verify the results derived. The statistical analysis between before exercise and after exercise pain was done by paired ‘t’ test. Unpaired ‘t’ test was applied between before exercise pain in females and before exercising pain in males, another unpaired ‘t’ was applied between after exercises pain in females and after exercise pain in males.

1) Gender distribution according the age group in the study:

The total number of females were 49 and males were 51.

**Table 1: Gender distribution according the age group.**

</tbody>
</table>

The prevalence of musculoskeletal problem in untrained exercising individuals was found to be 84%.

**Conclusion**

We found that musculoskeletal problem increased after practicing untrained exercises and pain was increased in the individuals and the most affected area was low back area, type of pain found to be more was sensory and intermittent type in relation to time.

**Discussion**

The present study “Prevalence of musculoskeletal problems in untrained exercising individuals” was conducted to find musculoskeletal problems in individuals who practice untrained exercises.

The objectives were to find untrained exercising individuals and to find out which all musculoskeletal problems arises due to untrained exercises in those individuals.

The study was conducted with 100 subjects both males and females were included. Prior consent was taken and were explained with necessary information before handing them with forms. Subjects were told about the McGill questionnaire and they were explained that the description fall into four major groups sensory(s) 1-10; affective (A),11-15; evaluative (E)16; and miscellaneous (M), 17-20. The sum of the rank value is the pain rating index (PRI). The present pain intensity (PPI) is based on a scale of 0-5 and were asked to rate the pain according to VAS in reference to before exercising and after exercising.
This study shows that 51 males and 49 female practiced untrained exercises.

Due to easy access towards social media in age group 20 to 30, 79 individuals were found to be practicing untrained exercises and in age group 31 to 40, 21 individuals were found to be practicing untrained exercises.

In the study conducted it was found that fitness related content on social media is influencing people’s lifestyles and as they compare themselves to other. Fitspiration provides many people with supportive online community, which encourage them to work out, to follow specific diets and online workout routines that are, and to strive for fit and toned body type this has been articulated by Makenzie Norton.(8)

Subject should take care while performing untrained exercises and should realize that exercises might be performed inaccurately in an unsupervised environment. 58 subjects experienced low back pain, 6 thigh pain, 9 calf pain, 26 knee pain and 5 subjects experienced shoulder pain. sensory type of pain was experienced by 45 subjects, affective by 19, evaluative by 26 and miscellaneous by 10 subjects. In relation to time the type of brief pain was experienced by 6, rhythmic by 1, continuous by 4, momentary by 24, periodic by 7, steady by 5, transient by 4, intermittent by 47 constant by 1 subject.

81 number of people practiced untrained exercise from You Tube and only 19 practiced self exercise.

The result show Extremely significant increase in pain in the individuals who practiced untrained exercises. This was confirmed by using statistical analysis by using ‘paired t-test’ p value found is <0.0001. This shows extremely significant increase in pain.

Conflict of Interest: The authors declare that there are no conflicts of interest concerning the content of the present study.

Source of Funding: This study was self funded.

Ethical Clearance: The study was approved by the Institutional Ethics Committee of KIMSDU.

Comparative Study of Laparoscopic-assisted Appendectomy and Open Appendectomy

Nooruddin W. Ansari
Associate Professor Department of General Surgery Mamata Academy of Medical Sciences, Bachupally-500090, (Telangana state)

Abstract

Out 60 patients aged between 12 to 50 years of both sexes. 30 were selected for laparoscopic appendectomy (LA) and 30 for open appendectomy post surgical complication were compared in both method. 7(23.3%) pain in LA patients and 15 (50 %) in OA, 9(30%) vomiting in LA patients and 12 (40%) in OA patients 6(20%) fever in LA patients 13(43%) in OA patients, 4(13.3%) constipation in LA patients 9(30%) in OA patients 5(16.6%) had paralytic Ileus in LA patients and 11(36%) in OA patients 10(33%) wound infection in OA patients and 0% in LA patients. Returns of Bowel sounds in LA patients was 42-43 hrs and 50-51 hours’ in OA patients 3 to 4 days hospital stay in LA patients and 7-8 days in OA patients. This comparative study of appendectomy will be quite useful to surgeon to evaluate the post-surgical complications and prevent the morbidity and mortality among such patients.

Keywords: LA= Laparoscopic Appendectomy, OA= Open Appendectomy, Appendicitis.

Introduction

As appendix and pharynx is the most constricted part of the gastro intestinal tract hence they are more to be infected. Moreover appendix is a soldier of the abdomen hence changes its position to tackle the antibodies hence frequently gets inflamed and infected. Acute appendicitis is the most common condition leading to emergency abdominal surgery in young adults. Traditionally the treatment for appendicitis has been a right lower quadrant incision with the removal of the appendix as described by MC Burney in 1894. However within the past decade, the introduction of laparoscopy has changed this approach. The laparoscopic appendectomy has allowed surgeon to diagnose and also treat appendicitis at the same time.

The advantages of laparoscopic appendectomy include less postoperative pain and faster return to work and laparoscopic procedure are longer operating time and greater cast but non-availability of costly laparoscopy instruments and laparoscopic expert, most of the patients prefer open appendectomy (MCburneys approach) as it is cost effective hence post-surgical complications of LA and OA has been compared.

Material and Method:

Out of 60 patients aged between 12 to 50 admitted at years surgery department of Mamata Academy of Medical Sciences, Bachupally. 30 were selected for laparoscopic appendectomy and 30 for open appendectomy with prior permission of the patients. USG, blood examination and history of each patient was recorded found fit to be surgery. The patients suspected to be malignancy; HIV and Co-existing CVS and CNS diseases were excluded from the study. The ration of male and females was 2:1.

The duration of study was about 2 years and 6 months.

Observation and Results

Table 1- Comparative post surgical study of LA and OA patients (30 Each)7(23.3%)LA patients had pain and 15(50%) OA had pain, 9(30%) of LA had vomiting and 12(40%) OA had vomiting, 6(20%) LA had fever and 13(43%) OA had fever 4(13%) LA had constipation and 9(30%) OA patients had constipation, 5(16.6%) had paralytic Ileus in LA patients 9(30%) OA paralytic Ileus 10(3%) OA patients had wound infections and 0% in LA patients.

Discussion

The present comparative study of laparoscopic assisted appendectomy (LA) and open appendectomy (OA) at different ages of Telangana populations 7(23.3%) post-operative pain in LA and 15(50%) at OA, 9(30%) vomiting in LA and 12(40%) in OA, 6(20%) fever in LA and 13(40%) in OA, 4(13.3%) constipation in and 9(30%) in OA, 5(16.6%) paralytic Ileus in LA and 11(36%) in OA patients 10(33%) wound infection in OA patients and 0%. In LA patients (Table-1) . Returns of bowel sounds 42-43 hours in LA and 50-51 hours in OA patients 3 to 4 days hospital stay in LA patients and 7 to 8 days in OA patients (Table -2) these findings were more or less in agreement with previous studies (6)(7)(8).

Laparoscopic Assisted appendectomy has not been accepted by surgeons as quickly because of longer operating time and greater cost of laparoscopic technique. However patients suffer less post operative pain and have shorter hospital stays with the laparoscopic technique. Thus in an era of cost conscious medicine, the choice of technique must be weighed carefully.

An additional advantage of laparoscopic is its use as a diagnostics tool. Diagnostic tests for suspected appendicitis including ultra sound, C T scan, and laboratory tests can be significant expense. The introduction of Laparoscopic surgery has allowed for a more accurate and less expensive method for diagnoses than was previously possible but it carries with it the risk of a surgical procedure and anesthesia (9). Many studies have shown that less length of hospital stay in LA was also reported as compared to OA (10). Moreover in LA patients have better tolerance to regular diet and early return to the normal activities.

Summary and Conclusion

The present study of comparison between LA and OA Patients and post surgical complications. LA was better than OA with regards to post operative pain, resumptions of bowel sounds post operative complications and duration of hospital stay. Even though duration of surgery was more than OA. But as India belongs to middle socio-economic status governments must install laparoscopic instruments and appoint laparoscopic experts in government hospital with minimum fees so that every patients can be benefitted.

This research paper was approved by ethical committee of Mamata Academy of Medical Sciences, Bachupally -500090 (Telangana)

Assessment of Mental Well Being among School going Adolescents Using GHQ-12

Antara S.1, Rahul Bansal2, ChhaviKiran Gupta3

1PG 3rd year, 2Prof & Head, 3Assistant Professor;
Department of Community Medicine, Subharti Medical College, Meerut

Abstract

Introduction: Adolescence is a transition period where many physical, social, emotional and psychological changes take place. As adolescents mature cognitively, their mental process becomes more analytical. The 12-Item General Health Questionnaire is the most extensively used screening instrument for common mental disorders, in addition to being a more general measure of psychiatric well-being.

Objective: To assess mental well being of school going adolescents of urban Meerut, UP.

Methodology: Purposive technique was used for the selection of schools and total enumeration of all the students belonging to age group of 12-19 years was done after obtaining clearance from institutional ethical committee and permission from schools making a total of 1185 sample size. This was followed by distribution of GHQ-12 questionnaire among all adolescents.

Results: Majority (80.9%) of adolescents had good mental well being and only 19.1% had poor mental well being with maximum score being 11 and minimum being zero. The mean score also lied in the range of good score representing good mental well being.

Conclusion: GHQ-12 score can be used to screen the mental health of the adolescents in the school so that the adolescents falling in poor score can be taken care of in school itself by proper counseling and appropriate behavior therapy.

Keywords: Mental Well Being, Adolescents, GHQ-12.

Introduction

Adolescence is a transition period where many physical, social, emotional and psychological changes take place1. As adolescents mature cognitively, their mental process becomes more analytical. They are now capable of abstract thinking, better articulation and of developing an independent ideology.2 Adolescence is a period marked by severe psychological and emotional stresses3. Adolescents have frequent mood changes reflecting feelings of anger, sadness, happiness, fear, shame, guilt, and love4. They are unable to understand the emotional turmoil happening within them and thus are unable to tackle effectively emotional pain, conflicts, frustrations and anxieties about the future which are often the driving force for high risk behavior5.

Today’s youth needs a lot of mental strength to cope with challenges and pressure. Poor tolerance towards criticism, lack of assertiveness and low self-esteem could cause neurotic breakdown6. In order for adolescents to achieve their life goals and obtain academic success, it is important to be in a psychologically healthy condition. As per Dwyer & Cummings, stressful atmosphere may create and/or elevate psychological distress and reduce adolescents’ academic performance7.

The 12-Item General Health Questionnaire (GHQ-12) is the most extensively used screening instrument for common mental disorders, in addition to being a more general measure of psychiatric well-being8. The GHQ was originally designed to be used in adult populations. However, it is noted in the GHQ manual that the scale has been used with adolescents9. The GHQ-12 is the shortest version and commonly used as a screening tool in a public setting10.

School is an appropriate place for screening mental well being as school plays an important role
in socialization of young people; access to children & adolescents on a large scale with experienced teachers & high credibility with parents & possibilities for short & long term evaluation. Thus, the present study was done to assess the mental well being of school going adolescents of urban Meerut.

**Methodology:** The present Cross Sectional study was conducted among school going adolescents of urban Meerut, UP. Total four schools were selected by purposive sampling technique. Total enumeration of all the adolescents belonging to age group of 12-19 years was done from each of the school making a total sample of 1185 adolescents. The study was conducted from March 2017 to February 2018 after obtaining clearance from institutional ethical committee of Subharti Medical College; permission from each school, consent from parents/ guardian and assent from each adolescent.

The inclusion criteria for the study included- Adolescents who were between the age group of 12 to 19 years; who were willing to participate in the study; whose parents gave consent for participation in the study and who were present in school on the days of data collection/ survey. The adolescents who were absent on the days of data collection but were in the age criteria were excluded as the data was not collected on any other subsequent days.

The tool used for data collection was General Health Questionnaire-12 (GHQ-12) scale. The questionnaire is comprised of twelve questions with four options each[9]. Higher the score obtained in GHQ-12, poor is the mental well being. A score of five or less indicates good mental well being and a score of six or more indicates poor mental well being.

**Statistical analysis used:** The collected data was entered and analyzed using SPSS software version 19.0. Chi square test was used to test the association between the dependent and independent variable and p-value <0.05 was considered as significant.

*Others in religion includes Jain/ Agnostic/ Do not want to reveal their religion.

In the present study, majority of adolescents were from the age group of 14-16 years (63.7%); and adolescents of less than 14 years (17.4%) and more than 16 years (18.9%) were almost similar. Most of the adolescents were males (52.7%) and belonged to nuclear family (57.2%). Also, majority of adolescents were Hindus (80.9%) and least were Christian (0.5%). “Others” category in religion included those who were either Jain or agnostic or not willing to reveal about their religion (Table 1).

More than half of adolescents’ fathers (55.7%) and almost half of the mothers (50.9%) were educated either up to graduate level or above. Also, 94.2% of the father’s were employed whereas only 16.9% of mothers were employed (Table 2).

Figure 1: Distribution of General Health Questionnaire (GHQ-12) score of study participants (n = 1185).

Majority (80.9%) of adolescents had Good GHQ-12 (score of 5 or less) indicating Good Mental Well being whereas only 19.1% of adolescents had Poor GHQ-12 (score of 6 or more) indicating Poor Mental Well being (Figure 1). The Mean GHQ-12 score of the adolescents was 3.47 which lied under Good Mental Well Being Score. Maximum Scored obtained by the adolescents was 11, which was Poor Mental WellBeing Score, the Minimum scored obtained was 0 which was Good Mental WellBeing Score and Range between them was 11. The value of Skewness (Sk) was 0.472 i.e. the frequency distribution of GHQ-12 Scores for the total sample was positively Skewed. The value of Kurtosis (Ku) was -0.263 i.e. the frequency distribution of GHQ-12 Scores for the total sample was Platy Kurtic.

<td>1185</td>
</tr>
</tbody>
</table>

Chi sq. = 14.366, df = 4, p-value = 0.006

*Other includes Jain/ Agnostic/ Do not want to reveal their religion, †Statistically significant association

Among all the poor mental well being scorers (19.1%), most of them were Muslims (31.4%) followed by Others (26.2%) and Sikhs (25%); and least were Christian (16.7%) and Hindus (17%). Among all the good mental well being scorers (80.9%), most of them were Christians (83.3%) and Hindus (83%) followed by Sikh (75%) and Others (73.8%) and least were Muslims (68.6%); and this association was found to be statistically significant as p-value calculated was less than 0.05 (Table 4). This indicated that Muslim adolescents had poorer mental well being compared to the other religions.

Conclusion

GHQ-12 score can be used to screen the mental well being of adolescents in the school itself so that the adolescents having poor mental well being can be taken care of at the school level by proper counseling, appropriate behavior therapy and referral to specialist if required. Such screening is required as mental well being is still neglected in developing countries like India. If the screening is done at adolescent age, the burden due to abnormal mental well being of the individual, their family, their social life and on the community as a whole can be reduced.

An Epidemiological Study of Diabetes Mellitus among Adult Population in an Urban Area of Odisha

Antaryami Sahoo¹, Archana Patnaik²

¹Postgraduate student, ²Professor, Department of Community Medicine, Hi-Tech Medical College, Bhubaneswar, Odisha.

Abstract

Introduction or Background: Type 2 Diabetes mellitus is the most common (85-90% of) non-communicable disease now a days in the World. It currently affects more than 62 million Indians with the average onset at 42 years. So the current study is carried out with the objectives of -1. To identify the prevalence of Type 2 Diabetes mellitus among adult population, 2. Assess the risk factors associated with development of Diabetes mellitus.

Materials and Method: A total of 170 adults were selected as study population after sample size calculation. During the study Fasting Blood Sugar (FBS) and post prandial blood sugar (PPBS) was estimated to identify diabetes mellitus. Information from the study population was collected through pre-designed and pre-tested questionnaire using different anthropometric measurements.

Results: Out of 170 study subjects, 105 were male and 65 were female. 27(15.9%) participants were having increased FBS and PPBS and are diagnosed as diabetes mellitus. Most of the diabetics are in the age group of 40 to 60 years. 11 (40%) diabetics in study population were found to be obese (BMI >30).

Conclusions: Prevalence of diabetes mellitus was higher (15.9%) in the study population. So repeated awareness campaigns with screening of diabetes mellitus are required in the community to decrease the complications arise due to the disease.

Keywords: Body Mass Index (BMI), Fasting Blood Sugar, Post prandial blood sugar.

Introduction

Diabetes mellitus (DM) is a disturbance in the metabolism of carbohydrate, fat, and protein that is caused due to loss of insulin producing cells in the pancreas or decreased tissues sensitivity to insulin that results in increased level of glucose in the blood[¹]. Asia will account the highest growth (42 million) with 4.9 million deaths per year due to diabetes mellitus[²]. Majority are progressing towards complications without awareness. Moreover, around 80% of the total numbers affected are living in low- and middle-income countries[³]. Diabetes is fast gaining the status of a potential epidemic in India with more than 62 million diabetic individuals currently diagnosed with the disease[³]. In 2000, India (31.7 million) topped the world with the highest number of people with diabetes mellitus followed by China (20.8 million) with the United States (17.7 million) in second and third place respectively[⁴]. With this background, the present study was conducted with the objectives to find out the prevalence of Type 2 diabetes mellitus among adult population and to assess the risk factors associated with diabetes mellitus.

Materials and Method

This cross-sectional study was carried out in the urban field practice area of Hi-Tech Medical college and hospital, Bhubaneswar. This study was started on 1st February 2018 and completed on 31st May 2018. Age group 20 years and above was considered as adults in my study population. With the help of our paramedical staff health awareness campaigns are done in the urban field practice area like 8 hour fasting before blood sample collection for fasting blood sugar estimation. Informed consent was taken from all study participants after
thoughly describing the purpose of study. Sample size was calculated by applying the formula, \( n = \frac{4pq}{L^2} \). As per a study by Ramchandran et al.\(^5\), prevalence of diabetes mellitus in adults is 12.1% and on that prevalence our sample size was calculated as, \( n = 4 \times 12.1 \times 87.9/5^2 = 170 \). Clinical assessment, anthropological measurement and pre tested questionnaires were used for data collection. Fasting blood samples were collected from the study population after filling up the questionnaires. Fasting blood sugar and post prandial blood sugar was detected by using standardized Glucometer. A person was considered to be having diabetes if he/she were already diagnosed case of diabetes or on treatment or current fasting blood glucose ≥ 126 mg/dl or current post prandial blood glucose ≥ 200 mg/dl\(^6\). Data was collected by stratified random sampling method till the desired sample size was met. Body mass index (BMI) was calculated by applying the formula weight in kg /height in m\(^2\) to know the prevalence of diabetes in obese study subjects and BMI ≥ 30 is considered as obese. All the data collected were analyzed in SPPS software version 20.

**Results:** Out of 170 study participants, 105 (61.7%) were males and 65(38.2%) were females. 52(30.5%) participants were in the age group 20-40 years. 65(38.2%) participants were in the age group 40-60 years. In the age group 60-80 years there are 53(31.2%) participants. Data on diabetes mellitus status were collected from all of the study subjects by using rapid diagnostic method. 14(8.2%) of the study participants were previously diagnosed as diabetes mellitus, and 13(7.7%) were detected to be having diabetes mellitus during the study. So the total prevalence of diabetes mellitus is found to be 15.9% (27) in this study (Table-2). It is revealed from the Table no-3 that out of 170 study participants 27(15.9%) participants had diabetic mellitus after lab tests and 143(84.1%) had no diabetes. In the age group of 20-40 years 5(9.5%) participants had diabetes and 47(90.5%) had no diabetes. In the age group 40-60 years 13(20%) participants had diabetes and 52(80%) had no diabetes. In the age group 60-80 years 9(16.9%) had diabetes and 44 (83.1%) had no diabetes. To find out the association between age group and onset of diabetes Chi-square test was fitted. The value of \( \chi^2 = 4.78 \) with d.f. = 2 and the test was significant at 5% level of significance with p value < 0.05 indicating association of higher age-group with onset of diabetes. Table no-4 depicts data on risk of diabetes with that of body weight. As 27 nos. of participants had clinically diabetes from which 11(38.9%) participants were obese, 5(18.5%) had over weights, 9(35.2%) were normal weight and 2(7.4%) were of under weights. 143(84.1%) study participants were non-diabetic from which 26(18.2%) were obese, 40(28%) were having over weights, 61(42.3%) had normal weights and 16(11.5%) had under weights. A Chi-square test was applied which shows significant association between obesity and onset of diabetes mellitus.

Discussion

In our study the prevalence of diabetes mellitus was found to be 15.9%. The National Urban Diabetes Survey showed an age-standardized prevalence of 12.1% for diabetes mellitus and 14% for IGT in six large metropolitan cities[7]. Two studies in Chandigarh, a very prosperous city in North India, showed high prevalence of diabetes mellitus. In the INDIA study, the city was found to have the highest prevalence of diabetes mellitus (13.6%) [8]. The Chandigarh Urban Diabetes Survey (CUDS) also reported high prevalence of diabetes mellitus and pre-diabetes i.e. 11.1 and 13.2% respectively[9]. Barik et al. in rural West Bengal, found that the prevalence of diabetes mellitus and pre-diabetes among adults >18 years was 2.95 and 3.34% respectively[10]. In another study, Little et al. reported a high prevalence of type 2 diabetes mellitus (10.8%) among adults population (>19 years) in rural parts of South India. These figures imply that though the prevalence of DM varies in different settings, it is certainly quite high and warrants immediate attention[11]. Majority(46.3%) of our study participants with diabetes were in the age group of 40-60 years. The most recent data from the International Diabetes Federation indicated that an estimated 415 million adults aged 20–79 years worldwide have DM in 2015 and the number will project to 642 million in 2040, with the prevalence increasing from 8.8 to 10.4%[12]. In this study, prevalence of type 2 DM in overweight subjects were 18.5% and in the obese population were 39.8%. The prevalence rates were relatively high because of overweight and obesity. In study conducted by Mandal et al found that the prevalence of type 2 diabetes mellitus, in the obese group of the study population were 20.2% and in the overweight population were 15.5%. They in their study also concluded that the prevalence of type 2 DM and increases with increasing weight of the individuals[13].

Conclusion

In the current study, prevalence of diabetes mellitus is very high. So regular screening method should be used to detect the undetected cases from the community. We found a significant association of diabetes mellitus with middle aged people i.e. 40 to 60 years, so screening program should focus on the middle aged people. The government sector could integrate non communicable disease like diabetes mellitus with the health packages which might help to create awareness in the community through health education. This will help in controlling diabetes mellitus through promote on early diagnosis and treatment.

Knowledge and Awareness of Oral Candidiasis among Dental Students

Roghithkannan¹, Archana Santhanam²

¹Department of Oral Pathology, ²Department of Oral Pathology, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University,

Abstract

Objective: To assess the knowledge and awareness amongst the dental students on oral candidiasis.

Method: This online based survey study was conducted among 100 students of Saveetha dental college. The questionnaire consisted of 10 questions which were based on knowledge, awareness and practices regarding oral candidiasis among the dental students in Saveetha Dental College. Results were analyzed and tabulated.

Results: Most of the students were aware of oral candidiasis. The knowledge on oral candidiasis caused by fungus (83%) is adequate. There was good adequate knowledge on risk factors (72%), chair side diagnostic aid (92%) and treatment (51%) of oral candidiasis.

Conclusions: Due to limited knowledge on oral candidiasis, the dental curriculum should include opportunities for structure interaction between students and patients with candidiasis both in classrooms and in clinical setting through objective structure clinical exam.

Keywords: Knowledge, Awareness, Oral candidiasis.

Introduction

There is limited literature showing the magnitude of oral manifestations and the extent of awareness on its occurrence in people. Oral manifestations are reported to have clinical significance across the globe. Oral candidiasis is a common infection of the oral cavity that is caused by an overgrowth of Candida species and is the most common human fungal infection especially in early and later life[1]. There are many types of Candida species, the ones seen in the oral cavity leading to oral candidiasis are: C. albicans, C. glabrata, C. guillermondii, C. krusei, C. parapsilosis, C. pseudotropicalis, C. stellatoidea, and C. tropicalis[2][3]. These species remain as a normal commensal micro-organism in humans and the occurrence of oral candidiasis varies depending on age and certain predisposing factors[4]. Risk factors include impaired salivary gland dysfunction, drugs, dentures and other immunosuppressive conditions. The diagnosis of oral candidiasis is predominantly clinical which can be confirmed by the microscopic identification of Candida which is based on the recognition of the lesions by the dental professional[5].

Limited knowledge on oral candidiasis results in delay in its diagnosis and treatment planning which affects the quality of life and cause further complications. To avoid this, it is important that health professionals especially dentists should not only be aware of the pathogenesis of the disease process but also the first clinical signs, its diagnosis and treatment. Hence, this study was undertaken to assess the level of knowledge, awareness and practices regarding oral candidiasis among the dental students in Saveetha Dental College.

Materials and Method: A cross-sectional, descriptive, questionnaire based survey method was carried out to assess the level of knowledge, awareness and practices regarding oral candidiasis among the dental students in Saveetha Dental College. The questionnaire was online based prepared in English and the content validity was assessed by distributing it among the faculty members from the Department of Oral Pathology.
The questionnaire comprised of 10 questions and was distributed among 100 undergraduate students in the internship phase. Informed consent was obtained from the students before proceeding with the survey. Results were analyzed and tabulated.

Questions presented in the questionnaire were as follows:

1) Have you heard of oral candidiasis before? Yes / no
2) Is candida a normal commensal? Yes / no
3) Oral candidiasis is caused by fungus? Yes / no
4) Is oral candidiasis a potentially malignant disorder? Yes / no
5) Is Oral candidiasis common in immunocompromised individual? Yes / no
6) Does oral candidiasis presents itself clinically as a white scrapable plaque? Yes / no
7) The main symptom observed in oral candidiasis is pain and burning sensation? Yes / no
8) Can oral candidiasis be misdiagnosed as burning mouth syndrome? Yes / no
9) Chair-side direct microscopy procedure for diagnosing oral candidiasis is through cytological smears? Yes / no
10) Can oral candidiasis be treated using nystatin? Yes / no

Result: Overall response rate was 100%. From the present study it was evident that 79% of undergraduate dental students were aware of oral candidiasis and 21% of students have not come across the term oral candidiasis. 54% of the students were unaware that candida is a commensal of the oral cavity. 83% of dental students think fungus as causative agent for oral candidiasis. However majority of the dental students (73%) consider oral candidiasis as a potentially malignant disorder and is common in immunocompromised individuals (72%). 92% of dental students said that oral candidiasis presents itself clinically as a white scrapable plaque, while 87% of students believe that pain and burning sensation is the common symptom associated with oral candidiasis. 91% of dental students considered Chair-side direct microscopy procedure was used for diagnosing oral candidiasis. 51% of dental students were aware that nystatin can be used to treat oral Candidiasis. Results are illustrated in Table 1

Discussion

In healthy individuals, Candida exists harmlessly in mucous membranes such as ears, eyes, gastrointestinal tract, mouth, nose, reproductive organs, sinuses, skin, stool and vagina, etc. It is known as “beneficial flora” and has a useful purpose in the body. When an imbalance in the normal flora occurs, it causes an overgrowth of Candida albicans. The term is Candidiasis or Thrush. This is a fungal infection (Mycosis) of any of the Candida species, of which Candida albicans is the most common. When this happens, it can create a widespread havoc to our overall health and well-being of our body [6].

Impaired salivary gland function can predispose to oral candidiasis. Immunosuppressive drugs such as the antineoplastic agents have been shown in several studies to predispose to oral candidiasis by altering the
oral flora, disrupting the mucosal surface and altering the character of the saliva. Other factors are smoking, diabetes, Cushing’s syndrome, immunosuppressive conditions such as HIV infection, malignancies such as leukemia and nutritional deficiencies – vitamin B deficiencies increases the risk of oral candidiasis increases when there is suppression of cellular immunity and phagocytosis\(^7\).

Oral candidiasis presents in a variety of clinical guises and may affect one or more mucosal surfaces\(^8\). Mostly presents clinically as confluent whitish-yellow creamy plaques on the surface of the oral mucosa and tongue\(^9\). Usually asymptomatic but may be associated with pain and burning sensation based on the severity of the disease\(^10\).

Generally, the diagnosis of oral candidiasis is based on clinical signs and symptoms in conjunction with a thorough medical history. Provisional diagnoses are often confirmed through further laboratory testing of clinical specimens. A number of method for sampling the oral mucosa for the presence of candida have been developed. But the most commonly used chair side diagnostics aid is by exploitive cytological smears. Drug of choice is dictated by several factors, including the patient’s medical history and oral symptoms. Common regimes are topical anti-fungal agents especially nystatin.

Despite the fact the oral cavity is accessible for visual examination and also most of the oral lesions have well defined clinical and diagnostic features but they are left undiagnosed at early stages. Hence the practitioner, who deals with any kind of oral pathology must for this reason, is in a situation to identify all suspicious lesions and be prepared to ask for professional guidance when unsure. At the same time the dental practitioners should be able to refer the patient to the most appropriate discipline. There is limited literature showing the magnitude of oral manifestations and the extent of awareness on its occurrence in people.

In the present study it was found that 46% of the dental students were aware that candida is a common pathogen of the oral cavity. Most of the of dental students (83%) think that fungus is the causative agent for oral candidiasis. But to our surprise we found that many of the students were aware that oral candidiasis is associated with pain and burning sensation which is the common symptom associated with it.51% of participants knew that oral candidiasis can be treated using nystatin. It was also found in the study of Cross et al that the use of oral antiseptic and antibacterial rinses such as Chlorhexidine was very effective in patients with oral thrush and denture stomatitis\(^11\). The WHO Global Oral Health program has worked hard over the years to increase the awareness of oral health worldwide as an important component of general health and quality of life\(^12\).

These results revealed an inadequate level of knowledge on oral candidiasis among the study population and suggested a need for improvement of undergraduate curriculum in oral candidiasis and for the provision of postgraduate and continuing education on oral candidiasis.

**Conclusion**

Due to limited knowledge on oral candidiasis, the dental curriculum should include opportunities for structured interaction between students and patients with candidiasis both in classrooms and in clinical setting through objective structured clinical exam. It is important to ensure that future dentist attitude towards these patients is not a barrier to their receiving the best possible oral care.

Brain Tumor Classification with Optimized Features using Firefly Algorithm

Arun Kumar1, M.A. Ansari2, Alaknanda Ashok3

1Research Scholar, 2Director, Woman Institute of Technology, Uttrakhand Technical University, India, 3Assistant Professor, Gautam Buddha University, India

Abstract

In present scenario tumor is a dangerous disease in the human life. In this study, the number of steps of medical image processing are used to process a Magnetic Resonance Image (MRI) to detect the brain tumor and also to define its type. Out of many steps, feature extraction and feature reduction is core of medical image processing. Different types of features like intensity, shapes and texture based features, are extracted from the segmented MRI images. Then, a machine learning model is developed by using the optimally selected features. Feature reduction approach is used to select the small subset of features which minimize redundancy and maximize relevance to the target. A bio-inspired Evolutionary computation (EC) based Firefly Algorithm (FA) has been used to reduce the size of feature set so that only key features will be used to classify tumor type using Support Vector Machine (SVM). At the end, classification accuracy has been compared results obtained with and without optimization.

Keywords: Brain tumor; Feature extraction and reduction; Firefly Algorithm; MRI; SVM

Introduction

Brain tumor is a very dangerous disease. When a tissue increases in unnatural manner it is called a tumor and when tumor occurs in the brain it is called a brain tumor1. Till now no conclusive report has been given by doctors, which can describe the main cause of brain tumor, but today’s life style of human being is surely one of the reasons for increasing the number of cases of brain tumor in urban areas. Various activities of the human body like thought, action and feelings are affected by the electrochemical impulses produced by the neurons after having a tumor in the brain. This type of harmful disease should be detected at the earliest stage accurately to save the life of patients by the physicians because most of the patients, which have brain tumor die within 1 year of having disease due to not proper diagnosis. A radiologist takes the help of MRI images to detect the brain tumor. By the high resolution of MRI images brain abnormal activities and changes are easily detected2. Brain tumors can be classified into primary and secondary, or in malignant or benign type. In a primary brain tumor, the tumor occurs in the brain and remains in the brain while in secondary tumor which is also known as metastatic, tumor may occurs in any body parts and then spread to brain3. Not all the tumor is cancerous some tumor is non cancerous which do not reoccur once they are removed. A benign tumor is one of them which have regular in shape and size while malignant tumors is cancerous in nature which may reoccur4. Although there are many types of brain tumor can be seen in patients all over the world, yet Meningioma tumor, Glioma tumor and Pituitary tumor are found commonly5. So we have associated the class with Type 1, Type-2 and Type-3 respectively, for each of the above discussed tumor types. All the discussed types are shown in Figure 1. Computer Aided Diagnosis system (CAD) can be designed which can take the MRI Image as input and diagnose the brain tumor area as output along with more accuracy in less time. Medical image processing field has great advancement in recent era which can be applied in designing this CAD system.

In this paper, we have designed a framework for a CAD system to classify 3 types of tumor with the implementation of bio-inspired EC algorithm known as the Firefly Algorithm (FA) along with SVM classifier. FA algorithm has been used for feature reduction. The rest of the paper has been organized as follows: section 2 contains the description of existing research; Section 3 describes the proposed method for the tumor
classification followed by an experimental set-up in section 4. The results of the study are dis-cussed in section 5 whereas conclusion and future scope is pro-vided in section 6.

(a)  (b)  (c)
(d) (e) (f)

Fig. 1: MRI images with (a) Normal brain (b) Benign tumor (c) Malignant tumor (d) Glioma tumor (e) Meningioma tumor (f) Pituitary tumor.

Related work study: The main work of the study is based on the feature reduction techniques. Jain AK et al. suggested lots of techniques for feature reduction for digital images like PCA, LDA, ICA, etc. but each have some advantages and disadvantages. Pydi V. et al. used PCA with SVM to detect brain tumors. RathiVP. et al. used LDA algo-rithm to reduce linear feature set. Raymer et al. proposed dimension reduction with genetic algorithm for the identification of favourable water-binding sites on protein surfaces which help in providing biochemical solution. With the help of a neural network and ant colony optimization (ACO) algorithm for feature selection (FS) was designed for image processing. Similarly, combination of Bee Colony Optimization and ACO was used in solving several optimization problems. Taie et al. used CSO, along with SVM to classify and detected brain diseases and compared the result with PSO. Another bio-inspired algorithm named FA was used for solution of non convex economic dispatch problem by Yang et al in 2012. Then many researchers also used FA with other combination after reducing features with FA for many applications.

So from this background work, it was observed that although there are so many method available for feature reduction, but each have some advantages and disadvantages both. As if in the case of PCA, LDA and ICA if we unswaveringly calculate all the subsets of features from a specified data then it will become an NP-hard problem because of the number of features grows very rapidly. Until now so many nature based Evolutionary Computing algorithms like PSO, GWO, BBO etc. have been used for feature reduction with successful results in many applications. However, we have used FA because of its effectiveness and simplicity.

Research methodology: Medical image processing is the backbone of this framework. Firstly the MRI image is pre-processed for the seg-mentation of brain tumor. Then features like space, intensity and texture based are extracted from that segmented image. After that-feature reduction process is done by optimizing algorithm named FA. The feature selection process of taking a small subset of features that minimize redundancy and maximize relevance to the target such as the class labels in classification. The SVM classifier have been used for the classification of tumor. The Final result has been compared with classification accuracy of SVM with and without feature optimization. Each subunit has been explained as below.

- MRI image pre-processing and segmentation

MRI image scanner always affected by the environmental conditions. Therefore filters are used for the noise reduction to improve the quality of the image. In case of an MRI image compression system, the tumor detection depends on the regions of interest which are full of noisy in nature and low contrast. Hence an image enhancement and de-noising may be required to preserve the image quality, highlighting the image features and suppressing the noise. The de-noising and feature enhancement techniques presented in this work will improve the reliability of image processing.

- Extract the feature from the MRI images

There are 14 features which are extracted from the MRI this work. Out of these 14 features; Area, Perimeter and Circularity are shapebased features. Mean, Variance, Standard Deviation, Skew-ness, Kurtosis are taken as intensity based features while Contrast, Cor-relation, Energy, Entropy, Homogeneity and IDM are taken as texture based features. Grey Level Co-occurrence Matrix (GLCM) techniques have been used for extracting these features.
• Firefly Algorithm and Feature Reduction

In 2010, Xin-She Yang developed Firefly Algorithm (FA) which was based on the sporadic patterns and activities of fireflies. In FA, firefly is attracted by another firefly based on the brightness because of their unisex. Less bright firefly always move towards brighter one, so as the distance between two firefly increases their brightness will decrease and if there is no brighter one found then they migrate randomly. The brightness of a firefly is determined by the landscape of the objective function in an artificial environment.

Variation of attractiveness $\alpha$ with the distance $d$ is given by (1).

$$\alpha = \alpha_0 e^{-\delta d^2} \quad (1)$$

Where $\alpha_0$ is the attractiveness at $d = 0$. From the movement of firefly, It will be determined that which features will be opted in optimal feature set after reduction.

• Classification of the features using SVM

Image classification is the process by which we categorizes any pixel of image to particular class e.g. in any remote sensing satellite image of earth we can classify any pixel that whether it belong to the water body area or land area depending upon its characteristics. Support vector machine (SVM) is a machine learning model which works on supervised learning models associated with adaptive learning algorithm that analyzed data used for classification and regression analysis. To evaluate the performance, we used Multi class SVM (support vector machine) and divided images with optimized features in 80:20 ratio, so 80% images is used as training data and remaining 20% is used as testing data. The performance of the feature selection is increased after applying FA.

**Experimental Setup**

Brain MRI images have been taken from online available data set BRATS-2015. The brain tumor data set consist of 3064 T1-weighted contrast - enhanced images. Out of these images after preprocessing total 1440 slices have been taken which contain 3 types of tumor as discussed in the first section. Label 1 represents the Meningioma tumor, which has 720 slices, label 2 represents the Glioma tumor, which have 466 slices and label 3 represent the pituitary tumor, which has the 254 slices. After that, tumor segmentation step is applied by morphological operation (opening and closing). Then total 14 features have been extracted by GLCM techniques. But instead of taking all these features for the classification process with SVM, the FA has been applied for feature reduction. Implementation of all the steps has been performed with MATLAB 2016a.

Current data has strings in the form of features and we need to first convert them to analytics. Many attributes has maximum number of zeros which don’t contribute in classification and bias the network training. So we select them programmatically and removed from the features set. FA optimization and feature selection are two isolated algorithms, but they work in a closed loop scenario. Both module functions in equilibrium, FA give the input as a binary matrix to ML module and gets the accuracy in its input from the ML module. This binary matrix is the set of features which must be included. The ‘1’ in the matrix represents the feature selected and ‘0’ represents that this feature is not selected. Features selected for a given input image are shown in Table 1. Features selected after optimization will vary with different type of tumor contained in image and rest of the features will be discarded.

**Result and discussion:** The main aim of the study is to classify a tumor when MRI Images is given as input. Some samples of result have been shown in Table 2 which shows all 3 types of classification result. Figure 2 shows the accuracy comparison of result after optimization with FA and without optimization.

We find that features optimization with FA takes only those features which lead to increase the accuracy of the SVM classifier due to which the accuracy achieved...
in 76.77% when only 7 features are participating in a classification task in comparison to an accuracy of 67.77% when all 14 features are used for classification. Figure 3 shows the specificity, sensitivity and balanced accuracy of classifier for a particular input.

It has also been observed that as the number of features selected after optimization will change with different type of tumor MRI images but FA always selected less numbers of features than total features so that accuracy of SVM classifier can be increased. Accuracy of classifier also varied with the no. of features selected by the FA as observed that accuracy of SVM classifier was 73.01% when 6 features have been selected while the accuracy of the SVM classifier is decreased to 68.25% when total 8 features have been selected by the FA for a given image.

**Conclusion and future work:** In this study, a hybrid model is developed with the use of bio-inspired FA algorithm to classify different types of brain tumor when MRI image is given. FA selects less number of features than the total features which were extracted from the segmented brain tumor image. Fewer features take less memory and computation time is also less. Moreover, Accuracy of SVM classifier has been increased significantly with these less number of features because these are the only features which are decisive for classification tasks. In future, some more bio-inspired algorithm can be applied for feature reduction to further increase the accuracy. Another conclusion is that, the number of features selected by FA will vary with different class of tumor image taken as input and due to which, accuracy of SVM classifier also varies accordingly, but accuracy will always be higher than the accuracy of SVM when no optimization algorithm is applied.

For future work, other bio-inspired algorithms can also be applied and compared so that accuracy of SVM classifier can further be increased.

Study on Attitude of Co-Workers Towards Employees with Intellectual Disabilities

Arun Kumar¹, S.K. Srivastava¹, Kishan Kumar Singh²

¹Assistant Professor, ²Professor, Department of Psychology, ³Research Scholar
Gurukul Kangri Vishwavidyalaya Haridwar, Uttarakhand, India

Abstract

Employment plays crucial role for everyone’s life, in present investigation we try to understand attitude of co-workers about the employment of intellectually disabled individual working in open environment. For this sample of 30 coworkers working at different work places with intellectually disabled employee were undertaken through purposive sampling technique. Results shows: t-test value reveals that there is no significant difference between male and female coworkers in respect to attitude towards intellectual disable employee. The findings of the study are: intellectually Disabled employee are honest, sincere, sociable, regular, punctual about job and need special attention and training. Coworker recommended towards intellectually disabled employee that they can do their job best with support and supervision of experts.

Keywords: Attitude, Intellectual Disability, Employee, Working in Open Environment.

Introduction

Being adult every youth wants to be employed; employment provides an opportunity to cope up with economic, social needs, and feeling of worth and dignity. However people with disabilities are underrated in the field of job market. In India there is no any organized study to get data of disabled employment rate. In India and other developing country has big unemployment issues, due to unemployment youths faces many challenges as psychological, physical, social, and economical. According to PwDact¹, 4% reservation for disabled candidate in government sector employment. When we talks about employment of disabled employee it’s vary according to types and degree of disability. Hernandez etal.² work and employment play a central role in people’s lives and are essential factors in social inclusion and well-being.

Philip Burge etal.³ conducted a study on “public views on employment of people with intellectual disabilities”. In finding of this study indicates that poor employment skill training was a main barrier to increase inclusions with others. 87% individuals believed that appointing a person with intellectually disability will not negatively impact at work place. Hernandezetz et al.² conducted a study on and found that employer shows positive attitude about employees with disabilities and reported that employer shows more positive attitude towards physically disabled workers than workers with psychiatric or intellectual disabilities.

McFarlinet al.⁴ concluded that many business executives believe that more should be done in their company and in others to integrate people with disabilities into the workforce. The appropriate Government and the local authorities shall, within the limit of their economic capacity and development, provide incentives to employer in private sector to ensure that at least five per cent of their work force is composed of persons with benchmark disability. Mapuranga Barbra⁵ conducted a study and recommended that co-worker needed to change their attitude towards employed with ID. The ministry of labour needs to establish incentive packages for companies that employ persons with disabilities to encourage employment of more persons with disabilities. Blessing et al.⁶ found that 78% of employers described the employment of a person with an intellectual disability as predominantly a positive one.

In recent time there are mainly two types of work design for intellectually disabled individual first is sheltered setting⁷ and second is open setting. Sheltered setting⁷ is where intellectually disabled individual work with other intellectually disabled employee, and wherein open setting employment intellectually disabled employees work alongside with non-disabled employee.

Working in open environment: like every adult intellectual disable individual also has aspiration to be employee, however, due to their intellectual limitation they find more difficulty to achieve their employment aspiration. Facing these difficulty not only
limitation of intellectually disabled individual it’s also
get affected by lack of creativity, imagination and
stereotype tendency some of employer and co-workers
towards disability.

Objectives

- To assess the level of attitude on co-workers in open
  environment.
- To compare the level of attitude among male and
  female.
- To compare the level of attitude among age.

Hypotheses

1. There will be no significant difference in level of
   attitude of co-workers in open environment, among
   male and female employee.
2. There will be no significant difference in level of
   attitude of co-workers in open environment, among
   ages.

Methodology: Sample is collected by purposive
sampling technique of 30 co-workers of ID (11 female
and 19 male) from NIEPID Secunderabad, rehabilitation
centers and NGO’s where intellectually disabled employee
working independently in normal settings with regular
employee. Age range of co-workers is between 20-60
years.

Inclusion Criteria

- Co-workers of employee with intellectual disabilities
  in open environment.
- Co-workers should have above normal IQ range.
- Co-workers should have direct contact through
  employee with intellectual disabilities.
- Co-workers should not have any disabilities
  (physically handicapped. etc.).

Exclusion Criteria:

- Co-workers don’t have any intellectual disable
  member in family.
- Co-workers are not rehabilitation professionals.

Tool used in The Study

1. Demographic data sheet: consists name, age, gender,
rural/urban, education, occupation and monthly
income of the co-worker.
2. Scale of Co-workers attitude towards employee
with intellectual disabilities was developed. For
the development of the attitude scale, primarily
total 50 item were selected in which 38 item were
selected as final item, all 38 item was finalized by
4 rehabilitation professionals who are working
in the area of rehabilitation, vocational training
and academics field for intellectually disabled
individuals with minimum 10 years’ experience.
After obtaining their suggestions total 38 items
were selected and all the items categories in their
work situation, working habit, behaviour towards
others, attraction towards others etc. it also gives
total Attitude score which means high score indicate
positive attitude and low score indicate negative
attitude. Scoring pattern is 6 to 1, ‘6’ for ‘I agree
very much’ and ‘1’ for ‘I disagree very much’.

Procedure of Data Collection: Keeping In
mind the inclusion and exclusion criteria data was
collected by administering Scale on Co-workers
attitude towards employee with intellectual disabilities.
The sample was collected from National Institute of
Mentally Handicapped (NIMH) General services and
rehabilitation centers. After selecting the sample for
Attitude scale was administer by the research on the
subject. The Scale was administered on the sample of 30
selected employee subjects. The item in the answer sheet
was score accordingly to the scoring pattern. The data
obtained was analyzed and interpreted by using various
statistical techniques.

Data Analysis: The data was analyzed using SPSS.
Item analysis and t-test were used to understand whether
the co-workers having different attitude across age and
gender of co-workers towards employee with intellectual
disabilities.

Results and Discussion

Table 1: Mean, standard deviations and t value
on attitude of co-workers towards employee with
intellectual disabilities.

</table>

NS- Not Significant

Table 1 shows that mean score of attitude level of co-
workers towards employee with intellectual disabilities of
the male co-workers is 160.79 and female co-workers is
149.73. The t-test is used to find out significant difference
of co-workers towards employee with intellectual
disabilities. t-value shows that there is no significance
difference found in male and female co-worker.
Table 2: Mean, standard deviations and t value on attitude of co-workers towards employee with intellectual disabilities.

</tr>
</tbody>
</table>

NS- Not Significant

Table 2 shows mean score of attitude of co-workers towards employee with intellectual disabilities level of below 35 years co-workers is 150.54 and above 35 years co-workers is 161.47. the t-test is used to find out the level on attitude of co-workers towards employee with intellectual disabilities, and t-value shows that there is no significance difference found in regarding the age of the co-worker.

The present investigation was conducted to Study on attitude of coworker towards employee with intellectual disabilities in open environment. Sample size was 30 (19 male and 11 female) and selected through survey method, attitude scale was developed and used to collected sample. After analyzing the results, it can be said that the hypotheses of the present study that there is no significant difference in level of attitude among male and female employee is partially conformed. And indicate that there is no significance difference between male and female co-worker toward employee with Intellectual disabilities. Finding shows that male (160.79 mean) coworker have piety high positive attitude than female (149.73 mean) coworker. The studies conducted by “Paola Paez8 conducted a study on “Managers’ attitudes towards employees with disabilities in the hospitality industry” find no significant differences were noted in attitudes based on manager’s age, gender, or experience with disabled employees, Hardeep Aiden and Andrea McCarthy9, nearly 38% people surveyed think of disabled people as less productive than non-disabled people, less capable than non-disabled people.

The item analysis result reveal that toward coworker attitude that is employees are agree pretty much on these statement:

- Employer of intellectually disabled employees should be less strict than other coworker.
- It would be best for intellectually disabled employees to live and work in sheltered employment.
- Intellectually disabled employees people show as much enthusiasm as other coworker.
- Intellectually disabled employees are usually more sensitive than other co-worker.
- Intellectually disabled employees are usually sociable.
- Most Intellectually disabled employees are usually different from other non-intellectually disabled employees.
- Most physically intellectually disabled employees have different personalities than normal co-worker.
- Most intellectually disabled employees need special attention
- Most intellectually disabled employees need special Training
- Employers should not be allowed to fire intellectually disabled employees.
- Most intellectually disabled employees are different from other non-intellectually disabled employees.
- Most intellectually disabled employees want more affection and praise than other co-worker.
Employees are disagreeing little much on these statements:

- The way intellectually disabled employees function is irritating.
- Most Intellectually disabled employees has no need to supervision.

The total item analysis says that coworker has positive attitude towards employees with intellectual disabilities. Research by Opinium found that the majority of UK adults generally believe that disabled people face prejudice in Britain. In line with previous waves of the British Social Attitudes survey, well over half (57%) of respondents agreed that there is ‘a little’ prejudice and a quarter (28%) agreed there is ‘a lot’. Nearly four in ten (38%) people surveyed think of disabled people as less productive than non-disabled people, over three quarters (76%) think of disabled people as needing to be cared for, and 13% think of disabled people as getting in the way some or most of the time.

The Finding of the Study:

- There is no significant correlation between the male and female coworkers.
- There is no significance difference between the below35 and above 35 years of age coworkers.
- Item analysis shows positive attitude of coworker towards employee with intellectual disabilities.
- Item analysis Result shows that intellectual disabled employee are friendly, sociable and job oriented.

Limitation of the Study

- Because of the small sample size it was very difficult to obtain enough information to identify statistically significant correlations. The replication of the present study on a larger sample would help in generalization of the findings.
- Sex ratio of the sample was unequal.
- Scale was not standardized.

Awareness of Medical Ethics among Undergraduate Students of Medical College in South Kolkata

Rekha Dutt¹, Ashish Kr Yadav², Soumya Chakraborty³, Arohita Siva⁴, Maitry Mondal⁴

¹Professor, Department of Community Medicine, ²Assistant Professor (Biostatistics), Department of Community Medicine, ³Professor, Department of Anatomy, ⁴Tutor, Department of Community Medicine, ESIC medical College, Joka, Kolkata

Abstract

A descriptive cross-sectional study was conducted to assess the awareness of medical ethics among 319 medical students in a medical college of West Bengal. A semi structured questionnaire that included questions on awareness of ethical principles and Medical Council of India code of Professional conduct, Etiquette and ethics was used. The data was analysed by descriptive statistical method. It was observed that MBBS undergraduate students didn’t have sufficient awareness on medical ethical principles and issues. There was no improvement in knowledge with seniority in medical college. The present study highlights the need of well-planned medical curriculum by multidisciplinary approach by different teaching modes to enhance cognitive, psychomotor and attitude towards medical ethics by trained teachers in subject of medical ethics.

Keywords: Awareness, medical ethics, undergraduate medical students.

Introduction

These days, we have been getting news of repeated attacks on medical professionals, because the confidence of public in health care professionals has been fading. The mistrust in doctors can be attributed to various causes like incompetency or inability to communicate or behave with patients or attendants. Lack of awareness about principles of medical ethics is the main reason of negative publicity against medical profession. Ethics has been defined as the moral principle that govern a person’s behaviour or how an activity is conducted and medical ethics as branch of knowledge concerned with moral principles(1). Medical ethics involved four principles i.e. respect for autonomy, beneficence, non-maleficence and justice(2).

Training in medical ethics have been made mandatory in UG training by MCI, that released MCI 2002, code of ethics which was regulatory document on professional conduct, etiquette and ethics of doctors(3). In present curriculum, medical ethics is taught in 2nd year MBBS by department of Forensic medicine and toxicology. Every medical student should be imparted knowledge and ways to imbibe it as attitude and practice these ethical values to safeguard patient and his interest as well.

The present study was planned to determine the awareness of medical ethics among medical students to collect baseline information along with comparison of students at different level of seniority in the college.

Material and method: A descriptive cross-sectional study was carried out from November 2017 to January 2018 among the medical undergraduates of different batches from first year to final year of ESIC Medical College Joka, Kolkata, after obtaining IEC clearance. A semi structured questionnaire was developed based on Medical Council of India code of Professional conduct, Etiquette and ethics guidelines and previous research publications(4,5). The questionnaire was pretested on 20 UG students and necessary modifications were done. The first section of questionnaire covered demographic information like age, gender and year of admission in medical college. The next section contained information on awareness of students about ethics and its importance, presence of IEC, source of information. Third section of questionnaire was based on principles of medical ethics. Fourth and fifth section comprised of knowledge regarding intimate physical examination, Medical Council of India code of Professional conduct, Etiquette and ethics respectively.
The investigators interacted with the MBBS students of 1st, 2nd, 3rd and 4th year, briefed them about the purpose of the study and requested them to participate, students were assured that participation was voluntary and their confidentiality would be maintained. Informed consent was taken from those who wished to participate. Of 380 students enrolled in institute, 339 participated. Once the data was collected the data frame was prepared using Microsoft office excel programme. Based on the objectives of the study, descriptive and inferential statistics was drawn. For categorical data, percentage along with frequency distribution was used and for quantitative variables mean and standard deviation was used to represent central tendency values in the dataset. Chi-square test and Fisher-Exact test was used to assess whether there is any association between awareness of medical ethics with different domains. Bar diagram and pie charts were used for graphical presentation of data. Knowledge of code of professional conduct, etiquette and ethics was assessed using standard MCI guidelines. Three-point Likert scale was used to categories the variables. A score of seventy percent and above constitute good knowledge, a score of fifty to seventy represent fair knowledge were as the score below fifty represent poor knowledge. The entire dataset was analysed using statistical software R Studio (R version 3.5.1).

**Results:** Among 339 participants, 184 (54.28%) and 155 (45.72%) were males and females respectively. Their age ranged from 17-28 years with mean age 21 years and standard deviation of 1.82. Number of students participated were 69, 48, 89, 78 and 55 from 1st, 2nd, 3rd, 4th and final years respectively.

Table 1: Percentage distribution of medical students according to their knowledge of medical ethics.

*No observation

Clinical training followed by lectures and ethical books are considered to be prominent source of knowledge on medical ethics. Majority of students opining clinical training as source of information are from 4th year (44%) followed by 1st year (38%). Maximum number of students (29%) from 3rd year followed by 4th year (19%), 1st and 2nd year (18%) and final year (13%) are of view that lectures are source of information on ethics. Again majority of students (37%) of 3rd year followed by 10-15% of other batch think that ethical
books are source of information. However, very few students got information from media. Only 29% students from 3rd year, followed by 25% of 4th year and 19% from final year were aware of Institutional Ethics Committee. Table 2 depicts that majority (81%) of 1st and 4th year opine that ethical conduct is important not only to avoid legal actions whereas approximately 89% and 83% from final and 2nd year think that it is important to discuss ethical issues during clinical rounds along with clinical aspect. It has been observed that most of the students do not have knowledge pertaining to medical issues and knowledge isn’t improving with years of seniority.

Table 3 shows knowledge of ethics during physical examination of patients. Majority of students except from 1st year opined that male doctor should not examine female patient in his chamber without any female attendant or nurse. Many were of the view that intimate (rectal/vaginal) examination should not be performed without informed consent, privacy of one patient should not be ignored for benefit of large groups and during system examination, writing within normal limits without examination is acceptable for documentation.

Figure 1 show percentage distribution of knowledge of Medical Council of India code of Professional conduct, Etiquette and ethics. Majority of students of all batches had poor knowledge, 4th year students have relatively better knowledge about medical ethics.

Discussion

Our study revealed that majority of MBBS students feel that ethical issues are not at all important in medical profession. This can be attributed to lack of training on the subject in theory as well as practical classes.

The main source of ethics knowledge in present research, was quoted as clinical training and ethical books similar to the finding of studies done in Chennai in 2014(6) and New Mexico in 2004 (7) where respondents preferred clinical training involving multidisciplinary approach over traditional didactic approach and studies conducted in Karnataka in 2014 (8) and West Bengal in 2012 (4) where books on ethics are considered main source of information to the students. Most of students of different batches feel that it is important to discuss ethical issues during clinical rounds along with clinical aspects in accordance with other studies (4, 5).

Majority of respondents were not aware of presence of IEC, similar to the findings of other studies conducted
among MBBS students in other parts of country (4, 6 and 8). Majority of students disagree that ethical conduct is important only to avoid legal action similar to finding of other studies\(^5\,^9\). Students expressed contradictory view on different ethical issues. Most feel that patients’ wishes should always be adhered to during treatment, while majority also feels that doctor should do whatever is best irrespective of patient’s opinion. Similar contradictory views were also reported in other studies as well\(^4\,^5\). Similarly majority of respondents opine that patient and his close relatives should always be told truth about patient’s condition, children should never be treated without consent of guardian, medical practitioner should take commission for introduction of patient who refuse treatment on religious grounds\(^4\,^5\).

Regarding respondent’s awareness on MCI code of Professional conduct, Etiquette and ethics, it is observed that more than 50% of students of final year opine that a physician can prescribe drugs with brand names highlighting urgent need of orientation of students before they independently start practicing profession. A comparison of per cent score of respondents studying in different years shows that there is no proportionate improvement in awareness with increase in years of medical education a finding in accordance to similar studies\(^4\,^6\). This suggests that didactic and textbook teaching on ethics does not increase awareness of this subject. A three year cohort study conducted at Canada, found that students understanding of ethics didn’t improve substantially with education. Majority of respondents remained at same stage of moral reasoning in their 3rd year (mean scores of 3.48) of study as in their first year (mean score 3.46)\(^10\).

All our findings emphasise need of well-planned curriculum including medical ethics as a subject in multiple disciplines to be taught by trained faculty members throughout undergraduate, internship and post graduate period. MCI has developed a curriculum with emphasis on AETCOM (Attitude ethics and communication) for Indian medical graduate to be implemented from year 2019\(^11\) with goal to develop ethically sound doctors.

**Conclusions**

The present study highlights the need of well-planned medical curriculum by multidisciplinary approach by different teaching modes to enhance cognitive, psychomotor and attitude towards medical ethics by trained teachers in subject of medical ethics. It should be on-going process involving UG, PG, Govt. and private practitioners.

In response to similar observations by different studies and to improve the ethical knowledge, MCI has revised its MBBS curriculum, which will roll out nationally from 2019 session. AETCOM curriculum acknowledges the importance of ethics, responsiveness to need of patients and families and fine communication skills to engage the ailing. These will be assessed along with competencies and skills to prepare Indian medical graduate of global relevance\(^11\).

Knowledge and Perception Regarding Pre Anaesthetic Check-up (PAC) among Patients in a Tertiary Care Hospital in Sub Urban South India

Smriti Sinha\textsuperscript{1}, Sathyajith Karanth\textsuperscript{2}, Avinash Kumar\textsuperscript{3}

\textsuperscript{1}Assistant, \textsuperscript{2}Professor, Department of Anaesthesia, Srinivas Institute of Medical Sciences & Research Centre, \textsuperscript{3}Associate professor, Department of Community Medicine, Kasturba Medical College, Mangalore

Abstract

Background: Anaesthesiology branch has traded a long journey from a branch managed by physicians to a specialised branch which handles not just operative cases but also pain management and critically sick patients. Pre anaesthetic evaluation has long journey to go, the various roles of pre anaesthetic evaluation is still not well known to patients, which leads into wastage of resources and increased morbidity and mortality. The present study was done to assess the knowledge and perception of patients regarding pre anaesthetic evaluation in suburban area of coastal district of south India.

Methodology: Across sectional study, conducted in a tertiary care medical college and hospital in Dakshin Kannada district of India. The patients were inducted in the study by using convenience sampling technique. A pre tested, semi structured questionnaire were used as the data collection tool. Data were analysed using SPSS version 16.0 and results were expressed as frequency and percentage.

Results: The reason to go to PAC clinic as pre operative evaluation was known by 30.90% participants but that will help in optimisation and risk reduction was known by only 3.03%. Only an anaesthesiologist can conduct a PAC was known to 23.03% and it will help in anaesthesia and surgery risk reduction was known to 18.18%. Almost half 48.48% participants were willing to communicate about their co morbidities to anaesthesiologist but that need to be optimised before surgery was known by 16.16%.

Keywords: Pre anaesthetic check-up, Optimisation, Anaesthesiologist.

Introduction

Pre-operative check-up (PAC) is the first and a vital interaction of patient and anaesthesiologist. It helps in development of doctor and patient relationship and is crucial for both. During PAC anaesthetist get chance to discuss various anaesthesia techniques, possible options and their probable complications, whereas the patient get the opportunity to discuss their query with anaesthesiologist which helps in relieving their anxiety. It is very important for anaesthesiologist too to understand the patient’s health condition better, optimise them pre-operatively, developing a plan for the operative and post-operative care and give safer and effective health services. More and more patients these days understand the role of anaesthesiologist, however pre-anaesthesia check-up and its relevance with the outcome still remains a less cared aspect. Patients do not disclose their medical conditions during pre-operative evaluation and do not follow the pre-operative instructions properly which compromises the safety of the patient. This not only undermines the purpose of pre anaesthesia check-up, but also increases peri-operative morbidity and mortality.

The aim of this study was to assess the knowledge and perception of patients presenting for elective surgery to a Tertiary Care Hospital in sub urban India regarding value and importance of pre-anaesthesia check-up.
Methodology: The present cross sectional study was conducted in Srinivas Institute of Medical Sciences and Research Centre (SIMS&RC), Mukka, India. It is a tertiary care medical college and hospital, situated in the outskirts of coastal district, Dakshin Kannada of India. SIMS&RC is a tertiary care hospital which caters to the rural population in the outskirts of Mangalore city in Dakshin Kannada district which is one of the most literate district of the country. Although Mangalore has the best medical facility in the region but there is no good medical facility except SIMS&RC in the outskirts of Mangalore.

Approval from the Institutional Ethics Committee and permission from the Medical superintendent of SIMS&RC was obtained prior to the study. Patients who were admitted in SIMS&RC and posted for elective surgery were sent to pre anaesthesia clinic for pre-operative assessment by anaesthesiologist. In PAC clinic before conducting pre anaesthetic check-up, patients who were in age group of 18-70 years, were explained about the purpose of the study in the language best known to them by using a patient information sheet. Written informed consent was obtained by all the patients before inducting them in the study and was assured of anonymity throughout the study. The patient information sheet, consent form and questionnaire were made available in the languages known to the patient. Patients who did not consent for the study, who had some psychiatric disorder, were unable to answer questions due to poor medical condition and illiterate were excluded from the study. It was explained to the patients that the questionnaire was only for the assessment of their knowledge and the results will be used only for research purpose. The total number of patients recruited for the study was calculated to be 330 using prevalence 27.4%. The patients were inducted in the study by using convenience sampling technique. A pre tested, semi structured questionnaire were used as the data collection tool. The questionnaire consisted of two sections, section A and B. Section A dealt with the demographic details of the study participants and section B consisted of questions to assess knowledge and perception regarding pre anaesthetic check-up. Patients were asked to tick the option which was most appropriate according to them.

Results: Table 1 show that maximum patients were in the age group of 45 – 70 years with 39.09%, and minimum in the age group of 30-45 years with 27.57%. Male patients were 59.69% among the study participants. Maximum patients were graduate with 40% followed by approximately 32% who did secondary schooling. For 73.33% participants it was their first exposure to pre anaesthetic clinic for evaluation whereas 26.66% had been to PAC clinic earlier.

Table 2 depicts the knowledge of the participants regarding pre anaesthesia check up. On being asked the reason to come to pre anaesthetic clinic 102(30.90%) patients correctly affirmed for pre anaesthesia assessment, 132(40.00%) participants answered that they came to comply with surgeons instructions while 15(4.54%) were unaware of the reason to go to PAC. Assessment and optimization are done in PAC clinics were correctly known to 10(3.03%) participants, whereas maximum patients 161(48.78%) considered it for some test which were needed for anaesthesia fitness.

Correct knowledge that only anaesthesiologist can perform pre anaesthesia check-up was known to 76(23.03%) participants while 127(38.48%) knew that any doctor in PAC clinic can perform it. When the question was asked about the importance of PAC before surgery, 60(18.18%) correctly said it reduces the risk of anaesthesia and surgery, 103(31.21%) responded that to get the date for surgery whereas 122(36.96%) did not know the importance of pre-anaesthesia check-up before surgery.

Almost one half, 160(48.48%) knew that heart disease, breathing difficulties and renal problems had to be revealed during PAC whereas 82(24.84%) knew that if these diseases are under control then it was not needed to be revealed whereas the rest did not know that they have to reveal the morbid condition. Pre-existing medical conditions need to be optimised before surgery was correctly known by 53(16.06%), while 54(16.36%) were unaware of it.

Habits of drinking and smoking affect the outcome of anaesthesia and surgery was correctly known to 116(35.15%) patients whereas rest were not sure of the outcomes. Pre anaesthesia check-up was required only if surgery has to be performed under anaesthesia was known to 117(35.45%), whereas 213(64.55%) had a negative response to it. Only 41(12.42%) patients wanted to discuss about their anaesthesia related fear and queries in PAC clinic, 205(62.12%) patients knew that it has to be discussed with surgeons in ward.

Table 3 shows that 158(47.87%) participants had no idea whether pre anaesthetic evaluation was required or not before surgery, 31.82% thought that PAC was not needed and 20.30% thought that it was required. 30.9% thought that PAC was wastage of time and money, 24.84% were against it and 44.24% had no idea. 21.12% patients were ready to follow advices given in PAC clinic for their own good, 26.96% were willing to continue till surgery gets over, 33.03% wanted to be instructed by surgeons to follow orders, and 18.78% were clueless.
Discussion

The anaesthesiology has evolved over years from a branch handled by physicians to specialist who handles operative cases, pain management and intensive care. The awareness about role of anaesthesiologist has been increasing over time. In a study conducted by Jathare et al. in Mumbai, found that only 38% patients were aware of the role of anaesthetist in pre anaesthetic clinic. A study conducted by Leite et al. in Brazil found that 79.1% patients were aware that anaesthesiologists are specialized physicians.

Pre anaesthesia evaluation is the process of clinical assessment by an anaesthesiologist, which precedes the delivery of anaesthesia care for surgery and non-surgical procedures. The goals of adequately conducted pre anaesthetic evaluations are to develop a rapport with the patient and their relatives, reduce the morbidity of the surgery, increase the quality, reduce surgical delay, reduce case cancellation and decrease the cost of pre-operative care. It consists of history taking, general physical evaluation, relevant investigations, optimization, if needed consult from other super specialties to optimise patient better for the surgery. Adequate pre anaesthetic evaluation is important to reduce morbidity and mortality of the patients. The knowledge about PAC clinic, preoperative evaluation and its role is still not well known to people. In developing countries especially in rural population the knowledge about the need of pre anaesthetic evaluation is even more limited.

Traditionally patients who gets admitted one day prior to surgery were to be seen by anaesthesiologist. But later this method was found not to be cost effective, so in an attempt to make PAC more effective cost and outcome wise, the new planning is to get PAC done immediately after taking decision for surgery. It helps in reducing case cancellation on the day of surgery due to inadequate optimisation. There are various studies which have been done to plan effective set up of PAC clinic and to sensitise patients about its need. A study conducted by D Singla et al in rural population of developing country found that 27.4% of study participants were aware that PAC clinic was for preoperative evaluation, while in the present study the awareness level was 30.90%.

The fact that pre anaesthetic evaluation is for assessment and optimization before surgery was comparable in both the studies, which was 3.2% in Singla et al study and 3.03% in present study. Only an anaesthesiologist can conduct a pre anaesthetic evaluation was known to 18.11% in Singla et al study and 23.03% in present study. The information that a well conducted pre anaesthetic evaluation helps in decreasing the risk of surgery and anaesthesia was known to 15.6% of study participants in Singla et al study while in present study it was found to be 18.18%.

Associated comorbidities like heart disease, renal disease, and breathing difficulties needs special care by anaesthesiologist pre operatively for optimisation, operative plan and even for postoperative care. The mortality and morbidity directly depends on it so if patients do not reveal it during pre-anesthetic check-up, the outcome may get affected. In the present study 48.48% participants understood the importance of informing about associated co morbidities while 24.84% did not considered it important if it is under control. The pre-existing medical conditions need to be optimised before surgery was known by 21.3% patients in Singla et al study while in present study it was known by 16.06%.

Smoking and hazardous drinking increases post-operative morbidity in dose-response relationship. The harmful effects of smoking on cardiorespiratory and immune system significantly reduce by abstinence of 3-8 weeks, so it is mandatory for the anaesthesiologists to know about habit of smoking and drinking of the patient. In our study 35.15% participants knew that smoking and drinking habits can affect the outcome of anaesthesia and surgery, while majority 43.93% had no idea of such correlation. A study done in rural India concluded that 23.7% patients were only aware of correlation between smoking and drinking habit. The patients should be evaluated before the surgery to develop a database upon which risk assessment and perioperative decision management will depend. Pre anaesthetic evaluations are done only before surgery was known by 36.9% patients in Singla et al study, in present study 35.45% study participants knew that PAC has to be done pre operatively. A study conducted by Chew et al to assess the patient knowledge about anaesthesia concluded that the main fear of surgery was pain, only 23.5% correctly knew that anaesthesiologist are responsible for analgesia in post-operative period. In Singla et al study 58.6% of the study participants wanted to discuss their fear related to pain and anaesthesia with surgeons, 16.5% wanted to discuss it with anaesthesiologist during PAC. In the present study 62.12% participants wanted to discuss their fear of pain with surgeons and 12.42% with anaesthesiologist in PAC clinic.

In a study conducted on orthopaedic patients, they found that there should be better and close communication between surgical, anaesthesia and operation theatre team to avoid case cancellation. During PAC, the advices given to the patients need to be properly followed for
optimisation of the associated medical condition. In a study conducted in rural populations 20.3% patients were willing to follow the advices which were given in pre anaesthesia clinic, while 21.21% participants were willing to follow advices for their own good in present study.

Some of the limitations of the present study were that the study was conducted in single medical college and so the results cannot be generalised to a bigger geographical distribution. Illiterate patients were excluded from the study to avoid any influence on knowledge of patient while explaining the questionnaire to them.

**Conclusion**

Awareness of patients regarding anaesthesiologist have increased but the need of pre anaesthetic check-up and its importance for surgery is still limited, especially in sub urban population even in a part of Dakshin Kannada district which has 91% female literacy rate and 96% male literacy.

A Study on Successful HR (Human Resource) Strategies for Past, Present and Future Business Environment

N. Manivannan¹, B. Chithirairajan²

¹M.Com.,M.Phil.,Ph.D., ²Assistant Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies (VISTAS), Pallavaram, Chennai.

Abstract

The Indian economy had undergone significant policy shifts in the early 1990s. The human resource is very important in the field of organisation because of all the action taken only by the HR manager. The strategies are to be followed in the business organisation for future development. The developmental process is to be imparting in the organisation. This article has contained all the information about the organisational activities. The HR strategies are followed in past at the same time present and also the future. Initially study was conducted among few respondents and changes were brought in the questionnaire. Analysis and interpretation is done using Chi-square method. Based on the findings, appropriate suggestions have been made for increasing the HR strategies.

Keywords: HR, business environment, HR strategies, HR Evolution, Virtual Reality, Future Leaders.

Introduction

The HR strategy is usable for the newly started business and also the existing, the real meaning of the HR is how to safer the organization from the unwanted problems. The HR practically followed by the organisation its will give good positive into our business¹. The human beings are ready to work inside and also outside the organisation is very interesting and also the eagerly. The organisation think about the future, they should be followed certain rules and regulation in the presently. The present norms are to be succeeding in the past one; it gave a certain type of ideas to the organisational authority³. The norms are framed by certain expert person is called as HR manager.

What Are the Work Done By Hr in A Company:

The HR in the organisation has to perform very well because of this is no only job it’s a mannerism of the authority. This type of person is an important asset in the organisation, these asset are utilized at very well it gives a expected result. These are the important part of the organisational promotional activities². So, every organisation must give priority to this type of people. These kind of peoples are concentrate only on the basis of organisational up gradation

What Is The Role of A Hr In A Company?⁶

Recruiting: Finds, hires, and onboards new employees.

Training and Development: The training programs are to given by the organisational authority for the purpose of clarifying the doubt and getting some ideas by the trainees.

Union Negotiations and Labor Relations: Instead of taking the CEO away from leading the company, HR will represent the executive team and deal with any complaints unions have about the enterprise.

Compensation and Benefits: The compensation not only for monetary level it gives some of the extra benefits, perquisites and family benefits to the employees and then labour.

Employee Relations: Baby sitting adults, unfortunately this is needed in companies.

Organizational Development: Determines who reports to who and why. They also determine if problems in the company are coming from, people, rewards, processes structure or strategy⁵.

Legal Compliance: Making sure that a company is doing everything the government says a company is supposed to be doing. I-9’s, W-4’s, Affirmative Action Plans, etc.

Employee Engagement: Figuring out how to make employees work more hours while being paid less money and having them be happy about it.

Human Resources Information Systems (HRIS): They run the computer system that keeps track of all the people records⁴.
Health and Safety: Creating and maintaining a working environment that humans can function and thrive in.

Most Important Characteristics of Human Resource Management

Every individual person must have the same of the character in his life, so character is very essential. The HR character is very needed on in the organisation. The HR in the organisation is one of the important roles playing activity; this activity is based on the following:

- It is pervasive
- Interdisciplinary and fast changing
- Focus on results
- People-Centered
- Human relations philosophy

Real Challenges Facing Hrm In The Future:

The challenges are ready to taken by the HR in his organisation, the activities of an of the HR can be pre-analysis and also predicted. The HR performance is based on future oriented because of organisation goes to shine in the long term. The long term life of organisation is fully based efficient work given by the HR. The HR is an important part and also the asset of the organisation, these asset are used at effective level it will gives better result in the organisation. The working manner is differ on the basis of effective step taken by the HR, the HR people is to interested to participate all the activities of the organisation in future oriented. The future of the organisation is in the hands of the HR.

Hr Evolution: Past, Present & Future: As the HR function continues to undergo rapid development and changes due to technology and globalization, it might be interesting to take a short trip to the past and discuss how the role has evolved and what implications it holds for the HR professional in the present and the future.

The Past: A Backend Support: The modern form of Human resources has arguably started from the early days of the industrial revolution in the 18th century where factories first introduced programs to enhance the satisfaction of workers so as to increase their productivity. It was only another century after that that organizations introduce the Personnel Management department to take care of employee related issues and compliance to labor laws. Human resources at this point in time played a largely administrative and supportive role. With globalization and the emergence of MNCs in the 70’s, personnel process and procedures revolving around the globalized workforce became more complex and the demand for increasing competent and skilled knowledge workers intensified, culminating into what was coined the war for talent by Steven Hankin of McKinsey & company.

This ushered in time of HR Management and Development where human resources managed complex HR information systems across the globe, ensured competitive and equitable compensation and benefit systems and orchestrated the training, development and placement of the right talents in the right position and the passing of the leadership baton through its talent management and succession planning strategies.

The Present: a Strategic Ally: As HR continued to add value to the organization and deliver better results, its position slowly morphed into what is more commonly known as a HR business partner role where HR professionals add greater value through a strategic focus with their business knowledge. Instead of a purely supportive role, HR now partners the business to provide holistic, long term and results focused solutions as a strategic ally. As a case in point, we can look at the recruitment or talent acquisition function. It’s no longer about filling headcounts now. It’s not even about finding good people. It’s about finding the right people who are not only good in their job but can also fit into the organization culture. It’s about finding the right people who are passionate and have the potential to take on bigger roles in the future. It might even mean tweaking the job sometimes to fit the job to the talent in certain cases. And this can only be done by a HR professional who knows the business demands well by working closely with the line managers.

As the expectation gets higher, naturally, the demand for the tools, skills and knowledge of the HR professional scales up accordingly, as its role becomes more collaborative and advisory. HR might even need to take the lead at times, such as when driving cultural changes or during implementation of new business processes and models like shared service centers.

The Future: Accelerated Changes: If past trend was anything to go by, we can all be sure that the HR function will evolve at a more accelerated rate. While it took more than a century for when employee welfare program started to the launch of the Personnel Management function in companies, it only took several decades for the metamorphosis of the Personnel Management into the Human Resource Management and Development functions. And subsequently, for its evolution into the current variation as a strategic business partner, it took barely two decades. As digitalization, technology, internet and social media continue to shape the world, it is certain that HR will continue to play a more strategic role and manage more complex functions. This present diverse opportunities for HR to add and create value...
through its data analytics, management of a generational changes in workforce to Gen Y & Z and also the advent of new learning technologies such as e-learning, mobile learning and gamification, just to list a few.

Thus, it is timely and heartwarming that a website such as ThriveInAsia.com came to fruition as HR professionals alike now have a very useful platform, community and resource centre to share ideas and thereby accelerate their learning to keep up with the accelerating evolution of the HR function.

Objectives of the study

4 Main Objectives of HR

1. To find out the reason for organisational development.
2. To give some of the suggestion to the HR people in the organisation.
3. To understand the HR is an assets in the organisation.

Research Design: Descriptive Research Design

Sampling Method: Since the population is large in number, the researcher undertook a sample survey. Convenient sampling method has been adopted to collect data from customers.

Sample Size: 500

Method of Data collection: Surveys questionnaire method and Personal Discussion.

Scope of the Study

• The HR strategies are used for the promotion of organisational improvement in the top level.
• HR practices provide a expected result in the future at effective utilisation of organisational resources.
• The promotion of organisation into the next level is based on efficient work given by the HR people.
• The inter-disciplinary action are taken by the management only for the purpose of organisational improvement.

Limitations of the Study

The HR peoples are working effectively but the same time they need equal rights to bargain his basic necessity.

The compensation is not favour for his work, so they are expecting additional benefits with properly.

The organisational performance is based on his own limit not for interpreting the other organisational performance.

**CHI SQUARE**

Df: (r-1)(c-1)

Table value: 21.03

Calculated Value: 63.33

**Result:** Since the calculated value of Chi Square is greater than the table value of $X^2$, $H_0$ is rejected. So the employee’s age group is influenced by the package system.

Hence there is evidence of association between age group of the respondent and Salary package system.

**Implication:** The implication HR strategies in the business organisation it must be promote from lower level to the top level. This type of participation will increase the environmental conditions at knowing the general people. Organisational strategies may give a positive approaches from the management level and also the labour level. Cooperation between the management and labourers its based on HR strategies. HR performance not a recently developed it is newly updated one, so we have to give a concentration about the HR strategies.

**Findings**

1. Majority of the people are willing do the duty with effective managerial functions.
2. Most of them felt under the HR strategy are based on learning process.
3. From the above most of them feel about present working conditions not well in the personal and business.
4. The modern business world needs a support of digitalisation, so we have to follow the HR strategies in present and also a future.

**Suggestions:** From the above details we have to give some suggestion to the HR people in the organisation. The strategies are not followed continuously these only for time duration. The organisational people thinking is
only for improve the organisation with support from the management. The management are to give a full support they are working effectively. The monetary and non-monetary benefits are liked by the most of them in the organisational side.

**Conclusion**

Finally the organisation must to develop only by the way of support the human resources. This type of supporting system will give unexpected result from the HR level, give a good salary, remuneration, increments, allowances, family packages, entertainment facility and other type of monetary benefits. The HR is very important role playing character inside the organisation, so we have to give certain liberalisation to him. They are working with effective and also the efficient manner in the organisation improvement.

Work Related Burnout among Software Professionals in India: A Questionnaire Study Using Maslach’s Burnout Inventory

Arumugam Suganya¹, Raja Pavithra¹, Bellamkonda Pavani², V. Anu²

¹Intern, Sathyabama Dental College and Hospital, Chennai; ²Senior Lecturer; ³Reader and Head, Department of Public Health Dentistry, Sathyabama Dental College and Hospital, Chennai

Abstract

Aim: The present study is designed to assess the work related burnout using Maslach Burnout Inventory among software professionals working in Chennai city.

Methodology: A cross-sectional study was conducted to evaluate the work related burnout among 900 software developers belonging to different companies in Chennai city. Burnout self test developed by Maslach was used to assess the burnout. Data collected was subjected to statistical analysis using Chi square test.

Result: Among the sample, 61.2% were males and 38.8% were females. More females suffered moderate burnout compared to male. Comparison between job designation and burnout showed that there is no statistically significant difference in the burnout experienced. Comparison between gender and burnout showed that, more females suffer moderate burnout compared to males and the difference is statistically significant.

Conclusion: More female software professionals are experiencing moderate level of burnout compared to their male counterparts.

Keywords: Software developers, Job burnout, Software professional, personal health, Stress.

Introduction

In recent years, the term burnout was used to refer to a state of emotional and psychological exhaustion from work¹. The term burnout is usually applied to strain symptoms in psychosocial professions. Among most definitions, burnout is depicted as an individual’s negative emotional experience leading to a long term phenomenon²,³. The definition of burnout has three components: emotional exhaustion, depersonalization and diminished personal accomplishment⁴. Most definitions include detachment and diminishing interest in the job, especially by persons who were more committed to their work. If wide concept of burnout is used, including physical and psychological exhaustion⁵, it becomes obvious that burnout symptoms also occur in skilled professionals. There are studies showing burnout to exist outside the field of human and social service⁶,⁷.

The consequences of burnout have been classified into physical consequences, emotional consequences, interpersonal consequences, attitudinal consequences and behavioural consequences⁷. Physical consequences include health issues such as poor appetite, headaches, fatigue, sleeplessness and may even lead to chest pain, gastrointestinal problems⁸,⁹. Emotional consequences include decrease in self-esteem, depression, irritability, helplessness or anxiety⁹,¹⁰. Interpersonal consequences include negative impact on personal, home and family lives like reduced socialization, withdrawal from friends¹⁰, greater impatience, moodiness and less intolerance¹¹, and also lower levels of organizational commitment¹²,¹³. Behavioral consequences include work related behaviors like turnover¹⁴, absenteeism¹⁵ and decrease in the quantity and quality of job performance¹⁶.

The possibility that burnout also occurs in software profession is suggested by studies¹⁷ which reported that stress levels of software engineers to be greater than those in other professions. In addition, work in software profession claims high intellect from the employees¹⁸. It is very demanding and requires constant learning and updating of knowledge¹⁹. Rubin and
Hernandes reported high inherent impulse to work in software professionals, and with addition of stressful circumstances, they are more prone to the development of burnout.

The present study is designed to assess the work related burnout using Maslach Burnout Inventory among software professionals working in Chennai city.

**Methodology:** A cross-sectional questionnaire study was conducted to evaluate the work related burnout among software professionals working in Chennai city. A pilot study was conducted to calculate the sample size which was found out to be 900. The study population was selected by convenient sampling methodology.

The study participants should be able to understand and communicate in English and those who were willing to participate were included. Informed consent was obtained from all the participants. Individuals who refused to give consent were excluded from the study. The research protocol was approved by the Institutional Review Board of Sathyabama Dental College and Hospital, Chennai.

The present study was conducted among 900 software professionals working in Chennai city. Among the sample, 61.2% were males and 38.8% were females. Their age ranged from 25-35 years. 34.2% of the participants were qualified with Bachelors degree in Engineering while others had degree in bachelors in arts and science (17.8%), masters in engineering (19.6%), masters in arts and science (14.8%).

Based on duration of work as software engineers: 40.2% of the study sample had work experience as software engineer for <2 years, while 15% had work experience of >15 years.

Designations of the study participants were listed as, data processor (30.1%), Team Leader (26.2%), Subject Matter experts (17%), Project Leader (15.1%), Supervisor (11.6%).

Comparison between gender and different sections of burn out showed that, there is no significant difference based on gender with Depersonalization or Personal achievement. Whereas comparison between gender and burnout showed that, more females suffer moderate burnout compared to males and the difference is statistically significant.

Discussion: A moderate level of stress is a significant driving factor which is considered normal and essential. If stress is extreme, continuous, and frequent, it becomes a negative event which can lead to physical and psychological issues.

Software development is one among the mentally demanding jobs. As a part of their job, employees often encounter unrealistic deadlines. It is common for Indian software professionals to spend 12 to 14 hours a day working on projects. Combined with inefficient facilities and infrastructure, they spend less time with the family. Over time, they tend to identify themselves personally with their job. Whilst lack of specific studies, informal evidence suggest that burnout, stress and risk of health problems are becoming common employment issues affecting the software industry.

In our study sample, males (61.2%) were more in number than females (38.8%). Other studies on IT professionals reflect similar findings. Studies in Europe reported that females represent only 25% of the software workforce and it was 20% in U.S. The gender difference may be largely due to cultural and social influences. Because of the variety of roles that women play, it might lead them to choose professions which are less time consuming and less stressful unlike software profession.

In this study it was found out that, irrespective of job designation, burnout was experienced among the software employees. Many previous studies too reported the levels of stress experienced by software professionals. In an online survey done among South Indian software engineers reported that 32.4% of their study sample to be distressed and 8.1% had severe psychological stress.

Another study done on IT professionals in Delhi reported that 35% of their study subjects to be stressed.

In the present study, it was also found out that more females suffer moderate burnout compared to males.

Study done on women software professionals in Chennai reported 55.22% of their study subjects to be experiencing moderate levels of stress, 28% of the study subjects had high overall stress and 1.6% had very high overall stress.

Studies have found that work family interference is experienced more often by women than by men. Depression is found to be one of the most consistent and strongest outcome of work family conflict.

In the Indian context, as women are expected to handle household duties, women software engineers might experience more work family interference, increasing the risk for developing depression.

Although, our study threw some light on burnout experienced by Indian software professionals, there are some limitations. In this study only screening questionnaires were used and screening was performed only for work related burnout. No other causal factors
for burnout were assessed. We have not assessed other possible triggering factors other than work related burnout.

Effectiveness of Informational Booklet on the Level of Knowledge Regarding the Effects of Junk Food on Health

Bhavna Sharma
Asst. Prof. Community Health Nursing, SNSR, Sharda University, Greater Noida

Abstract
Junk food is a pejorative term for food containing a large amount of calories from sugars or fats with little fiber, protein, vitamins or minerals.

Objectives: To assess the pre and post-test level of knowledge regarding the effects of Junk Food on health. To evaluate the effectiveness of an informational booklet on the effects of Junk Food on health in terms of gaining knowledge. To find out the association between the post-test level of knowledge regarding the effects of Junk Food.

Method: A quantitative evaluative research approach and pre-experimental design one group pre and posttest research design was used to conduct the study. Samples were 40 students studying in B.Sc. Nursing 1st Year in School of Nursing Science & Research, Sharda University were selected through non probability convenience sampling technique. A structured self-administered questionnaire was used to collect the information regarding eating habit. Results:-The data was analyzed by descriptive and inferential statistics. The obtained pre-test overall mean score was 8.675, SD 2.47435, mean percentage was 78.86% and range was 10. The obtained post-test overall mean score was 15.2, SD was 2.37724, mean percentage was 84.44% and range was 7. The mean difference between the pre-test and the post-test is 0 and the obtained “t” value was significant at 2.02269092. The correlation between the pre-test and post-test is 0.020051996. It was evident that compared to pre-test knowledge score there is significant increase in the post-test knowledge scores.

Keywords: Effectiveness, Informational booklet, Knowledge, Junk Food, Effects, Health.

Introduction
Junk food is defined as processed food with little nutritional value. It is often high in salt, sugar and fat. It includes convenience foods as well as fast foods. These foods are high in calories, without the benefit of providing you with minerals, vitamins or fiber that are needed to maintain a healthy mind and body. However, these items are made with the intention of being appealing or enjoyable so you are chemically programmed to crave more.1

Consumption of these foods in an un-controlled manner and over a prolonged period of time may result in obesity their by increasing the risk of other non-communicable diseases like Diabetes Mellitus, hypertension, coronary artery disease etc.2

The Effects of Fast Food on the Body:- While an occasional night of fast food won’t hurt, a habit of eating out could be doing a number on your health.

Digestive and cardiovascular systems:- When your digestive system breaks down these foods, the carbs are released as glucose (sugar) into your bloodstream. As a result, your blood sugar increases.

Sodium: Sodium can elevate blood pressure and put stress on your heart and cardiovascular system.

Respiratory System: Excess calories from fast-food meals can cause weight gain. This may lead toward obesity. Obesity increases your risk for respiratory problems, including asthma and shortness of breath.

Integumentary system (skin, hair, nails): Children and adolescents who eat fast food at least three times a week are also more likely to develop eczema, according to one study. Eczema is a skin condition that causes irritated patches of inflamed, itchy skin.

Skeletal system (bones): Sugar in fast food and processed food can increase acids in your mouth. These acids can break down tooth enamel. As tooth enamel
disappears, bacteria can take hold, and cavities may develop.

**Effects on society:** Today, more than 2 in 3 adults are considered overweight or obese. More than one-third of children ages 6 to 19 are also considered overweight or obese.

**Research Methodology**

**Research approach**
The research approach used for this study was quantitative evaluative approach.

**Research design**
Pre-experimental design one group pre and posttest design was selected to evaluate the effectiveness of informational booklet on knowledge regarding the effects of junk food on health.

**Independent variables**
In this present study the independent variable is informational booklet.

**Dependent variables**
In this present study the dependent variable is knowledge.

**Population**
The accessible population for the present study was students of B.Sc. nursing 1st year who were present on the day of data collection.

**Sample**
The sample selected for the present study was the students studying in B.Sc. nursing 1st year, SNSR, Sharda University, greater Noida.

**Sample size**
In this study the sample size was 40 students studying in B.Sc. nursing, SNSR, Sharda University, Greater Noida.

**Sampling technique**
In this study non probably convenience sampling technique was used to select the sample.

**Description of the tool**

**Section A**
It consists of demographic characteristics of students like gender, age, religion, place of residence, type of family, family monthly income, food habits, previous knowledge and source of health information.

**Data Collection Procedure:** Before collecting the data, permission was obtained from the concerned authority. Keeping in mind the ethical aspect of research, the data was collected after obtaining the informed consent of the sample. The samples were assured anonymity and confidentiality of information provided by them. The researcher collected the data from the subjects. Pretest was conducted, followed by distribution of informational booklet regarding effects of junk food on health. Posttest was conducted to evaluate the effectiveness of distribution of informational booklet.

Findings

The data was analyzed by descriptive and inferential statistics. Majority 29 (72.5%) were girls followed by 19 (47.5%) were in the age group of 19 years, 29 (72.5%) of respondent Hindu, 29 (72.5%) of respondent were day scholars, 22 (55%) of respondent lives in nuclear family, 17 (42.5%) had their family income Rs.61,000 and above, 21 (52.5%) were vegetarians, 31 (77.5%) had knowledge regarding the effects of junk foods, 14 (35%) gained knowledge by themselves and through TV/Radio. It was inferred that among 40 participants 16 (40%) had inadequate knowledge and 23 (57.5%) had moderately adequate knowledge and 1(2.5%) of had adequate knowledge. The post test was conducted after distribution of informational booklet regarding the effects of junk food on health among students of B.Sc. nursing 1st year. The obtained pre-test overall mean score was 8.675, SD 2.47435, mean percentage was 78.86% and range was 10.

The obtained post-test overall mean score was 15.2, SD was 2.37724, mean percentage was 84.44% and range was 7. The mean difference between the pre-test and the post-test is 0 and the obtained “t” value was significant at 2.02269092. The correlation between the pre-test and post-test is 0.020051996. It was evident that compared to pre-test knowledge score there is significant increase in the post-test knowledge scores. Hence the research hypothesis (H1) is accepted. Therefore it can be interpreted that the informational booklet was effective in improving the knowledge of B.Sc. nursing 1st year students regarding the effect of junk food on health.

Conclusion

On the basis of the finding of the present study, the following conclusion can be drawn:

“Informational booklet method was an effective method of giving information to students. This method helps for easy understanding and gives more awareness about effects of junk food on health.”

Practice of Self Medication and its Effects among Nursing Students

Blaze Asheetha Maria Rosario, Amitha Thomas, Chisale Roselyn Dukru, Christy Mary Jose, Meenu Michael, Rinu Varghese and Suby Rose Baby (IV B.Sc N Students)

Abstract

Background: Self medication or dosing oneself without prescription is actually an abuse which individuals often fail to confess. The menace becomes even more dangerous when knowledge received regarding medication is incomplete. The nursing students are one such population endangering themselves.

Methodology: A survey research approach, using a descriptive design, was adopted. Data was collected from 105 nursing students who were selected through a probability disproportionate stratified random sampling using a self administered structured self medication practice Checklist. The data gathered was analyzed and interpreted using descriptive and inferential statistics.

Results: The findings revealed that the nursing students had moderately satisfactory practice of self medications. The study recommends the need for awareness programs among Nursing students and general population.

Keywords: practice, selfmedication, effects, nursing, students.

Introduction

Self-medication is a problem that exists worldwide. The practice of taking medications to treat without consulting a doctor is hazardous to man and an apparent public health problem. In a developing country like India the system of self-medication is flourishing due to various factors like socioeconomic factors, lifestyle, previous experience of treating a similar illness, ready access to drugs and the increased potential to manage mild illness through self-care. Self-medication is a problem that has the potential to harm society at a large as well as individual patient. Self-medication provides a lower cost alternative for people who cannot afford the cost of clinical services which all contribute to the spread of self-medication.

Self medication is the use of medication without prescription, orientation or supervision of a physician or dentist. Self medication is a common practice worldwide and irrational use of drugs is a cause of concern. It assumes a special significance among nursing students as they are the future practitioners in the health field.

In several studies it has been found that inappropriate self medication results in wastage of resources, increases resistance of pathogens and generally entails serious health hazards such as adverse drug reactions, prolonged suffering and drug dependence. On the other hand if done appropriately, self medication can readily relieve acute medical problems, and can save time spent in waiting to see doctor, may be economical and can even save lives in acute conditions.

Self-medication begins in early adolescence, often during the middle school years. By the age of 16, nearly all adolescents have taken medicine independently.

A study conducted among the youth in Karnataka it is found that the prevalence of self-medication was 88.6%, which is very high. The above statistical burden and observation of the researchers led to the present study.

Statement of the Problem: “A descriptive study to assess the practice of self medication and its effects among nursing students in a selected institution, Bengaluru.”

Objectives:

- To assess the practice of self mediation and its effects among nursing students.
- To associate the practice scores regarding self medication and its effects with selected sample characteristics.
Hypothesis:

At 0.05 level of significance

H₁: There is a statistically significant association between practice scores regarding self medication and its effects with selected sample characteristics of Nursing Students.

Operational Definitions

- **Practice:** In this study it refers to the action of consuming over the counter drugs as measured in terms of practice scores using a self administered structured practice checklist.

- **Self medication and its effects:** In this study it refers to the act of consumption of drugs by the nursing students themselves, without the prescription of a physician and the resultant adverse effects related to the same.

Methodology: A descriptive study was conducted in the nursing student’s hostel of St. Philomena’s College of Nursing. A sample of 105 nursing students were selected using a probability disproportionate stratified random sampling technique. They were stratified based on the year (four from B.Sc (N) and three from GNM) of study. Data was collected from nursing students using self medication practice checklist (r = 0.83). The collected data was analyzed using suitable descriptive and inferential statistics. Thereafter the analyzed data was presented using tables.

Results and Interpretation

Sample characteristics of nursing students.

Majority of nursing students belonged to 18-23 year of age (93.4%), and most of them were Christians (82.8%).

With regard to educational qualification a little more than the half sample (57.2%) were from the B.Sc (N) stream and 42.8% were doing their G.N.M course. All most all 104(99.1%) the nursing students were residing in the hostel within the campus, 24(22.9%) of nursing students were residing for 1 year, 29(27.6%) of nursing students were residing for 2 years, 28(26.7%) of nursing students were residing for 3 years and 24(22.8%) of nursing students were residing in the hostel for 4 years and above.

According to sickness rate 38(36.2%) of nursing students fell sick often. Among the nursing students who fell sick often 57.9% of nursing students fells sick once in 6 months, 13(34.2%) of nursing students fell sick once in a month and 3(7.9%) of the nursing students fell sick once in a week..

Among 105, nursing students, 15(14.3%) of the nursing students had their family member working in health sector.

Based on the data collected 42(40%) nursing students took self medication due to non serious illness, 47(44.6%) of students got information from prior prescriptions, 72(41.9%) of nursing students were using fever relieving drugs and 39(35.8%).

### Table 1: Frequency and Percentage distribution of nursing students based on the determination of dosage.

A little more than a quarter, (Table 1) 30(27.5%) nursing students knew the dosage by checking the leaflet accompanying the package, 39(35.8%) of students knew the dosage by consulting doctors, 10(9.2%) of students knew the dosage by consulting pharmacists, 25(22.9%) of nursing students knew the dosage from previous experience and 5(4.6%) of nursing students knew the dosage from internet.

Section 2: Practice of self medication and its effects among nursing students.

Among the nursing students, much more than half of the nursing students (61.9%) had average practice, 36.2% had good practice and 1.9% had poor practice.
Table 2: Aspect wise practice scores of nursing students regarding self medication and its effects.

<td>Practice</td>
<td>8</td>
<td>6.43</td>
<td>80.37%</td>
<td>1.33</td>
</tr>
</tbody>
</table>

The aspect wise mean percentage scores computed showed (Table 2) that out of the six aspects, nursing students scored the highest, 92% for side effects and the least of 41.2% for prescription. Non judicious use of prescription is now the area of concern.

The above findings were supported by a similar study conducted on ‘evaluation of the practice of self-medication among college students, in west Uttar Pradesh’ to describe and examine the branded medicines used by college students, awareness, trust in medicine system, reasons behind self-medication, drug information resources, danger findings and knowledge of drug profile. Sample of 253 young students belonging to different regions of west Uttar Pradesh were randomly selected. Major reasons which was found as the reason of self-medication at student level were time saving, did not need advice from prescriber for minor illness, economic, fear from crowd at clinic. Most of the respondents had positive attitude in self-medication in minor illness and the majority of professional students had a poor knowledge about appropriate self-medication while the knowledge of the benefits and risks was not adequate.5

</tr>
</tbody>
</table>

The association between self medication and its effects with the selected baseline variables such as religion, course, year of study, place of residing, residing duration, tendency to fall sick, frequency of sickness, family members and source of information were found to be non significant at 0.05 level as the obtained chi-square or fisher exact values for these variables were less than their respective table values. Hence the research hypothesis (H1) was rejected for these selected baseline variables, whereas the computed chi square and fisher exact for age (4.17) and reason for self-medication (10.80)respectively were found to be significant at 0.05 level .Hence the research hypothesis (H1) is accepted only for these two baseline variables.

Nursing Implications

Nursing Practice: Nurses, empowered with pharmacological knowledge are expected to act in a matured way while handling medications. Practise nurses should be encouraged to follow drug hygiene which
includes updating knowledge and skills being proactive in following rights and principles during administration of medications. Every nurse should make sure that he or she thoroughly knows about the drug she is going to administer to her patients and explain it appropriately.

**Nursing Research:** Enormous studies have been conducted on the topic and to a great surprise self medication is very much prevalent among health care students and personnel. Many more interventional studies should be done to stop menace of Over The Counter (OTC).

**Nursing Education:** Though nursing curriculum includes pharmacology for nursing students the knowledge and skill in administering medication is still an issue. The tutors and the senior nurses should thereby encourage rationalized medication practice than merely a procedure for finishing nursing duty. Nursing teachers handling the students in clinicals should ensure creative method of their own to encourage students remain interested towards drug. Thus if a complete knowledge is taken care of, practice of self medication will remain a “caution”.

**Nursing Administration:** Nursing administrators should make sure that competent recruitment and selection policies for nurses include either a written test or oral interview regarding drug policies. Periodic short term transforming, training sessions, refresher courses must be arranged to make the staff nurses sharpen their drug knowledge. Record and issues pertaining to errors of any kind should be taken care off.

**Limitations:** The study was limited to:

- Student nurses studying in the selected College of Nursing, Bengaluru.
- Period (2 days) of data collection.
- Knowledge of the sample regarding self medication was not assessed, as the area of study was very minimum and found to be overlapping with practice.
- The data which was collected using self administered practice checklist. The practice was not assessed by the researcher themselves.
- The proposal of the study was not presented for ethical clearance.

**Recommendations**

- The effectiveness of the poster on ill effects of self medication can be assessed.
- Similar studies can be conducted among the healthcare personnel to assess the level of practice.
- Similar study can be conducted on large sample for generalization.

**Conclusion**

The study findings revealed that much more than half of the nursing students had moderately satisfactory practice and a very negligent percentage had unsatisfactory practice of self medication. The figures reported may be alarming as the occurrence is being reported in a medically literate group, the nursing students. There is an urgent need for awareness to be created, to ensure medications are handled safely and judiciously. For the current setting a poster creating awareness about ill effects of self medication was considered to be appropriate as almost all the nursing students resided in the same hostel.

Effect of Rood’s Approach in Diabetic Polyneuropathy

Brinda R Patel¹, Namrata Kadam², Pratik Pawar³

¹Intern, Faculty of Physiotherapy, ²Department of Paediatrics, Faculty of Physiotherapy,
³Intern, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed
to be University, Karad, Maharashtra, India.

Abstract

Objectives: The objectives of the study were as follows: (1) To find effect of rood’s approach in sensory abnormalities. (2) To find effect of rood’s approach in muscle weakness.

Method: Ethical clearance was obtained from the institutional ethical committee. A total of 23 diabetic neuropathy subjects were assessed and 20 were included in this study based on inclusion criteria, the individuals were allocated in one group: This group received Rood’s Approach, depending upon patients condition either facilitatory or inhibitory techniques were given. Diabetic neuropathy was diagnosed using Michigan Neuropathy Screening Instrument Questionnaire and Pre - and post – test were done for assessing severity of diabetic neuropathy using Visual Analogue Scale (VAS), Quantitative sensory testing (QST) and Walking impairment questionnaire (WIQ) and the outcome measures were analysed after 3 months.

Results: Within the group statistical analysis, Pre-Post V AS score was 6.43±1.628 and was extremely significant, Pre-Post QST score was 1.900±1.553 and result was extremely significant and Pre-Post WIQ score was 19.150±2.978 was also significant.

Conclusion: We found that facilitatory techniques of Rood’s Approach (Heavy joint compression and quick stretch) were effective in improving decreased sensations and improving motor performance in patients with painful diabetic polyneuropathy. We found that inhibitory techniques of Rood’s Approach (maintained stretch and light joint compression) were effective in decreasing hypersensitivity in patients with painful diabetic polyneuropathy. We found significant improvement in pain measure (VAS), Sensory measure (quantitative sensory testing) and Motor performance measure (walking impairment questionnaire.)

Keywords: Diabetic Neuropathy, Rood’s Approach, VAS, QST, WIQ.

Abbreviations: Visual Analogue Scale (VAS), Quantitative sensory testing (QST) and Walking impairment questionnaire (WIQ).

Introduction

Diabetic Neuropathy: It is the commonest complication of DM, affecting 20% patients with painful neuropathy. Cutaneous sensation is mediated by superficial receptors and deep sensation is mediated by deep receptors. Touch pressure sensation of non hairy skin is mediated by Meissner corpuscles and Pacinian corpuscles respond to vibratory stimuli.¹ Mechanism of injury / pathological process: Total hyperglycaemic exposure, Elevated lipids, blood pressure, Hypertension, Smoking, Increased Height, High exposure to neurotoxic agents, Genetic Factors.²

Clinical Presentation: Motor symptoms – In upper limbs– Distal motor symptoms which include fine hand co-ordination, In lower limbs – Mild drop foot or frequent tripping due to lower limb weakness. Sensory symptoms –Slow, sudden onset sensory neuropathy showing stocking and glove distribution in distal extremities. Negative sensory symptoms – feeling of numbness or deadness, loss of balance, especially with eyes closed and painless injuries due to loss of sensation. Positive sensory symptoms – burning, prickling pain, tingling, aching, tightness.

Diagnostic procedures - Testing includes assessment of gross light touch and pinprick sensation. First clinical
sign develops in diabetic symmetrical sensorimotor polyneuropathy is reduction of vibratory and pinprick sensation over the toes. Sensory loss occurs in stocking and glove appearance. Vibratory sensation is tested. Deep Tendon Reflexes are assessed.\textsuperscript{1,3,4}

Staging of diabetic polyneuropathy:
- NO – No Neuropathy.
- N1a – Signs but no symptoms of neuropathy.
- N2a – Symptomatic mild Diabetic Polyneuropathy.
- N2b – Severe symptomatic Diabetic Polyneuropathy.
- N3 – Disabling Diabetic Polyneuropathy

Medical management: Anticonvulsant – Pregabalin, Antidepressant – Duloxetine, Opioids - Dextromethorphan.

Physiotherapy Options Available For Diabetic Neuropathy: TENS, Infra Red Lamp, Aerobic and Resistance Training, Lifestyle changes. It is found in earlier studies that TENS is effective in reducing pain in Diabetic Neuropathy. Research also shows that aerobic and resistance training causes significant reduction in pain in painful diabetic neuropathy.\textsuperscript{6,7} However, there is limited research in physical therapy options in painful diabetic neuropathy treating both motor and sensory components.

Rood’s Approach: Rood’s Approach is a neurophysiological approach which is based on reflexes of central nervous system. Basic concept of Rood’s is that the motor patterns are developed from primitive reflexes through proper sensory stimuli to appropriate sensory receptors in normal sequential developmental pattern to improve motor performance. The basic principles of Rood’s approach are normalisation of tone, ontogenic developmental sequence, purposeful movement and repetition or practice.

Rood’s Approach includes of various facilitatory and inhibitory techniques. The facilitatory and inhibitory techniques used in this study are:

Facilitatory techniques – Quick stretch and heavy joint compression (in cases with decreased sensation)

Inhibitory techniques – Maintained stretch and light joint compression (in cases with increased sensation)

Facilitatory Techniques

1. Quick Stretch: Stretch is a physiologic stimulus which is used to activate the proprioceptors in selected muscles of the body. Quick stretch employs principles of reciprocal innervation. The muscle undergoing stretch was facilitated. Quick stretch was applied by holding the proximal bony prominences of the limb to be stretched while moving the distal joint in one direction.

2. Heavy Joint Compression: Heavy joint compression is defined as joint compression greater than applied through the longitudinal axis of the bone. The amount of force was more than that of the normal body weight above the supporting joint. It was used to facilitate co contraction at the joint undergoing compression. This approach can be combined with developmental patterns.

Inhibitory Techniques

1. Maintained Stretch: Positioning hypertonic extremities in the elongated position for various periods to cause lengthening of the muscle spindles. Rood recommended maintained stretch in the lengthened position for the stronger agonist muscle to increase the threshold of muscle spindle and antagonist muscle was then facilitated by cutaneous stimulation to offset the muscle imbalance.

These contractions were done repeatedly with no resistance and with gravity eliminated, spasticity was reduced.

2. Light Joint Compression: Joint compression of body weight or less than body weight was used to inhibit spastic muscles around a joint.\textsuperscript{8}

In diabetic neuropathy, there are positive as well as negative sensory symptoms. Negative sensory symptoms include feeling of numbness or deadness, loss of balance, especially with eyes closed and painless injuries due to loss of sensation. While positive sensory symptoms include burning, prickling pain, tingling, aching, tightness. Even there is muscle weakness along with these sensory loss. As Rood’s Approach is a neurophysiological approach which is based on reflexes of central nervous system and basic concept of Rood’s is that the motor patterns are developed from primitive reflexes through proper sensory stimuli to appropriate sensory receptors in normal sequential developmental pattern to improve motor performance.\textsuperscript{10} It even includes facilitatory and inhibitory techniques and including the principle motor output is dependent on sensory input there are chances that facilitatory techniques will be beneficial in improving sensory loss and inhibitory techniques will lead to decreased hypersensitivity and this sensory output will inturn improve motor performance.

Thus, there is a need to find effectiveness of Rood’s Approach on sensory as well as motor complaints in individuals with diabetic neuropathy.
Method

Ethical clearance was obtained from the institutional ethical committee. A total of 23 diabetic neuropathy subjects were assessed and 20 were included in this study based on inclusion criteria, the individuals were allocated in one group: This group received Rood’s Approach, depending upon patients condition either facilitatory or inhibitory technique was given. Diabetic neuropathy was diagnosed using Michigan Neuropathy Screening Instrument Questionnaire and Pre - and post – test were done for assessing severity of diabetic neuropathy using Visual Analogue Scale (VAS), Quantitative sensory testing (QST) and uWalking impairment questionnaire (WIQ) and the outcome measures were analysed after 3 months. Sampling Method: Cluster Sampling Method.

The study included only one group. Pre-intervention Michigan Neuropathy Screening Instrument Questionnaire score was used to diagnose patients with diabetic neuropathy. Pre-test and post-test pain measure (VAS score), Quantitative Sensory Testing and Walking Impairment Questionnaire was used to assess the patients. Rood’s Approach - (3 days/week for 3 months) (5 reps) : Facilitatory techniques – Quick stretch and heavy joint compression, Inhibitory techniques – Maintained stretch and light joint compression.

Results: Primary outcomes used for the result were VAS, QSTand WIQ.

GENDER DISTRIBUTION IN THE STUDY

Graph No 1: The pie diagram represents that out of 20 subjects, 20 males and 0 females have participated in this study.

AGE:

<table>
<thead>
<tr>
<th>Minimum</th>
<th>Maximum</th>
<th>Mean</th>
<th>Standard deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>44</td>
<td>74</td>
<td>58.5</td>
<td>9.288</td>
</tr>
</tbody>
</table>

The age group included in this study is 40-75 years. The table shows that minimum age group in the study is 44 years and maximum is 74 years. The mean of the age group is 58.5 years and standard deviation is 9.288.

Age Groups:

<table>
<thead>
<tr>
<th>Age group</th>

T- value is 28.754 and p value is <0.0001 and there was extremely significant improvement in walking post treatment.
Discussion

Painful neuropathy is the most disabling complication of diabetes and it occurs due to peripheral nerve damage. Peripheral Nervous system is affected in both types of diabetes mellitus. Pathophysiology of painful diabetic polyneuropathy is unknown but trials have shown that good glycaemic control reduces occurrence of complications.4

Several studies have shown that conventional treatment did not show any improvement in painful diabetic polyneuropathy.

In 2016, Kamaljeet Singh reported that D1 and D2 patterns of PNF for 3 days/week for 3 months were effective in treating both motor and sensory components. It improved sensorimotor control in patients with diabetic polyneuropathy.14

In 2013, Patricia M K reported that 10-week of aerobic and strengthening exercise training caused significant reduction in pain (-18.1+ 35.5 mm) , neuropathic symptoms (-1.24+1.8) and increased intraepidermal nerve fiber branching (+0.11± 0.15).19

In this exercise intervention study, we found that while the participants perceived pain, sensory abnormalities and muscle weakness from diabetic peripheral neuropathy did not change with medications, but they felt less hindered in certain aspects of their life by the painful neuropathy after 8 weeks of facilitatory or inhibitory techniques of Rood’s Approach. The small size of our sample limits interpretation of this study. This successful engagement of previously inactive and chronically debilitated population in a routine 8 week exercise programme suggests that supervised treatment are viable in people with diabetic polyneuropathy, while also posing a question regarding whether results have differed with greater adherence to intervention of greater duration.

Our findings show significant reduction in how the participants reported that their diabetic neuropathy pain interfered with their daily activities. A significant reduction in average pain interference scale reveals that the intervention may have played role on the impact of pain on quality of life. The participants may have experienced improvement in sensory abnormalities and muscle strength and have experienced less distress and increased confidence in walking.

This study did not address any physiological changes that occurred during or after the intervention.

We observed significant changes after giving Rood’s approach for 3 days/week for 3 months in VAS score (pain intensity), Quantitative sensory testing (sensory abnormalities) and Walking impairment questionnaire (motor performance). The therapeutic method studied here were well tolerated associated with any serious adverse effects. The results of this study support previous findings and indicate Rood’s approach is effective in treating both motor and sensory components. Large multi-center randomised, controlled trials with longer duration of treatment are needed to evaluate the efficacy of these procedures.

Conclusion

We found that facilitatory techniques of Rood’s Approach (Quick stretch and heavy joint compression) were effective in improving decreased sensations and improving motor performance in patients with painful diabetic polyneuropathy.

We found that inhibitory techniques of Rood’s Approach (Maintained stretch and light joint compression) were effective in decreasing hypersensitivity in patients with painful diabetic polyneuropathy.

We found significant improvement in pain measure (VAS), Sensory measure (quantitative sensory testing) and Motor performance measure (walking impairment questionnaire.)

Awareness Regarding Heart Diseases among Middle Aged Adults in a Rural Area of Rupandehi District

Chanda Sah¹, Priyanka Gyawali²

¹Department of Medical-Surgical Nursing, Lecturer, Universal College of Nursing Sciences, Bhairahawa, Rupandehi, Nepal, ²Department of Medical-Surgical Nursing, Clinical Instructor, Devdaha Medical College, Butwal, Rupandehi, Nepal.

Abstract

Cardiovascular diseases (CVDs) are the number one cause of death globally. Lack of awareness about CVDs risk can lead to delays in seeking treatment and increased risk for sudden death. This study was conducted to assess the awareness on heart diseases among middle-aged adults in a rural area of Rupandehi district, Nepal. Descriptive cross-sectional study was conducted among 107 middle-aged adults of Shudhodhan rural municipality, Rupandehi district. The samples were selected by non-probability purposive sampling technique. Pretested and pre validated semi-structured questionnaire was used for data collection. The data was analyzed using SPSS 16.0 version. More than half of the respondents (55.14%) had high level awareness on heart disease. About 71.03% had family history of heart diseases. Regarding risk factors of heart diseases cent percent respondents were aware of alcoholism, 98.13% were aware of smoking, 47.66% were aware of family history and 14.02% were aware of menopause. 99.07% respondents were aware of elevated blood pressure and chest pain as cardinal symptoms of heart diseases. The study reveals that respondents had low awareness on family history as risk factor of heart diseases whereas there is statistically significant association between family history of respondents and level of awareness regarding heart disease (p=0.002). Respondents (14.02%) also had low awareness on lifestyle changes with medicines as management of heart disease. Hence it is necessary to educate people about heart diseases risk factors and lifestyle changes for management and prevention of heart diseases.

Keywords: Awareness, heart disease, middle-aged adults.

Introduction

Cardiovascular diseases (CVDs) are disorders of the heart and blood vessels and they include coronary heart disease, rheumatic heart disease, congenital heart disease and other conditions. Triggering these diseases-which manifest primarily as heart attacks and strokes-are tobacco use, unhealthy diet, physical inactivity and harmful use of alcohol. An estimated 17.9 people died from CVDs globally in 2016, representing 31% of all global deaths and 85% of all CVD deaths are due to heart attacks and strokes. Over three quarters of deaths take place in low- and middle-income countries.¹

In Nepal from 2005 to 2015, the ischemic heart disease increased around 25.3% and Coronary heart disease reached 10.79% of total deaths.² About 40% of non-communicable admissions are due to CVDs.³ These facts create an enormous social burden reducing labour productivity and creating an overcharge of public fees, in a country with a poor healthcare system and a feeble economy. The earthquakes of 2015 also imposed critical social and epidemiological effects to the population resulting in lifestyle changes.⁴

A government data has shown that 99.6% of the Nepali population is at the risk of contracting cardiovascular diseases. The national survey carried out by the Health Research Council has recently found that a majority of people has one or more risk-factors including tobacco use, alcohol consumption, low fruit and vegetable consumption and physical inactivity that pose a threat for disease. Biological factors such as obesity, high blood pressure, high blood glucose level and abnormal lipids also contribute to the risk of the disease.⁵

The aim of the study was to assess the awareness on heart diseases among middle-aged adults in a rural area of Rupandehi district, Nepal.

**Material and Method**

Descriptive cross-sectional design was used for the study to find out awareness regarding heart disease in middle-aged adults. The study was conducted in Shudhodhan rural municipality, ward number 2, Rupandehi district, Nepal. The total population residing in this rural municipality is 8,865. Total 105 samples were selected using purposive sampling technique. Interview schedule was used for data collection with use of pretested and prevalidated semi-structured questionnaire, developed by researchers. There were 22 questions regarding heart diseases. Data was collected in between April to September, 2017. Administrative and ethical approval was obtained from concerned authorities prior to data collection. The researchers contacted each respondents, written informed consent for the study was obtained and interviewed. Descriptive statistical method was used with SPSS 16 version to analyze data using frequency, percentage and mean.

**Results**

As shown in table 1, out of 107 respondents, 40.19% of respondents belong to 40-46 years and 21.50% belong to 54-60 years of age. Similarly 56.07% respondents belong to female gender. Regarding educational status, 50.47% respondents are literate. As regard to occupation, 40.19% of respondents are homemakers. Majority of respondents (71.03%) had family history of heart diseases.

Discussion

The findings of the present study reveal that more than half of the respondents that is 55.14% had high level of awareness on heart disease which is consistent with the findings of study conducted by Tecla et al. (2015) in Western Kenya which showed that 58% of the respondents had knowledge regarding heart disease.

The findings of the study showed that 68.22% of respondents had awareness about sex, 87.85% were aware about age as non-modifiable risk factors of heart disease which is not consistent with the findings of study conducted by Acharya et al. (2012) in Kathmandu which showed 13.8% knew about sex and 46.9% knew age as risk factors of heart disease.

The findings of the study showed that 47.66 % of respondents had awareness about family history as risk factors of heart disease which is consistent with the findings of study conducted by Aharya et al. (2012) in Kathmandu which showed 46.9% respondents knew about family history as risk factor of heart disease.

The findings of the study showed that 98.13% respondents are aware about smoking, 66.36% are aware about obesity and 72.9% knew stress as risk factors of heart disease which is not consistent with the findings of study conducted by Acharya et al. (2012) in Kathmandu which showed that 70.4% respondents are aware of smoking, 58.8% knew obesity and 63.7% knew stress as risk factors of heart disease.
The findings of the study showed that 99.07% of respondents had awareness regarding chest pain as cardinal symptoms of heart disease which is not consistent with the findings of study conducted by Aharya et al. (2012) in Kathmandu which showed 24% knew about chest pain as cardinal symptoms of heart disease.7

The findings of the study showed that 24.30% of respondents had awareness regarding medicine with change in lifestyle as treatment of heart disease which is not consistent with the findings of study conducted by Ingvar et al. (2007) in Sweden which showed 48% knew medicine with change in lifestyle as treatment of heart disease.8

Conclusion

More than half of the respondents had high level awareness on heart disease. The study reveals that respondents had low awareness on family history, menopause as risk factor of heart diseases whereas there is statistically significant association between family history of respondents and level of awareness regarding heart disease (p=0.002). Respondents also had low awareness on lifestyle changes with medicines as management of heart disease. Hence it is necessary to educate people about heart diseases risk factors and lifestyle changes for management and prevention of heart diseases.

Abstract

The financing pattern of the health care system in a country largely determines the volume of health care available to the population and also the extent and ease of access of the poor to health care. Objectives of the paper are to examine the trend in public health expenditure; to observe the pattern of inpatient and outpatient treatment and to assess the impact of implementation of MukhyaMantriNishulkDawa Yojana (MNDY) scheme on outpatient care. Data is obtained from secondary sources such as various budget documents and reports of government of Rajasthan. Pre and post scheme growth rate have been calculated and chow test is also employed to see whether structural changes are found in the number of people seeking outpatient treatment after the introduction of MNDY scheme. Because of the state government’s free medicines and diagnostics schemes, the number of patients seeking medical care from public health system increased between 2010 and 2014. It is quite evident from the analysis that the number of patients accessing public health facilities had doubled since 2010. It should be strengthened and made more comprehensive.

Keywords: MNDY, Outpatient Care, Financing, Public health expenditure.

Introduction

It is widely acknowledged that health is a pre-requisite for development. Sen,1stated that empowerment of people comes from the freedom they enjoy, and this includes, among others, freedom from poverty, hunger, malnutrition and freedom to work and lead a healthy life. Ensuring access to health care helps to minimize absenteeism, enhance labour productivity, and prevents misery as highlighted by Rao and Mita,2. Also supported by Economic Research Foundation (ERF)3, that Government intervention in health is also argued for, due to the presence of high degree of asymmetric information and externalities in the health sector. The greater reliance on private delivery of health infrastructure and health services in turn implies that these will be socially underprovided by private agents, and also denies adequate access to the poor. Further, this has adverse outcomes not only for the affected population but for society as a whole. It adversely affects current social welfare and labour productivity and also harms future growth and development prospects.

Health care expenditure is very necessary for the social expenditure of any country. Like any other social expenditure, health expenditure also requires a significant contribution from the government. Whether it is developed or developing country the state’s role in developing a good health infrastructure and assuring good health to everybody becomes very critical and important. Health is a concurrent subject under the Indian constitution, but state governments are dominantly responsible for most health provision, both curative and public health aspects. State government accounts for about two-third and the centre government about one-third of the total public spending on health. Health spending by government would remain a key policy tool for achieving low out-of-pocket (OOP) spending on health. Public health financing is characterized by an emphasis on tertiary rather than primary care, urban rather than rural populations, medical officers rather than paramedics. Despite the rhetoric of primary health care, the structure of provisioning was largely curative, biased towards urban areas and in the secondary and tertiary levels of care as studied by Baru,4Mita,5 and Rao & Mita,2 found that Indian healthcare system is characterized by low levels of public spending; poor quality of health care services, with adverse effect on the population health status; a lack of focus on preventative health care; and dependency of the population, particularly the poor, on
the private health care providers and consequently high OOP spending and immiseration. Thus, the reforms in the health sector will have to address the issue of increasing the allocation to health care, focusing on preventative care, ensuring greater access to health care by the poor and significantly improving the productivity of public spending.

**Health Expenditure Scenario in Rajasthan**

State’s expenditure accounts for around 90 per cent of all public expenditure on the health sector. Central funds for the states are in the form of grants to particular programmes, e.g. family planning or as sponsored schemes. Thus, the state government provides the health care services to the community through the teaching and research based hospitals, district hospitals, sub-divisional hospitals, community health centres, sub-centres, primary health centres and health personnel etc. Further, beyond the health care services, a substantial portion of state health spending is used for the recurrent capital, health personnel, administration and direction, machinery and equipment, maintenance, drugs supplies and health education including medical education, training and research etc. The state government works as key monitoring actor and it distributes funds into main accounts via revenue and capital accounts. This chapter examines the allocations for health in the budget and the trend in state government’s expenditures.

Capital/Revenue expenditure on Public Health- As a welfare state, the state government spends a large amount in the provision of medical health services such as the construction of hospitals, promotion of medical education, establishments of Primary health centres and Sub-centres in the villages, etc. Such expenditures are expected to improve the productive capacity of the economy. On the other hand, revenue expenditure has a dominant role in the state government expenditure due to increase in programmes of social and economic development. The graph depicts the overview of total public health expenditure along with the revenue and capital health expenditure from 1984 to 2013. In the mid eighties, marginal growth was seen in the public health expenditure. However, with the beginning of the 20th century, a spurt in growth was seen and ever since the positive acceleration has been witnessed. Similarly, for the revenue expenditure the slow pace of increment is visible in the eighties. However, in 2001-02 there was a big dip seen in revenue health expenditure. But after this period, it began moving upward with the rapid rate of increase. Allocation of resources to capital expenditure for health has always been less which is reflected in Figure 1.

**Figure 1: Health Expenditure in Rajasthan.**

*Source: Various Budget documents of Government of Rajasthan.*

It clears that most of the health expenditure around 90 per cent is financed through revenue expenditure and a minor percentage of resources have been allocated to capital expenditure for health. Health expenditure includes three account heads ‘Medical’, ‘Public Health’ and ‘Family Welfare’ the sum of revenue and capital account of these head in total health expenditure. A large proportion of expenditure on medical and public health and family welfare comes from the revenue account (Figure 2).

**Figure 2: Revenue and Capital Health Expenditure on Medical and Public Health and Family Welfare.**

*Source: Various Budget documents of Government of Rajasthan.*

The achievements of the public health sector in improving health outcomes during 1980’s received a setback with the economic crisis of 1991 and the subsequent economic reforms which followed the Structural Adjustment Programme (SAP) strategy commandeered by World Bank. The public expenditure on health as a percentage share of Gross State Domestic Product (GSDP) is low in Rajasthan (0.98 per cent). Sen et al.7 conceded that Share of public spending on
health has been declining over the years (Figure 3), yet it is the highest among the low-income states of India. The public expenditure on health as a share of state expenditure is also on the lower side (4.91 per cent). The actual public expenditure on health is Rs. 1128.3 crore although the per capita public expenditure on health is high in Rajasthan i.e. Rs. 186.

The share of expenditure directed towards the health sector (both as a proportion of total budgetary expenditure and as a percentage of GSDP) has been declining over the years. While a bulk of the expenditure on health and family welfare is accounted through the budget, about three per cent is spent outside the budget under various centrally sponsored schemes like the disease control programmes and Reproductive and Child Health Programme (RCH) revealed in IIHMR. The state directs a significantly higher share towards tertiary and lower shares towards primary and secondary health care services than those suggested by the National Health Policy 2002; GoI.

Provision for good health is a merit good as health is generally regarded as an asset. In terms of protecting public health, Honorable Chief Minister Ashok Ghelot took a major step on the occasion of Birth anniversary of Mahatma Gandhi on October 2, 2011 towards providing social security to the citizens of his state in the form of supply of free medicines and free diagnosis to everyone. The MukhyaMantriNishulkDawa Yojana (MNDY), scheme ensures free generic medicines for all indoor and outdoor patients. The rationale for this scheme is that a large number of people in the state are not able to afford the expenditure on their treatment. High expenditure on health care is the major cause of rural indebtedness. Thus the scheme is providing qualitative medicines and surgical diagnosis free of cost. The Rajasthan Medical Services Corporation has been constituted and a centralised system of purchase of medicines has been developed, which is supplying medicines to all Government health institutions through District Drug Warehouses. Commonly used essential (generic) medicines and surgical (approximately 300) are being provided free of cost to the patients visiting any type of Government health institution. The quality of drugs is ensured by testing drugs through empanelled drug testing laboratories. There is an overwhelming response among the people regarding the scheme.

**Results**

Indoor patient care is that rendered to patients who occupy beds in the hospitals and outdoor patient care does not require their being placed in bed. Outdoor Patients (OPD) will get the medicines in hospital time; the Indoor Patients (IPD) will get this facility round the clock. From three crore in 2010-11, the number of patients accessing OPD services increased to nine crores in 2014-15. Similarly, visitors to IPD increased from thirty one lakh to thirty five lakh. During the 1984 to 1999 period, the number of indoor patients increased depicting growth rate of 1.92 per cent. On the other hand, with the beginning of the new millennium, growth rate propelled to 3.25 per cent during 2000-2015. Taking a composite view of the three decades (1984-2015), the cumulative growth rate was found to be 2.12 per cent (Figure 4).

**Figure 3: Health Expenditure as Percentage of Total Expenditure.**

**Figure 4: Number of Indoor Patients Treated (In lakhs)**

Similarly, with reference to outdoor patients, their pool during the fifteen year period (1984-99) showed a growth rate of 0.40 per cent. Its growth rate leaped from 0.40 per cent to 2.94 per cent, over the next fifteen years (2000-15). From an eagle’s eye view, the total growth rate for the three decades is recorded at 0.90 per cent for the same (Figure 5).
Therefore, it is clear from the figures that the number of patients seeking inpatient and outpatient treatment increased after the introduction of the MNDY scheme. Although the analysis is only limited to outpatient care because this scheme provides free medicines and drugs to these people and hence they do not get admitted to the hospitals. Therefore, vast improvement is seen in accessibility of outpatient care. Pre and post scheme growth rate have been calculated and chow test is also employed to see whether structural changes are found in the number of people seeking outpatient treatment after the introduction of MNDY scheme. For this, two time periods have been taken; one is from 2000 to 2010 and another is from 2011 to 2014. A growth rate of 2.13 per cent is seen in the number of outdoor patients during the period of 2000 to 2010. While the growth rate of 37.12 per cent is found in post scheme period (2011-2014) for the same. To assess the impact of implementation of MNDY scheme on outpatients growth, a semi-log model has been used with a dummy variable, which takes zero (0) value for the pre-scheme period and one (1) for the post scheme period. Results based on the semi-log-linear model with dummy variables discussed under methodology have been presented in Table 1a.

Source: Based on calculations

On the basis of table, the estimated results of model are as follows:

\[
\text{Ln Outdoor Patients} = 17.16338 - 3.509D + 0.0212t + 0.2987Dt \quad (1b)
\]

The above regression result shows, both the differential intercept and slope coefficient are statistically significant strongly suggesting that the growth of outpatient patients with respect to time for the two time periods (2000-2010 and 2011-2014) has been different. It indicates that MNDY scheme has affected number of patient seeking outpatient care manifold.

From (1b), derived equations are:

\[
\text{Ln Outdoor Patients} = (17.16338-3.509) + (0.0212+0.2987)t \quad (1c)
\]

Here it is clear through the value of induced factors i.e. β1 and (β1 + β2) in the corresponding equations of pre and post scheme period that launch of MNDY scheme have positively affected the growth of outpatients. It grew with an average growth rate of 2.12 per cent during pre- scheme period (2000-2010) while it accelerated in the post-scheme period (2011-2014) and reached to 31.99 per cent. It is quite evident from the analysis that the number of patients accessing public health facilities had doubled since 2010.
Conclusion

Public expenditure on health is an effective tool to improve the socio-economic welfare of the people. Stagnating government health expenditure, skyrocketing prices of drugs and rising cost of other health services, and increasing unregulated privatization of the health care sector raises serious concerns of the health scenario in the country. With rapid improvements in health particularly of the poor, “vicious circle” of poverty can be converted into “virtuous circle” of prosperity. Moreover, there exist very high inequalities in health and human development across states; between rural and urban areas and across economic and gender divisions. Relative performance differs across states and this is due to differences in not only in the health sector endowment but also on its efficient use. Public spending has the potential of bringing down the OOP expenditure and also entailing substantial health gains. The analysis clearly indicates that most of the state health spending comes from revenue account. The health spending on medical and public health is measured almost four times to family welfare which, follows the conclusion that most of the state health budget is allocated to the curative and clinical services, medical education, disease control programmes etc. while much less health budget is allocated for maternal, child health and immunization services (or primary and outreach services) GoI10. The state spends a higher proportion of its income on healthcare, but the absolute amounts are still low with a comparison of state’s health care needs, therefore more allocations should be made for the health sector to run more cost-effective health care programmes. But better use of existing funds-reforms as well as expansion has to be given higher priority, especially eying on the fiscal imbalance of the state. The low level of utilization of public services suggest that large increases in spending will not necessarily ensure positive results unless the management pattern is improved. In an era of Liberalisation-Privatisation-Globalisation (LPG) and the diminishing role of government in the health provision, the emphasis should be on improving the performance of the health sector.

A Rare Case of CNS Limited B-Cell Acute Lymphoblastic Leukemia Presenting as Acute Onset Psychosis

Kabi Shobhitendu1, Dalai Siba P2, Sahoo Surjeet3, Samal Priyanka4, KakolluVujwal R5

1 Professor, PG Department of Medicine, 2 Assistant Professor, PG Department of Medicine, 3 Professor, PG Department of Psychiatry, IMS and SUM Hospital, 4 Associate Professor, Department of Clinical Hematology and Stem cell transplant, 5 Junior Resident, PG Department of Medicine, IMS and SUM Hospital.

Abstract

We report a case of a 52-year old male who presented with acute onset psychosis without any systemic symptoms or signs, with normal routine blood biochemistry, peripheral smear and radiological imaging of the brain. Diagnostic lumbar puncture and Flow cytometry of CSF revealed evidence of B-cell Acute Lymphoblastic Leukemia with 44.2% blast cells. Further workup with bone marrow examination was surprisingly normal. PET-CT did not reveal evidence of any malignancy in any organ system other than CNS. B-ALL presentation limited to CNS is rare, and with sole psychiatric manifestation without any focal neurological deficits, meningeal and or systemic signs is even rarer. This case will definitely widen the scope of differential diagnosis of a case of acute-onset psychiatric symptoms in middle to late age.

Keywords: CNS limited B cell ALL, Psychosis, flow cytometry.

Case

A 52 years old male serving in a paramilitary battalion engaged in anti-insurgency operations presented with complains of withdrawn from environment, not eating or sleeping well and talking very little for about 25 days. There was no history of headache, vomiting, seizures, fever, loss of consciousness, respiratory or cardiovascular symptoms or GI symptoms. He had history of loss of his 22yrs old son in a road accident 8 months back. He was not a known case of hypertension or diabetes and had no contact with or pasthistory of tuberculosis. There was no history of psychiatric or personality disorder in the past. He was a social drinker (120-180 ml of rum 2-3 times a month) and a smoker (5-6 cigarettes per day for last 30 years). He had last consumed alcohol about 30 days ago and had reduced smoking significantly for last 30 days. Family history was negative for any known malignancy, cardiovascular or neurological diseases.

Examination revealed an average built and average nutritional status with a GCS of E4V4M6, BP 110/60 mmHg, Pulse 80/min regular, Temp 98°F and resp 18/min. He had no pallor, ecchymosis, icterus, edema, lymphadenopathy, thyromegaly, or testicular enlargement. Cardiovascular, respiratory and gastrointestinal system examination were normal. Examination of CNS revealed no papilledema or other cranial nerve deficits, no motor, sensory, cerebellar, meningeal or autonomic signs. Gait was normal. He was remaining silent, apathetic, occasionally responding to questions or speaking out spontaneously with clear speech but irrelevant mono or bisyllables. He was often not recognizing his colleagues. At times, he was restless and irritable but would suddenly become quiet, completely cut off from the environment. His Abbreviated mental test score (AMTS) was 6/10[3].

Routine investigations including complete blood count, comment on peripheral smear, fasting and post prandial blood sugar, basic electrolyte and liver panel, urine routine and microscopy, ESR, thyroid profile, chest X-ray, ECG and ABG were all normal. NCCT Scan of brain was normal. USG abdomen was suggestive of Grade-1 fatty infiltration of liver. Peripheral Smear Comment revealed normocytic normochromic RBCs with frequent band forms and no parasites with no evidence of immature cells. Vitamin B12 levels were within normal range. VDRL and HIV tests were negative.

Considering the scenario of late onset psychosis, six-D’s approach was used to rule out delirium, drugs, dementia, depression, delusion or disease[4].
Subsequently, contrast enhanced MRI was done which was normal. Lumbar Puncture was done for CSF study to rule out early CNS Koch’s, Toxoplasma or viral etiology which revealed 135 cells/mm3 with 100% lymphocytes, numerous large atypical cells with increased NC ratio, irregular distinct nucleoli & deep eosinophilic cytoplasm [figure 1]. CSF protein was 1399 mg/dl, glucose was 46 mg/dl with ADA of 36 U/ml. Viral Markers for HSV, CMV, Japanese B encephalitis were negative. ZN stain for AFB was negative. A strong suspicion of some lymphoid malignancy was raised and bone marrow aspiration cytology was done which showed erythroid cells 14%, Neutrophils 38%, Lymphocytes 22.5%, Myelocytes with Metamyelocytes 19% with normoblastic maturation with varyingly cellular marrow with focal areas showing mild lymphocytosis without any leukemic involvement.

![Figure 1: Cytosmear showing lymphoblasts (Diff-quick stain × 1000)](image)

Flow cytometry of CSF for Leukemia panel was done next. This showed 44.2% Blast Cells with following positive markers: CD10, CD38, CD19 and CyCD79a. The negative markers were CD20, CD34, CD66c, CD58, CyCD3, smCD3, CD7, cyMPO, CD13, CD33, CD14, CD64, CD117, CD11c, HLADr. Tdt status was positive (nuTdT positive 2.2%) in cell block preparation of the CSF sample. This was suggestive of B-cell Acute Lymphoblastic Leukemia.

We also documented negative serologies for HIV, Ebstein-Barr Virus, Cytomegalovirus and HTLV-1. Serum LDH was 284 U/L, Uric Acid was 8.60 mg/dl. Positron emission tomography-CT (PET-CT) was done to look for other sites of leukemic involvement which revealed leptomeningeal disease.

A final diagnosis of CNS- limited B-Cell Acute Lymphoid Leukemia was made and the case was taken over by Department of Clinical Hematology where he was started on methotrexate, dexamethasone, daunorubicin and vincristine both systemically and intrathecally. He showed good response with multiple repeat CSF studies showing clearance of leukemia cells and recovery from psychotic symptoms within 8-10 Days of starting induction therapy. Patient was later discharged from clinical hematology unit and has been lost to follow-up.

**Discussion**

Malignancies of lymphoid cells do involve Central Nervous System (CNS) in various stages with varying severity. The estimated annual incidence of Acute Lymphoblastic Leukemia (ALL) worldwide is 1-5 cases/100,000 population and more than two-thirds of cases of ALL are B cell phenotype[1]. Primary CNS lymphoma (PCNSL) accounts for less than 3% of all primary CNS neoplasms[2].

Our case presented as a late onset psychosis (Paraphrenia), without any other clinically significant signs and symptoms[4]. Lack of systemic signs and mild cognitive impairment as suggested by Abbreviated Mental Test Score (AMTS) prompted us to consider i). Depression (association with history of loss of his son), ii) Sub-dural hematoma (SDH) (associated with alcohol, paramilitary personnel), iii) Multi-Infarct Dementia iv) Intra Cranial Space Occupying Lesion as differential diagnosis.

Since the possibility of appearance of symptoms and signs of severe depression after 8 months of loss of his son was thought to be remote, it was considered prudent to look for possibilities of CNS Koch’s and other infectious etiologies which could have evaded detection in imaging studies. CSF study suggested CNS malignancy which was confirmed to be a case of B-cell ALL with flow cytometry.

B-ALL/LBL is primarily a disease of children, with three-quarters of cases occurring in children <6 years old; there is a second peak of incidence in adults >60 years old[5]. B-ALL occurs slightly more frequently in males than females. Majority of the clinical manifestations in ALL is due to accumulation of poorly differentiated malignant lymphoid cells within blood, bone marrow and extra-medullary sites. Constitutional signs of bone marrow failure, B- symptoms such as fever, night sweats and weight loss along with easy fatigability, bruising, and susceptibility to infections are a few important manifestations of the disease. Involvement of extramedullary sites results in lymphadenopathy,
splenomegaly or hepatomegaly which is seen in 20% of patients[6].

CNS being a sanctuary site, its involvement is a common event during active or hematological remission phase of acute lymphatic leukemia. Much less common is isolated CNS symptoms and signs in systemic ALL. CNS involvement in ALL at diagnosis is uncommon (5-7%) which present as cranial nerve deficits or meningeal signs[7]. 60-70% of these patients present with a solitary intracranial mass and 5-7% have leptomeningeal involvement alone[8][9]. Around 43% of patients present with neuropsychiatric manifestations during the course of a primary CNS lymphoma[10]. But psychiatric symptoms being the sole initial manifestation with normal peripheral smear picture, normal brain imaging and normal bone marrow cytology is extremely rare[11]. To our knowledge, this is the first ever case being reported.

Our case was definitely a case of acute lymphoid malignancy, with 44.2% blast cells and positive markers on flow cytometry. But in absence of bone marrow involvement, it was difficult to stamp this diagnosis. As the PET scan revealed, most likely, leukemic process involved the leptomeninges and there being no evidence of mass lesion, we arrived at a diagnosis of CNS limited B-cell ALL/ Primary B-cell CNS Lymphoma. Primary leptomeningeal lymphoma is a rare form of primary CNS lymphoma[12]. Cranial and spinal MRI with contrast medium can evidence enhancing lesions in about 70–80% of cases[13]. In recent years, the use of F-FDG PET and PET/CT together has a diagnostic sensitivity of 76%–100%[14]. It is also known that the margin between lymphoma and leukemia is not very sharp always and the clinical pattern can change in the course of an illness[15].

**Conclusion**

Our case highlights the workup and consideration of lymphoid malignancy as a differential diagnosis in a case of acute onset psychosis and mutism as a presenting feature of a more sinister disease in a middle to old age individual.

An Epidemiological Study of Cataract Patients: Findings From a Hospital-based Study

Daneshwar Singh¹ Rohit David,¹ Lalit Chandrawansi¹, Harshal G Mendhe²

¹Assistant Professor, ²Associate Professor, Department of Community Medicine, Government Medical College and Hospital, Rajnandgaon, Chhattisgarh.

Abstract

Background: Cataract, which refers to a clouding of the crystalline lens of the eye, stands out as the first priority amongst the major causes of blindness. Cataract is one of the important causes of low vision in both developed and developing countries. Cataract occurs more frequently with advancing age. Knowledge regarding magnitude and socio demographic factors will be helpful for healthcare managers. Therefore, the present study was conducted among the patients in ophthalmology department of a tertiary health center to study the epidemiological profile and causes of cataract.

Method: A Hospital based Cross Sectional Study conducted from July 2017 to December 2017 in a tertiary health center in central India. Total 336 patients who availed services from ophthalmology department during study period were included in the study and relevant data was collected from them. Data analysis was done by percentages, proportions, and tests of significance (Chi-square test).

Results: A total of 181 patients were investigated in the study with gender distribution of 67.7 % male. Most of the patients were above 60 years. Left eye was more commonly involved in cataract. Marital status, educational status and occupation of the patients were found to be statistically significant.

Conclusions: The present study concluded with the findings highlighting the huge burden of cataract in central India and the role of multiple factors in cataract genesis pointing towards a multi-factorial causation.

Keywords: CNS limited B cell ALL, Psychosis, flow cytometry.

Introduction

Cataract, which refers to a clouding of the crystalline lens of the eye, stands out as the first priority amongst the major causes of blindness. Today, an estimated 20 million people are blind from this condition. Cataracts are not generally amenable to prevention but currently available surgery can restore near normal vision in a large proportion of the cataract blind.¹ Cataract is one of the important causes of low vision in both developed and developing countries. Population-based studies and previous meta-analyses performed in different regions worldwide have reported that cataract is responsible for 47.8% to 51% of all global blindness.²³ In South East Asia, cataract is single most common cause of blindness being responsible for 50-80% of all blindness.⁴ In India, according to a recent survey in the Rapid Assessment of Avoidable Blindness (RAAB) study, cataract was responsible for 77.5% of avoidable blindness.⁵ The principle cause of blindness in India today is cataract, responsible for about 62.6% of all cases.⁶ Cataract occurs more frequently with advancing age. In the year 1991, the 60+ population which was around 56 million that has doubled in the year 2017.⁷ This means that the “at-risk” population for blinding cataract is increased exponentially.⁸ Senile cataract occur a decade earlier in India relative to Europe and America. Since cataract is a major cause of avoidable blindness in the developing countries, the key to the success of the Global Vision 2020: The right to sight initiative is a special effort to tackle cataract blindness.⁹ To deal with such a major problem of curable blindness it is necessary to know its magnitude where health resources are scarce in order to mobilize the resources and it is important to know about the knowledge of epidemiological factors associated with cataract. Knowledge regarding magnitude and socio demographic factors will be helpful for healthcare managers. Therefore, the present study was conducted among the patients in ophthalmology department of a tertiary health center to study the epidemiological profile and causes of cataract.

Materials and Method: This was a Hospital based Cross Sectional Study conducted in the Ophthalmology...
Department, Government Medical College, and Hospital Rajnandgaon (C.G).

**Study Population:** Patients of all age groups and gender admitted in ward and patients attending outpatient Department of Ophthalmology in GMCH, Rajnandgaon (C.G)

**Study Period:** Study was undertaken from the month of July 2017 to December 2017 for a period of six months.

**Inclusion Criteria:** All the patients attending Ophthalmology OPD in GMCH on the day of visit and willing to participate were included in the study.

**Exclusion Criteria:** Those who do not give consent to be a part of the study & seriously ill patients were excluded.

**Sample Size and Sampling Technique:** All patients who visited or admitted in ophthalmology department during study period. Total 336 patients, by applying universal sampling technique, investigated in the study.

**Study tool:** After obtaining verbal consent, data was collected by face to face interview of the patients using predesigned questionnaire which include patient identification data, socioeconomic status, Type of cataract, Stages of cataract, Causes of cataract, associated morbidities and visual function assessment.

**Data Collection and Procedure:** After the departmental and institutional ethical committee clearance. A structured self-administrative questionnaire was developed with the aid of available evidences by the researchers for data collection to fully meet the demands of this research. The developed questionnaire are corrected, revised and validated by clinicians. It was pretested before its use in this study. Examinations and interviews were carried out by an ophthalmologist and an epidemiologist with the help of trained ophthalmic assistants. After obtaining their informed consent the participants were interviewed using the basic parameters stipulated in our questionnaire. This was followed by General Physical Examination and ocular examination. Visual acuity was tested and lens opacities were graded at the slit lamp using the Lens Opacities Classification System (LOCS) III. Socioeconomic status was classified according to modified B.G. Prasad’s classification.

**Statistical analyses:** Data obtained were collated and analyzed statistically by Microsoft Excel and Epi Info 7.14 for proportions and Chi-square test was used as test of significance. The significance of the results was computed at the level of <0.05. Each completed questionnaire was coded on pre-arranged coding to minimize errors.

**Result:**

**Result:** A total of 181 patients were investigated in the study with gender distribution of 67.7 % male and 32.3 % females. Most of the patients were above 60 years, married (87%), and Hindu (96%). About 87% of respondents were rural residents and illiterate. Most of the respondents belong to lower class. On examination of the patients it was found that majority of them had difficulty in reading small letters of Snellen chart. The patients did not have any difficulty while cooking but had discomfort in watching television. Majority of respondents did not have poor night vision but complained of color halos in the vision. The patients did not have discomfort with bright light, but all the respondent complained of blurred vision. Most of the patients did not have decreased low
light vision or any double vision (Table 1). As for the etiological distribution of cataract, it was seen that majority of patients had senile form of cataract followed by cataract associated with metabolic cause (Table 2).

On evaluating the stage of maturity, eye involvement, family history of the patients it was seen that most of the patients had mature form of cataract. Left eye was more commonly involved in cataract. Majority of patients were not previously operated for cataract and did not have a positive family history of cataract (Table 3). On calculating the association between maturity of cataract with various variables it was seen that age, gender, religion type of family and residence were not statistically with maturity of cataract. However marital status, educational status and occupation of the patients were found to be statistically significant.

Discussion

This hospital based study was aimed at finding the epidemiological profile of cataract patients. Total samples of 336 patients were screened for cataract by the ophthalmology and community medicine departments of government medical college Rajnandgaon(C.G). Of the screened patients 181 patients were diagnosed with cataract, of which 130 were males and 51 were females. In the present study male outnumbered female. Similarly, Singh et al. also mentioned that the prevalence of cataracts was more in males in their study. However; in the study conducted by Raizada et al., prevalence of cataract was more in female. In a similar study by Sobti et al. 547 respondents were enrolled, 59 were males and 77 females. Majority of patients were above 60 years old, while in a study by Anjana et al., most of the patients were between 50-59 years. Age was the commonest risk factor observed for the cataract in the study conducted by Chaterjee et al. Similarly, in a study conducted by Raizada et al., incidence of cataract increased with the age. Lower prevalence of cataract in elderly compared to this study reported by Sharma et al in their study done in Northern India reported that 30% of the elderly population had cataract. In this study 159 patients were married and 22 were unmarried, similarly in a study by Khan et al. more married patients were enrolled. Similar association of cataract with marital status was shown by Shankar et al in rural Varanasi. Majority of patients were Hindu in our study, while in the study by Khan et al. most patients were Muslims. Nuclear type of family or they were living alone was seen in 123 patients. These finding were similar to a study by Khan et al. Majority of patients had residence in rural areas, similar to a study by Bharath et al., where also majority of patients were rural area residents. In this study 147 patients were illiterate; where in a study by Avachat et al. most of the patients were also illiterate. Previous studies have reported lower educational levels to be associated with higher prevalence of age related cataract. About 139 patients were not working, similarly majority of patients in a study by Sumathi et al. were also not working. Whereas, Athanasiov PA et al (2010) and Athanasiov PA et al (2008) observed no such relationship between cataract and outdoor occupation. Majority of patients belonged to lower social class; while in a study by Sobti et al. lower middle class had more patients. The etiological distribution of cataract showed that 55% patients had senile cataract followed by metabolic cataract and mature cataract was more common than immature cataract. These findings are in agreement with findings of Avachat et al., Sumathi et al. In the present study 59.67% cataract patients had mature cataract and 27.62% patients had hyper mature cataract. This variation in the stage of maturity of the cataract could be explained on the basis of variation in awareness, availability, and utilization of healthcare services. These findings are in agreement with findings of Avachat et al., Raizada et al. mentioned the incidence of 7.1% in their study; while incidence was only 1.4% in study conducted by Chaterjee et al. This variation in the stage of maturity of the cataract could be explained on the basis of variation in awareness, availability, and utilization of healthcare services. Most of the patients had symptoms associated with cataract, i.e. difficulty in reading, watching TV, colored halos and blurred vision. While symptoms like difficulty in cooking, poor night/ low night vision, poor color vision and double vision were not experienced by most patients. Similar findings with variations of symptoms were also seen in the study by Bharatwaj et al.

Limitations of This Study: The present study being a cross sectional study, it was difficult to establish a causal relationship between the dependent and independent variables. Also as universal sampling was done, the confidence interval cannot be calculated, thus limiting the scope of the study.

Conclusion

The present study concluded with the findings highlighting the huge burden of cataract in central India and the role of increasing age, low literacy status, indoor activities, Nuclear or living alone families, family history of cataract, metabolic disturbances and ocular injuries in cataract genesis pointing towards a multifactorial causation. Therefore, these factors need to be addressed to reduce the burden of cataract among elderly population.
Ethical Clearance: Taken from institutional ethical committee.

A Comparative Study on Perception Regarding Mentorship between Mentees and Mentors in a Selected College, Mangalore.

Swathi1, Sweeta Priya D'souza1, Teena Checha Thomas1, Theresa TomY1, Tiana Susan1, Dr. Devina E Rodrigues2

1Final year UG students, 2Professor, Father Muller College of Nursing, Mangalore.

Abstract

Introduction: Being a mentor is not an easy task. It is multifaceted responsibility of taking up teaching, counseling, guiding and supervising altogether. Availability of time, resources, personality traits, commitment, skill all need to be in sufficient amount and it should be accessible to the Mentee at any given time of the day. The relationship between Mentor and Mentee is like a two delicate end of a seesaw, a slight mismatch can lose its essence. “Mentors support the students in the clinical area & acts as a role model, facilitates the learning experience on placement1”. This investigation is an eye opener for the authorities to further strengthen the existing mentorship program for the well-being of the students. The objectives of the study were: 1) to compare the perception regarding mentorship between Mentees and Mentors. 2) to find the association between level of perception regarding mentorship and selected baseline characteristics of the Mentors and Mentees.

Method and materials: The descriptive, comparative research design was used to compare the perception of the Mentors and Mentees towards mentorship. The sample consists of 193 Mentees and their 18 Mentors. The entire Mentors population was taken for the study. The data were obtained by using a five-point rating scale. Out of total Mentees 91.7% were happy with their Mentors, and only a small proportion i.e. 8.3% were unhappy with their Mentors. The larger proportion i.e. 94.4% of Mentors were happy to be the part of the mentorship program. The overall 63.7% Mentees had a negative perception and 36.3% of Mentees had a positive perception, the Mentors’ negative perception is about 27.8% and 72.2% had a positive perception toward mentorship.

Conclusion: Mentors perception was better than Mentees.

Keywords: program, Mentor, Mentee, perception, Students, Nurses.

Introduction

The Mentor is a more professional and expertise person who guides the less skilled or less sensible members. In an educational institution, mentorship will help to guide the students to resolve academic problems as well as personal issues. Nurturing students is not an easy task, one cannot embrace the age-old techniques to deal with the current generation. The existing problems in the student population are plenty and more complex and quite different from what was existing a decade ago. It’s a huge challenge for the head of the institution and the current study is conducted with the same intention to identify the lacunae’s and to refine the program for the benefit of the students.

Materials & Method

The data were collected from 193 mentees and 18 of their mentors. Ethical consent was taken from the institutional ethics committee before the data collection. The investigator explained the purpose of the study to the subjects. Informed consent was obtained from the participants. The tool of perception regarding mentorship was prepared in two parts. The first part had common items (10) for both the Mentee and Mentors. The second
part had 9 items for Mentees and 9 items for Mentors. The total items for each Mentor was 19 and the same number of items for their Mentor. It was a five-point scale with maximum scores of 95 and minimum scores of 19. The reliability of all 3 parts has been conducted separately to test the internal consistency by using Chronbach’s alpha. The reliability of the part I (Existing Mentorship program) was 0.758. The part II (Mentees perception on Mentor) was \( r = 0.70 \), the part III (Mentors perception on Mentee) was 0.840.

**Study design:** Descriptive comparative design.

**Selection & Description of participants:** The entire Mentees population from the institute and their Mentors were selected, who fulfilled the inclusion criteria.

**Criteria for the sample selection:**

**Inclusion criteria:** Those teachers are currently the part of mentorship for the 2nd and 3rd B.Sc. Nursing Students.

**Exclusion criteria:**

Those who are the part of a mentorship program as Mentees for less than 6 months and their Mentors.

**Statistics:** SPSS 23 Version was used for analysis.

**Results:**

**Table 1:** Grading of overall and component-wise perception of the Mentees and mentors towards mentorship: \( N = 193 + 18 = 211 \)

<table>
<thead>
<tr>
<th>Components</th>
<th>Grading</th>
<th>Mentees (193)</th>
<th>Mentors (18)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>f</td>
<td>f</td>
<td>%</td>
</tr>
<tr>
<td>Overall perception</td>
<td>70</td>
<td>36.3</td>
<td>13</td>
</tr>
<tr>
<td>Perception regarding ongoing program</td>
<td>123</td>
<td>63.7</td>
<td>5</td>
</tr>
<tr>
<td>Perception towards each other</td>
<td>58</td>
<td>30.1</td>
<td>10</td>
</tr>
<tr>
<td>Negative perception</td>
<td>135</td>
<td>69.9</td>
<td>8</td>
</tr>
</tbody>
</table>

The overall and component-wise perception indicates that a large number of mentors had a positive perception than the mentees regarding mentorship. With all components, the majority (above 50%) of the mentees had a negative perception regarding mentorship.

**Table 2:** Mean, Standard deviation of overall & component-wise perception scores of the Mentees/ Mentors regarding mentorship.

<table>
<thead>
<tr>
<th>Group</th>
<th>Component</th>
<th>Mean/SD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mentees</td>
<td>Perception regarding existing program</td>
<td>33.48±5.60</td>
</tr>
<tr>
<td>Mentor</td>
<td></td>
<td>37.33±5.67</td>
</tr>
<tr>
<td>Mentees</td>
<td>Perception towards each other</td>
<td>31.95±5.19</td>

<td>Overall Perception</td>
<td>65.44±9.67</td>
</tr>
<tr>
<td>Mentor</td>
<td></td>
<td>72.8±9.37</td>
</tr>
</tbody>
</table>

From table 2, it can be said that the overall perception of the mentors was better than mentees i.e. mean% 76.07 and 68.88 respectively. The same observation was seen in component-wise also. The Mean percentages of the Mentors in all components were more than 74%, it shows their perception was positive towards mentorship and Mentees perception was negative.

**Table 3:** Comparison of overall & component wise mean perception scores of the mentors & Mentees regarding mentorship.

<td>2.37</td>
<td>.019*</td>
<td>5.49</td>
<td>.50</td>
</tr>
</tbody>
</table>

Note:* Significant

From table 3, it can be interpreted that there is a significant difference in the perception of Mentors and Mentees regarding the mentorship program. This is clearly depicted by P value .004, .006 and .019 in overall, component one and two. Hence, it can be interpreted that there is a significant difference between the mean perception scores of Mentor & Mentees. It also can be interpreted that only 04 out of 1000 subjects would expect, a group difference of 7.36 points by chance alone in their perception scores.

There is a significant difference between the level of perception and academic scores of the mentees, happy with Mentors and academic problems which is apparent at \( x^2(2) = 8.49, P \ value .02 \), \( x^2(1) = 4.26, P \ value .05 \), \( x^2(1) = 4.92, P \ value .05 \). However, the rest of the baseline variables had no significant association with level of perception regarding mentorship. There was small effect size of Phi 0.04 regard to happy with the mentor, .02 about academic problems, however, there was median effect.
size (Cramer’s V 0.2) between academic performance and baseline variables.

Found no significant association between Perception of mentors and their baseline characteristics.

**Discussion**

Mentees: In the current study, 16 students noted that they had academic problems and out of this total 87.5% had a negative perception of mentorship. Similarly, 18 of them had personal problems and 61.1% of this total had a negative perception. Out of total mentees, 158 had secured first class or distinction in their previous university examination, out of that 60.12% also exhibited a negative perception on mentorship. There were 17 of them unhappy with this program and 87.5% of them showed negative responses towards this program. Around 85% of the Mentees said that their mentors’ had a good interaction with them, there were 5.3% of them also felt that their mentors did not have a good interaction with them. The Nursing Students of Turkey felt that an effective feature of the clinical Mentor was communication ability. The overall mean perception scores of Mentees was 65.44±9.67 which is lower than Mentors total mean scores 72.8±9.37. The study conducted among Nursing students in Bijapur, out of 116 (65.5%) had a good attitude about their teachers behavior, 34.4% said that teachers’ behavior had a poor impact on them.

Mentors: The current study, 44.4% of the mentors were between 6-10 years of professional experience. The study conducted by Ellen indicated that the mentors were working on the study setup for 8.57 years. This indicates they were remained and quite familiar with the work routines of the organization. The current study, 94.4% of them had 1-5 yrs. of experience in mentoring. The study conducted by Ellen supports the study findings on average the mentors had 4.64 years of experience. A study conducted in 2006 among 336 students from 3 countries (UK, USA, Jordan) had shown the quality that students would look for in their Mentors was said to be “knowledge and skill”, which was ranked highest by the students of all 3 countries. The study conducted among doctoral students had indicated that they want to practice autonomously in the roles that will be expected of them, but valuable feedback and support from their mentors. From the study, it can be interpreted that the mentees value the mentors, but, expecting freedom to place their creativity.

**Strengths of the study:**

- The study has helped to know the perceived mentors’ qualities by Mentees, based on the findings, given an invitation in general to all mentors to refine their mentorship responsibilities.
- It has helped the organization to conduct annual short training sessions for mentors as well as to the mentees.

**Limitations:** The study was limited to one time data collection.

**Implication of the study:** A present study is a foundation to undertake an exploratory study to determine the various factors causing imbalance in the Mentor–Mentee relation.

**Suggestions:**

- Mentors should be allowed to participate in the annual mentorship training program.
- Students’ evaluation of teachers must be taken as one of the components for promotion.
- Personalities must be taken into consideration while promoting.
- Students should be given a choice to select their mentors.
- If mentee, prefers to have a same Mentee until her completion of her course to be considered.

**Future research directions:**

- A study can be undertaken to assess barriers in forming Mentor- Mentee relationship.
- The study can be replicated after a course of remedial actions.
- A similar study with multiple period data collected after several training & counseling sessions on mentorship can be useful.

**Ethical Clearance:** The ethical clearance was obtained from Father Muller Medical College Institutional Ethics Committee (Ethical Number: FMMCIEC/CCM/186/18 dated 12-3-2018)

**Source of Funding:** Self

**Conflict of Interest:** None

A Study to Assess the Professional Quality Life among Nurses of a Selected Institute in Mangaluru

Kesiya Reji¹, Meenu Mathew¹, Nimya T M¹, Remya Philip¹, Devina E Rodrigues²,

¹B.Sc Nursing Final Year Student, Yenepoya Nursing College, Mangalore
²Professor, Father Muller College of Nursing, Mangalore

Abstract

Introduction: An essence of work output is more or less lies in the quality of professional life. The members of the nursing fraternity have learned, realized and strongly believe in the concept that says the nursing is a noble profession and patient satisfaction is utmost important. The patient and their relatives at the time of vulnerable situation completely depend on nurses as they are available for them all 24 hours of the day. To give the best possible, efficient and effective care delivery we need to have a conducive work environment. Keeping these views in mind the investigators have conducted this study. The Objectives of the study were: 1) To determine the professional quality of life among nurses. 2) To find the association between the professional quality of life and selected baseline variables.

Method and material: A descriptive study was conducted among 80 nurses working in various wards and intensive care setups of a super specialty hospital at Mangalore. The data were conducted from 80 subjects who were selected by convenience sampling technique. The Instrument Used for the data Collection were five- point rating Scale prepared by Hudnall Stamm 2009-2012 version 5–Prof QOL.

Results: The mean scores of overall professional quality of life among the nurses were 94.33 ± SD 9.03 with mean% 62.88. The mean scores in the component of satisfaction was 36.8 ± SD 6.52 with mean% 73.6; The mean scores in the component of burnout was 30.9 ± SD 3.94 with mean% 61.8; The mean scores in the component of secondary traumatic stress was 26.5 ± SD 5.92 with a mean% 53.0; The findings revealed that subjects professional quality of life in the component related to secondary traumatic stress was low compared to the rest of the two components.

Conclusion: The study reveals that the intervention required directing towards the nurses to bring up job satisfaction, to reduce burnout and traumatic stress among the nurses.

Keywords: professional quality of life, burnout, secondary traumatic stress, fatigue.

Introduction

Nurses are the largest work force in the health industry, the long working hours, frequent night shifts, home and work responsibilities, ever-changing technologies are very challenging and it has a greater impact on their professional quality of life. The compassion fatigue, burn out and secondary trauma can endanger their workout put. The realisation of existing facts on these issues is essential to guard the work spirit of the nurses. Keeping this intention in mind to make the life of these little angels at ease the above mentioned study was conducted in a selected hospital at Mangalore.

Materials and Method

The data was collected from 80 nurses. Ethical consent was obtained & prior permission was taken from the concerned authorities before the data collection. The investigators introduced them and the purpose of the study was explained to the subjects. Informed consent was obtained from the participants. The Instrument Used for the data Collection were five point rating Scale prepared by Hudnall Stamm 2009-2012 version 5–Prof QOL and socio demographic proforma with 11 items. The study results were informed to the highest nursing

authority of the study setting to plan staff development program. The data collection was terminated by thanking the subjects for their participation.

**Study design:** Descriptive survey design

**Selection and Description of Participants:** 80 nurses were recruited using convenience sampling technique.

**Criteria for sample selection**

**Inclusion criteria**
1. Staff nurse and Ward In-Charges
2. Working in IP or OPD departments

**Exclusion criteria:**
1. The nurses working in the current hospital less than 1 month.
2. The middle level nurse managers such as Asst Nursing Superintendent, Nursing Superintendent, and Chief Nursing Officer.
3. ANMs (Auxiliary Nurse Midwives).

**Source of population:** In this study, population were all nurses working more than a month in the selected hospital at Mangalore.

**Statistics:** SPSS 23 version software was used for analysis.

**Results:**

**Table 1: Grading of professional quality of life of nurses.**

<table>
<thead>
<tr>
<th>Components</th>
<th>Grading</th>
<th>Scores</th>
<th>f</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compassion satisfaction</td>
<td>Low</td>
<td>≤ 22</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Average</td>
<td>23-41</td>
<td>80</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>High</td>
<td>≥ 42</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Compassion Burnout</td>
<td>Low</td>
<td>≤ 22</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Average</td>
<td>23-41</td>
<td>80</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>High</td>
<td>≥ 42</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Secondary Traumatic stress</td>
<td>Low</td>
<td>≤ 22</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Average</td>
<td>23-41</td>
<td>80</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>High</td>
<td>≥ 42</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

From the above table it can be interpreted that none of the nurses were with high job satisfaction. It is seen average burnout and secondary traumatic stress among the nurses. The mean scores of all 3 component were between 23-41 indicates the subjects were with moderate compassion satisfaction and moderate compassion fatigue. From the results it can be interpreted that the subjects were at moderate risk for burnout. It also can be interpreted that the subjects derive moderate amount of satisfaction from their job.

**Table 2: Mean and Standard Deviation of professional quality of life of nurses.**

<table>
<thead>
<tr>
<th>Components</th>
<th>Mean / SD</th>
<th>Mean %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compassion satisfaction</td>
<td>36.80±6.52</td>
<td>73.60</td>
</tr>
<tr>
<td>Compassion burnout</td>
<td>30.90±3.94</td>
<td>61.80</td>
</tr>
<tr>
<td>Secondary traumatic stress</td>
<td>26.50±5.92</td>
<td>53.0</td>
</tr>
</tbody>
</table>

From the above table it can be interpreted that the mean score of 26.50±5.92 in the component of secondary traumatic stress over mean scores of 30.90± 3.94 in the component of secondary traumatic stress that the subjects had experienced burnout more than secondary traumatic stress.

**Table 3: Association between professional quality of life of nurses and selected socio-demographic variables.**

<table>
<thead>
<tr>

<td>2</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td></td>
<td>≥ 20</td>
<td>1</td>
<td>3</td>
<td></td>
</tr>
</tbody>
</table>

From the table it can be interpreted that none of the socio demographic variables had association with Professional quality of life. Found higher the age the better professional quality of life. Similarly higher the experience more was their professional quality of life. The M.Sc qualified nurses were with better professional quality of life than rests of the nurses. Those who were drawing low salary had less professional quality of life, Area of work , family structure showed no much changes in their scores on professional quality of life.
Discussion

The study conducted in Gujarat NICU nurses had shown 19.4% with high compassion satisfaction, whereas the current study found none with high compassion satisfaction. The burnout and secondary traumatic stress were high (23.3%), the current study found no nurses experiencing with high burnout and secondary traumatic stress. The study conducted by Tara et al. among nurses working in the tertiary care hospital, New York had indicated 73% of the nurses had high levels of compassion satisfaction, and it was high among female nurses (Mean 50.3±10) than male (Mean 43.8±7.6). The mean of compassion satisfaction of current study is congruent with the study conducted among nurses of Latvia, they found compassion satisfaction mean as 37.41, however, the current study the burnout level mean was higher than the study conducted among nurses from Latvia (22.74).

The study conducted among Japanese nurses working in maternity service delivering units supports the current study. The compassion satisfaction was 33.5±6.8 and burnout 26.9±5.2. This study is in pace with the current study. The study conducted by Tara highlights 57% of the nurses working in critical care units reported to have low levels of burnout, 81% of them who had worked in single acuity units exhibited low burnouts. The study conducted by Hooper indicates that the 82% of nurses working in the emergency unit had moderate to high levels of burnout, and 86% of them exhibited high level of compassion fatigue. The study conducted in Korean Nurses indicates the secondary traumatic stress the mean scores 28.33±5.48, these results are congruent with the current study. The similar results also observed by Hegney who had conducted a study among Australian nurses indicated 24.7% of them with low compassion satisfaction, 25.6% having high burnout and 22.2% with high secondary traumatic stress.

Strengths of the study

1. The study was able to assess the situation of professional quality of life of nurses at the early stage so that based on the need assessment; it has helped the nursing authorities to take measurements to boost the professional quality of life of nurses through in-serve service education and staff welfare measures.
2. The study also helped to know the influence of certain contributory factors like age, salary in raising the professional quality of life of the subjects.

Limitations

1. The study was limited to a single hospital at Mangalore.

Implication of the study

The findings of this study have importance in the field of nursing practice, nursing administration and nursing research.

Nursing practice

The nurse administrators must consult the institute authority to initiate remedial measures to boost the professional quality of life of nurses at their workplace. It is essential to have informal meetings with the nurses to determine their work difficulties and satisfaction towards work.

Nursing research

The present study is a basic approach, further required to undertake an exploratory study to determine the various factors contributing as well as causing an imbalance in the quality of life of nurses and their profession.

Suggestions

1. Staff welfare and staff development committees must conduct frequent programs to uphold the professional quality of nurses. They should act as a mediator to place the nurses’ aspirations and demands in front of the authorities.

Future research directions

1. The study could be replicated on a larger sample drawn from different settings.
2. A qualitative study can be conducted to know the factors contribute/hinders the professional quality of life of nurses.

Ethical Clearance: Obtained from Yenepoya University, Ethics Committee, Deralakatte, Mangalore.

Source of Funding: Self

Conflict of Interest: Nil

Conclusion

The moderate scores in all three components indicated that the subjects might derive their satisfaction from activities other than their job, the moderate scores in the area of compassion fatigue in terms of secondary traumatic stress and burnout it can be interpreted that there is a need to find out further by a research study the potential indicators at the work and work environment that can increase or decrease the stress and burnout among the employees. The burnout, compassion
satisfaction levels to be ruled out as it can affect quality, safety and work out put in the health care setting.

Segmentation Strategies: Empirical Evidences from Pharmaceutical Companies

Dr. Dheeraj Nim¹, Dr. Shamily Jaggi¹

¹,²Assistant Professor, Mittal School of Business, Lovely Professional University, Phagwara, Punjab, India

Abstract

The Indian Pharmaceutical sector is highly fragmented with more than 20,000 registered units. The organized sector of India’s pharmaceutical industry consists of 250 to 300 companies, which account for 70 percent of products on the market, with the top 10 firms representing 30 percent. Multinationals represent only 35% of the market, down from 70% thirty years ago. Because of differences in the industry structure and combination of market opportunities for domestic companies and multinationals, they are likely to differ on strategic issues. Hence domestic companies and multinational firms need to pursue different strategies to achieve desired goals. The study covers pharmaceutical companies operating in Madhya Pradesh state of India. The data or information required is related to segmentation strategies adopted by these pharmaceutical companies. The participants are selected from the directory of pharmaceutical manufacturing units in India, published by national pharmaceutical pricing authority. ANOVA is used for testing of hypothesis. The results show that there are visible differences in the segmentation strategies followed by different pharmaceutical companies of Madhya Pradesh. Small & medium domestic pharmaceutical companies have very little inclination towards segmentation strategies. MNCs and large domestic pharmaceutical organizations in Madhya Pradesh are following the segmentation strategies but this is also limited to demographic and geographic segmentation mostly. They also follow integrated segmentation strategies to some extent.

Keywords: Segmentation strategies, pharmaceutical companies, integrated segmentation.

Introduction

In the field of drug manufacturing and technology, the Indian pharmaceutical industry holds an important position in global pharmaceutical industry. With its wide range of products from simple compounds to specialized medicines, the Indian pharmaceutical industry is fulfilling almost 75 per cent demand of the country’s pharmaceutical needs. Its expertise in terms of technology, quality and range of medicines manufactured makes it a key role player in promoting and supporting development in the critical area of medicines.

The Pharmaceutical industry in India is the world’s third-largest in terms of volume and stands 14th in terms of value. Indian generic drug’s contribution in global exports is 20% in terms of volume making India as the largest provider of generic drugs globally. Over the Counter (OTC) medicines and patented drugs constitute 21% and 9%, respectively, of total market revenues of US$ 20 billion.

There are more than 20,000 registered units in Indian pharmaceutical sector. It has expanded drastically in the last two decades. The organized sector of India’s pharmaceutical industry consists of 250 to 300 companies, which account for 70 percent of products on the market, with the top 10 firms representing 30 percent. However, the total sector is estimated at nearly 20,000 businesses, some of which are extremely small. These units produce the complete range of pharmaceutical formulations and bulk drugs. Multinationals firms reduced to only 35% of the market, from 70% thirty years ago.

When the performances of domestic pharmaceutical companies are compared with multinational pharmaceutical companies in the past five years, there is a noticeable change. The mid-sized and small domestic companies have shown tremendous growth, while the large domestic companies have managed to grow with the market. The multinationals appear to have lost some impetus and market share.

However there is a two-sided competition for large domestic companies. On one hand small and medium domestics companies can maintain the same growth path if they continue to pioneer market creation. On the other, multinationals can launch patented products to gain their position again in the market.
Because of different implications for domestic players and multinational companies, they are likely to differ on strategic issues. There are also differences in the industry structure and combination of market opportunities for the three groups. Hence domestic companies and multinational firms need to follow different strategies to achieve desired goals.

**Review of Literature:** Market segmentation is the process by which a market is divided into distinct subsets of customers with similar needs and characteristics that lead them to respond in similar ways to a particular product offering and marketing program. Segmentation is a rational and more precise approach to adjust the product message to the requirements of the target market.

Some researchers feel that highly standardized segmentation procedures are premature and undesirable. Possible problems with existing segmentation approach include; incomplete set of variables, a clustering approach that does not highlight useful differences across a common set of variables and difficulties with the identification of target segments.

To being closer to the market and to gain better understanding of customers, market segmentation is the most important step. Effective utilization of market segmentation can provide a point of consent for all stakeholders and a more firm basis for creating advantages that will direct the efforts to increasing sales and improving overall marketing performance. Awareness should also be made of the benefits of segmentation in terms of the immediate positive impact on a product campaign.

In the current competitive environment, where wide range of segmentation methodologies exists, there is growing significance of using complex and integrated approach to segmentation, especially when these include more subjective indicators such as attitude and life stage.

Author analyzed that the dependence of pharma companies on single segment is not sufficient for segmenting the prescriber’s base. They concluded that companies should focus on each and every variable and hence they advocated the use of psychographic and behavioural approach in addition to demographic and geographic approach for segmenting the prescriber’s base.

Author concluded that few companies (large or small) use market segmentation to its maximum potential although top executives in the pharmaceutical industry often advocate being market oriented and customer focused. A majority of pharmaceutical companies still base their product development and commercialization plans on cursory, incomplete, or intuitive marketing analysis in spite of dynamic competitive environment and development of more advanced strategic marketing planning. Hence missing fundamental opportunities and delivering incomplete or inappropriate strategies.

The internet is a channel for rapid interaction, requiring new approaches to customer response and real time analytics. For market segmentation, the internet is laboratory, where predictive approaches and various offerings can be tested through observing, interactions with websites, customer feedback and sales.

As most conventional segmentation relies on post hoc analysis of extensive surveys, it is often difficult to predict future behaviours, especially in a rapidly changing market environment. As pharmaceutical companies increasingly use tools such as e-detailing and CRM, segmentation methodologies will have to become more rapid and deliver a more individualized view of the market.

**Research Methodology:** The study covers pharmaceutical companies operating in Madhya Pradesh state of India. The data or information required is related to segmentation strategies adopted by theses pharmaceutical companies. The informants are limited to the relevant principle management members of the companies; for instance, the Chief Executive Officer and marketing or sales manager.

The participants are selected from the directory of pharmaceutical manufacturing units in India, published by national pharmaceutical pricing authority which includes 414 pharmaceutical manufacturing units in M.P. including 344 formulations and 70 bulk drugs units. The participants are also selected from the directory of Madhya Pradesh Pharmaceutical Manufacturers’ Organization (MPPMO) and Madhya Pradesh Small Scale Drug Manufacturers’ Association (MPSDM).

The simple random sampling method is used. The population is divided into the following groups for comparison purpose:

a. Large domestic companies
b. Small and medium sized domestic companies
c. MNCs operating in M.P.

From each group random sample are chosen and targeted to fill the questionnaires.

In order to collect the information, the 317 people at the level of chief executive officer/managing director or marketing/sales manager of different pharmaceutical companies were targeted. Total 98 people completed the questionnaire out of which 31 were from MNCs, 33 were...
from large domestic pharmaceutical companies and 34 were from small and medium domestic pharmaceutical companies. Out of 98 only 90 questionnaires were used, considering 30 from each type of companies mentioned above. The secondary data was also collected from various sources like published articles, research papers, business magazines, journals, periodicals and internet etc. ANOVA is used for testing of hypothesis.

Results and Discussion

Reliability Statistics

Reliability refers to the extent to which measures are without error. The reliability analysis was carried out to check the degree of accuracy of data. The data collected from respondents is tested for accuracy. The reliability score of data is given below:

Table 1: Reliability Statistics

<table>
<thead>
<tr>
<th>Cronbach’s Alpha Based on Standardized Items</th>
<th>Cronbach’s Alpha</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.873</td>
</tr>
<tr>
<td></td>
<td>0.836</td>
</tr>
</tbody>
</table>

As it is clear from the table 1 that Cronbach’s Alpha value is 0.873 which means the data is reliable.

Types of Segmentation Strategies

The various bases of segmentation and the responses from different pharmaceutical companies are shown in the table 2 below:

Table 2: Segmentation Strategies followed by various Companies.

<table>
<thead>
<tr>
<th>Segmentation Strategies</th>
<th>MNCs</th>
<th>Large</th>
<th>Small &amp; Medium</th>
</tr>
</thead>
<tbody>
<tr>
<td>Demographic Segmentation</td>
<td>50%</td>
<td>40%</td>
<td>5%</td>
</tr>
<tr>
<td>Geographic Segmentation</td>
<td>45%</td>
<td>20%</td>
<td>10%</td>
</tr>
<tr>
<td>Behavioral Segmentation</td>
<td>30%</td>
<td>0%</td>
<td>0%</td>
</tr>
<tr>
<td>Integrated Segmentation</td>
<td>20%</td>
<td>20%</td>
<td>0%</td>
</tr>
</tbody>
</table>

Source: As computed by the researcher.

It is found from the above table that MNCs concentrate on almost all type of segmentation. They follow demographic segmentation and geographic segmentation maximum but behavioural segmentation and integrated segmentation to some extent. The large domestic pharmaceutical companies adopt demographic segmentation to the most but concentrate integrated segmentation to some extent. Small & medium domestic pharmaceutical companies have very little inclination towards segmentation strategies. They use demographic and geographic segmentation to some extent. Hence only big pharmaceutical organizations in Madhya Pradesh are following the segmentation strategies but this is also limited to demographic and geographic segmentation.

Comparison of Segmentation Strategies

The results related to comparison of segmentation strategies of pharmaceutical companies of Madhya Pradesh are presented below. In the study it has been hypothesized that there is no significant difference between segmentation strategies and size of the pharmaceutical companies.

To test this hypothesis, we have used Analysis of Variance (ANOVA). The level of significance $\alpha = 0.05$. The value of F-ratio and level of significance is explained in table 3.

Table 3: ANOVA Results for Segmentation Strategies.

Source: As computed by the researcher

It is found that F-ratio value is equal to 26.371. It is statistical significant at 5% level of significance. Given that $p<0.05$, the null hypothesis is rejected which means that there is a significant difference between segmentation strategies and size of the pharmaceutical companies.

The multiple comparisons between three types of companies on the basis of segmentation strategy, using post hoc analysis, are shown in table 4.

Source: As computed by the Researcher

On the basis of post hoc analysis using Tukey HSD, it can be concluded that all the three types of company i.e MNCs, large domestic companies and small & medium domestic companies have significant differences in their segmentation strategy. This is shown in table 4 above.

As clear from table 2 and analysis of data above, there is a difference in segmentation strategies of pharmaceutical companies of all types. Author13 also analyzed the various segmentation bases for different pharmaceutical companies and found the similar results. He found that different companies use different segmentation basis. These bases include demographics, geographic and psychographic. They also concluded that a clear reading of prescriber’s needs, behavior, perceptions and prescribing processes is required to formulate accurate, verifiable segmentation strategies.

But the authors also suggested that the companies must go for integrated segmentation approach according to which the data first of all could be segmented on geographical basis based on priori segmentation technique followed by clustering analysis using demographic, psychographic and geographical variables. The importance of segmentation can also be seen from the results shown by17,18. They have the opinion that by 2020 the current role of the pharmaceutical industry’s sales and marketing workforce will be replaced by a new model as the industry shifts from a mass-market to a target-market approach to increase revenue. The pharmaceutical companies have to focus on infrastructure, so that they can deliver the high quality value to customers19.

Conclusion

There are visible differences in the segmentation strategies followed by different pharmaceutical companies of Madhya Pradesh. Small & medium domestic pharmaceutical companies have very little inclination towards segmentation strategies. MNCs and large domestic pharmaceutical organizations in Madhya Pradesh are following the segmentation strategies but this is also limited to demographic and geographic segmentation mostly. But pharmaceutical companies should not depend upon single segmentation strategies. Due to existence of high competition the companies need to concentrate on almost each and every variable. In pharmaceutical industry, marketing lies and moves around the print promotion and efforts made by the sales force, to move the product to ultimate consumers. Generally, while segmenting the prescriber’s base, strategy of market segmentation is not adopted. The managers and representatives try to fit the market to the product and not product to the market. The same product is promoted to number of heterogeneous prescribers by adopting similar approach. The Integrated segmentation approach analyzes individual prescribing behaviours, demographics, and psychographics (attitudes, beliefs, and values) of prescribers. Although MNCs and large domestic companies are using integrated segmentation to some extent, they must continue to focus on this approach according to which the data first of all could be segmented on geographical basis followed by clustering analysis using demographic, psychographic and geographical variables.

Research Limitations & Direction for Future Research

1. One important limitation relating to the operationalization of the study is the focus of the single industry in geographical areas of Madhya
Pradesh state of India. Future research will need to test whether these results hold across industries situated in other parts of the country.

2. The use of respondents can be another limitation. There are possibilities that perceptual biases may affect the response of the respondents as well as their assessments of the organizational variables. Hence use of multiple respondents is recommended in the future research.

**Ethical Clearance:** The study involves the perception of managers of pharmaceutical companies and did not involve any human trials. So no ethical committee clearance has been taken, although the informed consent has already been taken from them.

Non-Syndromic Impacted Supernumerary Teeth
– A Case Report

Divya Subramanyam

MDS, Pediatric Dentist, No 20, school road, venkateshwara nagar east phase, kodungaiyur, Chennai-600118

Abstract

Presence of impacted supernumerary teeth is quite common clinical phenomenon. However, Failure of eruption of permanent teeth may be attributed to some local and systemic factors. In general, systemic factors are responsible for eruption failure of multiple teeth whereas the local causes tend to affect one or few teeth. In this article, we describe a case of impacted permanent teeth and supernumerary teeth in a 13-year-old boy without any syndrome.

Keywords: Non syndromic, Supernumerary teeth, permanent dentition.

Introduction

Supernumerary teeth (STs) are defined as developmental alterations of number and morphology that result in the formation of teeth in excess of the usual number, which can be found in almost any region of the dental arch, erupted or impacted.1

The prevalence of supernumerary teeth ranges between 0.3-0.8% in the primary dentition and 0.1-3.8% in the permanent dentition.2 The male-to-female ratio for the incidence of supernumerary teeth was reported to range in between 1.18: 1 and 1.5: 1.

The most frequent locations for supernumerary teeth; midline of maxilla, palatal area of upper incisors, lower premolar area, distal of the upper and lower third molars. They are also associated with larger than average teeth which reflect their multifactorial etiology. Various hypothesis has been postulated by the authors to explain the phenomena of supernumerary teeth development, but the exact etiology is still unknown.3 The etiology of supernumerary teeth is not completely understood but both genetic and environmental factors have been implicated in the phenomenon.4 Several theories have been suggested to explain their occurrence such as Atavism, Dichotomy theory, Dental lamina hyperactivity theory.5

Case Report:

A 13-year-old boy was referred to the OP, Department of Pedodontics from the orthodontist with a chief complaint of delayed eruption of lower left permanent teeth. The boy was undergoing fixed orthodontic treatment for the correction of irregular teeth. A thorough general examination was carried out to rule out the presence of any syndrome. Medical and family histories were non-contributory. Extra-oral clinical examination did not detect any abnormalities. Intraoral examination revealed mixed dentition. Radiographic examination revealed presence of supernumerary tooth bud resembling odontome in relation 45 region hindering its eruption (Figure 1-2). Buccal object rule was applied and tooth was found to be in buccal position. On consultation, it was decided to remove both the deciduous teeth (75) and the underlying supernumerary tooth bud surgically, followed by orthodontic alignment of remaining teeth.
The condition was explained to the parents and they agreed for surgical intervention and informed consent was obtained. CARE Guide was used for writing this case report.

Before surgical procedures were carried out, routine blood examinations were done. The results were within normal limit. We planned to perform the operation under local anaesthesia. After adequate anaesthesia was achieved, primary molar was extracted and the underlying impacted supernumerary teeth was removed with an elevator (Figure 3). The extracted socket was closed with sutures after thorough irrigation. (Figures 4-5) Patient was recalled after 7 days for removal of sutures and post-operative check up. The post-operative instructions included use of prophylactic antibiotic coverage, antiseptic mouth rinse and to maintain good oral hygiene. Following extraction, permanent premolar erupted spontaneously within 3 months. The patient is now under regular review regarding fixed orthodontic treatment.

Discussion

Supernumerary teeth are considered to be one of the most significant dental anomalies affecting children and adolescents and they are also known as hyperdontia.7 Supernumerary teeth may be associated with different clinical problems like midline diastema, crowding, malocclusion due to insufficient space, tooth dilaceration, delayed, or failure of eruption of permanent teeth, root resorption of adjacent teeth, cyst formation, cheek bite, periodontal problems, dental caries, and other difficulties related to ectopic position. Earlier diagnosis can help to prevent these complications.8 X-Ray plays an important role in localization of supernumerary teeth, especially when they are impacted and need surgical intervention. Periapical radiographs, occlusal radiographs, and orthopantomogram does provide sufficient information, but accurate position of buccally or lingually placed supernumerary teeth is difficult to determine due to the superimposition by the surrounding structures.9

Clark and Richards had suggested horizontal and vertical tube shift technique, respectively, to determine exact location. Recently, Toureno et al. proposed cone beam computerized tomography technique along with two-dimensional imaging modalities for better assessment of ST.10 Whenever supernumerary teeth are diagnosed, single or multiple, a decision regarding the appropriate management should be made carefully.
Some authors recommend removal of supernumerary teeth as soon as detected, whereas others emphasized periodic monitoring and removal only in the case of any associated pathology or crowding along with esthetical problem and difficulty in oral hygiene maintenance or hindrance to any dental treatment especially the orthodontic treatment.11,12

Hogstrom and Andersson suggested either removal as early as it is identified or after completion of the adjacent tooth’s root formation.11 Early removal can disturb the growth of adjacent teeth. Recently, Omer et al. suggested the optimal time for the removal of ST during 6 to 7 years because during this age period, removal can be done with minimal disturbances to the adjacent teeth.13 In the present case, since the supernumerary tooth caused delayed eruption of underlying permanent premolar problem in relation to 45 and the patient was followed up regularly for fixed orthodontic treatment. The clinical management of multiple supernumerary teeth poses a great challenge to the clinicians. Therefore, it is important to do appropriate consultation and each case should be assessed appropriately.

**Conclusion**

Supernumerary teeth are relatively common and present a variety of complications ranging from crowding to cyst formation. Early identification and proper treatment planning are essential for its management. The practitioner should have thorough knowledge of signs suggesting the presence of supernumerary teeth. On appropriate diagnosis, early intervention is required either the surgical or orthodontic treatment and combination in order to minimize unwanted side effects to the developing dentition. Furthermore, multidisciplinary approach is necessary for the management of supernumerary teeth, if it is associated with complications.

Development of Educational Message through a Mobile Phone SMS to Improve Adherence and Recurrence Prevention in PLWHA

Evi Muslicha1, Nursalam2, Ahsan3

1Master Nursing Student, Faculty of Nursing, Universitas Airlangga,  
2Professor, Faculty of Nursing, Universitas Airlangga, Surabaya, 3Lecturer, Universitas Brawijaya, Malang.

Abstract

Background: A recurrence was the event of re-emergence of symptoms that have previously been progressed. Early detection of signs of deterioration in conditions and discipline of therapy was needed to prevent recurrence. The inquiry of HIV AIDS patients in ART and treatment was still quite high. This study aimed to develop a model of recurrence prevention in improving adherence and reducing recurrence.

Method: This study used the R & D method. Data were collected through questionnaires on 154 patients and FGD with 15 HIV AIDS teams to develop a mobile SMS-based recurrence prevention model, then conducted trials and evaluations. The evaluation was done by the post-test-only control group design method with a simple random sampling technique to get 50 respondents in each treatment and control group.

Results: The trial was conducted in September 2018. Results of the study were the establishment of a recurrence prevention model through educational text messaging contained information on adherence and recurrence prevention. The information provided were adjusted to the level of disease prevention. Mann Whitney test showed that the educational SMS had an effect on medication adherence (p = 0.001) and control compliance (p = 0.038), but this intervention model did not show a significant difference in the nutritional compliance of the control group and the treatment group (p = 0.287). In addition, the results of the study also showed that there was an influence on the psychosexual response with p-value 0.036. Increased compliance and psychosexual response of patients can be an indicator of recurrence and transmission prevention of HIV AIDS.

Conclusion: A mobile SMS-based recurrence prevention model through educational SMS can improve medication adherence and control compliance, improve transmission prevention behavior, and reduce the risk of recurrence in HIV AIDS patients.

Keywords: Recurrence, Adherence, Compliance, HIV, AIDS, Prevention, SMS.

Background

The use of antiretroviral drugs in HIV AIDS patients requires a high level of compliance. Non-compliance with antiretroviral therapy can have a resistance effect so that the drug cannot work optimally or even fail. This situation resulted in obstacles and delays in efforts to prevent and treat HIV epidemics and increase the mortality of people with AIDS. In addition, this can also have an impact on the client's biological response in the form of suppression and relapse of the virological response. The phenomenon that occurs is that the total number of deaths caused by AIDS in East Java is still quite high, around 3,925 cases, and this is largely due to the failure of therapy programs carried out by patients1.

A similar found in Waluyo Jati Kraksaan Hospital, the high number of HIV AIDS cases up to 2017 was not accompanied by a significant increase in the number of PLHIV who were regularly treated, but actually increase the number of client deaths year after year. From the monthly reports of HIV treatment, only around 48.4% or 511 people out of 1055 people living with HIV in Probolinggo District who took a regular ART treatment. In addition, the compliance rate of treatment for HIV-AIDS sufferers who carry out medication and treatment at Waluyo Jati Hospital in Kraksaan also tends to fluctuate every month. Some of them still show compliance rates below 80%. This also has an impact on the high incidence of opportunistic infections and
recurrence in HIV AIDS clients in the hospital, as seen from all the total clients treated only 12% or 62 people who showed CD4 increase and clinical improvement.

The high number of people with HIV AIDS requires an effort to prevent recurrence, as well as controlling and evaluating client compliance. One method that is being developed in improving compliance and facilitating access to HIV AIDS health services is the use of information technology with telehealth and telenursing approaches. Telenursing is part of telehealth. Nurses meet the basic needs of clients by using information, communication and web-based systems. In example, they could use the m-health application for HIV prevention and care, the most common method being SMS or text messaging. Previous studies have evaluated the effect of SMS on HIV disease prevention behavior (period before illness) and patient compliance with treatment (during illness). This study focused on preventing HIV AIDS recurrence (during illness) in addition to evaluating the effect of educational message through a mobile sms on patient’s adherence and recurrence prevention behavior.

**Method:** This research uses qualitative-quantitative method with research and development (R&D) approaches. This study also uses a research design consisting of two stages. The first stage is a descriptive exploration survey, until the development of an intervention model, the second stage is socialization and testing until the preparation of recommendations.

The first stage was the preparation of a mobile SMS-based recurrence prevention models through a descriptive analysis design with a cross-sectional approach. This stage aimed to explored information from the informants to evaluate the risk factors of a recurrence condition, and the implementation of recurrence prevention efforts that had been carried out in RSUD Waluyo Jati Kraksaan. Then followed by compiling and developing a mobile SMS-based recurrence prevention intervention model in HIV AIDS patients. The sample in this research consisted of 154 patients who visited the Clinic and 15 members of clinical teams as participants in the first FGD, taken by total sampling technique. The instruments used to evaluate the risk factors of a recurrence were a knowledge and biopsychosocial questionnaire, as well as focus group discussion guide.

The second stage was a trial and evaluation of recurrence prevention model until recommendations were made. Sample was divided into two groups, which are control and treatment group that consisted of 50 respondents for each group. Sample were taken through simple random sampling. Respondents from the treatment group received regular educational text messaging delivered for a month. The contents of the SMS or text message were about information regarding control and medication schedule, diet and nutrition, and a transmission prevention behaviour, as well as the use of condoms. The participants of the second group discussion were the hospital management team and HIV clinical team at RSUD Waluyo Jati Kraksaan, a total of 12 participants. Then followed by an expert discussion to get an improvement up to formulate recommendations. The instruments used to evaluate the intervention were biopsychosocial questionnaire, and a condom self-efficacy questionnaire.

**Results:** The results showed that based on the evaluation of risk factors for the cause of recurrence, it was found that; 1) Patients’ knowledge about HIV AIDS care and treatment is still lacking, 2) There are still some patients who show maladaptive and anxious psychological responses, 3) Stigma & discrimination are still perceived to be quite high, and 4) Patient compliance in carrying out care and treatment still needs to be improved. Table 1 below also describes the conditions of psychological adaptive responses, social responses, and family support felt by respondents. Most of the patients were in the bargaining stage (80%), this shows that the majority of respondents have been able to go through the denial and anger stages, so that it will be easier for them to accept reality and have more open minds about important information related to their recovery, including in this case the efforts to seek treatment and routine control.

In addition, most of the respondents (79%) showed a good social-emotional responses. Respondents’ assessment of every aspect of family support also showed good results. This is the basis for the development of a mobile SMS-based prevention models by using a mobile SMS education application to be easily accepted, understood, and used by the PLWHA. The SMS education content agreed upon based on the FGD results includes information related to treatment, control schedule, nutrition, and recurrence prevention behavior or condom use.

Socialization and testing of the use of educational SMS was carried out well and followed by 50 PLWHA who were the respondents from the treatment group. The trial was conducted for one month in September 2018 by sending SMS education content every Monday, Wednesday and Friday just before the scheduled medication or the day before the control schedule. Of all the text messages sent to 50 respondents in the treatment group, the researchers received some feedback as the results of the following trials: 21 respondents answered the SMS with a positive response, 7 respondents showed interest in consulting via SMS, and 6 respondents gave a positive response by making phone calls. While others did not reply to the SMS sent by the researcher.

Analysis of the effect of a mobile SMS-based recurrence prevention model found that there was an influence on treatment adherence and control compliance with p value 0.001 for treatment adherence and p value 0.038 for control compliance. A mobile SMS-based recurrence prevention models also showed an effect on psychosexual recurrence response with p value 0.036. However, the results of the analysis also showed that the mobile SMS-based recurrence prevention model had no effect on nutritional compliance and biological recurrence responses, each of which had a p value of 0.287 and 0.587.

The recommendation to develop a recurrence prevention model in accordance with the results of second FGD is that educational message intervention through a mobile SMS can be used as an alternative method to improve adherence and reduce the risk of recurrence.

### Discussion

To increase the benefits of antiretroviral therapy, high retention of care, choosing the right time to initiate ART, and adherence to treatment is urgently needed. Lost to follow up on ARV therapy can cause cessation of therapy, increase the risk of death, make it difficult to evaluate and deliver ARV therapy. If resistance occurs then treatment becomes ineffective and increases the risk of recurrence, so new efforts are needed to fight infection with other drugs. From an economic standpoint, treatment disobedience also results in an increase in medical costs with the high price of substitute drugs and the length of treatment in hospitals. This study have developed a a mobile SMS-based model of HIV AIDS recurrence by focusing on ongoing education, counseling and monitoring activities through short messages / SMS to PLWHA and their families. Prevention of recurrence is modified from the theory of primary prevention models and the stages of preventive stages, include prevention in the period before illness and during illness. There are three stages of prevention; primary, secondary and tertiary prevention, with preventive content based on the care response of HIV AIDS patients including; biological response (addition of BB, lab results, CD4 / VL, and clinical); psychological response (adaptive coping); social response (stigma & family support) and spiritual (worship needs). Several
studies have mentioned the importance of developing telenursing and telehealth in providing comprehensive insight, reducing stress burden caused by disease, improving family function in handling health problems, increasing communication relationships between clients and health care facilities, reporting side effects and supporting the presence of controls.\(^9,12,13\) In addition, Drummond et al. in his research also explained that telehealth-based depression management for PLWHA could lead to effective maintenance, cost effectiveness, and save maintenance operating costs in several locations with equally high levels of client and provider satisfaction.\(^14\) Cost effectiveness and ease of accessibility have made SMS one of the most widely used communication channels in the world.\(^15\) Research on the use of short message services to improve compliance has shown that the use of short message services is more innovative and has cost effectiveness.\(^16\) The use of short message reminder service applications is easier to increase adherence to treatment.\(^17\) This is the basis for the use of telecommunications via SMS or also called telenursing to help nurses in providing comprehensive nursing care, including efforts to prevent and treat HIV AIDS. Nurses and other health workers can use information and data remotely, socialization, education, further counseling and monitoring, and even conduct behavioral change interventions related to compliance and prevention of recurrence.

**Conclusion**

The conclusion of this study is; 1) the patient’s knowledge of HIV AIDS and its medication and treatment is still lacking, there are still some patients who show a maladaptive psychological response, and some patients still show low adherence, 2) compile the development of an SMS education intervention model for HIV AIDS patients containing information messages and reminder of control schedule, treatment, nutrition and behavioral prevention of transmission, 3) Dissemination and trial were going well and all participants were able to understand and use the educational SMS application, 4) Evaluation of the design of recurrence prevention models based on mobile SMS had met the standard function, efficiency and easy to use, 5) Recommended recurrence prevention models can be used as a method to improve adherence and reduce the risk of recurrence.

Abstract

Online advertising gives moment information about the item that we have to purchase and satisfy our everyday needs. The propensity for surfing the clients’ survey in the online networking is presently multi day’s normal highlights among the adolescents. The sharing of item exhibitions in the informal organization is urged by the advertisers to comprehend their clients’ fulfilment and additionally to know whether any trap is seen by the client. This will assist the maker with modifying/enhance the item likewise. The more general society connection the advertiser had with their clients will reflect in enhanced consumer loyalty, when clients audits were certain at that point rehash deals and new deals will extend exponentially. Presently, the general population in littler towns in India can approach purchase quality items and administrations like what individuals in the bigger urban communities approach through web based showcasing. It is evaluated around 60% of online customers would originate from past the main eight vast urban areas¹. After the passage of JIO web supplier, rivalry turned out to be more increased and now clients can get to an enormous measure of information in reasonable expense. This expansion in web infiltration has extended the potential client pool and for the most part among Gen Ys². Additionally, their simple winning limit offered opportunity to purchase their everyday necessities all alone form and satisfy their fantasies. Presently, they feel exceptionally advantageous to shop on the web, since it liberates them from specifically visiting to the store and uses their valuable time in some other fascinating occupations. It is the obligation of the advertisers to give the important item data to these surfers and have balanced contact to build open connection with them to support their business change proportion.

Keywords: Online marketing, Targeted customer, Customer satisfaction, Customer relationship.

Introduction

Web based advertising is an arrangement of instruments and techniques used to showcase items and administrations through web. Through the web we can manage the obscure essences of clients whom we have never met face to face to convey and associate flawlessly. Showcasing is the way toward advancing the items/administrations to the required/directed clients⁵. To distinguish these required/directed clients, enhancing Public Relations (PR) with shoppers is one of the require activity. Devices like sites, email, web-based social networking, web investigation, web indexes, and internet promoting are simply advertising emotionally supportive networks that assistance to assemble and keep up connections and in this manner make deals³. For rousing web based advertising, web/Wi-Fi associations may be available 24 × 7 in all spots with no obstruction in signs and ought to be given essentially less expensive than the overwhelming expense⁵. On the other hand, online advertisers may offer the remote web either free of expense or considerably more affordable; this will grow the turnover of web based promoting into multi overlay and makes our regular daily existence ease. Web based Marketing has unlimited chances and tremendous open space; consequently there is a place for everybody on the web. At the point when think about the developed nations, use of online marketing in India is still in the beginning time.

Online Marketing: Ideal web based showcasing can’t happen without clients. Individuals don’t plan to flop, yet they neglect to design appropriately. The critical step is the reasoning. Take in the privileged insights of site that serves and backings the client to change over their visits in to effective deal. Web based
Marketing gives mindfulness and draws in the clients to satisfy their requirements. You can have the best administration or item on the planet, however in the event that it isn’t known to the planned clients, what is the point? Mindfulness can originate from numerous sources like publicizing, inquiry advancement, referrals, web based advertising, customary promoting, informal showings. In these online days “Expression of mouse showcasing source is a lot quicker reach than all other promoting sources”. Correspondence is a basic segment of showcasing. It makes constructs and continues connections and all relationship lighted with an important association with trust factors. Advertising is tied in with adjusting before offering. Client benefit brings new deals to a close and develops rehash deals. You have to grasp the new idea of individuals to individuals relationship-driven promoting. We are living in a period crunched society that is dependent on prompt delight. Web based advertising serves this “I need now” outlook individuals. The web is the way to prompt data and wish satisfaction.

**Online Marketing Strategies:** Web based promoting technique fabricates organization’s notoriety and introduction online by utilizing an assortment of web apparatuses and arrangements. A site gives an online nearness that enables clients to think about your organization, administrations offered and items that you offer. Through internet advertising the organization name is presented to open. Presently multi day substantial number of potential clients search for data in the web amid their relaxation time. Buyers today are more cognizant and enabled. They have to know, as and trust before they purchase. Put resources into advertising that bolsters pulling in, creating, and holding connections and it will be a speculation that conveys an association for a considerable length of time.

**Various tools used in online marketing:** You can develop your own website and display your details in it. Search engine marketing (SEM), is the process and strategy of getting website exposure online with keywords related to your business. SEM includes pay per click (PPC) and search engine optimization (SEO). Pay per click is an advertisement that shows on web crawler result pages. The sponsor pays when the promotion is clicked by the client and is coordinated to their site or greeting page. PPC takes into consideration about quick introduction on the web and can give abnormal state cost straightforwardness. You can likewise publicize your organization, site, and administrations through long range interpersonal communication pages. A noteworthy reason that ads and substance on person to person communication sites help build up your organization through verbal. It enables you to utilize notoriety administration techniques, draw in with clients and answer questions. By drawing in with your clients, you urge them to share their encounters in the system. Web based showcasing methodologies incorporate email advertising too. Organizations utilize this device to contact current clients by conveying pamphlets, coupons or instructive messages. You can likewise urge new clients to agree to accept your pamphlet or mailing rundown to take in more data about the items or administrations that you give. A site is the present distributing stage, so you are what you distribute. Blogging is one of the most effortless approaches to begin building validity and increment perceivability.

**Benefits of online marketing:**
- 24 by 7 accessibility of data, deals, item bolster, Worldwide perceivability and Direct deals (no requirement for a customer facing facade)
- Targeted showcase (finding and serving individuals who need particular items and administrations with a tick of their fingertips)
- Competitive favourable position (to open new markets, save money on working costs, go out on a limb, get found quicker, associate better and serve/offer harder)
- Customer securing and maintenance are ease in web based promoting than conventional showcasing to pick up and keep clients.
- Savings in expense and HR (computerizing forms, utilizing the web to answer clients’ inquiries, streamlining request handling)
- Immediate following to quantify, streamline and burn through cash where it really matters.
- Growth in potential, Reduced costs, Elegant interchanges, Better control, Improved client benefit, and Competitive favorable position
- **Low costs:** Large gatherings of people are reachable at a small amount of customary publicizing spending plans, enabling organizations to make engaging customer advertisements.
- **Flexibility and accommodation:** Consumers may research and buy items and administrations at their relaxation time.
• Analytics: Efficient measurable outcomes are encouraged without additional expenses.
• Multiple choices: Advertising instruments incorporate pay-per-click publicizing, email promoting and neighbourhood seek reconciliation (like Google Maps).
• Demographic focusing on: Consumers can be demographically focused on substantially more adequately in an online as opposed to a disconnected procedure.
• Online advertising is a basic piece of maintaining an effective business in the present computerized world.

Method

To know the customers’ view, an objective type of questionnaire was prepared and distributed to them who had minimum two online purchasing experiences. The questionnaire was handed over and collected the filled questionnaire personally. The objective of this study is to find out the customers experience regarding their day to day online shopping experience, customers’ satisfaction and relationship with the marketers’ w.r.t different aspects of online marketing. The questionnaire provides the customer an opportunity to express their views and concerns which they face on a regular basis while buying through online. This study will help the marketers to identify the challenges affecting buying behaviour of online customers and to identify the areas where these marketers need to formulate the future policy that further helps in customer retention. The survey reveals a number of interesting facts when we interviewed the respondents. Selected customers in tier II cities namely Madurai, Tiruchirappalli and Coimbatore in Tamil Nadu were the respondents. Let us analyze few responses, which can be taken as a strong indicator for awareness of online marketing, its popularity over time and customers satisfaction/perception towards it.

Objectives of the study: General objectives of this research are to establish the extent to which online marketing is relay on customer satisfaction and customer relationship in the society. The research proposes

a) to evaluate the customer satisfaction and customer relationship in the tier II cities Tiruchirappalli, Madurai and Coimbatore in Tamil Nadu

b) to analyse the pattern of customer satisfaction and customer relationship while purchasing the products through online marketing

c) to ascertain the impact customer satisfaction and customer relationship through social media

d) to study the social media and other online marketing sites that encouraging customer involvement in sharing their online marketing experiences

e) to identify and evaluate the difficulties faced by the online marketing customers

f) to offer suitable suggestions on the basis of the findings of the study for improving the customer satisfaction and customer relationship.

Limitations of the Study: The data for the present study were collected through personal interview method. Since the data collected from three tier II cities in Tamil Nadu who had minimum 2 online purchasing experiences, the possibility of data bias exists and hence, the data collected would only be an approximation of actual facts.

It is clear that two third of consumers are utilizing internet for searching for product information, online shopping, social networks, chatting and news and article reading. This indicates that majority of them aware and involve in online marketing activities.

![Type of Problem faced during online shopping](image)

**Figure: 2 Type of Problem faced during online shopping (120 Responses - out of 720 occasions)**

During online shopping of 120 responses @ average six purchase during last two years i.e, about 720 purchases, they faced 48 times Quality related issues, 16 times delay in delivery, 8 times product damage and 1 time non delivery. Strict Quality control and improved packaging / transportation may avoid all these types of problems. Shoppers have to improve their processes to gain the consumers satisfaction. Through satisfied consumers, we can improve their perception in online marketing.

![Medium preferred by the 120 Pespontents](image)

**Figure: 3 Medium preferred for online shopping (120 Responses).**

Out of 120 respondents, 59% of them prefer cell phones, 23% prefer PCs, 12% prefer Tablets and rest of the 6% prefer I pods. This trend indicates most of them used cell phones for online purchasing and this will rise in future. Based on this information shoppers have to develop their own mobile apps to encourage cell phone users to meet their customers need for expanding their business.

![No of Respondents using Internet - Hrs per day](image)

**Figure: 4 Internet usages (120 Responses).**

Usage of internet for more than 2 Hrs is around 63 %, hence most of them well aware of online marketing in these tier two cities. Since the culture of knowing anything in the internet is in the growing trend, now, it is the shoppers’ responsibility to utilize this changing opportunity to do necessary improvement in online marketing and to gain customer satisfaction.
More than 90% of the respondents are surfing the product information in the net before buying. This shows they utilize all the facility in online marketing like comparing the price, alternative available in the market, users review about the product etc.

Statistics indicates that all the respondents uses internet for their online shopping. This positive trend has to be properly utilized by the online marketers to retain their existing customers as well as to attract new customers.

The response w.r.t major advantages given in the above graph indicates online marketing customers’ view. It is a highly positive sign that show customers had obtained major benefits through online marketing and improves customers’ satisfaction.
Majority of online marketing consumers are facing the following problems in product quality, mismatched/damaged product, delay in delivery, payment risks, returns and trouble free internet connections. Marketers have to ensure strict product quality and flawless payment transition system to improve customers’ trust. For easy return of faulty products, the companies should make the arrangement to collect at the customer doorstep. The government digital India programme will improve the internet/Wi-Fi connectivity, speed and reduce the cost of wireless connection.

**Conclusion and Suggestions**

Shoppers have realized the benefits of online purchasing over purchasing from Brick and Mortars. Consumer purchases are mainly based on the cyberspace appearance such as pictures, image, quality information, and video clips of the product, not on the actual experience. It is much easier for customers to find substitutes from competitors on the internet. This feedback forms the basis of market identification and segmentation that enables marketers to better position their products. With the use of the Internet there can be continuous customer support. Services can be made available through interactive e-mail systems on the net. Companies are now using the Internet to build closer relationships with consumers and marketing partners. The growth online marketing depends to a great extent on effective IT security systems for which necessary technological and legal provisions need to be strengthened constantly. Returns of faulty / unsatisfied products are to be made as simple to improve customers’ satisfaction. For easy accessibility of mobile users, mobile apps to be developed. Customer relationship and cost effectiveness plays critical role for retaining the existing customers as well as to attract new potential customers to penetrate in this online marketing business module. Online marketing has outsold traditional marketing in recent years and continues to be a high-growth industry. Effective online marketing, leverage consumer data, customer relationship management (CRM) systems and ensures increased customers’ satisfaction.

A Study on the Issues of Financial Ratio Analysis

Joy Thomas¹, S. Rabiyathul Basariya²

¹Research Scholar, Department of Management Studies, Bharath Institute of Higher Education and Research, Chennai, ²Associate Professor, Department of Commerce and Business Administration, Bharath, Institute of Higher Education and Research, Chennai

Abstract

Financial statement analysis consists of applying analytical tools and techniques to financial statements in an endeavor to quantify the in operation and money conditions of a firm. The stress of the analysis changes relying upon one’s relationship with the corporate. A analyst extending a short, unsecured loan to an organization can examine the firm’s income and also the liquidity of the company’s assets. A stock capitalist, on the opposite hand, is primarily searching for future growth in income and earnings. Investors generally examine variables which may considerably impact a firm’s money structure, sales, earnings production, and dividend policy.

Keywords: Ratio Analysis, Finance Operating performance, asset management, profitability ratio.

Introduction

Having examined the structure and basic interpretation of the record, earnings report, and statement of money flows within the initial 3 components of this series on budget analysis, we tend to come back to the central issue of however the information is employed in investment analysis. This text can take into account money magnitude relation construction and interpretation with a spotlight on ratios classified into in operation performance and liquidity and money risk classes. The money information accustomed illustrate the ratios are taken from the record and financial gain statements developed antecedently.

Ratio Analysis: Ratios are one in every of the foremost widespread money analysis tools. A magnitude relation expresses a mathematical relationship between 2 things. To be helpful comparisons, however, the 2 values should be connected in how. We’ve got chosen some wide used ratios that ought to be of interest to investors. Like all ratios, a comparison with different corporations in similar industries is helpful, and a comparison of those ratios for identical firm from amount to amount is vital in pinpointing trends and changes¹. It’s additionally necessary to stay in mind that these ratios are interconnected and may be examined along instead of severally.

Operating Performance

Operating performance ratios are sometimes classified into plus management (efficiency) ratios and profit ratios. Plus management ratios examine however well the firm’s assets are being employed and managed, whereas profit ratios summarize earnings performance relative to sales or investment². Each of those classes plan to live management’s talent and also the company’s accomplishments.

Asset Management

Total plus turnover measures however well the company’s assets have generated sales. Industries take issue dramatically in plus turnover; therefore comparison to corporations in similar industries is crucial. Too high a magnitude relation relative to different corporations could indicate too little assets for future growth and sales generation, whereas too low associate plus turnover figure points to redundant or low productivity assets.

Whenever the extent of a given plus cluster changes considerably throughout the analysis, it’s going to facilitate the analysis to reason the common level over the amount. this may be calculated by adding the plus level at the start of the amount to the extent at the tip of the amount and dividing by 2, or within the case of associate annual figure, averaging the quarter-end periods.

Inventory turnover is comparable in thought and interpretation to total plus turnover, however examines inventory³. We got used price of products sold instead of revenues as a result of price of products sold and inventory reach recorded at price. If victimization printed trade ratios for company comparisons make certain
that the figures are computed victimization identical technique. Some services could use sales rather than price of products sold. Inventory turnover approximates the amount of times inventory is employed up and replenished throughout the year. The next magnitude relation indicates that inventory doesn’t languish in warehouses or on the shelves. Like total plus turnover, inventory turnover is incredibly trade specific.

The assets turnover tells us what percentage times every amount the corporate collects (turns into cash) its assets. The upper, the turnover, the shorter, the time between everyday sales and money assortment. A decreasing figure over time could be a red flag. Seasonality could have an effect on the magnitude relation if the amount ends at a time of year once assets are usually high. Specialists advocate victimisation a median of the month ending figures to raised gauge the extent over the course of the year and turn out a figure a lot of cherish different corporations. Once averaging the assets, most investors can need to think about quarter-ending figures to calculate average assets.

Average assortment amount converts the assets turnover magnitude relation into a lot of intuitive unit days. The magnitude relation indicates the common range of day’s due is outstanding before they’re collected. Note that an awfully high range isn’t sensible and a awfully low range could purpose to a credit policy that’s too restrictive, resulting in lost sales opportunities. Purposeful trade comparisons associated an understanding of credit sales policy of the firm are crucial once examining these figures.

Profitability

Long-run investors purchase shares of an organization with the expectation that the corporate can turn out a growing future stream of money or earnings even once finance in rising industries like the web sector. Profits purpose to the company’s long-run growth and endurance. There are varieties of interconnected ratios that facilitate to live the profit of a firm.

Gross profit margin reflects the firm’s basic valuation selections and its material prices. The larger the margin and also the lot of stable the margin over time, the larger the company’s expected profit. Trends ought to be closely followed as a result of they often signal changes in market competition.

Operating ratio examines the link between sales and management-controllable prices before interest, taxes, and reserve expenses. Like the profits margin, one is searching for a high, stable margin.

Ratio is that the “bottom line” margin oft quoted for firms. It indicates however well management has been ready to flip revenues into earnings on the market for shareholders. For our example, concerning 4½ cents out of each dollar in sales flows into profits for the shareholder.

Enterprise comparisons are important for all of the profitability ratios. Margins vary from industry to industry. A high margin relative to an enterprise norm may point to a business enterprise with a competitive gain over its competitors. The advantage may variety from patent safety to a fairly green operation operating close to capability.

Return on total belongings examines the return generated by using the assets of the company. An excessive go back implies the property is effective and properly-controlled. go back on stockholder’s equity (ROE) takes this examination one step similarly and examines the monetary shape of the company and its effect on earnings. Return on stockholder’s equity indicates how much the stockholders earned for their funding inside the Organization. The level of debt (economic leverage) on the stability sheet has a massive effect in this ratio. Debt magnifies the impact of profits on ROE at some point of each precise and horrific year. When large variations between return on overall property and ROE exist, an investor should intently have a look at the liquidity and monetary risk ratios.

Liquidity

Liquidity ratios take a look at how without problems the company should meet its short-term duties, while economic danger ratios take a look at a organization’s ability to satisfy all liability duties and the effect of those liabilities at the stability sheet shape.

The modern ratio compares the extent of the maximum liquid assets (contemporary assets) towards that of the shortest maturity liabilities (cutting-edge liabilities). An excessive modern-day ratio indicates high degree of liquidity and less risk of financial trouble. Too excessive a ratio can also factor to needless funding in modern belongings or failure to accumulate receivables or a bloated stock, all negatively affecting profits. Too low a ratio implies illiquidity and the capacity for being unable to satisfy contemporary liabilities and random shocks like moves which can briefly reduce the influx of cash.

The fast ratio, or acid test, is much like the cutting-edge ratio, but it’s miles a extra conservative degree. It subtracts stock from the current assets side of the
comparisons due to the fact inventory may not usually be quickly converted into coins or may additionally ought to be substantially marked down in charge before it is able to be converted into cash.

Financial Hazard

Times hobby earned, or hobby coverage ratio, is the traditional degree of a agency’s capability to meet its interest payments. Times hobby earned shows how well a company is able to generate income to pay interest. The bigger and more stable the ratio, the less chance of default. Hobby on debt duties need to be paid, regardless of corporation coins flow. Failure to achieve the effects in default, if the lender will no longer restructure the debt responsibilities.

The debt-to-general-assets ratio measures the proportion of assets financed by using all varieties of debt. The higher the percentage and the greater the ability variability of income translates right into a more capacity for default. But, prudent use of debt can increase go back on equity. The debt-to-general-capital ratio is a famous measure of economic leverage, but its name may purpose confusion. Debt for this ratio is composed simplest of long-term debt, no longer general debt. Capital refers to all resources of lengthy-time period financing—long-term debt and stockholder’s fairness. This ratio is interpreted within the identical way as the debt-to-general-assets ratio; a high ratio indicates high chance. However, a low stage might not be an indication of low threat if contemporary liabilities are high.

Conclusion

Economic ratio evaluation is based on historical monetary statements to look at the beyond and develop an experience for a business enterprise’s beauty measured thru factors which include its aggressive role, monetary electricity, and profitability. Information of economic ratios has to provide buyers an experience.

A Study to Analyse the Effect of Exercise in Individuals With Alcohol Withdrawal Syndrome (Aws)

G. Yuvarani¹, V.Vijaya Priya¹, K.Kamatchi¹, G.Tharani¹, G.Vaishnavi¹

¹Assistant Professor, ²Faculty of Physiotherapy, Dr. M.G.R Educational & Research Institute, Chennai – 77.

Abstract

Objective: The aim of the study is to find out the effect of exercise along with medications in individuals with alcohol withdrawal syndrome and to compare their result with individuals taking medications alone for alcohol withdrawal syndrome.

Background of the Study: Worldwide alcohol consumption in 2010 was equal to 6.2 litres of pure alcohol which translates into 13.5 grams of pure alcohol/day. In 2012, about 3.3 million deaths were attributable to alcohol consumption. When someone stops using alcohol after a period of heavy drinking, a sought of symptoms typically includes anxiety, fast heart rate, shakiness, sweating, vomiting and a mild fever. More severe symptoms includes seizures, visual & auditory hallucination and delirium tremens (DTs). The symptoms typically begins around 6 hours following the last drink, and are worst at 24 to 72 hours. There are three stages of AWS. Stage 1(mild), stage 2(moderate) and stage 3 (severe).

The treatment for AWS includes only medical intervention and psychological therapy which has good improvement. This study aims to analysis the effect of exercise along with medical intervention and psychological therapy for better improvement.

Methodology: This was an experimental study design with comparative pre and post study type. Once the study is reviewed and approved by Institutional Review Board, 40 samples among 60 were selected from Turning Point Deaddiction Centre - Maduravoyal. The study includes the samples only if with stage 1, stage 2 AWS and those who are willing to participate in the study. Excludes those with stage 3 AWS, recurrent episodes of seizure, delirious mental state and old age people above 65 yrs. The outcome measure used was a questionnaire CIWA-Ar. After getting the consent, the 40 samples were equally divided and allocated into two groups–group A and group B. Group A received exercise in the form of relaxation exercise, breathing exercise, balance exercise (eg. Frenkel coordination) and low intensity high repetition endurance training along with medications. Group B received medications alone prescribed by consent registered medical practitioners in their rehabilitation centre. The intervention was carried out for 45 days. The exercise intervention for group A carried out for 5 days/week and 2 session/day. The endurance training was progressed once in a week. The post score was recorded. The pre and post data were analysed using SPSS version 21.0.

Result: On comparing the mean value, both the groups showed much reduction in signs and symptoms of alcohol withdrawal syndrome. The pre test mean value for group A is 38.80. After giving them exercise intervention for 45 days, the signs and symptoms reduced to greater extent with the post mean of 9.15. In Group B, the pre and post mean are 38.75 and 19.0 respectively which is significant at P ≤ 0.001. Hence Null hypothesis is rejected. On comparing the post mean of Group A and Group B, Group A showed much reduction in the signs and symptoms of AWS than Group B.

Conclusion: Exercise along with medication shows greater improvement among the individuals with alcohol withdrawal syndrome.

Keywords: Alcohol Withdrawal Syndrome (AWS), Strengthening Exercise, Balance Exercise and CIWA-Ar.
Introduction

Alcohol is a psychoactive substance with dependence producing properties. Numerous consumption of alcohol leads to health problems such as alcohol dependence, liver cirrhosis, cancer and injuries. The harmful use of alcohol ranks among the top five risk factors for disease, disability and death throughout the world. Harmful use of alcohol accounts for 5.9% of all deaths worldwide. Alcohol withdrawal syndrome is a distinctive clinical syndrome with potentially serious consequences such as autonomic hyperactivity, increased tremor, insomnia, visual hallucination, tactile hallucination, auditory hallucination, nausea or vomiting, psychomotor agitation, anxiety and seizures (American psychiatric association 1994). The symptoms usually begins as early as 6 hours following the last drink. The signs and symptoms of AW vary significantly among the alcohol dependent individuals. AW can be categorised into three stages. Mild or early stage, moderate or second stage and severe or third stage. Mild stage usually begins at 6 hours following the last drink and the Symptoms typically includes anxiety, insomnia, restlessness and nausea. Moderate stage withdrawal syndrome occurs within 1 or 2 days following the mild manifestations and the symptoms includes seizures, breathing difficulties and full body rigidity. The seizure caused due to alcohol withdrawal is known as grand mal or generalized tonic-clonic seizure. Severe stage of alcohol withdrawal develops in 1 to 4 days after the onset of early withdrawal symptoms. The severe symptoms includes severe mental disturbance, full body muscle tremors, deep sleep extends more than 24 hours and hallucinations. The withdrawal symptoms in the severe stage may include a dangerous condition called delirium tremens (DT). Severe medical problems may coexist with alcohol withdrawal, which includes altered blood chemistry, certain infection and Wernicke – korsakoff syndrome.

The questionnaire used in this study has much reliability and validity. AUDIT is a ten item scale used in the identification of alcohol dependence. This scales scores for each question ranges from 0-4. A score of 8 or more is associated with harmful or hazardous drinking, a score of 13 (women) and 15 (men) or more is likely to indicate alcohol dependence. It detects 97% of the alcohol-dependent individuals and has a high sensitivity and specificity. AUDIT is easy to use, quick and reliable and can be very useful in detection alcohol problems in sensitive populations. The Clinical Institute Withdrawal Assessment of Alcohol, commonly abbreviated as CIWA-Ar (revised version), is a ten item scale used in the assessment and management of alcohol withdrawal. The ten items evaluated on the scale are nausea and vomiting, tremor, paroxysmal sweats, anxiety, agitation, tactile disturbance, auditory disturbance, visual disturbance, headache and orientation & clouded sensorium. All items are scored from 0-7 where the orientation category scores only 0-4. The maximum score is 67. The CIWA-Ar scale is highly validated and has high inter-rater reliability.

The treatment for AW includes medications like antipsychotic drugs along with benzodiazepine, anticonvulsant and antihypertensives. Many studies had proposed the important role of exercise in the prevention and treatment of addictive disorders. Exercise reduces the depressive symptoms, negative moods and urge to drink in alcohol dependent patients. No studies had proposed the effect of exercise on withdrawal syndrome. Hence this study is focused to find out the effect of exercise in the improvement of AW symptoms.

Method and Materials

Once the study was approved by Institutional Review Board, 40 participants were selected among 60 volunteers from Turning Point Deaddiction Centre, Maduravoyal, Chennai – 95. After the pre test of filling the CIWA – Ar, participants were randomised into two groups (A & B). The samples were included only if with stage 1, stage 2 AWS and those who are willing to participate in the study. Excludes those with stage 3 AWS, recurrent episodes of seizure, delirious mental state and old age people above 65 yrs. The samples were fully explained about benefits of participating in the study and asked to fill the consent form in acceptance with participation of the study which is duly signed by the participants and the researcher.

Group A performed Progressive Muscle Relaxation, Deep Breathing Exercise, Balance & Coordination Exercise and Strengthening Exercise. Progressive muscle relaxation exercise repetitions depends on individual’s relaxation, deep breathing exercise was progressed once in 2 weeks from 3 minutes to 5, 7, 10 minutes, balancing exercise was progressed once in a week and strengthening exercise(low intensity high repetitive) was progressed once in 3 days. The exercise intervention was carried out for 1 session/day for about 45 days. Group B received only the pharmacological treatment which was prescribed by a consent medical practitioner in their rehabilitation centre. The post test was obtained using the questionnaire CIWA –Ar.

(***- P ≤ 0.001)

The above table reveals the Mean, Standard Deviation (S.D), t-value and p-value of the CIWA – Ar between pre-test and post-test within Group – A & Group – B. In CIWA - Ar, there is a statistically high significant difference between the pre test and post test values within Group A and Group B (**- P ≤ 0.001). (Graph-III)

Result: On comparing the mean values of CIWA-Ar, both the groups showed much reduction in signs and symptoms of alcohol withdrawal syndrome. The pre-test mean value for group A is 38.80 and post mean of 9.15. In Group B, the pre and post mean are 38.75 and 19.0 respectively which is significant at P ≤ 0.001. Hence Null Hypothesis is rejected. On comparing the post mean of Group A and Group B, Group A (9.15) shows much reduction than Group B (19.0).

Discussion

Alcohol withdrawal syndrome is a distinctive clinical syndrome with potentially serious consequences such as autonomic hyperactivity, increased tremor, insomnia, visual hallucination, tactile hallucination, auditory hallucination, nausea or vomiting, psychomotor agitation, anxiety and seizures. The treatment for AW includes medications like antipsychotic along with benzodiazepine, anticonvulsant and antihypertensives. Brown et al., in 2009 and Cranston et a., in 2010 proposed that the physical therapy interventions like aerobic exercise and functional training improved the alcohol withdrawal conditions[5,17].

In a previous study, Cranston et al., in 2010 proved that exercise intervention for 80 years old adult experiencing alcohol withdrawal syndrome showed improvement in his functional activities[17]. Beleiter et al., in 1996 suggested that regular alcohol intake affects the neurotransmitter system in the brain, which ultimately leads to functional effect in the brain. This in turn causes neuropathies and myopathies[6]. Jaswinder kaur et al., in 2014 described that Exercise has a beneficial role in treating the neuropathy and myopathy conditions[18].

Lolak S et al., in 2008 proposed that the progressive muscle relaxation technique is effective in reducing anxiety and depressive symptoms in chronic lung patients[19]. The deep breathing exercise increases the oxygen level, which in turns helps the blood vessels in the body to dilate, regulates blood pressure. Breathing exercise plays an important role in the management of panic disorder symptoms, helps to cope up with the shortness of breath, decrease in the accelerated heart rate and relieving muscle tension. Breathing exercise focus towards the rhythm of breath, clearing the anxious, fearful and negative thought of mind[20]. Smania N et al., in 2010 proposed the effect of the balance training in Parkinson’s Disease which improves the Postural instability[21]. Ari R. Assunção et al., in 2016 suggested
that the low intensity high repetition strengthening program improves the muscular fitness in untrained adolescents\cite{22}. Thereby all the previous studies suggests the effect of exercise in improving the symptoms like anxiety, shortness of breath, postural instability and muscular fitness.

In such a way, the present study was conducted to find out the effect of exercise in individuals with alcohol withdrawal syndrome (AWS) with the mean AUDIT of 31.5. It was noticed that progressive muscle relaxation, deep breathing exercise, balance & co-ordination exercise and strength training program showed improvement in the signs and symptoms of alcohol withdrawal syndrome. The selected individuals with the mean of AUDIT was treated with exercise along with medication. Before the exercise intervention the CIWA – Ar mean for Group A was 38.80 and Group B was 38.75. After exercise and medication for Group A and Group B their mean was reduced to 9.15 and 19.00.

**Conclusion:** The result of this study reveals that there is a significant difference in the post-test values of both the groups. The study concluded that the exercise program along with medication was effective in the management of alcohol withdrawal syndrome.

**Acknowledgement:** The authors would like to thank the authorities of Dr. MGR Educational and Research Institute, and the Principal Faculty of Physiotherapy and Managing Director Turning Point Deaddiction Centre, Chennai for providing the facilities required to conduct the study.

**Ethical Considerations:** The manuscript was approved by the Institutional Review Board of faculty of physiotherapy, ACS Medical College and Hospital. All the procedures were performed in accordance with the ethical standards of the responsible ethics committee of both (Institutional and National) on human experimentation and the Helsinki Declaration of 1964 (as revised in 2008).

Evaluation of Positional Accuracy of Conceptually Two Different Die Systems in the Fabrication of Fixed Partial Dentures

G.Vijaya Nirmal1, Narayana Reddy2, Sanjna Nayar3

1Post graduate, 2Professor, 3Professor and Head, Department of Prosthodontics and Crown & Bridge, Sree Balaji Dental College and Hospital.

Abstract

The success of any fixed prosthesis is multifactorial right from preparation to passive fit during cementation, various phases both in clinical and laboratory procedures. Die preparation is a procedure without which the success of any prosthesis is compromised. Different systems have been used for preparing die which serves as a platform for the construction of pattern for future prosthesis. Over the years, these die systems passed various modifications and innovations striving towards precision that governs the fit of any prosthesis. This article evaluates two such systems which evolved independently for their positional accuracy throughout a simulated laboratory procedure.

Keywords: Pindex, UniLock, Die systems, Invitro study.

Introduction

Fixed partial dentures gained its significance with the development of design and material, compatible to the oral tissues. For any fixed partial denture to be fabricated we require an accurate replica of prepared tooth/teeth with adjacent hard and soft tissues in the same planar relation. The master cast should allow visualisation and access to the proximal surfaces for better contouring and placing the margins at the exact finish line. Fabrication of wax pattern on a cast posed with certain difficulties like contouring the embrasures and margins. Proximal surfaces if not accessible leaves over contoured or under contoured restorations. This leads to stagnation of food particles as the sluice ways are not channelized properly. This contributes to the development of periodontal diseases and eventual failure of prosthesis.1 So a system was developed where wax pattern can be fabricated on a separate die on which we get access to all the surfaces and readily can be fixed back on the cast to evaluate the relation between the adjacent structures. Any die system should allow for removal and re-fixing of dies for required number of times from the cast without change in spatial position. There has been a gradual development in the die materials and die systems striving towards eliminating these inaccuracies.

This article compares two conceptually different systems for their positional accuracy even after multiple removals and re-fixings as mandated by the procedure in the fabrication of fixed dental prosthesis.

Materials and Method

Two dentoform moulds were chosen, one maxillary and mandibular. Type IV dental stone was poured and using recommended water powder ratio, twenty defect free casts were taken.

Two commercially available systems were compared.

Uni-Lock Tray system.

This system consists of a mould into which the trimmed cast is fitted and stabilized with plaster or stone over an independent base. The clip running around the tray locks it and the cast or the future dies in position.

Fig.1: UniLock Tray

For this study, the first pour of type IV die stone (ultra rock)2 is allowed to set for 1 hour, and the trimmed master cast is positioned so that the occlusal surface of the die is parallel to the base of the tray.

DOI Number: 10.37506/v10/i12/2019/ijphrd/192069
Once checked for parallelism. A type III dental stone of contrasting colour was poured over the tray and the cast was seated back and allowed to set.

**Pindex System:** This system, designed to drill parallel holes from the underside of the cast, permits the cementation of pins into each removable section. The Pindex system is composed of a precision drill mechanism (aligned drill and a light source) that locates each hole position and automatically stops when hole size and depth are achieved.

For this study, a twin pin (Denerica Dental Corp.,) was cemented in place with cyanoacrylate adhesive (Fevikwik, pidilite). Cast sleeves were then fitted to each cemented pin, the underside of the cast was lubricated, and the base was then poured for each cast with type III dental stone of contrasting colour. Each cast, with its base, was trimmed so that the inferior and superior surfaces were flat and parallel to each other.

Two molar teeth are trimmed in each cast to simulate the prepared teeth. The teeth prepared are 16 & 17 in the maxillary cast and 46 & 47 in the mandibular cast. These prepared teeth are mentioned as **ABUTMENTS** in future reference.

**Fixing of reference points:** Reference points are made with modification of casts. A ball point pen nib and modified 18-gauge wires were used for reference points.

**Movable Reference Points**

This is done on the proximal abutment tooth with a drill done with 702 bur mounted in a lab micromotor (marathon 4) and the nibs are secured with cyanoacrylate. This tooth will be sectioned for removal and re-fixing. This is referred as **REMOVABLE DIE** in future reference.

**Fixed Reference Points:** Distal reference point is made in the distal abutment tooth with a drill done with 702 bur mounted in a lab micromotor (marathon 4) and the nibs are secured with cyanoacrylate. This is used to measure the **ANTERO POSTERIOR DISTANCE**.

![Fig.2: Reference Points.](image)

The **OCCLUSO GINGIVAL HEIGHT** is determined by a modified reference point done with a 19-gauge wire bent at right angles with a triangular base so that the tip comes above the movable reference point. The triangular base is fixed to the UniLock Tray with self-cure acrylic materials.

On Pindex casts the **OCCLUSO GINGIVAL HEIGHT** is determined by modified 19-gauge wire bent at right angles and the base is also bent and secured into a hole drilled with 702 bur on the buccal side of base of the cast.

In Pindex cast, the **BUCCOLINGUAL DISTANCE** is determined by fixing a ball point nib in the lingual surface of the cast in line with the nib on the removable die.

In UniLock cast the **BUCCOLINGUAL DISTANCE** is determined by fixing a modified 19-gauge wire fixed on the lingual side of the tray with self-cure acrylic materials.

**Experiment**

A Travelling microscope provided with cross hairs and mounted in such a way that it can be moved along a base with a screw for making accurate measurements of distance.

![Fig.3: Travelling Microscope.](image)

A Travelling microscope is used to measure the horizontal distance (Bucco lingual and mesio distal) and **vertical distance** (occluso gingival). All measurements were within 10-2, i.e.) 10 micro meters. Each distance was measured three times and average value is chosen.

For vertical measurement the eye piece is tilted horizontally to observe the cast in the vertical plane.

The eye piece is aligned in a way the cross hair is centred with the centre of the ball in ball point nib. And the corresponding readings were noted.

**Sectioning of Dies**

The die is sectioned with a die cutting saw. The first molar tooth is chosen to be removable and the die is referred as removable die. The sections are made near parallel to one another or occlusally diverging. Once the die sections are made post section values are recorded. And the dies are removed and replaced first for ten times and the values are recorded after that. Then the
procedure is repeated for twentieth and thirtieth times and the respective values are recorded. The values were tabulated in a work sheet for further statistical analysis.

Results: The statistical analysis was done using SPSS version 21 software (IBM USA). Independent sample test or Student T test was done to calculate the P values. The total number of samples calculated were kept as 10 for each system. And they were calculated at 5 levels ie) pre-section, post-section, tenth removal, twentieth removal, thirtieth removal.

The first group statistics consists of mean values for Pindex system and UniLock system in the Antero Posterior direction. At presection level the mean values of Pindex and UniLock are found to be 1.1100 and 1.1067 respectively. On comparison the P value is found to be 0.398 which is statistically insignificant, whereas at the thirtieth removal the values for Pindex and UniLock is found to be 1.0930 and 1.10767 respectively which has a P value of 0.024 which is statistically significant.

The second group statistics consists of mean values for Pindex system and UniLock system in the Bucco-Lingual direction. At presection level the mean values of Pindex and UniLock are found to be 0.814 which is statistically insignificant, whereas at the thirtieth removal the values for pindex and UniLock is found to be 0.814 which is statistically significant.

The third group statistics consists of mean values for Pindex system and UniLock system in the Occluso-gingival direction. At presection level the mean values of Pindex and UniLock are found to be 0.758 and 0.851 respectively. On comparison the P value is found to be 0.461 which is statistically insignificant, whereas at the thirtieth removal the values for Pindex and UniLock is found to be 0.761 and 0.848 respectively which has a P value of 0.494 which is statistically insignificant.

In another intra group comparison done between pre-section values and post section at thirtieth removal, In Pindex system at anteroposterior direction the p value recorded as 0.04 is found to be statistically significant. But the same comparison done in the UniLock system yields P value of 0.839 which is statistically insignificant.

The same comparison when done in Bucco-lingual and Occluso-gingival directions in Pindex system shows P values of 1 and 0.987 respectively which are statistically insignificant, In UniLock, the movement in the Bucco-lingual and Occluso-gingival directions also gives insignificant values of 0.964 and 0.973 respectively.
Discussion

This article compares two conceptually different systems. Pindex system which is time tested though gives appreciable accuracy in earlier literatures is cumbersome to use. UniLock tray which has plastic base which confines and controls expansion.

Pindex system uses laser guided precise drills to locate the centre of any tooth or die and holes are drilled for cementation of pins. The pins vary from cross pins with sleeves made of brass, double pins and pins with index in beli St Claire, which has anti rotational features.

The UniLock tray system evolves from AccuTrac system where the dies are locked in horizontal movements but allows for vertical movement. But newer tray systems comes with a spine like arm which locks vertical movement also.

In this study, the sample size is kept as 10 for each. Earlier articles have also chosen the same number of sample sizes with which they were able to get statistically predictable results.

In this study, the measurements were done in three co-ordinates, anteroposterior, mesiodistal and occlusogingival. Earlier studies by Miranda, covo myerset al did with two variables anteroposterior (horizontal) and occluso gingival (vertical). serrano study included all three coordinates Richardson included only horizontal plane.

In another experiment by wee in 2002 to compare the die systems, he used steel balls of 1.98 mm diameter. Ball point pen nibs of 0.7 mm diameter is used in this experiment as reference points.

Earlier experiments used measuring apparatus ranging from scan tunnelling microscope, stereo microscope, travelling microscope, and coordinate measuring machine.

The traveling microscope with sensitivity range of 10 micrometre was used similar to the study by Michael myers who used stereomicroscope with wide filar micrometre graduated to 0.01mm. i.e.) 10 microns. Earlier experiments used micrometre with sensitivity of less than 1 microns also. Though this will increase the sensitivity of the of the experiment at micron level but has little clinical relevance as we have tooth movement in the range of 200 microns and the grain size of the stone is in the range of 15 to 25 microns.

The values were taken at five different stages, pre-section, post-section, after tenth removal, after twentieth removal, after thirtieth removal and was marked on a spread sheet, which is more extensive data collection making the analysis more reliable.

The data from these study reveals differences in each of the stages of reading taken. In the antero-posterior direction the mean values of pre-section(1.1100) and post section(1.11133) shows that in pindex it increases slightly immediately after sectioning and gradually decreases after thirtieth removal(1.09300)

The immediate shift after sectioning results from the expansion of the stone which is attributed to the growth and development of crystalline hemihydrate lattice from the super saturated solution and the accompanying outthrust of the gypsum crystals during setting. It has been said that the energy of crystalline of dental stone leaves residual stresses in the set mass. The release of such forces, however small they maybe, may affect the replacement of divided segments of casts.

This movement though inconsistent shows statistically significant change from the presectioned values (p=0.004). This is in coherent with earlier studies that the horizontal shift is inconsistent. The manual sawing causing the discrepancy which in some casts increased the inter die space might also be a reason for increased antero posterior movement. This is in coherence with the finding of L.V Covo et al which shows the dies sectioned with mechanical die cutter showed less discrepancy than the manually sectioned dies. This may be explained because of the advantage of the mechanical die cutter with thin sectioning diamond disc equipped with dust absorber to prevent debris trapped in the key ways.

The vertical shift in occluso gingival direction in the pindex system shows mid consistent increase as we increase the number of removal times. (see graph)

Though this is statistically insignificant (0.987), this might be because of any debris clogged in the pinhole which would have increased the height. Walter dilts have reasoned this shift to debris clogged in the key hole.

The movement in the Bucco lingual direction is very minimal to insignificant level (P=1). In earlier study by Richardson there was a lingual tilt in one model tray system. But as a double pin is used which has anti rotational feature and the land area raised to 1 mm to prevent theBucco lingual movement.

In UniLock system the antero posterior values shows though inconsistent antero posterior movement, the mean values are statistically insignificant(p=.836)

Even though the same saw was used to section the dies, the vertical slots in the rigid tray prevents further movement.
In buccolingual direction the movement is negligible statistically (.964) as it is locked up in the tray Buccolingually.

In the occluso gingival direction the movement is minimal towards the base. It has a p value of 0.973. This is in contrast with earlier studies which showed other tray system like accuratrac\textsuperscript{5} has statistically significant downward movement and in coherent with study concerning KO tray\textsuperscript{4} where an additional spine is added to prevent the downward movement. Likewise, a horizontal arm is added to prevent the downward movement of the die.

When pindex and UniLock system are compared, in all directions the movement are statistically insignificant except for in the anteroposterior direction where the mean value of pindex system is exceptionally higher in contrast with earlier findings\textsuperscript{6,5,7,12}. It may be due to manual sawing or movement of the pin which is cemented or due to expansion of the base or a cumulative effect of all. This is subjected to further studies.

As Pindex system is more reliable and time tested, the UniLock system which is relatively easy to use yields the same level of accuracy.

**Conclusion**

In the present study two conceptually different die systems were compared for positional accuracy. Within the limitations of the study, it was observed, Pindex system has statistically significant movement in the anteroposterior direction and insignificant movement in the buccolingual and occlusogingival directions. UniLock has no significant movement in anteroposterior, buccolingual and occlusogingival directions. When compared, pindex has statistically significant movement than UniLock system.

Vitamin C Intake Improve the Anthropometric Measurements, Lipid profile and Atherogenic Indices in Obese and Non Obese Females

Ganesh H. Ghanwat1, Ajit V. Sontakke2

1Tutor, 2Professor and HOD; Department of Biochemistry Krishna Institute of Medical Sciences, Karad, Maharashtra (India)-415539

Abstract
Background: Obesity and associated comorbidities are grave problem in India. Vitamin C intake seems beneficial to deal with obesity and associated complications.

Aim and objectives: To study effect of vitamin C intake on anthropometric measurements, lipid profile and atherogenic indices in obese and non obese females.

Materials and method: Total 41 females; (22 obese and 19 non obese), enrolled in this study who received 500 mg vitamin C, thrice a day for 3 months.

Results: Significant decrease in all anthropometric measurements (Except for WHR in obese females), TG, TC, LDL-C and VLDL-C (Except for TC in non obese females), all atherogenic indices and significant increase in HDL-C was observed in all study participants.

Conclusion: Intake of 500 mg of vitamin C, thrice a day for 3 months is effective enough to improve anthropometric measurements, lipid profile and curb atherogenic indices in obese and non obese females.

Keywords: Obesity, Vitamin C, Body Adiposity Index, Castelli’s Risk Indices, Atherogenic Coefficient.

Introduction

Obesity is a major health challenge of the modern world, with increasing rate in adults and children1. This rate is rapid in both developed2 and in developing countries like India3. Women are more prone to develop obesity than men1 and obesity has been stigmatized as most serious public health concern of the era4-5.

Dieting and exercise are two main treatments,6-7 but maintenance of weight loss becomes difficult and requires adoption of lifestyle modifications as an eternal part,8-9 still success rates with such modifications are low7. Medication is another option10 but concerns are raised due to their side effects on many organs11-12. Bariatric surgery seems useful but it is expensive13 and complications occur in most of the cases undergoing surgery14.

So, effective yet invasive solution needed to treat obesity. These days, use of antioxidants becoming popular approach to counteract obesity and associated morbidities15. Therefore, present work was designed to study effect of vitamin C on anthropometry, lipid profile and atherogenic indices in obese and non obese females.

Material and Method

Study design: This randomized trial, was performed during 2015-2016 on participants selected from Krishna Institute of Medical Sciences deemed to be University. Their written informed consent obtained. Utmost care in accordance with Helsinki Declaration16 practiced during work.

Inclusion criteria: Non-alcoholic, non-smoker, apparently healthy, 22 obese and 19 non obese females aged 20-45 years were selected.

Exclusion criteria: Subjects with diabetes mellitus, tuberculosis, malignancy, hepatitis, renal diseases, hypothyroidism, pregnancy, infectious diseases, subjects taking medication or any supplement also excluded.

Anthropometric measurements: Body height measured with standard stadiometer and weight on weighing scale. Waist circumference (WC) and hip
circumference (HC) recorded in duplicate to the nearest 0.10 cm with a stress resistant tape to ensure constant tension during measurement. WC measured at midpoint between lower margin of last palpable rib and top of iliac crest. HC measured around the widest portion of buttocks, with tape parallel to floor. BMI calculated as weight in kilogram divided by height in square meter (Kg/M²) and subjects considered obese if their BMI was ≥25 and non obese if their BMI was ≥18.5 up to 22.917, WHR calculated as waist circumference (cm) divided by hip circumference (cm).

Body adiposity index (BAI) was calculated as, [HC (cm)/Height (m)]1.5-18 and waist to height ratio (WHtR) as waist circumference (cm) divided by their height (cm).

Blood collection and biochemical analyses: After 12 hours of overnight fast, from antecubital vein 5 ml of blood collected in clot vial bulb. Serum separated within 1 hour at 3500 rpm and used for determination of lipid profile, using commercially available kits (ERBA-Mannheim) on EM-360 fully automated analyzer.

Intervention: Participants provided to take 500 mg vitamin C tablets thrice a day for 3 months. Weekly follow up was taken either meeting them or through phone calls.

By using standard method Triglyceride (TG)19, total cholesterol (TC)20-21 and HDL-C22 determined. Plasma very low-density cholesterol (VLDL-C) and LDL-C were calculated by using Friedewald equation as follow: VLDL-C = TG/5 and LDL-C = [(TC)-(HDL-C+VLDL-C)]23

Calculation of atherogenic indices: Atherogenic indices calculated as; Castelli’s Risk Index-I (CRI-I) = TC/HDL-C, Castelli’s Risk Index-II (CRI-II) = LDL-C/HDL-C24, Atherogenic Coefficient (AC) = (TC-HDL-C)/HDL-C25 and Atherogenic Index of Plasma (AIP) = log (TG/HDL-C)26

Statistical analysis: Data analysed using SPSS version 20, applying two-tailed paired and unpaired ‘t’ tests. Differences are considered significant if p<0.05.

Table 1: Vitamin C intake caused improvement in anthropometric measurements, lipid profile and atherogenic indices in obese and non obese females.

Vitamin C intake caused significant decrease in BMI, BAI, WC, HC and WHtR (p<0.0001) in obese females (OF) and BMI (p=0.0014), BAI (p<0.0001), WC (p<0.0001), HC (p<0.0001), WHR (p=0.0491) and WHtR (p<0.0001) in non obese females (NOF) (Table 1).

Likewise, in NOF; TG (p=0.0380), LDL-C (p=0.0002), VLDL-C (p=0.0380) decreased and HDL-C increased significantly (p<0.0001) after intake of vitamin C (Table 1).

Vitamin C intake caused significant decrease in CRI-I (p<0.0001), CRI-II (p<0.0001), AC (p<0.0001) and AIP (p=0.0001) in OF and CRI-I (p<0.0001), CRI-II (p<0.0001) AC (p<0.0001) and AIP (p<0.0001) in NOF (Table 1).
Compared to NOF, in OF the BMI, BAI, WC, HC and WHtR found significantly higher at baseline and in end values with \( p < 0.0001 \), while no difference in WHR \( (p > 0.05) \) (Table 2).

TG, and VLDL-C significantly high in OF at baseline and end \( (p < 0.0001) \) and HDL-C in end value \( (p = 0.0084) \), while no significant difference in TC and LDL-C in baseline and end values (Table 2).

At baseline CRI-I \( (p = 0.0033) \), AC \( (p = 0.0033) \) and AIP \( (p = 0.0002) \) and at end; CRI-I \( (p = 0.0021) \), CRI-II \( (p = 0.0175) \), AC \( (p = 0.0021) \) and AIP \( (p = 0.0001) \) significantly high in OF as compared to NOF (Table 2).

**Discussion**

It observed that, plasma vitamin C is inversely correlated with BMI, WC and WHR. In present study vitamin C caused significant decrease in all anthropometric measurements and ultimately the body mass (Table 1). This finding is supported by previous studies. Vitamin C is a key factor in degradation of fatty acids, which could have reduced fat mass in all study participants.

Higher WHR indicates greater cardiovascular hazard. Therefore, people under age of 40 years should have WHR <0.5 and for people aged 40–50 years the WHR <0.633.

Accordingly, present study indicates higher cardiovascular risk in OF than in NOF and vitamin C intake caused significant decrease in WHR in all of them (Table 1). This signifies beneficial effect of vitamin C on WHR and prolonged vitamin C intake may rationalize insane WHR.

A study showed, association of reduced HDL-C and increased TC, TG and LDL-C with raised coronary artery disease risk. In present study, vitamin C intake provided significant increase in HDL-C in OF and NOF (Table 1), which is supported by previous study. Some studies showed reduction in TC with intake of vitamin C, our result coincides with them (Table 1). A reduction in TG supported by study of Afkhami-Ardekani M. et al (2007). Vitamin C is essential for cholesterol and fatty acids, metabolism which would have decreased TG, TC, LDL-C and VLDL-C in all participants.

Rise in LDL-C is associated with atherogenesis. There observed inverse association of high LDL-C with low plasma vitamin C. In present study LDL-C decreased significantly with intake of vitamin C in both OF and NOF.

These days some novel indices like CRI-I41, CRI-II42, AC43 and AIP44 are used and values of CRI-I >3.5 in males, >3 in females, CRI-II >3.3 and AC >3.0 determine cardiovascular health whereas, AIP between -0.3 to 0.1 indicates low, ≥0.11 to 0.24 medium while >0.24, indicates high cardiovascular risk.

In present study all atherogenic indices reduced with intake of vitamin C, which disagree with previous results. It might be possible that, vitamin C and estrogen had collective effect on atherogenic indices in females.

**Conclusion**

1500 mg/day of vitamin C intake for 3 months is effective enough to sane body mass, lipid profile and curb atherogenic indices in obese and non obese females.

Abstract

Statement of problem:

Purpose: The aim was to investigate the relationship between the inter alar width (IAW) and the distance between the maxillary canines tip and also to determine the relation of the ala of nose and canine on individual side, for different arch forms, to aid in artificial denture teeth positioning.

Materials and Method: A total of 300 dentate subjects aged between 18-30 years, of both genders were selected, among them 150 were males and 150 females. The subjects were divided into three group based on their arch forms that is, square arch, ovoid arch and tapered arch forms. The subjects to be photographed were made to achieve the natural head position (NHP). All photographs were analyzed for inter-alar width. The inter-canine width using Adobe Photoshop-7 professional.

Conclusion: It is concluded that maintaining symmetry while fabricating a complete denture is not mandatory. After observing the data it is suggested that in both males and females for all arch forms teeth arrangement can be made with the alar lines extending distal to the premolar.

Keywords: Inter alar width, Inter canine width, Arch forms, Teeth arrangement.

Introduction

A first time Complete denture wearer desires to have a near similar previous dentate appearance and achieving this is a challenge to the operator but when achieved, surely improves the confidence of the patient¹. The basic important elements to achieve this esthet-ics are the maxillary anterior teeth. So the importance lies in the selection and arrangement of these teeth²³. Over the years, many suggestions have been given by artisans of dental profession regarding the norms, criteria and guidelines for esthetics but, no universally accepted parameter exist for selection of anterior teeth in local population⁴. This study was conducted to investigate the relationship between the inter alar width (IAW) and the distance between the maxillary canines tip and also to determine the relation of the ala of nose and canine on individual side, for different arch forms, to aid in artificial denture teeth positioning.

Materials and Method

The present study was conducted in the Department of Prosthodontics, SDS, KIMSDU, Karad, Maharashtra, India. The subjects were patients of Karad population seeking dental treatment in the college. A total of 300 dentate subjects of both genders were selected, among them 150 were males and 150 females. The subjects were divided into three group based on their arch forms that is, square arch, ovoid arch and tapered arch forms the division into these category was made on the following definition.

- For Square arch form the anterior teeth are straight up and incisal edges are even and approach is straight line.
- The ovoid arch is wider between the canines, the central incisor slant slightly inwards. The lateral incisors overlay the central and are depressed at the neck.

• In tapering form the arch is narrow between the canine to canine the teeth slant out and the incisal edges are forward from the cervical.

Demographic data and informed consent of all the subjects was obtained. The age group of all the subjects was between 18-30 years. The subjects were considered as per the following criteria. The one who is having an apparent esthetics or pleasing smile and having full component of natural teeth without Orthodontic or Prosthodontic treatment and with no overlapping, no spacing, no crowding, no proximal restorations, no abnormal or altered nose.

The subjects to be photographed were made to achieve the natural head position (NHP) by looking at a distinct point. NHP represents a valid cranio-facial reference system with larger inter-individual and intra-individual reproducibility compared to other planes. NHP is considered to be a repeatable and reliable head position and hence is used in the study. It was marked using a spirit level device (fluid level device) on the forehead using a double sided adhesive and a Velcro band(fig 3). Once the desired position was achieved and confirmed, the subject was made to position his/her chin on the custom made stand, by still maintaining the same head position and the photograph was taken using grid system in view-finder of the camera. The digital single lens reflex (DSLR) camera (Nikon D-80-with lens Nikon DX AF-S Nikon 18-135mm) was used to take photographs(fig 1). A smile view was taken at a fixed focal length of 100mm at a fixed subject lens distance of 11 inches using a custom made wooden stand (fig 3). The stand was made such that the distance between the subject and lens remains constant, when the subject rests his/her chin over the chin support of the stand and camera placed on the tripod on the other end of it(fig 2). The grid system in view finder of the camera was used to position the lens with central focus point focusing at the incisal embrasure between central incisors. A face view was clicked to confirm the head position of the subjects against a blue black-ground (fig 2). All photographs were transferred to the computer (Dell) and analyzed using Adobe Photoshop-7 professional. The interalar width was measured from the widest point on the photograph from one side to the other and was recorded. The inter-canine width from one canine tip to the other was measured and recorded. The width of the mouth was measured between the corners of the mouth. To know the relation of ala and canine a perpendicular line was dropped from the widest point of ala to the canine and its relation to the canine tip and was recorded as at the canine tip, mesial to canine tip or distal to canine tip.

Discussion

The study measured and compared the width of the nose with the distance between the tips of natural maxillary canine on the digital photographs in square, ovoid and tapered arch forms. The photograph was used as that would give the real picture as how the person looks when the artificial teeth would be arranged following the nasal width. It has been reported that the width of the nose may be used for selecting the size of anterior teeth, for positioning maxillary canine and for registering the curve of anterior arch4. The Interalar width of total sample showed a mean of 40.66 mm, ranging from 24 mm to 50 mm. The mean Interalar width in males was 44.36 mm and in females was 36.69 mm indicating the influence of male dominance factor. Nelson, latta, weaver and conkin found a mean of 43.93 mm with a range from 29.00 to 63.00 mm5,6 but this was done in the edentulous subjects. Hoffman, bonberg and hatch found a mean of 34.28 mm in dentulous subjects7.

In the present study the mean intercanine width was 36.31 mm, ranging from 27mm to 48 mm. The mean
Intercanine width in males was 38.26 mm and in females was 34.36 mm again indicating the influence of male dominance factor (Table 2). Hoffman, bonberg and hatch found a mean of 35.35 mm.

The alar lines proves, the right and left side of teeth placement are not symmetrical. In both the males and females the alar lines were found to be coinciding maximum distal to premolar. In males the sequence of alar line coinciding from maximum to minimum were found to be distal to premolar then distal to canine then mesial to canine and lastly at canine tip, for square arch forms. It was distal to premolar then at canine tip then mesial to canine and lastly distal to canine for tapered arch forms. For ovoid arch forms it was distal to premolar then mesial to canine then at canine tip and lastly distal to canine.

In females the sequence of alar line coinciding from maximum to minimum were found to be distal to premolar then canine tip and lastly distal to canine, for square arch forms. It was distal to premolar then at canine tip and lastly distal to canine for tapered arch forms. For ovoid arch forms it was distal to premolar then at canine tip and lastly distal to canine. For all the arch forms, no alar line coincided mesial to canine (Table 3).

**Conclusion**

Within the limitations of the study, it is concluded that maintaining symmetry while fabricating a complete denture is not mandatory. After observing the data it is suggested that in both males and females for all arch forms teeth arrangement can be made with the alar lines extending distal to the premolar. This could be done by asking the patient to smile and observe the alar lines during the try-in stage.

Adverse drug reactions (ADRs) occur due to the drugs that are prescribed in acute and chronic or terminal ailments. They are a bane to the healthcare society as they not only challenge the principles of prescribing individual drug candidates but also the prescribing of multiple drugs. This may hold the patient, especially geriatric and pediatric patients, at a high risk of unexpected, undesired and serious events. In the review of current literature, it was observed that it was the commonly prescribed drugs such as hematological agents, anti-hypertensive medications, anti-arrhythmic medications, neuroleptics, proton pump inhibitors and especially Nonsteroidal Anti-Inflammatory Drugs (NSAIDs) that caused most of the ADRs in elderly patients (60 years of age and above). In most cases, the affected systems were the Cardio Vascular System (CVS), the nervous system, the Gastrointestinal (GI) system and the most common symptoms seen were nausea, vomiting, headache, stomach ache, dizziness and vertigo that led to falls. In this article, the occurrence of ADRs due to polypharmacy or Potentially Inappropriate Prescriptions (PIPs) and how they affect children belonging to the pediatric age group (i.e. 16 years and less) were investigated. In this review of literature, it was found that the main reason for ADRs were off-label prescription of drugs. The off-label prescription of drugs refers to the prescription of drugs for a different purpose other than its approved use. Off-label prescription of drugs cause major psychiatric disorders, skin eruptions, enteral problems and some severe reactions like respiratory depression, hypotension, liver failure, seizures, bradycardia, bleeding etc. with the use of drugs such as anti-tussive agents, rhinological agents and GI drugs. Ultimately, it was determined that it was not the age group that determined the occurrence of ADRs, but it was the prescription errors, polypharmacy and drug-drug interaction that caused casualties and inpatient admissions, out of which some cases proved to be fatal.

**Keywords:** Adverse Drug reactions (ADRs), Potentially Inappropriate Prescribing (PIPs), Polypharmacy, Drug-Drug Interactions (DDIs), Geriatric ADR reporting, Pediatric ADR reporting.

**Introduction**

The World Health Organization (WHO) defines the science that involves the detection, assessment, understanding and prevention of Adverse Drug Reactions (ADRs) as Pharmacovigilance (PV). WHO also implies ADRs to be “a response to a drug which is noxious and unintended, and which occurs at doses normally used in man for the prophylaxis, diagnosis, or therapy of disease, or for the modification of physiological function”\(^{(1)}\)

This definition excludes trivial or expected side effects and poisonings or overdose.

The ADRs can occur instantaneously or only after a long period of administration of the drug or even after the stoppage of the drug.

The most common ADRs are due to polypharmacy i.e. simultaneous use of multiple drugs.

ADRs are most commonly divided into:

1. Predictable (Type A or Augmented) reactions
2. Unpredictable (Type B or Bizarre) reactions

Type A reactions are based on the pharmacological properties of the drug. (Mechanism based Adverse Drug Reaction). These are more common and are preventable and reversible.

E.g. bleeding from warfarin or a low therapeutic index, E.g. nausea from digoxin.

Type B reactions are related to the distinct characteristics of the patient and are not dependent on the pharmacology of the drug as such. They are more serious, uncommon and require the withdrawal of the drug immediately and include idiosyncrasy and allergy.

Some examples of Type A and type B reactions are given in Table 1.
Table 1: Type A and Type B reactions to several drugs.

Pharmacovigilance plays a very important role in the drug safety assessment of an individual drug candidate and keeps an account of ADRs provoked by the drugs used to cure diseases. In a the data provided by Food and Drug Association (FDA), it was observed that the rate of ADRs reported in 2006 increased to 20% in 2007 and data collected for 2008 showed a considerable increase of 32% in ADR reporting than compared to 2007 (New FDA Data: Adverse Event reporting Increase Dramatically).

Review of Literature: This literature study was performed to appreciate the trends in the occurrence, detection, identification, monitoring and prevention of ADRs in patients of different age groups and in patients with known co-morbidities who may or may not be under multiple prescribed medications or due to wrong self-medication.

While the data from different sites and demographics was studied, it was observed that the patients who were more than or equal to 60 years of age (geriatric group) suffered from ADRs more than any other age group apart from the terminally ill patients.

A study was performed at the University of Reins, France in the Dementia Management Unit where the patients with Alzheimer’s disease and its associated disorders like Behavioral and Psychological Symptoms in Dementia (BPSD) took part. The observations were recorded by the research team for a period of 19 months where the patients belonged to various socio-demographics, had varied clinical histories and were under different prescriptions of polypharmacy. In this study, it was observed that the drug candidates that showed the maximum ADRs were Angiotensin converting Enzyme (ACE) inhibitors, Antidementia agents, Antiarrhythmic agents and Neuroleptics. (Kanagaratnam et al. (2014))(2)

Different sets of studies were performed at different centers in Italy that showed that ADRs mainly occurred in the patients who were on long term therapy of hematological agents and proton pump inhibitors. The study conducted by Lattanzio MDet al. (2012) showed that the hematological agents like Warfarin, Acenocumarol and some of the proton pump inhibitors were responsible for the ADRs in patients. These ADRs were a result of drug-drug interaction (DDI). (3) Another study by Marengoni et al. (2014) showed that among 506 patients on prospective observation were found to have ADRs due to the commonly prescribed drug candidates that were mainly hematological agents, neuroleptics, respiratory drugs and antibiotics.(4)

Patients with many co-morbidities are often at higher risks of health hazards and suffer from various DDIs and sometimes medication errors. These medication errors may be referred as Potentially Inappropriate Prescriptions (PIPs). Management of such patients becomes challenging due to the co-existing chronic and/or acute health problems. A study conducted by Hedna et al. (2015) with 813 elderly patients showed that almost 374 (i.e. 46.0%) of the patients suffered from drug reactions due to PIPs and 159 (i.e. 19.5%) of them suffered from ADRs. In this case of PIPs and ADRs, it was observed that 60% of these reactions affected the vascular system, 50% were manifestations that affected the nervous system and 62.5% of them led to fall due to the patients’ unstable nervous conditions. The drug candidates that were observed to have such noxious reactions were vasodilators that mainly caused postural hypotension, Neuroleptics, first generation antihistamines and benzodiazepines that caused vertigo and loss of consciousness, which led to falls and fractures. (5)

A study by the World Health Organization (WHO) presented that almost 31% of the deaths caused globally are because of cardiovascular disorders and that 8.5% of the total global population suffers from diabetes. Both of these are chronic form of ailments that can be controlled, but not cured in most of the cases. Cardiovascular disorders and metabolic disorders bring along the co-morbidities that include hypertension, thromboembolism, chronic kidney disease secondary to diabetes mellitus, diabetic neuropathy, etc. All of the conditions that arise secondary to these diseases are known as the co-morbidities. These co-morbidities need a constant management for which multiple medications must be employed simultaneously for individual as well combinatorial therapy and management of them. In a study performed on 186 patients for 640 days by Cristina G et al. (2005), it was found that, out of all the medications that are prescribed in such chronic conditions the most common drug candidates that have been found to show the maximum ADRs were Nonsteroidal Anti-Inflammatory Drugs (NSAIDs), Digoxin, Anti-diabetics, Angiotensin Converting Enzyme (ACE) inhibitors and antibiotics. (6)
A study was conducted by Veehof et al. for a duration of 2 years involving 195 individuals who were studied for a cumulative 247 episodes of ADRs due to polypharmacy. The drugs that majorly caused ADRs were antibiotics, NSAIDs, anti-hypertensives, anti-depressants and diuretics. The most common ADRs that these drugs caused were nausea, vomiting, stomach pain, diarrhea, erythema and headache. These were observed in the elderly patients who had known Chronic Obstructive Pulmonary Disease (COPD), Coronary Artery Disease (CAD), asthma, sleeping disorders and Urinary Tract Infections (UTI). (7) Another study was performed by Pedrós et al. (2015) for a period of 7 years from January 2008 to December 2014 with 28,000 patients in the PV program of Bellvitge University Hospital where out of 30 cases, at least one was ADR and out of all the cases of ADRs, half of them were due to DDIs. The most common form of DDI reactions was Gastrointestinal (GI) bleeding due to anti-thrombotic agents and/or NSAIDs and intracranial bleeding caused due to Vitamin K antagonist. (8)

For this current study, the data of the pediatric age group were also collected from the reported researches worldwide. The worldwide ratio of the pediatric cases was lesser as compared to the ADRs and DDIs in elderly patients.

In the practice of medicine, when required for management of certain ailments, the Food Drug Association (FDA) has approved the prescription of drugs that are typically not used for the treatment of said ailment. Such a practice is known as off-label use/prescription of drugs. A study conducted by Mike Ufer MD et al. (2004) in a worldwide survey of spontaneous ADR reporting in children under 16 years of age. The authors identified 109 non-serious and 49 serious ADRs concerning 79 and 33 patients where none of the ADRs were fatal. Due to the non-approved age or dose, serious ADRs were found more in number and the most commonly found signs and symptoms were psychiatric disorders and mucocutaneous inflammatory reactions. Most commonly suspected groups include which caused ADRs were prescribed drugs: i.e.; antiasthmatics, antibiotics, antiepileptics and psycholeptics/analectics and off-label prescription of drugs such as i.e.; Rhinological agents, anti-tussives and gastrointestinal drugs. (9)

Another study was performed by Turner et al. (1999), which involved the prospective surveillance of five different pediatric wards (surgical, medical, neonatal surgical, cardiac intensive care and general pediatric intensive care units (ICU)) in Alder Hey Children’s Hospital for the patients ranging in age from 1 day to 18 years in which the patients’ ages, dates of birth, diagnoses, drugs administered, routes of administration, doses and indications for use were recorded. 936 of the 1046 admissions received medicines with 4455 drug courses. The admissions to each of the wards were as follows: Surgical - 376, Medical - 331, General ICU- 138, Cardiac ICU - 101, and Neonatal Surgical - 100. The incidence of unlicensed and off-label drug prescriptions was highest in the ICUs and 157 ADRs were experienced by the patients (Table 1), among which electrolyte imbalance was most common ADR found. 17 ADRs were found to be severe (Respiratory depression - 8, Hypotension - 4, Liver failure - 2, Seizures - 1, Bleeding - 1, Bradycardia - 1) and the groups of drugs responsible for the ADRs are shown in Table 2. Table 3: Commonly used drugs observed to cause ADRs.
Rivas et al. (2015), Madrid conducted a prospective cohort study in neonates ranging from ages 0 to 29 days who were admitted to the neonatal department at the Hospital Clínico San Carlos in Madrid (Spain). Demographic characteristics and the data of new drug administrations were recorded by the physicians. A total of 313 patients were included by the authors in the study and the route of administration used were IV (51%), Enteral (19%) and IM (12%). The authors identified 116 ADRs and the majority of the ADRs were experienced in the NICU.\textsuperscript{11}

Following tables enlist the common ADRs (Table 4) and ADRs in newborns (Table 5).

**Conclusion**

In this study, the literature on ADRs reported at various sites was reviewed and it was noted that ADR reporting were higher in elderly patients than in younger ones.

One of the most common reasons behind this observation is the use of polypharmacy, prolonged use of medications for and inappropriate prescription or inappropriate self-medication. ADRs may also be seen in patients who fail to adhere to the prescriptions, in terms of medications, their doses and their schedules of administration.

The ADRs commonly affected the cardiovascular system, musculoskeletal system and the nervous system. Most of the cardiovascular manifestations include myocardial sensitivity to beta-adrenergic drugs, fluctuation in BP, cardiac output and total peripheral resistance. The central nervous system manifestations included changes in weight and volume of the brain and may cause cerebral edema, memory impairment, and loss of consciousness followed by dementia. Some of the ADRs also show a prominent effect on the gastrointestinal system, which may cause an increase in gastric pH, deceased digestion, hampered excretion and reduced peristalsis.

The rate and extent of physiological changes and the response of various body processes like development, metabolism, differentiation, reproduction and homeostasis not only differ in patients of different ages like geriatric patients, adult patients and pediatric patients, but also differs highly on an individual basis. Newborn infants have a much slower rate of metabolism than children from older age groups. The premature babies are more likely to undergo slower metabolism and drug clearance than the normally born infants.

The main principal of dosing and drug selection highly depends on the age group. Different drugs may have different effects in elders and children. During birth, the renal and hepatic functions are not as developed as in adulthood. Drug clearance from the system may slow down and cause accumulation leading to toxicity in infants and small children. Thus, doses are designed based on the tolerability of the body to a dose. All the drugs do not cross the blood brain barrier (BBB), a layer formed by the endothelial cells of brain that allows only polar drugs to pass through. In newborn infants, the BBB is very delicate and many drugs can pass through causing severe CNS manifestations.

The most common pharmacokinetic effects of various drugs that have been observed in pediatric patients are staining of teeth during development of enamel, skin rashes and toxicity due to topical products if they are applied extensively, less distribution of fat soluble drugs due to lack of fat in children and infants. The pharmacodynamic effects may include
hyperkinesias, sedation, and kernicterus by displacement of bilirubin from albumin, hypothyroidism, dystonias and hepatotoxicity.

Some of the drugs may just transfer from breastfeeding of the infant and can cause toxicity due to their inefficient clearance mechanism. Those drugs include amiodarone, aspirin, benzodiazepine, chloramphenicol, ciprofloxacin, oral contraceptives, sulphonylureas, thiazide diuretics and vitamin A/retinoid analogues.

The pediatric medication-use process is complex and error prone owing to multiple steps required in calculating, verifying, preparing, and administering doses.

Assessment Helmet Usage among Two Wheeler Users in the South India

Gulappa. Devagappanavar¹, Pallavi Sarji Uthkarsh²

¹Degree: Master of Public Health (Honors) Project Fellow, Rajiv Gandhi University of Health Sciences, Jayanagar, Bangalore, ²Associate Professor, Rajiv Gandhi University of Health Sciences, Jayanagar, Bangalore

Abstract

Background: In India, road traffic injuries are one of the top four leading causes of death and health loss among persons of age group 15-49 years. The share of two wheelers in total road accidents has increased from 28.8% in 2015 to 33.8% in 2016. Out of total of 52,500 two wheeler riders killed in road accidents during the calendar year 2016, 10,135 two-wheeler riders (19.3%) were reported to be not wearing helmets.

Aims: Mandatory helmet usage law was enforced in January 2016 for both riders and pillions in Bangalore.

Settings and Design: Randomly selected Traffic Junctions of Bangalore city, Karnataka, India. Purposive sampling technique was used to obtain the helmet usage among two wheeler users.

Method and Materials: It is a cross sectional study, where 1471 two wheeler riders, pillions were observed at selected 6 traffic junctions using an observation checklist with different intervals of the time in weekdays and weekends. Information regarding socio demographic details and helmet compliance will be collected.

Results: In observational survey 1471 two wheeler users were observed at the 6 selected traffic junctions, among riders (82.18%) ,pillions (72.82%) wore helmet. Helmet usage (riders-87.64%) (pillions-76.03%) in inner city junction and in outer ring road junction (riders-74.88%) (pillions-55.12%) respectively. helmet usage in weekdays was 6% more than in weekends among riders.

Conclusion: Nearly 20% of riders and 30%of pillions were not wearing helmets. Compliance to ISI (Indian Standard) helmets and buckling of the helmets was poor in both the users.

Keywords: Helmet usage, helmet compliance, traffic junctions, standards of helmet.

Introduction

Road traffic injuries are a major cause of death and disability globally, with a disproportionate number occurring in developing countries. Road traffic injuries are currently ranked ninth globally among the leading causes of disability adjusted life years lost, and the ranking is projected to rise to third by 2020.[1] In India 13 States accounted for 87.8 % of share in persons injured in road accident in the entire country during the calendar year 2016. Tamil Nadu stood on top in persons injured in road accidents in the entire country with a percentage share of 16.6 % followed by Madhya Pradesh 11.7 % and Karnataka 11.0 % respectively.[2] The road accident scenario in Karnataka causes a great concern. More than 10000 persons die every year due to road accident. [3] Nearly 90% of road traffic crashes are due to human errors and faulty human perceptions. Among fifty million plus population cities, Delhi reported highest number of deaths followed by Chennai and Bangalore.[2]

Increasing individual modes of transport, heterogeneous traffic mix, rapid addition of high speed vehicles and less emphasis on the safety of vulnerable road users are some contributing factors. Increasing speeds, non-use of helmets, drinking and driving, poor visibility, failure to implement safety laws and poor trauma care are some factors recognized in India.[4]

The non-usage of seat belts or helmets, single roads and alcohol consumption contribute in majority of severe road traffic accidents.[5]

The most vulnerable group for road traffic injuries is identified as pedestrians, cyclists and those using motorized two and three-wheelers, they account for 46% of the global road deaths.[6]

Two-wheelers being smaller in size and not highly visible on the road make the rider particularly vulnerable...
to crashes. In the event of a two-wheeler crash, the head of the driver or pillion directly hits a mobile or immobile object causing injury. Several studies point to the fact that head is the most commonly injured organ among two-wheeler occupants in case of crashes. It is found that about 40 to 50% of those injured and more than one-third of those killed in two-wheeler crashes are found to have sustained brain injuries such as concussion, contusion and haemorrhage.[6]

Rapid growth in the use of motorized two-wheeled vehicles in many countries has been accompanied by increases in injuries and fatalities among users, but wearing a motorcycle helmet can reduce the risk of death by almost 40% and the risk of severe injury by approximately 70%. Helmet laws should apply to all riders (including children) and specify a helmet-quality standard, but only 44 countries (representing 1.2 billion people) have laws that apply to all drivers, passengers, roads and engine types; require the helmet to be fastened; refer to a particular helmet standard. Those with laws incorporating these characteristics are disproportionately high-income countries in the European Region. This is particularly worrying as the South-East Asia Region and the Western Pacific Region are known to have a high proportion of motorcycle deaths, while in the Region of the Americas the proportion of road traffic deaths among motorcyclists is on the rise increasing from 15% to 20% between 2010 and 2013. Enforcement is critical to the effectiveness of helmet laws, yet only 68 countries rate their helmet law enforcement as “good” (8 or above on a scale of 0 to 10), revealing that urgent attention needs to be given to ensuring helmets are up to standard and properly worn.[7]

Bangalore, a silicon city of India, city is a capital of Karnataka state, which has a vehicular population of about 1.5 million, with an annual growth rate of 7-10% and two wheelers constitute more than 70% of the total volume.[8]

On 1st January 2016 Karnataka state Government made Gazette notification that Karnataka motor vehicles, Rules 1989, in rule 230, for sub rule (1) Every persons while driving or riding (both for rider and pillion riders) a motor cycle of any type i.e to say motor cycles, scooters and mopeds irrespective of brake horse power of the vehicle within the limits of Karnataka state shall wear protective headgear (Helmet).[3]

Compulsory helmet law was enforced in Bangalore (2016) for riders and pillions. So far, no study had been undertaken to evaluate helmet law enforcement in Bangalore. Hence current study had been undertaken.

Objectives of the Study
1. To evaluate the compliance of motorized two wheeler users towards mandatory helmet law.
   1.1 To assess the current compliance of motorized two wheeler users towards usage of ISI standard helmets.
   1.2 To assess the current compliance of motorized two wheeler users towards strapping of helmets.

Materials and Method
(a) Study place: Bangalore, Karnataka, India
(b) Study subjects: Two wheeler riders and pillions at selected traffic junctions of Bangalore city for observational survey.
(c) Study Period: 5 months, July 2017 to December 2017.
(d) Study design: Cross Sectional
(e) Sampling design: Purposive sampling.
(f) Sample Size: Totally 1471 Observations were done by observing two wheeler users at the selected traffic junctions.

(i) Data Collection Tool: Helmet compliance data was collected using a pretested checklist developed based on review of literature.

Method of collection of data: Compliance to Helmet law was assessed by direct observations of two wheeler users at the selected traffic signalled junctions on different timings of the day.

Selection of junctions for observational surveys: Bangalore city has two major traffic divisions such as, East and West. East had Twenty number of traffic divisions and west had Twenty three number of traffic divisions. Further junctions were divided in to outer and inner city junctions.

   Total 6 junctions, three from each division were selected by random sampling method. Out of three selected junctions, two were from inner city junctions and one was from outer city junction. Madivala traffic junction, Wilson garden traffic junction from inner city junction and Konnapana agrahara traffic junction in outer ring road area were selected from East division. AnandRao traffic junction, K R Market traffic junction from inner city junction and Kodigehalli-Hebbala traffic junction in outer ring road area from West Division.

Data was collected by using observational survey to assess the compliance of two wheeler users.
Observational survey: Direct Observation of two wheeler users was done standing at the safest road side at selected traffic junctions during both weekdays and weekends at different timings of the day such as morning 9-10:30 am, afternoon 12-1:30 pm and evening 5-6:30 pm, to ensure the change in traffic volume and traffic composition at different timings of the days.

Both two wheeler riders and pillions in each traffic junctions were observed at traffic junctions when vehicles were stopped for red signal. Riders and pillions of vehicles traveling in one direction and those who have stopped at one side of the curb were observed to avoid confusions. A pretested checklist was used to collect information’s such as, gender, type of vehicle, rider/pillion, helmet/no helmet, type of helmet and strapping pattern.

**Table 5: Gender and Helmet usage among Riders and Pillions in Bangalore.**

Gender vs Helmet Usage: There was no much gender difference in helmet usage as a rider or pillions (table 4) but on the whole, total 3% more helmet usage was found among females (table 5).

Helmet usage in Bangalore before and after Mandatory helmet law for both riders and pillions.

Various studies done to assess the helmet usage among riders before the Mandatory helmet law showed that the prevalence of helmet usage was below 65% in the riders. After the Compulsory Helmet law was enforced in 2016 for riders and pillions, the helmet usage was more in two wheeler users in Bangalore.

**Discussion**

This is the first study to assess the helmet compliance in both riders and pillions in Bangalore after the enforcement of compulsory helmet law for riders and pillions in the year 2016 following Karnataka state Government Gazette notification in January 2016. Nearly 80% of riders wore helmet in Bangalore, where as a observation study done in Bangalore in 2010 by NIMHANS reported that nearly 60% of riders used helmet, showing the increase of 20% since last six years. Usage of helmet among pillions was assessed first time in Bangalore through this study, which reported nearly 70% of pillions using a Helmet.

Where as a study conducted in Delhi, an other city in India showed that 88.4% of pillions wore helmets following the enforcement.[9] This adds to the evidence that legislation and enhanced enforcement increases helmet use while the use decreases when the laws are repealed.[10]

In the current study it was found that helmet usage among riders and pillions was 15-20% more in inner city junctions compared to outer or peripheral junctions, which is similar to a study in Bangalore in 2010.[2] which might be due to highly vigilant police at inner roads compared to outer or peripheral roads.

In the current study it was found that the helmet usage of riders in weekdays 6% more than in the weekends which is similar to the study done in Bangalore in
2010 which is similar studies done in parts of other developing countries like which reported drop in helmet usage over weekends,[11],[12]

In this study it was observed that helmet wearing status among riders and pillions was more in the morning compared to afternoon and evening. which is similar to study done in Cambodia[13], and China.[11]

Not more than half of the riders and one fourth of pillions were using ISI Standard (brand) helmets and more than 30% of them had not strapped their helmets. Similar study done by NIMHANS in 2010 reported that more than half of the riders who used helmets were wearing construction hat like helmets, and many had not strapped helmets, which were more likely to fall off any time.[2] studies done in other low income countries showed that 54% were using non-standard helmets.[14] this might be due to increase cost of standard helmets or lack in strict enforcement of standard helmets. Making standard helmets available at affordable prices can increase helmet ownership while enhanced enforcement can encourage both helmet ownership as well as helmet use.[15]

Conclusion

Helmet compliance among riders and pillions was more after the enforcement of law in 2016 compared to 2010 with variations depending on the type of two wheeler user, timing of the day and type of roads. Compliance to standard helmets and to strapping of helmet was still poor.

Acknowledgement

To begin with it gives me immense gratitude and privilege to thank to Rajiv Gandhi Institute of Public Health and Centre for Disease Control. Rajiv Gandhi University of Health Sciences, Karnataka.

I extend my sincere thanks to Prof. Gangaboraiah, for his kind support and help rendered in statistical analysis.

A Comparative Study on Morbidity Status of Geriatric with Pre Geriatric Population in Rural Area, Tamil Nadu

H. Gladius Jennifer1, M. Bagavan Das2

1Assistant Professor Biostatistics, Department of Community Medicine, Karpaga Vinayaga Institute of Medical Sciences, Chinnakolambakkam, Madhuranthakam, Tamilnadu, 2Professor; School of Public Health, SRM University, Kattankulathur, Tamilnadu.

Abstract

Background: India has acquired the label of “an aging nation” with 7.7% of its population being more than 60 years old. Research on geriatric morbidity and associated factors are required to improve the delivery of health care to the elderly. The awareness should be initiated much in early years 45 to 59 years, but not many studies were available in India. Hence this study was an attempt to study the morbidity status of both groups which may serve as a baseline data and also help in planning the health services. The aim of the study was to find the morbidity pattern and depression status among geriatric and pre geriatric population in field practice area of Karpaga Vinayaga Institute of Medical Sciences, Kancheepuram, Tamilnadu, India.

Method: An observational study conducted in a rural area of kancheepuram district, Tamilnadu, India during the year 2016. 72 Study participants in geriatric and 97 in pre geriatric were enrolled and administered with pre tested, semi structured questionnaire after obtained informed consent. Descriptive statistics were calculated by using SPSS 18V.

Results: Among 72 geriatric people, common morbidity were arthritis (75%), Hypertension (63.9%), cataract (55.6%) and Diabetes (33.3%) which was statistically significant when compare to pre-geriatric(p<0.01). 61% of geriatric had reported more than one chronic illness. In pre geriatric groups, low back pain and other infections almost similar to geriatric which was not significant (p>0.05). The prevalence of depression was almost similar in both the groups.

Conclusions: There is high morbidity rate identified in this present study, similarly depression status was even increased in pre geriatric itself, this implies that need to develop pre geriatric health care services, counseling at primary health centre level at the early years of age.

Keywords: Geriatric, Pre geriatric, Morbidity, Depression.

Introduction

Aging is generally a process of deterioration in the functional capacity of an individual that results from structural changes, with advancement of age.1-3 It is not merely a matter of accumulating years but also a process of “adding life to years, not years to life.” The WHO Theme for the year 2012 was “Good health adds life to years”.1-3 The focus was how good health throughout life could help older men and women to lead a productive life and be a resource for their families and communities.3 India has acquired the label of “an aging nation” with 7.7% of its population being more than 60 years old.2,3 In India geriatric age group was classified as 60 years and above it may vary for other developed countries. The pre geriatric group defined like fifteen years before which was productive or non dependent age groups range from 45 years to 59 years. The inequality in morbidity prevalence among different population groups may not give a true picture because of the influence of subjectivity in measurement of morbidity. The morbidity point of view, at least 50% of the elderly in India have chronic diseases and approximately 35% - 40% percent of pre geriatric age (45 years to 59 years) group suffering with at least one non communicable disease now a days; similarly the prevalence of depression also higher in this age groups, which leads poor quality of life in their

DOI Number: 10.37506/v10/i12/2019/ijphrd/192074
later stages. India made significance improvement in reducing mortality rate in all the age group but morbidity rate is still in query. Early surveillance of these people’s health needs and knowledge of their situation and circumstances are essential to provide cost effective services and to plan strategies for intervention and care. Hence this study attempted. The objective of this study was to compare morbidity pattern and prevalence of depression among geriatric and pre geriatric population in rural area, Tamil Nadu.

**Materials and Method**

The observational study was conducted among geriatric (> 60 years) and pre geriatric population (45 – 59 years) in rural field practice area, Pullipakkam, Kancheepuram district, Tamil Nadu during the year 2016. The ethical clearance was obtained from Institutional Ethical Committee (IEC) and permission was taken from college authorities to conduct this study. 72 study participants were in geriatric group and pre geriatric group 97 participants who were between age group 45 years to 59 years, were selected through Simple Random Sampling techniques and explained the purpose of this study.

Primary Data was collected by pre tested structured questionnaire with Center for Epidemiological Studies Depression Scale by interview method after obtain informed consent. The questionnaire contains the demographic variables such as age, gender, education, occupation, income, SES, employment, religion, marital status, type of family, family support, own property, crisis, social security, any loss etc. Morbidity pattern were assessed system wise and collected information regarding duration of illness, place and cost of treatment and travel distance for treatment. CESD was developed to assess the depression status among people in community based studies and it can be used for all age groups. It has 20 questions assessed within 2 weeks of depression, scores ranges from 0-3 and the total score will be classified as mild, moderate and severe depression.

The data thus obtained was entered and analyzed in SPSS 21v. Descriptive statistics frequency, percentages, mean and standard deviation were calculated. Proportion test was used to find the difference between groups at 5% level of significance.

**Results:** The total number of study subjects was 169. Among them, 72 were geriatric population and 97 were pre geriatric populations for comparison. There were 23.3% males and 76.7% female participants. Most of them were Hindus 91%, Christians 8.3% and Muslim 0.8%. 30.8% were illiterates and 33.8% studied upto primary school level. Among geriatric population 38.9% were widows. Most of them belonged to lower middle class (61.1%) according to Modified Kuppuswamy Classification followed by 30.6% in lower class.

Among geriatric study participants 69.4% of them were living in nuclear family 25 % in joint family and 5.6% extended family. Majority of elderly 80.6% had family support, 77.8% had own properties. Nearly more than 77% of them depend on either their son or daughter. Only 8.3% had Health insurance and 40 % of them were receiving pension whereas 55.6% of them had no social security. Among abuse, verbal abuse (38.9%) was more common than physical abuse (2.9%) and drug abuse (5.6%).

Table 1 shows comparison of morbidity pattern among geriatric and pre geriatric study participants. Hypertension (63.9%), Diabetes (33.3%), Coronary Heart Disease (16.7%), Cataract (55.6%), Osteoarthritis (75%), Asthma or COPD (5.6%), Peripheral Neuropathy (11.1%) were showing significant difference from Pre geriatric population (p<0.01). Where in Low back pain, Reproductive Tract Infection, Urinary Tract Infection, Cognitive Impairment, disability, bowl infections, skin diseases are not showing any difference(p>0.05). Among geriatric population 55.6% of them utilized Primary health centers and 38.9% Government hospitals.

Graph 1 explains the prevalence of depression between the groups, 51% mild and 49% moderate depression among elderly wherein 57% mild, 39% moderate and 4% severe depression among pre geriatric population which was statistically not significant (p>0.05).

Graph 1: Bar diagram showing comparison of depression among geriatric and Pre geriatric population.

p>0.05

Discussion

The present study, the mean age group of geriatric population was 66.9 years and 49.6 years for pre geriatric which was similar in study by Barman et al but contradict to srinivas et al. Among the study subjects, 63.9% and 81.4% of them were females respectively almost similar to Anil et al study. 58.8% of them were illiterates as compared to 78% according to study conducted in Tamilnadu by Piramanayagam et al and Majority of them belonged to upper lower socio economic status according to Modified Kuppuswamy classification which was similarly observed in a study by Quadri et al.

This study revealed that elderly people aged 60 and above were having high burden of non-communicable disease like Hypertension, Diabetes, Cataract and Osteoarthritis. More cases have been reported or diagnosed because of increased literacy rate and frequent screening programs conducted and health education has been given to the study area regarding early diagnosis and prevention of complications. The most common morbidity in elderly was Arthritis (75%) and 63.9% of hypertension which was similarly observed in Anil et al. 55.6% of them had Cataract in our study, which was lower than a study conducted in Bihar (61.25%). However, higher in studies conducted in Andhra Pradesh (20%) and (40.16%) Aurangabad.

This study explained that nearly three or four times more prevalence rate with geriatric when compare to pre geriatric population regarding non communicable diseases such as diabetes, hypertension CHD, cataract and arthritis where in low back pain was almost equal to both the groups which shows that it might have started much early and preventive measures should also be done at the earliest. Peripheral neuropathy was high among geriatric which was almost similar to gill et al reproductive tract infection, urinary tract infection, skin diseases and respiratory infections shows higher among pre geriatric however not statistically significant. Not much studies were available for pre geriatric group, more emphasis are needed in this area.

Conclusion

The current study has highlighted increased prevalence of morbidity and depression status in both geriatric and pre geriatric populations. This explains to us the need to develop and strengthen the health care services in the developing countries like India and provide training to health care providers to manage the commonly existing health problems in the community. Social integration like guidance, counseling to the family members need to be provided. Health professionals need to be oriented regarding the needs.

Relationship Between Diabetes and Periodontitis: A Systematic Review

Rashmi Laddha¹, Austin Howard Jones², Amol Patil³

¹Reader, Department of Periodontics, Dr RR Kambe Dental College and Hospital, Akola, Maharashtra, India, ²PhD guide, Department of Periodontics, Pacific University, Udaipur, Rajasthan, India, ³Professor, Orthodontics Bharati Vidyapeeth Dental College, Pune, Maharashtra, India

Abstract

Periodontal disease and Diabetes Mellitus are two chronic diseases that share a cause and effect relationship with each other. Various studies have found a positive relationship between both of them. Not only the disease progression has negative effect on each other but even the control of the disease and its treatment also causes substantial improvement in the overall disease condition. Hence, it is very important for both the physician and the dentist to understand the relation between periodontitis and diabetes mellitus for overall appraisal of the patients.

Keywords: Diabetes, gingivitis, periodontitis.

Introduction

Chronic periodontitis is defined as the inflammation of gingiva leading to apical migration of the epithelial attachment which further causes loss of connective tissue attachment and alveolar bone¹. It is a result of the interaction between the pathogens and the immune inflammatory response of the host². A new outlook that the periodontal disease has serious insinuation not only on the systemic health but also on the progression and management of systemic diseases which cautions the dental physician to treat periodontal diseases more proficiently in order to improvise systemic health of the patient.

Diabetes mellitus is a metabolic disorder caused due to either due to defective secretion or inactivity of insulin and is mainly characterized by hyperglycemia³. Various clinical and epidemiologic studies have confirmed a positive association between periodontal disease and type 2 diabetes. This article systematically reviews the relationship between periodontitis and diabetes mellitus.

Diabetes mellitus: Chronic hyperglycemia is the most important feature of diabetes mellitus which is supplementary associated with irreversible complications such as retinopathy, nephropathy, neuropathy, peripheral vascular diseases, cardiovascular diseases, delayed healing and periodontal diseases⁴.

The American Academy of Diabetes (1997), defined periodontal disease as the 6th complication of diabetes. Periodontal diseases, including the reversible form (gingivitis), are highly prevalent and affect up to 90% of adults worldwide⁵,⁶.

The Effect of Periodontitis on Diabetes: Recently many investigators have attempted to determine whether the presence of periodontal disease influences the control of diabetes or not. Grossi and others⁷ have suggested that effective control of periodontal infection in diabetic patients reduces the level of AGEs in the serum. The key factor is the level of glycemic control. Tervonen and Karjalainen⁸ followed diabetic patients and nondiabetic controls for 3 years and found that the level of periodontal health in diabetic patients with good or moderate control of their condition was similar to that in the nondiabetic controls and those with poor control had more attachment loss and were more likely to exhibit recurrent disease. This phenomenon has been pointed out by other researchers⁹. From this, it can be concluded that prevention and control of periodontal disease must be considered an integral part of diabetes control. Genetic factor, especially in certain populations such as Aboriginal peoples¹⁰ is also considered to be a very strong factor. There is a 10 time increase in periodontal disease in diabetic patients who have habit of smoking, reported by the study. Contribution of periodontal
infection in insulin resistance and progression of diabetes and its complications is biologically conceivable.

**Effect of Antimicrobial Periodontal Therapy on Metabolic Control of Diabetes:** Yoshihiro et al. in his study on effect of antimicrobial (minocycline) periodontal therapy on serum TNF – α concentration and subsequent metabolic control of diabetes, concluded that antimicrobial therapy notably reduces the number of microorganisms in periodontal pockets. After treatment the circulating TNF – α was appreciably reduced, HbA1c was also reduced significantly. Conventional (non-surgical) periodontal treatment is very effective in diabetic patients.

Certain studies have shown that, if scaling and root planning are combined with systemic doxycycline, there is a marked improvement in the periodontal status of the patient, that significantly improves the glycaemic control, as can be monitored by the glycosylated haemoglobin assay (HbA1c).

**Effect of Periodontal Therapy on Metabolic Control of Diabetes:** A successful periodontal therapy did not result in statistically significant changes in glycemic control in diabetic subjects as been observed in meta-analysis of 10 interventional studies of periodontal treatment. However, most of the studies were small as merely 456 subjects were included.

Larger studies with randomized clinical trials are needed to determine the benefit of periodontal therapy on glycemic control in patients with diabetes mellitus.

**The effects of diabetes on periodontal disease:** Most of the studies have focused on type 2 diabetes, although type 1 diabetes also shows an identical effect on risk for periodontitis. It is considered that the increased risk of periodontitis is dependent on the level of glycemic control. Thus, in well controlled diabetes with HbA1c of around 7% (53 mmol/mol) or lower, there appears to be little effect of diabetes on risk for periodontitis. Diabetes not only increases the prevalence of periodontitis but also affects the extent of periodontitis and the severity of the disease.

The exact mechanism by which diabetes affects periodontal tissues is not fully elucidated. An altered immune-inflammatory response to bacterial pathogens has been suggested. Hyperglycemia affects periodontal tissues by causing imbalance between reactive oxygen species and antioxidants thus resulting in increased oxidative stress, which may eventually lead to accumulation of Advanced Glycation End products (AGE). The binding of AGE to their receptors (RAGE) triggers intracellular events that enhance the production of proinflammatory cytokines, chemokines and cell adhesion molecules.

The contributing factors in increased inflammation of the periodontal tissues in diabetic patients are the accumulation of reactive oxygen species, oxidative stress, and interactions between advanced glycation end products (AGEs) in the periodontal tissues and their receptor (RAGE, the receptor for advanced glycation end products). In diabetes, the disrupted energy metabolism in the tissues in diabetes can lead to changes in apoptosis which can varies depending on the insulin dependency of the particular tissue.

Hyperglycemia results in the formation of AGEs which further make endothelial cells and monocytes susceptible to the production of proinflammatory cytokines. Both diabetes and chronic periodontal disease therefore induce an inflammatory response, whether through AGE or bacterial accumulation, respectively, leading to the production of inflammatory mediators which cause hard and soft tissue destruction. Some authors, have speculated that AGE accumulations in the gingival tissue lead to increased vascular permeability, greater breakdown of collagen fibres, and accelerated destruction of both non mineralized connective tissue and bone.

**Periodontal disease and Pre – diabetes:** Pre-diabetes as defined by impaired glucose tolerance was associated with a higher mean pocket depth and greater alveolar bone loss in men. A study of bleeding following probing in individuals who had not received a diagnosis of diabetes revealed that patients above the median bleeding percentage demonstrated an increased likelihood of impaired fasting glucose or impaired glucose tolerance.

**Hyperglycaemia and cellular stress:** The enhanced susceptibility to periodontal disease in diabetes appears to be primarily driven by an altered host response to the bacterial challenge. Indeed, hyperglycaemia has been shown to contribute to the development and progression of other diabetic complications by exerting stress on multiple cell types critical to the pathogenesis of these complications.

Reactive oxygen species also have more wide ranging effects including effects on bone formation and recently revealed pathways involving the interaction of reactive oxygen species, Wntsignalling and activation of FoxO transcription factors in the regulation of osteoblast
activity suggest another novel pathway which may link periodontitis and diabetes\textsuperscript{25}. Effects on other relevant cell types have also been reported, such as decreased collagen production and increased collagenolytic activity by gingival and periodontal ligament fibroblasts\textsuperscript{26} and a hyper-inflammatory response by oral epithelial cells\textsuperscript{27}.

In summary, the hyperglycaemic state in diabetes has a number of effects on cellular function relevant to the pathogenesis of periodontitis, but the relative contribution of these individual observations remains to be fully determined.

A number of studies focusing on osteoclastogenesis-related factors have reported elevated levels of RANKL in diabetes-associated periodontal tissues\textsuperscript{28}. These studies have proposed that hyperglycaemia may modulate the RANKL/OPG ratio in periodontal tissues and this would, at least in part, explain enhanced alveolar bone destruction in diabetes. Interestingly, the AGE-RAGE axis has also been suggested to contribute to osteoclastogenesis via increased RANKL expression and OPG down-regulation in various cell types\textsuperscript{29}. In summary, evidence from clinical studies of mediators of bone resorption as well as relevant animal models strongly suggest that altered alveolar bone homeostasis is an important pathway in the pathogenesis of periodontitis in diabetes and there is evidence that this pathway may be important in both T1DM and T2DM.

**Mechanisms of interaction between diabetes and periodontal diseases**: Because periodontal diseases are infectious diseases, research initially focused on possible differences in the subgingival microbial flora of patients with and without diabetes. In some early studies it was reported that the periodontal pockets of patients with diabetes showed higher proportions of certain bacteria in, while in later studies involving cultures generally revealed few differences in periodontally diseased sites of subjects with diabetes and those of subjects who did not have diabetes. Because the pathogens associated with periodontitis do not appear to differ greatly in people with and without diabetes, researchers have focused attention on potential differences in the immunoinflammatory response to bacteria between people with diabetes and those without diabetes.

The role of neutrophils in the pathogenesis of periodontitis in diabetic patients has been analysed directly using numerous assays of neutrophil function. Although the dogma is that neutrophil function in periodontitis and diabetes is defective, the evidence obtained has been variable likely due to the variety of assays employed and the technical challenges in quantifying neutrophil function ex vivo\textsuperscript{30}. Importantly, levels of the neutrophil-derived enzyme b-glucuronidase and the neutrophil chemotactic factor IL-8 are depressed in chronic periodontitis patients with T2DM as compared to systemically healthy chronic periodontitis patients which might suggest compromised gingival neutrophil-mediated immune responses in diabetes\textsuperscript{31}.

However, other studies of IL-8 expression in gingival tissue and in GCF did not replicate these findings\textsuperscript{32}. Studies in diabetic rats have provided evidence of compromised gingival neutrophil function in vivo and in vitro\textsuperscript{33} and studies in diabetic mice also suggest changes in gingival neutrophil function\textsuperscript{34}.

Recent evidence suggests that T-cells, which accumulate in insulin sensitive tissues, are important in metabolic disturbances associated with obesity and diabetes, possibly through their ability to regulate macrophage function\textsuperscript{34}. T-cell subsets are diverse and plastic and their function is determined by the local cytokine milieu. However, although there is a substantial role for altered balance of Th1/Th2 cells in the pathogenesis and progression of periodontitis, there is no direct information about its role in periodontitis patients with diabetes.

In summary, evidence for a role of altered monocyte and T-cell function in diabetic patients with periodontitis is limited. The incidence and prevalence of diabetes mellitus have significantly increased in worldwide recent decades, mainly because of the increase in type 2 diabetes mellitus (T2DM). Long-term diabetes results in vascular changes and dysfunction, and diabetic vascular complications are the major cause of morbidity and mortality in diabetic patients. Therefore, the development of better treatments and novel prevention strategies for type 2 diabetes mellitus is a matter of great urgency.

**Conclusion**

Synthesis of existing and future studies will be helpful in elucidating these relationships and provide the direction for public health policies aimed at reducing their burden on the general public.

Sirtuins as Novel Protein Markers in Diabetes and Periodontitis

Rashmi Laddha¹, Austin Howard Jones², Amol Patil³

¹Reader, Department of Periodontics, Dr RR Kambe Dental College and Hospital, Akola, Maharashtra, India, ²PhD guide, Department of Periodontics, Pacific University, Udaipur, Rajasthan, India, ³Professor, Orthodontics Bharati Vidyapeeth Dental College, Pune, Maharashtra, India

Abstract

Sirtuins are a highly conserved family of proteins. The role of Sirtuins in diabetes and inflammation is well established but literature revealing sirtuins role in Periodontitis is very scarce. The present article demonstrates the role of inflammation in diabetes, inflammation and periodontitis.

Keywords: Inflammation, Periodontitis, Sirtuins.

Introduction

Sirtuins are a highly conserved family of proteins. A set of four genes, SIR1–4, replaced the name “MAR” with “SIR”. Sirtuins belong to class III histone deacetylase family of enzymes. There are 7 mammalian sirtuins with distinct protein structure, varied subcellular location, and unique functional properties.¹

The main function of these enzymes is to deacetylate the various proteins that regulate a wide variety of cellular processes regarding protein, carbohydrate and lipid metabolism, mitochondrial homeostasis and programmed cell death mechanisms including autophagy and apoptosis. Among them, SIRT 4 and-6 have an additional ADP-ribosyltransferase activity that is also important in telomere maintenance, genomic stability and longevity.² Sirtuins remove the acetyl groups from lysine residues of histones, transcription factors specific enzymes such as manganese superoxide dismutase and peroxisome proliferator activated receptor–γ (PPR-γ) -coactivator-1α (PGC-1α) and other miscellaneous proteins that have important roles in the cellular homeostasis. As a consequence of the deacetylation, nicotinamide and 2’O-acetyl-ADP ribose are generated.³

Sirtuins & Periodontal Disease: Most of the connective tissue destruction-taking place in periodontal disease results from the interaction of bacteria and their products with mononuclear cells. One possible mechanism to explain as to why diabetics have more severe periodontal disease is that glucose mediated AGE accumulation would affect migration and phagocytic activity of mononuclear and polymorphonuclear phagocytic cells resulting in establishment of more pathogenic subgingival flora.⁴ Evidence has consistently indicated that diabetes is a risk factor for increased severity of gingivitis and periodontitis. Conversely, periodontitis may be a risk factor for worsening glycemic control among patients with diabetes and may increase the risk of diabetic complications. Periodontitis may initiate or propagate insulin resistance in a manner similar to that of obesity, by enhancing activation of the overall systemic immune response initiated by cytokines.⁵

One recent report also demonstrated that the decreased levels of SIRT 3 in the skeletal muscle of streptozotocin (STZ)-induced diabetic mice and high fat-diet-induced obese mice were an important component of the pathogenesis of type 2 diabetes mellitus. SIRT 3 knockout mice exhibited decreased oxygen consumption and increased oxidative stress due to mitochondrial dysfunction via hyperacetylation of complex I and III in OXPHOS, and these factors led to JNK activation and impaired insulin signaling.⁶ In addition, SIRT 3 was shown to decrease the function of a component of complex II via the deacetylation of SDH. Therefore, agents that increase SIRT 3 activity or expression could therefore potentially reverse at least some of the adverse effects of type 2 diabetes mellitus.⁷

Periodontal disease is universally present in human beings. It is the infectious disease of the periodontium. There is an activation of immune-inflammatory mechanisms within the local periodontal tissues which
further causes destruction of collagen and alveolar bone. Clinically, patients present with redness and bleeding of the gingiva, detachment of the soft tissues from the teeth to produce periodontal pockets, and radiographic evidence of loss of alveolar bone height.\(^8\) Progression of disease results in increased tooth mobility, loss of masticatory function, pathological migration of teeth resulting in poor esthetics and tooth loss.

The disease varies in severity from gingivitis to aggressive forms of early onset periodontitis. Gingivitis is a reversible condition if it is controlled within time. It is evident in several forms all of which display early and rapid destruction of the periodontium and management becomes difficult. The issue of a genetic component to the disease experience of different individuals must be taken into consideration. First paradigm explains that all individuals are equally susceptible to one or several pathogenic bacteria; a second paradigm shows that all bacteria are equally dangerous and that host vulnerability determines onset of disease; or a combination of the above. The accumulation of microbial plaque and gingivitis may proceed to periodontitis resulting from immune and inflammatory response which in turn are influenced by his genetic constitution.\(^9\) Bacteria cause inflammation and ultimately periodontal tissues breakdown. Patient’s genetics and environmental modifiers, such as smoking along with bacteria determine the magnitude and quality of tissue changes. The net result of those factors produces clinical severity of disease.\(^10\)

DNA methylation, histone modification and RNA-associated silencing (micro-RNA) are three different types of epigenetic modifications. Immune response of a person makes it susceptible to periodontitis. Decrease in number of neutrophils also increases the susceptibility of infections.\(^11\)

Several environmental factors give rise to the progression of periodontitis. It has been found that alterations in DNA methylation status as a result of environmental stressors begin before birth though some epigenetic marks are potentially reversible.\(^12\) In a study, few DNA were extracted from the gingivae of 108 systemically healthy non periodontitis patient, blood samples from 110 patients with periodontitis and neoplastic tissues from 106 breast cancer patients and then all were tested for the methylation of E-cadherin and cyclo-oxygenase. It was found that in periodontitis patients there was 25% and 19% detection rate of hypermethylation of E cadherin and cyclooxygense and nothing was found in systemically healthy non periodontitis patient (92).\(^13\) Increased level of IL1 and IL1 gene polymorphism increased the susceptibility of individuals to periodontitis. Epigenetics and environmental factors such as diet, diabetes, aging, gender, BMI, race, smoking etc. changed the expression of DNA transcription.

Ari et al. (2016)\(^14\) found higher prevalence of the periodontal disease in India. Authors concluded that DNA methylation and histone modifications occur in the oral mucosa in response to bacteria and inflammatory process. Thus, identification of the genetic factors and epigenetic variations in periodontitis is useful in developing pioneering therapeutic interventions.

The epigenetic changes on pro-inflammatory mediators in periodontal disease have been associated to a number of environmental stimuli such as smoking and nutrition, and the oral bacteria themselves. Iacopino et al (2010)\(^15\) suggested that these changes in the humans can assist in bacterial colonization, increase inflammatory destruction and also offer bacteria with increased levels of carbohydrate for metabolism. They found that these findings have implications for the method used to diagnose periodontal disease and to identify patients at risk. Authors concluded that types of bacteria and epigenetic changes in the periodontal tissues along with bleeding and pocket depths, provides a new approach in management of periodontal problems.\(^16,17\)

Authors showed a lower level of DNA methylation of genes expressing proinflammatory cytokines in chronic or aggressive periodontitis patients as compared to those with a healthy periodontium, resulting in over-expression of these mediators in inflamed tissues.\(^18\)

Epigenetic changes demands excessive study to understand if the methylation status in chronic periodontitis could turn out similar to that in healthy individuals with no history of periodontitis, following an effective periodontal therapy, maintenance, and compliance.\(^19\)

**Sirtuins & diabetes mellitus:** Single nucleotide polymorphisms associated with obesity and Type 2 diabetes have been identified in the SIRT\(^1\) and SIRT\(^3\) genes, suggesting that sirtuins may play a role in the development of these conditions in humans. SIRT 3 has beneficial effects on glucose metabolism by increasing insulin sensitivity and decreasing serum glucose. Hirschey et al.\(^20\) recently demonstrated that high-fat diet feeding induces hepatic mitochondrial protein hyperacetylation in mice and down regulation of the major mitochondrial protein deacetylase SIRT 3. According to the results of this study, increased obesity, insulin resistance, hyperlipidemia, and steatohepatitis are prominent in mice lacking SIRT 3 compared to wild-type mice.\(^20\)
The diagnostic tools and therapeutic approaches, the pathophysiology of diabetes mellitus and cellular defensive mechanisms are unknown. The maintenance of cellular homeostasis requires a well-organized network between glucose, amino acid and lipid metabolism. Sirtuins are a group of NAD+ dependent proteins that are involved in cellular homeostasis due to their deacetylating activity. Of these, sirtuin 1, -3 and -4 have been the most extensively investigated.21

Another important sirtuin involved in glucose metabolism is SIRT4. One of the target enzymes of SIRT4 is glutamate dehydrogenase (GDH) which converts glutamate to α-ketoglutarate in the mitochondrion. SIRT4 inhibits amino-acid induced insulin secretion by repressing GDH. During the fasting state, SIRT4 is inhibited in liver. This induces gluconeogenesis from amino acids and fats and the inhibition of SIRT4 allows insulin secretion from β-cells. However, SIRT4 is activated and the reactions mentioned above are reversed in the fed state.22

It is shown that SIRT3 induces ketogenesis by activating acetylCo-A synthetase in mammalian cells. Hence, one might expect that SIRT3 may play an important role in the increased ketogenesis observed during diabetes mellitus. SIRT1, -3 and -4 play an important role in the pathogenesis of hepatosteatosis which is commonly seen in diabetic patients. When taken together, inhibition of SIRT1 and 3 and/or activation of SIRT4 might be attributed to this heightened risk of hepatosteatosis in the progression of diabetes mellitus. There was an association between the SIRT5 and SIRT6 gene variants with atherosclerosis.23

The low level of sirtuins may lead to DM. Recent studies have shown that therapy targeted at activating SIRT 3 have beneficial effect in patients with DM. Sirtuin 1 has shown to suppress bone break down through the direct activation of FOXO proteins through their deacetylation. The sirtuin has been shown to activate SOD2, resulting in the diminution of oxidative stress and the inhibition of inflammation-mediated bone loss. So, it can be presumed that it might play an important role as therapeutics for inflammation induced periodontal bone loss.24

Caton et al25 analyzed changes in SIRT3 expression in experimental models of type 2 diabetes and in human islets isolated from type 2 diabetic patients. SIRT3 expression was markedly decreased in islets isolated from type 2 diabetes patients, as well as in mouse islets or INS1 cells incubated with IL1β and TNFα. SIRT3 knockdown in INS1 cells resulted in lowered insulin secretion, increased beta cell apoptosis and reduced expression of key beta cell genes. SIRT3 knockdown also blocked the protective effects of nicotinamide mononucleotide on proinflammatory cytokines in beta cells. The deleterious effects of SIRT3 knockdown were mediated by increased levels of cellular ROS and IL1β. Decreased beta cell SIRT3 levels could be a key step in the onset of beta cell dysfunction, occurring via abnormal elevation of ROS levels and amplification of beta cell IL1β synthesis. Strategies to increase the activity or levels of SIRT3 could generate attractive therapies for type 2 diabetes.

SIRT3 expression in skeletal muscle is decreased in models of type 1 and type 2 diabetes and regulated by feeding, fasting, and caloric restriction. SIRT 3 knockout mice exhibit decreased oxygen consumption and develop oxidative stress in skeletal muscle, leading to JNK activation and impaired insulin signaling. This effect is mimicked by knockdown of SIRT3 in cultured myoblasts, which exhibit reduced mitochondrial oxidation, increased reactive oxygen species, activation of JNK, increased serine and decreased tyrosine phosphorylation of IRS-1, and decreased insulin signaling. Thus, SIRT3 plays an important role in diabetes through regulation of mitochondrial oxidation, reactive oxygen species production and insulin resistance in skeletal muscle.26

SIRT 3 might play an important role for the enhanced ketogenesis seen during diabetes. SIRT 1, 3 and 4 play an essential role in the pathogenesis of hepatosteatosis which is commonly seen in diabetic patients. When taken together, inhibition of SIRT 1 and 3 and/or activation of SIRT 4 might be attributed to this heightened risk of hepatosteatosis in the progression of diabetes.

Sirtuins & Inflammation: Metabolism is known to influence aging in rodents and a number of other species of organisms. Several lines of evidence suggest that benefits of calorie restriction are mediated through sirtuins. The most convincing link between aging and sirtuins was established after the effects of aging on NAD+ were studied. In addition to its role as a cofactor in many enzymatic processes, NAD+ regulates key metabolic processes. Sirtuins are NAD+ sensors. SIRT1 and SIRT6 are known aging related sirtuins. Evidence suggests that NAD+ levels are decreased in aging; NAD+ replenishment in aged mice restores mitochondrial homeostasis in a SIRT1 dependent manner. SIRT6 deficient mice show signs of accelerated aging and early death from hypoglycemia. Inflammation defends against severe stress responses and if successful must resolve. SIRT1, known as a major metabolic regulator, epigenetically reprograms inflammation by altering histones and transcription factors such as NFXB.
and AP1. Mounting evidence supports that inflammation sequentially links immune, metabolic, and mitochondrial bioenergy networks; sirtuins are essential regulators of these networks.27

**Several general concepts are relevant to the role of sirtuins in inflammation:**

1. The requirement for NAD+ as cofactor supports sirtuin function in redox and bioenergy sensing.
2. While sirtuin-dependent deacetylation activities dominate our present understanding of the functional roles of sirtuins in inflammation, other attributes such as ADP ribosylation (SIRT4) and removal of succinyl, malonyl, and glutamyl groups from lysine residues (SIRT5) may be important in inflammation Acetyl CoA levels and its support of histone-acetylation and other proteins are linked to nutritional status of cell. Fasted or survival state of cell utilizes protein deacetylation with SIRT. SIRT effects on inflammation can be a double edged sword, since low levels accentuate early acute inflammation-related autotoxicity by increasing NFκB RelA/p65 activity, and prolonged increases in SIRT1 during late inflammation are associated with immunosuppression.28

**Conclusion**

Sirtuins are important proteins which have shown significant role in inflammation, periodontitis and diabetes mellitus. Thus assessment of their level in humans may provide useful information regarding status of periodontium and level of blood glucose.

Hypertension Knowledge and Hypertension Caretaking Behavior of Urban Residents in Pondicherry Region, India

I. Sundar
Associate Professor and Coordinator of Economics Programmes
Directorate of Distance Education, Annamalai University, Annamalai Nagar, Chidambaram, Tamil Nadu,

Abstract
Hypertension is a major health problem in India. Prevention and control of hypertension is urgent need of the hour. The knowledge and awareness on cause of hypertension enables one to find the ways and means of control the hypertension. This paper deals with hypertension knowledge and hypertension caretaking behavior of the urban residents in Pondicherry region. It outlines the indicators on hypertension knowledge and hypertension caretaking behavior and such indicators are quantified with the help of 5 point rating scale. This paper concludes with some interesting findings along with policy suggestions.

Keywords: hypertension knowledge, medication, hypertension care, hypertension control.

Introduction
The study of hypertension is very important and it is a process of increase in the level of normal blood pressure. According to Cunha (2011), hypertension occurs consequent upon over pressure on main arteries and it is a public health problem. The normal blood pressure should be in the range of 120-80 and it also in the range of 140–90. It could be noted that high blood pressure is major health problem and it is called hypertension. In general high blood pressure is caused by aging, excess intake of salt content in the food, lack of moment in the life, genetic factors and occurrence of new diseases in the body.

Puska et al. (2003), report that sedentary life is the outcome of economic growth, modernization and urbanization and such situation results in hypertension. The high blood pressure is associated with obesity and it is the process of accumulation of body fat. Hence there is a need to reduce the consumption level of fat with a view to reduce the obesity condition. According to Stabouli et al. (2011), hypertension occurrence at the early age is associated with overweight and excessive salt intake in food. Moreover excessive intake of alcohol can raise the blood pressure.

Review on the Subject: Bussotti M, and Sommaruga M (2018) report that anxiety and depression are frequent disorders in patients with pulmonary arterial hypertension, but despite this only less than one-fourth of them is treated. Eghbali-Babadi M, Khosravi A, Feizi A, and Sarrafzadegan N (2017), bring to attention that trends in prevalence, awareness, treatment and control of hypertension and the effect of expanded chronic care model on control, treatment and self-care and lack of information about hypertension leads to failure in detection, treatment and reduced estimation of this disease effects. Joseph N1, Chiranjeevi M, Sen S, Singh P1, Saini M, and Beg S (2016), determine awareness, self-management practices and compliance with treatment among hypertensive patients.

Gu J1, Zhang XJ, Wang TH, Zhang Y, and Chen Q (2014) conducted a study on hypertension knowledge, awareness, and self-management behaviors of 3,328 hypertensive patients, including 1,935 females and 1,390 males with a mean age 70.6 years in China. The authors observed that patients who knew that ‘high blood pressure is related to salt intake and were willing to receive regular health education were less likely to fail in hypertension control. The authors concluded that patients who visited clinics because of fear of complications and visited medical institutions other than community health centers for hypertension were more likely to fail in hypertension control.

Aly Z et.al., (2009), conducted a study on 398 individuals with reference to hypertension and stress and the overall awareness of the study population regarding stroke was shown to be inadequate by this study and knowledge was significantly greater in participants of younger age and a higher level of education. Lam AY (2008), examined the medication consultations, hypertension control, awareness, and treatment among
elderly Asian community dwellers. The most prevalent non-adherent behavior reported was self-adjustment of medication dosing. The authors reported that among 65 participants who received HTN medication-related advice, majority of them reported changes in medication therapy and showed significant improvement in BP at six months before and after the self-report. HTN awareness/treatment rates were low in the entire population.

Method and Materials

This study deals with urban residents hypertension knowledge and hypertension care behavior in Pondicherry region. The researcher has selected the 200 urban residents in Pondicherry region, representing different occupational groups. The relevant data are collected from them with the help of interview schedule method, focusing information on hypertension knowledge and hypertension care behavior. The collected qualitative data are quantified with the help of 5 point rating scale. The data interpretation has been done with the help of mean, t test ranking method and Anova two way analysis.

Findings

This section deals with the respondents’ rating on knowledge on hypertension. It can be assessed with the help of 17 factors on a 5 point rating scale. These indicators are individually measured and analyzed. The age wise variation and occupation wise variation among the hypertension patients has been observed.

Table 1: Age Wise Respondents’ Rating on Knowledge on Hypertension.

Hypertension Care

This section deals with the respondents' rating on hypertension care. It can be assessed with the help of 27 factors on a 5 point rating scale. The hypertension care has been measured and analyzed. Based on the analysis age wise variation and occupational wise variation has been observed among the hypertension patients with respect to their level of hypertension care.

Discussion

It could be seen clearly from the above discussion that the respondents have high level knowledge on hypertension by citing the indicators that hypertension caused by excessive stress and fear, over weight is a risk factor for hypertension, high work expectations cause blood pressure, risk of developing hypertension due to family inheritance, increase in blood pressure above 140/90 mm hg is called hypertension and smoking is a risk factor for hypertension as per their secured a mean score above 3.50 on a 5 point rating scale. The respondents have moderate level knowledge on hypertension by citing the facts that hypertension can lead to life threatening condition, both sexes have equal chance of developing hypertension, ageing is greater risk of hypertension, stress causes high blood pressure, hypertension is treatable condition, regular physical exercise reduces hypertension, knowing normal values of blood pressure as 120/80 mm hg and medication can control hypertension as per their secured a mean score in the range of 2.5 to 3.5 on a 5 point rating scale. The respondents have low level knowledge on hypertension by citing the incidences that eating fatty foods is a risk factor for hypertension, hypertension progress along with the age and more salt consumption increases hypertension as per their secured means score below 2.5 on 5 point rating scale.

The findings of respondents’ rating on hypertension care behavior reveal the following facts. The respondents have high level hypertension care by citing the practices that consume diet rich in potassium, practicing yoga therapy, strict diet control, taking care during the time of symptoms of high blood pressure, individuals with increased blood pressure must take their medication in a manner that make them feel good, following a low fat diet, changing lifestyle and maintaining a healthy weight will help prevent hypertension, individuals with increased blood pressure must eat fruits and vegetables frequently and individuals with increased blood pressure must take their medication only when they feel ill as per their secured a mean score above 3.50 on a 5 point rating scale. The respondents have moderate level hypertension care practices by citing the facts that follow doctor advice regarding blood pressure control, reducing worry and anxiety in life, walking frequently, best meat for individuals with increased blood pressure is white meat, individuals with increased blood pressure must take their medication throughout their life, avoiding smoking, checking blood pressure regularly, patients with hypertension should consume antihypertensive medication every day and consume a diet rich in calcium and magnesium as per their secured a mean score in the range of 2.5 to 3.5 on a 5 point rating scale. The respondents have low level hypertension care by citing the practices that leading peaceful life, taking the recommended dosage of medicine, discussing worries with friends, trying to control stress, exercise to reduce weight, drugs for increased blood pressure must be taken every day, reduction in consumption of saturated fat, taking low cholesterol food and following a low salt diet as per their secured a mean score below 2.5 on 5 point rating scale.

Conclusion

It is observed from the study that hypertension knowledge and hypertension caretaking behavior of urban residents in Pondicherry region, India has been influenced by occupational status and educational status of the urban residents. It could be noted that higher the occupational status and educational status, higher the hypertension knowledge and hypertension caretaking behavior and the vice versa. In general old age people need more attention towards their hypertension care behavior.

Suggestions

There is a need to increase the knowledge on hypertension awareness among the old age group respondents, agricultural labor respondents, primary level educated respondents, and female respondents through health awareness generation programmes.

Efforts could be made to increase the hypertension care among the old age group respondents, low level age group respondents and agriculture labor respondents through public health programmes.

Efforts should be made to improve the hypertension knowledge among the women through health workers programmes.

Conflict of Interest: In this study, data collection from the respondents is a laborious work. Many hypertension patients are not in a position to explain their hypertension care behavior and hypertension awareness. In such situation, the researcher faced a lot of difficulties in data collection.

Source of Funding: The author made use of his own money in conducting research, data collection, data analysis and report preparation.

Ethical Clearance: It is a social science oriented method of investigating the hypertension patients and there is no question of ethical clearance.

Attitude Towards Prescribed Drugs in a Rural Training Center of Tertiary Care Hospital in Puducherry: From Patients Perspective

T. Prasad¹, J. Arun Daniel¹

¹Assistant Professor, Department of Community Medicine, AVMC.

Abstract

Background: Patient’s information regarding the usage of drugs isn’t just of indispensable significance in the anticipation of medication related issues, yet in addition a central point that impacts treatment achievement and thus if given, it offers an open door for one to accomplish a full wellbeing potential.

Objective: To reason out patients perspective regarding prescribed drugs and injections.

Materials and Method: The study was carried out among patients attending rural training center at a tertiary hospital in Puducherry. Two hundred and sixty patients, who gave their informed consent, were enrolled by consecutive sampling method. A prevalidated questionnaire regarding knowledge, attitude about prescribed drugs and injections was filled up. Data was analyzed with suitable statistical tests.

Results: 231(88.8%) patients took medications as prescribed by doctors. 226(86.9%) patients preferred low cost drugs since most of them came from low socio-economic status and 140(53.8%) patients were satisfied with medications without injections. Regarding knowledge, 73.8% of patients knew about the adverse effects of prescribed drugs (p value<0.01). 168(64.6%) of patients knew about the adverse effects of injections (p value<0.01) and hence only 80(30.8%) of them requested for injections.

Conclusion: Patients had a positive attitude and knowledge regarding prescribed drugs and injections, while further awareness is needed about prescribed drugs and injections focusing on the patients general education and knowledge adverse drug events to empower them to choose healthier therapies.

Keywords: Attitude, drugs, injections, patients.

Background

Patient’s information regarding the usage of drugs isn’t just of indispensable significance in the anticipation of medication related issues, yet in addition a central point that impacts treatment achievement and thus if given, it offers an open door for one to accomplish a full wellbeing potential. Their insights about the medicine can reflect the communication amongst doctors and patients and the social and dialect contrasts existing between them. Poor comprehension of medicines and trouble in perusing names isn’t phenomenal and may prompt an adverse drug event (ADE). ADEs can be caused by the medications themselves, or result from related factors, for example, incorrect medicines, supply and monitoring of drugs.

Worldwide, ADEs related hospital admissions are on the increase annually and occurs irrespective of inpatients or outpatients. One of the important factor that causes adverse drug events being inadequate basic health literacy among the other various factors. The American Medical Association (AMA) defines health literacy as ‘A constellation of skills, including the ability to perform basic reading and numerical tasks required to function in the health care environment. Patients illiteracy and prescriptions with multiple drugs are more prone for blunders while inadequate or complex instructions adds to the complexity of the adverse drug events.

Doctors’ knowledge and practices regarding therapeutic injections and drugs has been studied in developing countries. The attitudes of patients to injections have
been reported for migrant farm workers in the USA and among Tanzanians. There are very few published data on the views of patients toward prescribed drugs and injections in India, and very little information on this from other places in the developing world. Hence this study was designed to reason out patients perspective regarding prescribed drugs and injections.

Method and Methodology

• **Study Design:** Descriptive Study
• **Study Area:** Rural Health Training Center, Puducherry.
• **Study Duration:** 1 Month
• **Study Population:** Totally Around 260 Patients Selected By Consecutive Sampling Method (On An Average 10 Patients Per Day)

**Data Collection Procedure:** Data will be collected by trained investigator during the scheduled duration of study. Patients knowledge and attitude towards the use of drugs and injections prescribed by doctors will be assessed by pre-designed and pre-tested proforma. Information regarding patients socio-demographic profile will also be recorded.

**Statistical Analysis:** The data will be recorded and analyzed using MS excel. Patient’s attitude and knowledge towards the use of drugs and injections prescribed will be expressed in percentages.

**Results:** Total 260 patients were included in the study among which females were 156 (60%) and males were 104 (40%); mean age group of the patients was 40.79 years. Among the 260 patients, 241(92.6%) patients were married. 192 (73.8%) were old patients and 68 (26.2%) were new patients visiting the health centre. Regarding the education status, 93(35.8%) patients had no formal education and only 46 (17.7%) patients had secondary school education and above. Most of them, around 223 (85.7%) hail from poor and middle socio-economic status according to modified B.G.Prasad’s socio-economic classification. 10

<td>66 (25.4%)</td>
<td>194 (74.6%)</td>
</tr>
</tbody>
</table>

Around 231(88.8%) patients took medications as prescribed by doctors, while 209(80.4%) of patients found difficulty in taking multiple tablets. 226(86.9%) patients preferred low cost drugs since most of them came from low socio-economic status and 140(53.8%) patients were satisfied with medications without injections. Moreover 194(74.6%) had the disbelief that injections alone can cure diseases. More than half of the patients 149(57.3%) sought the help of old prescription for similar complaints suffered before and it was found that 75(28.8%) of patients used to shared their prescribed drugs with their family members for similar complaints. Regarding knowledge, 73.8% of patients knew about the adverse effects of prescribed drugs (p value<0.01) and
this may be one reason why 170(65.4%) patients always consulted doctor for ailments.

Table 4: Patients knowledge and attitude regarding injections.

<table>
<thead>
<tr>
<th>S. No</th>
<th>Factors</th>

<td>168 (64.6%)</td>
<td>92 (35.4%)</td>
</tr>
<tr>
<td>6.</td>
<td>Aware of disease transmitted by unsterile needle/syringe</td>
<td>165 (63.5%)</td>
<td>95 (36.5%)</td>
</tr>
</tbody>
</table>

When it comes to knowledge regarding injections, 168(64.6%) of patients knew about the adverse effects of injections (p value<0.01) and hence only 80(30.8%) of them requested for injections. 165(63.5%) of patients were aware about the diseases transmitted by unsterile needles and syringes with p value <0.01, which was highly significant but still around 95(36.5%) were not aware of any diseases transmitted by unsterile needles and syringes, the reason may be because most of them come from poor socio economic status and education and to some extend since we had new patients who were not given health education. Comprehensively it was found that most of the patients were satisfied with tablets alone than injections.

**Discussion**

Research on adherence has typically focused on the barriers patients face in taking their medications. Common barriers to adherence are under the patient’s control, so that attention to them is a necessary and important step in improving adherence. In responses to a questionnaire, typical reasons cited by patients for not taking their medications included forgetfulness (30 percent), other priorities (16 percent), decision to omit doses (11 percent), lack of information (9 percent), and emotional factors (7 percent); 27 percent of the respondents did not provide a reason for poor adherence to a regimen.11 Physicians contribute to patients’ poor adherence by prescribing complex regimens, failing to explain the benefits and side effects of a medication adequately, not giving consideration to the patient’s lifestyle or the cost of the medications, and having poor therapeutic relationships with their patients.12-15

To improve the patient’s ability to follow a medication regimen, all potential barriers to adherence need to be considered. An expanded view that takes into account factors under the patient’s control as well as interactions between the patient and the health care provider and between the patient and the health care system will have the greatest effect on improving medication adherence.16,17 One might suggest that good medication knowledge could possibly bring about more positive attitude and consequently better compliance in the general population, as reported in several studies.18,19

In this study only 50% considered injections superior to tablets even though many patients did not have any formal education and nearly 63.5% of them were unaware of diseases transmitted by unsterile needles in compared to a study conducted in Pakistan where 64% considered injections to be more powerful than tablets which too had poorer and less educated patients tending for more injections and having less knowledge regarding the risks of injections with unclean needles.20 The attitude of the patients regarding injections were rather balanced and open, an injection was regarded neither as a panacea nor as the only viable treatment. Study conducted at Africa, very few people consulted doctor for advise, whereas in this study 65.4% consulted doctor for advice which is well appreciated. In a study done in Portugal the level of knowledge about drug therapy was considered good in 11.3% of participants21 while the percentage of patients was higher in this study around 73.8% were aware of side effects of drugs, the reason mainly by repeated health education given to them.

**Conclusion**

Patients had a positive attitude and knowledge regarding prescribed drugs and injections, while further awareness is needed about prescribed drugs and injections focusing on the patients general education and knowledge, adverse drug events to empower them to choose healthier therapies.

Artificial Intelligence: A Tool For Medical Diagnosis & Treatment a Narrative Review

Jissa Donel

Nursing Tutor, College of Nursing, All India Institute of Medical Sciences, Raipur

Abstract

Artificial intelligence is gaining significant momentum in healthcare and is forecast to have the potential to transform the industry, as well as the way practitioners interact with their patients. AI is bringing a paradigm shift in the healthcare sector, powered by the increasing availability of health care data and rapid development in analytical techniques. The use of AI in healthcare will go far forward turning data into useful and actionable information that benefits the health and care of patients. Several researches had been conducted and many randomized control trials are in progress around the globe using various AI technologies to find out the extensive scope of artificial intelligence in clinical diagnosis and treatment. This review summarizes the recent research studies that utilizes artificial intelligence and its contribution to health care.

Keywords: Artificial intelligence, Diagnosis, Treatment of diseases, Health care.

Introduction

According to the father of artificial intelligence, John Mc Carthy, AI is the science and engineering of making intelligent machines, especially intelligent computer programmes. Concept of AI is developed by incorporating the study results of how a human brain thinks, analyses, and takes decisions etc when trying to solve out a problem. Based on this, intelligent softwares and algorithms are formulated. AI is defined as the study of algorithms that gives machines the ability to reason and perform cognitive functions such as problem solving, object and word recognition and decision making. It is a combination of different technologies that enables machines to sense, comprehend, act and learn so that they can perform administrative and clinical health care functions. (1,2)

Impact of Artificial Intelligence In Healthcare:

AI is after all an extension, a by-product of the natural intelligence which Homo Sapiens are endowed with. AI in health care focuses on converting data generated in care settings into usable and actionable information that benefits health and care of patients. Health care industry is a data rich industry driven by digital health, image capture, wide spread electronic health record adoption etc. Nurses have been diligently entering data while documenting patient’s care and treatments. Healthcare witnessed an exponential growth in the data.”Big Data” refers to extremely large data sets that cannot be analysed and interpreted using traditional data processing method. (4) According to Harvard Business Review, 30% of world’s electronic data storage is occupied by health care information. (5) Statistics revealed that an average person will leave a trail of more than 1 million gigabytes of health related data in their life time. (6) All these big data of healthcare industry can be extracted first, and secondarily aid as a guide in aiding clinicians in delivering standard care to the patients and thus improving the quality of clinical practice. Processing of these data offers the promise of unlocking novel insights and accelerated breakthrough in health care industry.
**Contribution of Artificial Intelligence In Diagnosis And Treatment of Diseases: A Review Through Recent Research Contributions**

Powerful AI techniques can unlock clinically relevant information hidden in the massive amount of data which in turn assists in clinical decision making. AI technologies have been extensively utilized in areas like oncology, cardiology, orthopaedics, neurology, obstetrics & gynaecology surgery, ophthalmology, psychiatry and in many other streams for diagnosis and treatment of diseases.

**Oncology:** Chen and colleagues conducted a study using an AI technology called Conventional Neural Network (CNN) machine learning on detection of lymphnode metastasis. AI achieved image level scores above 97%, whereas human pathologists could achieve only 73.2% sensitivity. (7) Esteva et al analysed clinical images to identify skin cancer subtypes. They also utilized CNN technology, and found out that CNN technology performed at a level of competency comparable to dermatologists in classifying skin cancers from biopsy proven clinical images. (8) Several studies have suggested that the incorporation of computer-aided detection (CADe) systems into the diagnostic process can improve the performance of image interpretation by providing quantitative support for clinical decision-making, particularly in the differentiation of malignant and benign tumours. Li et al studied the uses of abnormal genetic expression in long non-coding RNAs to diagnose gastric cancer. (9) Somashekhar et al demonstrated that IBM Watson for oncology is a reliable AI system for assisting the diagnosis of cancer through a double blinded validation study. (10) AI can serve as a useful modality in diagnosis and treatment of lesions of the oral cavity and can be employed in screening and classifying suspicious altered oral mucosa undergoing premalignant and malignant changes. The advantage would be no observation fatigue, and even minute changes at single pixel level can be detected which might go unnoticed by the naked eye. (11) In May of 2018, the Annals of Oncology published a landmark German study where a deep learning convolutional neural network (CNN) trained on 100,000 images outperformed an international group of 58 dermatologists from 17 countries in diagnosing malignant melanomas. Google deep mind machine learning algorithms are utilized to identify areas to be treated or avoided during radiotherapy to improve the efficiency of cancer treatment especially around head and neck. (12)

**Cardiology:** In the research presented by Moss et al in this issue of Critical Care Medicine, the authors employed an automated rhythm classification methodology to analyze continuous electrocardiograms (ECGs) of critically ill patients to detect AF and AFL. Of note, 7.5% of all ICU admissions had new-onset subclinical AF as identified by the automated rhythm classification. The authors demonstrate how machine learning applied to routinely captured clinical data can generate new information and potentially new insights that are missed by the clinician who cannot continuously observe all ongoing ECG patterns. (13) Dilsizian and Siegel discussed the potential application of the AI system to diagnose the heart disease through cardiac image. (14) Arterys recently received clearance from the US Food and Drug Administration (FDA) to market its Arterys Cardio DL application, which uses AI to provide automated, editable ventricle segmentations based on conventional cardiac MRI images. (15) The Ultromics system, trialled at John Radcliffe Hospital in Oxford, uses AI to analyse echocardiography scans that detect patterns of heartbeats and diagnose coronary heart disease.

**Orthopaedics:** Within musculoskeletal medicine, machine learning and active shape modelling have proven influential in understanding biomechanics, orthopaedic implant design, bone tumour resection, prediction of progression of osteoarthritis based on anatomical shape assessment, and robotic surgery. The analysis of complex physiological data via ML has been used in patients with spinal degenerative changes. (16-19) Hayashi et al focused on gait analysis as a classification method to improve diagnostic accuracy in patients with multilevel spinal stenosis. (20) Eskenazi et al created an ANN-based contact model of the tibiofemoral joint using over 75000 evaluations of a fine-grid elastic foundation (EF) contact model. (21)

**Neurology:** AI tools are being developed that analyse speech patterns to predict psychotic episodes and identify and monitor symptoms of neurological conditions such as Parkinson’s disease. Bouton et al developed an AI system to restore the control of movement in patients with quadriplegia. (22) Farina et al tested the power of an offline man/machine interface that uses the discharge timings of spinal motor neurons to control upper-limb prostheses. (23) Shin et al developed an electrodiagnosis support system for localising neural injury. (24) In a study of 1271 head trauma records, artificial neural networks (ANN) and
multivariable logistic regression models were compared in their ability to predict outcomes in head trauma. Reproducibility of the findings were studied. ANNs significantly outperformed logistic models in both fields of discrimination and calibration, but under performed in accuracy. Prediction of intracranial pressure trends with ANN has been reported. ANN proved superior to logistic regression models in predicting recurrence of chronic subdural hematoma and cranioencephal injuries. Brain death prediction, based on ensemble ANN networks, in a neurosurgical intensive care unit has been reported. Objective grading of facial paralysis using AI analysis of video data has been reported. Clinical decision support systems (CDSS) based on machine learning algorithms could assist in combined stimulation and medication therapies for Parkinson’s Disease. Accurate prediction occurred in 86% (12/14) of motor improvement scores, 100% in tremor outcome and 93% in speech outcome, one year after surgery. The authors emphasise that prediction accuracy is dependent on the quality of the clinical measurements, used to populate the database. Automatic seizure detection using scalp electroencephalogram (EEG) and advanced artificial intelligence techniques have been reported following preprocessing with filtering and artefact removal. AI has been used in the management of stroke, in the areas of early detection and diagnosis, treatment, outcome prediction and prognosis evaluation. The US Food and Drug Administration (FDA) has approved an mHealth app that uses AI software to analyze CT scans for signs of a stroke, and then sends a text message to a neurologist. Ophthalmology: Long et al, who analysed the ocular image data to diagnose congenital cataract disease and Gulshan et al, who detected referable diabetic retinopathy through the retinal fundus photographs. Surgery: AI technological approaches have been used in the analysis of preoperative images to help the surgeon define intraoperative bone resection levels in upper limb arthroplasty. Robotic tools controlled by AI have been used in research to carry out specific tasks in keyhole surgery, such as tying knots to close wounds. Brain tumor ablation has been identified as an ideal procedure for autonomous robotic surgery. It involves perception of the environment by the robotic system and a corresponding adaption of its behaviour to the changing environmental parameters. Obstetrics & Gynaecology: The effects of AI have already been felt in the areas of fetal heart monitoring and fertilization. An example of AI utility is its application in assessing cardiotocographs during labor. Intrapartum monitoring is dogged by inconsistencies between different centers and between obstetricians. Examples of where AI has been tested in CTG analysis include CAFE (Computer Aided Foetal Evaluator) and the INFANT study protocol, both highly integrated systems involving complex algorithms developed to overcome difficulties in CTG analysis. System 8000 is another such technology which was designed to take account of episodic changes in FHR and fetal movements characteristic of sleep states by recording CTG quality, uterine contraction peaks, basal heart rate, variation, decelerations, and accelerations. A much needed boost for earlier detection of epithelial ovarian cancer (EOC) using noncoding RNAs has been attempted with a neural network model, and initial results suggest that circulating miRNAs have the potential to develop as a noninvasive diagnostic test for ovarian cancer. Attempts have also been made to predict preterm labor by analyzing uterine electrical signals (electrohysterography), a specific type of electromyography. AI could also provide better and more consistent outcomes for IVF results between different clinics.

Psychiatry: 707 patients with mental health issues were studied. Using 345 variables, an analysis was carried out with AI tools. The authors reported that eventually AI tools could help to reduce the risk of suicide. A study from Taiwan reported that Bayesian statistics (learning from evidence as it accumulates) helped clinicians explore other potential risk factors for dementia.

Conclusion

The top applications that represent the greatest near-term value are robot-assisted surgery, virtual nursing assistants and administrative workflow assistance, fraud detection, clinical trial participant identifier, automated image diagnosis etc. AI-powered solutions have made small steps towards addressing key issues, but still have yet to achieve a meaningful overall impact on the global healthcare industry, despite the substantial media attention surrounding it. If several key challenges can be addressed in the coming years, it could play a leading role in how healthcare systems of the future operate, augmenting clinical resources and ensuring optimal patient outcomes.

A Case of Bullous Lung Disease

Babitha K Devu1, Johny Kutty Joseph1

1Assistant Professor, Shri Mata Vaishno Devi College of Nursing
SMVD Narayana Hospital Campus, Kakryal, Katra, J&K, India,

Abstract

Bullous Lung disease is the formation of bullae in the lung due to multiple factors. The risk factors of COPD are adjunct with the risk of bullous lung disease. The affected patients commonly exhibit the respiratory symptoms similar to that of COPD cases. Usually chest imaging reveals the condition. Men are more likely to get affected. In this article we report a case of Bullous Lung Disease in a 57 year old male patient.

Keywords: Bullous Lung disease, Giant Emphysematous bulla.

Introduction

Bullous Lung disease is an entity described by the nearness of bullae in one or both the lung fields, with ordinary mediating lung. Bullous lung disease is portrayed by the advancement of bullae inside the lung parenchyma.1 A bulla is a changeless, air-filled space inside the lung parenchyma that is around 1 cm in size and has a thin or inadequately developed wall; it is flanked just by remainders of alveolar septae and additionally pleura.1,2

Etiology & Risk Factors of developing bullous lung disease

• Affected people will, in general, be more seasoned (typically > 45).4
• Exposures and ecological factors, for example, prolonged presentation to smoke from burning of tobacco (more typical) or different biomass fuels utilized for warming or cooking, for example, wood, coal, peat, and lamp oil.5
• The IV infusion of heroin or smashed oral tablets (e.g., methylphenidate) has been related with a basilar-prevalent bullous lung ailment.4
• Genetic factors, for example, Alpha-1 Antitrypsin Deficiency expands defenselessness to smoke-actuated bullous emphysema. A number of epidemiological studies show that Marfan’s and Ehlers-Danlos disorder have been connected to an expanded danger of bullous lung infection and pneumothorax.6
• Human immunodeficiency infection (HIV): Multiple observational investigations have demonstrated that even after alteration for other hazard factors, these patients (HIV positive) create COPD at a marginally more youthful age and with somewhat bring down dimensions of tobacco presentation contrasted with HIV-negative controls.6

Classification: Bullous lung infection can be arranged into a few classifications dependent on the state of the encompassing lung parenchyma.

• Bullous emphysema alludes to the development of bullae inside emphysematous lung parenchyma. Patients for the most part show airflow deterrent on spirometry.

• Bullae inside typical lungs are frequently solitary and encompassed by morphologically ordinary lung tissue. This class is far less normal than bullous emphysema. It results in dynamic air catching. Notwithstanding when symptomatic, patients with this type of illness may display typical PFT.1

• Bullae in late stage lung fibrosis, for example, late stage sarcoidosis or pneumoconiosis.

• Vanishing lung disorder or idiopathic giant emphysematous bulla, is an uncommon disorder in which bullae take up > 30% of the influenced hemithorax with no recognizable basic etiology. The upper flaps are frequently included, and the nearness of subpleural bullae is an overwhelming component. The positive treatment for the most part requires careful bullectomy.1

Clinical Manifestations: Generally, symptoms are typically insidious, but sudden and severe dyspnea or chest pain in a patient with bullous lung disease which may raise suspicion for pneumothorax due to
a ruptured bulla or bleb. Rarely, fever and malaise +/- increased sputum production may signal an infected bulla. Shortness of breath or chest tightness, particularly with exertion, cough and sputum production may be present. Occasionally, a sense of abdominal fullness or bloating due to airway obstruction may be seen.6

There are other diseases that can mimic bullous lung disease such as Blebs: Effectively “blisters” that occur within layers of the visceral pleura, rather than within lung parenchyma itself, Cystic lung disease, Cystic bronchiectasis, Cavitary lung disease, Pneumatocele, Pneumothorax.6

Making or excluding the diagnosis of bullous lung disease.

The Chest X-ray may reveal focal areas of radiolucency surrounded by thin curvilinear density, suggesting the presence of bullae. Cross-sectional imaging using CT allows more detailed characterization of the number, size, and location of bullae, as well as the condition of the surrounding lung parenchyma. A CBC may exclude anemia as a contributor to dyspnea, and in severely affected patients, may occasionally reveal polycythemia associated with hypoxemia. Pulse oximetry with exercise will reveal which patients require supplemental oxygen. ABG can evaluate for hypercapnia in those with severe respiratory impairment. The patient has undergone Chest X-ray and HRCT (High Resolution Computed Tomography)3,7

Case Report

An 57 year old male patient, normotensive, nondiabetic, euthyroid, known case of COPD since 13 years presented to the hospital with chief complaints of breathlessness which has increased progressively over time. There was no history of fever, cough and cold. General and systemic examination revealed the history that he was a chronic cigarette smoker and alcoholic for 24 years but has stopped smoking and alcoholism since 13 years.

X-Ray Chest revealed Giant bullous emphysema with involvement of bilateral lungs. Chronic collapse involving basal segments of left lower lobe. Small left pleural effusion. Subcutaneous emphysema along chest wall and visualized lower neck on left side.

HRCT (High Resolution Computed Tomography) revealed the presence of widespread emphysematous changes with presence of giant bullae replacing the normal lung parenchyma. These bullous spaces are more extensive on left side with largest bulla measuring approximately 24.8 (CC) x 9.5 (TR) x 17.5 (AP) cms. There is extensive fibrotic opacities with associated architectural distortion. There is chronic collapse involving basal segments of left lower lobe.

Figure 1: Chest X-Ray reveals bilateral Giant bullous emphysema.

Figure 2: HRCT showing giant bullae.

Serological examination revealed low Hb (12.0g/dl), Low RBC Count (million/ul), Low PCV(36.7%) and high Total Leukocyte Count (14.3 Thou/ul), high neutrophils and low lymphocytes. The SGPT was increased (80U/L).

Medical & Surgical Management: Symptomatic patients often experience clinically significant improvements in symptom control and exercise tolerance from usual COPD treatment such as bronchodilators, inhaled corticosteroids, and oxygen as needed and pulmonary rehabilitation. With smoking cessation and medical therapy, many patients with bullous lung disease experience stabilization of lung function.6

However, even patients who are aggressively treated may occasionally experience progressive dyspnea, airflow obstruction, exercise limitation, and poor quality of life. Patients with bullous lung disease are at increased risk for developing spontaneous secondary pneumothorax because of rupture of blebs or bullae.

In this case the patient was administered following medications Inj. Deriphyllin, Lupituss Suspension, Syp. Looz, Inj. Tazact, Inj. Azee, Inj. PCM, Inj. Rablet and Inj. Solu Medrol. The dosage and duration of the medication was as prescribed by the concerned Medical Practitioner. The patient was educated regarding the action of each medication and the side effects were monitored.
The patient was also advised for Betadine Gargle and Steam Inhalation. Nebulization was administered with **Duolin** (Salbutamol / Ipratropium bromide 2.5 mg / 500 mcg in 2.5m) and **Budecort 0.5 MG Respules** (corticosteroid).

**Nursing Management/Diagnosis**

1. Airway clearance, ineffective related to expiratory airflow obstruction as evidenced by wheezing sounds on auscultation.

**Nursing Interventions:**

   a. Assessed lung sounds every 2 to 4 hours
   b. Encouraged turning, deep breathing every 2 to 4 hours
   c. Provided semi fowlers position
   d. Administered oxygen as prescribed
   e. Assisted with the treatment in administering medications used in inhalation therapy

2. Breathing pattern, ineffective related to decreased lung expansion secondary to chronic airflow limitations as evidenced by the use of accessory muscles of respiration and adventitious breath sounds.

**Nursing Interventions:**

   a. Assessed for the indicators of respiratory distress
   b. Auscultated Breath sounds
   c. Instructed to use of pursed-lip breathing
   d. Monitored the response of oxygen administration
   e. Administered bronchodilator therapy as prescribed

3. Gas exchange, impaired related to airway obstruction secondary to the buildup of secretions as evidenced by decreased oxygen saturation shown by ABG analysis.

**Nursing Interventions:**

   a. Assessed the frequency and depth of breathing
   b. Provided comfortable position
   c. Observed nail beds for cyanosis and clubbing
   d. Evaluated patient hydration status
   e. Noted blood gas results

**Outcome and Follow-up:** At the end of the 3-week treatment plan, the patient was able establish natural breathing to certain extent. The person was able to perform his activities of daily living although he was not completely asymptomatic. The patient was re-evaluated by the Pulmonologist and Physician, who acknowledged maximal medical improvement of the initial symptoms but insisted regular follow up and prevention of risk factors that exacerbate the symptoms.

**Discussion**

Untreated, the natural history of bullous lung disease is generally one of gradual increase in the size and extent of bullae, as well as gradual progression of dyspnea and airflow obstruction. However, both the rate and extent of progression over time are highly variable and depend on many factors. Smoking cessation is the most important intervention to slow the progression of bullous lung disease.

**Conclusion**

In conclusion, this case exemplifies the importance of diagnosing the bullous lung disease and providing the required attention in preventing the complications. In this case the presence of bullae was confirmed by HRCT. The given treatment improved the quality of life of the patient.

**Ethical Clearance:** For this case study we have taken the consideration of ethical issues. No significant ethical concerns were raised during the study. Ethical clearance was obtained from Shri Mata Vaishno Devi Project Evaluation Committee (SMVDPEC). Consent was obtained from the patient and he was assured about the confidentiality of the data obtained from him.

Effectiveness of Platelet-rich Plasma in Knee Osteoarthritis

Jyoti
Assistant Professor Physiotherapy Department
Guru Jambheshwar University of Science & Technology

Abstract

Osteoarthritis is a degenerative condition which is characterized by joint pain, tenderness, stiffness, swelling, restricted movement and joint deformities decreased range of motion. In recent years, an increasing number of patients are being diagnosed with osteoarthritis, which has a notable impact on human health and quality of life. The causes of osteoarthritis are very complex, and the pathogenesis of this disease is not well understood. Osteoarthritis is divided into two categories i.e primary and secondary osteoarthritis according to the presence of local and systemic risk factors. Knee osteoarthritis is a degenerative disease which may develop due to ageing, obesity, strain, congenital abnormal joints, joint deformity or trauma. Etiology is multifactorial, such as degradation of articular cartilage injury, joint edge and subchondral bone hyperplasia of reactivity. Positive results have been uniformly found by various researchers for the use of platelet-rich plasma (PRP) in early osteoarthritis (OA) knee in the past few years. Platelet-rich plasma (PRP) is a concentrate of autologous blood growth factors which show some symptomatic relief in early osteoarthritis (OA) of the knee. Prolonged and sustained release of growth factors from platelets could possibly help in much better biological healing in body and sustained clinical effects. This article intends to discuss the role of the PRP and ideas for improvising PRP in early OA knees based on available evidence.

Keywords: Early OA knee, Platelet-rich plasma.

Introduction

Osteoarthritis (OA) is a leading cause of disability in population and doubles the number of visit of patients to primary care practitioners for those with the condition in comparison to those without. Knee joint is most commonly affected by OA than any other joint. The joint destruction arising from OA occurs as a result of an imbalance between the breakdown and repair of the joint tissue while a combination of cellular changes and biomechanical stresses causes various secondary changes in the joint itself. Recent research has been found a number of key biochemical pathways that could be targeted therapeutically through biological intervention.

There are various conservative treatments for knee OA that have short-term relief with their own benefits and disadvantages. For example, Non steroidal anti-inflammatory drugs (NSAIDs) and intra-articular corticosteroid are common treatments for arthritis. Despite their easy access and low cost, these treatments have various systemic adverse effects and may cause destruction of joint cartilage and flaring up of the osteoarthritic process. Also common treatments for cartilage tissue repair rarely achieve an ideal level of functional capacity for the patient of OA.

Because of the high costs of management of knee OA, therapeutic options that are effective in tissue healing have been taken into consideration in recent years in order to prevent the progression of OA. Among these intervention there are growth factors that have been studied both in vitro and in vivo as effective factors for the cartilage healing in OA with promising results. Growth factors are effective in chemotaxis, mesenchymal stem cells differentiation, proliferation of chondrocyte, and synthetic activities of osseous and cartilaginous cells; therefore, they have important roles in both healing and remodeling of cartilage tissue.

Platelet-rich plasma (PRP) is an autologous biologic treatment including patients’ own plasma which contains growth factors released from platelets and endogenous fibrin scaffold.

Platelet-rich plasma (PRP) promotes proliferation cell and differentiation of synovial cell and may recover promotes cartilage morphology. Previous research has suggested that PRP exhibits beneficial effects on
injurious articular cartilage repair through the removal of harmful inflammation factors in patients with joint diseases. The main rationale for the use of PRP is to stimulate the cascade of natural healing process and tissue regeneration by a “supraphysiologic” release of platelet-derived factors directly at the treatment site.

Most studies found that therapeutic PRP should have platelet concentrations four to six times greater than whole blood (200,000 mm$^{-3}$). Some authors stated that the concentrations less than or greater than this amount may be ineffective or inversely lead to suppression of cascade of the healing process. PRP is classified into following four categories, depending on leukocyte and fibrin contents: 1. pure platelet-rich plasma (P-PRP); 2. leukocyte-and platelet-rich plasma (L-PRP); 3. pure platelet-rich fibrin (P-PRF); and 4. leukocyte- and platelet-rich fibrin (L-PRF).

Previous study reports have indicated that inflammatory cytokines have an essential role in the initiation and development of osteoarthritis, targeting the synovium in joint diseases. PRP injections in patients with knee OA resulted in decrease of pain, improved function and global assessment, and changes regarding joint imaging. A study by Meheux et al. suggested that PRP injection significantly improved validated patient reported outcomes in patients with symptomatic knee OA.

Osteoarthritis (OA) is a leading cause of disability in population and doubles the number of visit of patients to primary care practitioners for those with the condition in comparison to those without. Knee joint is most commonly affected by OA than any other joint. The joint destruction arising from OA occurs as a result of an imbalance between the breakdown and repair of the joint tissue while a combination of cellular changes and biomechanical stresses causes various secondary changes in the joint itself. Previous study reports have indicated that inflammatory cytokines have an essential role in the initiation and development of osteoarthritis, targeting the synovium in joint diseases. PRP injections in patients with knee OA resulted in decrease of pain, improved function and global assessment, and changes regarding joint imaging. A study by Meheux et al. suggested that PRP injection significantly improved validated patient reported outcomes in patients with symptomatic knee OA.
Objectives: The current study aimed at the role of PRP of certain specifications for management in the early knee OA.

Methodology
A Comprehensive computerized search performed on google scholar, pub med etc. (Publication from 2014-2018) is used.

Search Strategy: Knee–osteoarthritis
Platelet rich plasma (PRP)

Mechanism by which PRP works for knee OA
Osteoarthritis alters the metabolism of normal joint by favouring increased catabolism and decreased anabolism. Platelet alpha-granules contain and release various growth factors, including hepatocyte growth factor (HGF), vascular endothelial growth factor (VEGF), platelet-derived growth factor (PDGF) and transforming growth factor-b (TGF-b)\(^\text{18}\), which could alter the changing joint milieu in OA. In cartilage it decreases catabolism, increases anabolism and promotes chondral remodelling. Higher amounts of collagen II and synthesis of prostaglandin (PG) have been documented by Akeda et al.\(^\text{19}\) and Pereira et al.\(^\text{20}\). With the increasing proliferation of chondrocyte and production of matrix molecules have also been documented\(^\text{21-24}\). Synoviocytes are influenced by increased hyaluronic acid (HA) secretion\(^\text{25}\), that creates a more favourable and balanced state for angiogenesis\(^\text{19,26}\), and a decreased interleukin-1 (IL-1)-mediated rise in some matrix metalloproteinases (MMPs)\(^\text{27,28}\). The apoptotic pathway of osteoarthritic chondrocytes is influenced as insulin-like growth factor 1 (IGF-1) in PRP may downregulate the programmed cell death 5 (PDCD5)\(^\text{29}\). Lower levels of apoptosis were detected in vivo studies by Mifune et al.\(^\text{30}\)and the authors suggested that complex interaction of PRP within joint might positively influence apoptosis of chondrocyte.

What specific type of PRP is ideal for Knee OA?
Based on the available literature, there are some answers and but more questions which need to be answered. Different PRP preparations – Magalon et al.\(^\text{31}\) studied five different commercial PRP preparations in a single donor/subject model and noticed various significant biological variation in the PRP products among different preparations and postulated this to be a reason for the variability of results in PRP studies. Intra-individual variations were observed by Mazzocca et al.\(^\text{32}\) in the same individual, and there were variations in the PRP yield by the same method in samples drawn at different time periods. Storing platelets in freezing conditions can alter the morphology of platelets and decrease the functional properties of platelets by degradation of alaphagranules\(^\text{33}\). However, freeze thawing PRP is better in terms of compliance of patients of OA as the PRP can be prepared in a single sitting. Roffi et al. studied the effect of freezing/thawing on the PRP molecule release, and its effects on the chondrocytes and synoviocytes metabolism. They noticed decreased level of protein secretion in the freeze thawed PRP but the gene expression in cultured chondrocytes and synoviocytes was similar as that in fresh PRP.

Summary of included study’s characteristics:
-Mandeep S. Dhillon, Sandeep Patel, and Rakesh John (2017), PRP in OA knee – update, current confusions and future options. A Review article concluded that PRP of certain specifications is used for the management of knee in the early knee OA\(^\text{34}\).

-Liam G. Glynn, Alaa Mustafa, Monica Casey, Janusz Krawczyk, Jeanete Blom, Rose Galvin, Ailish Hannigan, Colum P. Dunne1, Andrew W. Murphy and Christian Mallen (2018), Platelet-rich plasma (PRP) therapy for knee arthritis: a feasibility study in primary care. A feasible study concluded that Platelet-rich plasma therapy is a simple and minimally invasive treatment which is feasible to deliver in primary care for patients to treat osteoarthritis of the knee joint. Well-designed randomised controlled trials are needed to measure outcomes, durability of effect and effectiveness of cost\(^\text{35}\).

-Seyed Ahmad Raissadat, Seyed Mansoor Rayegani, Hossein Hassanabadi, Mohammad Fathi, Elham Ghorbani, Marziah Babaei and Kamran Azma (2014), Knee Osteoarthritis Injection Choices: Platelet-Rich Plasma (PRP) Versus Hyaluronic Acid (A one-year randomized clinical trial). A Randomized Controlled Trial concluded that PRP injection is more effective than HA injection in reducing symptoms and improving quality of life in patients of knee OA and is a therapeutic option in patients with knee OA who have not responded to conventional treatment\(^\text{36}\).

-Guolin Huang, Sha Hua, Tuanmin Yang, Jibing MA, Wenxing Yu and Xiujin Chen (2018), Platelet rich plasma shows beneficial effects for patients with knee osteoarthritis by suppressing inflammatory factors. A Randomized controlled study concluded that treatment with PRP for patients with knee osteoarthritis presented
beneficial effects in alleviating inflammation of joint, cartilage destruction and bone damage, and repairing joint tissue. These results suggested that PRP may be a potential therapeutic agent for knee osteoarthritis.37

-Bahram Naderi Nabi, Abbas Sedighinejad, Mohnsen Mardani-Kivi, Mohammad Haghighi, Zahra Atrkar Roushan, Samaneh Ghazanfar Tehran, and Gelareh Biazar, (2018), Comparing the Effectiveness of Intra-articular Platelet-Rich Plasma and Corticosteroid Injection under Ultrasound Guidance on Pain Control of Knee Osteoarthritis. In this A Randomized Controlled study concluded that three intra-articular injections of Triamcinolone and PRP could decrease pain and improve articular function in patients with grades II-III knee OA. However, pain relief and improvement in the outcomes were more effective and more prolonged secondary to PRP injections than corticosteroids.38

Discussion

The purpose of the present study was to demonstrate the efficacy and safety of PRP in patients with knee osteoarthritis. It was observed that PRP not only decrease inflammation through humoral and cellular immune responses, which was consistent with a previous study.39 Platelet-rich plasma therapy is a simple, cheap and minimally invasive treatment option which is feasible to deliver in primary care to treat degenerative diseases of articular cartilage of the knee. Previous studies have investigated the effect of PRP on arthritis of different origins.40-42

Conclusion

Osteoarthritis is a serious chronic degenerative disease that affects the health of patient and quality of life. Although osteoarthritis may affect all joints of body, knee osteoarthritis is the most common type of arthritis among adolescents and adults.40 In recent years, non surgical treatments for knee osteoarthritis have become more widely used, such as PRP, corticosteroid injection and hyaluronic acid.40-42 A previous study described various method for treatment of knee osteoarthritis, including decompression with bone morphogenic proteins, growth factors, bone grafting and stem cells.45 Therefore, it is necessary for clinicians to monitor clinical responses and tolerability when patients are treated with PRP. In conclusion, the present study indicate that PRP treatment for patients with knee osteoarthritis has beneficial effects in regulating inflammatory factors, and alleviating joint inflammation, cartilage destruction and bone damage. In futureresearchers should also focus on developing a better PRP product by combining it with various molecules such as gelatin, chitosan and others. PRP is definitely there to stay for OA therapy use in future.

Quality of Life After Stroke Patients with Disability

K. Monica Blessy1, A. Kumerasan2
1MPT (Neurology) 2nd Year, 2(PHd), Assistant Professor, Saveetha College of Physiotherapy, Saveetha Medical Technical Sciences, Thandalam, Chennai

Abstract

**Background:** Stroke Specific Quality of Life Scale (SS-QOL) is a recognized and important outcome after stroke. Patients are socially, physically, psychologically affected due to stroke. An increased survival and the presence of moderate impairment in long-term stroke patients impact their SS-QOL.

**Methodology:** Observational study was used in this study. Conducted in Saveetha hospital. 16 subjects with chronic stroke were recruited with mild to severe disability. For disability outcome measure Modified Rankin scale is used. Assessment of the post-stroke Quality of Life done using SS-QOL.

**Result:** There were 2 stroke patients with slight disability, 6 stroke patients with moderate disability and 8 stroke patients with severe disability. There were 7 female and 9 male stroke patients. Mean values of SS-QOL -129.93.

**Conclusion:** Patients who have severe disability have poor quality of life compared to mild to moderate disability in who came to Saveetha medical college and hospital for this last one month.

**Keywords:** Quality of life, stroke, disability, Stroke Specific Quality of Life Scale (SS-QOL), modified rankin scale.

Introduction

Stroke is the sudden loss of neurological function caused by an interruption of blood flow to the brain. It is a major chronic disabling neurological disease that often changes lives in a radical and permanent way. Incidence: 119-145 / 100,000 based on recent population studies. Prevalence: 84-262 / 100,000 in rural areas and 334-424 / 100,000 in urban areas. The entire nervous system in the body is a continuous structure that slides when we move and the movement shows physiological processes such as blood flow to the neurons. Quality of life after stroke affected by impaired consciousness, speech and language disorders, dysphagia, cognitive dysfunction, altered emotional status, convulsions, bladder and bowel dysfunction, cardiovascular and pulmonary dysfunction, deep vein thrombosis and pulmonary embolism. Disability is a disability that can be cognitive, developmental, intellectual, mental, physical, and sensory or a combination of these factors. The stroke-specific quality of life scale (SS-QOL) is a recognized and important outcome after a stroke. The quality of life of stroke can be measured in health-related quality of life (HRQOL) and disability can be measured in Modified Rankin Scale (MRS). Patients are socially, physically and psychologically affected by stroke. Depression is a common consequence of stroke and is known to be associated with deterioration in quality of life. The concept was only vaguely defined. It is generally accepted that quality of life refers to the subjective well-being and satisfaction of the person’s life. Also other activities in the community, personal development and active recreation.

**Methodology**

This study is conducted in Saveetha College of physiotherapy OPD Thandalam, Chennai, India. Patients have participated and were screened for inclusion (patients with chronic stroke) of both the gender within the age group of 60 years or more, the patients were able to understand simple verbal instructions, and exclusion criteria (unconscious, aphasia) samples were selected.
using convenient sampling technique. After the sampling technique due to poor health, refusal, or other reasons, all patients were not investigated but patients were examined based on neurological and neuropsychological after their stroke. Our study is based on the 16 patients who were able to reply to the quality of life questionnaire. Then it was continued by the Assessment of the post-stroke Quality of Life done using SS-QOL.

The questionnaire includes mainly with 12 questions designed to investigate the quality of life was used in addition to regular examinations. The questionnaire was constructed on the basis of the literature as well as on clinical experience with stroke patients. Questions requested information from before and after the stroke covering the following domains of life 1) energy, 2) family roles, 3) language, 4) mobility, 5) mood, 6) personality, 7) self care, 8) social roles, 9) thinking, 10) upper extremity function, 11) vision, 12) work or productivity. The patients answered the questions as to how things were before the stroke and as to how the same things were after the stroke. The differences between the pre-stroke and poststroke answers were used in estimating the changes in the quality of life. Depending upon the domain results before and after stroke the patient quality of life changes gradually, and these may lead to changes in all aspects as in ADL. These changes are overcome by strengthening the patient emotionally and help them in doing exercises required.

Then the disability of the patient is measured through the modified Rankin scale which consists of 0-6 were 0- no symptoms, 1- no significant disability, 2-slight disability, 3-moderate disability, 4-moderately disability, 5-severe disability, 6-dead. Where the scale shows that 2 patients are having slight disability, 6 patients are having moderate disability and 8 patients are having severe disability. Accordingly the patients with slight and moderate are been guided and instructed so that the restoration may take place soon after the post stroke which helps the patients to regain their ADL back to their normal form.

Statistical Analysis: The statistical analysis revealed significant difference (P<0.0001) between pretest and post test values of quality of life of stroke in patients with disability within the group. The pretest mean value SSQOL -118.93 and the post test mean value SSQOL -129.93. This shows that quality of life of stroke in patients with disability of test in posttest values were comparatively less than pretest value- p<0.0001. (table 1)

<table>
<thead>
<tr>
<th>Table 1: Change in the stroke patient through the pre and post test mean value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Result: According to SSQOL scale among stroke individuals conducted in Saveetha medical college OPD. The mean value SSQOL-129.93. For disability modified Rankin scale is used where there were 2 stroke patients with slight disability, 6 stroke patients with moderate disability and 8 stroke patients with severe disability. This shows that quality of life of stroke in patients with disability.</td>
</tr>

Discussion

The main aim of our research is to develop a reliable, valid and sensitive measure of the specific quality of life for stroke. The domain of of social roles of the SS-QOL is to measure patients with stroke consider significant changes in social functions after stroke. In future validation studies, additional measures of social roles may be required to establish validation of SS-QOL social role domain. The SS-QOL domains respondes between 1 and 3 months after stroke, and only vision domain had a ceiling effect (63% with the maximum score). More effort is needed to evaluate the responsiveness of SS-QOL in patients with more severe stroke. It is important to emphasize the theoretical nature of the SS-QOL domains. It is possible that in a large sample validation, where the techniques of confirmatory factor analysis and multiple method multimetry can be used, the number of domains can be reduced. The exact number of domains is less important than the content of the elements that make up the SS-QOL. It is crucial to include elements that measure aspects of post-stroke function that are important for patients. Although we are encouraged by the preliminary data of reliability, content and construction validity and response capacity, the SS-QOL is in the initial phase of development and there are still many questions to be answered, including the problems of the respondents, interviewer versus self-administration, weighted versus unweighted domains and performance in patients with more serious stroke.
However, we are encouraged that the SS-QOL appears to detect significant changes, even in patients with mild stroke, and we are re-validating the SS-QOL, including assessing the reliability of the repeat test, the responses by power of attorney and the mode of administration, in a cohort. This includes the most seriously ill patients. Currently, we suggest that resources permitting, the 78 elements of the SSQ-SS be included when populations with moderate to severe stroke are studied, as a modification of these elements may be required for optimal QS-SS performance in these patients. In addition, since we found that the “amount of help” response set was not responsive, probably due to the good functional outcome of our patients, we recommend converting the personal care items to “quantity of help” responses “because of their greater ability to respond to clinically significant changes after stroke. As for recovering the quality of life from stroke in disabled patients by approaching and strengthening them, motivating and energizing them by indicating the best course of action with exercises for slow movement. Therefore, after all that, we find a restoration change in the form of an increase in the average value after a stroke. SS-QOL is a valid and reliable measure of the specificity of stroke. The SS-QOL has excellent content validity. SS-QOL shows reasonable construct validity. Several other determinants and predictors of quality of life have been reported, such as: physical disability of stroke survivor, behavioral disorders after stroke, personal attributes and caregiver depression, and social support. They are more or less similar to the predictors of the direction of change and their role in the quality of life, as well as in the load, can vary between the acute and chronic phases of stroke. It has been demonstrated in the scientific literature that the increased burden is significantly related to the deterioration of health-related quality of life among stroke providers, particularly in the areas of mental health and social functioning. The limitations of this study are the language and the cognitive domains of SS-QOL are not correlated. SS-QOL social role domain scores, but not social functioning subscale scores, were significantly different among patients with various dysfunction reports, suggesting that the SS-QOL social role domain measures this. That stroke patients consider significant changes in social functions post-stroke.

**Conclusion**

Patients who have severe disability have poor quality of life compared to mild to moderate disability. Changes can take place if there is a correct action of course in the mild and moderate patients, where the restoration of ADL takes place. Recommendations are the SS-QOL is a valid and reliable measure of stroke-specific. The SS-QOL has excellent content validity. SS-QOL show reasonable construct validity. The language and cognitive domains of the SS-QOL do not correlate. SS-QOL social roles domain scores but not the social functioning subscale scores were significantly different in patients with varying reports of dysfunction, suggesting that the SS-QOL social roles domain is measuring what stroke patients consider to be meaningful changes in post stroke social functions.

**Ethical Consideration:** The study was approved by Institutional Ethics Committee (Number 015/02/2017/IEC/SU on 28/02/2017) and was done in accordance with Ethical Guidelines for the Human Participants. This study protocol was approved by institutional ethical committee.

A Study on Estimation of Chlorine in Drinking Water in an Urban Slum of Guntur District

K V S Prasad1, Anil Kumar Bathula2, R Nageswara Rao3, Satya Kishore4

1Associate Professor, 2Assistant Professor, 3Professor & HOD, Department of Community Medicine, Guntur Medical College, Guntur, AP, India, 4Assistant Professor, Department of Community Medicine, PSIMS & RF, Gannavaram, AP, India

Abstract

Background: The share of urban population to the total population of India has increased from 27.81% in 2001 to 31.16% in 2011. This increase has also been accompanied by rapid growth of slums in cities. The 2011 Census of India reveals that 17.4% of urban households in India live in slums. This survey was conducted in the urban slum area of Anandapet, Guntur.

Objective: estimating the quality of drinking water, storage method at household level and waste disposal of both solid and sewage in that area and also to estimate chlorine levels in the drinking water consumed by the residents in the wake of the recent GE (gastroenteritis) epidemic in Guntur.

Methodology: A community based Cross-sectional study was carried out during May to June 2018 with the objective of estimating the quality of drinking water, storage method at household level and waste disposal of both solid and sewage in that area.

Results: 77 (38.5%) houses do not follow any method of disinfection of water. Whereas 70 (35%) houses follow boiling. 38 (19%) houses use filter, and 15 (7.5%) use water purifier for disinfection of water. Among those 70 houses that boil the water, 59 houses use different well maintained vessel for storage of boiled water and 11 houses use same vessel for storage of boiled water.

Conclusions: Majority of the households in the study area had access to improved source of drinking water. But a few households practiced unhealthy storage and treatment practices like cleaning the overhead tank/sumps once a month or once in 15 days, not treating water prior to consumption, dipping the glass into the water drum. Absence of free chlorine suggests the need for attention by the concerned authorities and the households.

Keywords: Sanitation; Slum; Disinfection, Safe Drinking Water; Sanitary Latrine.

Introduction

Access to safe water in adequate quantity is one of the biggest challenges in the recent times. Despite the national commitment to supply safe drinking water, access to water is difficult especially in the rural areas. (1) Water scarcity in terms of quantity and quality has severe implications on the overall development and health of citizens. Factors such as poor availability, affordability and distance between water source and home may lead households to depend on less safe sources and reduce the volume of water used for hygiene purposes, (2) resulting in water-related infections.

Many infectious diseases such as bacterial, viral, and protozoal are result of drinking unclean water. Major etiological agents. responsible for more than a million diarrheal deaths are Escherichia coli, Rotavirus, Vibrio cholerae, Shigella, etc., which spread through unsafe drinking water. Worldwide, diarrhea is the second leading cause of mortality among children <5 years. In India, pneumonia and diarrhea are responsible for...
50% of deaths of children <5 years and this is because of drinking contaminated water; however, the recent studies from India reported even higher prevalence of water-borne diarrheal disease. In diarrhea, cholera is one of the most virulent and if left untreated, it will lead to fatality rate 25%–50%.[3]

In India, 66% of the rural population practices open air defecation. Despite comprehensive programs like total sanitation campaign, Swacch Bharath Mission open defecation still remains the predominant norm and poses one of the biggest threats to the health of the people.[4]

A significant proportion of water may be contaminated at the source itself and the local geographical conditions may have a role to play in it. Hence, water treatment assumes utmost importance in order to ensure the safety of the water consumed. At the community level, it is the responsibility of the municipalities to chlorinate the water being supplied to the households and public taps. Also it is up to the individual household to ensure that the drinking water they consume is adequately safe.[5]

This survey was conducted in the area of Anandapet, Guntur with the objective of estimating the quality of drinking water, storage method at household level and waste disposal of both solid and sewage in that area and also to estimate chlorine levels in the drinking water consumed by the residents in the wake of the recent GE (gastroenteritis) epidemic in Guntur as several patients were admitted to the Government General Hospital, Guntur especially from the region of Anandapet. The data obtained is for the purpose of getting a clear cut idea about the current situation of Anandapet so that necessary measures can be undertaken to prevent the occurrence of such epidemics in the future.

Methodology

A community based Cross-sectional study was carried out during May to June 2018 at Anandapet, Guntur District, Andhra Pradesh with the objective of estimating the quality of drinking water, storage method at household level and waste disposal of both solid and sewage in that area. Approval from the institutional ethical committee was obtained before the start of the study. Initially a pilot study was conducted to assess the chlorination practices in the study area. It was found that 20% of the households used chlorination as one of the method of disinfecting drinking water source.

Sample size was calculated using the formula \(4pq/L^2\), considering \(p=20\%\) and an allowable error of \(6\%\) the minimum sample size was estimated to be 180 which was approximated to 200.

A semi-structured questionnaire was used to collect relevant data from the households regarding the sanitary practices at the household level. Drinking water samples are collected from each house and chlorine levels are estimated with iodometric method of chlorine testing. The results were duly noted, analysed & organized to look up on for easier evaluation.

The final data obtained was analyzed using Microsoft Office Excel 2007 and IBM SPSS statistics 20.

Results: Among the 200 households interviewed, majority were Muslims (70%), followed by Hindus (15%), Christians (14%) and others (1%). 39% of the study population was illiterate. The socio-economic grading of the households in the study according to modified Kuppuswamy classification was as follows: upper lower class (19%), lower middle class (46%), upper middle class (29%), upper class (5%) and lower class (1%). Based on the type of family, 63% were nuclear in nature and 37% were joint families.

The main source of drinking water among the households in the study was municipal water 159 (79.5%) houses, followed by mineral water in 34(17%) houses, public tap water by 7(3.5%) houses and bore well by 1 house (0.5%). The main alternative source of drinking water in the study area was mineral water followed by bore water and water tanker.

About 57.5% of the households surveyed, used buckets/drums to store water. Other method of storage were overhead tanks (35%) and sumps (1%). 6.5% of the study population do not use a proper sanitary method for storing the water. 68% of those who store water in either drums/tanks, clean them once in 7 days. The rest of the population do not have the habit of cleaning the drums/tanks regularly.

77(38.5%) houses do not follow any method of disinfection of water. Whereas 70(35%) houses follow boiling. 38(19%) houses use filter, and 15(7.5%) use water purifier for disinfection of water. Among those 70 houses that boil the water, 59 houses use different well maintained vessel for storage of boiled water and 11 houses use same vessel for storage of boiled water.

The method used for dispensing water from stored vessel include dipping glass directly into the vessel by
98 (49%), pouring into the glass by lifting the tumbler 30(15%), by filter tap 35(17.5%) and normal tap by 2(1%). 

Among the study population 198 (99%) houses follow hygienic practice of washing the hands with soap after defecation and 197(98.5%) houses responded the importance of washing hands before eating food and after defecation.

Among the houses surveyed, 49 houses (24.5%) had the history of water related diseases in the past 1 year. Among the surveyed population, all the houses responded that purest form of water is clear water without odour. 184(92%) houses follow the hygienic practice of disposing the solid waste by segregating it and disposing it by the help of municipal waste collectors. The rest 16(8%) houses are indiscriminately thrown the solid waste outside their houses.

Orthotoludine test was used to test for chlorine in the water samples and it was identified that 100 out of 200 houses were tested negative for OT test. Which predispose them for water related diseases.

Discussion

The majority of study population were Muslims and About 39% of Head of the families are illiterate. Most of the families belong to lower-middle class (46%) according to modified kuppuswamy classification. 63% of families are of nuclear type. The major source of drinking water to the area is from the Municipal water supply (79.5%) and the major alternate source of drinking water is through Mineral water cans (46%). Buckets & drums are the primary mode of storage of water. In 43% of the houses, residents clean their sumps/drums daily. 38.5% of household do not follow any method to maintain cleanliness of drinking water while the majority of others follow boiling method (35%) & candle filters (18%). Almost the entire population knows the importance of washing hands before eating food & post-defecation. 100 homes out of the 200 we surveyed are being supplied unsafe/unchlorinated water. Around 14 of the homes in Anandpet 2nd line complained of muddy water with bad odour being supplied to their homes. Some of the houses in Anandapet 4th line are lacking water connections as a whole. Most of the GE cases were treated in a government facility, some of them only requiring outpatient treatment whereas others were admitted in the hospital for an average duration of 7 days. All the people who suffered from GE have completely recovered and did not require dialysis during their hospital stay among the houses we surveyed. Majority of the households hand over their solid waste to the Municipal Waste Collector. In conclusion, safe water practices have to be enforced by the municipality and in every house.

Conclusion

Majority of the households in the study area had access to improved source of drinking water. But a few households practiced unhealthy storage and treatment practices like cleaning the overhead tank/sumps once a month or once in 15 days, not treating water prior to consumption, dipping the glass into the water drum. Absence of free chlorine suggests the need for attention by the concerned authorities and the households.

Recommendations: Health education is very important for better use of existing facilities and also to prevent the incidences of water and sanitation related diseases. Emphasis needs to be given to behavioural change communication to create awareness among the households regarding the importance of water and sanitation practices by using various media for education.

Prevalence of Developmental Tongue Lesions in South Indian Population

R. Krittika¹, K. R. Don²

¹Graduate Student, ²Senior Lecturer, Department of Oral and maxillofacial Pathology, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences (SIMATS), Saveetha University, Chennai

Abstract

Background: The presence of developmental anomalies on the tongue is relatively common reason that patients visit dental clinics. Diagnosis of a wide variety of developmental anomalies is an essential part of a daily dental practice.

Objective: The aim of this study was to evaluate the type and prevalence of developmental anomalies of tongue in patients in South Indian population.

Study Design: A total of 800 patients were screened for developmental tongue lesions. The developmental tongue lesions were found in 32 of 800 patients examined. The prevalence pattern was examined.

Result: The most prevalent tongue lesion was found to be fissured tongue 14(44%). The least prevalent was found to be macroglossia 1(%). The tongue lesions such as microglossia, hairy tongue and lingual nodule were not present. The developmental tongue lesions were found to be more in males (75%) than females (25%) in the survey.

Keywords: Developmental Tongue lesions, Ankyloglossia, fissured tongue, Bifid tongue, geographic tongue, median rhomboid glossitis, macroglossia, microglossia, hairy tongue.

Introduction

The tongue is the most accessible organ of the oral cavity. The tongue shows lesions just like other parts of the mouth. The tongue is the site and source of a symptom, which is unique to it. Traditionally, tongue lesions have been considered disorders of primary concern regarding oral and general health.

The presence of developmental anomalies on the tongue is relatively common reason that patients visit dental clinics. Diagnosis of a wide variety of developmental anomalies is an essential part of a daily dental practice. It is important for every dentist to have knowledge of the type and prevalence of developmental anomalies of tongue.

In recent years, epidemiological studies have shown that tongue lesions constitute a remarkable proportion of oral mucosal lesions and that prevalence rates vary in different parts of the world. These variations may be the result of race, sex and age differences of the examined samples as well as because of differences in diagnostic criteria, methodology and sampling procedures of the different investigators. The aim of this study was to evaluate the type and prevalence of developmental anomalies of tongue in patients in South Indian population.

The various developmental tongue lesions assessed are as follows. Ankyloglossia which is also known as tongue-tie. Hypoglossia is congenitally short tongue. Macroglossia is an abnormally large tongue, seen in some disorders such as Down syndrome. Median rhomboid glossitis is a condition characterized by an area of redness and loss of lingual papillae, situated on the dorsum of the tongue in the midline. Geographic tongue is a common disorder which causes a burning sensation without pain. Hairy tongue is a condition of the tongue

DOI Number: 10.37506/v10/i12/2019/ijphrd/192084
where the filiform papillae elongate with brown or black discolouration, giving a black and hairy appearance. Fissured tongue is a benign condition characterized by deep grooves in the dorsum of the tongue. Bifid tongue is a congenital structural defect of the tongue in which its anterior part is divided longitudinally for a greater or lesser distance.

Method

A total of 800 patients attending the dental clinic for routine dental check-up or dental treatment were screened for our study. The patients were interviewed regarding their medical history, drug history, occupation, habits like smoking and drinking.

The 800 patients were screened dividing them into different age groups, children (1-18), adolescents (19-30), adult (31-45), old age(46-60). These included 100 males and 100 females in each group. (Table 1)

The study was performed during the period of January 2015 to April 2015. All the patients were examined for the presence of any one of the following tongue lesions: 1) ankyloglossia, 2) bifid tongue, 3) fissured tongue, 4) geographic tongue, 5) median rhomboid glossitis, 6) lingual nodule, 7) hairy tongue, 8) macroglossia, 9) microglossia.

The criteria for a positive finding in the 9 tongue lesions studied were as follows:

1) **ankyloglossia:** A thick frenulum on the ventral surface of the tongue that does not allow protrusion of the tip of the tongue beyond the vermilion border of the lower lip.

2) **bifid tongue:** Bifurcation at the tip of the tongue.

3) **fissured tongue:** Multiple linear fissures of various depths on the dorsal surface of the tongue.

4) **geographic tongue:** Patchy areas of papillary atrophy with partly sharp demarcation and partly surrounded by whitish serpiginous lines. In this condition, there is the recurrent appearance and disappearance of red areas on the tongue.

5) **median rhomboid glossitis** is an abnormality in the midline of the dorsum of the tongue at the junction of the anterior two-thirds with the posterior third. It may be rhomboid, diamond shaped, or irregular.

6) **lingual nodule:** A nodule of variable size located on the dorsal surface of the tongue at the foramen cecum.

7) **hairy tongue:** The filiform papillae can become elongated and air-like, forming a thick fur on the dorsum of tongue.

8) **macroglossia:** Congenital enlargement of the tongue.

9) **microglossia:** Abnormal smallness of the tongue.

The patients were examined sitting on a dental chair, in light, using a pair of disposable mouth mirrors. The personal data such as gender, age, occupation, and the different tongue lesions to be identified were recorded on specifically designed survey forms.

The exclusion criteria was the medical history of a systemic disease that results in a reduction of several functions of tongue and receiving medication that could have side effects on the oral mucosa and tongues.

The photographs of the representative cases of the various conditions were taken. Data were recorded. Statistical analyses were performed using the computer package of SPSS, version 12.

Results: The developmental Tongue lesions were found in 32 of 800 patients examined. The prevalence rate of these tongue lesions was assessed in this survey. The developmental tongue lesions were found to be more in males (75%) than females (25%) in the survey. (Table 2).

Out of 32 samples in our study, the most prevalent tongue lesion was found to be fissured tongue (44%). The least prevalent tongue lesion was found to be macroglossia (1%). The tongue lesions such as microglossia, hairy tongue and lingual nodule were not present. (Table 2 and 3).

In our study, out of 5 cases, ankyloglossia was seen in 4 males (80%) and 1 female (20%). The most predominant age group in ankyloglossia was found to be 1-18 age group -5 cases (100%). (Table 2 and 3)

In our study, Out of 14 cases, fissured tongue was seen in 9 males (64%) and 5 females (36%). The most
predominant age group in fissured tongue was found to be 31-45 age group – 7 cases (50%). (Table 2 and 3)

In our study, out of 2 cases, bifid tongue was seen in 2 males (100%) and 0 female (%). The most predominant age group in bifid tongue was found to be 1-18 age group – 2 cases (100%). (Table 2 and 3)

In our study, Out of 6 cases, geographic tongue was seen in 5 males (83%) and 1 female (17%). The most predominant age group in geographic tongue was found to be 31-45 age group – 3 cases (50%). (Table 2 and 3)

In our study, out of 4 cases, median rhomboid glossitis was seen in 3 males (75%) and 1 female (25%). The most predominant age group in median rhomboid glossitis was found to be 46-60 age group – 3 cases (75%). (Table 2 and 3)

In our study, Out of 1 case, macroglossia was seen in 1 male (100%) and 0 female. The most predominant age group in macroglossia was found to be 19-30 age group – 1 cases (100%). (Table 2 and 3)

Discussion

There are many published studies on the prevalence rates of several tongue lesions in different geographic locations of the world. But the reports on prevalence of developmental tongue lesions vary greatly, depending on the investigated population, race, age, gender, diagnostic criteria, methodology and sampling procedure of the different investigators. There are only very few studies on the epidemiology of developmental tongue lesions in Indian populations. So, this study was done to evaluate the prevalence pattern of developmental anomalies of tongue in patients of South Indian population.

The prevalence of ankyloglossia is between 0.1% and 3.7% in different studies. In our study, the prevalence rate of ankyloglossia was 16% and was seen in more predominantly in males (80%) than females (20%). The most predominant age group in ankyloglossia was found to be 1-18 age group-5 cases (100%). In a study performed in Nigeria, the prevalence of ankyloglossia was as low as 0.2%, and in a Saudi Arabian study, this prevalence was 0.1%. Sedano et al examined Mexican children and found ankyloglossia prevalence relatively higher than others (0.8%), and a much higher prevalence for ankyloglossia in the boys than in the girls. Ankyloglossia can be complete or partial. Inextreme cases of ankyloglossia, nursing and feeding may become a problem shortly after birth, necessitating the surgical removal of the fibrous band. Mild cases of ankyloglossia may go noticed for a few years, until the time that speech becomes impaired. Children with ankyloglossia may have difficulties pronouncing certain words. Therefore, their phonetic developmental is interfered with, and this affects personality development. So, we strongly suggest treatment of this congenital developmental condition at an early age.

In our study, the prevalence rate of fissured tongue was 44% and was seen in 9 males (64%) and 5 females (36%). The most predominant age group in fissured tongue was found to be 31-45 age group-7 cases (50%). There are varied prevalence reports for fissured tongue in the literature, from 0.8-16%, depending on the populations studied. Fissured tongue is thought to be of multifactorial etiology. Although developmental nature seems most likely, we can also consider extrinsic factors such as chronic trauma or vitamin deficiencies as possible causes of fissured tongue. Therefore, we can attribute this difference between the prevalence to different exposure factors of the groups. In the literature, there is no consistency in the distribution of this anomaly between genders. In this study, the occurrence of fissured tongue was more common in males than in females. This result is in accordance with Sawyer et al and Kullaa-Mikkonen et al.

In our study, the prevalence rate of bifid tongue was 2% and was seen in 2 males (100%) and 0 female (%). The most predominant age group in bifid tongue was found to be 1-18 age group-2 cases (100%). Sedano et al’s survey indicates a prevalence of bifid tongue as 5.3% per 1000, with a higher proportion of boys affected, and a prevalence ratio of approximately 2 boys per one affected girl. In Sedano et al results also, it was found that boys (0.6%) were high likely to be affected compared with girls (0.4%).

In our study, the prevalence rate of geographic tongue was 19% and was seen in 5 males (83%) and 1 female (17%). The most predominant age group in geographic tongue was found to be 31-45 age group -3 cases (50%). The reported prevalence rates of geographic tongue varies from 0.1% to 14.4%, and most studies report the condition in about 1-2% of the subjects examined. According to the study of Rezaei et al (2015), the prevalence of geographic tongue was about 7% in Iran. Other studies reported the prevalence of geographic tongue to be 2% among people in the United States (Greenburg et al., 2014). Sedano et al values showed a slight, nonsignificant male predilection when compared with females. Salem et al and Sawyer et al found geographic tongue with approximately equal frequency in both gender in their population. Kullaa-Mikonen et al on the contrary, found that the percentage of geographic tongue was higher in females than in males. Avcu et al showed Geographic tongue with prevalence rate of 1.2% and had no difference between sexes. No sex differences was seen in study by Redman et al.

In our study, the prevalence rate of median rhomboid glossitis was 12% and was seen in 3 males (75%) and 1 female (25%). The most predominant age group in median rhomboid glossitis was found to be 46-60 age group - 3 cases (75%). The reported prevalence rates of median rhomboid glossitis vary from 0% to 3.35%. The female to male ratio of median rhomboid glossitis in the Turkish dental outpatients is 12:1. Median rhomboid glossitis is once thought to be a congenital abnormality. The possible role of Candida albicans has been stressed, as many of these observed “lesions” have been associated with candidal infection and the clinical changes disappear or are greatly improved following
antifungal treatment. However, some uncertainty remains, since some of these lesions are not controlled by the use of antifungal agents (17).

In our study, the prevalence rate of macroglossia was 12%. The prevalence of macroglossia in the study done by patil et al was 1.5%. Macroglossia is associated with Down’s syndrome, tuberculosis, sarcoidosis, hypothyroidism, amyloidosis, multiple myeloma, neurofibromatosis, infection and allergic reaction.

In our study, the tongue lesions such as microglossia, hairy tongue and lingual nodule were not present.

**Conclusion**

It can be concluded that the prevalence pattern of developmental tongue lesions in South Indian population was relatively similar to the studies from other parts of the world with some geographic differences. Variations in results when compared to other studies may be due to differences in sample size and different ethnicity. Still more studies are required in this field.

Factors Underlying Dental Fear: A Fresh Insight

Andria J N Sirur¹, K. R. Pillai²

¹Assistant Professor, Department of Commerce, MAHE, India, ²Professor, School of Management, MAHE, India

Abstract

Background: Dental fear leads to lower use of oral-healthcare services, and, thereby, forming a dynamic vicious cycle of an important psycho-social factor causing avoidance of dental treatment and lack of attendance to dental treatments. The present study attempted to contextualize the dental fear scale, drawing on extant literature.

Method: The study instrument was circulated through social networking sites and online professional groups. Factor analysis was the major analytical tool.

Results: The results found a low and moderate level of dental fear among the respondents. The results, further, offer evidence to infer that education and employment are significant predictors of dental fear, but fail to establish the role of age structure on dental fear.

Conclusions: The moderate level of dental fear signals favourable attitude towards preventive dental care leaving lesser room for the occurrence of any avoidable dental health emergency and its inherent spill-overs in future.

Keywords: Dental fear, Dental fear scale, Factors underlying dental fear.

Introduction

Oral health is an inherent component of the overall general health and well-being of an individual thereby affecting his/her quality of life, appearance and self-esteem as well. Oral health conditions are universal public health challenges creating burden among all sections of population. The burden, however, can be reduced through home care and professional dental care, which, when received appropriately, on a regular basis, helps prevent and diagnose conditions through seeking of early intervention. Dental care is defined by many parameters such as dental visits per person annually, emergency versus routine care, and lack of dental visits in a given period of time. Nevertheless, plethora of studies confess that the attitude of the society, with respect to their oral health status, does not seem to be conducive to an overall favorable oral health environment.

Cohen et al. concede that those disadvantaged at receiving treatments for their oral health concerns are more likely to exhibit behavioural impacts that have effects on activities of daily living. Gender, age, education, feelings of vulnerability, need perceptions, language problems, treatment costs, transportation, dental workforce, individual’s health status, residence, charisma and beliefs of dental health care personnel are major barriers to utilization.

Context of the Study

A major reason for dental diseases is because of dental fear and anxiety that patients face, which, in turn, leads to their cancelling of appointments with the dentist or complete avoidance of treatment. Dental fear, delayed dental visits, increased dental problems and symptom-driven treatment forming a vicious cycle that feeds back into the fear experience of the patients, leading to an insoluble psychological problem. Multiple studies indicate that treatment avoidance owing to dental fear is a major public health problem.

In this backdrop, a quasi-exploratory study was undertaken using a structured instrument. The study
also endeavoured to contextualise the dental fear scale compatible to comparable socio-cultural situations.

**Review of Literature**

Armfield et al.\(^{15}\) have clearly delineated the difference between dental anxiety and dental fear, though they are often used interchangeably. Fear is a *physiological, behavioural and emotional response to a feared stimulus, whereas anxiety is a feeling of dread or worry focused on exposure to a feared stimulus*.\(^{14}\) Dental practitioners often find it easier to treat patients with dental anxiety but when it comes to dental fear, psychological and pharmacological strategies need to be adopted.\(^{18}\) Al-Madi and AbdelLatif\(^{19}\) clearly demarcate dental fear from dental anxiety.

An antecedent of dental anxiety and a widely experienced problem is dental fear\(^{20}\) which has been found to vary across cultures and across populations in regard to the content, pattern and levels. Considering demographic variables, prior study\(^{14}\) reports variation of fear among males and females, where in women were found to have higher levels of dental fear among different age groups, with the middle aged group, signaling high levels of dental fear.\(^{14}\) Individuals with poor socio-economic strata feared dental visits extensively. Additionally, dentate individuals, and people with fewer remaining teeth visit dentists less often\(^{14}\)

**Methodology**

The study followed a cross-sectional design and net survey method was used to collect data from prospective respondents. The study assessed dental fear using relevant scale. A structured questionnaire was designed drawing upon extant literature of dental fear. Dental fear was measured using a modified dental fear scale drawn upon Cohen et al.\(^{9}\), Goyal et al.\(^{13}\), Domoto et al.\(^{17}\), Nakazono et al.\(^{21}\), Al-Shammari et al.\(^{22}\), Armfield et al.\(^{23}\), Jakkola et al.\(^{24}\), and Abrahamson et al.\(^{25}\) Total number of 15 items were finalized in the deliberations and in consultation with experts.

The survey instrument was shared in various social networking sites and online professional platforms soliciting responses. Responses from those subjects, who never visited a dentist before, were excluded from the study to meet the stated objectives. A total number of 180 cases were considered for analysis after scrutiny. Principal component analysis\(^{26}\) was used to elicit modified dimensions of dental fear.

**Result and Analysis**

**Demographic profile of respondents:** Personal information of the respondents was considered crucial for better analysis and comparisons. Results of demographic profile of the respondents are presented in table 1.

*Source: Present study*

The minimum and maximum ages of the respondents covered in the study 18 years through 80 years respectively. When considering age groups, it is noticed that larger number of respondents belonged to the age group of 18 – 30 years (52 per cent). The survey responses were gender skewed with more number (56 per cent) of female respondents. Relatively high proportion of respondents with post-graduate and above level of education (54 per cent), with employment (58 per cent) and who hailed from urban location (78 percent) were the notable demographic attributes of the respondents.

**Factors underlying dental fear:** Factor analysis was conducted to identify the latent dimensions of dental fear. Principal component method was used for the analysis in Varimax rotation process. The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy test offered a value (0.789) well above the threshold level to ensure the sampling adequacy with respect to the number of items being considered for factor analysis.\(^{28}\) The Bartlett’s test of sphericity confirmed the suitability of factor analysis and which gives an indication of the inter-item co-relation, with an estimated Chi-square value 867.520 with p value of 0.000. The relevant result (rotated component matrix) of factor analysis is presented in the table 2.

Extraction Method: Principal Component Analysis.
Rotation Method: Varimax with Kaiser Normalization.
a. Rotation converged in 6 iterations.

The factor loadings table attests the multidimensionality of the concept of dental fear. Dimension reduction process elicited four factors. These factors are Psychological fear, Procedural fear, Functional limitation, and Health concern. All indicators hold moderately high factor loadings to validate impeccable correlation between a particular factor and an item loaded under it. The total variance explained all the four factors is 61.12 per cent, signifying higher level stake of these factors in determining the dental fear of the respondents. The scale reliability is 0.793, showing high level internal consistence among the indicators. All the factors, except health concern, display reliability co-efficient above the threshold level.

Psychological fear is understood to be the most prominent component of dental fear, with maximum number of indicators loaded under this factor. The relatively higher eigen value (4.055) and variance (27.031) associated to this factor also subscribe to this fact. The factor reliability co-efficient of this factor is also the highest (0.807), ascribing higher inter-item consistency among the group. Health concern is a weak factor, comparing to its counterparts, with only two indicators loaded under it. This factor holds a reliability co-efficient (0.551) well below the threshold level.

An examination of the status of dental fear has disclosed the presence of a moderate level of the same, as indicate in table 3. The study has also attempted to understand the relative levels of fear across the four dimensions of dimensions of dental fear. The results disclose that procedural fear outweighs its other three factor counterparts. Two major indicators of procedural fear are discomfort due to drilling teeth and administering of injection inside mouth. Though psychological fear is the most underlying element of dental fear, its is the lowest among the group pertaining to the status of dental fear.

Role of demographics on dental fear: The study considered five demographic factors such as gender, location of residence, age group, level of education and employment status to be instrumental for dental fear. Two-sample t-Test was used to examine the role of gender and domicility on dental fear and its various dimensions. The results are recorded in table 4.

Source: Present study

Gender has shown statistically significant impact on the overall dental fear. However, with respect to its various dimensions, psychological fear is the single most factor that has recorded any statistically relevant impact due to gender aspect. The location of residence, rural-urban dichotomy, manifests no impact either on dental fear or its various individual dimensions.

The role of age structure, education and employment status, as antecedents to dental fear, was examined using one-way ANOVA. The results, as presented in table 5, convey no evidence of statistically significant role of age structure, which is attributable on dental fear and its various dimensions. Whereas, the results offer evidence to infer that education and employment are significant predictors of dental fear. With respect to the dimensions, education has statistically significant bearing on procedural fear and functional limitation. Whereas, employment status is instrumental for psychological fear.

Discussion

The current study offers evidence to Hmud and Walsh's27 notion of the prevalence of oral health problem, despite improved awareness. as majority of respondents have reported minimal level of dental fear. The effects of demographic variables of dental fear and dental anxiety varied in different studies.A study by Domoto et al.17 clearly specifies that dental fear did not vary with age, which is consistent with results of the current study.

Patients tend to have greater levels of knowledge about their health that they question their doctors if they notice any discrepancy in the type of treatment provided to them. As such, the fear and anxiety levels that forbid patients to visit healthcare services has also reduced. The rise in health and beauty consciousness drive more people to visit their healthcare providers. When it comes to oral health people opt to have cleaner and beautiful smiles and visit the dentist more often which was observed in this study.

The major limitation wasthat it could not conduct a longitudinal assessment to validate the scale. Future researchers can focus on this lacunae. Empirical relation between dental fear and dental anxiety need to be examined for proper policy intervention.

Conclusion

The current study, therefore, aimed to determine the factors underlying dental fear of a cross section of society. The prevalence of dental fear, leading to dental anxiety, is on the decline owing toincrease in knowledge and awareness of oral health related factors. An increase in general and oral health consciousness through means of adoption of preventive healthcare practices gives an indication of an improved general and oral health-seeking behaviors among the masses. Findings of this study offer evidences of a moderate dental fear, which signals no room for the occurrence of any avoidable dental health emergency and its inherent spill-overs in future.

Conflict of Interest: The authors report no-conflict of interest.

Source of Funding: The authors received no funding for this study.

Ethical Clearance: The research team had not sought the Ethical Clearance committee of any hospital, as the survey was conducted outside hospital. The data collection process was no way coercive.

An Analysis of College Teachers’ Attributions Stress level especially with Students in Cheyyar Taluk

Dr. K. Indira 1, R.V. Suganya2, Dr. R. Lakshmi3

1Assistant Professor, 2Associate Professor, Department of Commerce, Vels University (VISTAS), Pallavaram, Chennai

Abstract

Background and Purpose: The word stress typically describes the negative concept where it affects the physical and mental fitness of human. Teacher’s stress is a real phenomenon and associated with number of variables. Stress among the College teachers is caused mainly because of student’s attitudes.

Method: This study is based on both primary and secondary data. The primary data is collected from Female Government College Teachers working in Cheyyar. The researcher distributed 100 questionnaires to the Select Female Government College teachers working in Cheyyar Taluk. The researcher used convenience sampling method.

Results: The highest stress score of 368 is attributed to ‘Responsibility to increase the pass percentage of the slow learners makes me to get stress’. Professional development is needed in order to grow and them reflect professionally. In order to reduce stress and increase retention, teachers need better professional development that they can see as useful contributions to their teaching.

Conclusion: Promote new learning experiences among staff, they should actively participate in organizational committees and groups in correlation with their council; engage staff in the change process and reward positive changes in behavior and practices. More motivated activities can be organised to help teachers develop their positive relationships with students.

Keywords: Stress, Female Teachers, Students, College, Government.

Introduction

The word stress typically describes the negative concept where it affects the physical and mental fitness of human. Hans Selye struggled unsuccessfully all his life to find a satisfactory definition of stress. In attempting to extrapolate his animal studies to humans so that people would understand what he meant and he redefined stress as “The rate of wear and tear on the body”.

Teacher’s stress is a real phenomenon and associated with number of variables. Stress among College teachers is caused mainly because of students’ attitudes. The widely prevalent belief that College teachers’ role is quite simple having no complexities, tensions and conflicts is not correct because this is the outsider’s perception on the role of women College teachers. The stress faced by women College teachers’ is substantial. Psychosocial hazards can severely damage the working environment in Colleges and the main stress factors for teachers are students’ inadequate knowledge and ignorance, behavioural attitudes, disciplinary problems, teasing mentality and so on. These problems can lead to physical and emotional exhaustions.

Review of Literature: Hargreaves (2000) explained in his article that the organizational structure of secondary education can make it somewhat more difficult for secondary teachers to feel personally connected with their students. He told that secondary teachers experienced more alienation from students and more often felt unknown and stereotyped by their students, which was repeatedly mentioned as a source of negative emotion.

Geving (2007) found that poor student behavior is a main contributor to teacher stress, especially secondary level teachers. Other cited reasons for (2005) teacher stress or lack of administrative support and the excessive number of tasks that are required of new teachers who have not acquired successful task-management skills.
Kyriacou (2001) in his study divided coping strategies into direct action and palliative techniques. Direct action refers to strategies that teachers can do to eliminate sources of stress. For instance, if time pressures and deadlines are creating stress, a direct action to reduce the problem would be to seek a time extension, or to seek a change in deadline. Palliative techniques do not deal with the source of stress itself, but it focuses on reducing the feelings of stress from those sources.

Pianta (2001) defined in his article ‘conflict or anger’ depicts the relationship between teacher and students conflict that evoke anger in teachers.

Yoon (2002) indicated that teacher’s stress predict the negative impact in teacher and student relationship. In his study he found the significant correlations among teacher’s stress and negative relationship between teacher and student. He also found that teacher’s stress arises from being unable to discipline pupils in the way they would prefer.

Vivek B. Waghachavare (2013) assessed stress among students of various professional colleges and its association with various academic, social and health-related factors. The calculated total sample size was 1,200. A pretested self-administered questionnaire was used for the data collection. Analysis was done using percentage, the chi-square test, binary logistic regression and multinomial logistic regression. Students from all the three fields studied were exposed to stress. Academic factors were one of the most important stressors.

Minarik et al., (2003) in their article found that the rate at which teachers leave the profession is significantly higher than the departure rate in other professions.

Kokkinos (2007) Organizational and social pressures such as administration workload, classroom management issues, and lack of supervision and team support have been extensively studied.

A review of relevant literature revealed that the teaching profession is an extremely stressful occupation globally.

Statement of the Problem: Stress in teaching profession have been a major worldwide problem till now. The critical analysis of the literature on teacher-student relationship and the female teacher stress management illustrates the different levels of stress among the female teachers by the reason of students attitudes. Questions have been raised about female College teachers service, encounters stress, outcomes of stress and coping strategies. It is noted that the different causes of stress have been studied about the demographics and stress level. But this research intends to look beyond the outcomes of stress due to the service encounters. The review concludes that causes of stress mainly related to work dissatisfaction, job environment, insufficient pay and professional conflict.

In Tiruvannamalai District, particularly in Cheyyar Taluk as far as the researcher’s knowledge goes, no study has been carried out about the stress of female College school teachers. This study will fill the gap in research that hasn’t done so far.

Objectives of The Study

1. To examine the demographic details of the Female Govt. College teachers.
2. To identify the service encounters among the Female Govt. College teachers.
3. To evaluate the outcomes of stress among Female Govt. College teachers.
4. To find out the coping strategies of the Female Govt. College teachers.

Research Methodology

Research Design: This study is based on both primary and secondary data. The primary data is collected from female Government College teachers working in Cheyyar Taluk. The secondary data depends upon magazines, research articles and periodicals.

Data Collection: The researcher distributed 100 questionnaires to the Select Female Government College teachers working in Cheyyar. The researcher used convenience sampling method to collect data from the respondents.

Questionnaire Design: The primary data is collected through the well-structured questionnaire which consists of both optional types as well as scaling type questions. The questionnaire consists of 4 parts. The first part deals with demographic variables of female Government College teachers. Second part is useful to find out the level of service encounters stress among the female Government College teachers using Likert’s 5 point scale. Third part contains outcomes of stress. It helps to find out to what extent the stress has affected the female Government College teachers in their day-to-day work. The fourth part was completely framed to assess how
often they apply some techniques and actions to cope up with their stress level.

**Tools used for Data Analysis:** The collected data from female Government College teachers in Cheyyar Taluk is systematically tabulated and arranged for the data analysis process. The following statistical tools are systematically used to anatomically analyze the primary data.

1. Anova is used to find the significant differences between demographic details and Service encounters.
2. Mann-Whitney U test is used to find the significant differences between demographic details and Service encounters, Coping strategies.
3. Wilcoxon W test is used to find the significant differences between demographic details and Outcomes of stress.
4. Z test is used to find the significant differences between demographic details and Service encounters.
5. Correlation is used to find the relationship between experience and total stress.

**Analysis and Interpretation**

**Service Encounters:** Service encounters score is calculated by adding up the ratings on five point scale. The first service encounter (‘Students’ response to teacher and teaching is good.’) and the seventh service encounter (‘I condemn the irregularity of the students’) are reverse scored as higher score indicates less stress level. The analysis of service encounters is tabulated in Table 1.

<table>

</tbody>
</table>

In can be concluded that the highest stress score of 368 is attributed to ‘Responsibility to increase the pass percentage of the slow learners makes me to get stress’. This aspect puts unnecessary stress on college teachers.

The second most stress to college teachers with a score of 357 is caused by students’ inadequate knowledge and ignorance.

The factors ranked third to ninth relate to discipline and students attitude which has to be dealt with firmly by both teacher and the management. The tenth ranked service encounter is found to be least stressful as most of the respondents get good response for their teaching from students.

**Outcome of Stress**

<table>
<thead>

<td>.023</td>
</tr>
</tbody>
</table>

Mann-Whitney U Test reveals significant difference in ‘Deep breathing’ coping strategy’s frequency of use between Single (Mean = 2.08, n = 26) and Married (Mean = 1.68, n = 74) teachers, U = 669, z = –2.5, p = 0.012.

Mann-Whitney U Test reveals significant difference in ‘Thinking positively’ coping strategy’s frequency of use between Single (Mean = 2.35 ,n = 26) and Married (Mean = 2.66, n = 74) teachers, U = 718, z = –2.27, p = 0.023.

**Major Findings of the Study**

- The highest stress score of 368 is attributed to ‘Responsibility to increase the pass percentage of the slow learners makes me to get stress’.
- The first service encounter ‘Students’ response to teacher and teaching is good ‘ and the seventh service encounter ‘ I condemn the irregularity of the students’ are reverse scored as higher score indicates less stress level.
- The second most stress to teachers with a score of 357 is caused by students’ inadequate knowledge and ignorance.
- The tenth ranked service encounter is found to be less stressful as most of the respondents get good response to their teaching from students.
- There was a strong, positive, partial correlation between experience of teachers and total stress, controlling for age of teachers, r = 0.723, n = 100, p < .0005, with high levels of experience being associated with higher levels of total stress.
- It is found that higher experience has partial, strong correlation of 0.723 to total stress, which indicates 52.27 per cent (0.723 x 0.723 x 100) shared variance.
- Experience helps to explain nearly 52.27 per cent of the variance in respondents’ scores of total stress experienced by teachers.

**Suggestions:** The results supports the hypotheses that the effect of occupational stressors on professor’s psychological well being vary depending on the level of perceived Student’s attitudes. However, although Students’ response to teachers and teaching is good support buffered with the effects of some occupational stressors, Students’ inadequate knowledge and ignorance exacerbated the adverse effects of others. Disciplinary student attitude can be resolved by a mix of empathy and firm disciplinary action. This will help bring down
teachers’ stress level. Psychological outcomes like Nervousness, Irritation, Emotional outbursts and Lack of satisfaction with the job are reduced by proper emotional support and social network support of colleagues and family. Singleteachers are thus more likely to use Deep Breathing and Thinking Positively as a method of coping with stress.\(^9\)

**Conclusion**

Teaching is a stressful career and few will refute the significance amount of stress involved in the career. Professional development is needed in order to grow and reflect professionally. Teachers desire this form of collaboration. In order to reduce stress and increase retention, teachers need better professional development, with that they can see useful contributions to their teaching. Professional development activities can range from simple school-level tasks for new teachers such as copy machine usage and how to complete administrative tasks to more advanced sessions on content knowledge or best practices.

To be more effective the practice of coping strategies may be followed regularly. It may be beneficial to begin using it after the school day when it is possible to take a few minutes to reflect on the day’s events. With practice, it will be helpful to begin using these techniques during stressful situations, not just after they have subsided. More motivated activities can be organised to help teachers develop positive relationships with students.

The Exploring Strategies for Reducing Occupational Stress of Female Physiotherapist

K. Indira¹, R.V. Suganya¹, M. Vetrivel¹

¹Assistant Professor, Department of Commerce, Vels University (VISTAS), Pallavaram, Chennai

Abstract

Background and Purpose: Stress is a part and parcel of our very existence, and probably the only stress free state is death. Physiotherapists help people affected by injury, illness or disability through movement and exercise, manual therapy, education and advice. The objective of this study is to find out the work stress in Female physiotherapist and to reduce their stress by the way of remedial strategies.

Method: This study is based on both primary and secondary data. The primary data is collected from female Physiotherapist working in Thiruvannamalai and Kanchipuram District. The researcher distributed 30 questionnaires to the Select Female Physiotherapist. The researcher used convenience sampling method to collect data from the respondents. Pearsons chi-square test is used to anatomically analyze the primary data.

Results: Stress causing factors should be detected and procedures should be followed to balance these factors. The results show that the level of stress in most of female Physiotherapist is in medium level. These results are similar to other studies.

Conclusion: Promote new learning experiences among staff, they should actively participate in organizational committees and groups in correlation with their council; engage staff in the change process and reward positive changes in behavior and practices. In short, this work provides some insight about the level of stress among female physiotherapists Thiruvannamalai and Kanchipuram District.

Keywords: Stress, Female, Physiotherapists, Outcomes, Coping Strategies, Occupational Stress.

Introduction

In the fast changing world of today, no individual is free from stress and no profession is free from stress. Stress is a part and parcel of our very existence, and probably the only stress free state is death. Stress cannot be avoided totally in any society. One has to learn to live with it, manage it and cope with it, if possible try to overcome it.

Women are important to society in the workforce and in the home. Women today are busier than ever. As working parents, they work long hours or hold multiple jobs. As a stay-at-home mothers, they take care of active and busy children while managing their home and sometimes even working from home. They are creating new possibilities, starting or running businesses and pursuing their dreams. With all that’s going on in a woman’s life, it seems almost impossible to find ways to de-stress. But it depends on how a woman adopts to it. Women continue to juggle multiple roles, including those roles related to the home and family, for which the women may have sole or major responsibility.

Review of Literature: Yuri Kawano (2008) explained in his article, stress factors are also associated with mental and physical health of nurses. The physical and mental health of nurses might affect their time off, the quality of care and patient satisfaction. However, many Japanese studies of nurses focused on the association of job related stress factors with job satisfaction or burn out.

Marc A. Campo (2009) et al., determined the levels of psychological job demands and job control reported by physical therapists in a national sample, compared those levels with national norms, and determined whether high demands, low control, or a combination of both increases the risk for turnover or work-related pain. More than one half of the therapists reported work-
related pain. Risk factors for work-related pain included low job control and job strain.  

Elisah Margretha Buining (2015) et al., explore the so-called ‘therapist-effect’, by looking at the influence of intrinsic therapist factors, specifically personality traits, on treatment outcome in patients with CD. Therapist variables were measured using a questionnaire consisting of demographics and the Big Five traits: Extraversion, Neuroticism, Agreeableness, Conscientiousness and Openness to experiences.  

N. Nathiya et al., (2017) found that Community physiotherapists are under increasing pressure and managing their time for working with small amount of resources and management skills. The aim of their study are concentrated the musculoskeletal injury for finding the occupational stress factors over sixty five physiotherapists in top ten hospitals using subjective scale study. Two groups were formed using the participants, i.e., physiotherapists from government hospital (GH) and physiotherapists from private hospital (PH).  

Statement of the Problem: Stress in the medical profession has been a major worldwide problem for quite something now. Work-related stress problems are on the increase among caring professions, such as nursing, in developing countries. The critical analysis of the literature on stress management of Female Physiotherapist illustrates the different levels of work stress among the Female Physiotherapist. Questions have been raised about their work related stress, outcomes of stress and coping strategies. It is noted that the different causes of stress have only been studied at the demographics and stress level. But this research intends to look beyond the outcomes of stress due to the work stress. The review concludes that causes of stress mainly related to work dissatisfaction, job environment, insufficient pay and professional conflict.  

In Thiruvannamalai and Kanchipuram Districts far as the researcher’s knowledge goes, no study has so far been carried out about the stress of Female Physiotherapist. This study will fill the gap in research that has not been well researched into.  

Objectives of The Study: The objective of this study is to find out the work stress in female nurses and to alleviate their stress by the way of remedial measures. Several questions are designed to obtain more detailed information about stress and its management. The study is done based on the data collected from the select Female Physiotherapistin working in Thiruvannamalai and Kanchipuram District.  

Research Methodology  

Research Design: This study is based on both primary and secondary data. The primary data is collected from Female Physiotherapist working in working in Thiruvannamalai and Kanchipuram District. The secondary data depends upon magazines, research articles and periodicals. The researcher distributed 30 questionnaires to the Select Female Physiotherapist working in working in Thiruvannamalai and Kanchipuram District. The researcher used convenience sampling method to collect data from the respondents.  

Questionnaire Design: The primary data is collected through the well structured questionnaire which consist of both optional types as well as scaling type questions. The questionnaire consists of 4 parts. The first part deals with demographic variables of Female Physiotherapist. Second part is useful to find out the level of work stress among the Female Physiotherapist working in Thiruvannamalai and Kanchipuram District using Likert’s 5 point scale. Third part contains outcomes of stress. It helps to find in what extent the stress has affected the Female Physiotherapist in their day-to-day work. The fourth part completely framed to assess how often they apply some techniques and actions to cope up with their stress.  

Tools used or Data Analysis: The collected data from Female Physiotherapist in Thiruvannamalai and Kanchipuram District is systematically tabulated and arranged for the data analysis process. The following statistical tools are systematically used to anatomically analyze the primary data.  

1. Simple percentage analyzes is used to describe the demographic profile.  
2. Pearsons chi-square test  

ANALYSIS AND INTERPRETATION  

Hypothesis Testing  

$H_0 = $ There is no significant relationship between age, education, monthly income, nature of employment, experience, family type, travel distance, monthly income and Work Related Stress.  

$H_1 = $ There is Significant relationship between age, education, monthly income, nature of employment, experience, family type, travel distance, monthly income and Work Related Stress.
Table 1: Relationship Between Demographic Variables and Work Related Stress

</tr>
</tbody>
</table>

** at .10 percent level

Chi-Square was used to test the independence, homogeneity and goodness of fit among the various factors with the demographic variables. The main purpose of using the test was to test whether there is a significant association between two variables.

The pearsons chi-square calculated value for all the “Work related stress” was significant at 0.05 level. Using, SPSS, if the significant value is less than 0.05 then reject null hypothesis and accept alternate hypothesis. In the above obtained results the significant value is less than 0.05 so, reject null hypothesis. Hence, there is significant association between all the mentioned variables and work related stress mentioned above in the table.

Hypothesis Testing for Outcomes of Stress

H₀ = There is no Significant relationship between age, education, monthly income, nature of employment, experience, family type, travel distance, monthly income and Stress Outcome.

H₁ = There is Significant relationship between age, education, monthly income, nature of employment, experience, family type, travel distance, monthly income and Stress Outcome.

** at .10 percent level

Chi-Square was used to test the independence, homogeneity and goodness of fit among the various factors with the demographic variables. The main purpose of using the test was to test whether there is a significant association between two variables.

The pearsons chi-square calculated value for all the “Outcome of stress” was significant at 0.05 level. Using, SPSS, if the significant value is less than 0.05 then reject null hypothesis and accept alternate hypothesis. In the above obtained results the significant value is less than 0.05 so, reject null hypothesis. Hence, there is significant association between all the mentioned variables and work related stress mentioned above in the table.

Hypothesis Testing for Coping Strategies

H₀ = There is no Significant relationship between age, education, monthly income, nature of employment, experience, family type, travel distance, monthly income and Coping Strategies.

H₁ = There is Significant relationship between age, education, monthly income, nature of employment, experience, family type, travel distance, monthly income and Coping Strategies.
Chi-Square was used to test the independence, homogeneity and goodness of fit among the various factors with the demographic variables. The main purpose of using the test was to test whether there is a significant association between two variables.

The pearsons chi-square calculated value for all the “Coping Strategies” was significant at 0.05 level. Using, SPSS, if the significant value is less than 0.05 then reject null hypothesis and accept alternate hypothesis. In the above obtained results the significant value is less than 0.05. So, reject null hypothesis. Hence, there is significant association between all the mentioned variables and work related stress mentioned above in the table.

**Major Findings of the Study**

- There is a significant association between all the mentioned variables and work related stress.
- There is significant association between all the mentioned variables and outcome of stress.
- There is a significant association between all the mentioned variables and coping strategies.

**Suggestions:** The results show that the level of stress in most of Female Physiotherapist in Thiruvannamalai and Kanchipuram Districts is in medium level. These results are similar to other studies. The most effective coping strategies which would decrease work stress are doing yoga, exercises and meditation. In general, salary hike to employees make less stress and will improve the sense of autonomy, confidence and responsibility. Support of spouse is very important to reduce their stress level. To give proper monetary incentives and a good working.

The Female Physiotherapist can be made to work in a stress free or less stress environment by assigning them proper work load considering their abilities and skills, makes them to realize their responsibilities, giving them opportunities to participate while taking decisions, providing them with all the facilities, making bases for a social links, paving way to their job improvements.

**Conclusion**

In conclusion, health care professionals are more susceptible to occupational stress because of intense daily activity. Female Physiotherapist are not ever thought of as needing help but only as the care givers, and applying some techniques for Female Physiotherapist stress burnout prevention is more important than we ever thought. To reduce occupational stress among Female Physiotherapist, create fun work environment, encourage and reward creativity among staff to generate ideas and implement new practices, discuss opportunities with staff to increase sense of autonomy such as shared governance and self-scheduling; use case studies to reinforce problem-focused strategies versus stress reduction. In short, this work provides some insight about the level of stress among Female Physiotherapist. It acknowledges the need for further research to explore source of stress among Female Physiotherapist their possible solution and preventive measures and also to determine the effect of any change secondary to implementation of preventive strategies at different levels.

An Anatomical Study on Position of Mandibular Foramen in Dry Adult Human Mandibles

Govindarajan Sumathy1, Bhaskaran Sathyapriya2, Balasubramanian Chandrakala3, Ramachandran Tamilsevi4

1Prof. & HOD, 2Professor, 3Senior Lecturer, Department of Anatomy, 4Reader; Department of Conservative Dentistry & Endodontics, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education and Research, Chennai, Tamil Nadu, India

Abstract

In dentistry field the inferior alveolar block technique is most common. The aim of this paper is to summaries the knowledge about the anatomy of the mandible and with the localization of anteroposterior and superoinferior position of the mandibular foramen in adult mandible and also to emphasize the most significant clinical suggestion of the current studies regarding anesthesia carried out in the area of the mandible.

Keywords: Mandible, human anatomy, inferior alveolar nerve block, mandibular foramen.

Introduction

The mandibular foramen is an opening in the internal or medial surface of the ramus of the mandible. The mandibular vessels and nerve to pass through the mandibular foramen. The foramen is guarded by a bony protrusion called lingula. The mandibular canal starts at the mandibular foramen and descends obliquely forward in the ramus, and later in the body of mandible accommodates the inferior alveolar neurovascular bundle1.

Knowledge of the position and its exact localization of the mandibular foramen are important for both diagnostic and clinical purposes. Clinically, during routine block injection application during tooth extraction and surgical procedures like sagittal split osteotomy2,3 the inferior alveolar nerve could be injured. The most frequent technique failure in anesthesia of the inferior alveolar lies in the inappropriate setting of the needle, due to the inaccurate location of anatomic structures mandible foramen4.

In different populations, this foramen occupies different position. But its most frequent position on the mandible is found to be in the mid of ramus5-7. Therefore, the purpose of this study is to investigate any difference occurs in the position of the mandibular foramen of dry adult human mandible.

Materials and Method

For this study 50 dry adult human mandibles of unknown sex and age were collected and studied in Department of Anatomy, Sree Balaji Dental College and Hospital, Bharath University. In order to standardise the measurements, the subsequent mentioned points were determined: (A) mandibular foramen; (B) mandibular notch; (C) inferior border of the ramus; (D) anterior border of the ramus; and (E) posterior border of the mandible (Fig 1). The line connecting B-A-C and D-A-E determined the height and the width of the mandible, respectively. Any mandible with signs of defects were noticed and barred for the study. We have also excluded the edentulous mandible. The height and the width of the mandible were taken on both sides using vernier caliper.

All bones were subjected for the measurements as:

• Vertical measurement (Superoinferior position)
• Horizontal measurement (Anteroposterior position)

The measurements was made by taking the references spot like

• AB-MF: Nearest point on the anterior border of the ramus of mandible to the mandibular foramen (AB- anterior border, MF – mandibular foramen)

• MF- PB: Nearest point on the posterior border of the ramus of the mandible to the mandibular foramen. (PB- posterior border, MF – mandibular foramen)

• MN-MF: Mandibular notch to the mandibular foramen.

• MF-IB: From mandibular foramen to the inferior border of the mandible

The distances from the mandibular foramen to various bony landmarks were recorded. The mean and standard deviation were calculated separately for right and left sides and tabulated (Table 1)

The A-P position of the MF on the ramus was determined by drawing a perpendicular line from the MF to the tangent of the posterior border of the ramus (AP line) as described by Fujimura et al. 8.

All the measurements were taken on the either side of the mandible. The mean values and standard deviation were calculated using SPSS version 20.0. The parameter were compared using students T test with significance of p=0.05.

Result

The purpose of this study is to locate the position of mandibular foramen in relation to the anteroposterior and superoinferior directions. Different investigators have adapted different method to study the position of mandibular foramen. In certain studies radiographs 9, 10 were used while others used the dry mandibles for foramen localization 11, 12.

In our study the superoinferior dimension on the right side the mean distance from mandibular notch to the mandibular foramen is 22.26 ± 0.258 SD and from mandibular foramen to the inferior border is 23.5± 24.1 SD. On the left side the mean distance from mandibular notch to the mandibular foramen is 22.7 ± 0.282 SD and from mandibular foramen to the inferior border is 24.1± 0.268 SD (Graph 1). In anteroposterior dimension (Graph 2) the mean distance from anterior border to mandibular foramen is 17.7 ± 0.188 SD and the mean distance from mandibular foramen to posterior border is 15.8 ± 0.320 SD on the right side. On the left side the mean distance from anterior border to mandibular foramen is 17.14 ± 0.292 SD and the mean distance from mandibular foramen to posterior border is 15.2 ± 0.174 SD (Table1). The pronounced deviations were observed in these measurements may due to alter in the shape of the foramen. The mandible foramen is located near the centre or at the centre of the mandible ramus. However there is no marked change were observed in the position of the mandibular foramen on the right and left sides.

Discussion

The mandibular foramen which is considered as an important landmark for orthosurgeries in vertical ramus osteotomy, inverted L-ostectomy, endodontic treatments and lesions diagnosis, accomplish inferior alveolar block. During these surgical procedures the inferior alveolar nerve is at great risk of injury. Failure to locate neurovascular bundle will result due to inaccurate localization of mandibular foramen. Incorrect estimations of its location might be the reason for the unsuccessful anesthesia of the inferior alveolar nerve. Our present study investigated the location of the mandibular foramen and compared to the other studies done in south Indian population. A study carried out by Lavanya Varma et al stated that the mean distance of MF from 3rd molar tooth was 1.5 cm and 1.8 cm in right and left side of the mandible in South Indian population. Padmavathi et al found that the distance of mandibular foramen was situated at an average distance of 0.9 ± 0.8 mm posterior to the center of the width of the ramus and at an average distance of 1.4 ± 0.6 mm superior to the center of the vertical height of the ramus. One of the most common reasons for the failure in the technique of inferior nerve block is due to the lack of the proximity between anesthetic needle and mandibular foramen and thus the inaccurate localization of the structures of the mandibular foramen. Thus our current study explains the position of the MF with references to the various landmarks. In this study the position of the mandibular foramen seems to be bilateral symmetry in adult human dry mandibles. The result shows no significant difference between right and let sides which coincide with Gopalakrishna et al., 2016. The knowledge of the position of the MF is of a great importance for many procedures in dentistry. Its accurate location enables a more effective anesthesia, which in turn leads to an easier patient conditioning.

Conclusion

The understanding of the landmarks for location of mandibular foramen is a considerable importance for the surgeons and radiologists to perform successful inferior alveolar nerve anesthesia, dento alveolar surgeries, endodontic treatments and lesions diagnosis and prevent the damage of neurovascular structures passing through it and subsequent complications. Thus our study is very useful for clinicians who work in the area of the mandible.

Protective Effects of Plants Against Nicotine Induced Reproductive Toxicity in Male Animal Models: A Literature Review

S. Kanimozhi1,2, Govindarajan Sumathy3

1Research scholar, Department of Anatomy, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education, 2Assistant Professor, Sri Sai Ram Siddha College, Tambaram, 3Prof. & HOD, Department of Anatomy, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education, Chennai

Abstract

Nicotine the major ingredient in Cigarette is said to have many adverse effects on Spermatozoa and its parameters and affects various other fertility factors. The damages caused by cigarette smoking are due to the biological finding that Nicotine increases the level of free radicals, which results in oxidative stress. These increased the free radicals which also causes DNA damage and lipid peroxidation in human sperm, thus resulting in impairment of sperm quality. Nicotine administration in experimental animals affect spermatogenesis, epididymal sperm count, motility and the fertilizing potential of sperms. A huge number of medicinal herbs have been listed in siddha system that improve spermatogenesis and increase the quality of sperm. This review provides an overview on the association between male fertility induced by nicotine and protective effects of various herbal plants against sperm damages.

Keywords: Nicotine, Tobacco, Male infertility, Free Radicals, Antioxidants, Testosterone.

Introduction

In developing countries infertility is an understudied concern in sexual and reproductive health, yet its impact can be staggering. An inability to conceive or bear children can result with psychological, economic, and medical implications. The quality of human sperm is deteriorating in South India over the years, most probably due to environmental, nutritional, life style or socioeconomic causes1. Nicotine, a pharmacologically active alkaloid, is the most important component of tobacco. Administration of nicotine compounds through any route decreases the sperm count and motility. Only a few Scientific analyses are done on the Impacts of cigarette smoking on male infertility. 30% of studies reveals the cause of infertility as reduction in sperm count 42% of studies reveals the cause as reduction in sperm morphology and 40% of studies reveals the cause as reduction in sperm motility3. Nicotine can damage sperm membrane and DNA and induce apoptosis in interstitial cells of testis. The role Anti-oxidant properties of herbal plants on reproductive hormones, epididymis pathway, and sperm count and motility in nicotine induced infertility have not been investigated so far. In Siddha system many herbs are used to improve the sperm quality and other fertilizing characters of sperm. Many Plants and their extracts that are rich in antioxidants play a major role in protecting testicular damages caused by nicotine. The plants listed in this review may be of high scientific relevance. There is need to conduct Preclinical and Clinical studies to support the traditional claims and thus to work out cellular and molecular mechanism of infertility induced by nicotine.

Nicotine Dosage: The Tobacco in a single Tobacco Cigarette rod containing approximately 1–2% nicotine is equal to 1–2 g per 100 g or 0.8–1.9 mg nicotine. An average cigarette delivers roughly 10–30 μg kg⁻¹ peak
plasma levels of Nicotine\textsuperscript{4,5,6}. In most of the preclinical studies nicotine is administered intraperitoneally\textsuperscript{(7)}. In a few studies nicotine is administered intramuscularly. Nicotine is administered either in salt form (Nicotine tartarate) or as Liquid Nicotine. The most common dosage of Nicotine are as follows 0.1 mg/100 g BW\textsuperscript{(12)}, 0.25 mg/100g/day\textsuperscript{(2),(11)}, 0.3 mg/100g, 0.4 mg/100g \textsuperscript{(17)}, 0.5 mg/100g \textsuperscript{(63),(14)} and dose of liquid nicotine is 0.5 ml/kg body weight of animal\textsuperscript{(9)}. Nicotine (free base) \textsuperscript{162} g mole\textsuperscript{−1} MW, whereas nicotine hydrogen tartrate=498 MW.

In calculating the amount (mg) of the salt form needed to be administered, the following equation is useful\textsuperscript{76}: 
\[ \text{dose, mg/kg } \times \text{ BWt, kg } \times \frac{\text{nicotine salt form MW}}{\text{nicotine free base MW}} \]/injection volume, ml

Nicotine on reproductive tissue: The Nicotine which is consumed is oxidized to its metabolite cotinine, which has a long half-life period. This nicotine and the cotinine adversely affect spermatogenesis and decrease epididymal sperm count, motility, and the fertilizing potential of sperms. Presence of increased amount of Nicotine in the body stimulates high amount of collagen fibres deposition under the basal lamina leading to thickening of Tunica propria. It also causes degeneration of Junctional specifications between the Sertoli cells\textsuperscript{8}. Tubulin is a protein particle that is abundant in the cytoplasm of all multiplying cells that plays a major role in cell division. Nicotine reacts with Tubulin and causes disorders in cell division\textsuperscript{3,4}. Nicotine produces both reversible and irreversible damages in most tissues of all living beings and the extent of damage is species specific and depends on age, gender, genetic background, period of exposure and route of administration. The oral administration of nicotine in rats at a dose of 2.5 mg/kg body weight/day for the duration of four weeks is equivalent to the constant exposure to nicotine in smokers in humans\textsuperscript{(2)} Nicotine (0.5 mL/kg) significantly decreased the motility, count and normal morphology of sperms (p<0.05)\textsuperscript{(9)}

List of Plants That Prevent Nicotine Damages:
In Siddha system many herbal plants are used in the treatment of male infertility. Only a few scientific studies are available to prove the efficacy of those plants and their extracts that combat nicotine-induced toxic effects on spermatogenesis. Some of those plants are reviewed and listed for future reference.

Curcumin, an extract from Curcuma longa is useful in the treatment of male infertility owing to oligospermia and decreasing male sexual hormones\textsuperscript{(9)}

Coconut water, the liquid endosperm of coconut, contains sugars, vitamins, minerals, proteins, free amino acids and growth promoting factors which promote Spermatogenesis.

Aqueous extract from the plant Chlophytum borivilianum result in amelioration of sexual dysfunction, and improves sexual performance.

Date Palm pit reduces the toxicity produced by Nicotine on testis and result in significant increase of testosterone level in serum and stimulates spermatogenesis\textsuperscript{10}

Effects on Sperm Count and Abnormal Sperms:

Common abnormalities seen in nicotine treated rats were sperm head twisted body, detached head, abnormal neck, round tail. The sperm count can be calculated by Johnson criteria, a convenient and rapid method for quantitative analysis of spermatogenesis. Gradual increase in dose of curcumin for 50 days significantly increased the Sperm count and normal morphology of sperms. \(^{(9)}\)

Tender Coconut water and Mature Coconut water administered with nicotine showed significantly \((p \leq 0.05)\) higher epididymal sperm density, improvement in vas deferens weight and sperm count in comparison with the nicotine treated control rats. The percentage of spermatozoan with progressive movement was considerably \((p \leq 0.05)\) reduced on plant toxin treatment. Coconut water supplementation significantly protected the sperms from the damaging effect of nicotine and exhibited a significant \((p \leq 0.05)\) decrease in percentage of sperm abnormality. Tender Coconut water showed good improvement in progressive movement of sperm. Mature coconut water also showed significant \((p \leq 0.05)\) sperm protective effects and decreased the sperm abnormality. Coconut water commonly increased sperm motility.

Eruca sativa seed oil showed a significant improvement in all the testicular parameters of nicotine treated rats. Eruca sativa seed oil play a major role in stimulating the process of spermatogenesis in rats immediately.\(^{(2)}\)

Green tea prevented the appearance of few scattered pyknotic nuclei in the basal cell layers. It also increased the Interstitial Leydig cells \(^{(11)}\).

Zingiber officinale was very effective in preventing the nicotine induced testicular damages by increasing the pro infertility potentials in nicotine induced male and also female rats.

The plants that are rich in antioxidants improve the sperm quality by increasing the expression of antioxidant genes in rats.

Effects on Morphometry and Sperm Motility:

Curcumin decreased all types of toxicity induced by nicotine in the fatty tissue.\(^{(9)}\) Reduction in Testicular weight is an important marker of gonadal toxicity. Minimal administration of nicotine for 21 days showed a markable reduction in weight of testes. Nicotine \((0.5 \text{ mL/kg})\) caused a significant decrease in the diameter seminiferous tubules in comparison with control \((\text{ethanol-saline})\) group \((p<0.05)\). Curcumin played a significant role in regulating diameter of seminiferous tubules \(^{(9)}\).

As a result of Genotoxic effect of nicotine there is excess production of two highly mutagenic nitrosamine, \(N’-\text{nitrosonor nicotine (NNN)}\) and \(4-(\text{methyl nitrosamine})-1-(3-\text{pyridyl})-1- \text{butanone (NNK)}\) which is a by product from nicotine during tobacco curing or burning. Green tea improved the capacity of spermatozoa to penetrate oocytes.

---

**Fig. 1:** Analysis of the effect of control, nicotine, plant - nicotine on testicular weight.
**Effects on Hormonal Imbalance:** Nicotine degenerates the germ cells by reducing intra testicular concentrations of testosterone, which is essential for the normal spermatogenesis as well as for the maintenance of the structural morphology and normal physiology of the seminiferous tubules. The plants listed here are rich in unsaturated fatty acids that stimulate the activity of 17 β-hydroxysteroid dehydrogenase, the most important key enzyme in the testosterone biosynthesis pathway. Crocin elevated testosterone level (P=0.00) even in highly toxic animals. Nicotine caused a significant decrease in spermatogenesis quantity and Johnson’s score, sperm parameters, and sex hormones. Plants that increase Melatonin production can increase sperm chromatin integrity, and improves spermatogenesis.

**Conclusion**

This review was conducted to evaluate the protective effects of various herbs plants and their extracts against sperm damages in nicotine administered male rats. Though a number of evidences were available in literature, for plants used as aphrodisiacs and those increase sperm count and quality, Only a very few has been listed and proved scientifically about the mechanism in managing nicotine induced damages. Efficacy of all other herbs and their extracts against nicotine induced infertility needs scientific updation. Various pathways involved must be taken into account to come up to find a lead molecule of herbal origin to treat nicotine induced sexual impairment. All the plants that improve the quality of sperm seems to be rich in natural antioxidants like flavanoids. These antioxidants help in scavenging the free radicals and helps to prevent lipid peroxidation within testes, thus enhancing the testosterone levels and results in normal sperm counts.

Histological Studies on Pancreatic Tissue in High Fat Diet with Low Multiple Dosage of Streptozotocin Induced Type 2 Diabetes After Gymnema Sylvestre Administration

Arumugam Rajalakshmi1-2, Govindarajan Sumathy3

1Research Scholar, Department of Anatomy, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education and Research, Chennai, Tamil Nadu, 2Assistant professor, Department of Anatomy, Melmaruvathur Adhiparasakthi Institute of Medical Sciences, Melmaruvathur, Tamil Nadu, 3Govindarajan Sumathy, Prof & HOD, Department of Anatomy, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education, Chennai

Abstract

Gymnemasylvestre is a medicinal plant for the potential management of diabetes mellitus. The leaves are used in herbal medicinal preparation. phytochemical study shows its therapeutic value and for treating the patient with type 2 diabetes mellitus(11). The present study deals with the ethanolic extraction from powdered leaves of gymnemasylvestre through the soxhlet apparatus carried out for 48 hours. the active phytochemical component of gymnemagenin and its antidiabetic and hypolipidemic property(6) is tested by standard procedure. The chemical test such as thin layer chromatography shows the presence of gymnemic acid. isolation and quantification of the powdered leaves of gymnemasylvestre is revealed the presence of gymnemagenin(2). Type 2 diabetes is confirmed with the values of fasting bloog glucose and c-peptide level. The ethanolic extract of gymnemasylvestre(14) with dose of 200mg/kg body weight and 400mg/kg is administered to low multiple dose 40mg/kg body weight streptozotocin induced type 2 diabetes mellitus and the parameters of blood glucose, body weight are taken and it is compared to normal control group. The histopathogical study shows a significant changes in the recovery of pancreatic beta cell in the treatment of gymnemasylvestre(7). The result indicates the component of gymnemic acid(5) from gymnema sylvestre is useful in controlling the blood sugar level to treat type 2 diabetes mellitus in the earliest stage of disease.

Keywords: Gymnemasylvestre, gymnemagenin, c-peptide, type 2 diabetes, pancreas.

Introduction

Metabolic syndrome causes many risk factor for cardiovascular problems which includes hyperglycemia, obesity, hypertension. Nowadays there is a tragic increase in the risk of developing type 2 diabetes mellitus across the world. Patients with type 2 diabetes are often associated with obesity which shows reduced insulin sensitivity and causes excess insulin secretion and hyperinsulinemia. Type 2 diabetes mellitus has become common syndrome in society due to sedentary life style and dietary habits. So effort has to be taken to prevent the prevalence of type 2 diabetes mellitus. To achieve this goal, an appropriate experimental animal are used to establish the pathogenesis, disease syndrome such as obesity, hyperlipidemia along with type 2 diabetes mellitus which is exactly close to the humantype 2 diabetes mellitus.

Various drugs are used to induce diabetes mellitus but streptozotocin is the drug commonly used to induce both type 1 and type 2 diabetes mellitus. The dosage and the diet varies to develop type 2 diabetes mellitus. Many studies reported that the rat fed with high fat diet and the combination of low multiple dose of streptozotocin induces type 2 diabetes mellitus, which are more closely
related to the human type 2 diabetes mellitus. Many studies reported that the high fat diet will initiate the insulin resistance which is the important feature of non-insulin dependent diabetes mellitus. Many authors reported that streptozotocin has the capability to induce mild to severe type of diabetes mellitus and the reports indicates low multiple dose of streptozotocin induces type 2 diabetes mellitus in a animal model. In order to induce type 2 diabetes mellitus the present study is planned to use streptozotocin as the drug.

Although there are many anti-diabetic drugs are produced and suggested to the patients. Still, type 2 diabetes mellitus is a major metabolic syndrome in India. Many authors reported that prolong use of these antidiabetic drugs may cause side effects. Sulfonyl urea drugs. In order to avoid the progression of hyperglycemia and destruction of beta cell, progression of insulin resistance in beta cell. Many traditional medicinal plant drugs shows a remarkable changes in reducing the symptoms of disease and use of this reduces the risk of developing side effects and less toxic in nature. In the present study the traditional medicinal plant called Gymnema sylvestre has antidiabetic property and its component gymnemagenin, saponin play a major role to reduce the hyperglycemia, prevent insulin resistance in type 2 diabetes mellitus. The present study was designed to evaluate the protective effect of ethanolic extract of Gymnema sylvestre on hyperglycemia, hyperlipidemia, hyperinsulinemia, obesity and organ weight in male wistar albino rats.

Materials and Method

Streptozotocin was purchased from viva scientific company, chennai. The plant of gymnema sylvestre were collected from nithya herbal gardens from Chidambaram and the plant material was properly identified and confirmed with plant authentication no.PARC/2018/3985. The plant leaves were air dried under shade and the dried were made into fine powder, the powder is kept in a freezer until further use. The present study protocol was approved by animal ethical committee of sathyabama institute of science and technology with CPCSEA noSUS/CLATR/IAEC/XI/100/2018.

Male wistar albino rats, weighted 140 to 160g were used for the study and the animals were kept under polypropylene cage inside a ventilated room. Each cage consist of 4 rats, they are maintained under standard laboratory condition of 12:12 hours light/dark cycle with temperature 22-25 degree c with relative humidity of 50-60% and had a free access of water.

Diet and Chemicals: The animals were fed with high fat diet and water. The high fat diet consists of carbohydrate 43%, fat 40% and protein 17% were used for the study and the regular chow diet for control group which consists of carbohydrate 49%, fat 3% and protein 21%.

Preparation of Ethanol Extract of Gymnema Sylvestre: 100g of dry leaf powder was packed in a soxhlet thimble and then extracted with 80 percent ethanol. The 80 percent ethanol is added until the powder is exhausted, the extraction procedure were carried out for 48 hours till the ethanol extract was obtained. The collected solution from the flask were filtered through whatman no.1 filter paper. The solvent was evaporated under pressure at 90 degree c by rotary evaporator and the extract was stored at -20c in a freeze until for further use.

Preparation of Streptozotocin Solution: Streptozotocin was dissolved in 50Mm sodium citrate buffer (pH 4.5) to a final concentration of 4mg/ml and this solution is always prepare freshly should use it within 5 -10 min. using 1ml syringe and 22-g needle, inject the low multiple dose of streptozotocin solution intraperitonially at 40mg per kg body weight (1.0ml/100g) for 5 consecutive days in the experimental group of animals and the dose were calculated according to the body weight of animals.

Experimental protocol: The animals were divided into six groups. Each group consists of six animal in the study. In this six groups, control group receive normal chow diet and water, control high fat diet group receive high fat diet till the end of experiment, remaining all the four groups receive high fat diet before induction of the low multiple dose of streptozotocin. Before injection, the albino rats were fasted overnight and then given intraperitonial injection in a citrate buffer (pH 4.5) next morning. After induction the group 3 - low multiple dose streptozotocin induced, group 4 - low multiple dose streptozotocin induced + high dose (400mg/kg body weight) Gymnema sylvestre, group 5 - low multiple dose streptozotocin induced + low dose (200mg/kg body weight) Gymnema sylvestre, group 6 - low multiple dose streptozotocin induced + metformin 25mg/kg body weight were fed with normal, the control group and the high fat diet group receive regular and high fat diet respectively. On 43rd day all the animals were fasted.
overnight and sacrificed with deep anesthesia with ketamine. The liver, kidney, pancreas, heart and aorta were dissected and weighted immediately. The tissue were fixed in 10% formalin for histological analysis, body weight was measured weekly, food and water consumption is monitored daily.

**Result**

Blood glucose: Fasting blood glucose level were taken before starting the experiment and after treatment. Fasting blood glucose was measured once every 15 days. It was measured by collecting a drop of blood from tail vein, this was measured by using a rapid glucose analyser with a glucose strip inserted in a glucometer and the values are recorded in terms of milligram per deciliter of blood. The results are given in tabular column below 1

Body weight: Animals were weighed before and after starting the experiment and during respective treatment and after completion of each treatment group. The record of these observation was maintained and given in the tabular column 2.

**C-Peptide Level:** Blood is collected from retroorbital vein and the blood is collected immediately in potassium ethylenediaminetetraacetic acid (EDTA) tube and measured using immunoussay analyser is stable at room temperature. The parameter of c-peptide level is taken before induction of streptozotocin and after administration of streptozotocin which is given in a tabular column below. ref tab.3

**Histopathological Study:** All the animals were sacrificed by cervical dislocation after completion of experiment and the pancreas tissue was fixed in 10% formalin and the tissue were processed, embedded in paraffin wax and section were taken with 5µ thickness in a microtome. Sections were stained with haematoxylin and eosin stain to see the histological changes of pancreas through microscope.

**Statistical Analysis:** All the values are reported with mean ± SD. Statistical analysis was carried out by ANOVA test with the significance of p value.

**Histological Study:**

The histological study of pancreas of type 2 diabetic group showed shrinkage of islets of langerhans, damage of acini and the number of beta cells are reduced whereas in treatment group there is regeneration of islets of langerhans and beta cell number also increased due to the ethanolic extract of *gymnema sylvestre*. According to hafizurrahman improvement of beta cell function was observed in *gymnema sylvestre* treated diabetic rat in his immunohistochemical study\(^7\).

**Discussion**

According to diago the low dose streptozotocin with high fat diet induces type 2 diabetes\(^3\), in the present study the food and water intake is observed, the result shown a significant reduction in body weight and increased water intake and food intake of type 2 diabetic group of wistar albino rats when compared with control group. In the treatment group administration of *gymnema sylvestre* showed a significant raise in body weight. The high intake of food and water intake after streptozotocin injection is a significant characteristic of type 2 diabetes mellitus. According to wang\(^15\) in his study the 30-40mg/kg were utilized to induce type 2 diabetes mellitus when combined with high fat diet. In the present study 40mg/kg were chosen to induce type 2 diabetes mellitus. In the present study here is
marked increase in fasting blood glucose level after streptozotocin injection and during treatment with Gymnemasylvestre, the fasting blood glucose level is markedly reduced this shows the hypoglycemic activity of ethanolic extract of Gymnemasylvestre. The fasting blood glucose level is raised in a diabetic group of wistar albino rats when compared with control group and there was a recovery of fasting blood glucose is seen in the treatment group. In the present study the streptozotocin induced type 2 diabetes mellitus shows a marked decrease in body weight and pancreatic tissue weight the body weight is slightly increased after giving the treatment with ethanolic extract of gymnemasylvestre. According to Nath s.k(10) in his study he reported the pancreatic gland weight is decreased in high fat diet induced type 2 diabetes whereas in the present experiment also reduction in pancreas weight occurs. In the present case of treatment group of gymnemasylvestre with a dose of 400mg/kg body weight, the fasting blood glucose becomes normal than gymnemasylvestre with a dose of 200mg/kg body weight. According to dipak(4) in his study 70% ethanolic extract of gymnemasylvestre is taken for treatment but in the present study 80% ethanolic extract of gymnemasylvestre is given for treatment group of animals which shows increase in pancreatic beta cell regeneration which related to author syed rana(13).

Conclusion
The result indicates high fat diet with low multiple dose 40mg/kg streptozotocin induces type 2 diabetes mellitus and the high dose of Gymnema sylvestre 400mg/kg posses high hypoglycemic activity than the low dose.

Abstract

Breast cancer exhibits diagnostic and therapeutic challenges due to tumour heterogenicity and poor efficacy of anti cancer drugs at the metastatic sites. Recently, nanomedicines provide a potential benefit to breast cancer treatment by their increased bioavailability, selective targeting, increased efficacy and lower toxicity. This work aimed to evaluate the cytotoxic potential of A. annua silver nanoparticles (AGNPs) on human triple-negative breast cancer cell lines. The mechanism by which A. annua AGNPs exhibit growth inhibition was analysed by using the status of LDH, Mitochondria Membrane potential [MMP], and ATP levels. Finally, the ability of A. annua AGNPs to mediate cell death was studied by protein expressions of Bax, BCL-2, Caspase 3 and Caspase 9. We observed that A. annua AGNPs show a remarkable cytotoxic effect by increasing levels of LDH with loss of MMP and reduced ATP levels. Here in this study, protein expression of Bax, BCL-2 ratio, Cyt C and Caspase 9 protein expression level favors apoptotic induction during AGNPs treatment. Henceforth we prove that A. annua AGNPs can be useful as alleviative regiment against breast cancer and can be explored for other cancers and its related pathologies.

Keywords: Breast Cancer, Bax, Bcl-2, Apoptosis, Mitochondria, Caspase 9.

Introduction

Breast cancer is one of the most common invasive cancers in women with high mortality worldwide. The increased mortality rate is high due to lack of early detection, effective less treatment, severe side effects and drug resistance [1]. Based on molecular markers for hormones breast cancer is of 3 types of Estrogen receptor [ER] positive, Progesterone receptor [PR] positive and Hormone receptor [HR] negative. Currently, triple-negative breast cancer recurs more frequently than the other 2 subtypes due to uncertain benefits of chemotherapy and endocrine therapy which warrants greater attention towards identifying novel drugs to inhibit and as well as to prevent its recurrence.

Artemisinin the active component of Artemisia annua [sweet worn wood] is well known for its unique potential against malarial infection. It is a sesquiterpene lactone containing an unusual endoperoxide bridge that shows marvelous action on apoptotic induction, angiogenesis inhibition, autophagy, cell cycle arrest and metastases prevention on cancer cells [2]. Nanotechnology provides a new frontier for cancer treatment providing an alternate strategy to circumvent multidrug resistance, theranostic action and synergistic effect with plant formations [3,4]. Recently a number of researches have successfully documented the synthesis of AGNPs using plant extract which exploits sustained anti-tumor activity [5,6]. This study describes the effect of AGNPs synthesis by a biogenic method using Artemisia annua against invitro breast cancer MDA-MB231 cells. We aimed to find out A. annua AGNPs cytotoxic effect against breast cancer by determining the levels of LDH leakage, mitochondrial membrane integrity and apoptotic protein expression levels.

Materials and Method

Chemical and Method: Trypsin, Bovine serum albumin (BSA) and Dimethyl sulfoxide (DMSO) were obtained from Sigma (St. Louis, MO, USA). RPMI
1640 medium, fetal bovine serum (FBS) and antibiotics were purchased from Gibco (Carlsbad, CA, USA). FBS was stored at −20°C and then freshly prepared aliquots were used for cell culture complete medium. Primary antibodies [Bax (# CAT No: sc-7480), Bel-2 (#CAT No: sc-7382), Caspase 9 (# CAT No: sc-133109), Cyt-c (#CAT No: sc-13561), and GAPDH (# CAT No: sc-59540)], and secondary antibodies were obtained from Cell Signaling Technology (Beverly, MA, USA). Phenylmethanesulfonylfluoride (PMSF), Radioimmuno precipitation lysis buffer (RIPA buffer) Protease inhibitor coin tail, and sterile PBS, bicinchoninic acid (BCA) Protein Assay Kit were obtained from Thermo Fisher Scientific (Rockford, IL, USA). Rockford, IL, USA. PVDF membranes were purchased from Bio-Rad (Hercules, CA, USA). SuperSignal West Dura extended duration Substrate for ECL was obtained from Thermo Scientific (Waltham, MA, USA). All the other chemicals used were of analytical grade unless otherwise stated.

**Cell line culture:** MDA MB231 was produced from NCCS [national centre for cell science] Pune, cells were maintained in DMEM augmented with 10% FBS and 1% antibiotic penicillin, streptomycin solution at 95% humidity and 5%CO₂ were retained for cell culture.

**Lactate Dehydrogenase release assay (Membrane integrity):** Membrane integrity of MDA-MB 231 cells treated with and without *A. annua* AgNPs was determined by measuring the activity of lactate dehydrogenase (LDH) as per manufacturer’s instructions (CytoScan™ LDH Cytotoxicity Assay kit, 786-324, G-Biosciences). LDH assay is based on the release of LDH, a cytosolic enzyme from cells with compromised membrane integrity. Here the status of *A. annua* AgNPs induced cytotoxicity was assessed quantitatively by measuring the activity of LDH in the supernatant. Briefly, cells were treated with AgNPs for 24 h, then 100 μL cell-free supernatant from each sample was transferred in triplicates into 96-well plates, and added with 100 μL of LDH assay reaction mixture and incubated for 3h under standard conditions. Then the optical density (OD) determined at a wavelength of 490 nm using a Microplate Reader.

**Mitochondrial membrane potential analysis:** MDA-MB 231 cells were treated with *A. annua* AgNPs for 12 h, after treatment cells were incubated with prewarmed 2 μg/ml of lipophilic cationic probe 5, 5′, 6, 6′-tetrachloro-1, 1′, 3,3′-tetraethylbenzimidazolcarbocyanine iodide (JC-1) in fresh medium for 30 min. Followed by incubation, cells were washed with PBS twice, and then the cells were visualized by detecting fluorescence and images were captured using fluorescence microscope.

**ATP Measurement:** ATP levels in MDA-MB 231 cells were measured as per manufacturer’s instructions (ab83355). MDA-MB 231 cells were treated with *A. annua* AgNPs for 24 hrs and the levels of ATP were measured.

**Immunoblot Analysis:** Immunoblot analysis was performed using standardized method with slight modifications based on the method of [37]. Briefly, MDA-MB 231 cells were treated with and without *A. annua* AgNPs for 24 h. Cell lysates were collected and the total protein was immediately extracted using RIPA containing 1% (PMSF) and 1% protease inhibitor cocktail for 30 min at 4°C. Aliquots of proteins were used to estimate the total protein content using BCA™ Protein Assay Kit (Pierce, Rockford, IL, USA). Then equal amounts of proteins loaded on to sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE), electrophoretically separated and transferred to a PVDF membrane followed by blocking in 5% BSA for 1 h at RT. The membrane was incubated with specific primary antibodies against BCl-2, Bax, Cytochrome-C, Caspase-9 (1:1000) and GAPDH (1:2000) overnight at 4°C in a humidified chamber followed by incubation with the corresponding secondary antibodies for 2 h RT. The specific protein bands were visualized with an ECL advanced western blot analysis detection kit (Thermo Scientific, USA).

**Statistical Analysis:** Experiments were performed independently as triplicates (n=3). The mean ± standard deviation (SD) was determined for each group. One way analysis of variance (one-way ANOVA) and Tukey’s’ test were used for statistical analysis. Statistical value of p <0.05 was used for considering statistical difference between groups.

**Results and Discussions**

The present study heed on investigating the *invitro* anti-carcinogenic effect of biogenic AGNPs using *A. annua* against breast cancer MDA MB231 cells. Even though there are several method to asse the cytotoxic effects, the LDH assay seems to be the best for ascertaining cellular cytotoxicity effect with damaged cellular membranes Fig 1B showed that LDH was significantly increased right from 2.5 mg/
ml *A. annua* AGNPs concentration in dose-dependent manner when compared to control and *A. annua* extract alone. LDH is a soluble cytosolic enzyme that can be released extracellularly upon loss of membrane damage. Moreover, MDA MB231 cells treated with *A. annua* extract alone do not show significant cytotoxicity as compared to *A. annua* AGNPs. This denotes that AGNPs was more effective as a cytotoxic agent which is evident from increased LDH release upon AGNPs treatment for 24 h thereby leading to lytic cell death. Our result substantiated with previous reports of cytotoxicity of biogenic AGNPs from streptomyces species [7,8].

Mitochondrial dysfunction plays a vital role in cell death by apoptotic induction. Hence, we intended to determine the status of mitochondrial function by determining the mitochondrial membrane potential (MMP) and ATP levels in MDA-MB 231 cells treated with *A. annua* AgNPs [10]. Mitochondrial membrane potential in MDA-MB 231 cells was determined using the ability of JC-1 to change from red to green fluorescence, with a decrease in MMP. As shown in Fig 4, there is a significant shift in red to green fluorescence in *A. annua* AgNPs and DOX (positive control) treated cells (24 h) compared to control and *A. annua* extract-treated cells. Altered MMP can significantly impact ATP generation. Here, our results showed a significant reduction in ATP levels in *A. annua* AgNPs and DOX treated cells compared to control and *A. annua* treated cells. Our results show that *A. annua* AgNPs induces a change in MMP which can be an underlying reason for the observed loss of cell viability and altered redox status as mentioned in earlier sections. AgNPs induced loss of MMP and ATP levels might eventually result in apoptotic induction.

When the cells are enforced with cytotoxic stress beyond its threshold i.e “point of no return” the prime event can be breaching of MMP with low ATP levels. Such breaching favors the release of mitochondrial proteins like cyt C to release into cytosol that ends up with rapid activation of caspasers [9,10]. So to determine the status of MMP in *A. annua* AgNPs treated MDA-MB 231 cells, we probed using JC-1 fluorescent dye. It is mitochondrial specific and readily shits fluorescence from red to green fluorescence and such a shift in color is directly proportional to loss of MMP. Observed intense green fluorescence in *A. annua* AgNPs and DOX treated cells showed a loss of MMP in MDA-MB 231 cells.

Further to evaluate the status of apoptotic mediators, protein levels of cytochrome-c, Bax, Bcl-2 and Caspase 9 were determined in MDA-MB 231 cells. Protein expressions of Cytochrome-c, Bax, and Caspase-9 were significantly increased in MDA-MB 231 cells treated with *A. annua* AgNPs compared to control and AgNP extract-treated cells (Fig 5), whereas Bcl 2 protein level was significantly reduced as compared to the above.

Collectively our results denote *A. annua* AgNPs induces apoptosis by reducing anti-apoptotic BCL-2 proteins thereby enabling death driving cysteine protease called caspase, which in turn cleaves a range of substrates like nuclear proteins plasma membrane proteins and mitochondrial proteins leading to cell death. Results of the present Study depicting AgNPs inducing apoptosis is similar to other natural products like Heparicidin [11]. Based on our investigation, our future goal is to investigate the mechanisms of *A. annua* AgNPs cellular uptake and its ability to form protein-corona [12] in cellular components of MDA-MB 231 cells and which will enable to promote its anti-cancer efficacy at clinical levels.

Collectively our results denote *A. annua* AgNPs induces apoptosis by reducing anti-apoptotic BCL-2 proteins thereby enabling death driving cysteine protease called caspase, which in turn cleaves a range of substrates like nuclear proteins plasma membrane proteins and mitochondrial proteins leading to cell death. Abstract

From ancient period, the plants are used as a treatment for dreadful disease due to the presence of medicinal value. Even in modern generation, many herbal plants are focused in research field to brief about its higher potential of efficacy in curing & also reducing the side effects. In this study, we reviewed the traditional plant physalis minima Linn which is commonly called as native gooseberry are used in treating several disease due to the presence of phytochemical constituent having properties such as anti-inflammatory, antioxidant, anti-proliferative, antibacterial. This paper will give brief review about the all parts of the plant of physalis species to signify the good efficacy on the disease condition.

Keywords: Physalis minima, phytochemical constituent, anti-inflammatory, antioxidant, anti-proliferative, antibacterial.

Introduction

Many fruits & vegetables of plant has valuable effect to reduce the cause of common disease such as cold, dizziness, sneezing, dry cough etc. In response to that nowadays the medicinal value plant are used in treating the dreadful disease such as cancer, cardiovascular disease, muscular dystrophy, Diabetes mellitus, hypertension & obesity. Among these the cancer becomes most common in both the gender, due to overproduction of free radical thus it become a serious issue on human health. The therapeutic value of medicine are altered as the synthetic products by identifying the bioactive compound & are used in current medical field to cure the disease along with reduce the side effects in long term of drug intake. Due to modern lifestyle, the production of reactive oxygen species in an organism is increased, though these ROS plays role in cell signaling processes & protecting mechanisms the increased production accumulates the ROS thus affects the cell & causes various consequences by damaging the lipid, proteins, DNA, & decrease cell survivality. To reduce the cell from adverse effects, the medicinal plants plays a vital role due to the presence of antioxidants such as flavones, isoflavones, flavonoids, anthocyanin, catechins etc. Apart from the above compounds certain foods contains ascorbic acid, tocopherol, beta carotene which also possess the antioxidant potential.

According to the traditional uses of medicine in Indian system the root, seed, leaf, fruit, all parts of the plants are used. The aim of the present study is to review the plant physalis minima Linn to bring out the traditional uses, phytochemical investigation carried out for assessing the maximum potential of the plant. As like many medicinal plant, this plant species were used as traditional medicine in the treatment of ulcers, sores, gonorrhea, and skin disease. Many studies also confirmed that the plant has certain therapeutic value such as hypoglycemic action, anticancer, anti-inflammatory & anti-ulcer action.

The plant physalis minima Linn which belongs to the family solanaceae has other common names such as Native gooseberry, Ground cherry, Sunberry (English), Kupanti, sodakku thakkali, Tholtakkali (Tamil), Ban Tipariya, Chirapati, Rasbhari (Hindi), Gadde Hannu
Pharmacognostical studies on Phyalis minima Linn.

Macroscopical characteristic of seed: The plant stem, root & leaves are fresh green, full grown animal plant growing around 50cm height, found in waste ground near houses, roadsides, in organic soils in the Tropical region. The macroscopic characteristic investigated as small annual herb, leaves are soft & smooth, with many margins 2.5-12cm long, it covered with short soft hair with dark green on upper side, light green on other side, taste like an edible tomato.

Microscopical & Powder Characteristics:

Flower of the plant: The cylindrical portion of plant is straight, axillary, solitary, pedicellate, and yellow with purple colour.

Fruit of the plant: A globose berry, overtopped by inflated calyx, seeds many compressed.

Leaves of the plant: Arranged alternative, simple type, elliptic-ovate shape, acute apex with obliquely rounded acute with coarsely toothed margin.

Seeds of the plant: Cotyledons ovate-lanceolate 6-9 × 2.6mm petiole about 3mm long

The organoleptic study of plant by powder analysis shows that the coarsely powdered with greenish grey colour, bitter in taste & having unpleasant odor.

Physicochemical constants: Total ash (14%), Water insoluble ash (6.2%), Acid insoluble ash (1.1%), moisture content (8%), volatile oil content (0%), sugar content [Total sugar (3.83%), reducing sugar (2.53%)], fibre content (54.34%).

Medicinal uses: In traditional aspects, all parts of the plants are used as a diuretics, antipyretic, alterative, and appetizer. Bitter, diuretic, laxative, tonic, remedy for headache, itches, earache, febrifuge, vermifuge, fevers, hypertension, diabetes, reduce the lower abdominal pain.

Phytochemical studies: According to WHO’s survey about 80% of the population have belief on efficacy of traditional medicine. The valuable medicinal properties of different plants are due to presence of several component such as phenolic compounds, alkaloids, flavonoids, saponin, tannins, terpenoids, quinone, based on this the phytochemical work has been carried out for identification of active component by GC-MS analysis. The whole plant extract are reported to contain 30 compounds such as (i) Tetradecane (CAS n-Tetradecane), (ii) Cyclohexasiloxane, dodecamethyl, (iii) Cylocaptaisoxane, (iv) 1, 2-Benzenedicarboxylic acid, diethyl (v) 2, 4-Imidazolidinedione, 1-[(5-nitro- (vi) Cylocstasiloxane, Hexad (vii) Heneicosanoic acid (viii) 1, 3-Diphenyl-1, 3, 5, 5-Tetramet (ix) Octadecamethylcyclonona (x) Phthalic acid, butyl ester, ester(xi) 2-Pyridinepropanamide, N-P(xii) Bicyclo[4.1.0]

Pharmacological studies: The repute use of plant in cure of multiple disease was highly increased due to belief on the herbal plants with its pharmacological activity. The detailed pharmacological activity of physalis species are such as antitumor activity, antidiabetic activity, cardiovascular activity, gastro protective activity, pulmonary activity, anti-inflammatory activity, nephroprotective activity.

Antitumor activity: In many studies the treatment using P. minima extracts & compound inhibits the cell proliferation, but the mechanism of cell death unclear. The invitro studies on human adenocarcinoma NCI-H23
cells, study reveals that the chloroform extract has ability to inhibit cell proliferation by inducing the apoptosis mechanism\textsuperscript{(11)}. The chloroform extract was found to significantly abolish the growth of NH-H23 cells depend on dosage concentration on time limit. The further observation of apoptotic morphological features was directed in various studies of anticancer agents such as synthetic agent which induce apoptosis in C6 glioma cells\textsuperscript{(12,13)}.

The other similar observation was founded by Lee and Houghton et al 2005 in cytotoxicity potency of methanol crude extract towards the breast MCF-7 & lung COR 123 carcinoma cell\textsuperscript{(14)}. The crude extract brings the anti-proliferation activity by inducing signal cascade mechanism, activation of caspase-3 by four fold increase at the period of treatment, because of activation of downstream process of apoptosis of caspase-3 reported by\textsuperscript{(15)}, in human renal carcinoma A498 cell. The effect of bioactive compound suggesting that it decrease the survival of cancer by increase dosage of plant extract.

\textbf{Antidiabetic activity:} The effects of stem, leaf, root & flower crude extract of P.minima (1100mg/kg) administered for acute toxicity studies, this dose does not produce significant change in physicochemical alteration of the animals. In acute study, the diabetic induced rat after administration of the extracts of various plant parts of P.minima, where observed & the result suggest that he flower & leaf extracts has good efficacy in reducing the fasting blood glucose level towards the normal\textsuperscript{(17)}.

Further, the in-vivo studies are carried on chronic condition, the effect of plant flower extract & leaf extract positively brings down the fasting blood glucose of rats. Thus, it concludes that the extracts may have the properties to stimulate or rejuvenate the β-cells of islets of Langerhans for the secretion of insulin & are most effective for controlling diabetes by various mechanism(ie) the plant extract enhance the glucose utilization in diabetic induced rats or hyperglycemic rats.

\textbf{Anti-inflammatory, Analgesic and antipyretic activities:} Although a large number of studies are carried out to demonstrate the clinically use of anti-inflammatory and analgesic drugs, still the search for new effective drugs with significant safety profile remains dynamic. An in-vivo model was used to investigate the anti-inflammatory, analgesic and antipyretic action of P.minima, in crude methanol (58%) and chloroform fraction(62%) in NMRI mice and Wistar rats of either sex at 200 and 400 mg/kg, respectively. The extract significantly inhibited the carrageenan induced pay edema in rats at 400 mg/kg. The significant activity of the extracts and standard drug observed may be due to inhibition of the mediators of inflammation such as histamine, serotonin and prostaglandin\textsuperscript{(18)}. Both crude extract and chloroform fraction showed noticeable anti-inflammatory and analgesic activities as compared to a control. Thus concludes, the whole plant of Physalis minima Linn could be considered as a potential aspirant for natural anti-inflammatory and analgesic agents.

\textbf{Anti-lipid Oxidation:} The quenching of the free radicals production are proved by using ethanolic extract of P.minima. An in -vivo study of anti -lipid oxidation by using Goat liver as a source & assessment done by MDA (malondialdehyde) of tissue homogenate\textsuperscript{(19)}.

\textbf{Conclusion}

Our review study report concludes that, the investigation of pharmacognostic activities of whole plant of Physalis minima Linn has significantly found be having maximum potential of all pharmacological properties against the dreadful disease & can be used as an available source of natural antioxidants with subsequent health benefits. Even further studies are needed to explore the bioactive compound using pre-clinical trial & clinical trial to clear about the various mechanism of action at molecular level.

Abstract

Aim: The purpose of this randomized control study was to determine the effect of the administration of the preoperative ketorolac on the success of the inferior alveolar nerve (IAN) block in patients with symptomatic irreversible pulpitis

Materials and Method: Ninety adult volunteers who were actively experiencing pain participated in this study. The subjects were divided into 3 groups on a random basis and were randomly divided into three groups. Group 1 patients were advised to take tablet Ketorol-DT for 2 days as per the dosage recommendation by the manufacturer before the endodontic procedure. Group 2 patients were given tablet Ketorol-DT 1 hour before anesthesia and group 3 patients receive no preoperative medication. All patients received standard inferior alveolar nerve block of 2% lidocaine with 1:80,000 epinephrine. Endodontic access preparation was initiated after 15 minutes of initial inferior alveolar nerve block. Pain during treatment was recorded by using Heft Parker visual analog scale. Success was recorded as none or mild pain.

Result: Preoperative administration of tablet Ketorol-DT before 2 days has a significant effect on success rate of Inferior alveolar nerve block in patients with irreversible pulpitis. There is no statistical difference between group 2 and group 3.

Conclusion: Preoperative administration of tablet Ketorol-DT before 2 days has a significant effect on success rate of Inferior alveolar nerve block in patients with Irreversible pulpitis.

Keywords: Premedication, Ketorol, Pain management.

Introduction

The standard and most commonly used technique for achieving pulpal anesthesia in mandibular molars is the inferior alveolar nerve block (IANB). But in patients with irreversible pulpitis, there is decreased rate of success of its anesthetic efficacy which could be due to the activation of nociceptors by inflammation. Inflammatory mediators reduce the threshold for activation of nociceptor neurons to a point that a minor stimulus now might fire these neurons. This inflammatory process is mediated via prostaglandins (PGs), which are end products of Arachidonic acid (AA) metabolism, produced via Cyclo oxygenase (COX) pathway. PGs act by sensitizing nerve endings to Bradykinins and histamines and hence enhance the pain and tenderness of inflammation.¹ ² IANB has a high

failure rate, ranging from 7%–77%. Various mechanisms have been hypothesized to explain the failure of local anesthetics including anatomic variations like cross innervations and accessory innervations, decreased local pH, tachyphylaxis of anesthetic solutions. Non steroidal Anti inflammatory drug (reversible inhibitors of COX) Ketorolac, a pyrrolo-pyrrole derivative, is as effective as morphine or meperidine for pain relief. Many researchers have identified inflammation as an important component of the pathogenesis of hyperalgesia and failure of local anesthesia.\(^3\)\(^,\)\(^4\) Because NSAIDs reduce nociceptor activation by decreasing the levels of inflammatory mediators, it is hypothesized that premedication with NSAIDs will affect the success rate of local anesthesia in patients with irreversible pulpitis. The present study was planned to evaluate the effect of premedication with tablet Ketorol-DT on anesthetic success rate in terms of pain during endodontic procedure. No other studies in the literature stated the effectiveness of taking tablet Ketorol-DT 2 days before endodontic procedures. Therefore, the aim of this study randomized control study was to determine the effect of the administration of the preoperative tablet Ketorol-DT on the success of the inferior alveolar nerve (IAN) block in patients with symptomatic irreversible pulpitis. The null hypothesis stated is that tablet Ketorol-DT has no influence on the success rate of inferior nerve block in patients with irreversible pulpitis.\(^5\)\(^,\)\(^6\)

**Methodology**

Ninety adult volunteers who were actively experiencing pain participated in this study. The subjects were divided into 3 groups on a random basis (Computer generated random numbers) and were randomly divided into three groups. Ethical clearance was taken from the ethical committee. Informed consent from the patients were taken after explaining to them about the possible discomfort and risks involved in the procedure.

Inclusion criteria were adults [age >18 years], in good health with vital mandibular molars with moderate to severe pain. Exclusion criteria were patients allergic to ketorolac, gastrointestinal problems, pregnancy, lactating mothers and who could not give informed consent. Patients were randomly divided into 3 groups with 30 patients in each group. Group 1 patients were advised to take Tablet Ketorol-DT for 2 days as per the dosage recommendation by the manufacturer before the endodontic procedure. (1st day -10mg for four times; 2nd day-10mg for three times). Group 2 patients were given Tab Ketotorol-DT, 1 hour before the administration of local anesthesia. Group 3 patients receive no preoperative medication. All patients received standard Inferior alveolar nerve (IAN) block of 2% Lidocaine with 1:80,000 epinephrine. After 15 minutes of the initial IANB, each patient was asked if his or her lip was numb. If profound lip numbness was not recorded within 15 minutes, the block was considered unsuccessful, and the patients were excluded from the study. Endodontic access preparation was initiated after 15 minutes of initial Inferior alveolar nerve block. Pain during treatment was recorded by using a Heft Parker visual analog scale. Success was recorded as pain present or absent.

**Results**

Premedication with Ketorol DT given before 2 days gave 78% success rate. Premedication with Ketorol DT given before 1 hr gave 24% success rate. Premedication without ketorol DT gave 0% success rate. There was statistically significant difference between the 3 groups.
**Discussion**

Inferior alveolar nerve block is an effective tool in management of mandibular endodontic procedures by reversibly interrupting the propagation of inferior alveolar nerve impulses. IANB might provide successful anesthesia in 70% of uninflamed pulp, but the success rate drastically decreases to 30%\(^7\). The literature suggests activation of nociceptors by inflammatory mediators such as PGs as a major cause of increased incidence of failure of IANB in patients with irreversible pulpitis. Pathogenesis of irreversible pulpitis includes inflammation of pulp, leading to breakdown of damaged cell membranes and release of AA, mediated by either secretory (sPLA2) or cytoplasmic (cPLA2) phospholipases. In response to various inflammatory stimuli, AA is acted on by COX or prostaglandin H synthase (PGHS) enzymes and gets converted into 20 carbon chain molecules called eicosanoids, which are further converted by various cell-specific isomerizes and syntheses to produce 5 biologically active primary PGs that include PGD2, PGE2, PGF2a, prostacyclin (PGI2), and thromboxane A2 (TxA2).\(^8,9\)

COX is available in body in 2 isoforms, COX-1 and COX-2. COX-1 regulates normal cell activities in the stomach, kidneys, and platelets by synthesizing prostanoids that have cytoprotective functions. The COX-2 is normally not present in tissues (except kidneys) and is present only in areas of tissue injury and inflammation. Traditional Non steroidal anti-inflammatory drugs (NSAIDs) act by nonselective inhibition of COX activity, resulting in some gastrointestinal side effects. Specific COX-2 inhibitors were developed to deliver equivalent pain relief to that of the nonselective NSAIDs, but without the accompanying risk of gastrointestinal complications. Because of efficacy of NSAIDs to effectively block the COX pathway, it was hypothesized that premedication with NSAIDs will help in management of patients with irreversible pulpitis by inhibiting the formation of PGs and thus minimizing the activation of nociceptors. In the present study, effect of premedication with ketorolac was studied by using pain response on modified Heft Parker VAS in a prospective, randomized, single-blind trial.\(^10\)

**Conclusions**

Preoperative administration of tablet Ketorol-DT before 2 days has a significant effect on success rate of Inferior alveolar nerve block in patients with Irreversible pulpitis then the preoperative administration of ketorol DT before 1 hr of the procedure

Effect of CPP ACP and Nano Hydroxyapatite Incorporated GIC on Remineralization of Dentin

Ramachandran Tamilselvi1 Malarvizhi Dakshinamoorthy2, Karthick Arumugam2, Bhaskaran Sathyapriya3, Purushothaman Lakshmanan4

1Reader, 2Professor, Department of Conservative Dentistry & Endodontics, 3Professor, Department of Anatomy, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research, 4Consultant Orthodontist, Apollo Hospitals and Apollo White Dental & Sree Venkateshwara Dental College & Hospital, Chennai, Tamil Nadu

Abstract

The objective of this invitro study was to investigate, whether the remineralization potential of conventional GIC in human dentin could be improved by combining with CPP - ACP and nano hydroxyapatite. Class I cavities were prepared in sound human extracted third molars and they were randomly assigned to 3 groups according to the restorative materials. Group I: Conventional GIC, Group II:Conventional GIC and CPP-ACPand Group III: Conventional GIC powder & Nano hydroxy apatite. The samples were subjected to remineralizationand demineralization cycles for period of 2 weeks. Energy dispersive X-ray analysis was used to evaluate the remineralization. The elemental compositions were analyzed using One way ANOVA, Post Hoc and Mann Whitney tests. The calcium and phosphate concentration were statistically significantly greater in Group III than Group I and II (P<0.05).Nanohydroxy apatite with GIC remineralized the demineralized dentin almost equal to normal dentin.

Clinical Relevance: GIC with nanohydroxy apatite might be superior restorative/base with an improved remineralization potential of dentin.

Keywords: GIC, DENTIN, HYDROXYAPATITE.

Introduction

The caries process is a dynamic balance between demineralization and remineralization of the dental hard tissues that may eventually result in cavitation.[1] The metabolic products of dental plaque bacteria, including lactic, acetic, and citric acid, reduce pH in the microenvironment of the tooth surface and demineralize the dental hard tissues. Thus, any mechanism that inhibits such acid production, increases the resistance to demineralization, and/or facilitates remineralization and is of considerable clinical interest.

Remineralization is the repair process of the demineralized teeth and relies on calcium and phosphate, and is enhanced by fluoride to rebuild a new surface on existing crystal remnants in the sub-surface lesions. Some restorative materials release fluoride, which may help to inhibit recurrent caries.[2-8] It appears that the primary mechanisms by which fluoride prevents caries are both by improving resistance to demineralization and by facilitating remineralization of hard tissues.

Glass ionomer cements (GIC) are commonly used in minimal invasive dentistry. The advantages of conventional glass ionomer cements are anticariogenic property by incorporation of fluoride, chemical adhesion to tooth structure.[10] non–shrinking setting reaction

and biocompatibility\cite{9}. Physical properties of GIC can be modified by changing the powder/liquid ratio or chemical formulation.\cite{11}

Bioactive agents based on milk products (Tooth Mousse) have been used in remineralization of the enamel and dentine. This is based on a nano complex of the milk protein casein-phosphopeptide (CPP) with amorphous calcium phosphate (ACP). It has been claimed that it promotes remineralization of the carious lesions by maintaining a supersaturated state of enamel mineral.\cite{12} The presence of CPP-ACP on dentine surfaces provoked lower demineralization and higher remineralization in comparison with the dentine surfaces without CPP-ACP.\cite{13}

Hydroxyapatite (HA) is one of the most biocompatible and bioactive materials and is widely applied to tooth roots.\cite{14} Nano-sized particles have similarity to the apatite crystal of tooth enamel in morphology, crystal structure and crystallinity.\cite{15} An increasing number of reports have shown that nano-hydroxyapatite has the potential to remineralize artificial carious lesions following addition to toothpastes, mouthwashes, etc.\cite{16-18} Tan et al., proved the remineralizing potential of demineralized human dentin, treated with hydroxyapatitenano particles suspension.\cite{19}

Though GIC has an ability to remineralize dentin, Massara et al.\cite{20} observed morphological changes and increased levels of calcium in dentine underneath GIC after 3 months. Conventional GIC showed higher reactionary dentin formation only after 60 days.\cite{21} Therefore, the objective of this invitro study was to investigate, whether the remineralisation potential of conventional GIC in human dentin could be improved by combining with CPP - ACP and nano hydroxyapatite.

**Materials and Method**

**Preparation of teeth specimens:** Thirty sound human impacted third molars, extracted within one month period and stored in saline solution at 4°C, were selected. Class I cavities were prepared in each tooth using 245 carbide bur at high speed with an air/water spray. Cavity outlines were previously traced with a marker pen, determining mesiodistal - 6mm, bucco lingual - 3mm a measure; the depth of the cavity - approximately 2 mm, calibrated by a pre-marked periodontal measuring probe. The cavity finishing was accomplished with a hand instrument. The teeth were sectioned into two equal halves buccolingually.

The cavities were randomly assigned to 3 groups according to the restorative materials. The groups were as follows, Group I: Conventional GIC (Fuji II GP, GC Co., Tokyo, Japan), Group II: Conventional GIC and CPP-ACP, the GIC containing CPP-ACP (Recaldent\textsuperscript{TM}) was prepared by manipulation of GIC powder with 1.56% w/w CPP-ACP followed by mixing with GIC liquid.\cite{22} Group III: Conventional GIC powder & Nano hydroxy apatite (Skyspring nanoparticles, Houston, Texas) [20:1 (w/w)] was mixed together.\cite{23} Then, the mixture was mixed to GCliquid. The restorative materials were manually mixed and the powder: liquid ratio used, was as recommended by the manufacturer. The cavities were restored in a single increment with the restorative materials, after dentin conditioning and placed in a humidor for 24 hours at room temperature.

**Preparation of acetate demineralizing solutions:** The demineralizing solution was an acetate buffered solution at pH 4.3 as described by Ten Cate and Duijsters.\cite{24} The solution contained glacial acetic acid (50 mM/L), CaHPO\textsubscript{4} (2.2 mM/L) in deionized distilled water (DDW) with pH adjusted to 4.3. Thymol crystals were added to make a 0.1% solution to prevent growth of mould. The solution was stored in tightly sealed bottles until ready for use.

**Preparation of remineralizing solutions:** The remineralizing buffer was as described by Zuidgeest et al.\cite{25} and consisted of the following: 20 mM HEPES Buffer; 1.5 mM calcium as CaCl\textsubscript{2}; 0.9 mM phosphate as K\textsubscript{2}HPO\textsubscript{4}; 10 ppm fluoride as NaF, with the pH adjusted to 7. Thymol crystals were added to provide a 0.1% solution.

**Demineralization/remineralization cycles:** The teeth were submitted to 14 cycles of demineralization and remineralization. Each cycle consisted of the immersion of specimens in 5 ml of demineralization solution for 6 hr, washing with 5 ml of deionized water and immersion in 5 ml of remineralization solution for 18 hr in the container having separate chambers for each samples. The specimens were cycled for 14 days.\cite{26}

**Energy dispersive X-ray analysis:** The restored teeth specimens were re-sectioned again into two equal halves buccolingually. Element content in weight % of Ca, P and F was measured with energy dispersive X-ray analysis (EDX) (Hitachi S3400N, Japan). The surfaces were photographed at a magnification of 27x. The values of the spots at 0.5 - 1mm from restorative material
towards pulp space and 1-1.5mm from restorative material towards pulp were measured (Fig. 1 and 2) and statistically evaluated using One way ANOVA, Post Hoc.

**Results**

The results of mineral analysis of dentine have been presented in Tab. 1. In areas 0.5 – 1 mm and 1-1.5 mm from restorative material, calcium and phosphate concentration were statistically significantly greater in Group III than Group I and II (P<0.05). No statistically significant difference was found between the two different areas analyzed (0.5-1mm and 1-1.5mm) and inter group comparison of other elements (Al, Si, Sr, F) (P>0.05). The mineral analysis of dentin treated only with demineralization and remineralization solution for 14 cycles had Ca – 15.17 % and P – 11.21 %. Calcium and phosphate of normal dentin was 39.82% and 9.01%.

**Discussion**

Dental caries progression or reversal depends upon the balance between demineralization and remineralization.[27] This balance is based on various factors e.g. salivary Ca and P concentration, bioavailability of fluoride, pH and prevention of secondary caries. To prevent secondary caries, remineralization of the dentine left in the cavity is likely to occur due to the application of highly bioactive adhesive restorative materials. Permeation of elements from restorative materials to dental tissues has been reported in several studies. Studies carried out in vitro by Hott et al.[28] and Extercate et al.[29] on bovine teeth revealed elevated fluoride levels in the dentine adjacent to glass ionomer fillings. Energy dispersive X-ray analysis was used in the present study to evaluate the remineralization of dentin as it provides a reliable data of the surface composition of objects non-destructively.[36]

In the present study, nanohydroxyapatite was combined with conventional GIC, as nanohydroxyapatite and has bioactive, biocompatible properties and increased penetrability, since the surface area and proportion of atomicity increases with decreasing particle size.[30] Nano-sized particles have similarity to the apatite crystal of tooth enamel in morphology, crystal structure and crystallinity.[31] Kim et al.[17] demonstrated that surface hardness of the demineralized enamel increased with increasing nanohydroxyapatite concentration when nanohydroxyapatite was added to a NaF mouthwash. Moshaverinia et al proved nanohydroxyapatite added to GIC, exhibits higher compressive strength, diametral tensile and biaxial flexural strengths.[23]

An increasing number of reports have shown that nano-hydroxyapatite has the potential to remineralize artificial carious lesions following addition to toothpastes, mouthwashes, etc.[17,32] Studies have found no significant difference between NaF and nanohydroxyapatite on the effect of remineralization of initial enamel lesions.[33] Tan et al.[19] reported that nanohydroxyapatite caused remineralization of dentin. The results of the current study using Energy dispersive X-ray analysis also showed a remarkable increase in Ca and P of dentin restored with GIC and nanohydroxyapatite than conventional GIC. This could be due to sedimentation and penetration of acicular crystals of nanohydroxyapatite into the demineralised tooth surface which acts as a template and attracts large amount of Ca$^{2+}$ and PO$_4^{3-}$ from the remineralisation solution. These crystals directly fill up defects and micropores on demineralized teeth.[34]

CPP-ACP release elements that enhance remineralization of the enamel and dentine, under cariogenic conditions. Rahiotis and Vougiouklakis.[35] reported that the presence of agent CPP-ACP on dentine surfaces provoked lower demineralization and higher remineralization in comparison with the dentine surfaces.
without the presence of any agent. Incorporation of 1.56% w/w CPP-ACP into a GIC was shown to increase compressive strength and microtensile bond strength. [22] Mazzaoui et al concluded that GIC with CPP – ACP enhances remineralization of dentin by the release of Ca, P, & F from the restored material in acidic PH which was calculated by the measurement of ions realized in the solutions. [22] On the contrary, the results of the present study showed, CPP - ACP with GIC had increased remineralization than GIC, assessed by energy dispersive X-ray analysis. But, the results were not found to be statistically significant, which may be due to decrease in bioavailability of calcium and phosphate from CPP - ACP when reacted with polyacrylic acid.

As GIC, CPP - ACP and nanohydroxyapatite individually favors remineralization of tooth, we intended to investigate the effects of remineralization of dentin when used in combination. Further research is required to find the adhesive properties of GIC combined with CPP ACP and nanohydroxyapatite to tooth.

**Conclusion**

Nanohydroxy apatite with GIC remineralized the demineralized dentin almost equal to normal dentin. Thus, GIC with nanohydroxyapatite might be superior restorative/base with an improved remineralization potential of dentin.

Abstract

The tissue dissolution property of irrigating solutions is important for successful endodontic treatment. Sodium hypochlorite (NaOCl) is a well-known tissue dissolvent, but no data have been published on herbal alternative to NaOCl. The purpose of this study was to investigate the pulp tissue dissolution capacity of sodium hypochlorite, ethanolic extract of Drosera rotundifolia and digestive fluid of Nepenthes khasiana. Freshly extracted intact vital teeth, extracted for orthodontic and impaction reasons were collected and stored at – 20 °C. The pulp tissues were removed by splitting of the teeth when required.

Method: The pulp tissues were randomly divided into 4 groups (n = 10), individual sample was weighed 7 mg each. The groups were as follows, Group I: 5% NaOCl, Group II: digestive fluid of Nepenthes khasiana, Group III: Drosera rotundifolia (ethanolic extract), Group IV: distilled water. The test solutions were added to tubes containing tissue samples, the tissues were removed from the test solutions at 5, 15, 20, 30 min, 1,2,3,4,5,6,7 hr blotted dry with the tissue paper and weighed using precision balance.

Results: The results showed complete dissolution of pulp tissue in Group I at 20 minutes, Group II at 7 hr, Group III and IV showed no dissolution of pulp at the investigated time intervals.

Conclusion: The digestive fluid of Nepenthes khasiana could be considered as an herbal alternative to NaOCl for pulp tissue dissolution as it completely dissolved the pulp tissue similar to 5% NaOCl, but at different time intervals.

Keywords: Sodium Hypochlorite, tissue dissolution, Insectivorous plants, Nepenthes, digestive.

Introduction

The major role of endodontic treatment for a tooth is to clean the root canal by removal of the infected pulp and microorganisms. Irrigation is an indispensable aid in achieving thorough debridement and in preparing and disinfecting the canal¹. The complex anatomy of root canals favors the persistence of residual pulp tissue, infected dentin or bacteria in the root canal system which might be responsible for treatment failures². The tissue
dissolving capability of irrigating solutions enhances root canal cleansing by removing pulpal remnants in the inaccessible areas of the tooth.

Sodium hypochlorite (NaOCl) has been the favored endodontic irrigant as it is effective in dissolving both vital and nonvital tissues\(^{(3-5)}\). It is an effective antimicrobial agent\(^{(6)}\), and acts as a lubricant for instrumentation \(^{(7)}\). The cytotoxicity of 5.25% NaOCl towards periapical tissues\(^{(8-12)}\) remains a principal concern especially in open apices and causes disastrous effects such as paralysis of muscles and permanent nerve damage\(^{(13)}\). Hence, a diluted concentration of 2.5% was recommended\(^{(19)}\), but was found to be cytotoxic\(^{(14)}\). NaOCl in concentrations higher than 0.01% was lethal to the cells\(^{(15)}\). NaOCl has also caused allergic reactions\(^{(16, 17)}\).

Traditional herbal medicines have gained attention in the global health market due to their various advantages like complete absence or negligibility of side effects and are preferred to the drugs manufactured using chemical substances. The carnivorous/insectivorous plants trap their prey, mainly insects, and digest their proteins primarily by their endogenous proteinase(s) and absorb the digested products as the nitrogen source\(^{(18)}\). The Drosera and Nepenthes are the two important Genuses of carnivorous plants. Drosera was found by Charles Darwin, characterized by leaves covered with glandular hairs, which trap and digest insects. These plants contain 100 species distributed widely in tropical and temperate areas of the northern and southern hemispheres\(^{(19)}\). Drosera rotundifolia is commonly used in the treatment of epilepsy and whooping cough\(^{(20)}\). African or Asian Drosera species (e.g. Drosera madagascariensis DC. and Drosera peltata Smith) have been used for medicinal purposes\(^{(21)}\). The antimicrobial activity of extracts of Drosera peltata against oral bacteria has been proved to be due to flavonoids and naphthoquinones\(^{(22)}\). However, the tissue dissolving property of these plants has not been studied so far.

Unlike Drosera, Nepenthaceae offers a special condition, where the pitchers secrete a quantity of digestive fluid before they open for digestion of insects. The digestive fluid is secreted in far greater quantities within the pitchers of Nepenthes (several tens of ml by pitcher) compared to the micro liters quantities secreted by leaves of Drosera\(^{(18, 23)}\). The digestive fluid is colorless, odourless, tasteless and of varying consistency\(^{(18)}\). The fluid contains several hydrolytic enzymes such as proteases and phosphatases\(^{(24)}\) and potassium, sodium, magnesium, calcium, chlorine (as hydrochloric acid) and organic acids\(^{(18)}\). Nepenthes comprises of approximately 90 species of carnivorous plants\(^{(25)}\), distributed in the tropical region. They use highly specialized pitcher-shaped leaves to capture insects\(^{(26)}\). The bottom part of each pitcher is filled with a digestive fluid in which the captured insects drowns and subsequently gets digested.

In this study, carnivorous plants were considered to serve as an herbal alternative to NaOCl due to its enzymatic proteolytic activity. Hence, the aim was to investigate the pulp tissue dissolution capacity of NaOCl, ethanolic extract of Drosera rotundifolia and digestive fluid of Nepenthes khasiana.

**Materials and Method**

**Plant Material:**

**Drosera Rotundifolia:** A commercial product of Drosera rotundifolia mother tincture, 100ml (Dr. Willmar Schwabe India Pvt. Ltd, Noida, India) contains powdered plant extract in 60% of ethanol.

**Nepenthes Khasiana:** Fresh digestive secretion was collected from the pitchers of the carnivorous plant, Nepenthes khasiana using sterile pipettes from Tropical Botanic Garden and Research Institute, Trivananthapuram, Kerala, India.

**Analysis of pH:** The pH of ethanolic extract of Drosera rotundifolia and digestive fluid of Nepenthes khasiana were analyzed using pH meter (Elico; LI 612, Hyderabad, India).

**Pulp tissue sample preparation:** Freshly extracted, intact vital teeth, extracted for orthodontic and impaction purposes were collected and stored at -20°C. The teeth were thawed to room temperature. Two longitudinal grooves on the proximal surfaces of the teeth were made with diamond disc. The teeth were split into two halves with chisel and mallet. The pulp tissue was removed with tweezers and washed with distilled water to remove excess blood and then blotted dry. All pulp samples were combined to create a random mix of tissues. Then, 40 pulp tissue samples of similar weight (7 mg each) were prepared using sterile scalpel. Initial weight of each specimen was measured with a precision balance (Sartorius; BS 2235, Germany). Throughout the experiment, the tissues were handled only with tweezers to avoid errors in weight as a result of perspiration \(^{(27)}\). Then, the samples were randomly divided into 4 groups...
(n = 10) and individually placed into 2 ml propylene tubes. The tubes were randomly assigned to 4 groups of 10 each, corresponding to the type of solution tested.

The groups were as follows, Group I: 1ml of 5% NaOCl (positive control), Group II: 1ml of digestive fluid of Nepenthes khasiana, Group III: 1ml of Drosera rotundifolia (ethanolic extract), Group IV: 1 ml of distilled water (negative control). The test solutions were added to the tissue samples, the tissues were removed from the test solutions at 5, 15, 20, 30 min, 1, 2, 3, 4, 5, 6, 7 hr, blotted dry with the tissue paper and the tissues were weighed with precision balance.

**Results**

The results showed complete dissolution of pulp tissue by Group I within 20 minutes. Group II dissolved the pulp tissue completely within 7 hours. Group III showed no dissolution of pulp. Instead, had initial weight loss and the weight was maintained constant for 7 hours. Group IV showed no change in weight.

The mean weight change of the pulp tissue (table 1 and figure 1) by the test solutions were compared using one-way analysis of variance (ANOVA) followed by Tukey HSB test for post hoc multiple comparisons. A P value < 0.05 was considered to indicate a significant difference between the groups. Among the groups, at all time intervals, P value was found to be < 0.001** by one-way analysis of variance. The result was statistically significant between Group I and other groups at all time intervals, except Group II, 7 hours. Statistically significant result was found between Group IV and other groups at all time intervals except with Group II, 5 min.

**pH:** The pH of ethanolic extract of Drosera rotundifolia, and Nepenthes khasiana was found to be 4.1 and 4.4.

**Discussion**

The tissue dissolving property of irrigating solutions is important because they dissolve and removes the pulp tissue from the root canal. Among the different irrigating solutions, NaOCl has the unique tissue dissolution property. When NaOCl is added to water, hypochlorous acid (HOCl) is formed. The HOCl is responsible for strong chlorinating and oxidizing action on tissue and provides the property of tissue dissolution to NaOCl. The tissue dissolution efficacy of root canal irrigants were investigated using bovine pulp(27). The concentration of collagen was comparatively lower in bovine than in human pulp(28). Hence, vital human pulp tissue and its dissolution by irrigants were checked at room temperature to simulate clinical conditions.

Different method were used for assessing the pulp dissolution like analyzing the hydroxyproline content(29), measuring the amount of total phosphate extracted, loss of tissue collagen(30). Hydroxyproline content is 13% of the collagen content of pulp. Therefore, analyzing the tissue dissolution based on any single content cannot reflect the dissolution of the whole tissue. Hence, a simple, reliable, weighing method was used to quantify specimen dissolution. In this study, distilled water served as a control instead of isotonic saline because, saline dissolved a mean 10.48% of bovine pulp tissue(30). The digestive fluid of unopened pitchers are sterile, whereas, the fluid of opened pitchers, whether containing insects or not, invariably contained bacteria in large numbers(18). Hence, the fluid of unopened pitchers was used in this study.

In the present study, NaOCl dissolved the pulp tissue in 20 minutes due to several chemical reactions such as, saponification, neutralization and chloramination reaction(31). These reactions occur simultaneously and synergistically leading to liquefaction of organic tissue.

The ethanolic extract of Drosera rotundifolia was used for pulp tissue dissolution assuming that along with flavonoids and naphthoquinones, the active components present in the digestive fluid, responsible for digestion of insects could also be extracted from whole plant using ethanol as a solvent. But, the tissues were not dissolved, become firm in consistency and revealed an initial mild reduction in weight in 5 minutes, which could be due to dehydration by alcohol. Alcohol, when used as a solvent denatured the proteins i.e., proteolytic enzymes which are responsible for the tissue digestion by disruption of the side chain intramolecular hydrogen bonding between amide groups(32).

The digestive fluid of Nepenthes khasiana caused complete dissolution of pulp at 7 hours. It has been attributed to the presence of protease in digestive fluid, which belong to a category of acid protease such as pepsin(33), called as nepenthesin(34). Similar to pepsin, nepenthesin acts on proteins, splitting them into protease, peptones and polypeptides(35). Pepsin is most efficient in cleaving peptide bonds between hydrophobic and preferably aromatic amino acids such
as phenyl alanine, tryptophan, and tyrosine. Athauda et al purified two acid proteinases (nepenthesins I and II) from the pitcher fluid of Nepenthes distillatoria and found that the proteolytic activity was largely due to two groups of Nepenthesins. Both Nepenthesins I and II were remarkably stable at or below 50˚C and extremely stable over a wide range of pH from 3 to 10 for over 30 days. Nepenthesin I and II had a high content of cysteine residues (12 residues/molecule), which were assumed to form six unique disulphide bonds. The presence of carbohydrate moieties in Nepenthesins reduces the possibility of autolysis and/or denaturation of Nepenthesins.

Further studies are required to reduce the pulp tissue dissolution time, by increasing the concentration of digestive fluid. It might be used as an alternative to NaOCl to achieve pulp tissue dissolution especially in patients, allergic and prone to NaOCl accidents, such as open apices.

Conclusion

The digestive fluid of Nepenthes khasiana could be considered as an herbal alternative to sodium hypochlorite for pulp tissue dissolution as it completely dissolved the pulp tissue similar to 5 % NaOCl, but at different time periods. The ethanolic extract of Drosera rotundifolia was found to be ineffective in dissolution of pulp.

Permanent Mandibular Central Incisor with Two Root Canals: A Case Report

Loganathan Saatwika, Venkatachalam Prakash, Balasubramaniam Anuradha, Arunajetasan Subbiya

1st Yr. Post Graduate, Professor, Reader, Professor and Head, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayananpuram, Pallikaranai, Chennai, Tamil Nadu, India

Abstract

The main reason for endodontic failure of mandibular incisor is the inability to detect the presence of second canal. Varying number of the root canals, their anatomy and interconnections in different teeth have been studied and reported. This case report describes the successful endodontic treatment of mandibular incisor having two root canals.

Keywords: Mandibular incisor, additional canals, Endodontic management.

Introduction

The most complex among all phases of anatomic study in human system is the morphology of pulp cavity morphology. The main reason for failure of endodontic therapy is the lack of knowledge about the anatomical variation of root canals. Lack of knowledge of root canal morphology or lack of experience and skill to negotiate the canal is the reason the canal being unnoticed and treated. The dentist must have a complete understanding of the root canal morphology before starting endodontic treatment. The entire root canal system must be explored, adequately debrided, and filled to attain a good prognosis after root canal treatment. The root canal system of single rooted teeth often have three pulp horns and a single root canal, but some studies have demonstrated that the root canal anatomy of mandibular incisors is not as easy as it appears to be on periapical radiographs, and that it may be complicated by the presence of bifurcated and lateral canals.

The incidence of two canals at the tooth apex was reported to be as low as 11% to as high as 43%. It is generally accepted that many mandibular incisors have two canals, which may merge into 1 canal before reaching the apex. In rare cases, separate foramina may form. This case report presents the endodontic treatment of mandibular incisor having two separate canals which merge into a single canal before exiting the tooth through a single apical foramen.

Case Report: A 55-year-old male patient reported to the department of Conservative dentistry and Endodontics with the chief complaint of pain in lower front tooth region for past 1 day. History of pain is mild, intermittent, nocturnal, aggravates on mastication and relieves at rest. There was no previous dental history and Patient’s medical history did not reveal any systemic diseases and on intraoral examination generalized attrition was seen and 41 had dental caries with tender on percussion. Pulp sensibility test showed negative response. On radiological examination attrition was seen and 41 had dental caries. Tooth was isolated using rubber dam. Access cavities of 41 were slightly modified.
in labiolingual direction using an endo access bur to gain straight-line access into the second canal. Canals revealed Vertucci type II morphology of root canals (Figure 2). The patency was checked using a no. 10k file. Working length was determined in the buccal and lingual canal as 17 and 16mm respectively using digital radiography (Figure-3). Biomechanical preparation was carried out using conventional hand instruments, 2.5% of sodium hypochlorite and 17% EDTA were used for irrigation. After each instrument change the canals were rinsed with normal saline. Master apical cone radiograph was taken (Figure-4) obturation was done using lateral condensation technique (Figure-5).

Discussion

It is assumed that mandibular incisor is the most easy tooth to treat but sometimes these teeth are difficult to treat because of presence of extra canal which is present more linguually and often misdiagnosed and leads to treatment failure. Success of root canal treatment depends on careful diagnosis of additional canal and thorough debridement of root canal space and obtaining a fluid-tight seal. According to Benjamin and Dowson 41.4% of the mandibular incisors showed two separate canals in a radiographic study of 364 specimens; of these, only 1.3% had two separate foramina. In a study of 1,085 specimens by Miyashita et al J Endod 1997 reported that only 3.1% of the samples had separate canals and foramina. Of the two hundred seventy-nine teeth examined in this study, 27.6% (77) had the center of the plotted straight-line access facial to the incisal edge, whereas 72.4% (202) had straight-line access at the incisal edge. No teeth had straight-line access plotted lingual to the incisal edge. The amount of incisal wear can be used as a guide to show where access should be made. In mandibular incisors with unworn incisal edges, the crown slopes toward the lingual from the long axis of the tooth. In these teeth, ideal access will be positioned facially 68.1% of the time. When teeth show “extensive” or “moderate” incisal wear, the access should be made in the incisal edge 86.5% of the time.
The crown of the mandibular incisor slopes toward the lingual, as the incisal edge wears the access moves more to the incisal relative to the incisal edge. An isthmus is an intercanal connection between two root canals comprising dental pulp and pulp-related tissue. In the same root between any two root canals isthmus can be seen. As the isthmus contains the dental pulp, it might serve as a potential site for the growth of bacteria thus, making complete debridement impossible. An isthmus should be suspected whenever two or more canals are seen and all attempts should be made in detecting and debriding it. Careful interpretation of the radiograph is essential to ensure that additional root canals are not missed. This may necessitate imaging the tooth from different angles so that the root canals may be distinguished in the resulting films. In addition, if an obvious canal ends abruptly, the clinician should be suspicious that there are in fact two canals. Adequate exploration of canal chamber with an endodontic file or endodontic explorer (DG 16) facilitates to navigate extra canal. The practice of endodontics should involve the buccolinguinal extension of access for the mandibular anterior teeth.

**Conclusion**

Clinician might think that treating one canal would be sufficient since the apical foramen would be sealed, but still one would see more failure in these teeth. However, one should not feel secure in treating only one canal since the second canal would become necrotic and can liberate noxious byproducts through the accessory and lateral canals into the periodontal ligament space or moreover through the insufficient apical seal of root canal filling materials. In the recent era, the use of clinical microscope for root canal treatment allows a higher detection of extra root canals and also enables proper visualization and cleaning of the isthmus, thereafter increasing the quality and success rates of the endodontic treatment. A successful treatment is more expected when the experienced clinician has not only adequate armamentarium and technology but also a comprehensive knowledge of the root canal anatomy of the tooth.

A 3-Dimensional Approach in the Management of Endodontic Pain: A Review

Dhakshinamoorthy Malarvizhi1, Arumugam Karthick1, Anuradha Balasubramanian2, Hareendranath Velayudhan Nair3

1Professor, 2Reader, 3Undergraduate Student, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

Abstract

Recent advances in the understanding of pain physiology and pharmacology have provided dental practitioners with more reliable information upon which clinical decisions in the treatment of endodontic pain can be based. One of the effective strategies currently used in these cases is structured to evaluate the painful condition through a 3-D approach which establishes a differential diagnosis, definitive treatment, and rational use of drugs, based on the most appropriate scientific evidence available in the literature. This article provides practical treatment strategies based upon current scientific evidence and uses information presented in the articles.

Keywords: Pain physiology, endodontic pain, 3-D approach.

Introduction

Managing pain can be one of the more challenging aspects of the clinical practice of endodontics, and one by which the skill of the clinician is often judged. Unfortunately, root canal therapy is still perceived by many as a standard against which painful experiences are judged. This is a two-edged sword. Because patients are expecting pain, it often makes their pain management more difficult. On the other hand, advances in local anesthesia and modern pharmacology allow dental practitioners to deal effectively with the patient experiencing odontogenic pain and, in most cases, exceed their expectations. In Endodontics, the management of pre- and post-operative pain should include important aspects for its controlling and prevention, such as anxiety reduction and control of pre/transoperative pain through local anaesthetic techniques and pharmacological drugs [1]. The effective strategy for managing the endodontic pain is based in the pain assessment through a 3-D approach that consists of establishing the differential diagnosis, definitive treatment, and rational use of drugs [2]. This literature review aimed to identify and systematize the clinical approaches for pain control during endodontic emergency care through the accurate diagnosis and clinical and pharmacological intervention.

There are three D’s that needs to be done in order to treat any pain.

1. Differential Diagnosis: The diagnosis should be the starting point for pain control, because the pain cause may involve anatomic and psycho factors [1, 3]. The first D consists of establishing the differential diagnosis based on identifying oral pathologies and their origins through step-guided investigation, obtaining objective and subjective information on the problem. The pain can be defined as an unpleasant sensorial and emotional experience associated to a real or potential tissue damage. Acute pain is defined as a recent damage of limited duration; chronic pain is related to persistent

e-mail: drmalaendo@gmail.com
duration\(^1\). Although the majority of patients who present with a complaint of tooth pain actually suffer from odontogenic pain, it is clear that this is not always the case. If the pain and origin sites are different, this is so-called referred pain. The radiographic evaluation provides useful information on the involved structures; however, the radiograph is an adjunctive examination complementary to the clinical examination\(^1\). The adjunctive tests for pulp diagnosis, especially the cold test, will determine the pulp sensitivity. Thus, developing a differential diagnosis is an essential first step in effective pain management strategies. Table 1 provides an overview of major clinical conditions that can mimic odontogenic pain.

2. **Definitive Treatment:** The second D is the definitive dental treatment or the emergency dental care required for pain remission. The diagnosis accuracy leads to the safe and correct treatment, using adequate procedures that allows significant pain reduction and the correct drug association that contributes to pain control and relief\(^3\).

Pulp inflammations may cause unbearable pain, and emergency care is required through the complete removal of the inflamed pulp (pulpectomy), especially if pain after percussion is present \(^4, 5\). Notwithstanding, because the patient who search for emergency care is not scheduled, the operative time is very reduced to perform pulpectomy. Thus pulpotomy is an acceptable treatment to cease the pain, aiming at removing the affected coronal pulp tissue without touching the root canals \(^6, 7, 8\). The high success rate of pulpotomy is associated to the alteration in pulp hemodynamics and pressure of the interstitial fluid because the pain relief occurs due to the decompression of the enlarged pulp tissues due to the inflammatory process \(^6\). Partial pulpectomy can be accomplished mainly in multi-rooted teeth by completely removing the pulp tissue of the larger straighter canals (palatal canal of maxillary molars and distal canal of the mandibular molars). Because of the complex morphology of the buccal roots of the maxillary molars and mesial roots of the mandibular molars, it is not advisable to prepare these canals, due to difficult in proper cleaning during emergency care, resulting in hemorrhage and increase in inflammation and patient’s discomfort. In cases presenting pain at percussion, it is recommended to establish the working length, instrument all canals up to file #25, and perform occlusal adjustment \(^9\).

According to Agnihorry et al. \(^10\), the irreversible pulpitis is characterized as one of the main causes motivating the patients to seek emergency care. The most indicated approach is endodontic treatment associated to analgesic or anti-inflammatory drugs. However, a significant number of dentists still prescribes antibiotics to relief the pain during irreversible pulpitis. According these authors, the literature reports little evidence that antibiotics reduce the pain. The authors still recommended that the antibiotics prescription does not replace pulpectomy in these cases \(^9\).

The complete instrumentation is the ideal treatment for symptomatic teeth, mainly when the periodontal ligament is injured, indicating the presence of acute apical periodontitis. Thus, at the emergency appointment, all necrotic tissue must be removed. In single-rooted teeth, complete pulpectomy is easily performed, while multi-rooted teeth demand a more complicated preparation due to anatomical variations. Notwithstanding, the preparation length is at 2-3 mm below the radiographic apex for all canals \(^10\).

A tooth with acute dentoalveolar abscess is extremely sensible to mastication, percussion, and palpation, but does not respond to any pulp test and has many mobility degrees. At the radiographic examination, the periodontal ligament space may be enlarged and shows periradicular radiolucency. At the vestibule bottom and adjacent soft tissues, swelling may occur that complicates the treatment and demands the following-up of the remission of these signs and symptoms after emergency care. The presence of fever, swelling, prostration, cervical and submandibular lymphatic nodes sensible to palpation (lymphadenitis) evidences that the infectious process is not properly controlled by the normal defense mechanisms and requires antibiotic therapy.

The treatment of the acute intraosseous alveolar abscess is not different from that of the necrosed pulp, in which there is the presence of unbearable pain and lack of extra or intraoral edema. In these cases, the exudation is confined to the apical area and the drainage is obtained through the total instrumentation of the canal with the foramen trepanation attempting to drain the pus through the canal \(^11\).
According to Siqueira and Barnett [11], the factors causing pain during endodontic procedures are of chemical or mechanical origin and commonly associated to iatrogeny, microbial factors present in pulp and periradicular pulp, and presence of periapical lesion induced or aggravated during root canal treatment [11]. The microorganisms may cause pain in between appointments due to the following situations: apical extrusion of debris, incomplete instrumentation leading to alterations in the endodontic microbiota, and secondary intraradicular infections [7]. The occurrence of mild post-operative pain is not rare, even with the endodontic treatment followed acceptable standards. The mild pain after chemical-mechanical preparation may occur in approximately 10-30% of the cases, and in most cases, the discomfort is decreased with common analgesic drugs to relieve the symptoms [12]. The development of moderate to severe post-operative pain, with or without swelling, on the other hand, ins uncommon and demands emergency care [11].

3. **Systemic drugs for controlling the pain:** The third D denotes drugs which are needed to control the pain and infection.

Anesthesia techniques for different teeth Various specific techniques have been described to help achieve predictable anesthesia in different teeth. For mandibular central and lateral incisors, a combination of buccal and lingual infiltrations provides significantly higher rates of success of anesthesia compared to either a labial or a lingual infiltration[13,14]. The palatal-anterior superior alveolar (P-ASA) injection has been described for anesthetizing maxillary incisors and canines. However, this technique has a potential for being painful during needle insertion, and also during and after injection. Moreover it can cause swelling, numbness, and parasthesia of the incisive papilla even when a computer aided injection system was employed [15]. For maxillary molar teeth, the combination of buccal and palatal injections significantly increased the duration of anesthesia from 21 to 57 min [16]. Greater palatine and high tuberosity second division nerve blocks are effective techniques for anesthetizing the first and second maxillary molars in most cases, whereas only about two-thirds of second premolars were anesthetized with these techniques. No significant difference was found between the efficacy of these techniques, although more post-injection pain was reported with the high tuberosity second division injection technique [17]. Higher success rate of anesthesia for mandibular molar has been reported when the Gow-Gates mandibular nerve block technique was compared with either conventional IANB or buccal and lingual infiltrations [18]. However, two other studies found no significant differences between different anaesthetic techniques for mandibular molars [19,20]. No significant difference was found between the posterior superior alveolar nerve block, buccal infiltration and buccal plus palatal injection for anesthetizing maxillary first molars with irreversible pulpitis [21].

One study used frequency dependent stimulation for blocking inferior alveolar nerve following IANB and found no significant increase in pulp anaesthesia in mandibular teeth [22]. In conclusion, dentists should employ techniques that provide higher success rates while having less injection pain and less post-injection pain and discomfort for the patient. Supplementary or alternative techniques should be used when the first injected is not successful in providing profound anesthesia.

Other anaesthetic techniques are used for controlling endodontic pain such as intrasosseus, intraligamentary, and intrapulpar [23,3,24]. According to Fan et al. [8], the alveolar inferior nerve blocking may be associated with the anesthesia of the buccal nerve or intraligamentary anesthesia to increase the anesthesia success in cases of irreversible pulpitis [25]. The intrasosseus injection (II) enables placing the local anaesthetic solution directly on the cancellous bone adjacent to the tooth to be anesthetized [21].

Currently, a system is available on dental market so-called Stabident. Stabident is composed by a slow-speed perforator (micro motor) coupled with burs to create a small orifice on the cortical plate. The anaesthetic solution is placed on the cancellous bone through a 27-gauge needle, placed on the orifice previously made by the perforator, a very effective technique if the conventional techniques failed [26].

The intrapulpar infiltrative anaesthesia is an extreme resource in teeth with deep caries and pulp exposure. The anaesthetic solution is directly injected on dental pulp, and the liquid injection should be fast because the injection pain is instantaneous.

The use of drugs to control the pain should be
planned rationally and strictly to situations requiring pharmacological management, adjunctive to the dental treatment \cite{12, 14}. The dentist is allowed to prescribe any drug with proven indication in Dentistry, including those with controlled use. Such approach demands that the dentist knows the prescribed drug, including the side effects, possible interactions, indications, and contraindications \cite{3, 12}. The anti-inflammatory drugs comprise two groups: non-steroidal and steroidal (corticoids). Nonsteroidal anti-inflammatory (NSAIs) are effective against dental pain \cite{23}. The clinician can also use the corticosteroids indicated with safe in Dentistry: dexamethasone and betamethasone \cite{3, 12}.

This problem may directly affect Dentistry because the effectiveness of the most used antibiotics may decrease. According to Andrade \cite{3}, many dentists still considered erroneously. The antibiotics should be considered as adjunctive treatment in controlling the infections (Figure 1)

The indiscriminate and incorrect use of antibiotics may lead to the appearance of multiresistant bacteria that are not sensible to any antibiotics available in the market and whose control can be complex.

The current evidence indicates that local root canal instrumentation procedures, combined with analgesic medications are sufficient for management of the vast majority of symptomatic endodontic cases. When diagnosing a case with odontogenic infection, it is important that the clinician make a distinction between localized infections, which may include cases with periradicular radiolucencies, pain and localized swellings, and those with spreading systemic infections. Antibiotic treatment is generally not recommended for healthy patients with localized endodontic infections.

**Figure 1: Antibiotic recommendation for Symptomatic Endodontic patients**

**Conclusion**

The emergency care because of orofacial pain requires immediate dentist’s attention. Accordingly, the dentist should be apt to identify the pain evolution by analyzing the characteristics and causal factors, to establish a differential diagnosis and treatment plan capable of relieving the pain. A systematic approach to understand the pathologic problem consists of
establishing the precise diagnosis, effective definitive treatment, and rational use of drugs. This review pointed out some important approaches that may be key factors for the effective pain remission, control, and prevention in endodontic procedures. The pain management requires clinical approach based on scientific evidence whenever possible to choose the best treatment alternative in cases of pain. Thus, the constant updating of the therapeutic approaches is necessary.

Role of Neutrophils in Periodontitis: A Review

Harini Venkata Subbiah¹, Usha Subbiah², Athira Ajith¹, Ramesh Babu Polani³

Abstract

Periodontitis is a multifactorial disease caused by periodontopathic bacteria and influenced by both environmental and genetic factors. In a healthy oral environment, there is a balance between symbiotic bacteria and when this balance is breached, inflammation appears and more immune cells are recruited to the site of infection. Neutrophils are the professional antimicrobial phagocytes that form the first line of defense against bacterial invasion in periodontal disease and connect innate and adaptive arms of the immune response. Neutrophils efficiently control pathogens by oxygen-dependent and oxygen-independent antimicrobial mechanisms and by neutrophil extracellular traps. Some studies indicate that excessive neutrophils are responsible for tissue damage and disease progression in periodontitis whereas other studies indicate that neutrophil deficiencies in patients also result in the periodontal condition.

Keywords: Periodontitis, Neutrophil, defensin, neutrophil extracellular traps.

Introduction

Periodontitis is an inflammatory condition and periodontopathic bacteria are recognized by neutrophils, macrophages and other immune cells with the help of pattern recognition receptors (like Toll-Like receptors) that recognize pathogen associated molecular patterns (PAMPs- lipopolysaccharides) of microbes and this interaction triggers the production of inflammatory molecules such as cytokines and chemokines by immune cells. If the inflammation continues, it extends deep into the tissues causing alveolar bone loss and the formation of periodontal pockets characteristic to periodontitis. There is tight control of neutrophil survival after bacterial clearance by induction of apoptosis which exerts protective effects toward host tissues and prevents inflammatory tissue damage. A failure to properly regulate neutrophil abundance and turnover directly contributes to the pathogenesis of periodontitis. In addition to the pathogenic effects of periodontal bacteria, dysregulation of neutrophil activity has been found to play a role in periodontitis. Neutrophils function as a double-edged sword in periodontitis, causing not only the mobilization of defense mediators and tissue-repairing mechanisms but also further tissue damage.

Pathogen Killing strategies of neutrophils

Phagocytosis: Neutrophils recognize pathogens through pattern recognition receptors or opsonins and initiate phagocytosis whereby the pathogen is internalized by the cell into a vacuole called the phagosome. The principal opsonin receptors of neutrophils, Fc receptors and a subgroup of b2 integrins, bind to an immunoglobulin or complement-coated particles, respectively and initiate phagocytosis. After engulfment of bacteria, the nascent phagosome matures by fusing with lysosomes forming phagolysosome. Neutrophils produce an oxidative burst resulting in the rapid release of high levels of bactericidal reactive chemical species that is generation of ROS, such as superoxide anion, hydrogen peroxide (H₂O₂), hydroxyl radicals (HO·), hypochlorous acid (HOCl), nitric oxide (NO) under

the catalyzation of NADPH oxidase, myeloperoxidase (MPO) or nitric oxide (NO) synthetase\[6\]. ROS create a toxic environment to the pathogen but not all pathogens are killed inside the phagosome. Some have developed advanced strategies to survive inside neutrophils and these strategies include interfering with engulfment, modulating phagosome maturation, and creating a more hospitable intraphagosomal environment\[7\]. Excessive neutrophils as seen in some periodontitis conditions contribute to the destruction of periodontal connective tissues and extracellular matrix through increased production of reactive oxygen species ROS \[8\]. In an in vitro study, the phagocytic activity of crevicular and peripheral blood neutrophils in aggressive periodontitis was found to be reduced. It was also inferred that altered neutrophil function could severely weaken the host defense resulting in the initiation and progression of periodontal disease\[9\].

**Degranulation:** Neutrophils are the most abundant type of granulocytes of white blood cells. They contain primary or azurophilic, secondary or specific, tertiary or gelatinase and secretory vesicles. The primary granules are the main storage site of elastase, myeloperoxidase and human neutrophil peptides (α-defensins). The secondary granule contains alkaline phosphatase, lysozyme, NADPH oxidase, collagenase, lactoferrin and cathelicidin. Tertiary granules contain matrix metalloprotease 9 (also known as gelatinase B), cathepsin. The secretory vesicles in human neutrophils contain human serum albumin and other substances. Granule release is tightly controlled and not released from neutrophils until they receive a signal from receptors in the plasma membrane or phagosomal membrane. *Porphyromonas gingivalis*, the keystone pathogen in chronic periodontitis, inactivate granular enzymes and evade neutrophil-mediated killing and persist in the periodontal pocket\[10,11\].

**Neutrophil Extracellular Traps:** Neutrophil extracellular traps (NETs) comprise decondensed nuclear DNA and associated histones that are extruded into the extracellular space and associated with the web-like strands of DNA is an array of antimicrobial peptides (AMPs), which facilitate the extracellular destruction of microorganisms that become entrapped within the NETs\[12,13\]. Neutrophil's infiltration of gingiva, influx into the crevice and subsequent NETosis is a crucial feature of periodontitis. Exaggerated NETs are unable to maintain periodontal health and contribute to the body's overall inflammatory burden and worsen conditions such as atherosclerosis, diabetes mellitus and obstructive pulmonary disease \[14\]. Oxygen-dependent and oxygen-independent antimicrobial factors and extracellular bacterial traps render neutrophils very efficient at controlling periodontal pathogens and result in the containment of pathogens within the oral cavity.

**Neutrophil components involved in periodontitis.**

**Alphadefensins:** Alpha defensins1-4 (α-defensins) are also known as human neutrophil peptides and are found in the oral cavity whereas α-defensins 5-6 are found in mucosal Paneth cells associated with the gut. α-defensins induce non-oxidative killing in phagocytes or can act directly as an antimicrobial when discharged into the tissue\[15,16\].

Lactoferrin: Lactoferrin, an iron-binding glycoprotein, is an important component of human secretions including saliva, synthesized by exocrine glands and neutrophils and represents an important defense factor against periodontopathic bacteria through its ability to decrease bacterial growth, biofilm development, iron overload, reactive oxygen formation and inflammatory processes \[17\]. Periodontopathic bacteria reside as a biofilm in supragingival and subgingival plaque and lactoferrin were able to reduce their biofilm development \[18\]. The antibiofilm activity of lactoferrin against *P. gingivalis* and *Prevotella intermedia* highlights the potential usefulness of lactoferrin in the prevention and treatment of periodontal diseases and as an adjunct therapy for periodontal diseases.

Cathelicidin: Cathelicidin is abundantly expressed in neutrophils and mucosal epithelia such as airways, buccal mucosa, tongue, esophagus, cervix, vagina and salivary glands \[19\]. Humans express only one cathelicidin known as hCAP-18 (human cathelicidin antimicrobial peptide of 18kDa). The cathelicidin hCAP-18 is characterized by a highly conserved cathepsin-L-inhibitor (cathelin)-like domain which is flanked by a signal peptide domain on its N-terminus and by an antimicrobial peptide region on its C-terminus called LL-37 (37 denotes the length of the peptide and “LL” denotes the first two amino acids formed by Leucine) \[20,21\]. The antibacterial C-terminus region (LL-37) is cleaved from hCAP-18. LL-37 exerts direct bactericidal effect by inserting into the bacterial membrane and triggering cell rupture and leakage of cytoplasm \[21\]. It has been shown that the production of LL-37 is up-regulated in the inflamed gingival tissues compared to healthy gingival tissues \[22\].
and has also been found to possess antibacterial activity against periodontopathic bacteria such as *P. gingivalis, P. intermedia* and *A. actinomycetemcomitans* [23]. A novel missense mutation in cathelicidin antimicrobial peptide gene, serine to asparagine substitution mutation was reported by Turkoglu et al., 2011 and found that generalized aggressive periodontitis was significantly associated with the mutation but not chronic periodontitis and the substitution mutation was a contributing factor for developing generalized aggressive periodontitis [24].

**NADPH oxidase:** Upon activation, neutrophils generate reactive oxygen species (ROS) in a process known as the respiratory burst by NADPH oxidase that belongs to the family of NOX proteins. The leukocyte specific NADPH oxidase is a multi-subunit entity with membrane-bound and soluble components that assemble into a heteromeric complex when the cells are stimulated [5]. The assembled oxidase generates ROS that serve as highly effective antimicrobial agents. Deficiency of NADPH oxidase subunit gp91phox promoted the colonization of *A. actinomycetemcomitans* in the murine oral cavity, leading to severe periodontal bone loss and inflammation after infection and suggested that ROS-dependent mechanisms are involved in the clearance of the periodontopathogen [25]. The mutation in NADPH oxidase p22phox C242T predisposed to aggressive periodontitis through modulation of neutrophil superoxide production. NADPH oxidase p22phox T allele was found to be enriched in aggressive periodontitis patients compared with controls with increased release of superoxide from neutrophils [26]. Excess ROS is likely to contribute to bone loss in periodontitis and the lack of ROS is harmful to periodontal health so there has to be a balance for the maintenance of periodontal health [25].

**Formyl peptide receptor:** Bacterial formylpeptides act as chemotactic stimuli that are recognized by formyl peptide receptors (FPRs) of neutrophils and in response neutrophils migrate toward infection sites. Binding of formylpeptides to FPRs triggers a cascade of intracellular signals that coordinate cytoskeletal reorganization, formation of pseudopodia and migration of neutrophils up a chemotactic gradient [27]. Aggressive periodontitis is associated with impaired neutrophil chemotaxis toward bacterial N-formyl peptides. Gene analysis showed that the homozygous FPR1 348T genotype was associated with an increased risk of aggressive periodontitis and significant impairment of neutrophil chemotaxis [27]. Diseases associated with neutrophil defects.

**Papillon–Lefèvre syndrome (PLS):** Papillon–Lefèvre syndrome (PLS) is a rare autosomal recessive disorder and characterized by palmoplantar hyperkeratosis and severe early-onset periodontitis, leading to premature loss of deciduous and permanent dentition at a very young age [28]. PLS is caused by mutations of the cathepsin C gene (CTSC) and reduction in CTSC activity resulted in reduced host responses against bacterial [29]. It has been shown that in PLS, neutrophils have a substantially reduced capacity for NET production, higher ROS generation and defective chemotaxis. A range of above said functional neutrophil defects have been noted in PLS in addition to the CTSC deficiency and consequent failure to activate neutrophil serine protease (NSPs), these cumulative effects have been found to destroy periodontal tissues [30].

**Neutropenias** In autoimmune neutropenia, autoantibodies attack neutrophil membrane resulting in their destruction or alteration of their function [31]. This leads to an aberration in their homeostasis and increased susceptibility to periodontitis.

**Chediak-Higashi Syndrome:** Chediak-Higashi syndrome (CHS) is a rare autosomal recessive disorder and the primary defect is abnormal granule formation in the cells secondary to a mutation of a lysosomal trafficking regulator gene (LYST) leading to multiple infections including periodontitis [32]. Because of defective intracellular trafficking, giant lysosomal granules develop within neutrophils and other cells (e.g., melanocytes, fibroblasts and neural Schwann cells), leading to abnormal lysosome fusion with phagosome, which subsequently results in impaired function of multiple body cells [33]. LYST mutations in CHS patients affect TLR-2 and TLR-4 expression/function, leading to dysregulated immunoinflammatory response, which in turn influenced the periodontal phenotype in CHS patients [33].

**Leukocyte adhesion deficiency:** Leukocyte adhesion deficiency type I (LAD-I) is an autosomal recessive immunodeficiency disorder characterized by impaired adhesion and chemotaxis due to defects in the integrin receptors of white blood cells [34]. In LAD, individuals had defective neutrophil recruitment to the periodontium (compromised neutrophil adhesion and extravasation to sites of infection) affecting both the primary and permanent dentition leading to aggressive periodontitis [35].
Chronic Granulomatous Disease: Chronic granulomatous disease (CGD) is an extremely rare congenital immune deficiency disease characterized by recurrent severe infections due to the inability of neutrophils and macrophages to mount a respiratory burst and kill invading bacteria and fungi[36]. Mutations in the genes encoding the components of the NADPH oxidase complex cause CGD and the disorder can be inherited in an X-linked or autosomal recessive (AR) manner. The most common form of CGD is the X-linked recessive CGD caused by mutations in the CYBB gene, encoding gp91phox subunit. The other forms of CGD are AR and are due to mutations in CYBA, NCF1 and NCF2, encoding p22phox, p47phox, and p67phox, respectively[37]. Patients with CGD develop oral lesions reflecting susceptibility to oral infections and inflammation[36].

Conclusion

Neutrophils are an important constituent of the host immune defense mechanism and play a pivotal role in maintaining homeostasis. But when there is excessive activation of neutrophils, these powerful components of immune system work destructively in the periodontium. Neutrophil deficiency results in recurrent and severe periodontal infections while also their unregulated release leads to pathology from excessive inflammation. Therapies should concentrate on preventing detrimental inflammation and periodontal tissue breakdownby inhibiting hyperactivity of neutrophil mediators without compromising the antimicrobial activity of the neutrophils.

Malignant Hyperthermia: A Systematic Review

Visalakshi Kaleeswaran¹, R. Kirthika¹, R. Balakrishnan³
¹Post Graduate Student, ²Professor, Sree Balaji Dental College and Hospital, BIHER

Abstract

Background: Malignant hyperthermia (MH) is a potentially fatal pharmacogenetic disorder of the skeletal muscles that presents as a hypermetabolic response to potent inhalational anaesthetic agents such as halothane, sevoflurane, desflurane, isoflurane and the depolarizing muscle relaxants like succinylcholine, and rarely, due to vigorous exercise and heat.

Method: A systematic review was carried out using the database PubMed central and MEDLINE using the keywords General anaesthesia, malignant hyperthermia, systematic review. This literature search yielded 1174 articles published up to the year 2018. INCLUSION CRITERIA: peer reviewed retrospective and prospective cohort studies, cross sectional studies, case descriptions were included in the study.

Objective: The objective of this systematic review is to provide a wide and objective assessment of the incidence of Malignant Hyperthermia in patients undergoing surgery with or without general anaesthesia

Keywords: Malignant hyperthermia, Anesthesia, Bradycardia.

Introduction

Malignant hyperthermia is a potentially fatal pharmacogenetic disorder triggered on exposure to potent volatile anaesthetic agents. MH is a genetic disorder of calcium receptor that is linked to ryanodine receptor 1 gene. MH causes a progressive depression of almost all the organs.¹²³

Mild Hypothermia:
- Heavy shivering
- Cold diuresis and
- A cold white skin

Moderate Hypothermia:
- Reduced shivering
- Hyporeflexia
- Ataxia
- Bradycardia

Severe Hypothermia:
- The cessation of shivering
- Bradycardia (with possible cardiac arrest),
- Hypotension,
- Hypoventilation (with possible apnea), areflexia, oliguria, coma, and eventually death

Ethical Issues: No funding agency for this study and this systematic review did not require any ethical approval or informed consent since there is no direct contact with the patients and is based only on previously published data.

Inclusion and Exclusion Criteria: Peer reviewed retrospective and prospective cohort studies, cross sectional studies, case descriptions were included in the study.

Reports of neuroleptic malignant syndrome or hyperpyrexia of unclear etiology will be excluded.
Discussion

In 1973 King jo and denborough - King denborough syndrome patients are MH susceptible

In 1980 Gronert and denborough et al Reported patients with awake MH episodes with exercise and heat stroke as potential triggers. All of them responded to dantrolene sodium.

In 1984 Schwartz L et al Succinylcholine induced MMR occurs in one in 100 children with anaesthesia and are susceptible to MH in patients induced by halothane.

In 1994 Lazzell et al Found that the incidence of MH that occurs on induction with succinyl choline is same following induction with sevoflourane and much lesser following induction with thiopental.

In 2009 Browne et al Reported exertional heat stroke as a possible vital trigger linked to MH.

In 2010 Wei et al MMD an early onset congenital myopathy is associated with MH susceptibility.

In 2012 Yuen et al Found that heat stress triggers fulminant MH in mice expressing the rabbit equivalent of human RYR1 gene T4826I mutation.

In 2014 Larach et al Likelihood of complication increases 2.9 times per 2 degree raise in the core body temperature and 1.6 times per 30 minute delay in the use of dantrolene sodium.

In 2015 Albakari et al Dominant or recessive mutations in RYR1 are identified cause of MH susceptibility and there are 48 mutations proven to be causative for MH.

In 2016 Bamaga et al Majority of the reported cases of MH are caused by mutations in two genes RYR1 and CACNA1S which are associated with skeletal muscle calcium regulation.

Conclusion

In individuals undergoing general anesthesia using volatile agents MH remains a serious susceptible risk
factor. Mutation of two genes RYR1 and CACNA1S have been unequivocally linked to causation of Malignant hyperthermia however the potential for the involvement of other genes cannot be discounted. The incidence of death due to MH has decreased in the last thirty years and there is a significant reduction in mortality rate from 80% to 1.4%. Dantrolene sodium is the only curative approach and there should be no treatment delay; all the medical practitioners must be well aware of these measures inorder to facilitate early detection and treatment.

Role of Genetics in Dentistry: A Review

Athira Ajith¹, Usha Subbiah¹, Harini Venkata Subbiah¹

¹Human Genetics Laboratory, Senior Research Fellow, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Chennai, Tamil Nadu, India

Abstract

Our genome plays a key role in odontogenesis and oral diseases. The dental tissues are unique and share many basic molecular mechanisms that are common to tissues throughout the body. Dental caries, periodontal diseases, malocclusion and oral cancer are the most common manifestation of genetic and environmental interaction and several genes have been primarily involved in human dentition. Consideration of genetic factors is essential for diagnosis that underlies virtually all orofacial anomalies. Common genes involved in orofacial genetic disorders are listed. It is important to identify the genetic factors that cause the existing dental problem, which may also influence the outcome in oral diagnosis. The application of the principles of genetic medicine to the diagnosis and treatment of dental diseases will fundamentally change the delivery of oral health care.

Keywords: Dental diseases, Orofacial disorders, Tooth agenesis.

Introduction

The contribution of hereditary factors to dental diseases has become increasingly evident in dentistry, as there are several implications of systematic genetic disease on oral health care. Genetic makeup influences the healthy teeth and gums, the alignment and strength of the teeth, and susceptibility to oral diseases and tooth decay. During the odontogenesis, the cytodifferentiation of dental epithelial cells produce enamel. Mesenchyme surrounding the tooth bud forms the supporting structure of the tooth. Like other processes during the embryonic development, morphogenesis and differentiation of teeth is the result of complex interactions at the molecular level between the ectoderm and the mesenchyma forming the supporting structure of the tooth. For example, the periodontal ligament anchors the tooth to the alveolar bone. Tooth development is regulated by dynamic interactions encoded either by universally expressed genes or tooth-specific genes that are regulated in a spatiotemporal manner and until now more than 200 genes are involved in these processes [1][2]. Mutations in these genes have pleiotropic effects in addition to causing non-syndromic dental abnormalities and dental anomalies associated with different genetic syndromes.

Genetics of Dental Diseases: Dental caries, periodontal diseases and malocclusion are the most common problem caused by an interaction of genetic and environmental factors. The heritability of these diseases has historically been estimated from twin studies. Further, the genetic linkage studies have been routinely used to locate disease susceptibility genes in the genome; such studies typically involve detailed genetic and phenotypic studies in families that appear to manifest a genetically inherited disease predisposition.

Dental Caries: Genetic studies of dental caries were published by Finn and Caldwell (1963) and by Zengo and Mandel (1972)[3]. Several variables related to caries experience (i.e. the number of teeth present, percentage of teeth restored, percentage of surfaces restored, percentage of teeth affected by caries, percentage...
of surfaces affected by caries) showed statistically significant concordance rates in monozygotic twins, but not in dizygotic twins[^4]. Genome-wide linkage studies on caries using the candidate-gene approaches include three main groups of genes i.e genes involved in enamel development, saliva formation and composition, and in the immune response. Candidate genes for the study of caries in humans are TUFT1, AMELX, ENAM, TFIP11, AMBN, MMP20 AMD many more. TUFT1 is expressed in the developing and mineralized tooth and nonmineralizing soft tissues which showed association with higher caries experience. This association was dependent of the presence of *Streptococcus mutans*. AMELX gene is involved in the mineralization during tooth enamel development and is associated with higher caries experience. TFIP11 genes interact with tuftelin and play a major role in spliceosome disassembly in Cajal bodies which is associated with the initiation of carious lesions and higher caries experience[^5].

**Periodontitis:** In periodontitis, the host-activated inflammatory and immunological cascades cause destruction of connective tissue and bone under genetic control. Evidence suggest for a genetic contribution to individual differences in risk of early onset periodontitis. In case of chronic periodontitis, studies of adult twins indicated that a substantial proportion of the population variance for periodontal measures-such as pocket depth, attachment loss, and bone loss may be attributable to heritable factors. Aggressive periodontitis is often familial and the likelihood of inheriting aggressive periodontitis was high in family studies[^6]. There are several potential difficulties in periodontal disease research: First, genetic heterogeneity in the etiology of adult periodontal disease detection of a specific mode of inheritance. Second, it may be difficult to determine affected status or to measure periodontal health in edentulous family members, adults who had early-onset periodontitis rather than adult periodontal disease. Third, there are other factors that affect periodontal disease susceptibility, some of which may be heritable themselves, such as a propensity for tobacco use, or which may cluster in families and oral hygiene habits. Cytokines such as interleukins (IL-1A, IL-1B, IL-6, and IL-10, among others), surface receptors such as the Fcy family (FCGRs), and cyclooxygenase- (COX-) 2 and matrix metalloproteinase (MMP) genetic polymorphism are considered key factors in the progression of periodontitis[^7].

**Malocclusion:** Genetic factors play an important role in the etiology of malocclusion. Genetic pathways that play a role in anteroposterior and vertical skeletal variation observed in patients with malocclusion and in skeletal malocclusion. Genetic basis of dental disorders provides the evidence for the heritability of various type of malocclusion from family and twin studies[^8]. The single nucleotide polymorphisms within FGFR2, EDN1, TBX5, and COL1A1 showed associations with type of skeletal malocclusion[^9]. Extensive cephalometric studies determined the heritability of certain craniofacial parameters in class II division I malocclusion. Most malocclusion studies to date have focused on Class III malocclusion. Several candidate genes within a linkage region on chromosome 12q22-q23 harbouring DUSP6 gene are implicated in the regulation of maxillary or mandibular growth[^10]. Genetic studies for Class I and II malocclusions are rarer. Single nucleotide polymorphism in rs6504340 within the HOXB cluster for Class I malocclusion was associated with delayed tooth eruption and occlusion irregularities[^11] that genetic identification might be required orthodontic therapy.

**Oral Cancer:** Chromosome segregation, telomere stability, genomic copy number, loss of heterozygosity, telomere stabilities, regulations of cell-cycle checkpoints, DNA damage repairs and defects in notch signalling pathways are involved in the progression of oral cancer. These changes cause loss of tumour suppressor activity and give rise to a phenotype capable of increasing cellular proliferation, weakening cell cohesion and causing local infiltration and metastasis. More than 90% of oral cancer is oral squamous cell carcinoma is caused due to genetic alterations the genes COX-2, EpCAM and MMP-2,6[^12]. Several biomarkers have a major role in oral cancer. Su et al[^13] studied that defined like guanine nucleotide exchange factor proteins was highly expressed and favoured anchorage-independent growth in oral cancer tissue compared to adjacent normal tissue. The overexpression in cells promotes cell migration and induces cell invasion in cancer cell lines. Saintigny et al.[^14] demonstrated the gene expression profiles in oral leukoplakia patients. The microRNA-based strategies might, therefore, be considered in future chemoprevention studies. The keratinization and high miR-21 levels were important indicators of oral cancer patient prognosis and two keratinization-associated miRNAs (miR-7 and miR-21), could contribute to the regulation of the tumour suppressor gene RECK in oral cancers[^15].
Genetic disorders of orofacial regions: Most of the disorders affecting the orofacial region are an autosomal dominant trait. The disorder mainly affects jaws, dental tissues and oral mucus membrane. Mutations in genes and single nucleotide polymorphism are the genetic risk factors of orofacial disorders.

Cleft lip and palate: Cleft lip and palate (CLP) is a congenital deformity that affects the upper lip and the roof of the mouth. CLP is a multifactorial condition comprising both genetic and environmental factors. Defects of growth factors and their receptors have been shown to cause non-syndromic or syndromic oral clefts in humans. Three genes - T-box transcription factor-22, poliovirus receptor-like-1, and interferon regulatory factor-6 - are responsible for causing X-linked cleft palate, cleft lip/palate-ectodermal dysplasia syndrome and Van der Woude and popliteal pterygium syndromes, respectively[16]. Linkage and sequencing studies of families have identified mutations in the FGF8 and FGFR1 genes causing non-syndromic cleft lip and palate[17]. TGF3 genes have also been involved in oral cleft formation in humans[18]. The inactivation of the growth factor BMP7, another member of the TGF family caused defects in tooth development and clefts in the soft and hard palate[19]. A mutation of the T-box transcription factor-22 gene was found in a large Icelandic family with X-linked cleft palate (CPX) and in several smaller families from other countries[20]. TBX22 is a major genetic determinant in human palatogenesis.

Tooth agenesis refers to the failure of tooth development. In humans, tooth agenesis involves one or more teeth (or classes of teeth). Failure of development of the third molars is the most common agenesis (10–25%). Although agenesis is occasionally caused by environmental factors (trauma in the dental region such as fractures, surgical procedures, chemotherapy, radiotherapy), in most cases the causes are genetic. 4 genes have been identified to be associated with non-syndromic hypodontia/oligodontia [21]. The major genes involved in tooth agenesis are PAX, MSX, DLX, AXIN, EDA, LHX, BARX, RUNX. MSX1 gene plays an important role in craniofacial development, including odontogenesis. Vastardis et al[22] identified an Arg to Pro substitution in MSX1 gene homeodomain that causes hypodontia and inherited in the next 4 generations. The PAX9 gene which encodes a transcription factor is involved in the development of teeth[23]. The sequencing of PAX9 gene showed a transition of A → G in the initiator AUG codon, in samples from a Chinese family.
with many cases of oligodontia. This is the first mutation found in an initiator codon that caused a severe inhibition of translation in tooth development [24]. The genetic variability in these genes influences the growth of teeth and lead to orofacial disorders.

### Conclusion

We still do not know all the causes of dental diseases, but their genetic basis is not a neglected factor. The genetic causes of dental pathologies are multiple and its severity depends on the affected gene, the type and location of the mutations. Improved method in diagnosis, treatment and prevention have enabled the investigators to focus more of their attention on the role of genetic in oral and dental disorders.

Abstract

Fosfomycin, a broad spectrum bactericidal agent had been recommended by the Food and Drug Administration for the treatment of uncomplicated urinary tract infections. However, studies on the susceptibility rate of Enterococcus faecalis against fosfomycin are inadequate. Hence, this study was aimed to determine the in vitro susceptibility to fosfomycin among urinary E. faecalis. A total of about 70 non-repetitive isolates of Enterococcus faecalis isolated from the urine samples were included in the study. Susceptibility to fosfomycin, linezolid, teicoplanin, high level gentamicin, high level streptomycin was determined by Kirby Bauer disk diffusion method. Preliminary screening to minimum inhibitory concentration of high level aminoglycosides was assessed by agar dilution method. Vancomycin resistance was detected by agar screening method and further confirmed with e-test and interpreted as per CLSI guidelines. Our results indicate, increased susceptibility to teicoplanin (98.57%) followed by fosfomycin (95.71%) and linezolid (68.57%). Of note, none of the isolates were resistant to vancomycin. Of the 70 E. faecalis isolates screened, 61.43% isolates exhibited HLGR phenotype and 37.14% exhibited HLSR phenotype. HLG R HLS R phenotype was observed among 32.9% of the isolates. MIC of gentamicin and streptomycin was found to be ≥512µg/mL (HLGR isolates) and ≥2000µg/mL (HLSR isolates) respectively. 91.3% of our HLAR isolates (93% HLGR, 92.3% HLSR) were susceptible to fosfomycin. Hence, it could be speculated that fosfomycin can be considered in the treatment of uncomplicated urinary tract infections caused by high level aminoglycoside/linezolid resistant/glycopeptide resistant E. faecalis.

Keywords: Enterococcus faecalis, fosfomycin, HLRG, HLSR.

Introduction

Urinary tract infections (UTI) are the most common infections in clinical practice. According to the annual estimates of 2018, over 150 million uncomplicated and complicated cases of urinary tract infections are reported worldwide[1]. The increasing incidence of multidrug-resistant (MDR) uropathogens is worrisome. UTIs are the most common of the enterococcal infections associated with significant morbidity[2]. Enterococci especially,
Enterococcus faecalis and Enterococcus faecium are the frequently encountered etiological agents of UTI[3,4]. The astounding ability of Enterococci to exhibit intrinsic resistance to myriad of antibiotics limits the therapeutic options and hence is a cause of concern[5,6].

Fosfomycin, a phosphonic acid derivative is known to possess a broad spectrum of activity against Gram positive and Gram negative bacteria and had been recommended by the FDA (Food and Drug Administration) for the treatment of uncomplicated urinary tract infections[6]. The current CLSI guidelines also recommends the testing and reporting of the susceptibility of E. faecalis urinary isolates to fosfomycin[7]. However, clinical data on the efficacy of fosfomycin in the treatment of UTI caused by multidrug resistant E. faecalis is inadequate. Hence, the present study was aimed to ascertain the in vitro efficacy of fosfomycin against urinary tract infections caused by multidrug resistant E. faecalis.

Materials and Method

A total of 70 isolates of urinary E. faecalis isolated were included in the study. In vitro antibiotic susceptibility testing was done by Kirby Bauer disk diffusion method and the results are interpreted as per CLSI guidelines[7]. Antibiotics tested includes high level aminoglycosides such as high level gentamicin (120µg), high level streptomycin (300µg), vancomycin (30µg), teicoplanin (30µg), linezolid (30µg) and fosfomycin (200µg) (each disc containing 50 µg of glucose-6-phosphate). Determination of minimum inhibitory concentration (MIC) of gentamicin and streptomycin against the urinary isolates of E. faecalis was determined by agar dilution method. Resistance to vancomycin was detected by agar screening method (6 µg/mL) and further confirmed by determination of MIC by e-test.

Results

Table 1 depicts the antibiotic resistance profile of the study isolates. Agar screening method revealed that, none of the isolates were resistant to vancomycin i.e. 100% susceptible to vancomycin. High rate of susceptibility was observed for teicoplanin (98.57%) followed by fosfomycin (95.71%) and linezolid (68.57%). Three isolates (4.29%) exhibited intermediate susceptibility to fosfomycin.

Of the 70 E. faecalis isolates screened, 61.43% isolates were resistant to high level gentamicin (HLG R phenotype) and 37.14% isolates were resistant to high level streptomycin (HLS R phenotype). Combined HLR pattern (HLG R HLS R phenotype) was observed among 23 (32.9%) isolates (Table 2). MIC of gentamicin and streptomycin was found to be ≥512µg/mL (HLGR isolates) and ≥2000µg/mL (HLSR isolates) respectively.

Discussion

Fosfomycin is reported to be a potent bactericidal drug as it interferes with cell wall synthesis by inhibiting UDP-N-acetylglucosamine enolpyruvyl transferase (MurA), an enzyme that catalyses the formation of N-acetyl muramic acid. This unique mode of action of fosfomycin (affecting the peptidoglycan synthesis) confers lesser cross resistance with other antibiotics and provides a broad spectrum of activity against the major genera of Gram positive (Staphylococcus spp., Enterococcus spp.) and Gram negative (Enterobacteria) bacterial pathogens including multidrug-resistant strains<sup>[8,9,10]</sup>.

Oral fosfomycin had previously been used in the treatment of uncomplicated UTI. Nevertheless, Fosfomycin is not being routinely used in clinical practice. Fosfomycin has an array of advantages viz., active against both Gram positive and Gram negative bacterial<sup>[6]</sup>, effective against <i>E. faecalis</i> and <i>E. faecium</i> irrespective of their resistance to vancomycin<sup>[11]</sup>, enhances the synergistic effect to other antibiotics such as β-lactams and aminoglycosides<sup>[12]</sup>, good distribution in tissues, does not undergo any metabolic changes when excreted in urine (an advantage for the outpatient)<sup>[13]</sup>, reduces bacterial adherence to the uroepithelial cells<sup>[11]</sup>. Owing to the above merits, fosfomycin has currently regained the attention of clinicians in the treatment uncomplicated urinary tract infections.

Previous reports have documented increased vancomycin resistance rates of 1–24% in our country<sup>[14,15,16,17,18]</sup>. In contrary, other reports, have documented complete absence of vancomycin resistant <i>E. faecalis</i><sup>[19,20,21]</sup>. In line with these studies, we report a complete absence of VRE isolates. This could plausibly be attributed to the restricted use of vancomycin in our setting.

Owing to their good pharmacokinetics, aminoglycosides are the frequently prescribed antibiotics in clinical practice. Treatment of serious enterococcal infections necessitates the synergistic combinations of a cell wall active agent, such as a β-lactam (ampicillin) or glycopeptide (vancomycin), plus an aminoglycoside (gentamicin)<sup>[22]</sup>. However, the emergence of HLR refutes the utility of the above said synergistic combination. In our study, High level aminoglycoside resistance observed among 65.7% of the isolates (HLG<sup>R</sup>HLS<sup>R</sup> (32.9%), HLG<sup>R</sup>HLS<sup>S</sup> (28.6%) and HLG<sup>S</sup>HLS<sup>R</sup> (4.2%)) negates this synergistic bactericidal effect. Our results are corroborate with the previous Indian reports that document an increased dissemination of aminoglycoside resistance genes in our setting<sup>[23,24,25,26]</sup>.

This study gains significance as it evaluated the in vitro efficacy of an older, broad spectrum antibiotic, fosfomycin that had been previously recommended for the management of uncomplicated urinary tract infections including those caused by multidrug resistant isolates. Fosfomycin susceptibility was observed among 95.71% (n=67) of the study isolates. This is in line with the reports of increased fosfomycin susceptibility from the studies documented by other authors<sup>[27,28,29]</sup>. It is noteworthy that in our study, 91.3% of our HLR isolates (93% HLG<sup>R</sup>, 92.3% HLS<sup>R</sup>), teicoplanin resistant isolate and all the linezolid resistant (100%) isolates were susceptible to fosfomycin. Based on the results of our study, it could be speculated that fosfomycin can be considered in the treatment uncomplicated urinary tract infections.
infections caused by high level aminoglycoside/linezolid resistant/glycopeptide resistant *E. faecalis*.

Abstract

Diabetes and aging are associated with reduced vascular endothelial function, 20 controls and 20 subjects with type 2 diabetes age <40 and age > 40 participated, a series of experiments were conducted to examine the interrelationship between age, Type 2 Diabetes Mellitus and endothelial renal function. This complication is first manifested as an increase in UAE [microalbuminuria] which progresses to over albuminuria and then to renal failure. In subjects with diabetes age < 40 were more prone to nephropathy which progress to End Stage Renal Disease [ESRD]

Keywords: Diabetes Mellitus, Aging, Type 2 Diabetes Mellitus, ESRP, Nephropathy.

Introduction

Diabetes Mellitus is a group of metabolic diseases characterized by high blood sugar [glucose] levels (WHO, 2006), which results from defects in insulin secretion or action or both. Type – 1 or insulin dependent diabetes mellitus (IDDM or juvenile – onset diabetes). Type – 2 or non – insulin dependent diabetes mellitus (NIDDM or adult onset diabetes). IDDM can occur at any age, but it usually starts in people younger than 30. NIDDM accounts for 90 % of all cases.

Acute complications of diabetes includes diabetic ketoacidosis, non ketotic hyper osmolar coma, hypoglycemia, and amputation chronic complications includes micro vascular disease like diabetic retinopathy, diabetic neuropathy, diabetic nephropathy and macro vascular diseases like atherosclerosis, diabetic myonecrosis etc. polyuria, polydipsia, polyphagia are clinical features of diabetes mellitus1,2

Diabetic Nephropathy: Diabetic nephropathy [nephropatia diabetic] also known as klimmelstiel – wilson syndrome and intercapillary glomerulonephritis is a progressive kidney disease caused by angiopathy of capillaries in the kidney glomeruli(Parving HH et al).

Diabetic nephropathy is the chief cause of morbidity and premature mortality in patients with both IDDM and NIDDM. This complication is first manifested as an increase in UAE [microalbuminuria] which progresses to over albuminuria and then to renal failure. At this stage the kidney may start allowing more albumins into normal urine and this can be detected by sensitive tests for albumin. This stage is called “microalbuminuria”.3,4

Albuminuria:

Normoalbuminuria: Normoalbuminuria was defined as a ratio of albumin (measured in micrograms) of less than 17 and for female patients as a ratio of less than 25.

Microalbuminuria: Microalbuminuria was defined as a ratio of albumin to creatinine in the intermediate range - 17 to 299 for male patients and 25 to 299 for female patients. elevated albuminuria is an early predicator of progressive renal function loss in type 1 and type 2 diabetes(Gambara et al. and Fioretto et al).
The scope of the study is to diagnose albuminuria at an early stage in diabetic patients before the condition become worse, which progresses to ESRD (Chalmers J, et al, 2008)\textsuperscript{4,5,6}

**Normal Kidney**

**Diabetic Nephropathy kidney**

**ESTIMATION OF GLUCOSE by Glucose oxidase method**

**Reagents**

1. Enzyme reagent
2. Glucose standard 100 mg/dl

**Procedure:** Add 1 ml of reagent to the test tubes labeled blank, standard and test, then 10 µl of glucose standard was added to the standard test tube, 10 µl of sample was added -only to test- Mix well all the tubes and measure the absorbance of standard and test against the reagent blank at 505 nm (490 - 530 nm). Glucose levels are expressed in mg/dl.

**Estimation of Glycosylated Haemoglobin**

**Kit Contents**

1) Profiled resin tube – 10 x 2 ml
2) Lysing reagent – 5 ml
3) Resin separators – 10 ml

Venous blood mixed with lysing reagent for the preparation of hemolysate. Elimination of the labile schiffs base is achieved during hemolysis. The hemolysate is then mixed with a weakly binding cation exchange resin. The non-glycosylated hemoglobin binds with resin leaving glycosylated hemoglobin free in the supernatant. The percentage is determined by measuring the absorbance of the glycosylated hemoglobin fraction and the total hemoglobin at 415 nm.

**Estimation of Urea by Urease Method:**

**Reagent:**

1. Working reagent 1 (W1) dissolve the enzyme reagent 1 in deionised water
2. Working reagent 2 (W2) hypochlorite and salicylate

**Procedure:** Add 1 ml of reagent to the test tubes labeled blank, standard and test, then 10 µl of standard urea was added to the standard test tube, 10 µl of serum sample was added -only to test- Mix well all the tubes and add 1ml of chromogen to the test tubes labeled blank, standard and test. Mix well and incubate at 37 °C for 5 minutes. Measure the absorbance of standard and the sample against the reagent blank between 580 - 630 nm within 60 minutes. Serum urea levels are expressed in mg/dl.

**Estimation of Creatinine by Jaffe’s Method:**

**Reagents:**

1. Alkaline buffer
2. Picric acid reagent
3. Acid reagent
4. Creatinine standard 2 mg/dl
5. Working reagent: Mix alkaline buffer (1) and picric acid reagents (2) in 1:1 ratio (Equal volumes)

**Procedure:** Add 2ml of working reagent in test tube labeled as a blank (B), Standard(S) and test (T). The test includes both urine and serum sample. Then 0.1 ml of standard creatinine was added to the standard test tube, 0.1 ml of dilute urine and 0.1 ml of serum is taken in the test. Then add 0.1 ml of acid reagent in each blank, standard and test tubes respectively. Mix well and incubate at 37°C for 5 minutes, and read absorbance on
spectrophotometer at 520nm. Serum creatinine levels are expressed in mg/dl. Urine creatinine levels are expressed in gms/day.

**Estimation of Albumin**

**Kit Contents:**
1. Reagent A: Borate buffer 0.1 mol/L, sodium azide 0.95g/L, pH 10.0
2. Reagent B: Suspension of latex particles coated with anti human albumin antibodies, sodium azide 0.95 g/L
3. Albumin standard: Human albumin
4. Working reagent: Mix 1ml of Reagent B, and 9ml of Reagent A

**Procedure:**
1. Bring the working reagent and standard solutions to room temperature.
2. Take two test tubes T1 and T2 and add 1.0ml of working reagent to both tubes.
3. Add 7.0 µl of standard in T1 and 7.0 µl of sample in T2.
4. Mix well, insert the cuvette in automated analyzer and start the stopwatch.
5. Record the absorbance at 540 nm before 10 seconds ($A_1$) and after 2 minutes ($A_2$)

Urinary Albumin concentration is expressed in mg/L

**Results**

Values are expressed as Mean ± Standard deviation (N=20) except for UAE.

**Expressed in mean**

Statistical analysis done by students –t- Test, Comparison was made between Group 1 and Group 2, *p<0.05 **p<0.01 ***p<0.001 NS=Non Significant.

**Discussion**

The results on various parameters are useful to diagnose diabetes mellitus and to assess the relation with early stage of nephropathy in the diabetic patient. Diabetic nephropathy has been in the diabetic patient, especially of type 2 is the most common cause of ESRD.

Table 1 shows the levels of glucose (FBS & PPBS), HbA1c, S.CR, S.UR, U.ALB, U.CR, UAE of the control and experimental group of patients.\(^7\)\(^8\)

There was significant difference (p<0.001) in the levels of glucose between 3 groups, which shows the test groups are diabetic. Also the level was more increased in-group III who belong to age > 40, than group II of age < 40.

These result shows that group III patients are more hyperglycemic than group II. Studies have shown that hyperglycemia and associated metabolic abnormalities were sufficient to induce diabetes related kidney disease.
HbA1c levels are higher in diabetic patients who develop micro and macroalbumin evidence both in type 1 and type 2 diabetes, that poor blood glucose control contributes to the development of albuminuria (WHO 2011). Intensive diabetes therapy reduces the risk of transition from normo to microalbuminuria by approximately 35% but does not abolish it$^9,10,11$.

Table1 also shows the level of urine albumin. The level is found to be significantly (p<0.01) increased in group II and the increase in highly significant (p<0.001) in group III when compared to Group I.

Table1 also shows the comparison of urine albumin between group II and III, and which shows a significant (p<0.01) increase. From this it is clear that Microalbuminuria is seen in diabetic patients irrespective of age, but it is very high in patients above 40 years. So this elevated level of urinary albumin clearly indicates the incidence of nephropathy.$^{13}$

The Albumin: creatinine ratio is important to assess the Microalbuminuria exactly. Also UAE(Urinary Albumin Excretion) is increased in group III when compared to Group II and Group I. This suggests that individual with higher levels of plasma glucose are at risk of Microalbuminuria. Microalbuminuria is most likely caused by the deleterious effects of hyperglycemia on cell function and extra cellular structures such as the basement membrane and mesangial matrix.$^{14,15}$

**Conclusion**

The various observation of this study leads to the conclusion that there is a strong evidence of microalbuminuria with diabetic nephropathy. Also these observations show that diabetic patients above 40 years are highly susceptible to diabetic nephropathy. Hence all diabetic especially more than 40 years have to undergo regular screening of renal function test in order to prevent the complication of nephropathy and the progression to ESRD (Chalmers J, et al, 2008).

Abstract

Eleusine coracana (seed) (finger millet bran) is rich in dietary fibre (free of gluten) and micronutrients and has been extensively studied for its anti-diabetic, anti-tumorogenic, anti-diarrheal, anti-ulcerative, anti-oxidant and anti-microbial potential. However, the immuno-modulatory potential and mast cell membrane stabilizing ability of E. coracana L (Ragi seeds) needs to be evaluated. Hence, this study was designed to evaluate the ability of ethanol extract of E. coracana L to potentiate immunomodulation and inhibit mast cell degranulation of human macrophages and mice peritoneal mast cells respectively. Ethanol extraction of E. coracana L (Ragi seeds) was performed by cold percolation method. Assessment of In vitro immunomodulatory activity was carried out using human PMN layer, Candida albicans and morphological criteria was adopted to calculate the phagocytic index. In vitro evaluation of inhibition of mast cell degranulation was determined using isolated mice peritoneal mast cells. In vitro evaluation of phagocytosis revealed that ethanol extract of E. corocana L (seed, ethanol extract) (25 mg/mL) was found to inhibit polysorbate 80 induced mast cell degranulation.

Keywords: Eleusine coracana, Macrophages, Ethanol.

Introduction

Eleusine coracana L. known as finger millet, ragi and manduais one of the ancient millet crop that belongs to the family Poaceae (grass). Finger millet has the advantage of being cultivable in diverse environments, semi-arid, arid, and rainfall limited hill agro-ecosystems[1]. Being a hardy crop it is drought resistant, pest and disease resistant with a short growing season and is being cultivated in several regions of India. The remarkable property of these grains that can resist storage pest for long years, makes it an indispensable crop for famine-prone areas[2]. The nutritional value of finger millet is remarkable that, it is a rich source of carbohydrate and prolamins including a high level of glutamic acid, proline, valine, isoleucine, leucine and phenylalanine and low levels of lysine, arginine and glycine. Also, finger millets are rich in essential amino acids (methionine and cystine), calcium (0.38%), dietary fibre (18%), phytates (0.48%), protein (6%–13%), minerals (2.5%–3.5%), tannins (0.61%), and phenolics (0.3%–3%)[1].

Milled finger millet is rich in dietary fibre (free of gluten) and micronutrients. Finger millet’s fat consist of oleic acid, linoleic acid, palmitic acid and traces of linolenic acid. Layers of Seed coat of the finger millets contain tannins and polyphenols, both free and bound forms[3,4]. Milled finger millet being a gluten free dietary fibre is regarded to be ideal for patients suffering from celiac disease[5]. Previous studies have documented the anti-diabetic, anti-tumorogenic, anti-diarrheal anti-ulcerative, anti-inflammatory, anti-oxidant and anti-microbial potential of finger millet[6,7,8,9,10]. However, the immunomodulatory and mast cell membrane stabilizing...
ability of *Eleusinecoracana*is yet to be explored. Hence, this study was designed to evaluate the ability of ethanol extract of *Eleusinecoracana* L. to potentiate immunomodulation and inhibit mast cell degranulation of human macrophages and mice peritoneal mast cells respectively.

**Materials and Method**

**Ethanol extraction of *E. coracana* L (Ragi seeds):**
Finger millet (*Eleusinecoracana* L.) was procured from the local market, washed well and was shade dried. Ethanol being a polar solvent could bring into solution all the metabolites present and hence was used for extraction. *E. coracana* L (seed) (10 g) was soaked in 50 ml of ethanol and was left a room temperature for 24 h. The extract was filtered through Whatman No. 1 filter paper. Solvent was evaporated to dryness under vacuum. Different concentrations (1000 µg/mL, 500 µg/mL, 250 µg/mL, 125 µg/mL and 62.5 µg/mL) of the dried extract was prepared in 10% dimethyl sulfoxide (DMSO).

**Assessment of in vitro immunomodulatory activity:** *Candida albicans* was confirmed using germ tube test and was inoculated in Saboraud’s Dextrose Broth. Overnight culture was centrifuged at 2000 rpm for 15 min. The cell pellet was washed four times with sterile Hank’s balanced salt solution (HBSS). The final cell button was suspended in sterile HBSS and human serum in a proportion of 4:1 and the cell density was adjusted to 1.5 ×10^8 cfu/ml using MacFarlands standard.

**Preparation of PMN layer:** Human capillary blood (0.2 ml) was collected by finger prick method and was spread to 1.5×1.5 cm on a clean grease free glass slide. The slide was incubated at 37°C for 25 min. The blood clot was gently removed using sterile normal saline, taking care to retain the adherent polymorphonuclear neutrophils (PMNs) intact on the glass slide.

**Determination of phagocyte index (PI):** Phagocyte index (PI) was calculated as per Brune et al., 1973. Briefly, the PMN layer on the slides was flooded with the ethanol extract (0.1 ml) of *E. coracana* (test) and the slides were incubated at 37°C for 15 min. After incubation the PMN layer was covered with *C. albicans* cell suspension (100 µl) and the slides were further incubated at 37°C for 60 min. The PMN layer was washed twice with sterile normal saline and fixed with methanol for 5 min. The PMN layer was stained with diluted (1:10) Giemsa for 25 min. The excess stain was removed using sterile HBSS and air dried. The slides were observed under the oil immersion (100 X) objective. Sterile normal saline was used as control.

Morphological criteria was adopted to determine the phagocyte index (PI) i.e. the mean number of *C. albicans* cells phagocytosed by PMNs on the slide for 100 granulocytes. Immuno-stimulation (%) was calculated by using the formula.,

\[ \text{Stimulation} \% = \frac{\text{PI (test)} - \text{PI (control)}}{\text{PI (control)}} \times 100 \]

**In vitro evaluation of inhibition of mast cell degranulation:**

**Isolation of mice peritoneal mast cells:** Ethanol extract of *E. coracana* L (Seed) (0.2 ml of 25 mg/ml) was injected intraperitoneally into Swiss albino mice (n=4) (25-28 g) for six days prior to the isolation of peritoneal mast cells. On the 7th day, 10 mL of Tyrode solution (containing 5 units of heparin/mL) was injected intraperitoneally in mice. After a gentle massage for about 30-45 s, the mast cell rich peritoneal fluid was collected over ice. The peritoneal fluid was centrifuged at 4°C at 2000 rpm for 5 min. and the cell pellet was washed twice with chilled Tyrode solution. The pellet was finally resuspended in 1 ml tyrode solution. These isolated peritoneal mast cells were used to study polysorbate 80 induced mast cell degranulation in vitro.

Mast cell membrane stabilizing ability of *E. coracana* L was assessed as per Kim *et al.*, (1997). Briefly, 0.1 ml of ethanol extract of *E. coracana* L (25 mg/ml) was added to 0.1 ml peritoneal mast cells suspension incubated at 37°C for 15 min. Then 0.1 ml of the degranulating agent (polysorbate 80) was added and further incubated for 10 min. The cells were stained with neutral red and % protection of degranulation of mast cells in control and treated groups were calculated by counting the mast cells under high power of light microscope.

**Results**

*In vitro* evaluation of phagocytosis revealed that ethanol extract of *E. corocana* was found to be cytotoxic at all the concentrations tested (1000 µg/mL to 62.5 µg/mL) and the macrophages were found to highly vacuolated compared to the control (Figure 1, 2). *In vitro* study showed that *E. corocana* (seed extract) (25 mg/mL) was found to inhibit polysorbate 80 induced mast cell degranulation when compared to the control. (Table 1) (Figure 3,4).

Figure 4: In vitro polysorbate 80 induced degranulation of isolated peritoneal mast cells – saline (control).

Discussion

E. corocana L has been used as staple food and is known to possess an array of health benefits such as, hepatoprotective, blood glucose lowering, cholesterol lowering, wound healing, anti-tumorogenic, anti-diarrheal, anti-inflammatory, anti-oxidant, anti-ulcerative and anti-microbial activity[10,14]. Also, previous studies have demonstrated that regular consumption of whole grain cereals and their products offer protection against the risk of cardiovascular diseases, type II diabetes, gastrointestinal cancers and a range of other disorders[15]. However, the immunomodulatory potential of finger millet needed investigation. Immunomodulatory agents of plant origin are documented to increase the host immune response against pathogens by stimulating the non-specific immune system. The results of our study on In vitro evaluation of phagocytosis revealed that ethanol extract of E. corocana instead of potentiating phagocytosis of C. albicans, E. corocana L (seed extract) was found to be cytotoxic to the human macrophages as evident by the excessive vacuolations compared to the control.

Despite the availability of various mast cell stabilizers including gold standard mast cell stabilizer, disodium cromoglycate, used in the preventative
treatment of allergic conditions like bronchial asthma, allergic conjunctivitis and vernal keratoconjunctivitis, there still remains an urgent need to design substances of natural origin that are cost-effective and require less frequent dosing schedules. Mast Cell stabilizers are known to inhibit the release of allergic mediators especially histamine from mast cells in order to prevent allergic reactions. Fine & Walsh, 2013 have elaborated an array of naturally occurring mast cell stabilizers that belong to the family of Flavonoids, coumarins, phenols, terpenoids and amino acids. In this context, we explored the mast cell membrane stabilizing potential of ethanolic extract of *E. corocana* (seed). In our study, ethanol extract of *E. corocana L* (seed extract) was found to stabilize mast cell membrane, thereby inhibit the release of inflammatory mediators. Inhibition of polysorbate 80 induced degranulation of isolated peritoneal mast cells (*in vitro*) signifies the anti-inflammatory potential of *E. corocana L* (seed extract).

Abstract

Today millions of people die due to cigarette smoking in the world. Smoking is the most common method of consuming tobacco. Tobacco smoking is the practice of burning tobacco & inhaling the smoke. Cigarette smoking is one major consequence to develop oxidative stress which will damage the lung lead to death. Cigarette contains nicotine an addictive stimulant that causes psychological and physical dependency. The aim of the study is to evaluate the oxidative stress by novel non-enzymatic antioxidant between young chronic smokers and non-smokers in the fasting state.

Keyword: Alpha tocopherol, PUFA, Vitamin C, betacarotene, ROS, Smokers and Non-Smokers.

Introduction

Smoking is the most common method of consuming tobacco. Tobacco smoking is the practice of burning tobacco & inhaling the smoke. Tobacco is a product processed from the fresh leaves of plants in the genus Nicotiana. The genus contain a number of species such as Nicotiana tabacum & Nicotiana rustica containing higher concentration of nicotine. These leaves are harvested & cured to allow for slow oxidation & degradation of carotenoids in tobacco leaf. Cigarette smoking is addictive & harmful (Okuyemi KS et al. 2007). A single cigarette contains 4000 toxic chemicals in which more than 60 chemicals are carcinogens. Cigarette contains nicotine an addictive stimulant that causes psychological and physical dependency.

Materials and Method

Fifty healthy male non-smokers in the age group of 20-35 years were placed in the group I. Fifty male smokers in the age group of 20-35 years were placed in the age group II. Blood samples were collected from smoking volunteers were smoke since past 15 years. Blood samples were collected from each of the subject for 90 days and analyzed for the following parameters: alpha tocopherol (Baker and Frank et al. 1980), vitamin C (Kyaw 1977), Beta carotene (Neeld and Pearson 1942)

Results

The non-enzymatic antioxidant Tocopherol (vitamin E) level was higher in non-smokers (2.1 ± 0.81 in blood) than smokers (0.91 ± 0.12 in blood). The Ascorbate (Vitamin C) level was higher in non-smokers (1.22 ± 0.20 in blood) than smokers (0.97 ± 0.19 in blood). The Beta Carotene showed a similar trend, where the levels are increased in non-smokers than smokers (3.90 ± 2.17 in group I blood and 2.52 ± 0.9 Group II blood). The significant decrement in the level of alpha tocopherol and Ascorbic acid by 56.47% was recorded in smokers compared to that of non-smokers.
Beta-carotene (p<0.01) changes were not statistically significant when compared with the corresponding value in the non-smokers and smokers.

Discussion

Natural antioxidants, vitamin E are preferentially oxidized before the oxidation of polyunsaturated fatty acid [Hayes JD, et al.(1999)] Free radicals are atoms or groups of atoms with an odd (unpaired) number of electrons and can be formed when oxygen interacts with certain molecules. Antioxidants such as SOD, CAT, VIT E, β – CAROTENE are molecules which can safely interact with free radicals and terminate the chain reaction before vital molecules are damaged.  

Vitamins also directly scavenge ROS & up regulate the activities of antioxidant enzymes. Among them, vitamin E is recognized as one of the most important antioxidants. Vitamin E is the term for a group of tocopherols and tocotrienols, of which α-tocopherol has the highest biological activity. Due to the potent antioxidant properties of tocopherols, the impact of α-tocopherol in the prevention of chronic diseases believed to be associated with oxidative stress has often been studied, and beneficial effects have been demonstrated [Tappel, A. L. (1962)]  

Vitamin E as a fat-soluble antioxidant, it stops the production of reactive oxygen species formed when fat undergoes oxidation. [Herrera; Barbas, C (2001), Rimbach G (2001) et.al] As it is fat-soluble, it is incorporated into cell membranes, which protects cells from preoxidation of PUFA in membrane phospholipid from oxidative damage [Topinka, Jet. al (1989)]. Vitamin E interacts directly with lipid peroxide in plasma Lipoproteins and cell membranes neutralizethem.  

Vitamin E is oxidized by the O2 generating system and reacts with OH in [Fridovich J et.al (1976)]. Vitamin E functions as a chain breaking agent in the lipid peroxidation process. It does not act as a direct antioxidant but as a provider of antioxidant activity due to its ability to donate a hydrogen atom to a free radical.
antioxidant. As an antioxidant, vitamin E acts as a peroxy radical scavenger, preventing the propagation of free radicals in tissues, by reacting with them to form atocopheryl radical, which will then be reduced by a hydrogen donor (such as Vitamin C) and thus return to its reduced state. [Stocker, R. (2000)].

The plasma \( \beta \)-carotene was not significantly altered in the smokers. There is the possibility that increasing free radicals in cigarette smoke may considerably decrease the bioavailability of vitamin C and \( \beta \)-carotene as antioxidant nutrients with increasing years of smoking. The reduced plasma vitamin C concentration in smokers in the present study suggests that these individuals may be at the risk of developing chronic obstructive Pulmonary disease. Plasma \( \beta \)-carotene is especially noted among the class of nutrients that is regarded as potential chemo preventive agents due to its antioxidant properties. [Epstein, (2003) Knekt et al. (1994)] had earlier reported that serum concentration of Vitamin C and \( \beta \)-carotene appears to play some important roles in the prevention of Pulmonary damage initiated by oxidants.

The cellular antioxidant defense enzymes SOD & CAT were significantly reduced in smokers, this might have let decreased antioxidant defense and increased oxidative stress. [Julius et al. (2014)]

The decrease levels of non-enzymatic antioxidant vitamin E, Vitamin C in the plasma might be due to the increased utilization to trap the free radicals that were generated during nicotine induced oxidative stress.

**Conclusion**

The study results show that smoking decrease level of vitamin E, vitamin C & alteration in \( \beta \)-carotene is due to increased level of free radicals indicate that the oxidative stress induced in human by smoking.

Abstract

Fixed orthodontic appliances made of metal alloys are routinely used in dental practise to correct malocclusion. Oral environment favours the biodegradation of metal alloys. The discharged metal ions accumulate cumulatively on the adjacent tissues and results in toxic effects on cellular metabolism and DNA stability. The study was designed to evaluate localized genetic and cytokinetic toxicity due to fixed orthodontic appliance by measuring micronuclei frequency and other nuclear abnormalities in the buccal mucosal cells. Subjects with orthodontic appliance were selected as exposure cohort (n=20) and subjects without orthodontic appliance were selected as comparative cohort (n=20). Buccal smears were collected and DNA specific feulgen stain was used. Micronuclei, nuclear bud and binucleate cells frequency were recorded and compared between the study groups. We found a significant increase in the frequency of cells with micronuclei (p<0.001) and binucleate cells(p=0.002) in the exposure cohort compared to controls. The increase in the indicators of genotoxicity and cytokinetic toxicity in the exposed cohort compared to controls could be attributed to the exposure to the metal ions released from long term orthodontic appliance treatment. Increase in binucleate cells in subjects with fixed orthodontic appliance was demonstrated for the first time in our study. The cellular changes due to toxicity could be the predisposing factor for the occurrence of immune mediated oral mucosal lesions in orthodontic patients.

Keywords: Micronuclei, nuclear bud, binucleate cells, metal ions, fixed orthodontic appliances.

Introduction

Fixed orthodontic appliances are routinely used in dental practise to correct malocclusion. Fixed orthodontic appliance consists of bands, brackets and wires made of metal alloys containing nickel, chromium, cobalt, iron and titanium. The treatment requires the patient to wear this appliance for a period of two to three years. The physical and chemical characteristics of oral environment are favourable for the biodegradation of metal alloys[1,2]. Hafiz et al have stated that even...
though many invitro studies on the amount of metal ions discharged from orthodontic appliance have found the levels below the recommended dietary levels.

The discharged ions like Ni were reported to be a strong immunologic sensitizer. These metal ions are non-biodegradable hence, their sustained release can result in cumulative accumulation on the adjacent tissues. This results in toxic effects on cellular metabolism and DNA stability [3,4,5]. The toxicity can be evaluated by well established assays like buccal micro nucleus cytochrome assay (BMCyt assay). This assay measures DNA damage through end points like micronuclei (Mn), nuclear bud (NuBd) and cytokinetic defects by binucleate cell formation (BiNu) from exfoliated buccal mucosal cells. Buccal mucosa is an easily assessable site for collecting cells in a non-invasive manner[6].

The previous studies on genotoxicity in patients with fixed orthodontic appliance using buccal mucosal micronuclei have used non DNA specific stains[7]. This can increase the false positive results affecting its validity.[8] To our knowledge, no studies have evaluated parameters of cellular toxicity like buccal mucosal NuBd and BiNu in patients with fixed orthodontic appliance.

Hence, we designed this case control study, where markers of DNA and cytokinetic damage like Mn, NuBd and BiNu frequency are evaluated using a DNA specific stain (fuelgen stain) from the buccal mucosal cells of a study cohort of subjects using fixed orthodontic appliance and compared with a non exposed cohort.

**Materials and Method**

**Subject Selection:** This case control study was designed to evaluate the toxicity in subjects undergoing fixed orthodontic treatment. Study and comparative cohort were randomly selected form subjects reporting to the department of orthodontics in a dental college.

Subjects wearing fixed orthodontic appliance for period of six months to three years were selected as exposed cohort. Subjects with no history of orthodontic treatment were selected as comparative cohort. Both exposed and comparative cohorts were selected within an age range of 16 to 25 years. Exposed and comparative cohorts were matched for age and sex. Subjects with metallic restorations, alcohol or tobacco related habits, history of any systemic illness or subjects taken oral radiographs since 3 months were excluded from the study.

Sample size was calculated for 80% power and 5% α error using mean difference and standard deviation referred from literature.[7] Sample size of n=20 each for study and comparative cohorts were calculated using nMaster ™ sample size calculation software. Institutional review board approval was obtained and informed consent was taken from the study subjects.

**Specimen collection and staining technique:** Buccal cells were collected by rubbing the buccal mucosa with hard bristled cyto brush. The cells are directly spread on a clean glass slide and fixed in methanol acetic acid (3:1) for 20 minutes[6,7]. The smears were stained by Fuelgen technique with slight modifications of the existing protocol[8]. Smear was denatured by exposing to IN HCl at 60°C for 8 minutes following which the smear was flooded with Schiff’s reagent for 20 minutes and counter stained with 1%Light green for 10 seconds. The slide was washed in deionised water and blotted gently to dry. Slide was mounted and observed[9].

**Scoring technique:** A minimum of 500 cells were counted under 400x magnification. The Mn, NuBd and BiNu recordings were standardized using the published photomicrographs[6]. The evaluators simultaneously recorded the frequencies of Mn, NuBd and BiNu using multiheaded microscope in order to reduce the inter observer variability.

**Scoring criteria[6]**

**Micro nuclei:**

1. The diameter of Mn should be 1/3rd or 1/6th of the size of the main nucleus.
2. Mn should be separated from the main nucleus with clear nuclear boundaries.
3. Mn should have similar staining like the main nucleus.
4. Mn should be on the same plane of focus as main nucleus.

**Nuclear Bud:** Nuclei with an apparent sharp constriction at one end.

**Binucleate Cell:** Cell with two main nuclei.

**Statistical Analysis:** The data was entered in SPSS software v.18. Mean with standard deviation was calculated. Comparison between the groups was be done by paired t test. p value less than 0.05 was considered as statistically significant.
Results

Demographics: The average age of subjects in exposed and comparative cohorts were 21.18±1.25. Exposed and comparative cohorts were comprised of 70% females and 30 % males.

Comparison of Nuclear abnormalities between exposed and controls: Nuclear abnormalities like Mn, NuBd and BiNu were observed and recorded in both exposed and non exposed cohorts. There was a statistically significant increase in the micronuclei (p<0.001) and binucleate cell (p=0.002) frequency in exposed cohort compared to nonexposed cohort. But there was no statistically significant difference in nuclear bud frequency between exposed and comparative cohort. (p=0.541). There was a statistically significant increase in the overall nuclear abnormality frequency in study cohort compared to comparative cohort. (p<0.001) (Table 1).

Discussion

Orthodontic appliance used in dentistry is made of alloys containing nickel, chromium, cobalt, iron and titanium\cite{10}. Various studies have found that oral environment provides ideal condition for the degradation of these alloys and release of metal ions. Saliva acting as an electrolyte, fluctuation in pH, temperature, enzymatic activity, and the foods introduced to the oral cavity all contributes to metal corrosion\cite{11}. The metals ions released from the orthodontic appliance are reported to be taken up by the tissues which are in direct contact with them. There will be a cumulative effect on these cells due to sustained metal release\cite{12}. Mekulewicz et al and Langes et al have reported that significant sustained release of Ni and Cr ions occur from orthodontic appliance in the oral environment. Ni ions are reported to act as an allergen and mutagenic agent. They were found to suppress the promoter sites of the genes by hypermethylation\cite{10,13}. Even though acute exposures may not produce biological effects, the sustained release of metal ions from long term orthodontic appliance use has been reported to result in its cumulative accumulation in adjacent tissues. This resulted in chronic toxic effects on cellular metabolism and DNA stability\cite{3,4,5}. Hafez et al has reported that a significant increase in the Ni and Cr content in the buccal mucosal cells would be formed by a six month period of orthodontic appliance use\cite{12}. So in order to understand the long term toxic effects of orthodontic appliance use we selected cases with a minimum of 6 months of orthodontic appliance treatment.

The genotoxicity of chronic metal ion exposures on adjacent cells were evaluated in many studies. They have used surrogate markers for genotoxicity like micronuclei or comet assay on the buccal mucosal cells\cite{1,2,7}. Westphalen GH et al found that micronuclei assay was more reliable in recording the genotoxic events due to fixed orthodontic appliance\cite{1}.

Micronuclei (Mn) assay is based on the frequency of chromosomal fragments or whole chromosomes which are not included in the main daughter nuclei during cell division. This arises due to DNA breakage leading to chromosomes or chromatin lagging during anaphase\cite{1}. The frequency of micronuclei is being established as reliable marker for genetic damage due to low doses of mutagen exposure\cite{13}. Other nuclear features which indicate genetic and cellular damages are nuclear buds and binucleate cells. Binucleate cells occur due to defects in the cytokinesis\cite{6}.

Age and sex of the subjects are reported to be confounding factors that can influence the Mn frequency\cite{6}. Ferreira et al has reported an increase in the frequency of Mn as age advances\cite{16}. In order to avoid this confounding effect, we selected age and sex matched controls.

In our study we found a significant increase in the Mn frequency in cases compared to controls (p<0.0001) (Fig 2, Table 1). This increase in Mn frequency was similar to previous studies done by Westphalen et al and Natarajan et al\cite{1,7}. But the mean Mn frequency was much lower in our study (3.5±0.89) compared to these previous studies (259±233)\cite{7}. These previous studies have used non DNA specific stains like Geimsa and PAP in order to evaluate Mn frequency. However,
it has been established that the use of non-DNA specific stains increase false positive results because non nuclear material like keratin bodies in degrading cells can resemble like micronuclei[8].

Nuclear bud (NuBd) is reported to be another indicator of genetic damage. They are nuclei with a sharp constriction at one end suggestive of a budding process. It is an indication of elimination of amplified nuclear material[6]. In our study we found Nu Bd formation in both cases and controls. Also, there was no significant difference in its frequency between cases and controls (Fig 3, Table 1).

In our study we recorded binucleate (Bi Nu) epithelial cells in both cases and controls (Fig 4). We found a statistically significant increase in the mean frequency of Bi Nu cells in cases compared to controls (p=0.002) (Fig 4, Table 1). Philips et al has reported that Bi Nu cells are indicative of failed cytokinesis following last nuclear division. This was found to be a checkpoint mechanism for aneuploid cells[6]. Bi Nu frequencies were found to be higher in patients with higher rates of aneuploidy[16]. To our knowledge this is the first time, Bi Nu cell frequencies were recorded in buccal mucosal cells of subjects using orthodontic appliance.

We also evaluated total nuclear abnormality (Mn+NuBd+Bi Nu) frequencies between cases and controls. We found a significant increase in nuclear abnormalities in cases compared to controls (p<0.0001) (Table 1, Graph 4). Mn,Nu Bd and Bi Nu are all established nuclear alterations indicative of genotoxicity[6]. Hence this increase in nuclear and cytotoxicity abnormality frequency in cases is an indication of toxicity on oral epithelial cells in patients using metal orthodontic appliance. Genelhu et al has reported that patients wearing orthodontic appliance, exhibited immunologically mediated mucosal reactions like labial desquamation, angular chelitis and erythema multiforme[17]. These immunologically mediated reactions are probably caused due to the cellular injuries caused by the exposure to environmental agents like metal ions. These cellular injuries expose hidden cellular materials (epitopes) to antigen presenting cells triggering immunologically mediated mucosal reactions[18].

Our study has demonstrated that subjects with fixed orthodontic appliance have increased incidence of localized genotoxicity as indicated by an increase in Mn frequency. Cellular markers of cytotoxicity like Bi Nu cell frequency was also found to be raised in our cases compared to controls. Bi Nu cells occur due the aneuploidy state of the affected cell. These cellular toxic events predispose orthodontic patients, for possible occurrence of immune mediated oral mucosal lesions. Other cellular markers of cytotoxicity like Bi Nu cell frequency was also found to be raised in cases compared to controls. Bi Nu cells occur due the aneuploidy state of the affected cell. These results will help in sensitizing the clinicians regarding the possible biological effects of long term fixed orthodontic therapy and the need for regular patient follow up/monitoring. Further research should be focused in developing better biocompatible dental materials.

Porphyromonas Gingivalis fimA Genotype in Chronic Periodontitis

Krishnan Mahalakshmi

Professor and Head, Dept of Microbiology/Research Lab for Oral-Systemic Health, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Velachery-Tambaram Road, Chennai, Tamil Nadu, India

Abstract

**Background:** Periodontitisis an inflammation of the periodontium with varied etiology leading to loss of periodontal supporting tissues of the teeth including the periodontal ligament and alveolar bone. Periodontitis progresses as a result of the direct effects of bacterial virulence factors on host tissues, as well as self-damaging host responses to the colonizing bacteria.

**Method:** PCR was performed on the sub gingival plaque samples positive for *P. gingivalis* from chronic periodontitis patients (n=103) and healthy subjects (n=22) Chi-square test was performed to calculate the statistical significance.

**Result:** *P. gingivalis* type II fimA genotype was positive in 50.5% and 13.60% among patients with chronic periodontitis and health respectively. Positivity for *P. gingivalis* type II fimA genotype. Statistical significance was observed for the prevalence of *P. gingivalis* type II fimA genotype (p=0.03) in chronic periodontitis group.

**Conclusion:** The significant presence of *P. gingivalis* type II fimA genotype in chronic periodontitis compared to health suggests their role in the etiology of chronic periodontitis.

**Keywords:** Periodontitis, Inflammation, Plaque.

Introduction

Periodontitis is an important global public health problem which involves mostly the adult population over 35-40 years of age. “Periodontitis” refers to an inflammation of the periodontium with multi-factorial etiology leading to loss of periodontal supporting tissues of the teeth including the periodontal ligament and alveolar bone. The disease is initiated due to colonization by a group of gram-negative anaerobes in the form of a subgingival biofilm. Periodontitis progresses as a result of the direct effects of bacterial virulence factors on host tissues, as well as self-damaging host responses to the colonizing bacteria. This disease results from complex interactions between the host and a predominantly anaerobic microflora. In periodontal diseases, the junctional epithelium at the base of the gingival crevice migrates down the root of the tooth to form a periodontal pocket. This is partly as a result of direct action by the microorganisms themselves. The main types of periodontal disease are gingival disease, chronic periodontitis, necrotizing form of periodontal disease and aggressive periodontitis. Chronic periodontitis (ChP) is defined as an infectious disease inducing an inflammatory reaction and subsequent loss of supporting tissue and alveolar bone of the teeth if no periodontal treatment is provided. It results in periodontal pocket formation and/or gingival recession. It is estimated that more than 500 bacterial species can be identified within...
the plaque biofilm of the gingival pocket. Possibly, 10 – 30 species may play a more critical role in the pathogenesis of periodontal disease. The red complex, which comprises Porphyromonas gingivalis, Treponema denticola, and Tannerella forsythia are known as the putative periodontal pathogens in chronic periodontitis. $P. gingivalis$ is a gram-negative, anaerobic, non-motile, asaccharolytic and black pigmented rod that forms greenish-black colonies on blood agar plates is documented as putative periodontal pathogen. Chronic periodontitis patients predominantly harbor $P. gingivalis$ type II fimA in various geographic regions. Hence, the study was opted to verify in South Indian population.

**Method**

Subgingival plaque samples positive for $P. gingivalis$ from chronic periodontitis patients (n=103) and healthy subjects (n=22) were used for the study. To detect type II fimA gene of $P. gingivalis$, polymerase chain reaction was performed in a volume of 50 μl containing 5 μl of the template, 5 μl of 10X PCR buffer and 1 U Taq polymerase, 0.25 mM of each dNTP, 2.5 mM MgCl$_2$, and 0.8µM primer. The primers for amplification of type II fimA gene of $P. gingivalis$ was: forward 5’-ACAACTATACTTATGACAATGG-3’, reverse 5’-AACCCCGCTCCCTGTATTCCGA-3’.[12] Chi-square test was performed to calculate the statistical significance.

**Results**

$P. gingivalis$ type II fimA genotype was positive in 50.5% of $P. gingivalis$ positive subgingival plaque samples of patients with chronic periodontitis. While, healthy samples showed 13.60% positivity for $P. gingivalis$ type II fimA genotype. Statistical significance was observed for the prevalence of $P. gingivalis$ type II fimA genotype (p=0.03) in chronic periodontitis group.

**Discussion:**

$P. gingivalis$ fimbriae are adhesive filamentous appendages that have been demonstrated to be essential for virulence in rodent models of periodontitis. Insertional inactivation of the fimA gene, with concomitant loss of fimbrial production, results in a phenotype significantly less able to cause periodontal bone loss in the gnotobiotic rat model.[13] Many studies suggest a strong association between the expression of fimbriae and periodontal tissue destruction in humans. Fimbriae have been classified into six genotypes: type I- V and type Ib based on the nucleotide sequence of the fimA gene. These fimbriae are thought to play an important role in adhesion and invasion of bacteria into the host cells (Amano, 2003). Several epidemiological investigations have reported the distribution of fimA genotypes in subjects of different race and with different periodontal conditions. A majority of Japanese periodontitis patients were found to carry fimA genotype II.[12,14,16] Moderately high prevalence of type II fimA genotype was observed among Chronic Periodontitis patients (50.5%) compared to Guo et al., 2005.[17] The prevalence of $P. gingivalis$ type II fimA + genotype was consistent with other reports.[12,14,18]

**Conclusion**

The results obtained in the present study demonstrate that $P. gingivalis$ strains that possess the type II fimA gene are most predominantly present in the oral flora of the chronic periodontitis patients and that the type II fimA organisms might be involved in the etiology of chronic periodontitis.

Bacterial Etiology of Neonatal Sepsis: A Mini Review

Krishnan Mahalakshmi1, V. Ankayarkkanni2

1Professor and Head, Dept of Microbiology/Research Lab for Oral-Systemic Health, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Velachery-Tambaram Road, Chennai, Tamil Nadu, India, 2Lecturer, Dept of Physiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Bacterial Etiology of Neonatal Sepsis-A Mini Review

Abstract

Neonatal sepsis can be generally classified as early onset or late onset. Early-onset sepsis is observed during first week after birth. Late onset sepsis is seen between seven days of life to three months of age. Early-onset neonatal sepsis is linked with acquiring of microorganisms from the mother. Infection can occur through bloodstream, vertical transmission from infected mother or by infection during parturition. The bacterial etiology in neonatal sepsis is on increase currently following the raise in antibiotic resistance among the bacterial community. This brief review highlights the bacterial species implicated in neonatal sepsis.

Keywords: Microorganisms, Infection, Sepsis.

Introduction

Septicemia is a life-threatening complication that is caused when bacteria from a different habitat enter the blood stream and spread all over the body. Septicemia affects two extremes of age, those with prolonged illness and those who have undergone surgery recently. The cause of sepsis in hospitals consists of severe community-acquired and nosocomial pneumonias, pyelonephritis, intravenous line infections, viral hepatitis, septic pulmonary emboli, antibiotic-associated diarrhea/colicitis, infected decubitus ulcers, and intra-abdominal or pelvic infection due to perforation, trauma, or surgery.

Discussion

Sepsis is one of the major causes of death among new-born children globally, mostly in developing and undeveloped countries[1]. Approximately three million new-born deaths occur every year, and 36% of these are due to neonatal septicaemia[2]. Neonatal septicemia can be classified as early onset (EOS) if septicemia manifests within three days of life or late onset (LOS) if it manifests after three days of life[3] New-born children obtain bacteria present on the skin surface, blood or vagina of the mother before birth or during delivery. This is commonly observed in EOS. Hospital acquired and environmental microbes adds further risk following delivery. This is seen in LOS.[4, 5] This short review discusses the bacterial species frequently encountered in neonatal septicaemia in varied geographical area.

In hospital southwest Iran, coagulase negative Staphylococcus, followed by Staphylococcus aureus and Escherichia coli was most commonly encountered[6]. In Northwest Ethiopia S. aureus followed by coagulase negative Staphylococcus and Klebsiella pneumoniae was reported[7]. S. aureus and Streptococcus pneumoniae were most prevalent in Africa, while Klebsiella was highly prevalent in South-East Asia. A notably higher prevalence of Group B Streptococcus was present in neonates aged 7 days or less in South-East Asia[8]. In a study in Nepal, coagulase-negative Staphylococcus followed by S. aureus, Acinetobacter species and K. pneumoniae[9]. In Haiti, the percentage of bacterial species cultured in descending order is Streptococcus
agalactiae, K. pneumoniae, Pseudomonas aeroginusa, Enterobacter aerogenes, S. aureus and Proteus mirabilis.

[S] aureus (52%), 30.7% of which were methicillin-resistant S. aureus (MRSA), K. pneumoniae (12%), E. aerogenes (8%), Enterococcus spp. (8%), E. coli (4%), and other Gram-negatives (12%) were the bacterial species isolated from neonatal sepsis in Nigeria. E. coli and Klebsiella were the most common bacterial species causing neonatal septicemia in a tertiary care hospital in Bangladesh. Suitable prenatal care and health education should be promoted in the obstetrics and gynecology settings to prevent neonatal sepsis.

Conclusion

Neonatal septicemia can be classified as early onset (EOS) if septicemia manifests within three days of life or late onset (LOS) if it manifests after three days of life. This short review discusses the bacterial species frequently encountered in neonatal septicemia in varied geographical area.

Antibiotic Resistance-as a Threat to the Future and its Role in Dentistry

Shruthi Parthasarathy1, Sarumathi Thirugnanamurthy2 Amudhan A.3, Hemalatha V.T.3, Manigandan T.2

1Post Graduate, 2Professor, 3Associate Professor, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital BIHER, Chennai

Abstract

The prescription of antibiotics is reaching its peak day by day in all specialities. This is causing antibiotic resistance in many bacteria along with evolution of newer multiple drug resistant strains of bacteria. If this situation continues then we would tend to ‘lose battle against the bugs’. Dentistry is a speciality commonly prescribing antibiotics all over the world. Lack of proper knowledge and lethargic attitude of many dentists contribute largely to the increasing antibiotic resistance among patients.

Keywords: Antibiotics, Bacterial resistance, dentistry.

Introduction

In the 18th and early 19th century, the primary cause of death was infectious diseases. Later, after the discovery of the first antimicrobial drug - Penicillin by Alexander Fleming, in 1928, and with further discovery of other potential antimicrobials, death rate drastically declined. But recently, the concept of microbial resistance has been rising and exploding among the population. In this alarming rate, we would be facing history again with increase in mortality rate due to antimicrobial resistance.

Nowadays antibiotics are being judiciously prescribed therapeutically as well as prophylactically by all medical and dental practitioners.

Antibiotic Resistance: Bacteria are said to be resistant to an antibiotic if the maximum dose taken tolerable by the host, does not affect the organism.

Bacteria develop antibiotic resistance in two forms—Genotypically or phenotypically.

Genotypic resistance is when a bacteria genetically carries certain elements responsible for resistance. While, phenotypic resistance is when a bacteria can outgrow and survive in the presence of antibiotic drug concentrations, either clinically or in laboratory.

Antibiotic resistance is further classified into natural or acquired.

Natural resistance occurs when bacterium does not possess certain structures which are target molecules for some antibiotics. Eg: cell wall is absent in bacterium like Mycoplasma and hence exhibit a natural resistance to Betalactam antibiotics.

Acquired resistance can be developed through two mechanisms. 1) through mutation of bacterial genome responsible for resistance 2) through horizontal gene transfer which is the most common type, where a part of genetic material (responsible for resistance in this case) from one organism gets transferred to another

Factors Leading to Antibiotic Resistance:

Empirical Antibiotic Therapy: Usually antibiotics should be prescribed only after identifying the causative microorganism and establishing its susceptibility to it. But in exceptional cases, when the patient is critical and a delay in therapy would cause serious complications, empirical therapy is indicated. But in most of the health care centers empirical therapy with broad spectrum
antibiotics are started for all patients admitted with an infectious etiology, even before the culture results are out. 

- **Multidrug therapy/Combination therapy:** Unnecessary use of multiple drugs or combination antibiotics also contributes to development of resistance and newer strains of bacteria. Practitioners being over precautious about the therapy being inadequate or fear of facing medical or legal issues are the major causes for multidrug therapy in many cases.

- **Lack of knowledge among doctors regarding updated guidelines for antimicrobial prophylaxis and therapy**
- **Patients missing doses or not following the prescribed regimen**
- **Inappropriate prescription of antibiotics, due to pressure from patients**

**Resistance Mechanisms:** There are various mechanisms by which bacteria exhibits their resistance to antibiotics.

1. **Chemical alterations of the antibiotic:** Production of enzymes by the bacteria which chemically alter the structure of the antibiotic. Eg: Aminoglycoside modifying enzymes (AMEs) produced by certain species which which covalently modifies the amino group of the antibiotic

2. **Destruction of the antibiotic molecule:** A classic example is production of Beta lactamase enzymes by the bacteria which destroys the beta lactam ring of the antibiotics rendering it inactive. To overcome this newer beta lactam antibiotics which are

3. **Decrease in permeability of the antibiotic molecule:** Antibiotics enter the bacteria through the outer and the cytoplasmic membrane. Bacteria develops certain mechanisms to reduce the penetration of the antibiotic and prevent them from reaching into the cell. Eg: Beta lactams, tetracyclines, fluoroquinolones

4. **Efflux Pumps:** Bacterial cell possess certain pumps which are capable of pumping the antibiotic out of the cytoplasm. Eg: E. coli pumps out concentrated tetracyclines out of them.

5. **Target protection:** The bacterial chromosomes mediate certain determinants which protects the antibiotic target site in the bacterial cell, thereby preventing the action of antibiotics.

6. **Modification of target site:** Target site in the bacterial cell wall is modified by genetic mutation, enzymatic alterations of the binding site or by replacement of the target

7. **Resistance due to global cell adaptation:** Through years of evolutional development, bacteria have faced lots of environmental stress and pressures. In order to cope up with this, bacteria have developed certain sophisticated mechanisms to survive in this hostile environment

**Common Antibiotics Used in Dentistry and their Resistance Mechanisms:** Oral cavity consists of a diverse ecosystem comprising of many bacterial species including Streptococci, Staphylococci, Neisseria, Enterococcus, Lactobacillus, Hemophilus, Actinomycetes, etc. Most of the oral infections are known to be associated with Gram positive aerobic cocci, Alpha hemolytic streptococci, Peptostreptococci and Gram negative anaerobes.

Chlorhexidine and triclosan known to be potent prophylactic agents in dentistry and often prescribed to the patients for long term use are also known to exhibit resistance. Hence unnecessary use of long term antibacterial prophylactic agents should be minimized. Rather, patients should be encouraged to use mechanical prophylactic agents and professional cleaning should be insisted.

**Role of Dentists in Reducing Antimicrobial Resistance:** Dental practitioners prescribe antibiotics either prophylactically or therapeutically. Dentists can optimally control the prescription of antibiotics to avoid resistance by following certain principles.

- By strictly following infection and sterilization protocols to prevent the growth and multiplication of resistant strains
- By educating the patients regarding antibiotic abuse and its harmful effect, and importance of following the prescribed regimen
- By updating knowledge about the recently established guidelines for antibiotic prophylaxis and therapy.

According to the American heart association, antibiotic prophylaxis before a dental procedure is only indicated for the following heart conditions.
I. Prosthetic cardiac valves, including trans catheter-implanted prostheses and homo grafts.

II. Prosthetic material used for cardiac valve repair, such as annuloplasty rings and chords.

III. Previous Infective Endocarditis.

IV. Unrepaired or repaired cyanotic congenital heart disease, with residual shunts or valvular regurgitation at the site of or adjacent to the site of a prosthetic patch or prosthetic device.

V. Cardiac transplant with valve regurgitation due to a structurally abnormal valve.

Any other heart conditions other than these are considered as low risk category for infective endocarditis and does not require antibiotic prophylaxis before the dental treatment.

The AHA also offers a wallet card for patients containing the indications for antibiotic prophylaxis and the recommended dosage.

The American Academy of Orthopaedic Surgeons and the American Dental Association has updated their guidelines in 2007 mentioning that antibiotic prophylaxis is not necessary for patients with prosthetic joints.

### Conclusion

The responsibility of preventing bacterial resistance against antibiotics, lies greatly on the shoulder of medical and dental health care professionals. Hence, Practitioners must keep themselves updated about the recent protocols and guidelines on antibiotic prescriptions and strictly adhere to it. Patient education on avoiding OTC drugs without a prescription should also be insisted. Following these guidelines would help us to prevent a large medical catastrophe from happening and ensure the safe use of antibiotics.

Abstract

Obesity is a common and often neglected health problem with high economic and health consequences. Obesity, which is now considered as a disease can be easily prevented which otherwise can impact the lives of people of all age groups. Obesity is associated with increased risk of illness, disability, and death. Last decade has witnessed a striking increase in obesity prevalence. It is an easily preventable and treatable health problem which is increasing at an alarming rate in the society now and currently an important health issue. Early intervention of this often-neglected problem will lead to healthy adults and decreased economic burden in health care industry.

Keywords: Obesity, BMI, Diet, Weight loss.

Introduction

Obesity is defined as an abnormal accumulation of body fat, that is 20% higher than what is considered as a healthy weight for a given height. The medical branch specializing in the control and treatment of obesity and allied diseases is known as Bariatrics. Obesity is the most pervading, chronic illness requiring newer approach for medical management and prevention. (Wright, S.M. & Aronne, L.J 2012). As a leading cause of mortality, morbidity, disability, healthcare utilization and healthcare costs, the high prevalence of obesity has strained the healthcare system.

A diagnostic tool for screening for obesity is Body Mass Index. Body Mass Index (BMI) “is a person’s weight in kilograms divided by the square of height in meters”. A person is called obese if the Body Mass Index is more than or equal to 30.

Classification of overweight and obesity in adults according to BMI. (Ruth S.M Chan and Jean Woo, 2010)

Rationale: Obesity is a common often neglected health problem with high economic and health consequences. Obesity, which is now considered a disease entity is easily preventable health condition which can impact the lives of people of all age groups. Its a health condition by controlling which, a plethora of many other illness associated with it can be prevented. It is an easily preventable and treatable health problem which is increasing at an alarming rate in the society now and currently an important health issue.

Epidemiology of Obesity: Obesity is associated with increased risk of illness, disability, and death. Last decade has witnessed a striking increase in obesity prevalence. This increase is prevalent across males and females, all age groups, and every race. Since 1980 there is a double fold increase in obesity prevalence worldwide. There is an increase in mortality rate because of obesity in many countries today. In recent times childhood obesity is becoming increasing prevalent. (Muhamad Hanafiah Juni, 2015)

According to a research published in Lancet, after the United States and China, India ranks third in the list of top ten countries with the largest number of overweight people. In India, there is an upsurge in the prevalence of obesity among middle-income people. This increase is attributed to the higher percentage of refined sugar, trans fat and other artificial agents in the processed food which has been consumed largely. (Neetu Chandra Sharma 2014)
Prevalence of overweight in the four regions of India (Pradeepa R et al 2015)

Causes of Obesity: The weight of a person depends on the balance between the calorie consumed and the energy spent. Overweight is the result of more calorie intake than that is metabolised, as the body stores the extra energy as fat. The person will lose weight if the calorie consumed is less than that metabolised by the body. The two main reasons for overweight are overeating and physical inactivity. Other factors that influence body weight are genetics, environment, metabolism, culture and behaviour.

Genetics: There is a higher risk of the person becoming obese if either or both of the parents are overweight. Genes play an important role in obesity as it affects hormones responsible for fat regulation. Genetic leptin deficiency is one of the causes of obesity. Fat cells and placenta produce leptin and it signals the brain to stop eating if the fat stores are high in the body.

Overeating: Overeating of fatty foods with high energy density lead to weight gain. Food high in simple carbohydrates escalates the blood glucose levels, which stimulates insulin release from the pancreas, and fat tissue growth and leads to overweight. Compared to complex, simple carbohydrates are absorbed rapidly thus, in turn, releasing more insulin, which contributes to obesity.

Physical inactivity: Active people burn more calories than persons who are sedentary. According to The National Health and Nutrition Examination Survey (NHANES), physical inactivity is a high-risk factor for obesity.

Medications: Diabetic medications, antidepressants, anti-epileptic medicines, steroids and certain hormones used in contraception leads to weight gain. Obesity is also associated with some antihypertensives and antihistamines. The mechanism of weight gain differs for each medication.

Psychological factors: One of the contributing risk factor for weight gain is psychological factors such as stress, lack of interest in life and temperament. Binge
eating is an important reason for seeking treatment in thirty percent of obese people.

**Systemic illness:** Many systemic diseases like thyroid problems, polycystic ovary syndrome, Cushing’s syndrome and insulin resistance, causes obesity. (Jerry R. Balentine 2015).

**Other factors associated with obesity:**

**Ethnicity:** The age and rapidity at which obesity starts are influenced by ethnicity. Compared to Asians and Caucasians the Hispanic and African-American women become overweight at a younger age. White non-Hispanic men are less obese compared to Hispanic and Non-Hispanic black men.

**Childhood weight:** Adult obesity is influenced by the weight of the individual during their childhood and adolescent years. Teenage obesity is a predictor of adult obesity.

**Hormones:** Women gain weight during menopause or pregnancy or while using oral contraceptives. (Africa Federation - Health Bulletin 2015)

**Consequences of Obesity:** Obesity leads to numerous negative consequences. Overweight leads to numerous health conditions compromising the lifespan because of heart disease, diabetes mellitus, certain cancers, and osteoarthritis. Expenditure in managing obesity and its related conditions have increased exponentially over the years. (Cawley J, Meyerhoefer C, 2012).

**Economic effects:** There is an increased economic burden on the healthcare industry because of obesity and its related illness. Obesity and its related conditions are economically associated with direct or indirect costs. Preventive, investigative, and management services of obesity are related to direct costs. The mortality and morbidity associated with it come under the indirect costs. (Colditz GA, 1992)

**Health Effects:** Obesity leads to numerous health consequences. Some of the health effects of obesity includes:

**High blood pressure:** Excess fat accumulated in the body requires nutrients and oxygen this, in turn, requires blood circulation in the fat tissue. The heart’s workload is increased as it needs to pump more blood through the extra blood vessels and puts extra pressure on the walls of the artery leading to high blood pressure.

**Diabetes:** Lifestyle associated type 2 diabetes is caused mainly because of obesity. The prevalence of type 2 diabetes is increasing in children in recent years. Moderate obesity also increases diabetic risk dramatically.

**Heart disease:** Obese individuals are ten times at a higher risk of developing atherosclerosis than thin persons. Fat deposited in the heart vessels leads to the development of coronary artery disease. Reduction in the blood flow because of narrowing of the heart vessels leads to heart attack.

**Joint problems:** Overweight leads to increased stress placed on the hips and knee joints causing joint problems.

**Sleep apnea and respiratory problems:** Overweight leads to heavy snoring and sleep apnea causing sleep disturbance because of difficulty in breathing. Hypertension is also a consequence of sleep apnea. The squeezing of chest wall because of overweight leads to restricted breathing and respiratory problems.

**Cancer:** Obese women are at a higher risk of uterine, breast, colon, and gallbladder cancer. Prevalence of prostate and colon cancer is higher in overweight men. (Michael T. Murray Joseph Pizzorno, 2012)

**Management of obesity:** Management of obesity includes weight reduction, maintaining the weight loss, as well as, treating and controlling the risk factors associated with it. Appropriate treatment can be chosen based on the BMI, waist circumference and the associated risk factors. Obesity is managed by three approaches, which includes non-pharmacological method like diet modification, exercise and behavioural therapy, pharmacological and surgical method. (Srinivas Nammi et al 2004)

**Non - pharmacological management:**

**A. Dietary therapy:** Primary treatment line is calorie restrictions through low calorie food which will provide 100 - 1500 kcal per day, which can result in eight percent weight loss over a period of six months. (Srinivas Nammi et al 2004)

**B. Physical activity:** Regularly exercising benefits everyone. There is reduction in the fat storage because of the increase in the expenditure of energy
during physical activity. Research has proved that regular exercise improves the cardiac health and also has positive psychological benefits. Exercising regularly for thirty minutes a day is a part of a comprehensive health care and for losing the over weight. (Wyatt HR et al 2002)

C. **Behaviour therapy:** Behavioural intervention compliments the weight loss therapy along with the other management modalities. In behaviour therapy self control on eating habits and awareness on balanced health diet is taught. It also help in the maintenance therapy after the weight loss is achieved. (Srinivas Nammi et al 2004)

**Pharmacotherapy:** In persons with the body mass index above 27 kg/m² along with the presence of other systemic risk factors or body mass index of above 30 kg/m², pharmacotherapy or drug therapy is given. This therapy is given along with diet and behavioural counselling. (National Institutes of Health 1998)

**Surgery:** When the BMI is above 40 kg/m² or its above 30 kg/m² with the associated risk factors bariatric surgery is indicated. There are serious nutritional and gastric complications associate with surgery. Its only the last treatment option when the other method of weight loss have failed. (Srinivas Nammi et al 2004)

### Weight Loss Interventions Based on Risk and BMI (kg/m²)

(Clinical Practice Guideline for Screening and Management of Overweight and Obesity 2014):

**Prevention of Obesity:** Infants: Breastfed babies for long duration are twenty to forty percent at lower risk of becoming obese.

**Children and Adolescents:** Encouraging children to have a healthy life style with balanced eating habits combined with physical activity prevents obesity.

**Preventing Obesity in Adults:** Being healthy with ideal body weight can be achieved by eating a healthy balanced diet and exercising regularly. Obesity prevention is vital because fat cells once formed can only be reduced in size and it will remain forever in the body. Prevention is better than cure. (Stanford health care)
Conclusion

Obesity is a significant health threat posing a challenge to the health care industry. It impacts the society in various ways. Obesity management and prevention will lead to a healthier society.

Banned Fixed Drug Combinations of NSAIDS: An Update for Dentists in India

Bhargavi R.1, Hemalatha V.T.2, Amudhan A.3, Sarumathi T.4, Manigandan T.5

1Post Graduate, 2Associate Professor, 3Professor, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

Abstract
Being the most common medical professionals in prescribing of Non-steroidal anti-inflammatory medications, Dentist in India are to be essentially aware of banned medications, that due to various reasons, still haven’t been withdrawn from market. Many fixed drug combinations are easily available without any scientific justification behind them. This article aims in creating an awareness among the dentist regarding banned fixed drug combinations of NSAIDS in India since September 2018.

Keywords: Banned drugs, NSAIDs, Fixed Drug Combinations.

Introduction
The field of medicine has gained enormous success with vast use of drugs. These drugs are essentially chemical ingredients that are administered to a living organism to alter its metabolic functioning. This alteration of metabolism has enabled the use of drugs as medications in obtaining favourable health conditions during an illness.1

The widely accepted form of medications as a single dosage unit has proven its therapeutic efficacy and drug safety in humans. The concept of drugs in various combinations have been tried globally with proven advantages.

Rationale for combination of drugs are based on:
• Favourable synergistic effect without any added toxicity.
• Difference in mechanism of action of drugs in combination.

• Similarity in their pharmacokinetic and pharmacodynamic properties.

Some rational drug combinations include – Trimethoprim with sulfamethoxazole and Anti-Parkinson’s drug such as levodopa and carbidopa.2

Fixed Drug Combinations: A Fixed Drug Combination or FDCs is fusion of two or more drugs or their active ingredients in a single dosage form. Though the idea of combination of drugs is seemingly brilliant, it does come with its own share of demerits.

Demerits of FDCs:
• Pharmacokinetic/Pharmacodynamic mismatch
• Increased chance of Adverse Drug Reactions (ADRs)
• Increased chance of drug interactions.
• Undesirable super added effects.

Indian drug market scenario: Indian drug market provides huge space for irrational drug combinations that have been manufactured with intention of marketing purposes only. These combinations have no scientifically proven justification and can cause significant health hazard to humans. The Drug regulatory bodies in India are governed by both State and Central Government organisations.4
**CDSCO:** In India, the Central Drugs Standard Control Organization (‘CDSCO’) is the main regulatory body currently regulating import, sale and manufacture of medical devices which have been notified as drugs by virtue of Section 3(b) (IV) of the D & C Act, 1940. Within the CDSCO, the Drug Controller General of India (DCGI) is responsible for the regulation of pharmaceuticals and medical devices. The DCGI is advised by the Drug Technical Advisory Board (DTAB).\(^4\)

### Conclusion

A good medical practice is highly influenced by good prescription of medications. This will lead to increased overall health maintenance of people of the nation. It is important for dental professionals to have up-to-date knowledge regarding the regulatory affairs of the country – atleast concerning with NSAIDs and Antibiotics. Dentist are among the highest medical professionals to prescribe Nonsteroidal anti-inflammatory drugs and Antibiotics to the population, in general. Good knowledge of these banned drugs shall enable the reduction of their demands in market, thus reducing their sale, even when not withdrawn by the pharma companies.

Management of Anaphylaxis in Dental Clinics: A Review

Angelinteena S.¹, Nalini Aswath², Hemalatha V.T.³, AMUDHAN A.⁴, Sarumathi T.⁴

¹Post Graduate, ²Professor & Head, ³Associate Professor, ⁴Professor, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

Abstract

Anaphylaxis is a severe, life-threatening, generalized or systemic hypersensitivity condition with increased mortality and requires immediate management. Dentist will face this kind of risky entity most commonly while administering local anesthesia. This review is just to update and to impart knowledge regarding management of anaphylaxis to the dentists to avoid fatality.

Keywords: Anaphylaxis, dentistry, adrenaline, lignocaine.

Introduction

Anaphylaxis is a type I hypersensitivity reaction. It is a serious, life-threatening allergic reaction. If a pre-sensitized host comes in contact with the allergen the mast cells release chemical mediators initiates the anaphylactic reaction. The reaction can take place within seconds or minutes of exposure to an particular allergen in sensitized individual. The mediators released by the mast cells are histamine, serotonin, arachidonic acid derivatives, NO, cytokines, chemokines, reactive oxygen species etc. these mediators causes bronchoconstriction, vasodilation, increased vascular permeability. Severe anaphylaxis leads to shock, coma and death. Blood pressure drops suddenly and airways narrow, blocks the breathing. In dentistry as such condition develops mostly while administering local anesthesia (lignocaine). All dental practitioners should be aware of the diagnosis and management of emergencies such as anaphylaxis that may arise from the use of local anesthetic agents in their clinical set up.

Signs and Symptoms of Anaphylaxis:

- SKIN REACTIONS, such as rashes, hives, pruritis, and flushed or pale skin
- Angioedema, Anasarca
- RESPIRATORY—coughing, hay fever, constriction of airways and a swollen tongue or throat, which can cause wheezing and trouble breathing.
- CARDIOVASCULAR—weak and rapid pulse, dizziness, loss of consciousness
- GASTROINTESTINAL—Nausea, vomiting, diarrhea
- NEUROLOGICAL—anxiety, feeling of doom

Risk Factors:

Persons with preexisting:

- Cardiovascular disease.
- Substance abusers.
- Asthma and other respiratory diseases.
- Initial exposure to the allergen by injection (intravenous [IV] medication).
- Frequent exposure to the allergen, particularly if exposure is followed by a long delay and then a re-exposure.

Anaphylactic Shock: Anaphylactic shock is extremely serious life threatening condition. It can block the airways and prevent breathing. It can also stop the function of heart. Because of the decrease in blood pressure that prevents the heart from receiving enough oxygen. It also leads to potential complications such as brain damage, kidney failure, and other organ damage, cardiogenic shock, a condition that causes your heart to not pump enough blood to body, arrhythmias, heart attacks, and death.

DOI Number: 10.37506/v10/i12/2019/ijphrd/192259
Emergency (Acute) Management:

Assessing the Patient:

Airway: The initial steps in anaphylaxis management involve a rapid assessment of the patient’s airway. Give high-flow oxygen using a mask with an oxygen reservoir.

Breathing: Look for bronchospasm and signs of respiratory distress. If marked stridor or respiratory arrest is present, start intubation immediately.

Circulation: Patient might look pale and clammy, increased pulse rate (tachycardia), low blood pressure. Make the patient lie down with raised legs. If the patients made to sit up or stand up there may be chance of worsening of condition.

Disability: Airway, Breathing and Circulation problems can all these alter the patient’s neurological status because of decreased brain perfusion. There may be confusion, delirium, agitation, dizziness, and loss of consciousness.

Patients Positioning: All patients should be placed in a comfortable and safe position. The following factors should be considered:

- If the patient is conscious and with Airway and Breathing problems may prefer to sit up as this will make breathing easier.
- Lying flat with or without leg elevation is helpful for patients with a low blood pressure because this position increases the circulatory flow. If the patient feels faint, do not sit or stand them up - this can cause cardiac arrest.
- Patients who are breathing and unconscious should be placed on their side (recovery position), keeping them lying flat make the tongue fall back and block the airway.
- Pregnant patients should lie on their left side to prevent caval compression.

Cardiorespiratory Arrest Following An Anaphylactic Reaction: Start cardiopulmonary resuscitation (CPR) immediately and continuing until the help arrive. Rescuers should ensure that help is on its way as early with advanced life support systems. The 2010 AHA Guidelines for CPR and ECC recommend a change in the BLS sequence of steps from A-B-C (Airway, Breathing, Chest compressions) to C-A-B (Chest compressions, Airway, Breathing) for adults, children, and infants (excluding the newly born; see Neonatal Resuscitation section).

Pharmcotheraphy:

Adrenaline (Epinephrine): Adrenaline is one of the emergency drug used for the management of an anaphylactic reaction. Adrenaline causes peripheral vasoconstriction which improves the circulation. It also inhibits the IgE mediated chemical mediators to control the inflammatory response. Adrenaline increases the force of contraction, vasoconstriction, heart rate and bronchodilation. The intramuscular (IM) route is the first and easier route for administering adrenaline to the victim. The best site for IM injection of adrenaline is the anterolateral aspect of the middle third of the thigh. The needle used for drug administering should have sufficiently long enough to ensure that the adrenaline is injected into muscle[5].

Adrenaline IM Dose – Adults

- 0.5 mg IM (= 500 micrograms = 0.5 mL of 1:1000) adrenaline

Adrenaline IM Dose – Children

- > 12 years 500 micrograms IM (0.5 mL) i.e. same as adult dose
- 300 micrograms (0.3 mL) if child is small or prepubertal
- > 6 – 12 years 300 micrograms IM (0.3 mL)
- > 6 months-6 years 150 micrograms IM (0.15 mL)
- < 6 months: 150 micrograms IM (0.15 mL)

Adrenaline IV Route: Administration of IV adrenaline only applies to those experienced in the use and titration of vasoressors in their normal clinical practice (e.g., anesthetists, emergency physicians, intensive care doctors). Patients who are given IV adrenaline must be monitored continuously with ECG and pulse oximetry and frequent non-invasive blood pressure measurements.

Ensure patient is monitored

- Adrenaline IV bolus dose – adult: Titrate IV adrenaline using 50 microgram boluses according to response.
- If repeated adrenaline doses are needed, start an IV adrenaline infusion.
The pre-filled 10 mL syringe of 1:10,000 adrenaline contains 100 micrograms/mL.

A dose of 50 micrograms is 0.5 mL, which is the smallest dose that can be given accurately.

Do not give the undiluted 1:1000 adrenaline concentration IV.

**Antihistamines:** Antihistamines are a second line of drugs used in the treatment for an anaphylactic reaction. Antihistamines (H1-antihistamine) may help counter histamine-mediated vasodilation and bronchoconstriction. But they are insufficient alone to treat anaphylaxis.

**The dose of chlorpheneramine depends on age:**
- >12 years and adults: 10 mg IM or IV slowly
- >6 – 12 years: 5 mg IM or IV slowly
- >6 months – 6 years: 2.5 mg IM or IV slowly
- <6 months: 250 micrograms/kg IM or IV slowly[^4]

*[^4]* Diphenhydramine: 50 mg or 1 mg/kg IV slowly repeated if necessary.

Ranitidine: 50 mg IV 8 hourly.

**Oxygen:** Initially, give the highest concentration of oxygen possible using a mask with an oxygen reservoir. Ensure high flow oxygen (usually greater than 10 liters per min) to prevent collapse of the respiratory system during inspiration.

**Steroids:** Corticosteroids may help to prevent or shorten protracted reactions. Inject hydrocortisone slowly intravenously or intramuscularly, taking care to avoid inducing further hypotension.

**The dose of hydrocortisone for adults and children depends on age:**
- >12 years and adults: 200 mg IM or IV slowly
- >6 – 12 years: 100 mg IM or IV slowly
- >6 months – 6 years: 50 mg IM or IV slowly
- <6 months: 25 mg IM or IV slowly

**Fluid Replacement:** Large volumes of fluid may leak from the patient’s circulation during an anaphylactic reaction. There will also be vasodilation, a low blood pressure and signs of shock. Give a rapid IV fluid administration (20 mL/kg in a child or 500-1000 mL in an adult) and monitor the response continue further doses as necessary.

**Investigations:** The specific test to help confirm a diagnosis of an anaphylactic reaction is the measurement of mast cell tryptase. Tryptase is the major protein component of mast cell secretory granules. In anaphylaxis, mast cell degranulation leads to markedly increased blood tryptase concentrations[^7].

**Follow Up:** The patient may need to stay in the hospital for 24 h to make sure no new symptoms occur. For a severe reaction, the doctor may monitor heart function or admit the patient to the intensive care unit. Ideally, all patients should be assessed by an allergy specialist and have a treatment plan based on their individual risk. An auto-injector is not usually necessary for patients who have suffered drug induced anaphylaxis.

**Dental Clinic Should Contain These Things in the Emergency Trolley:** Adrenaline 1:1000 (consider adrenaline autoinjector availability, particularly in rural locations, for initial administration).

- 1 mL syringes; 21-gauge needles
- Oxygen
- Airway equipment, including nebuliser and suction
- Defibrillator
- Manual blood pressure cuff
- IV access equipment (including large bore cannulae)
- At least 3 litres of normal saline

**Conclusion**

To manage as such emergency situation dentist should have the knowledge about the management of anaphylactic reaction to prevent this life-threatening condition.

**Ethical Clearance:** Not required since it is a review article.

Efficacy of Locally Delivered 1% Metformin (MF) in Treating Periodontal Intrabony Defects: A Systematic Review

Keerthana S.A.¹, Ramya V.², Bagavad Gita³

¹Post Graduate Student, ²Reader, ³Professor and Head, Department of Periodontics, Sree Balaji Dental College and Hospital

Abstract

Periodontitis is characterized by destruction of supporting structures of tooth and may also lead to loss of teeth if untreated. The aim of this review is to systematically evaluate the efficacy of 1% MF in the treatment of periodontitis. An electronic search was carried out using the keywords ‘metformin’, ‘periodontal’ and ‘periodontitis’ via the PubMed/Medline, ISI Web of Science and Google Scholar databases for relevant articles published from 1949 to February 2019.

Keywords: Metformin, Intrabony Defects, Periodontitis, Diabetes Mellitus

Introduction

Periodontitis, a multifactorial disease affects 40–90% of the global population [1]. In the study done by Eke et al., 2012 estimated that 46% of the adult population in united states of America is affected by periodontitis[2]. Periodontitis is characterized by the progressive destruction of all the supporting structures of teeth and subsequently, loss of teeth[3][4].

Lack of oral hygiene leads in the formation of dental plaque[5][6] a biofilm containing multiple microbiomes that have been implicated in periodontitis[3][7]. The gold standard approach to periodontal therapy is mechanical debridement which reduces the inflammatory process. Although mechanical therapy is the most frequent other treatments such as flap surgery, bone grafts and barrier membranes are also done after phase 1 therapy to improve the overall health[8][9]. Recently, a number of agents such as melatonin, platelet rich fibrin and metformin are also been proven to cure periodontitis[10][11][12].

Metformin is an antidiabetic agent used to treat type 2 diabetes. It is a second-generation biguanide which is orally administered anti-hyperglycemic drug[13]. There are two mechanisms of action that have been suggested for the osteogenic effect of MF: increased proliferation of osteoblasts and reduction of osteoclast activity. Studies indicate that after MF is taken up by osteoblasts, their proliferation is increased[14][15] and another study it was observed that exposure to MF led to a decrease of osteoclast and bone formation. MF down-regulates the production of receptor activator of nuclear factor kappa B ligand (RANKL) and up-regulates the production of osteoprotegerin (OPG) from osteoblasts[16]. This study is aimed to perform a systematic review based on the effect of metformin in periodontal therapy to treat chronic periodontitis.

Method

Focused Question: According to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines [17], a focused question was constructed based on the Participants, Interventions, Control, Outcomes (PICO) principle [18].

The focused question was: ‘Is 1% metformin (MF) effective in reducing intrabony defect and increasing bone fill in chronic periodontitis?’

Criteria for the selection of studies: The inclusion criteria: (1) original studies published in the English...
language, (2) clinical studies, (3) animal studies and (4) Intervention: topical or systemic MF to treat periodontitis.

**Exclusion criteria:** (1) historic reviews, (2) letters to the editor, (3) case series and reports and (4) clinical trials.

**Search Methodology:** An electronic search was carried out using the keywords ‘Metformin’, ‘periodontal’ and ‘periodontitis’ via the PubMed/Medline, ISI Web of Science and Google Scholar databases for relevant articles published from 1949 up to February 2019. The titles and abstracts of the articles found were read independently by two authors (k and R). The references in the potentially relevant articles were read by both the authors to find additional studies which the authors checked agreement via discussion.

**CAL,** Clinical Attachment Level; **IBD,** Intrabony Defect; **MF,** Metformin Gel; **OFD,** Open Flap Debridement; **PD,** Probing Depth; **SRP,** Scaling and Root Planing. **DDR,** Defect Depth Reduction; **GI,** Gingival Index; **PI,** Bleeding Index; **AV,** Alovera Gel, **RSV,** Rosuvastatin, Plasma Rich In Growth Factor – **PRGF,** modified sulcus bleeding index (mSBI)

**Results**

**Search Results:** Following the removal of the duplicate search results, the primary search resulted in 20 articles in total. Two articles were excluded based on title and abstract. Hence, remaining eight articles were read completely for eligibility. After exclusion of another two irrelevant studies, six studies (Xinyi Zhou 2019., Aline De Sousa 2018., Deepak kumarkhajuria 2017., Shabnam 2019., Ida G Kurian 2017., Dileep P 2017) were included in this review.

Three studies were animal studies (Xinyi Zhou 2019., Aline De Sousa 2018., Deepak kumarkhajuria 2017.,) and remaining three studies were human trials (Shabnam 2019., Ida G Kurian 2017., Dileep P 2017).

**Animal Studies:** All three animal studies were in vivo prospective studies. The number of animals used as test subjects ranged from 8 to 20 (Xinyi Zhou 2019., Aline De Sousa 2018., Deepak kumarkhajuria 2017.,) In first study, periodontitis was induced by Oral Intrapерitoneal STZ Injection (Xinyi Zhou 2019.,) test group received oral metformin (200 mg/kg/day) from 8 weeks of age for 10 weeks, control groups received a mean volume of sterile water based on that of the test group. In second study chronic periodontitis was induced by means of ligatures (Aline De Sousa 2018.,) In Experimental groups 1 twenty animals with diabetes and with periodontal disease and Metformin 50 mg/kg/day, twenty animals with diabetes and periodontal disease and Metformin 100 mg/kg/day. In third study periodontitis was induced by Pгр-LPS injections in combinations with ligatures (Deepak kumarkhajuria 2017.,) test groups (periodontitis + CMIDF-A (1.99 ± 0.09 mg metformin; total mass-4.01 ± 0.05 mg), (periodontitis + CMIDF-B (2.07 ± 0.06 mg metformin; total mass-7.56 ± 0.09 mg), and (periodontitis + chitosan film (7.61 ± 0.08 mg), control groups were healthy and untreated periodontitis. The follow-up period ranged from 11 days to 16 weeks in all the three groups.

**Human Studies:** All human studies were randomized control trials (RCTs) trials (Shabnam 2019., Ida G Kurian 2017., Dileep P 2017). Number of patients included the studies ranged from 8 to 90 in which the number of female subjects ranged from 5 to 46, the number of male subjects ranged from 3 to 46. (Shabnam 2019., Ida G Kurian 2017., Dileep P 2017). The age of the patients ranged from 35 to 45 years. In all studies, MF gel was used in combination with other treatment modalities and the Concentration of MF was only 1% in all the three studies (Shabnam 2019., Ida G Kurian 2017., Dileep P 2017) In first study (Shabnam 2019) test Group 1 received flap debridement with 1% MF, Group 2 received oral flap debridement with PRGF gel and the control group received oral flap debridement only. In second study (Ida G Kurian 2017) test Group 1 received SRP + Alovera gel, Group 2 received SRP + 1% MF and the control group received SRP + PLACEBO. In third study (Dileep P 2017) test Group 1 received SRP + 1.2% RSV gel, test Group 2 received SRP + 1% MF gel and the control group received SRP + PLACEBO. The follow-up period ranged from 3 to 12 months in all the three groups.

**Assessment of Parameters:** In animal studies (Xinyi Zhou 2019., Aline De Sousa 2018., Deepak kumarkhajuria 2017.,) In first study (Xinyi Zhou 2019.,) Micro CT, Western Blot, Immune Fluorescence analysis
were assessed. In **second study** (Aline De Sousa 2018.), Micro CT, Tomography, Histological Immune Histochemical Analysis were assessed. In **third study** (Deepak Kumarkhajuria 2017.), Micro CT, Tomography, Histological Analysis were assessed.

**Outcome of Studies:** In animal studies (Xinyi Zhou 2019., Aline De Sousa 2018., Deepak Kumarkhajuria 2017.)

In this study done by (Xinyi Zhou 2019.) concluded that metformin treatment can robustly ameliorate periodontal infection and tissue destruction and reduce blood glucose and serum IL-1β levels in mice with diabetic periodontitis.

In human studies (Shabnam 2019., Ida G Kurian 2017., Dileep P 2017). In this study (Shabnam 2019) showed All the groups exhibited improvements in all the clinical parameters after 6 months. Inter-group comparison of GI, CAL and PPD parameters revealed no statistically significant differences. Radiographic changes in the group of 1% metformin with PRGF revealed statistically significant differences compared with other groups; however, there were no statistically significant differences in other groups.

**Discussion**

In animal studies (Xinyi Zhou 2019., Aline De Sousa 2018., Deepak Kumarkhajuria 2017.)

In this study (Xinyi Zhou 2019.) A range of techniques were carried out in this study: microCT, western blotting and immunofluorescence were used to analyze periodontal tissues. We found that metformin treatment can robustly ameliorate periodontal infection and tissue destruction and reduce blood glucose and serum IL-1β levels in mice with diabetic periodontitis. Moreover, gingival tissue exhibited less macrophage infiltration and decreased expression of Nek7, NLRP3, caspase-1 and mammalian target of rapamycin (mTOR), which were simultaneously observed in RAW 264.7 cell models stimulated with metformin. CMIDF might play a role in limitation of periodontitis and alveolar bone loss Therefore, it can be speculated that themetformin and chitosan are compatible and can be formulated into films. Micro-CT results by demonstrating that treatment with CMIDF increased the alveolar bone formation and suppressed periodontitis induced alveolar bone destruction. Metformin invigorates bone growth and bone mineralization by initiation of osteogenesis via osteoblasts aside from restraining osteoclastic resorption.

In human studies (Shabnam 2019., Ida G Kurian 2017., Dileep P 2017). This study (Shabnam 2019) was conducted on patients with moderate chronic periodontitis with two walled intra-bony periodontal defects. The study groups consisted of open flap debridement/metformin/PRGF/metformin + PRGF. Results showed that use of MF with PRGF was effective in improving the level of the clinical parameters, though both RSV and MF possess anti-inflammatory and osteoplastic properties only RSV has an inhibiting action on osteoclastogenesis.

**Conclusion**

Metformin is an effective medicament in improving the outcomes of surgical and non-surgical periodontal therapy. Nevertheless, in 100% of the RCTs, local intra-bony administration of MF resulted in better clinical and radiographic parameters. However, owing to the lack of histological and bacterial studies and short follow-up periods of reported studies, there is risk of bias in the RCTs and long-term efficacy of metformin in the treatment of intrabony defects is not yet ascertained. Further research is required to investigate long-term efficacy of metformin for chronic periodontitis management.

Abstract

Pharmacovigilance is useful to reassure the safety of drugs and protecting the consumers from their injuries effects. A number of single drugs as well as fixed dose combinations have been banned from manufacturing, marketing and distribution in India. An important issue about the availability of banned drugs over the counter in India is that sufficient adverse drug reactions data about these drugs have not been reported. The most common categories of drugs withdrawn in the last decade were non steroidal anti inflammatory drugs (28%), antidiabetics (14.28%), antiobesity (14.28%), antihistamines (14.28%), gastroprokinetic drugs (7.14%), breast cancer and infertility drugs (7.14%), irritable bowel syndrome and constipation drugs (7.14%) and antibiotics (7.14%). Drug withdrawals from market were made mainly due to safety issues involving cardiovascular events (57.14%), liver damage (14.28%), and carcinogenic reasons. Majority of drugs have been banned since 3-5 years in other countries but are still available for sale in India. The present study says about how to manage adverse drug reactions and to prevent it in advance and provides implications for developing a system that can ensure the safety and efficacy of drugs in India. There should be a multidisciplinary approach towards drug safety that should be implemented throughout the entire duration spanning from drug discovery to usage by consumers.

Keywords: Pharmacovigilance, Adverse drug reaction, drug safety, multidisciplinary approach.

Introduction

Almost all healthcare students enter clinical practice immediately after graduation and are required to prescribe, distribute, administer, and/or monitor drugs on a day to day basis1-2. The need to perform these duties effectively and to ensure the safe use of drugs, healthcare students (especially in medicine, pharmacy, dentistry, and nursing) should know about minimum set of pharmacovigilance before they graduate and start clinical practice3. For seeing, recollecting, managing, and reporting adverse drug reactions (ADRs) are an important part of safe prescribing and are integrated into steps of the WHO- Guide to Good Prescribing. Our healthcare curricula often teach little on pharmacovigilance and ADR reporting. Many studies have expressed concern about the lack of healthcare professional competencies in pharmacovigilance. This lack of education and training in pharmacovigilance is related with the low level of knowledge, skills, and actions seen not only in physicians but also in practicing pharmacists, dentists, and nurses2. In spite of the emergency of this problem, every year millions of drug users experience ADRs ranging from minor discomfort to hospitalization, permanent disfunction, or even loss of life. ADRs are the reason for 3.0–6.5% of all hospital admissions, 0.15% of all deaths, and could have been prevented in 47– 72% of cases by excellent pharmacological and pharmacovigilance skills and knowledge. Pharmacovigilance centers have a main role in spreading knowledge of present pharmacovigilance. The data available are mostly dependent on reports after marketing, which is important for recognising previously unidentified, uncommon, or very serious ADRs.
What is pharmacovigilance?: Pharmacovigilance is defined as “the pharmacological science relating to the recognition, assessment, understanding and prevention of adverse effects, particularly long term and short term adverse effects of medicines.” Pharmacodynamic effects are the characteristic drug effects that are important to know for treating diseases. Pharmacodynamic effects are recorded in animal studies then in Phase I and Phase II studies in human beings and finally in Phase III clinical trials. Provided the dosage is enough, they occur in all individuals. During the development of drug, the pharmacodynamic effect that is of greatest clinical application is found. Phase III trials are structured to measure the selected pharmacodynamic outcome (in the examples above, efficacy against gout or analgesia). These results are used by regulatory agencies to define the clinical indications of the medication. Side effects branch from recorded pharmacological properties of the medication that is present in addition to the selected pharmacodynamic effect. Side effects may be beneficial or harmful.

Pharmacovigilance in India: According to the 2011 census, India is the second highest populated country in the world with over 1.21 billion people. The pharmaceutical industries present in India is valued at 18,000 million dollars and its growth is estimated at the rate of 12-14% per year. Pharmaceutical exports are also raising at 25% compounded annual growth rate (CAGR) every annum. On a global scale, India is being viewed as an emerging country of clinical trials, medicine discovery, research and development. Immediately reporting by healthcare professionals is the most important step for preventing or reducing ADRs. The ADR reporting rate in India is below 1% in comparison to the worldwide rate which is 5%. One of the reason for lower rate in India might be attributed to the awareness about pharmacovigilance and ADR monitoring among the Indian healthcare professionals.

National pharmacovigilance program of India: The national pharmacovigilance program (NPP) was established by the Ministry of Health and Family Welfare in New Delhi in the year 2010 as a reason to gather ADR reports throughout India. The NPP comprises of a national coordinating center that gets ADR information from individual pharmacovigilance centers about the cause, source and the personnel involved in an adverse drug event via a vigiflow software interface operated by Uppsala Monitoring Center.

Causes of failure of implementation of pharmacovigilance in India: Many newer medications is being introduced in our country, so there is a need to improve the pharmacovigilance system in order to prevent the Indian population from potential harm that may be caused by some of the new medicines. Moreover, there are numerous issues and problems that have prevented building a robust pharmacovigilance system, which are described below:

1. Pharmacovigilance systems are not well-funded and properly systematized for a highly populated country like India to provide service to patients and the public.
2. The data collected to date in the zonal centers from various peripheral centers is mostly poor and not well-analyzed. Research on ADRs is inadequate in India, so the exact incidence of specific ADRs is not known.
3. Healthcare professionals involvement and knowledge and motivation for pharmacovigilance is negligible. We need a little encouragement from the department of health to provide more training and to create more awareness for better reporting.
4. There are several consumers groups in our country who encourage patients to report any adverse reactions encountered by them, but there is no information for patients to report to ADRs directly.

Adverse Drug Reactions: Adverse drug reactions (ADRs) are harmful effects of medications that lead to large-scale morbidity and mortality in developed countries. However, there is inadequate research on ADR presence in developing countries like India. A few studies have examined the outcomes of ADRs mainly by seeing the hospital readmissions. Serious ADRs are reported in 6.7% patients on an average in our country. Involvement of healthcare and the number can be as high as 8% in rural South India. In South India ADRs are reason for 0.7-3.4% hospital admissions, 3.7% hospital readmissions and 1.3% mortality.

Adverse drug reactions (ADRs) may cause serious health problems which can lead to drug-related hospitalizations. To increase knowledge and awareness about ADRs among healthcare professionals, more education in the field of ADRs and pharmacovigilance (PV) is needed.

ADRs fall into four categories: Category A
(“Augmented”) effects which reflect augmentation of the pharmacodynamic properties of the drug (e.g. sedation with a muscle-relaxing benzodiazepine)\(^2\)

Category B (“Bizarre”) effects which are unrelated to known pharmacodynamic properties (e.g. unwanted allergic reactions), \(^2\)

Category C (“Continuous”) effects which occur in the long term (e.g. pharmacological dependency or rebound effect)\(^2\)

Category D (“Delayed”) effects which occur after discontinuation of medication (e.g. cancer, birth defects, or impaired reproductive capability). Pharmacovigilance is the study of ADRs.\(^2\)

A serious adverse event (SAE) is any unexpected medical manifestation, that at any dose: \(^3-4\)

• Which results in death
• Which threatens the life of an individual (well-defined as an event in which the subject was at risk of death at the time of the event)
  • Which requires in-patient hospitalization or causes prolonged hospitalization
• Which results in persistent or significant disability/incapacity
• Which causes a congenital anomaly/birth defect
• Which results in an important medical event (defined as a medical event(s) that may not be immediately lifethreatening or result in death or hospitalization but, based upon suitable medical & scientific judgment, may require intervention to prevent one of the serious outcomes as listed above).

Understanding the Importance of PV: We must also need knowledge about the extent of drug-induced harm at a population level, which can be visualized using drug-related hospital admissions and with historical examples of drug-induced disasters such as limb deformities following maternal use of thalidomide. These examples gave rise to the present-day regulatory framework and the way in which the safety monitoring of drugs is organized. \(^2\)

Food–drug interactions may influence drug absorption or drug metabolism; for example, grapefruit juice inhibits drugs metabolized by cytochrome P450 (CYP)-3A4\(^4\). Information about these risk factors is generally available in drug labelling, treatment guidelines and medical literature, which healthcare workers must learn to use and interpret. \(^2\)

Recognizing ADRs: It is important that healthcare workers know how to recognize symptoms of ADRs in patients. Identifying ADRs can be difficult, because sometimes they are hard to distinguish from underlying diseases or comorbidity. This comes the need for knowledge of clinical pharmacological principles of ADRs, such as types of ADRs, dose-relatedness, pharmacological actions, hypersensitivity reactions, time relationship and risk factors. Training in clinical reasoning with a focus on causality reasoning is important to differentiate a suspected ADR from other medical conditions or background incidence. \(^2-3\)

Observations of ADRs and framing individual treatment plans for managing ADRs will strongly contribute to the development of awareness of the impact of ADRs in patients and on the importance of PV at a population level.\(^2-3-4\)

Managing ADRs: Patients who experience an ADR need special and individual care. Furthermore, ADRs may negatively influence a patient’s compliance with therapy. Actions for treatment include drug discontinuation, dose adjustment or additional treatment of the symptoms. Sometimes, alternative treatment for the initial disease should be chosen. After experiencing a severe ADR, patients might fear for any drug treatment in general. Healthcare workers need the skills and knowledge to classify an ADR and the capability to respond when they come across serious or severe ADRs, which can be difficult. \(^2-3-4\)

Communication skills are also needed to better explain safety data to colleagues and patients and encourage and understand feedback from those involved in PV.\(^2\)

Healthcare workers should furthermore develop the ability to explain ADRs to patients and their families, advising about which drug to use and which drug not to use to avoid the chances of the ADR recurring. \(^2-3-4\)

At last, relevant elements of the ADR must to be recorded properly into the patient’s healthcare record. \(^2\)
Reporting ADRs: Beyond the awareness of ADRs in individual patients, PV also focuses on the improvement of public health regarding the safe use of drugs. Healthcare workers need to understand that information on ADRs before marketing phase. Healthcare professionals have an important duty to share their clinical experience in the real world with regulatory authorities. Spontaneous reporting systems continue to be an effective method of signal detection. ADR reports from Healthcare professionals and patients often trigger the detection of potential new medicines safety signals. They improve general information about ADRs. Reporting an ADR to PV centers or other relevant organizations is a skill that can be developed easily during clinical internships.2

Summary of the key aspects and content of the World Health Organization pharmacovigilance

Future aspects of pharmacovigilance in India:
An appropriately working pharmacovigilance system is essential if drugs are to be used safely. It will provide advantage for all parties including healthcare professionals, regulatory authorities, pharmaceutical companies and the consumers. It helps pharmaceutical companies to continuously monitor their drugs for risk and to devise and implement the effective risk management plans to save their medicines in difficult situations.2

Having considered the problems and challenges facing the development of a strong and healthy pharmacovigilance system for India, the following proposals might be follows:

1. Building and maintaining a strong and healthy pharmacovigilance system.
2. Making pharmacovigilance reporting compulsory and introducing pharmacovigilance inspections.
3. High-level discussions are to be conducted with various stakeholders.
4. The office of drug control general of India must to be strengthen with trained scientific and medical assessors for pharmacovigilance.
5. To create a single country-specific adverse event reporting form to be used by all.
6. To create a clinical trial and post marketing database for SAEs and ADRs for signal detection and access to all related data from various stakeholders.
7. To create a list of all new drugs/indications by maintaining a standard database for every pharmaceutical company.
8. To Educate and train medical students, dentists, pharmacists and nurses in the area of pharmacovigilance.
9. To collaborate with pharmacovigilance organizations with advancements in information technology in enhancing drug safety, there has been the emergence of new opportunities for national and international collaborations that can enhance postmarketing surveillance programs and increase drug safety.
10. To build a network of pharmacovigilance and pharmaco epidemiologists in India.

Conclusion

If all healthcare professional including physicians, dentists, nurses, pharmacists and others including the patient report all ADRs which will help regulatory authority to take action as soon as possible, and drugs which are banned worldwide will also be not available in India too. The importance of encouraging physicians, dentists, pharmacists, other health-care professionals, and patients to continue to report serious suspected adverse drug reactions, whether unknown or known, to manufacturers and their local regulatory agencies cannot be made to much. Drug development is becoming increasingly difficult. Continued attrition of potentially useful drugs because of serious untoward effects will not help. Careful premarketing screening helps in reducing the problem but may also reduce the number of potentially useful drugs available for full development and subsequent licensing. Better risk management strategies are needed to handle problems when they come, by means other than revocation of licenses.4-5

Pharmacovigilance systems are needed to safeguard public health. Unusually small prominence has been put into engendering information that can assist a healthcare professional or a patient in medication decision-making processes. The collecting and dissemination of this information is a chief goal of Pharmacovigilance. Pharmacovigilance method must be capable to designate which patients are at risk from medication use. A suitably working Pharmacovigilance system is important if medicines are to be used intelligently. It will be of great advantage for healthcare professionals, regulatory
authorities, pharmaceutical companies and consumers to monitor medicines for risk.4-5

Oral Mucosal Lesions among Tobacco Users in Chennai, Tamil Nadu: A cross sectional study

Manigandan Thiruppathy1, Pavani D.2, Kishore Kumar S.3, Julius Amaldas4, Sankar Narayanan R.5

1MDS, Professor and Research Scholar, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Pallikaranai, Chennai, Tamil Nadu, India, 2BDS, Lecturer, Department of Conservative Dentistry and Endodontics, Sathyabama Dental College and Hospital, Semmanchery, Chennai, Tamil Nadu, India, 3Professor, Department of Orthodontics, Sree Balaji Dental College and Hospital, BIHER, Pallikaranai, Chennai, Tamil Nadu, India, 4Professor & Head, Department of Biochemistry, Sree Balaji Dental College and Hospital, BIHER, Pallikaranai, Chennai, Tamil Nadu, India, 5Reader, Sree Balaji Dental College and Hospital, BIHER, Pallikaranai, Chennai, Tamil Nadu, India

Abstract

Background: Oral cancer is eighth most common cancer worldwide. They may arise from potentially malignant disorders. The etiology of Oral cancer is multifactorial, the most common among those are the effects of tobacco usage. The tobacco is used in various forms in our country. Tobacco chewing and smoking are associated with oral mucosal lesions such as Leukoplakia, Oral submucous Fibrosis which are potentially malignant lesions. This study was aimed at identifying the prevalence of these oral mucosal lesions and to motivate the tobacco users about the various deleterious effects associated with tobacco and to help them to quit their habits.

Aim: The aim of this study is to determine the prevalence of oral mucosal lesions among the tobacco users in Chennai.

Materials and Method: The study sample was randomly selected and comprised 1483 patients attending the Department of Oral Medicine and Radiology, Sree Balaji Dental College and hospital, Chennai between January 2017 and December 2018. The ages ranged from 18 to 65 years and are tobacco users were eligible to participate in the study. The data collected was tabulated in Microsoft Excel and further analysed using SPSS Version 21.0 (IBM), software for statistical analysis.

Results: A total of 1483 patients were examined to diagnose the lesions associated with the use of tobacco. The most frequently seen lesion was Smokers Melanosis [921(62.1%)], followed by Frictional Keratosis [696(46.9%)], Periodontal Inflammation [551(37.2%)], Leukoedema [304(20.5%)], and Stomatitis Nicotina Palatini [160(10.8%)].

Conclusion: The overall prevalence of potentially malignant disorders have slight variations when compared to other studies. This may be due to difference in habits, duration and frequency of use.

Keywords: Tobacco smokers; Tobacco Chewers; Oral Lesions.

Introduction

Oral cancer is eighth most common cancer worldwide. The oral cancer may arise from potentially malignant disorders. Potentially malignant disorders are those disorders where not all lesions and conditions described under this term may transform to cancer, instead there is a morphological alteration among which
some may have an increased potential for malignant transformation. Oral cancer is multifactorial and it depends on individual response to these factors. The most common risk factor is tobacco use both smoking and chewing, separately or in conjunction with betel quid chewing and alcohol drinking.

The etiology of Oral cancer is multifactorial, the most common among those are the effects of tobacco usage. Tobacco usage has become one among the five greatest risk factors for mortality. Tobacco consumption in India is a major risk factor responsible for oral and oropharyngeal cancer. The tobacco is used in various forms in our country. It can be either smoking tobacco like cigarette, beedi, hookah, and other pipes like chillum, chutta, dhumti, cherrot and cigar or smokeless tobacco like chewing plain tobacco, khaini, zarda, kiwam, bajar/tapkheer (dry snuff), masheri/mishri, and gutka. Among all the forms the most commonly used is chutta and cigarette. Smokeless Tobacco users chew the tobacco in the mouth and spit out the juice that builds up. Nicotine and other constituents in tobacco are absorbed in the lining of oral cavity. There are many chemical constituents present in smokeless tobacco which are carcinogenic in nature, among which nitrosamine is the most prominent. The consumers are not aware of the harmful effects associated with tobacco use and it has been reported that they are consumed for some beneficial effects, such as mouth freshening, aids in digestion, killing of germs, astringency, mood enhancement, tension relief, and oral cleaning. Initially, tobacco usage leads to keratotic or hyperkeratotic changes in the oral cavity which is related to duration and site of tobacco placement. Tobacco chewing and smoking are associated with oral mucosal lesions such as Leukoplakia, Oral submucous Fibrosis which are potentially malignant lesions.

The aim of this study is to determine the prevalence of oral mucosal lesions among the tobacco users in Chennai and to motivate the tobacco users about the various deleterious effects associated with tobacco and to help them to quit their habits.

**Materials and Method**

**Study design:**

A cross sectional study: Study Population: Patients attending the Out Patient Department in Sree Balaji Dental College and Hospital. Individuals in the age group of 18 to 65 years, including both genders who are tobacco users are included in this study.

**Sample selection:** The study was carried out from January 2017 to December 2018. The study sample was randomly selected which consists of total sample size of 1483 patients who were tobacco users (Smoking and Smokeless Tobacco). The study was approved by Institutional Ethical Committee and was done as per the ethical guidelines.

**Data collection:** All the patients were informed about the study and an informed consent was obtained from the patients. A detailed case history was taken following which they were asked about their tobacco habits which include forms of tobacco, duration, frequency, site of placement, duration of contact with the mucosa. Clinical Examination of hard and soft tissues was done using mouth mirror and gauze under proper illumination. Examination was done by two examiners separately and the size, site, consistency, colour of the lesion were recorded. If the lesion is found to be premalignant/malignant, biopsy was done for confirmatory diagnosis and reports were recorded. Those patients whose results were positive were referred for further definitive treatment.

The data collected was tabulated in Microsoft Excel and further analysed using SPSS Version 21.0(IBM), software for statistical analysis.

**Results**

The study included a total sample of 1483 subjects with a mean age of 32.4 years. About 908 (61.2%) were males and 575 (38.8%) were females. About 1068 (72%) were south Indians. The majority of participants 1112 (75%) were of urban origin. Only 522 (35.2%) were educated, 1290 (87%) were of lower socioeconomic income group. In regards to the tobacco use, Smoking tobacco users were 860 (58%), Smokeless tobacco users were 460 (31%) and those who consume both smoking and smokeless tobacco users were 163 (11%). Among the smoking forms, Beedi was most common (62%), Cigarettes [249 (29%)], Chuttas [69 (8%)] and Hookah [9 (1%)]. Among the Smokeless forms, Raw tobacco was most common [235 (51%)], Pan Masala were [87 (19%)], Gutkha were [51 (11%)], Khaini and Mishri were [32 (7%)], Mawa were [32 (7%)] and other forms (Rajinigandha, Hans, Pan Parag) were [32 (7%)].

Discussion

Various case–control studies and two cohort studies were conducted among tobacco users and it was reported that there is increased risks for oral cancer for betel-quid chewing with tobacco. There was also a strong dose–response relationship for frequency and duration of tobacco use12.

The present study is a original research conducted in Sree Balaji Dental College and Hospital for assessing oral mucosal lesions, potentially malignant lesions or malignant lesions associated with tobacco use. Results showed the gender distribution with a higher percentage in males 908(61.2%) than females which is similar in ratio compared to other studies conducted in India (T.R Saraswati et al13). The most common form of tobacco use is smoking tobacco among which beedi[533 (62%)] is most commonly consumed.

On clinical examination, patients had oral mucosal lesions(93.9%) who were present with a wide range of lesions shown in table 1 & 2 which is higher than the prevalence among rural Indians by Bhowateet al(49.9%)14. This difference can be due to the variations in the study population surveyed that is a hospital-based study with mixed population and differences in the pattern and duration of habits. Smokers Melanosis [212 (62.1%)] was most commonly seen oral mucosal lesion which is present in more than half the study group.

Leukoplaikia was reported to be 81(5.5%) which is similar other studies15,16. Some studies show that 13.6% of smokers is associated with leukoplaikia17. While few others studies says there is no relation between leukoplasia and smoking18. The present study shows a statistically significant relation is seen between tobacco use and leukoplia. Oral submucous fibrosis is seen in 35(2.34%) which is similar to that seen in other studies15. Oral Squamous Cell Carcinoma was seen in 12(0.87%) of the study group which is attributed to the prolonged duration of habits and frequency of use.

Conclusion

We found overall prevalence of potentially malignant disorders in tobacco users have slight variations in our study when compared to other studies. This may be due to difference in habits, duration and frequency of use. Similar studies should be conducted with wider samples in different regional population across India and among the world with similar protocols to identify the various prevalence rates. With the wider data various tobacco control programs should be implemented so as to create awareness among the public regarding the deleterious effects of tobacco use and to implement various tobacco cessation programmes.

Abstract

Swelling of neck always have a wide range of differential diagnosis. Salivary glands are group of organs that secretes saliva which helps in normal functioning of the oral cavity. Many conditions affect the salivary gland because of its size and location. Sialadenitis is the inflammatory condition of the salivary gland which is commonly encountered yet infrequently discussed topic. Sialoliths are calcified organic matter that forms with in the secretory system of the major and minor salivary glands. Sialolithiasis is one of the major causes for sialadenitis which has been shown in many studies. Here we have discussed about a swelling which was present in the right submandibular region with a duration of 3 weeks for which OPG, Lateral Ceph and Ultrasound has been taken for finalising the diagnosis.

Keywords: Sialolithi, OPG, Parotid, Submandibular.

Introduction

Salivary glands are group of organs that secretes saliva which helps in normal functioning of the oral cavity. Many conditions affect the salivary gland because of its size and location. Sialadenitis commonly encountered yet infrequently discussed topic. Old age, debilitated and dehydrated patients are more prone to this disease¹. Sialadenitis may be caused by bacterial or viral infection, radiation, allergic reactions, trauma and autoimmune disorders². It can be of acute, chronic or recurrent.

Sialolithiasis is the formation of calculi in the salivary gland. It is both a cause and a consequence of chronic recurring sialadenitis. These commonly measure between 5 and 10 mm in size and all stones over 10 mm can be reported as sialoliths of unusual size and giant sialoliths measuring more than 35 mm are rare³. Since the glands are encapsulated, there is little space for expansion and enlargement that causes pain and discomfort⁴. Here is a case of sub mandibular siladenitis and intra ductal sialolith causing pain in the neck region.

Case Report: A 58 year old male patient came to the department of Oral Medicine and Radiology with a complaint of swelling in the right side of neck region for past 3 weeks. History revealed that he had pain in neck for past 1 week followed by a sudden onset of swelling, where it gradually increased in size to attain the present size. There was mild pain on touching the swelling and the pain got subsided on medication but the swelling did not reduce in size.

Image 1: Image showing swelling seen in the right sub mandibular region.
On general examination patient had normal gait, posture and was well oriented, conscious and moderately built. There was no evidence of pallor, icterus, cyanosis and clubbing. Patient’s medical history was unremarkable.

There was a diffuse solitary swelling seen in the right submandibular region which was about 4x3 cm in size approximately and the colour of skin over the swelling was normal. The surface of the swelling was smooth and margins and edges were ill defined. Pulsation and movement of the swelling on swallowing was absent. On palpation the swelling was firm in consistency, tender and mobile.

Intra oral examination revealed dental caries in relation to 36 and 47 and generalized periodontitis.

On correlation with history and clinical examination a provisional diagnosis of **right submandibular lymphadenitis and a differential diagnosis of Chronic Submandibular Sialadenitis** were made.

The investigatory work up included complete hemogram, intra oral radiographs, orthopantomogrph, Lateral cephalograh and ultrasonography. Routine hematological investigations were within normal limit. OPG and Lateral cephrrevealed a radiopaque structure seen on the right side angle of the mandible which was about 4x3 cm in size of oval shape and with a well defined periphery and smooth borders. The internal structure was completely radiopaque. There was also a radiopaque structure seen in the periapical region of 33. The IOPA and Occlusal radiographs showed no abnormalities.

Ultrasound of the neck showed right submandibular gland was enlarged in size and measures 3.3x2.2cm. The duct was also dilated measuring 4mm and shows 2 calculi within it, each measuring 13mm and 6mm in size.

The final Diagnosis was given as **Sialadenitis of right submandibular gland with intraglandular and intra ductal sialolith and** the patient were referred to the department of Oral Maxillofacial surgery for the management of removal of calculi.
Salivary gland diseases most commonly affect Parotid and submandibular salivary glands. Formation of calculi, inflammatory swelling of the salivary gland is very common these days. Sialoliths are calcified organic matter that forms within the secretory system of the major and minor salivary glands. The exact etiology and pathogenesis of salivary calculi is unknown. Most accepted retrograde theory proposed for sialolithiasis says, retrograde flow of substances or bacteria within the oral cavity into the salivary ducts lead to the formation of organic nidus that further shows calcification. Salivary stasis, increased alkaline nature of saliva, infection or inflammation and physical trauma to salivary duct or gland may predispose to calculus formation. It is difficult to determine since many cases are asymptomatic and very painful, due to its severity in pain and characteristics swelling, clinicians may tend to confuse with odontogenic infections and diseases. Studies have indicated that 92% of sialolithiasis occur in the submandibular gland, 6% in the parotid gland, and 2% in both the sublingual and minor salivary glands. Our case stands for this. Sialolithiasis one of the major causes for sialadenitis which has been shown in many studies.

Sialadenitis is the inflammatory condition of the salivary gland. This predominantly affects the Parotid and Submandibular salivary gland. Clinically, submandibular sialadenitis differs from parotitis mainly in the site of the swelling and discharge of pus from Wharton’s duct. A wide variety of bacteria has been incriminated, but *Staphylococcus aureus* has been the most frequently reported isolate. The other isolated organisms have included streptococci, *Pseudomonas aeruginosa*, *Escherichia coli* and *Moraxella catarrhalis*. During an acute inflammatory process, there is swelling of the affected gland, overlying pain, gland tenderness, fever, and on occasion difficulty in opening the mouth. Often the pain is intensified with eating in that food ingestion stimulates saliva flow, which will typically cause the gland to swell and thus exacerbate the pre-existing symptoms. In chronic gland disorder, the symptoms are similar, although much less intense.

**Conclusion**

The differential diagnosis of masses of lymph nodes or the submandibular salivary gland origin can be considered for swelling in the submandibular region. A careful history taking places a vital rule along with bimanual, intraoral and extraoral palpation is the first step in diagnosing and distinguishing between the masses of the submandibular gland and the nonsubmandibular gland origin.

Novel Oral Anticoagulants: A Review

Manigandan Thiruppathy1, Pavani D.2, Amudhan A.3, Sarumathi T.A.3, Hemalatha V.T.4

1Professor and Research Scholar, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Pallikaranai, 2Lecturer, Department of Conservative Dentistry and Endodontics, Sathyabama Dental College and Hospital, Semmanchery, 3Professor, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Pallikaranai, 4Associate Professor, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Pallikaranai, Chennai, Tamil Nadu 600100, India

Abstract

Dentists come across various medically compromised patients. Patients who are under anticoagulant and/or antiplatelet drugs should be taken into consideration as they are at a high risk to have increased bleeding tendency during minor oral surgical procedures. The substances, which prevent or prolong coagulation of blood, are called Anticoagulants1. The most commonly used medications for oral anticoagulant therapy are Warfarin, Aacenocoumarol. The novel oral anticoagulants (NOACs) or directly acting oral anticoagulants [DOACs] were developed with more pharmacokinetic and pharmacodynamic relationships, faster onset of action, and fewer potential interactions. The Novel anticoagulants include Dabigatran Rivaroxaban, Apixaban.

Keywords: Novel Anticoagulants, Dabigatran, Apixaban.

Introduction

Dentists come across various medically compromised patients. Among those, the number of patients who are under anticoagulants are constantly increasing. As dentists commonly perform minor oral surgical procedure in a outpatient setup. Patients who are under anticoagulant and/or antiplatelet drugs should be taken into consideration as they are at a high risk to have increased bleeding tendency during minor oral surgical procedures. Achieving hemostasis should be our primary goal. Managing such patients is a challenge for dental professionals. So, as a dentist we should have a thorough knowledge on mechanism of hemostasis, management of such patients and various anticoagulants which are used including the new orally administered anticoagulants.

The substances, which prevent or prolong coagulation of blood, are called Anticoagulants1. Blood clotting is natural response towards damage of blood vessels from injury or invasive procedures. Platelets in the blood are activated locally, resulting in an increased tendency to attach to each other and to the endothelium of the damaged blood vessels. At the same time, a cascade of reactions is initiated that converts inactive coagulation factors to their active forms, ultimately leading to the production of protein fibrin, the activated cross-linking form of fibrinogen2.

There are millions of patients worldwide who are administered medications that alter homeostasis and decrease the risk for thromboembolic events3. The most commonly used medications for oral anticoagulant therapy are: Anticoagulants with indirect action (Coumarin derivatives) which include Aacenocoumarol, Warfarin sodium. Warfarin interacts with many commonly used medications (notably non-steroidal anti-inflammatory drugs - NSAIDS and antibiotics) and some foods (green vegetables, grapefruit juice and Cranberries)3,4. Depending on the reason for the anticoagulation therapy (cardiovascular thromboembolic risk), the patient’s target INR therapeutic ranges may differ. Patients with atrial fibrillation or stroke have...
a target INR of 2.0 to 3.0, whereas after undergoing cardiac valve replacement surgery, patients have a target range of 2.5 to 3.5.5,6

There has been a need for a more convenient oral anticoagulant, which does not require frequent monitoring. Several alternative anticoagulants have been developed and have undergone large-scale clinical trials to ascertain efficacy and safety. These trials have shown that the new anticoagulants to be as, or more, effective than warfarin.7,8 The novel oral anticoagulants (NOACs) or directly acting oral anticoagulants [DOACs] were developed with more pharmacokinetic and pharmacodynamic relationships, faster onset of action, and fewer potential interactions. The Novel anticoagulants include Dabigatran, Rivaroxaban, Apixaban, Edoxaban.

Discussion

The mechanism of action of anticoagulants and pharmacokinetic and pharmacodynamics properties are explained in figure 1 and table 1

![Mechanism of Action of Anticoagulants](image)

Dabigatran Etxilate (Pradaxa): Dabigatran Etxilate (Pradaxa) is absorbed as a pro-drug with a bioavailability of 6%. It is subsequently converted into its active form by circulating esterase. Elimination is 80% renal, which has to be taken into account when the drug is given to patients with impaired renal function. Its half-life is 14–17 hours; therefore it is given twice daily. The recommended dose is 150 mg taken orally, twice daily for patients with creatinine clearance (CrCl) > 30 mL/min and 75 mg twice daily for patients with CrCl 15-30 mL/min. Dabigatran is a drug that is a viable alternative to warfarin in the prophylactic treatment of stroke and systemic embolism in patients with atrial fibrillation.

Patients treated with dabigatran can undergo invasive dental procedures without altering the dose of the medication. The dentist should consult the patient’s physician to plan the procedure, and confirm whether the patient will continue with the same dose after surgery in order to prevent thromboembolism, as well as, excessive bleeding.

Rivaroxaban: It is Factor Xa inhibitor that blocks FXa both in its free and prothrombin-bound states. It has a half-life of 7–11 hour requiring once- or twice-daily dosing, and a dual mode of elimination, with two-thirds of the drug being metabolized by the liver and one-third eliminated unchanged by the kidneys.

Apixaban: Apixaban is a potent, reversible, highly selective, direct inhibitor of free and prothrombinase bound factor Xa. It is characterized by > 50% oral bioavailability, peak plasma concentrations 1-3 to 4 hours after administration, and a 12-h terminal half-life. In contrast, the elimination of apixaban is only 25% renally and 75% metabolized by the CYP3A4 (Cytochrome P450 3A4) and via the CYP-independent mechanisms of the liver. It is indicated in the prevention of venous thromboembolism (VTE) after major orthopaedic surgery, treatment of acute VTE, prevention of stroke or systemic embolism in patients with atrial fibrillation and for secondary prevention in ischemic heart disease. It has low potential for drug-drug interactions.

Edoxaban: Edoxabanis a novel, orally available, highly specific, and direct inhibitor of factor Xa.

It is rapidly absorbed with good bioavailability, a half-life of 8–10 hours, and elimination largely via the kidneys. It has demonstrated a safety and efficacy profile comparable to warfarin in Phase I and II clinical trials. In comparison with other anticoagulant medications, edoxaban shows some safety benefits and does not require constant monitoring.

There is presently insufficient evidence to directly compare the relative bleeding risks associated with the various anticoagulants medications including the newer drugs for dental patients. Various clinical trials shows that incidence of bleeding risks in patients with atrial fibrillation who are taking dabigatran, apixaban or rivaroxaban were similar or lower than for those taking warfarin.

Conclusion
The dentists should be aware of the novel oral anticoagulants and other anticoagulants, their mechanism of actions, indications, contra indications, adverse drug reactions. Nowadays lot of patients are on novel anticoagulant for their systemic illness. So thorough knowledge about the medical history and drug history of the patient is important before doing any minor or major surgical procedures to avoid complications.

Immunomodulators in Oral Diseases: An Update

Jemima Judith¹, Manigandan T.², Sarumathi T.², Amudhan A.², Nalini Aswath³

¹Post Graduate, ²Professor, ³Professor & Head, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

Abstract

Immune-mediated diseases are some of the diseases that affect the patient’s quality of daily life due to their chronic nature. Of which most of them are mucocutaneous diseases and they involve the oral cavity. The treatment of these diseases is oftentimes challenging due to their immunological nature, comorbidity, frequent relapses and long term use of medications and their complications. Immunomodulators are the most rapidly developing current trend. They are used quite often for a large number of these diseases. This article discusses some of the lesions where immunomodulatory drugs are used.

Keywords: Immunomodulators, Immunosuppressants, Immunostimulants.

Introduction

Most mucocutaneous oral disorders are mediated by cellular or humoral response against the mucosal tissues. Immunomodulators can stimulate (immunostimulators) or suppress (immunosuppressors) the immune system and thereby regulating its responses¹ Some of the indications for immunomodulators are when there’s no response to corticosteroids and when it’s contraindicated, for recurrent cases and cases resistant to steroids and cases of the previous history of severe adverse effect with steroids.²

Classification:

According to Patil US etal (2002)³:

Immunosuppressants:

**Glucocorticoids:** These traditional immunosuppressants lead to reduce vasoactive and chemotactic factors, decreased lipolytic and proteolytic secretion, decreased leukocyte extravasation into inflammatory areas and so reduced fibrosis. The expression of proinflammatory cytokines (COX2 and NOS2) can also be decreased by glucocorticoids. The cytokines, IL-1, IL-6 and TNF-α activate the HPA axis to increase ACTH release and directly facilitate the glucocorticoid stimulation are reduced. Cytokine network elements include IFN-γ, GM-CSF, IL-1, IL-2, IL-3, IL-6, IL-8 and IL-12, the colony-stimulation factor and TNF-α, which will be impeded.

**Therapeutic Uses:**

**Lichen Planus:** Topical steroids are used as a mouth rinse or a gel. Drug of choice 0.05% clobetasol propionate (very potent), 0.1 % Triamcinolone acetonide, 0.05% fluocinonide, 0.1%, fluocinoloneacetonide. The reasonable approach may be to apply the drug 2-3 times a day for 3 weeks followed by tapering during the following 9 weeks until a maintenance dose of 2-3 times a week is reached.

Systemic Corticosteroids should be administered only in recalcitrant lesions 1mg/kg bodyweight for 7 days, followed by a reduction of 10 mg each subsequent day. A maintenance dose with topical steroids may be commenced during the tapering of the systemic steroids.

Intralesional Corticosteroids used to manage persistent localized lesion and lesions unresponsive to topical therapy. 10-20mg of insoluble Triamcinolone acetonide is diluted with 0.5ml saline or 2% lidocaine injected to the lesion which solubilizes gradually 3-4 times/week or 2 times/week.

**Erosive Lichen plauns:** 0.5% Clobetasol gel: Erythematos lichen planus of gingiva - After prefabricated plastic trays, steroid gels in each treatment can be used to increase the steroid concentration in the gingival tissue for 30 minutes if symptoms persist.

OSMF- Intralesional submucosal injections of a combination of dexamethasone (4 mg/ml) and 2 parts of hyaluronidase (1500 IU) diluted in 1.0 ml of 2% xylacaine twice a week.

**Recurrent Apthous Stomatitis:** Topical agents-Dexamethasone 0.05 mg/ml rinsing three times a day, Dexamethasone 0.05 mg/ml with 0.2% chlorhexidine mouthwash for rinsing thrice a day, Clobetasol ointment 0.05% in orabase (1:1), Fluocinonide ointment 0.05% in orabase (1:1) three times a day, Triamcinolone acetonide 0.1% oral paste.

Systemic corticosteroid therapy- recommended for patients with recalcitrant cases Hydrocortisone 20 mg or triamcinolone 4 mg, Prednisolone (10-30mg/day) for 10-15 days.

SLE- to obtain relief of symptoms, potent topical steroids such as clobetasol propionate gel 0.05%, betamethasone dipropionate 0.05%, or fluticason propionate spray 50 μg aqueous solution is usually required.

**Erythema multiforme - Prednisolone 0.5–1.0 mg/kg/day tapered over 7–10 days:** Stevens-Johnson syndrome & Toxic epidermal necrolysis-Intermittent administration of high doses of IV corticosteroid and cyclophosphamide, (Pulsed therapy) three daily doses of dexamethasone (100 mg) or methylprednisolone (500–1000 mg) and cyclophosphamide (500 mg) given monthly as a single dose.

**Pemphigus Vulgaris:**

Mild case- Prednisolone 40–60 mg/day: Severe case - 60–100 mg/day in for 6–8 weeks. The dose should be increased by 50–100% increments until there is control if there is no response within 5–7 days. If doses
above 100 mg/day are required, pulsed intravenous steroids could be used.

**Bullous pemphigoid:** Localized lesions - High-potency topical steroids - clobetasol or betamethasone.

Moderate disease - minimize the use of systemic steroids (daily prednisolone equivalents of 0.5 to 0.75 mg/kg) by the use of dapsone or tetracycline, doxycycline.

Extensive disease - Systemic corticosteroids used alone or combined (daily prednisolone equivalents of 0.75 to 1.25 mg/kg) with immunosuppressive drugs such as azathioprine, cyclophosphamide, mycophenolate or rituximab.

**Mucous membrane pemphigoid:** Topical drugs Fluocinonide 0.05% or clobetasol propionate 0.05% in an adhesive thrice daily for 9–24 weeks. Triamcinolone acetonide can be used intralesionally (in a dilution of 5.0–10 mg/ml) to treat isolated erosions.

Systemic corticosteroid- Prednisolone 40 mg daily for 5 days followed by 10–20 mg daily for 2 weeks.

Behcet’s disease- Prednisone is used in combination with Azathioprine.⁸

Orofacial Granulomatosis-Intralesional corticosteroids-Triamcinolone 10–20 mg per dose (intralesional with weeks to months between doses).

**Calcineurin inhibitors:**

**Cyclosporines:** It specifically & reversibly inhibits immunocompetent lymphocytes in the G0 and G1 cell cycle phase. It binds with cyclophilin then binds to and inhibits calcineurin. Calcineurin-induced dephosphorylation is required for the induction of cytokine genes activates a nuclear component of T cells that initiate gene transcription for the IL-2 formation.²

**Therapeutic Uses:** Lichen Planus- Recalcitrant cases of OLP, Mouth rinse-5 ml of medication (containing 100 mg of cyclosporine per milliliter) three times daily (i.e., 500-1500mg/day). In a bioadhesive, 100 mg/ml, added to the alcohol phase of Zilactin to a final concentration of 0.5 mg/dl.⁶

Recurrent Aphthous stomatitis-Topical cyclosporine 100mg/ml for moderate cases. Systemic cyclosporine 3 to 6 mg/kg/day for chronic cases

Bullous pemphigoid-Cyclosporine 3 to 5 mg/kg daily, is infrequently used in addition to systemic corticosteroids.

**Mucous membrane pemphigoid -100 mg/ml:** Behcet’s disease - Topical cyclosporine 100mg/ml for moderate cases. Systemic cyclosporine 3 to 6 mg/kg/day for chronic case.⁸

**Orofacial Granulomatosis -Cyclosporine A – 25 mg, oral capsule:** Sjogren’s syndrome- Prescription eye drops containing 0.05% cyclosporine emulsion may help some with ocular moisture.

Graft Vs Host Disease (GVHD)- Prophylactic therapy with immunomodulatory and immunosuppressive drugs such as cyclosporine and prednisone should be given to prevent GVHD

**Tacrolimus:** It inhibits calcineurin by interacting with FK506-binding protein-12. Inhibits lymphokine apoptosis and degranulation, Inhibits calcineurin thereby inhibits T cell activation and cytokine release. Topical tacrolimus penetrates the skin better and its 100 times more potent than topical cyclosporine.

**Therapeutic Uses:** Erosive Lichen Planus - 0.1% Tacrolimus ointment application 2-4 times a day for 4-8 weeks. Also used for refractory erosive oral LP.

Lichen Planus (LP) and erosive LP- 1% Pimecrolimus application 2-4 times a day for 4-8 weeks

**SLE- Tracolimus 2-3 mg daily:** Pemphigus Vulgaris- 0.1% tacrolimus ointment twice daily for 3 to 4 weeks

**Antimetabolites:**

**Azathioprine:**

Mechanism of action is explained in (Flow chart 1)

Following exposure to nucleophiles, azathioprine is cleaved to 6- mercaptopurine

↓

6- thio-IMP (inosine monophosphate)

↓

6- thio-GMP(guanosine monophosphate)

↓

6-thio –GTP(guanosine triphosphate)
Incorporated into DNA
↓
Disrupts DNA and RNA formation and process of cell division
↓
Suppress cell-mediated immunity

Flow Chart 1: Mechanism of Azathioprine

**Therapeutic Uses:**
- **Lichen planus** - 50 mg twice PO (2mg/kg/day) for 3-7 months, daily.
- Recurrent Aphthous stomatitis - Azathioprine – Chronic cases, are non-respondent to primary drugs. 1 to 2 mg/kg/day (100–150 mg/day), Starting with 50 mg/day and escalated up to 150 mg/day.
- **SLE** - Azathioprine 2 mg/kg/day PO with or without low-dose corticosteroids
  - Erythema multiforme - Azathioprine 100 to 150 mg/day (2mg/kg/day in those with normal thiopurine methyltransferase [TPMT] activity), Pemphigus Vulgaris - Azathioprine - 0.5–4 mg/kg depending on TPMT level.
  - Bullous pemphigoid - Azathioprine is 1 to 3 mg/kg daily
  - Mucous membrane pemphigoid - Azathioprine - 1–2 mg/kg daily depending on TPMT levels.
  - Behcet’s disease - Azathioprine – Used for chronic cases, are non-respondent to primary drugs. 1 to 2 mg/kg/day (100–150 mg/day), Starting with 50 mg/day and escalated up to 150 mg/day.
  - Orofacial Granulomatosis - Azathioprine - 2.5 mg/kg/d (125 mg)

**Methotrexate:** Prevent conversion of dihydrofolate (DHF) to trihydrofolate (THF) by inhibiting dihydrofolate reductase. THF is required in purine and pyrimidine synthesis. DNA and RNA synthesis is suppressed.

**Therapeutic uses:**
- Oral lichen planus - Methotrexate - 7.5-10 mg weekly for 8 weeks.
- Erosive Lichen planus - Methotrexate -2.5 to 12.5 mg/wk
- Recurrent Aphthous stomatitis - Methotrexate - 7.5 to 20 mg weekly is effective in severe oro-genital lesions
- SLE- Methotrexate 7.5 to 25 mg per week for 3-6 weeks
- Bullous pemphigoid- Methotrexate 10 to 50 mg weekly.
- Behcet’s disease- Methotrexate - 7.5 to 20 mg weekly has been proved to be effective in severe oro-genital lesions.
- Orofacial Granulomatosis - Methotrexate 5–10 mg administered PO weekly

**Mycophenolate mofetil (MMF):** The active form, Mycophenolic Acid (MPA), a selective potent inhibitor of inosine monophosphate dehydrogenase (IMPDH), and is an essential enzyme in the de novo pathway of guanine nucleotide synthesis that was hydrolyzed from the prodrug, MMF. This prevents the synthesis of de novo purine synthesis by inducing IMPDH, affected cells B and T cells and also selectively inhibits lymphocyte proliferation and antibody formation, cellular migration, and adhesion.

**Therapeutic uses:**
- Lichen planus- Mycophenolate mofetil- 2–4 g day.
- SLE- Mycophenolate mofetil (Induction: 1 g PO q12hr with a glucocorticoid or 2-3 g for 6 months with glucocorticoids. Maintenance: 0.5-3 g/day or 1 g PO q12hr or 1-2 g daily).
- Erythema multiforme - Mycophenolate mofetil 1000 mg twice daily
- Pemphigus Vulgaris - Mycophenolate Mofetil - 2-2.5 g/day
  - Bullous pemphigoid-Mycophenolate mofetil (1000 mg, twice daily) is given in addition to systemic steroid therapy and is stopped when remission is achieved.
- Behcet’s disease- Mycophenolate Mofetil 2 g/day.
- Orofacial Granulomatosis - Mycophenolate Mofetil 2 g/day.

**Alkalysing agent:**

**Cyclophosphamide:**

It suppresses the proliferation of B-lymphocytes but can enhance T-cell’s response. By cross-linking DNA strands by forming covalent bonds by introducing alkyl groups with nucleophilic moieties, thereby preventing cell division and protein synthesis.
**Therapeutic uses**: SLE- Cyclophosphamide (500 mg IV every 2 weeks for 6 doses plus corticosteroids, then maintenance with mycophenolate mofetil or azathioprine)

Pemphigus Vulgaris- Cyclophosphamide - used alone i.e. 0.5–2 mg/kg daily or with steroid in the form of pulse therapy for severe cases.

Bullous pemphigoid- cyclophosphamide is 2 to 2.5 mg/kg daily, followed by aggressive oral hydration, and IV cyclophosphamide must be combined with oral or IV Mesna to prevent bladder toxicity.

**Biologics**:

**Therapeutic uses**: Lichen planus- Alefacept 15 mg/week IM for 12 weeks, Etanercept -25 mg twice weekly, Adalimumab - 40mg every other week.

Refractory oral lichen planus- Basiliximab, Etanercept

Erosive LP- Efalizumab- An initial dose of 0.7 mg/kg, followed by a dosage of 1.0 mg/kg/week, approximately 3 weeks had been administered successfully.

SLE- IV Rituximab 375 mg/m^2 weekly for a total of four courses, Belimumab Initial: 10 mg/kg IV q2Weeks x3 doses, then Maintenance: 10 mg/kg IV q4Week

Epidermolysis bullosa- Rituximab - 375 mg/m^2 of body-surface area weekly IV.

Pemphigus vulgaris- Rituximab is administered at a dose of 375mg/m^2 body surface area weekly for four weeks.

Behcet’s disease- Etanercept -2×25 mg/week subcutaneously, in a regressing oral ulcer, Infliximab- Refractory and recurrent oral and genital aphthous ulcer in a dose of 5 mg/kg body weight intravenously.

**Orofacial Granulomatosis-Infliximab 5 mg/kg**: Sjogren syndrome- Etanercept subcutaneously, 25 mg. 1,000 mg infusions of rituximab two weeks apart using a standard protocol with an escalation of the infusion rate to a maximum of 400 mg/hour. Infliximab 3 mg/kg IV, administered in week 0, week 2, week 6 and once every 8 weeks. Sjogren syndrome- Belimumab, 10 mg/kg IV, at weeks 0, 2 and 4 and then every 4 weeks.

Graft Vs Host Disease (GVHD) - Basiliximab used to prevent immediate transplant rejection in people who had received kidney transplants, in combination with other agents and is effective in the treatment of corticosteroid-resistant GVHD.

**Vaccine**: (BCG): BCG had been used to enhance immunity nonspecifically by the reticuloendothelial system stimulation.

**Therapeutic uses**: Erosive LP - Intralesional injection of 0.5 ml BCG-PSN every other day for 2 weeks can be administered.

**Antihelminthics- Levasimole**: It enhances Dendritic cells (antigen presenting cells) maturation and also increases the expression of major histocompatibility complex [MHC] molecules and costimulatory molecules like CD80, CD83, and CD86. Antigen and MHC complexes activate the T cells. Activated T cells release interferon γ thus enhancing the immunity.

**Therapeutic uses**: Lichen planus- Levasimole - 150-300 mg/day for 3 months (Monotherapy). In combination with 15 mg/day Prednisolone for 3 consecutive days each week and 150 mg/day levasimole.

Refractory oral candidiasis- Levasimole 150 mg/day for 2-4 days each week.

Aphthous ulcer- Levasimole- 150mg/day with or without combination with steroids (15 mg Prednisolone).

HSV- Levasimole- 150 mg/kg.

**Thalidomide**: It is banned for its teratogenic effect but reintroduced as an immunomodulator, and angiogenesis inhibitor antitumour drug and has anxiolytic, antiemetic, anti-inflammatory, adjuvant analgesic/antipyretic properties.

**Therapeutic Uses**: Severe corticosteroid resistant erosive oral lichen planus: Topical- Thalidomide 1% paste (150 mg Thalidomide powder dissolved in pure glycerol into a paste) Apply 3 times/day for 1 week. The systemic dose-Initial dose of 50 to 100 mg/day.

Recurrence Aphthous stomatitis- Thalidomide - 100 to 200 mg/day to start with and to be continued till remission, followed by a maintenance dose of 50 to 100 mg daily or 50 mg every other day.

SLE- Thalidomide 50 mg daily

Erythema multiforme- Thalidomide 100 mg daily
Graft Vs Host Disease (GVHD) - Thalidomide is a useful drug in cases of chronic GVHD which are resistant to standard therapy.

Recombinant cytokines:

Interferons (α, β, γ): Interferon causes certain enzymes to be induced by binding to cell surface receptors, inhibiting cell proliferation and enhancing the immune activity, including increased macrophage phagocytosis and increased specific T-lymphocyte cytotoxicity.

Therapeutic uses:

Leukoplakia – human β interferon105 I.U./g

OSMF- Intralesional injection of interferon γ (0.01–10.0 U/mL) 3 times a day for 6 months can be given.

Behcet’s disease- Intermediate (e.g. 6 × 106 IU thrice a week) or high doses (e.g. 9×106 IU thrice a week) of Interferon α2a (Roferon A) and b (Intron A) are principally more effective than low doses (3 ×106 IU thrice a week). Lower doses are recommended as a maintenance therapy when treatment is successful in the first 1 to 4 months.

Conclusion

A new line of therapeutic options is available in the form of steroid-sparing medications and biologics to prevent or recalcitrant oral lesions. Nonetheless, up until this point, the data is scarce to provide any clinical guidance. For scientific evidence using these newer medicines to establish the risk-benefit ratio for the treatment of oral lesion patients, properly powered randomised controlled studies are needed.

Abstract

Ayurveda is one of the world’s oldest forms of medicinal treatment which has been practiced since 12th century BC. Ayurveda aims to accomplish physical, mental, social and spiritual well being by adopting preventive, health promoting and holistic approach towards life. Dental and general health problems can be treated by balancing the three doshas (humors) of the human body- the vata (wind), the pitha (bile) and thekapha (phlegm). Side-effects arising with usage of allopathic medications can be avoided with an alternative therapy like Ayurveda. Treatment for any chronic diseases is made possible by use of herbs and herbal preparations that contain parts of plants or other plant materials as active ingredients in Ayurveda. This review article explores the various herbs used for treating oral diseases and to sustain oral health.

Keywords: Ayurveda, Oral health, Disease, Dental.

Introduction

In India, the different systems of medicine include Allopathy, Ayurveda, Homoeopathy, Naturopathy, Siddha, Unani, and Yoga [1]. Among these, Ayurveda is one of the oldest medical systems primarily practiced in India known since 12th century BC. Ayurveda uses varieties of herbs, herbal extracts and preparations containing parts of plants or other plant materials as active ingredient for treating diseases. There are approximately 1,250 medicinal plants being used in these formulations. Outcome of the treatment is seen on long-term use as the whole medicinal plants and their extracts work in conjunction with each other [2]. The two main characteristics that distinguish it from an allopathic drug is the use of crude herbs and prolonged usage.

Oral disease is a major health concern worldwide and gained importance as it is imperative to systemic health. The Use of herbs for various oral diseases is well described in ayurvedic classical Texts like Sushruthasamhitha and Charakasamhitha. There are numerous Ayurvedic drugs can be used in prevention as well as management of oral and dental diseases like dental caries, halitosis, oral ulcers, gingival and periodontal diseases. This article reviews the various herbs and practices adopted in Ayurveda for alleviating oral health problems and aid in oral care.

Ajowan (Trachyspermum ammi): It is also known as bishop’s weed. It has major phenolic compound thymol, which has germicidal, antispasmodic and antifungal properties. Ajowan has anticariogenic property and acts against Streptococcus mutans by inhibiting its adherence and biofilm formation on the tooth surface.[3] Aloe Vera (Aloe barbadensis): Aloe vera has many beneficial oral and systemic actions. Aloesin, aloemannan, the constituents of aloevera provides anti-inflammatory effect, anti tumor and immunosuppressive effect, potential immunostimulant, antiviral, antineoplastic, and gastrointestinal properties. It improves wound healing by enhancing the collagen turn-over rate and production [4]. A research conducted on acemannan, the clear-inner gel of aloevera exhibited dentin formation and increased pulp cell proliferation. Additionally, the commercially available SaliCept patch can be used as a dressing in the management of alveolar osteitis . It is considered an acceptable alternative to most used alvogyl as a dressing in the management of alveolar osteitis [5].

DOI Number: 10.37506/v10/i12/2019/ijphrd/192266
Clove oil (Syzygium aromaticum): Clove oil is a most important ingredient for treating many oral problems. This ingredient is incorporated in tooth paste, mouth washes, tincture (1:5, 25% ethanol) and gels due to its medicinal values. Clove when used in gel form, proved as an alternative to benzocaine in topical anesthetics. Its extract consists of essential oil, eugenol, eugenol acetate and β-caryophyllene, lesser amounts of benzyl alcohol, chavicol, acetyl salicylate, humulenes and nutrients like calcium, minerals, iron, potassium, phosphorus, sodium, vitamin A & vitamin C [6]. It is used for treating bleeding gums, tooth ache, sore gums, mouth ulcers, post periodontal surgeries, root canal filling and as a temporary filling for tooth decay. [7]

Green tea (Camellia sinensis): Green tea has significant action against S. mutans, Porphyromonas gingivalis, and Streptococcus sobrinus producing anticariogenic effect. Catechin, an essential ingredient in green tea inhibits the growth of P. gingivalis, Prevotella nigrescens, Prevotella intermedia and the adherence of P. gingivalis on human buccal epithelial cells thus preventing occurrence of periodontal disease. [8]

Haritaki (Terminalia chebula): Haritaki in mouth rinse proved to be effective against the carious organisms like S. mutans by increasing salivary pH which is a prerequisite for a mouth wash. [9]

Honey: Honey is shown to have antibacterial properties on nearly sixty pathogens. It acts by altering the chemical pH and osmotic effect thus aiding in antibacterial action. Propolis is a natural resinous mixture produced by honey bees has high anti-inflammatory property and can be used in severely infectious cutaneous wounds. It also has an effective result in various oral ulcerative conditions like aphthous ulcer, acute necrotizing gingivitis, periodontitis and pulpitis. [10]

Liquorice (Glycyrrhiza glabra): The root portion of liquorice has many medicinal values. Its extract contains glycyrrhizin which shows anti-adherent property and acts by inhibiting glucosyl transferase activity of S. mutans, which is involved in the formation of insoluble glucans required for biofilm formation. Liquorice added with acidulated phosphate-fluoride solution, showed increased fluoride uptake by the enamel. Glycyrrhizin is fifty times sweeter than sucrose, acting on gustatory areas which may increase the salivary flow and hence reduced incidence of caries. [11] Liquorice is integrated in oral hygiene products like mouth rinse, tooth paste, gels etc.

Mango (Mangifera indica): Studies on mango leaves have reported that it possess inhibitory effect against P. gingivalis, P. intermedia, Streptococci, Lactobacillus acidophilus. Mango is rich in tannins, bitter gum and resin which aids in management of oral hygiene. Mango leaf in conjunction with a tooth brush will be the best home care for maintenance of oral hygiene. [12]

Miswak (Salvodorapersica): Miswak has antibacterial and antiplaque effect that helps in maintaining proper oral hygiene. Also chewing of miswak sticks have shown to provide antibacterial effect against cariogenic organisms [13].

Pomegranate (Punica granatum): Pomegranate is rich in polyphenolic flavonoids. Studies has shown that pomegranate possess antimicrobial activity against certain bacteria like Staphylococcus epidemidis, L. acidophilus, S. aureus, S. mutans, S. sanguinis and S. salivarius which is due to the presence of hydrolysable tannins and polyphenolics like substance punicalagin and gallic acid in its extract. [14, 15]. The phenol punicalagin which accounts for more than 50% of the juice has potent antioxidant activity.

Triphala (Myrobalans): It is traditional formulation which consists of three fruits, known as myrobalans. Triphala has many medicinal values towards oral health. Triphala along with sesame oil, alum, kshara (alkali), khadira (acacia catechu) can be used to treat the gingival hypertrophy by gently massage over the gingiva. Triphala is rich in tannins and phenolic compounds and provides antioxidants property [16]. Though chlorhexidine is a gold standard for mouth washes, triphala can also be used as mouthwash. Studies has showed that when 6% triphala mouth rinse used after scaling and root planning reduced the plaque index, gingival index and oral hygiene index with no staining of the tooth when for long term period. [17]. It also has anticariogenic property as it reduced the considerable amount of S. mutans count when compared to chlorhexidine. [7]

Tulsi (Ocimum sanctum): Traditionally tulsi has numerous medicinal values and was used to treat various diseases. It consists of tannins (4.6%) and essential oil (upto 2%), eugenol (upto 62%), methylchavicol (upto 86%), and α- and β-caryophyllene (upto 42%), methylcinnamic acid, linalool and 1,8-cineole. [18]. Tulsi produces COX-2 inhibitors which is helpful in reduction
of pain in tooth ache. It has a significant effect on oral diseases like oral submucous fibrosis, pemphigus, leukoplakia, lichenplanus,candidiasis and aphthous ulcers\[^{23}\]. Studies have proved that 4% tulsi extract used as mouth rinse significantly reduced S. mutans count\[^{18}\].

**Mustard oil (Brassica Nigra):** Mustard oil consists of oleic acid, fatty acids, and uric acid that help in prevention of periodontal disease. It is rich in antioxidants and produces antibacterial effect. Mustard oil stimulates and enhances blood circulation when massaged over the gingiva.\[^{7}\]

**Eucalyptus (Eucalyptus globulus):** Chewing gums containing eucalyptus extract has eloquent effect against plaque activity, probing depth, gingival and periodontal index. Macrocarpal, a constituent in eucalyptus acts against cariogenic bacteria and helps in maintaining alkaline pH in saliva.\[^{20}\]

**Amla (Emblica officinalis, Phyllanthusemblica):** Amla is generally known as Indian gooseberry or Dhatriphala. Regular intake helps in maintaining the teeth and gums. It is rich in vitamin-C which helps in production of hydroxyproline from proline. Amla is used along with triphala as mouthwash to treat periodontal disease \[^{21}\]. It also has antioxidant and astringent property that helps in preventing bleeding gums and gingival inflammation\[^{22}\].

**Garlic (Allium sativum):** Garlic is effective in reducing the tooth ache when crushed and applied on the tooth surface due to Allicin constituent \[^{23}\]. Also it strengthens the immunity and helps to fight against many diseases. It decreases blood pressure and cholesterol level and has a blood thinning property thus enhances the effect of antiplatelet drug and NSAIDS by inhibiting the prostaglandins production.\[^{24}\]

**Tumeric/Curcumin oil (Curcumin longa):** Turmeric is one of the beneficial herbs used from ancient times. It has constituents like monoterpenes, sesquiterpenes, zingiberene, curcumin, α- and β-turmerone. These constituents are also known as curcuminoids. It has various therapeutic actions and act as strong antioxidant, analgesic, anti-inflammatory agent by reducing histamine level. It also has antifungal, antiseptic, and anticarcinogenic properties. Studies have reported that turmeric can inhibits metastasis of melanoma cells and deactivates the carcinogens in chronic smokers.\[^{25}\]. Massaging roasted turmeric over the aching tooth reduces the pain and swelling. Combination of powdorof turmeric, cloves, and dried leaves of guava is used as a mouth rinse can reduce the tooth pain. Paste mixture of turmeric, salt and mustard oil when massaged over the gums, provides relief from periodontitis and gingivitis\[^{26}\].

**Jasmine (Jasminum grandiflorum):** Leaves of jasmine has antiulcer and antioxidant property which can be used in treatment of ulcerative stomatitis and other oral ulcers. \[^{27}\]

**Oral Care Practices in Ayurveda:**

**Dantapavan/Dattuna (Chewing stick for brushing):** Removal of plaque from the tooth surface helps in maintaining proper oral hygiene and prevents gingival and periodontal diseases. According to Sushruthasamhitha, chewing Dattuna (herbal sticks) in the morning after a meal provides anticariogenic and antibacterial property. A soft and healthy stem of the herb without knots and leaves is recommended for use. The soft part of the Dattuna is used as brush and it is chewed. After brushing the stick is torn and used as for tongue scapping. These herbal sticks are 9inches longer and thickness of a little finger. Advantages of using herbal brushes are low cost and various medicinal properties. Ayurveda recommends that the chewing sticks must be obtained from stems of specific plant which should have astringent (kashaya), bitter taste (tikta), pungent (katus) \[^{28}\].

**Pratisarana/Gingival Massage:** It is done with paste/combination of herbal powder/herbal oil. Commonly used powders in pratisarana include kushta (herb) with other herbs of Triphala, Trikatu, Trijata and oils used are mustard oil, triphala oil and turmeric oil. Massaging with turmeric oil can reverse precancerous changes in oral submucous fibrosis. Curcumin, an essential ingredient of turmeric has various therapeutic effects. \[^{29}\] Cikrikci et al., has reported that a combination of turmeric, salt and mustard oil when massaged on the gingiva and gums have showed improvement results in gingivitis and periodontitis.\[^{30}\]

**Kavala and Gandusha (Gargling):** In Ayurveda, Kavala and Gandusha are depicted as Dincharya, which means a daily regimen that is useful in preventing oral diseases. Gandusha means loading of medicinal oil or medicated oil inside the oral cavity for few minutes till there is uncontrollable salivation or lacrimation from eyes or mucosal discharge from nose. Kavala means holding a small quantity of medicated liquid inside
the oral cavity for few minutes followed by swishing, gargling and spitting out. This practice aids in preventing oral malodour, gum bleeding, oral ulcers, xerostomia, cracked lips and also helps to strengthens gums and teeth. The mechanism by which the oil pulling therapy causes plaque reduction is not known but it is suggested that viscosity of the oil inhibits bacterial adhesion and plaque co-aggregation on tooth surface. Other possible mechanism proposed was by saponification or the ‘soap-formation’ process that occurs as a result of alkali hydrolysis of fat. Emulsification enhances the surface area of the oil there by increasing its cleansing action. Commonly used oil for gandusha is sesame oil, coconut oil, sunflower oil and olive oil. Gargling with salt water or adding of fennel or peppermint to water has beneficial effects against gingivitis, periodontal disease and reduces the swelling abruptly.

Practicing Gandusha exerts an increased mechanical pressure inside the oral cavity which stimulates presso-receptor (stretch reflex) that are present in the mouth. Once these receptors are stimulated, they send signals to salivary nuclei in the brain stem (pons and medulla). As a result, there is an increased parasympathetic nervous activity which triggers motor fibre of facial (VII) and glossopharyngeal (IX) nerve increasing the salivary output and exerts an anticariogenic effect. Benefits of practicing gandusha are feeling of freshness, good cleansing effect and improved perception of taste and sense organs. A study on oil pulling with sesame oil has reported reduced incidence of gingival and plaque index and reduces count of aerobic bacteria causing plaque induced gingivitis.

Jivanirlekhana/Tongue Scraping: Jivanirlekhana is performed after brushing the teeth. It is done either with gold, silver, copper, stainless steel tongue cleaner with blunt end. This helps in removing numerous bacteria residing on the tongue causing halitosis and also improves taste sensation, proper oral hygiene and enhances digestion by stimulating reflex points and secreting digestive enzymes.

Conclusion

Ayurveda has been used from ancient years and has provided comprehensive and downright approach to various diseases. Our country is bound with enormous herbs and plant materials but still it’s usage in dentistry is not much implemented and practiced. Awareness is the need of the hour towards effectual application and implementation of ayurvedic practices. By integrating traditional ayurvedic formulation with modern dental practices, various oral diseases can be prevented and also can be made economically affordable to lower socioeconomic groups in the society.

Implant Surgery: What Can Go Wrong?

Vijay Ebenezer

Professor and Head of the Department, Department of Oral and Maxillofacial Surgery, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

Abstract

Implant surgery complications are frequent occurrences in dental practice and knowledge in the management of these cases is essential. The aim of this review was to highlight the challenges of treatment plan-related, anatomy related, and procedure-related surgical complications as well as to discuss the etiology, management and treatment options to achieve a satisfactory treatment outcome. (Implant Dent 2008;17:159–168).

Keywords: Dental implants, implant complications, implant failures.

Introduction

Surgical complications during implant placement are not uncommon. According to a retrospective study by McDermott et al, 1677 patients (2379 implants) were investigated, and an overall frequency of complications was 13.9%. Operative complications made up a mere 1% of the overall, whereas inflammatory and prosthetic complications were 10.2% and 2.7%, respectively.

A. Planning complications.

1. Lack of a Proper History: Well organized, thorough treatment plans lead to successful implant treatment and patient satisfaction, which are the ultimate long-term goals. Patient selection is one of the most important determinants of success or failure. Predictability of implant success can be jeopardized by absolute and relative risk factors. Therefore a complete medical record and patient analysis post treatment play a significant role.

2. Errors in Angulation: Implant angulation is yet another determinant for implant success. Proper angulation should be determined according to the future prosthesis with the consideration of buccolingual, apicocoronal, and mesio-distal positions. Surgical guides can help control the implant placement angle if they are made and used correctly.

Mandibular teeth in the natural dentition are lingually inclined in relation to both the mandibular base, specifically as 109 degrees, as well as the maxillary opposing arch dentition (eg, lingual cusp buccal inclination) and therefore implants should be placed at a similar inclination. Failure to do so may result in perforation of the lingual concavity, constriction of the lingual space or damage of the lingual artery.

Teeth adjacent to implant sites and surgical guides with long drill channels, often require the use of drill extensions and maximum opening by the patient which may be strenuous. Short breaks to relieve muscle tension, using a bite block and having the patient shift their jaw to the opposite side can help ensure the correct angulation of the drill. Yet another issue is the finger placement. Due to the length of implant drills (~10#20 mm), using a finger rest while drilling, results in an inclination of the drill towards the hand that is steadied. Hence, using finger rests is an ergonomic principle that should not be used for implant placement.

e-mail: drvijayomfs@yahoo.com
3. Improper Implant Location: It should be ensured that the implant body is 1.5mm from the adjacent teeth and 3-4mm between adjacent implants. Preoperative measurements and planning are essential to achieve an ideal implant placement that facilitates future implant prosthesis. Hypothetically, a surgical complication could also occur, but not be realized by the surgeon at the actual time of surgery, especially when placing multiple implants, the one placed the away from an adjacent implant can have adequate stability and function but may later result in lateral bone loss.

4. Communication Failures: An informed consent form is an excellent way of communicating potential surgical risks and complications to a patient. Common problems to address include but are not limited to postoperative infection, bleeding, swelling, facial discoloration, transient pain, paresthesia, neuralgia, fracture, joint pain, muscle spasm, tooth looseness and sensitivity, recession, speech change, trismus, and swallowing of foreign objects. Should a complication occur during the post operative healing time, it is recommended to give emergency contact information as well.

B. Anatomical Complications:

1. Nerve Injury: When placing implants in the mandible, proper radiographs and pretreatment planning must be done to ensure complete aversion of the inferior alveolar, mental, incisive or lingual nerves. If the mandibular canal cannot be seen on a panoramic radiograph, a computer tomography (CT) scan should be taken to verify the location. Possible causes of nerve injury include poor flap design, traumatic flap reflection, accidental intraneural injection, traction on the mental nerve in an elevated flap, penetration of the osteotomy preparation and compression of the implant body into the canal. Radiographs should be taken if the surgeon has any doubt about where the drill is or if the drill or implant is in close proximity to or invading, neural anatomical structures. If the situation is the latter, the implant needs to be removed, or a shorter body implant should be placed instead. Within days or months, minor trauma injuries usually heal but permanent damage from neuritis can occur. Treatment options include neuronal anti-inflammatory drugs such as clonazepam, carbamazepine or vitamin B-complex.

2. Bleeding: Risk sites as described above in the posterior mandible include the sublingual fossa and lingual cortex. Life-threatening airway obstruction is a serious threat and early treatment is essential. Treatment involves having the patient stick out their tongue to compress the blood vessels against the body of the mandible. Placing pressure with gauze in the sublingual area does not work as one would intuitively think. Extraoral pressure to the submental or submandibular arteries for 20 minutes against the body of the mandible helps. The posterior superior alveolar and infraorbital arteries are located approximately 19 mm above the maxillary alveolar ridge, and the anastomoses of these arteries can pose a risk during sinus lift procedures by lateral window preparation. Bone wax, pressure, crushing, and electrocautery can alleviate hemorrhage. In summary, hemorrhage treatments at implant osteotomy sites include compression, finger pressure, vasoconstriction, cautery, bone graft, bone cement, and ligation of arteries.

3. Cortical Plate Perforation: The buccal cortical plate varies in thickness throughout the mouth and traumatic dental extractions can cause markedly thin plates or concavities, as well as overall ridge width deficiency. When preparing osteotomy sites or placing implant fixtures in areas with minimal labial plate thickness, or if the implant is placed too buccally, a fenestration or dehiscence implant defect is a common finding. Immediate correction with particulate bone grafting with or without a membrane during the time of implant placement, can be done as long as primary stability has been achieved. “Flapless” implant surgeries should be avoided in areas of potential perforation of the buccal or lingual bone.

4. Sinus Membrane Complications: Sinus complications often occurred when the membrane is perforated at time of surgery. Bone density after grafting should be assessed, regardless whether or not a perforation occurs, because poor bone quality often lead to a higher implant failure rate. Lastly, losing an implant into the maxillary sinus is a relatively uncommon surgical complication. However, in cases with less than 5 mm of bone, mastication can cause the implants to move during the graft maturation timeframe.
endoscopic surgery is a reliable, minimally invasive method for retrieving displaced objects from the maxillary antrum with minimal complications, but it does require having an endoscope or a referral to an ENT or oral surgeon.

C. Procedure Related

1. Mechanical Errors: Dense cortical bone (eg, type I bone quality), when compared with type III or IV soft cancellous bone, can be overheated when preparing osteotomies because more pressure is needed to advance the drill apically in comparison to soft bone. To reduce frictional heat, high speed handpieces, an up-down motion technique of the bone preparation, and copious irrigation can be used. According to Quirynen et al, 55 overpreparation or overheating osteotomies can result in inactive and active retrograde peri-implantitis lesions that can be detected on radiographs as periapical radiolucencies up to a month after insertion.

2. Lack of Primary Stability: It should be dealt with at the time of implant surgery. An unstable implant should be removed or an attempt to place a larger diameter should be completed. To leave an unstable implant without action can often lead to fibrous encapsulation that causes implant failure.

3. Mandibular Fracture: The mandible is the most frequently fractured facial bone. Attempts to place implants in patients with severely atrophic mandibles increases the risk of fracture, especially when monocortical grafts and ridge-splitting surgeries are completed. A fracture of the mandible should be restored to maintain form and function. Management should include stabilization with an attempt to also simultaneously eliminate atrophy if indicated. The most relevant option of our field includes combined bone augmentation, fixation and simultaneous implant placement. Increasing mandibular height after augmentation may be unpredictable but using implants concurrently may reduce bone resorption.

4. Aspiration and Ingestion: Most instruments have a special tip to help ensure screws and abutments transfer directly from the surgical tray into the patient’s mouth, but nevertheless, accidents happen. For these reasons, preventative measures such as gauze throat screens and floss ligatures on implant pieces are encouraged. If a patient swallows or aspirates an implant component, they should be referred to the hospital because acute obstruction can be life threatening and prolonging the removal of foreign objects may make a bronchoscopy technically more difficult. If the foreign object is aspirated it should be removed within 24 hours.

Conclusion

Surgical implant complications are not uncommon and should be addressed immediately. Causality may be iatrogenic, due to poor treatment techniques, or lack of communication between dental disciplines. Time should be spent in the implant “planning” stages, such as tracing preoperative radiographs, measuring models, taking CT scans and making proper surgical guides. Basic anatomy must not be forgotten and should be reviewed by the surgeon in every case. As more surgically inexperienced dental professionals start placing implants an increase in surgical complications will likely occur. In summary, a competent surgeon should be able to treatment plan a predictable surgery, and recognize how to remedy a problematic dental-implant situation.

Peri-Implantitis: Effective Treatment Regimens

Vijay Ebenezer

Professor and Head of the Department, Department of Oral and Maxillofacial Surgery, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

Abstract

Peri-implantitis is a site-specific infectious disease that causes an inflammatory process in soft tissues, and bone loss around an osseointegrated implant in function. The etiology of the implant infection is conditioned by the status of the tissue surrounding the implant, implant design, degree of roughness, external morphology, and excessive mechanical load. Treatment will differ depending upon whether it is a case of peri-implant mucositis or peri-implantitis. This review article deals with the various treatment options in the management of peri-implantitis.

Keywords: Dental implant, peri-implantitis, peri-implant mucositis.

Introduction

Peri-implantitis is an inflammatory process resulting in loss of supporting bone whereas peri-implant mucositis has been defined as a reversible inflammatory change of the peri-implant soft tissues without bone loss (Albrektsson & Isidor 1994). These two descriptions of inflammation around implants are congruent with inflammation around natural teeth. The development of an adherent layer of plaque (of the biofilm) on the implant seems to be critical to the development of peri-implant diseases and could possibly be responsible for altering the biocompatibility of implant surfaces. The concept that bacteria play a major role in the etiology of peri-implant mucositis and peri-implantitis is well documented in the literature of implants. Peri-implant diseases have been associated with a predominantly Gram-negative anaerobic microflora (Pontoriero et al. 1994, Augthun & Conrads 1997, Salcetti et al. 1997, Mombelli & Lang 1998, Leonhardt et al. 1999, Quirynen et al. 2002, 2006). Reduction of the bacterial load to a level allowing healing is difficult to accomplish with mechanical means alone. Therefore, adjunctive therapies like antibiotics, antisepsics and laser treatments have been proposed in order to improve the non-surgical treatment options of periimplant mucositis and peri-implantitis. The following signs and symptoms are typical for peri-implantitis lesions: radiological evidence of vertical destruction of the crestal bone. There is usually a saucer shaped defect and there is osseointegration of the apical part of the fixture; vertical bone destruction associated with the formation of a peri-implant pocket; bleeding and suppuration on probing; possible swelling of the peri-implant tissues, and hyperplasia. Pain is an unusual feature, which, if present, is usually associated with an acute infection. The diagnosis of peri-implantitis needs careful differentiation from peri-implant mucositis, primary failures to achieve tissue integration, and problems lacking an inflammatory component. The diagnostic parameters used for assessing peri-implantitis include clinical indices, using a rigid plastic probe for peri-implant probing, bleeding on probing (BOP), suppuration, mobility, peri-implant radiography, and microbiology.

Management Modalities of Peri-Implantitis:

1. Local Debridement: The implant should be cleaned by instruments softer than titanium, such as polishing with a rubber cup and paste, floss, interdental
brushes, or using plastic scaling instruments\textsuperscript{2}. These have been shown not to roughen the implant surface unlike metal and ultrasonic scalers. Sub-mucosal debridement alone, accomplished by utilizing either an ultrasonic device or carbon fiber curettes, is not sufficient for the decontamination of the surfaces of implants with peri-implant pockets $\geq 5$ mm and exposed implant threads. So it seems reasonable to suggest that mechanical or ultrasonic debridement alone may not be an adequate modality for the resolution of peri-implantitis.

2. Impant Surface Decontamination:

Four Method were Experimented:

1. Air-powder abrasive technique followed by citric acid application
2. Air-powder abrasive technique
3. Gauze soaked in saline followed by citric acid application
4. Gauze soaked alternately in 0.1% chlorhexidine and saline.

Photodynamic therapy is a non-invasive method that could be used to reduce microorganisms in peri-implantitis.\textsuperscript{16} 2\% chlorhexidine or 3\% hydrogen peroxide can be used as topical antiseptics. Decontamination of affected implants with titanium plasma-sprayed or sandblasted/acid-etched surfaces may most easily and effectively be achieved by applying gauze soaked alternately in chlorhexidine and saline\textsuperscript{3}.

3. Anti-infective Therapy: The study by Schwarz et al. demonstrated that the treatment of peri-implant infection by mechanical debridement with plastic curettes combined with antiseptic (0.2\% chlorhexidine) therapy may lead to statistically significant improvements in bleeding on probing\textsuperscript{4}, peri-implant probing pocket depth, and clinical attachment level at 6 months compared with baseline. Patients suffering from localized peri-implant problems in the absence of other infections may be candidates for treatment by local drug-delivery devices. Local application of antibiotics by the insertion of tetracycline fibers for 10 days\textsuperscript{5} can provide a sustained high dose of the antimicrobial agent precisely into the affected site for several days. The use of minocycline microspheres as an adjunct to mechanical therapy is beneficial in the treatment of peri-implant lesions, but the treatment may have to be repeated.

4. Surgical Technique: Surgical resection is generally confined to implants placed in non-aesthetic sites.

A randomized comparative clinical trial by Romeo et al.\textsuperscript{7} concluded that resective surgical procedures coupled with implantoplasty could have a positive influence on the survival rates of rough-surfaced implants. The study by Schwarz et al. demonstrated that both nanocrystalline hydroxyapatite and guided bone regeneration provided clinically significant improvements in clinical parameters following 6 months of non-submerged healing.\textsuperscript{8} The application of the combination of natural bone mineral and collagen membrane seemed to correlate with greater improvements in those clinical parameters and, hence, was associated with a more predictable and enhanced healing outcome.

Discussion

The long-term success of oral implants depends on the maintenance of healthy tissue around them\textsuperscript{8}. Periimplantitis is a plaque-induced progressive marginal bone loss. It is observed on radiographs of implants that are surrounded by soft tissues exhibiting clinical signs of inflammation. Roos-Jansaker and colleagues reported periimplantitis rates of 16 percent for machined implants, with higher rates expected for roughened implants. Peri-implantitis is progressive, and studies with multiple-year follow-up are required to determine whether treatment is successful. Researchers have proposed different treatment strategies for this condition, including mechanical debridement techniques with or without local or systemic antibiotic therapy, resective surgery, grafting techniques and implant polishing.

Conclusion

Prognosis of the affected implant will be contingent upon early detection and treatment of peri-implant mucositis and peri-implantitis. Even though the studies dealing with different treatment modalities of peri-implantitis are not comparable, an overall picture of some clinical improvement emerges with the use of anti-infective therapies, in terms of resolution of inflammation and bone healing. This observation, coupled with our knowledge of the indisputable role of periodontal pathogens in the etiology of peri-implantitis, indicates that some form of anti-infective therapy must be coupled with any other strategy for dealing with this problem.

Short Implants: A New Solution in Rehabilitation

Vijay Ebenezer

Professor and Head of the Department, Department of Oral and Maxillofacial Surgery,
Sree Balaji Dental College and Hospital, BHARATH University,
Chennai-600100, Tamil Nadu, India

Abstract

Insufficient alveolar bone height is a common clinical situation encountered more in the posterior jaws. Advanced surgical procedures such as bone grafting, sinus lifting, and nerve repositioning are required to overcome this condition and make implant treatment possible for such patients. Short implants are considered as a viable alternative in patients with reduced alveolar bone height to avoid more invasive surgical procedures. They simplify the implant treatment, reduce patient morbidity, shorten the duration of treatment, and make it less expensive. With the improvements in the surface topography of implants, which increase the bone implant contact, and use of adapted surgical protocols similar survival rates as that of regular implants have been reported even with short implants.

Keywords: Bone grafting, bone implant contact, short implants, viable alternative.

Introduction

Quality of life in adults can be highly affected by tooth loss as a consequence of compromised oral function, loss of social status and diminished self-esteem [1]. The oral rehabilitation using implants has a positive implication in the reestablishment of all these factors that affect the life of patients. Oral implant placement also provides a more comfortable and aesthetical treatment option for partial and complete denture wearers, being widely accepted by patients as an efficacious method for replacing missing teeth [2, 3]. Multiple tooth extractions induce a considerable reduction in bone height, mainly in the posterior jaws [4]. In the maxilla, the absence of teeth promotes sinus pneumatization and consequently vertical bone loss [5], whereas the presence of the inferior alveolar nerve in atrophic mandibles limits the length of implants [6]. Therefore, the rehabilitation of edentulous posterior regions using implants becomes complex when severe ridge atrophy is presented. Rehabilitation with implants should be simple, cost effective, highly predictable, and of shorter duration. Short implants are considered as a viable alternative in patients with reduced alveolar bone height to avoid more invasive surgical procedures [2-4]. With the improvements in the surface topography of implants and use of adapted surgical protocols similar survival rates as that of regular implants have been reported even with short implants [5].

Rationale for opting short implants: When stress is applied to the natural tooth, it is distributed in to the underlying bone along the entire root length due to the presence of periodontal ligaments as the tooth tends to pivot around the center of the root. However in case of implants, where periodontal ligament is absent, the greatest magnitude of stress concentration is seen at the crest which tapers apically up to 5 mm from the crest. Stress concentration in the apical region is much less. [6] A basic mechanical principle states that when two materials of different moduli of elasticity are placed together with no intervening material and one is loaded, the stress concentration can be observed where the two materials first come into contact [7].

Increase in implant length will increase the total surface area of the implant and improve the primary stability by increasing the bone implant contact (BIC).
But the area that transfers the compressive and tensile loads to bone that is, functional surface area (FSA) is confined to the crestal 5-7 mm. Increasing the length of the implant will not change this where as a short implant with a wider diameter provides both, improved primary stability and increased FSA.[8]

Advantages of short implants: The main advantage of using short implants is that it simplifies the implant surgery by avoiding the more invasive procedures like bone grafting, sinus lifting, nerve repositioning, etc., and thus decreases morbidity and reduces the healing period. Advanced imaging modalities may not be required which will reduce the radiation exposure. Patient acceptance will be more as it avoids the need for complicated surgeries, reduces the duration of treatment period and cost. The poor quality of bone in the posterior region, especially in the maxilla, where short implants are mostly used is another contributing factor.

The following factors are important in the success of short implants:

1. Implant diameter
2. Surface topography
3. Macro geometric design
4. Bone density
5. Photofunctionalization of implants
6. Biomechanical method for stress reduction

Implant Diameter: An increase in the diameter reduces stress at the implant neck and is associated with good distribution of force compared with increases in implant length.[9] Implant strength and fracture resistance can be improved by increasing the diameter of the implant. Wider implants also facilitate the creation of a better emergence profile, especially in the posterior segment. An increase in diameter by 1 mm will increase the surface area by 30–200% depending on the implant design.[10]

A three-dimensional FEA demonstrated that increasing the implant diameter resulted in a 3.5-fold reduction in crestal strain, whereas increasing the implant length resulted in only 1.65-fold reduction in crestal strain.[11]

If wider implant cannot be placed, each molar can be supported with 2 short implants, thereby increasing the FSA.

Surface Topography: The fact that alteration of the implant surface can influence the success of osseointegration has been proven in various studies.[12-14] Rough implants offer extensive area for osseointegration. It increases the BIC and FSA in addition to improve the wettability of the implant surface.

Macro Geometric Design: Increasing the diameter is a logical option for increasing the surface area of short implants. But there is an anatomical limit to how much the diameter can be increased. Increasing the number of threads per unit area (decreased thread pitch) and increasing the thread depth also enhance the FSA of short implants.

Bone Density: Bone density is directly proportional to its strength. Less dense bone may demonstrate a reduction of its strength by 50-80% compared to higher density bone. Poor bone quality is strongly linked to higher failure rates in implants.[15] Increased failure rates of short implants in the early trials were attributed to the use of machined implants in poor quality bone, especially in the posterior maxilla. This negative effect is somewhat dampened by rough surfaced implants now. A two-stage implant placement approach was suggested by Gentile et al.

Photofunctionalization of Implants: Treatment of implants with ultraviolet (UV) light has been found to increase the BIC from 55% to near maximum level of 98.2%. This resulted in 3-fold increase in the strength of osseointegration.[16-18] A recent human study has demonstrated the effectiveness of photofunctionalization in complex cases using short implants with lesser diameter.[19] It allows for the placement of short implants in the alveolar ridges which are not wide enough to allow the placement of larger diameter implants.

Discussion

During oral rehabilitation of atrophic areas, the avoidance of bone augmentation procedures reduces discomfort, treatment time and costs for the patient. All these factors make the placement of short implants an attractive choice of treatment for both patient and clinician if the success rates are not substantially decreased. Short implants (≤7 mm) had a survival rate similar to longer implants placed in the augmented bone area after oneyear post-loading, however, the marginal bone loss at short implants sites was lower than the longer implants sites. Placement of short implants is a predictable alternative for the rehabilitation of atrophic
posterior regions, avoiding all the disadvantages intrinsic to bone augmentation procedures.

**Conclusion**

Insufficient alveolar bone height for implant placement is a commonly seen problem in the posterior jaws. Traditional way of overcoming this difficulty is by undergoing adjunctive surgical procedures. Though they are proven to be successful, these procedures result in delayed healing, increased morbidity, and prolonged treatment period. Short dental implants have been successfully used in such situations with comparable survival rates with that of longer implants. Various method to increase the surface area and BIC along with the stress reduction to the implant prosthesis have made short implants a viable and more predictable alternative to advanced surgical interventions.

Superior Orbital Fissure Syndrome: A Review of Literature

Balakrishnan¹, Vijay Ebenezer²

¹Professor, ²Professor & HOD, Department of Oral and Maxillofacial Surgery, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

Abstract

Superior orbital fissure syndrome is a complex of cranial nerve impairment that affects the CN III, IV, V and VI all of which enters the orbit through the superior orbital fissure. Superior Orbital fissure syndrome occurs as a result of compression of all or some of these nerves passing through the fissure. Three major factors contributing to the syndrome includes traumatic injury, neoplasm and inflammation. This article takes into account the various data previously reported in literature and aims at providing a detailed knowledge about the anatomy of the superior orbital fissure to provide a better understanding about the syndrome.

Keywords: Superior orbital fissure, trauma, cranial nerve.

Introduction

Superior orbital fissure syndrome is a very rare complication occurring as a result of craniomaxillofacial trauma which was first described by Hirschfeld in 1958[1]. Later in 1896, Andre Rochon Duvigneaud a French ophthalmologist considered the syndrome as a pathological entity and presented a report on the syndrome in four syphilis patients[2]. Other etiological factors that results in SOFS due to either compression of SOF contents or un natural narrowing of the SOF includes vascular disorders[3] like spontaneous aneurysms of the Internal carotid artery; neoplasm in cavernous sinus or the orbital apex like meningioma, pituitary gland tumours; inflammation in the orbital apex and cavernous sinus thrombosis can also attribute to the development of SOFS[4].

Anatomy of the Superior Orbital Fissure: The boundaries of the superior orbital fissure are as follows:

Laterally – Greater wing of sphenoid bone
Medially – Lesser wing of sphenoid and
Superiorly – Frontal bone

The superior orbital fissure lies at the orbital apex and at the border between the orbital roof and the lateral orbital wall. It serves as a pathway between the orbit and the middle cranial fossa. The shape of the fissure looks like an elongated pear with its broader part at the nasal side medially to the apex laterally with the long axis extending upward at a 45 degree angle. The size of the fissure in an adult is around 22mm in length, 2 to 3mm width at the apex and about 7 – 8 mm at the base[5]. The tendon of the lateral rectus muscle divides the tissue into two parts: the superior and inferior part. The superior part contains the trochlear nerve (IV), frontal and lacrimal branches of the ophthalmic division of the trigeminal nerve and the superior branch of the ophthalmic vein whereas the inferior part contains the superior and inferior branches of the oculomotor nerve(III), abducens nerve (VI), nasociliary nerve(V) and the inferior branch of the ophthalmic vein. All these structures are confined within the tendinous ring making them more susceptible to shearing injury during craniomaxillofacial trauma.

Clinical Signs: Superior orbital fissure syndrome presents with the following signs

- Paraesthesia – loss of sensation over the forehead, cornea, upper eyelid and bridge of the nose
resulting from the compression of the ophthalmic division of the trigeminal nerve involving the supratrochlear and supra orbital branches. There might also be lacrimal hyposecretion and possibly retro orbital pain along the path of the nerve[6].

- External ophthalmoplegia – it is the slowly progressive paralysis of extra ocular muscles that develops secondary to the transmission blockade of the oculomotor, trochlear and abducent nerves. Patients also will typically present with ptosis as a result of loss of tension and loss of function of the levator palpebrae superioris muscle and loss of tone in sympathetically innervated mullers muscle.

- Proptosis – prolapse of the globe anteriorly out of the orbit as a result of loss of extraocular muscle tone or retrobulbar hematoma or ophthalmic vein compression[7,8].

- Ptosis- Drooping of the upper eyelid because of loss of tension and loss of function of the muscle levator palpebrae superior and loss of tone of mullers muscle.

All of these clinical signs present in various degree depending upon the severity of injury and stage of healing. CN III,V and the nasociliary nerve passing through a tendinous ring are more susceptible to compression injuries than the other contents of the superior orbital fissure. Complete/partial involvement of these three nerves is indicated by the term “partial superior orbital fissure syndrome”. In SOFS the optic nerve and the vision is usually unaffected; if the optic nerve gets involved and if there is a subsequent compromise of vision the condition is termed as “orbital apex syndrome” coined by kjaer[9].

Radigraphic Considerations: Diagnosis is usually based on the clinical symptoms and radiographic examination. However a plain film cannot be obtained in case of severely traumatized patients. In such patients Caldwell projection[10] is used which is a 20 – 25 degree tilt of the head that facilitates optimal projection of the superior orbital fissure.

CT scan serves as an excellent tool for the diagnosis of SOFS. CT slices of 2mm thickness are usually recommended for visualization of any compression around the fissure. The development of new spiral CT serves as a promising tool for improving the accuracy of a radiographic diagnosis by providing clear details of the SOF in axial and coronal projection without the need for neck extension.

Treatment:

**conservative/medical management**
- Observation until complete recovery of sensory and motor function
- Steroid therapy
  - A. Dexamethasone 4mg Q6H
  - B. Loading dose of 1mg/kg dexamethasone followed by 0.5mg/kg Q6H
  - C. Megadose steroid with methylprednisolone 30kg IV loading dose followed by 15mg/kg Q6H for 3days

**surgical intervention**
- Only in cases of comminuted fracture + optical atrophy
- Four routes for decompression
  - A. Extra nasal-intraorbital
  - B. Modified Extra nasal-intraorbital
  - C. Extra nasal Tranethmoidal
  - D. Tran temporal
Conclusion

Therefore the treatment plan for various cases will differ from case to case and a tailormade treatment has to be given. Certain cases will require conservative approach and some will require a surgical approach. It also depends on the choices made by the doctor or surgeon, for there is the famous phrase “The only good surgeon is a surgeon who knows when not to touch the knife”.

Tissue Repair in Maxillofacial Region

Balakrishnan¹, Vijay Ebenezer²

¹Professor, ²Professor & HOD, Department of Oral and Maxillofacial Surgery, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

Abstract

The region of face is the most aesthetic part of the body and one of the most important parts of the personality of a person. Thus trauma or congenital defects resulting in aesthetic defects in the face are a huge problem to a person’s confidence. Over the decades, craniofacial plastic surgeons, maxillofacial surgeons and aesthetic surgeons have struggled to administer the best possible treatment to achieve near absolute aesthetic results. This also is dependent on the material used as a graft to fill the void in the defect. This article aims to review various articles and find out the efficacy of the various materials used for graft.

Keywords: Tissue repair, tension, scar, wound closure.

Introduction

The face is the most important means of communication and not only in term of verbal communication. The principal aim of the maxillofacial reconstruction still remains to avoid or to repair gross aesthetic disfigurement in cases of congenital malformation, tumor resection, post traumatic deformities. In addition to facial aesthetics, maxillofacial reconstruction also has important functional aspect in the reconstructive measures strive for the institution of the complex functions of the upper oro-digestive tract.

Methodology:

Pubmed database was searched for the keywords “Tissue repair” “Maxillofacial trauma” “Maxillofacial reconstruction” 40 articles were found.

Out of the 40 articles, the non dental articles were excluded to get 38 articles.

The duplicates were excluded to get 31 articles

Discussion

Tissue repair, management of surgical or traumatic soft tissue wounds is an important precondition for successful plastic reconstruction because adequate skin coverage of the reconstructed part is mandatory and access to deeply situated structures has to pass through the skin surface. Closure of a skin¹ wound generally should be accomplished without tension. Lines of minimal skin tension running across the face in a well-known pattern which represents adaptation to two different types of functional mechanisms; The first type is represented by the lines of habitual expression in the face the second type, the lines of skin relaxation (such as circular lines in the neck). A scar within or parallel to the lines of minimal tension is not subjected to the intermittent pull of sub adjacent muscle and subsequent widening of the scars from tension.

A tissue graft² is defined as a portion of tissue removed from one side and placed at another, either in the same or in another individual, in order to repair a defect caused by operation, accident or disease. The autografts reflects the traditional way of solving surgical problem, namely success obtain mainly through pragmatic approach. Allograft³, because they present problem of immunology, vitality, remodeling and storage. Have demanded a more extensive scientific study using animal to achieve some clinical success (BURWELL 1994).
Clinical uses and function of bone graft: Bone graft is used to provide a bridge of osteogenic tissue. The condition which surgeons are called to treat bone grafting include:

1. The delay and non-union of fractures
2. The arthrodesis of joint.
3. The filling of cavities in bone
4. The replacement of bone and joint loss
5. The augmentation of skeleton deficiency in the face.
6. The fusion of bone growth plate cartilages.

Autografts: The autogenous bone graft has several advantages over allo- or xenograft. It has greater osteogenic capacity and is biocompatible. As the autograft resorbs, revascularization recruits mesenchymal cells differentiates as osteogenic, chondrogenic or other cell lines (BROWN & CRUESS). The high osteogenic potential of cancellous bone derives from the bone marrow it contains, and the marrow part as such can be used to induce bone growth into different porous materials (NAD et al. 1983). The cancellous graft is moldable and resistant to infection. It vascularize fast and can be obtained quiet easily, usually as ‘chips’ from the iliac crest (BURWELL, 1966). Unfortunately the amount of cancellous bone is limited moreover, it cannot be used in stress bearing area, and harvesting causes morbidity such as pain, hematoma, infection, nerve injury (BANWART et al 1995) or even iliac hernia or ureter injury (CHARLES et al 1975); (ESCALIS & DEWALT 1977). Major complication rate is 8.6%, minor complication 20.6% (YOUNGER & CHAPMAN 1989).

Cortical bone is used when mechanical support is needed. Common donor site used to be fibula, ribs and iliac crest. Unfortunately to biocompatibility of the compact bone is poorer than the cancellous bone. Microvascular graft has overcome some of the drawbacks associated with the reconstruction of some of the large defects. Large cortico-cancellous grafts can be harvested with their nutrient vascular pedicle allowing the vessel to be anastomosed to suitable artery and vein in the recipient site. The healing takes place in the interface of graft and recipient bone as in the normal bone situation(WEILAND et al 1984). Donor site complication may however be more severe because the graft tends to be very large.

Allograft: The known limitation of autografting example secondary operation, limited availability of bone and operation morbidity, have encouraged the search for other option. The natural choice is allograft bone, human bone, usually harvested from a dead person or obtained in a hip fracture. The basic concept underlying allograft bone use was established in the early 1990’s (BASCHIRZE V & PETROV) showed that most of the cell components in the graft after transplantation and that bone regeneration starts from the host bed (1992)

Allografts demonstrate a lower osteogenic capacity, higher resorption rate and larger immunogenic response and less revascularization of the grafts than autograft (CHASE & HERDON, 1955; FRIEDLANDER et al, 1978). Despite of these drawbacks allograft offers a useful adjunct to the range of bone graft material. Bone can be minced and mixed with autogenous grafts in spinal fusion or hip prosthesis surgery’s (BURWELL, 1966). Allograft bone can even be used for large grafts comprising whole joints in tumor surgery. The results however are somewhat contradictory(AHO et al, 1998). To maintain the availability of the allograft bone, a well organized bone bank is needed (TOMFORD et al, 1987). The possibility of transmitting viruses may limit the use of allograft (BUCK & MALIN, 1994; KHAN et al 1998).

Xenografts: The xenogenic bone graft, that is a graft made with bone from another species, presents similar problem as that of allograft. It elicited acute antigenic response with high failure rate. Partial deprotonations and defatting have been demonstrated to increase the antigenic response (KIEL BONE) at the cost of osteoinductive capacity. They are indeed rarely used.

Demineralized bone, decalcified bone was first studied in the rat in 19th century, when it was mainly used for filling cavity’s in osteomyelitis operation (SENN,1889). It is manufactured in a process whereby first the bone marrow is removed, then the bone is defatted and then finally the mineral contents are decalcified with hydrogen chloride leaving the collagen matrix intact. Demineralized bone can be used in powder form, in chips, or in corticancellous form. YUREST & coworkers noted the osteogenic capacity of demineralized bone and latter attributed to the influence of morphogenetic protein. Clinical demineralized bone has been used primarily for craniomaxillary reconstruction (MULLIKAN et al 1951).
The successful transfer of tissue for the closure of defect or repair of a defect depends on the survival of the graft, which in turn depends on the adequate vascular supply. Regarding the vascular supply it may be divided into no vascularized pedicle and vascularized flaps or grafts.

Cartilagerafts\(^3\), unlike iliac bone or rib bone cartilage autograft survive well when in contact with cartilage or other tissues (muscle, fat, fascia) \(\text{PIERIE, 1964}\). Costal cartilage, costochondral graft are widely used for reconstructive surgery. Such, grafts are obtained as living transplant are used for augmenting the external nose, forehead, zygoma, maxilla, mandible, mastoid, auricle and eyelids (\text{GILLIES & MILLARD, 1957}). The perichondrium should be retained when the costochondral graft is used (\text{BREADON et al., 1972}).

Auricular grafts\(^\text{10}\), the uses and limitations of auricular composite autografts to reconstruct the external nose; nasolabial angle and auricle in man have been reviewed (\text{CARLMOUNT & CONLY, 1978}).

**Conclusion**

The term transplantation designates the removal of a colony of living cells from a donor area and its transfer to the recipient site where it is capable of propagating a lineage of living cell. Skeleton tissues are now widely used in surgery as transplant to serve many proposes.

A Review on Role of Tongue in Malocclusion

Kalai Selvi A., K. Gnana Shanmugham, M.S. Kannan

1Post Graduate Student, 2Professor, Department of Orthodontics and Dentofacial Orthopaedics, 3Professor and Head Of Department. Department of Orthodontics and Dentofacial Orthopaedics, Sree Balaji Dental College and Hospital, Pallikaranai, BIHER, Chennai

Abstract

Tongue is the most agile, versatile appendage in the body. It is the largest organ of the oral cavity. Dental arches are enveloped on both the sides by muscular tissues. Tongue alone counteracts various buccal forces exerted by cheek and lip musculature. Precise balance between these forces is utmost importance for normal inter and intra arch relationship. The unstable forces induced by abnormal functions such as mouth breathing, tongue thrust, swallowing and unilateral chewing and abnormal postures of oral circumferential muscles such as forward tongue thrust, tongue biting, low tongue at rest were correlated with varieties of malocclusion. Thus it is necessary for proper understanding of these structures. The purpose of this article is to discuss the role of tongue in malocclusion.

Keywords: Tongue, malocclusion, abnormal posture.

Introduction

The morphology of the craniofacial complex, the dynamics of the stomatognathic system & the arrangement of the dentition is an integrated functioning unit. Muscles are potent force, whether they are in active function or at rest. The teeth & supporting structure are constantly under the influence of the contiguous musculature.

Since long time, role of tongue in malocclusion has been remained controversial. LeFoulon (1839) was the first to propose role of tongue in malocclusion. “When tongue strikes against the upper front teeth, it pushes teeth forward”. Breitner (1942) was the first to highlight the importance of functional equilibrium among the forces of tongue and those produced from action of lips and cheek musculature. Sweet (1948) pointed out that in improper swallowing, tongue thrusts forward against the anterior teeth and hard palate in order to push bolus of food into the pharynx. This thrusting force cause proclination of anterior teeth. Proffit, based on his equilibrium theory, proposed “that duration of force is much more important than magnitude of any force acting on dental or skeletal units”. According to this theory, concept of tongue hitting and moving the anterior teeth forward is not valid but, abnormal posture and position of tongue can definitely cause malocclusion.

Discussion

Development and anatomy of tongue: Tongue, a soft muscular tissue is mainly made of mucosa, muscles and its vascular and nerve supply. The mucosa of body of tongue (anterior 2/3rd) is formed from the first pharyngeal arch and the mucosa of base of tongue (posterior 1/3rd) is formed from the third pharyngeal arch.(fig.1) Skeletal muscles of tongue develops from myoblast that migrate from occipital somites. Tongue starts its development near the end of 4th week of embryonic life. Another important developmental aspect of tongue is it’s contribution for normal development of palate.¹

Extrinsic Muscles

Muscle | Action
--- | ---
Genioglossus | depresses tongue, its posterior fibers protrude tongue
Hyoglossus | depresses and retract tongue
Styloglossus | retracts tongue
Palatoglossus | retracts tongue and draws it up

Basis for possible involvement of tongue in malocclusion: Tongue alone counteracts various buccal forces exerted by cheek and lip musculature. Any disturbance in this delicate equilibrium will lead to instability of dentoalveolar complex.

Buccinator Mechanism: Starting with the decussating fibers of the orbicularis oris the buccinator runs laterally and posteriorly around the corner of the mouth it inserts into the pterygomandibular raphe just behind the dentition. Here it mingles with the fibers of superior constrictor which attaches to pharyngeal tubercle of occipital bone. Thus completely encircling the face.

Lingual pressures are significantly greater during postural rest, deglutition and even little more during maximal effort. Resting pressure appears greater only on the labial aspect of the mandibular incisors. Imbalance in these muscle forces is compensated by metabolic activity within the periodontal membrane through phenomenon of ACTIVE STABILIZATION. According to Garliner, tongue may act as impeding force or as a moving force.

- Impeding force prevent any natural movement of dental units (eg prevent eruption of teeth).
- As moving force, it actually moves the teeth. But again, duration of force (impeding or moving) is more significant than magnitude of force.

Figure 1: Development & Muscles of Tongue
Tongue Movements and Malocclusion: Tongue, a bundle of muscles with a free end, moves in complicated ways. In orthodontic practice, it has been controversial whether abnormal movement of the tongue during improper swallowing induces malocclusion.

1. Infantile (Visceral) Swallow

Characteristics of Infantile Swallow:

- The jaws are apart, with the tongue between the gum pads
- The mandible is stabilized by contraction of the muscles of the 7th cranial nerve & the interposed tongue.
- The swallow is guided, & to a great extent controlled by sensory interchange between the lips & the tongue.

Transition Period: At about the 5 to 6th month of age, as the incisors begin to erupt, certain proprioceptive impulses come into play & the peripheral portions of the tongue starts to spread laterally. An average infant would show a dominant & exclusive thrusting swallow for the first 6 months of life,a transitional thrusting & lateral spread of tongue during the next year & a dominant somatic swallow thereafter.

2. Mature (Somatic) Swallow

Characteristics of Mature Swallow:

- The teeth are together
- The mandible is stabilized by contraction of the mandibular elevators, which are primarily 5th cranial
- The tongue tip is held against the palate, above & behind the incisors. There are minimal contractions of the lips during the mature swallow.

Deglutition Cycle:\textsuperscript{3}

- **Preparatory Swallow:** Starts as soon as liquids are taken in, or after the bolus has been masticated. The liquid or bolus is then in a swallow preparatory position on the dorsum of the tongue. The oral cavity is sealed by lip & tongue.

- **Oral phase of swallowing:** Soft palate moves upward & the tongue drops downward & backward. Larynx & hyoid bone move upward. Smooth path for the bolus as it is pushed from the oral cavity by the wave like rippling of the tongue. Oral cavity is stabilized by the muscles of mastication, & maintains the anterior & lateral seal.

- **Pharyngeal phase of swallowing:** Begins as the bolus passes through the fauces. The pharyngeal tube is raised upward en masse. Nasopharynx is sealed off by closure of the soft palate against the posterior pharyngeal wall. Hyoid bone & base of tongue move forward as the pharynx & tongue continue their peristaltic - like movement of the bolus of the food.

![Figure 2: Infantile & Mature Swallow](image-url)
• **Esophageal phase of swallowing:** Commences as the food passes the cricopharyngeal sphincter while peristaltic movement carries the food through the esophagus, the hyoid bone, palate & tongue return to their original positions

---

**Figure 3: Preperatory Swallow, Oral Phase of Swallowing, Pharyngeal Phase of Swallowing, Esophageal Phase**

---

3. **Simple Tongue Thrust:** Defined as tongue thrust with teeth together swallow. Usually associated with history of thumb/digit sucking habit even though this predisposing habit no longer be practiced. Prolonged thumb sucking habit lead to development of anterior open bite which necessitate tongue to form anterior oral seal. hence, this simple tongue thrusting habit is almost always adaptive response to open bite malocclusion rather than being cause of it.

4. **Complex Tongue Thrust:** Defined as tongue thrust with teeth apart swallow. Complex tongue thrust is likely to be associated with chronic naso-respiratory distress, tonsillitis etc. When tonsils are enlarged and inflamed, root of tongue encroach these enlarged tonsils causing pain and discomfort. To avoid discomfort, mandible reflex drops down separating teeth and providing room for tongue to thrust forward during swallow for more comfort.

**Malocclusion associated with complex tongue thrust has two distinguished features:**

• **Poor occlusal fit:** There is no firm intercuspidation when study models are oriented together. This finding is unique for malocclusion associated with complex tongue thrust. Reason being that since teeth are not held in centric occlusion during swallowing, which over a prolonged period of time, will lead to instability of natural occlusal fit.

• **Generalized anterior open bite:** Unlike simple anterior tongue thrust, open bite produced by complex tongue thrust is diffuse

---

**Figure 4: Simple Tongue Thrust**

---

**Effects of Tongue Thrusting:** Thumb sucking + Tongue thrusting: If the finger displaces the maxillary incisors labially, the tongue thrusts forward to maintain lip seal. Accentuates the open bite tendency & prevents the incisors from erupting & forces them labially. Lips become more hypotonic & no longer contact each other during rest. Mouth breathing is aggravated.

Increased over jet – lower lip cushions to the lingual of the maxillary incisors. Mentalis muscle activity increases – puckering of the chin. Tongue drops lower in the mouth & no longer approximates the palate. Tongue elongates in shape. Balancing effect on the buccal
segment is decreased. Lateral peripheral portions no longer overlie the occlusal surfaces of posteriors.\textsuperscript{4}

**Net Effect:**
- Narrowing of the maxillary arch
- Over eruption of the posteriors
- Inter occlusal space is eliminated
- Posterior cross bite

**Figure 5:** Figure Horizontal Growth Pattern & Vertical Growth Pattern

**Tongue posture and malocclusion:**\textsuperscript{5}

- **Tongue Posture in Neonates:** Tongue is postured forward & touches the lips while the gum pads are held slightly apart.

**Infantile to Mature Tongue Posture**

1. Eruption of incisors
2. Downward & forward growth of the mandible – increases the intraoral volume
3. Growth of the alveolar process in vertical direction

- **Mature Tongue Posture:** During mandibular posture, the dorsum touches the palate slightly and the tongue tip normally is at rest in the lingual fossa or at the crevices of the mandibular incisors.

- **Abnormal Tongue Posture:** Abnormal tongue posture produces more obvious malocclusion than tongue thrust because abnormal posture is maintained almost all the time unlike thrust which occur only during swallow.

1. Retracted tongue posture
2. Protracted tongue posture
   A. (Retained infantile tongue posture) Endogenous
   B. Acquired adaptive

1. **Malocclusion Associated with Retracted Posture:**
   - Crowded mandibular incisors with lingual tipping & rotation
   - Excessive overclosure
   - Distoocclusion
   - Posterior open bite
2. **Protracted Tongue Posture**
• **Endogenous Protracted Posture**: Retention of infantile tongue posture Adaptation to excessive anterior facial height

• **Acquired Protracted Posture**: Transitory adaptation to enlarged tonsil, pharyngitis or tonsillitis

**Facial morphology and tongue dysfunction**: Morphology of facial skeleton and effects of tongue dysfunction are related to some extent.

• A horizontal growth pattern in conjunction with tongue thrust results in bimaxillary dentoalveolar protrusion A vertical growth pattern with tongue thrust, lower incisors are inclined lingually while upper incisors are proclined.

**Tongue Posture in Various Malocclusions**

• **Class I malocclusion**:
  - Most common type of tongue abnormality seen in class I cases is tongue thrust habit causing anterior openbite.
  - Occasionally bimaxillary protrusion is partly attributed to tongue abnormality being large or posture forward causing forward positioning of both arches

• **Class II Malocclusion**
  - Class II div I
    - Retracted and low
    - Buccinator force is not balanced by the tongue & this leads to narrow, ‘V’ shaped maxillary arch.
    - Lip and tongue team up to accentuate deformity.

  - Class II, Division 2 malocclusion: Since most of class II div 2 cases have horizontal growth pattern, deep bite and large free way space, tongue tends to accentuate the excessive curve of Spee by interting with the eruption of the posterior teeth. (lateral tongue thrust).

  - Class III Malocclusion:
    - The tongue tends to lie lower in the floor of the mouth below the occlusal plane
    - Since the maxillary arch does not have the balancing effect of tongue, the maxillary arch is usually narrow and the interocclusal space is either very small or entirely absent.

---

**Figure 6: Tongue Posture**
Abnormal Size of the Tongue

1. Macroglossia
   - Psuedomacroglossia
     1. Habitual posturing
     2. Hypertrophied tonsil/adenoid
     3. Low palatal vault
     4. Severe mandibular deficiency
   - True Macroglossia
     Congenital:
     1. Muscular hypertrophy
     2. Glandular hyperplasia
     3. Hemangioma
     4. Lymphangioma
     5. Downs syndrome
     Acquired:
     1. Acromegaly
     2. Cretinism/Myxedema
     3. Amyloidosis
     4. Cysts/tumor
     5. Tertiary syphilis

Clinical Features of Macroglossia:
- The oral cavity is filled by the tongue mass
- Epipharynx is narrow
- Patient is able to extend the tongue to the nose tip/chin
- Indentations are evident on the tongue periphery
- Generalized spacing between the teeth
- Procumbent anteriors
- Open bite
- Treatment: Surgical trimming of the tongue

2. Microglossia or Hypoglossia
- Rare condition
- Protruded tongue tip reaches the lower incisors at best
- Floor of the mouth is elevated & visible on each side of the diminutive tongue
- Dental arch is collapsed & reduced with extreme crowding in the premolar area
- Severe class II malocclusion
- Impacted III molars

Conclusion

Though it is not yet established cause and effect relationship between tongue dysfunction and malocclusion, it seems that tongue thrust and/or particular posture and position of tongue may be associated with particular type of malocclusion.

As most of the tongue thrusting habits are adaptive in nature, care should be taken not to provide any room iatrogenically for this habit to start or continued. Complex thrusting and retained infantile swallow habits have definite effect on occlusion.

A thorough functional analysis of tongue should be performed to know exact dysfunction of tongue since prognosis varies for each of the abnormality. Wherever possible, underlying cause should be identified and eliminated.8

Invisalign: A Review of Literature

A. Arif Yezdani

Professor and Director, Department of Orthodontics and Dentofacial Orthopedics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research (BIHER), Chennai, India

Abstract

The purpose of this narrative review was to analyze publications that assessed the accuracy and efficiency of the Invisalign® system. A search strategy to identify articles that referenced Invisalign®, which were published between 2001 and 2019 was adopted and the relevant articles were segregated and perused to evaluate the accuracy of Invisalign technology in achieving predicted tooth positions with respect to direction of tooth movement and tooth type as also its indications, limitations, advantages & disadvantages. It could also be surmised that in comparison with the traditional fixed appliances, patients treated with Invisalign had a better periodontal health but the results achieved with it were not as accurate as those achieved by treatment with fixed appliances.

Keywords: Invisible orthodontics; Invisalign; Clear aligners.

Introduction

Movement of teeth without the use of bands, brackets or wires was described as early as 1945 by Dr. H. D. Kesling, who reported on the use of a flexible tooth positioning appliance. Minor tooth movements have also been achieved with a technique developed by Raintree Essix (New Orleans, LA) which used clear aligners formed on plaster models of the teeth. However, movements were limited to 2 to 3 mm and beyond this range another impression and a new appliance was needed.

Invisalign, a trademark held by the developers of the system “Align Technology, Inc.” was introduced in 1999 in USA. This appliance was the first orthodontic treatment method to be based solely on three-dimensional (3D) digital technology. The CAD-CAM technology was used in combination with laboratory techniques to fabricate a series of aligners in polyurethane capable of producing tooth movement in increments of about 0.25-0.3mm. Development of new aligner materials, staging of tooth movement, interproximal reduction, attachments on teeth and interarch elastics to address a wider range of malocclusions were the other dramatic improvements made in this Invisalign technology.1,2

Discussion

This review of literature highlights the role of the Invisalign system in orthodontics as also sheds light on the indications, contraindications, advantages, disadvantages and techniques of the same.

Boyd RL & Vlaskalic V3 (2001) reported the treatment results for cases of complex malocclusions including extractions. Patients in this study demonstrated excellent compliance, little discomfort and improved esthetics and hygiene when compared to fixed appliances.

Norris RA et al4 (2002) reported an interdisciplinary treatment approach using the Invisalign system for orthodontics in combination with restorative dentistry. The Invisalign system was used for opening the bite anteriorly, space distribution and midline correction. The restorative dentistry procedures involved veneering to enhance the maxillary incisor length-to-width ratio and provide anterior guidance.
Meier B et al. (2003) conducted a prospective study to produce a profile of those patients who were interested in treatment with the Invisalign® system and concluded that women between 20 and 29 years of age were interested in it for esthetic reasons.

Neumann et al. (2004) stated that the Invisalign system could be used as a space-maintaining and regaining appliance for a comfortable, rapid and hygienic distal movement and uprighting of the maxillary first molars after premature loss of deciduous molars and subsequent loss of space in sagittal dimension.

Miethke RR & Vogt S. (2005) evaluated the periodontal health in patients during treatment with either fixed orthodontic appliances or the Invisalign system. They concluded that periodontal health was not jeopardized even though the Invisalign system aligners covered all the teeth and the keratinized gingiva in part.

Giancotti A & Ronchin M. (2006) stated that malocclusions treated with the Invisalign system initially involved only mild crowding of 3-6mm. However, more complex cases involving premolar extractions, molar distalization, deep bites, open bites, crossbites, and periodontal complications have also been reported. The article demonstrated a case report of pre-restorative treatment of a non-growing patient using Invisalign appliance.

Kuncioa et al. (2007) in a comparative cohort study compared the postretention dental changes between patients treated with Invisalign and those treated with conventional fixed appliances and concluded that patients treated with Invisalign relapsed more than those treated with conventional fixed appliances.

Breznia N & Wasserstein A. (2008) concluded that OIIRR phenomenon (orthodontically induced inflammatory root resorption) was seen in a patient treated by the Invisalign technique. They treated a patient with Class III malocclusion using Invisalign technique. The patient experienced severe root shortening during treatment. They concluded that the OIIRR phenomena can unpredictably appear with the Invisalign treatment technique just as it does with all other orthodontic treatment modalities.

Eliadesa T et al. (2009) stated that the aligners were safe and do not release Bis-phenol A (BPA). The results showed that there was no evidence of cytotoxicity on human gingival fibroblasts and no stimulation of proliferation of the MCF-7 cell line at any concentration, indicating no estrogenicity of aligner elements.

Marcuzzi E et al. (2010) stated that recent advances in the Invisalign technique – particularly attachment designs that improved the three-dimensional control of tooth movement had resulted in new treatment strategies for patients who needed orthognathic surgery. The InvisalignClinCheck could be used for diagnosis, visualization of treatment results and sharing of information with the patient and dental colleagues throughout treatment.

Schupp W et al. (2010) stated that the Invisalign offered a comfortable and almost invisible treatment option for closing anterior open bites and that simulated rotation of the mandible in the ClinCheck analysis could be helpful if intrusion of the posterior segments was planned.

Schott TC & Goz G. (2011) evaluated the color fading in aqueous solutions of the blue dot wear-compliance indicators of the Invisalign Teen H System outside the oral cavity and concluded that the compliance indicators were not immune to simple intentional or unintentional manipulations and that they can best show an estimate of wear time but cannot be recommended as objective wear-time indicators.

Drake CT et al. (2012) examined the role of in vivo aligner material fatigue and subject-specific factors in tooth movement and concluded that over eight weeks, in two-week intervals, material fatigue did not play a significant role in the rate or amount of tooth movement.

Thyagaseely et al. (2014) evaluated the cellular responses of oral epithelium exposed to Invisalign plastic in vitro. Oral epithelial cells were exposed to eluate obtained by soaking Invisalign plastic in either saline solution or artificial saliva for 2, 4, and 8 weeks. Cells grown in media containing saline solution or saliva served as controls. Morphologic changes were assessed by light microscopy. Exposure to Invisalign plastic caused changes in viability, membrane permeability, and adhesion of epithelial cells in a saline-solution environment. It was opined that microleakage and hapten formation secondary to compromised epithelial integrity might lead to isocyanate allergy, which could be systemic or localized to gingiva. However, the results suggested that saliva might offer protection.

Marieke et al. (2014) quantified the forces and
moments delivered by a single aligner and a series of aligners and investigated the influence of attachments and power ridges on the force transfer. The forces and moments generated by aligners of the Invisalign system were within the range of orthodontic forces and it was deduced that the force change was exponential while a patient was wearing removable thermoplastic appliances.

Fujiyama et al\textsuperscript{18} (2014) evaluated and compared the difference in the level of pain using the visual analog scale (VAS) between cases treated with edgewise appliance and Invisalign and concluded that Invisalign treated patients experienced less pain than edgewise appliance.

Gerard et al\textsuperscript{19} (2015) investigated the mechanical and chemical alterations of Invisalign appliances after intraoral aging and concluded that despite the lack of detectable chemical changes, intraoral aging adversely affected the mechanical properties of the Invisalign appliance.

Ojima et al\textsuperscript{20} (2016) reported that a successful outcome with satisfaction, motivation and improved compliance by accelerating orthodontic tooth movement while changing aligners every three days, by means of accelerated treatment with OrthoPulse could be successfully achieved.

Houle JP et al\textsuperscript{21} (2017) investigated the prediction of transverse changes with Invisalign and came to the conclusion that for maxilla the mean accuracy of expansion planned with Invisalign was 72.8% and that for the mandibular arch it was 87.7% and that Clincheck overestimates expansion by bodily movement; when in actuality more tipping was observed.

Flores-Mir et al\textsuperscript{22} (2018) surveyed patients to assess their oral health-related quality of life and satisfaction immediately after completion of their orthodontic treatment and concluded that Invisalign and bracket-based treated patients except for chewing and eating had statistically similar satisfaction outcomes across all dimensions analyzed and that more satisfaction was reported by the Invisalign group.

Galan-Lopez et al\textsuperscript{23} (2019) did a systematic review to analyze publications that assessed the efficiency and accuracy of the Invisalign® system and concluded that the results achieved by it were not as accurate as those achieved by treatment with fixed appliances.

Indications for clear aligners:
- Mildly crowded and malaligned problems (1–5 mm).
- Spacing problems (1–5 mm).
- Deep overbite problems (Class II division 2 type malocclusions) where the overbite can be reduced by intrusion and advancement of incisors.
- Narrow arches that can be expanded without tipping the teeth too much.
- Minor tooth rotations.
- Orthodontic relapse.
- Active and passive retainers.

Limitations:
- Crowding and spacing over 5 mm.
- Skeletal antero-posterior discrepancies.
- Centric relation and centric occlusion discrepancies.
- Severely rotated teeth (more than 20 degrees).
- Anterior and posterior open bites.
- Extrusion of teeth.
- Severely tipped teeth (more than 45 degrees).
- Teeth with short clinical crowns.
- Arches with multiple missing teeth.
- Impacted teeth.

Advantages:
- Esthetics
- Comfort
- Better oral hygiene
- Bonding to enamel defects
- Numerous restorations and crowns
- Speech
- Appointments can be spaced at greater intervals
- Fewer emergencies
- No metal allergy
- Control of bruxism

Disadvantages:
- Limited control over root movement (such as
root paralleling), gross rotation correction, tooth uprighting and tooth extrusion.

- Limited intermaxillary correction: Severe skeletal discrepancies cannot be contemplated with Invisalign alone.
- Lack of operator control. If the treatment goes off track, then new impressions are needed and the case is ‘rebooted’ through the ClinCheck® mechanism and the treatment should be started from scratch.
- As they are removable, application of continuous force is questionable.
- Largely dependent on the patient’s habits and their consistency in wearing.
- Removal and re-insertion each and every time during eating.
- Damage to aligners while grinding or clenching teeth during sleep.

Techniques and Technology

Data Collection: It is essential to take high quality pre-treatment records- study models, panoramic and lateral cephalometric X-rays and photographs. These records (apart from the study models) are sent to Align Technology. Digital X-rays, digital models and photographs are an advantage. If impressions need to be taken they should be done with a polyvinyl silicone material, a single phase impression technique, or Pentamix 2, a dual-phase impression technique. Alternatively, it is possible to use a polyether material, a single-phase impression technique. A silicone bite material is also needed to record maximum intercuspation. The orthodontists’ input into this technology is the ‘prospective’ treatment planning. Unlike conventional orthodontics, Invisalign asks us to ‘visualize’ the completed result, so we can convey our intentions in the treatment planning process.

Treatment Planning: The orthodontists’ prescription is followed in positioning the teeth and the bite to proper alignment virtually on the computer with the company’s Treat software (Align Technology, Santa Clara, Calif). Once the final setup has been done, tooth movements are staged so that there are no occlusal and interproximal interferences. The data is then sent to the referring orthodontist to check the proposed treatment on the Invisalign Web site. The treatment plan is then translated into tooth movements and the orthodontist can view this ‘virtual correction’ stage by stage and from any angle. This process is called ClinCheck and alterations to the treatment plan are unlimited. Once the orthodontist has approved the treatment plan, the aligners will be manufactured so that the movements seen on the computer screen can be transferred clinically to the patient. The 3-D models of each step in the realignment are transformed into hard copy models through a process of laser build up. These models are then used to make the pressure formed aligners. A movement of 0.5 mm can be made with the initial aligner appliance and the teeth can be moved 1 mm with each of the following appliance. A typical Invisalign treatment will take around 25 aligners and 50 weeks of treatment, but can vary from 10 to 50 aligners depending on the severity of the problem.

Conclusion

Invisalign is an appliance to effect tooth movement in orthodontic therapy carried through ‘an invisible’ way. It adopts a method of fabricating clear custom fabricated aligners designed to gradually and sequentially move teeth to their desired positions using a computer assisted technology. However, future prospective randomized clinical trials with sound scientific evidence is deemed mandatory to accept this modality of treatment in the broader perspective of invisible orthodontics.

Finite Element Method in Orthodontics

Jeenu Raj¹, T. Faisal Tajir², M.S. Kannan³

¹Post Graduate Student, ²Professor, ³Professor and Head of the Department, Department of Orthodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

Abstract

Finite element analysis, an engineering method for analysing stress and strain has created a niche in the field of orthodontics because of its ability to deliver detailed and precise information regarding stress on load application. It divides the object of study into a finite number of elements and the connected by a meshwork and equations are developed for each elements thereby making each element an individual object of study. Several studies have been conducted using the finite element method and there is a lot of scope for this experimental method to be used in future as well.

Keywords: Finite element analysis; mesh; software.

Introduction

Finite Element Method (FEM) is a mathematical method in which, the shape of complex geometric objects and their physical properties are computer constructed. It is a modern tool for numerical stress analysis, which can be applied to solids of irregular geometry that contain heterogeneous material properties. For orthodontists, it provides quantitative data that can extend the understanding of physiologic reactions that occur within the dentoalveolar complex. Using FEA, the orthodontic force applied can be simulated and the results can be shown on a three dimensional model that can be fabricated using a CT scan. One can derive a precise and detailed description of the responses of periodontal structures to stress application.[1]

History: Finite element analysis was initially developed in the 1940’s, where R. Courant first developed this technique to study structural defects in aircrafts [2]. It was introduced in implant dentistry in 1976 by Weinstein. In 1972 Yettram started using this tool for orthodontic purposes.

Steps:

• Pre-processing.
• Conversion of geometric model into finite element model.
• Assembly/Material Property data representation.
• Defining the boundary conditions.
• Loading Configuration.
• Processing.
• Post-processing.

Pre processing:

Construction of the Geometric model:

• This can be achieved by:
• 3D – CT scanner: done for modeling complex structures or living tissues. eg: craniofacial skeleton, maxilla or mandible
• To achieve improved resolution CT cross-sections of at least 0.25 mm should be obtained. The sections will be recorded on DICOM format (Digital Imaging and Communication in Medicine) and imported into an image processing and digital reconstruction software and a virtual model is built using software(I Cat, Xoran Technologies).[3]
• Micro CTs can capture more details on gauge scale; but the high radiation, high costs and difficult access justifies the use of computed tomographies.\(^{(3)}\)

• 3D – Laser scanner: done for modeling inanimate objects.
  eg: modeling of brackets.

• to build a virtual model (Fig 1) using an image, processing and digital reconstruction softwares, such as Mimics (Materialize, Leuven Belgium), Simpleware 4 (Simpleware Ltd., Exeter, United Kingdom) or ITK-SNAP Open Source Software are used.

• The constructed models are stored in STL format.

---

**Fig 1: Virtual reconstruction of maxilla using computed tomography**

**Conversion of Geometric model to Finite Element Model:** Discretization is the process of dividing the model into several small elements, connected with nodes (Fig 2). All elements and nodes help to establish a matrix connectivity which affects the computing time. It is essential that the elements are not overlapping but are connected only at the key points, termed as nodes.

The joining of elements at the nodes and eliminating duplicate nodes is termed as ‘Meshing’\(^{(4)}\) Fig 3. The process of representing a component as an assemblage of finite elements is known as discretisation. The process of meshing can be done by softwares like MSC Patran (MSC Software, Inc., USA), Ansys Inc., Canoneburg, PA, USA).

---

**Fig 2: Schematic view of linear discretization of elements and nodes**
Assembly/Material Property data representation:

- For each element in the FEM mesh equations are developed and a set of global equations that model the properties of the entire system is assembled.
- Basic material properties required are poisons ratio and young’s modulus.

<table>
<thead>
<tr>
<th>Material</th>
<th>Young’s modulus (kg/mm²)</th>
<th>Poisons ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tooth</td>
<td>$2.6 \times 10^6$</td>
<td>0.15</td>
</tr>
<tr>
<td>PDL</td>
<td>$6.8 \times 10^2$</td>
<td>0.49</td>
</tr>
<tr>
<td>Alveolar Bone</td>
<td>$1.40 \times 10^3$</td>
<td>0.15</td>
</tr>
</tbody>
</table>

Defining the Boundary Conditions:

- Boundary conditions means that if an element is constructed on the computer and a force is applied to it, it will act like a free-floating rigid body which will undergo a translatory or rotatory motion or a combination of the two without any deformation.
- To evaluate its deformation, restricting some degrees of freedom (movement of the node in each direction $x$, $y$, and $z$) is necessary for some of the nodes. Such constraints are called boundary conditions.

Loading configuration:

- Applying force at various points of geometry and its configuration

Processing:

- Is the process of solving the system of linear algebraic equation.
- The stresses are determined from the strains by Hooke’s law.
- Strains are derived from the displacement functions within the element combined with Hooke’s law.

Post-Processing:

- The output from the FEM is primarily in numerical form. It usually the output is in the form of nodal displacement and element stresses.
- Graphic outputs and displays are usually more informative.
- The curves and contours of the field variable can also be plotted and displayed. Deformed shapes are displayed and superimposed on unreformed shapes.
- The output is primarily is shown in the form of color-coded maps. Interpreting these maps help in the quantitative analysis. Fig 4.

Discussion

FEM is a technique where a complex mechanical problem is divided into a collection of much smaller and simpler domains (elements) in which the field variables can be incorporated by using shape function. The FE analysis has the following advantages: it is a noninvasive technique; the actual amount of stress experienced at any given point can be theoretically measured and is very accurate since its based on mathematical properties of the structure; Structures like the tooth, alveolar bone, periodontal ligament, and craniofacial bones can be simulated and their material properties can be assigned to the nearest one that possibly can simulate the oral environment in vitro; the displacement of the tooth can be visualized graphically; the displacement of the tooth can be visualized graphically; the displacement of the tooth can be visualized graphically; the point of application, magnitude, and direction of a force may easily be varied to simulate the clinical situation; reproducibility does not affect the physical properties of the involved material; and the study can be repeated as many times as the operator wishes\[^5\].
Application in Orthodontics: Finite element modeling can be applied in three areas:

(i) analysis of the skeleton,
(ii) analysis and design of orthopedic devices
(iii) analysis of tissue growth, remodeling and degeneration.

The FEM can also be applied to the problem of stress strain levels induced in internal structures. Thus, FEM becomes an ideal method for accurate modeling of the tooth and periodontium though it has a complicated 3-dimensional geometry. The FEM makes it possible to analytically apply the various complicated orthodontic force systems at any point and in any direction. Orthodontic tooth movement is achieved by remodeling processes of the alveolar bone, which are triggered by changes in the stress/strain distribution in the periodontium. The finite element (FE) method can describe the stressed situation within the periodontal ligament (PDL) and surrounding alveolar bone. It is also an effective tool to study orthodontic tooth movement. FEM is also used for morphometric analysis in craniofacial biology.

The cephalometric finite element analysis (CEFEA) program incorporates the advanced features of the finite element method. This program uses the color graphics display of common personal computers to show size change, shape change, and angle of maximum change which are pictured as colored triangles of clinically relevant regions between pre- and mid- or post treatment lateral head films. The program have their features of interest in both clinical practice and research.

The effect of altering the geometry of the bracket base mesh on the quality of orthodontic attachment employing a three-dimensional finite element computer model is another application of FEM in orthodontics as discussed by Knox et al. The CAD/CAM template helps orthodontists to safely place miniscrews.

Conclusion

FEM is powerful analytic tool for calculating stresses and strains within mechanically loaded structures. Through this method models of intricate structures consisting of various shapes and materials under complex loading can be made.

In Orthodontics, FEM is one of the very important applications in the field of bio-mechanics and cranio-facial biology. The orthodontist can precisely determine the effect of various biomechanical materials involved in tooth movement and provides quantitative and detailed data regarding physiologic response in tissues. The only drawback is the roots, periodontal ligament and teeth are represented in idealized geometric forms and physical properties are assumed to be homogenous, isotropic and linear.

Ethical Clearance: Not required since it is a review article.

Role of Vitamin-D in Orthodontics: A Review

R. Mohan Pradeep¹, S. Kishore Kumar², M.S. Kannan³

¹Post Graduate, Department of Orthodontics, ²Professor and Vice Principal, ³Professor and Head of Department, Department of Orthodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

Abstract

Orthodontic tooth movement is planned for moving the teeth inside the tissues of the alveolar procedure of the maxilla and mandible, and changing the occlusal conditions, in this manner it is conceivable to improve the capacity and style of the masticatory framework. The orthodontic treatment depends on a powerful procedure of rebuilding the tissue structures of the alveolar procedure of the maxilla and mandible. At the point when the power is applied on teeth for quite a while, cutoff points of versatile disfigurements of tissues can be surpassed and translational relocation of a tooth can be watched. The got tooth development influences changes in the shape and organization (particularly in connection to the calcium-phosphate balance) of bone tissue and encompassing delicate tissues.

Keywords: Vitamin-D, Calcium, Lumisterol, Tachysterol.

Introduction

Historical and Physiological Perspectives:
Vitamin D is comprehended in light of the fact that the most seasoned all things considered and specialists have found the nearness of this ailment inside the early verdure species Emiliani huxleyi¹, that produces calciferol following sun exposure¹. elective maritime living things use the high calcium substance of E. huxleii for neuromuscular and metabolic exercises. As vertebrates advanced in territories encompassing seas, they held their requirement for calcium, a fundamental component in the improvement of the skeleton and bone mineralization¹. Be that as it may, vertebrates expected to keep up Vitamin D generation for calcium ingestion on land¹. A human body needs around 3,000–5,000 IU of vitamin D each day². A considerable extent of the body’s day by day prerequisite of vitamin D3 originates from dietary admission, particularly greasy fish, eggs, and braced foods³,⁴. An ongoing cross-sectional investigation in the UK contrasted meat and fish eaters with veggie lovers and veggie lovers, uncovering that vitamin D plasma levels were altogether higher among nonvegetarians contrasted with vegetarians⁵. Hosseinzadeh and Holick⁶ demonstrated that when individuals ingest vitamin D, the body joins it into chylomicrons. The body at that point discharges it into the lymphatic framework, and from that point, it enters the venous blood⁶. In the venous blood, vitamin D ties to vitamin D-restricting proteins and lipoproteins, which are moved to the liver⁶. Next, the liver procedures vitamin D2 and vitamin D3 by 25-hydroxylation to make vitamin D metabolite, which clinicians and scientists use to work out patients’ calciferol standing⁶. At that point, in the kidneys, the vitamin D metabolite experiences further hydroxylation to frame the secosteroid hormone calciferol⁶,⁷. Be that as it may, the principle wellspring of vitamin D is daylight presentation. In another investigation, Hollik demonstrated that following sun introduction, the body changes over vitamin D into previtamin D3, lumisterol, and tachysterol by means of a procedure known as photoconversion, and that sun presentation improves isomerization to sustenance
D3 by a warmth instigated membrane4. When vitamin D3 is shaped, vitamin D-restricting proteins convey it to the dermal slender bed8. During this procedure, the nearness of tachysterol and lumisterol averts vitamin D inebriation when people are presented to sunlight based bright B (UVB) radiation for delayed durations8. A few variables have been appeared by scientists to impact sustenance D3 generation, including skin pigmentation, age, apparel, the utilization of sunscreen salves, time, season, scope, and altitude2,7-9. In winter, the wide peak edge of the sun causes the sun oriented UVB photons to travel longer through the ozone layer before coming to the earth8. This may clarify why above and underneath around 33° scope, little, assuming any, nourishment D3 is made inside the skin all through winter10. This could moreover put forth a defense for why sustenance D3 blend happens exclusively between pretty much ten inside the morning and 3 toward the evening in central regions10.

Effect of VIT D3 on Tooth Movement: Vitamin D3 has conjointly pulled in the eye of some someone to its job inside the increasing speed of tooth development; 1,25 dihydroxycholecalciferol could be a discharge style of fat-dissolvable vitamin and assumes a significant job in nuclear number 20 harmony with thyroid hormone and endocrine (PTH).

Another arrangement of investigators 10, has caused a test where they to have infused vitamin D metabolite on the PDL of felines for a little while; it was discovered that vitamin D had quickened tooth development at an hour over the administration bunch in view of the addition of osteoclasts on the weight site as recognized histologically. A correlation between neighborhood infusion of vitamin D and PGEs on two distinct gatherings of rodents was likewise researched.

It was discovered that there’s no significant qualification in speeding up between the 2 groups. In any case, the quantity of osteoblasts on the weight aspect that was infused by fat-dissolvable vitamin was greater than on the PGE2 feature. This shows fat-dissolvable vitamin could likewise be progressively handy in bone turnover11.

Another specialist that may influence tooth development is vitamin D, 1,25-dihydroxycholecalciferol is the most dynamic metabolite of this vitamin. It primarily anabolically affects the bone tissue (to a little degree likewise catabolic)12. So also to PTH, sub-periostal organization of vitamin D upgrades the action and multiplication of osteoblasts13. These properties provoked analysts to style creature tests endeavoring to change the course of treatment.

Collins et al. utilized calcitriol broke up in DMSO (dimethylsulfoxide) – an intensify that promptly enters cell layers, just as has a high solvency coefficient for vitamin D) – controlled every day into the periosteum14,15. Following 3 weeks, the withdrawal scope of the canines was 60% higher contrasted with the benchmark group. Different specialists arrived at comparable resolutions, this time testing the activity of this vitamin on rodents. They saw an expanded number of the two osteoclasts and osteoblasts16-18. Kawakami and Takano-Yamamoto underlined the continuation of escalated redesigning during the maintenance time frame as well17. Thusly, Kale et al. seen that distalization of the maxillary incisors expanded by 23%.20 In a couple of clinical preliminaries, the increasing speed of orthodontic tooth development was likewise demonstrated19. After a day by day oral portion of 0.25 μg of vitamin D, the mean contrast in the withdrawal development between the exploratory gathering without vitamin D, there was a huge impact of vitamin D organization was higher than in the gathering and the benchmark group (who experienced orthodontic treatment without supplementation) was 1 mm/multi day. Notwithstanding, the utilization of a low portion of the enhancement in the examination seems, by all accounts, to be sketchy (10 IU versus the day by day proposals of 1000–2000 IU).

Narmada et al20 led an examination and presumed that osteoclast and RANKL expression in the gathering with vitamin D organization was higher than in the gathering without vitamin D, there was a huge impact of vitamin D on the tooth development in pregnant rodents. Vitamin D can quicken orthodontic tooth development by animating alveolar bone renovating during pregnancy.

Bone redesigning, following the utilization of orthodontic powers, incorporates resorptive and bone arrangement stages at the alveolar process21. A connection has been appeared between vitamin D receptor polymorphisms and periodontitis and bone metabolism22. Specialists have indicated that vitamin D, parathyroid hormone, and calcitonin direct calcium and phosphorus levels23,24. In different examinations, vitamin D invigorated bone resorption by inciting the separation of osteoclasts from their forerunners and expanding the movement of existing osteoclasts24-26. One of the previous endeavors was made by Boyce and Weisbrode27, who assessed the impacts of calcium-rich
weight control plans and vitamin D metabolite infusion on bone development in rodents. On day 1, osteoclasts in treated rodents expanded in contrast with controls. On days 3 and 4, the scientists watched a reduction in the quantity of osteoclasts. Boyce and Weisbrode reasoned that the exploratory gathering encountered a net increment in bone arrangement. Collins and Sinclair exhibited that intraligamentary infusions of vitamin D metabolites cause an expansion in the quantity of osteoclasts, and thusly in the pace of bone resorption, prompting an increment inside the pace of tooth development all through canine withdrawal. Afterward, in 2004, Kale et al thought about the impact of the organization of prostaglandin and 1,25-dihydroxy cholecalciferol (1,25 DHCC) on tooth development. Both were found to expand the measure of tooth development essentially when contrasted with controls. An expansion in the quantity of osteoclasts on the outer surface of the alveolar bone was expanded after the organization of 1,25 DHCC in contrast with prostaglandin organization. In this manner, the creators made open the job of 1,25 DHCC in encouraging tooth development through the guideline of bone testimony and the resorption processes. Some agents have proposed that notwithstanding quicker teeth development, limited organization of vitamin D improves tooth position soundness.

These research center investigations recommend that orthodontic patients with vitamin D inadequacy may encounter a more slow pace of tooth movement. There was a significant beginning increment in osteoclastic movement pursued by an osteoblastic action. These discoveries propose that vitamin D and its metabolites may encourage orthodontic treatment. Additional proof is expected to see the security of cholecalciferol treatment in orthodontic patients yet due to the best amount and site of use for this reason. Plus, given the high commonness of vitamin D insufficiency worldwide, it is significant that analysts investigate the clinical utilization of vitamin D metabolites to help the speed of tooth development during orthodontic treatment.

Consequences of Vitamin D Deficiency: The work of a fat-dissolvable vitamin is to deal with humor nuclear number 20 and phosphate fixations, which are significant for some physiological functions. These incorporate ordinary mineralization of bone, muscle compression, nerve conduction, and counteractive action of hypocalcemic tetany. Scientists accept that 1,25(OH)2D is fundamental for the body’s capacity to lift intestinal calcium ingestion to 40% and intestinal phosphorus assimilation to 80%, which are essential for skeletal prosperity in humans. Sniadecki contended that lacking presentation to daylight in youth causes destroying bone deformations known as rickets.

This ascent in the occurrence of hypercalcemia drove specialists to preclude the stronghold of milk and other dairy items with vitamin D. Researchers have connected vitamin D inadequacy to muscle torment and muscle weakness. In extreme situations, scientists have discovered that muscle decay is elucidated to optional hyperparathyroidism, coming about in hypophosphatemia. An ongoing meta-examination of old individuals indicated that taking supplemental and dynamic assortments of the fat-dissolvable vitamin day by day decreased the rate of falls by 19% and 23%, respectively. Additionally, a few examiners have demonstrated that the occurrence of specific sorts of malignant growth was higher among populaces in higher scopes, who experienced diminished sun exposure. Past examinations have revealed insight into the association between vitamin D insufficiency and cardiovascular diseases. In the planned Intermountain Heart Collaborative Study, which had in excess of 40,000 members, the scientists demonstrated that members with levels of 1,25(OH)2D under 15 mg/mL were bound to experience the ill effects of hypertension, hyperlipidemia, fringe vascular sickness, coronary supply route malady, myocardial dead tissue, cardiovascular breakdown, and stroke contrasted and sound controls. Truth be told, the frequency of type 2 diabetes mellitus was 52% higher among people with vitamin D levels over 25 mg/mL contrasted with those with levels underneath 14 mg/mL. From another point of view, a few investigations have indicated connects between the degree of vitamin D and the rate of immune system diseases. Numerous sclerosis, provocative entrail ailment, rheumatoid joint pain, and Crohn’s infection are progressively normal in high scopes and in regions with low sun exposure. This relationship was additionally bolstered by a few analyses exhibiting the job of vitamin D in controlling chemokine creation, checking immune system aggravation, and empowering the separation of invulnerable cells. Besides, specialists have demonstrated that vitamin D improves invulnerability against tuberculosis, flu, also, popular upper respiratory tract infections.
Various examinations have assessed the outcomes of vitamin D inadequacy. Notwithstanding, the information have been conflicting, which may be because of varieties in the demonstrative marks and cut-off qualities in characterizing an insufficiency state. Osteocalcin as a Skeletal Maturity Indicator: A Review

S. Vaibava Keerthana¹, A. Arif Yezdani², Kannan M.S.³

¹Post Graduate, ²Professor and Director, ³Professor and Head, Department of Orthodontics & Dentofacial Orthopedics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research (BIHER), Chennai, India

Abstract

Bone mineral metabolism helps in understanding the sequence of boneloss and bone remodeling and in identifying those persons at risk from osteoporosis. One of the approaches that has yielded useful information is the examination of the role of collagenous and noncollagenous bone proteins in bone mineral metabolism. Osteoblasts are the cells responsible for new bone formation, and osteoclasts the cells for resorption. Osteocytes are derived from osteoblasts but their function although not precisely established probably involves calcium homeostasis and bone cell destruction comparable to osteoclastosis. The term remodeling or bone turnover refers to the sequential processes of resorption and subsequent formation for maintenance of mineral homeostasis. In normal man this remodeling cycle occurs at a particular site about every 3 months. The osteoclasts and osteoblasts which are responsible for remodeling appear to be anatomically linked or coupled in equilibrium. Osteocalcin (OC) acts as a regulator of bone mineralization. It also regulates osteoblast and osteoclast activity. This review article lays emphasis on the structure and interaction of OC with various other molecules; its skeletal effects and therapeutic applications.

Keywords: Osteocalcin; remodeling; bone turnover; osteoclasts; osteoblasts.

Introduction

Osteocalcin (Gamma carboxyglutamic acid or Gla) isolated and sequenced in 1977 is the most abundant non-collagenous matrix protein associated with bone. It is a small gamma carboxyglutamate protein preferentially expressed by osteoblasts and able to bind to calcium ions.¹ Osteocalcin (OC) was irrevocably established as a marker of bone formation and bone turnover.² In 1974, Vitamin K was identified as a cofactor for the formation of Gamma-carboxyglutamic acid (Gla). OC was thus identified as a vitamin K-dependent protein that undergoes carboxylation to bind hydroxyapatite in bone and has higher affinity for calcium facilitating bone mineralization.³

Methodology: A Pubmed search for articles relevant to the topic “Osteocalcin- A skeletal maturity indicator”, was done using MeSH terms – Osteocalcin, Skeletal Maturity Indicator. The search was limited to the period January 1980 to December 2019. 76 abstracts were perused out of which 37 articles pertinent to the topic were selected for the review.

Discussion

Osteocalcin has been observed to be high in cortical bone in comparison to trabecular bone.⁴,⁵ Higher peak osteocalcin values are observed in males as compared to females and this might be associated with greater cortical thickness observed in males as compared to females.⁶ Different mechanisms with complex interactions between associated biomarkers may regulate bone growth during puberty. The endocrine hormone such as the growth hormone stimulates skeletal growth by various mechanisms and it is also known to induce the production of osteocalcin in osteoblasts.⁷ The level of osteocalcin is correlated with the bone formation rate and hence is considered a more sensitive marker than serum alkaline phosphatase.

With increasing age the presence of osteocalcin in bone matrix may alter bone remodeling by promoting osteoclastic activity.⁸ Mature osteoblasts secrete osteocalcin into the extracellular space where this protein either enters the circulation or diffuses through osteoid and binds mineralized bone. An important step in the resorption of bone requires the recruitment and fusion of

DOI Number: 10.37506/v10/i12/2019/ijphrd/192276
monocytes or macrophages to augment the population of multinucleated osteoclasts. Several studies suggest that the presence of osteocalcin in the extracellular matrix of bone may represent an important chemotactic signal for resorption.

The immunohistochemical distribution of osteocalcin in the extracellular matrix of bone indicated changes in the pattern of distribution of osteocalcin within individual osteons and these changes were age and gender specific. Bone is heterogeneous with respect to the distribution of osteocalcin in osteons. The presence of immunodetectable osteocalcin in the outer lamellae of osteons and its absence in the inner aspects may reflect the maturational state of the osteon. Perhaps the morphologic pattern of osteocalcin in osteons of male and female bone is due to alterations in the endocrine milieu associated with age or gender that affect bone remodeling. These site-specific biochemical changes in osteocalcin may in turn impart altered bone remodeling. During bone resorption, degradative products from bone matrix, including osteocalcin, are released into the extracellular space and are thought to further promote monocyte recruitment. Site-specific differences in osteocalcin in the extracellular matrix may influence site-specific remodeling events.

The Gamma carboxyglutamic acid (Gla) residues and the helical register in osteocalcin structure is essential to fully achieve the adsorption specificity for hydroxyapatite. The affinity of osteocalcin for hydroxyapatite is greatly diminished by decarboxylation of the Gla residues. When osteocalcin is adsorbed to hydroxyapatite, its Gla residues are protected from thermal decarboxylation. When Gla content is diminished, it results in reduced affinity for bone mineral. The low concentration of osteocalcin in human bone may relate to its apparent content of only two Gla versus the usual three Gla.

Osteocalcin synthesis is induced by the vitamin D metabolite, 1,25-dihydroxy-D3 (1,25(OH),D3). This induction is transcriptionally mediated by the nuclear vitamin D receptor (VDR), by virtue of a 1,25(OH),D3 response element in the osteocalcin gene. Vitamin A (retinoic acid) is also involved in the genomic regulation of osteocalcin synthesis.

Specific hormone interactions for each cell type are needed, and retinoic acid is required for the phenotypic expression of the 1,25(OH),D3 and thyroid hormone response element. The 1,25(OH),D3 response element of the osteocalcin gene is the element conferring retinoic acid responsiveness. Thus, vitamins K, D, and A are all involved in osteocalcin synthesis regulation. The interrelations between vitamin K, osteocalcin, and osteoporosis were reviewed by Binkley and Suttie.

The Gla protein is encoded by the bone gamma-carboxyglutamate gene located in the long arm of chromosome. The transcription of this gene requires modifications in the chromatin structure and nucleosomal organization that renders the regulatory sequences at promoter level.

Runx2 belongs to the RUNT domain transcription factors family and regulates the basal bone specific trancription of the OC gene; Mutations of the Runx2 sites results in altered chromatin structure and reduces OC transcriptional activity in bone-derived cells. Vitamin D serves as the principle enhancer of OC expression after basal transcription is initiated by Runx2. Vitamin D3 modulates the expression of the OC gene, presumably depending on the different skeletal site of origin and is able to increase OC gene transcription by three to fivefold. Hence, Runx2 gene and Vitamin D3 are considered to be the key regulators of osteocalcin.

Osteocalcin is also synthesized by odontoblasts but not by enamel-synthesizing cells (ameloblasts).

Osteocalcin may play a regulatory role in both resorption and mineralization. Evidence strongly supports OC being involved with mineralization and appearing at the time of mineralization. Osteocalcin also retards mineralization of bone and dentine and contributes to serum calcium homeostasis by inhibition of calcium phosphate precipitation and hydroxyapatite-seeded crystal growth. As OC strongly associates with calcium ion and hydroxyapatite, it also acts a negative regulator for mineral apposition and bone formation. It is proposed to be a chemo attractant for progenitor/mature osteoclasts.

The level of serum osteocalcin which represents the fraction escaping from the aqueous phase near the mineralization front may reflect osteoid volume rather than the rate of mineralization. Normal values of Osteocalcin range from 3-25 ng/ml depending upon the antisera employed. Hyperparathyroidism is associated with high levels of osteocalcin. The level of serum osteocalcin has been found to correlate with levels of PTH, serum calcium and adenoma mass. The increase
in OC in primary hyperparathyroidism has been shown with Ca kinetics or by bone histomorphometry to correlate with bone mineralization rate and formation. The estimated levels of OC are found to be more accurate than alkaline phosphatase.  

In normal males and females, some studies have reported an increase in serum osteocalcin with increasing age. The increase in females appears to be most striking at the time of menopause. This increase correlates inversely (P < 0.001) with concomitant decrease in bone mineral density of the lumbar spine, mid-radius, and distal radius. The overall positive correlation with alkaline phosphatase, urinary hydroxyproline, and serum PTH suggests an increase in bone turnover with aging. OC has been shown to exhibit chemotactic activity in the presence of peripheral blood monocytes and this activity may assist in the recruitment of monocytes to phagocytose dead bone or may cause osteoclastic bone resorption.

Osteocalcin is a negative regulator for mineral apposition and bone formation. Osteocalcin-deficient mice developed a phenotype marked by higher bone mass and bones of improved functional quality. The absence of OC in the mice lead to an increase in bone formation without impairing bone resorption. Hence, osteocalcin is proved to be a determinant of bone formation.

In light of these pieces of evidence and considering the role of vitamin K as the cofactor of carboxylase that converts uncarboxylated OC into OC, it is not surprising that low vitamin K status and intake predicted the risk of fracture in elderly women. A recent report demonstrated that uncarboxylated OC decreased significantly in the earlier period immediately after steroids administration in patients treated with risedronate. Moreover this steroid effect is not reversed by vitamin K supplementation, bringing into question the studies that demonstrated the uncarboxylated-Osteocalcin as an indicator of vitamin K status. It is also presumed that vitamin K itself is not able to correct the inhibition of OC synthesis by glucocorticoids which act at promoter level and suppresses the OC transcription gene.

It has been reported in literature that local application of osteocalcin accelerated the rate of orthodontic tooth movement by enhanced recruitment of osteoclasts on the pressure side. Serum osteocalcin levels undergo circadian rhythmicity in normal men and women. Changing hormonal status in women with regular menstrual cycles did not affect the pattern. Osteocalcin levels fluctuated twofold over the 24-hour study period. Hence, if OC is used as a marker in clinical investigations it is important to regulate the time of serum collection. Evidences report that various other factors also might influence the amount of circulating osteocalcin. Catabolism of osteocalcin is dependent on renal function, while 1,25-dihydroxyvitamin D3 is known to regulate its synthesis. It has been suggested that OC has effects on regulation of energy metabolism and fat mass. OC is the principle osteoblast secreted peptide that regulates energy metabolism and fat mass, targeting adipocytes and β pancreatic cells.

Besides its role in energy metabolism, it appears that OC may also have role in the regulation of angiogenesis and male reproduction. Further investigations are needed in humans to identify the extra-skeletal effects of osteocalcin and its therapeutic applications.

**Conclusion**

The relationship of bone activity, renal function, age, hormones and minerals to osteocalcin rhythmicity is mutual, however, extensive studies are required before firm conclusions could be drawn.

Association of Dental Occlusion, Body Posture and Temporomandibular Disorders: An Overview

Jasleen Kaur Walia¹, Saravanan²

¹Post Graduate Student, ²Professor, Sree Balaji Dental College and Hospital, BIHER, Chennai

Abstract

Correlation between malocclusions and body posture and temporomandibular disorders have been a controversial topic, even though it has been discussed in the last decades, but there is still a lack of consensus in the literature. The available literature was searched to determine the current evidence regarding: (i) The relationship of the dental occlusion–body posture physiology, (ii) The relationship of temporomandibular disorders with occlusion and body posture and (iii) The availability and accuracy of the instrumental devices (surface electromyography, kinesiography and postural platforms) to measure the dental occlusion–body posture–Temporomandibular disorders relationship. The above said method and devices do not find any association between body posture and dental occlusion. This result can be due to the many compensation mechanisms taking place within the body’s neuromuscular system. The use of clinical and instrumental method for assessing body posture is not supported by the available literature, mainly because of wide variations in the techniques.

Keywords: Temporomandibular, Occlusal, Sensitivity, Specificity.

Introduction

Over the last 100 years, many theories have attempted to explain the cause of malocclusion. Most have stated that it is inherited, but, more recently, greater emphasis has been placed on the influence of the environment, especially the activity and the posture of the oral soft tissues. Unfortunately, it is not possible to measure long-term posture with any precision, and this has reduced its perceived importance. When some evidence is missing and much of the rest conflicting, there is merit in moving from the traditional “prove-it” attitude to philosophical reasoning to separate the probable from the improbable. We do not know to what extent posture and parafunction might be inherited, but there can be no doubt that facial and dental structures are, at times, strongly influenced by the soft tissues and that some malocclusions appear to have a postural basis.¹,²,⁴

Appropriate measures need to be adopted to measure the stomatognathic function and to assess its relation with the body posture. For this, several mechanical or electronic devices have been used as measurement tools in the research setting, they include surface kinesiography (KG), electromyography (sEMG), postural platforms and posturographic devices. However, their use in the clinical setup as stand-alone diagnostic method has raised a lot of negative criticism within the scientific community (5-6). Of course, the most common application for some of the above devices is in the diagnosis of TMD symptoms (8).

Method: A Pubmed search for articles relevant to the topic “Dental occlusion, body posture and temporomandibular disorders”, was done using MeSH terms –“occlusion,posture,temporomandibular joint “. The search was limited to the period January 2005 to September 2019. 98 abstracts were perused out of which 58 articles pertinent to the topic were selected for the review.

Occlusion, body posture and TMD symptoms: Undeterred by the attempts made to assess and improvise the accuracy of the instrumental devices for the research of the stomatognathic system and its association with body posture (9-13), they have their own limitations to their clinical use due to the lack of normative values controlled for age, sex, weight, facial morphology and height.

Furthermore, data interpretation is unreliable due
to the high intra- and inter-examiners variability(14). Most of the instrumental data on the stomatognathic system were achieved with sEMG recordings, which aid in assessing the kinesiology of movement disorders, myoclonus and dystonia, to evaluate gait and pace disorders, to discriminate between different tremors, to measure psychophysical reaction time. The most useful and unique field of application for sEMG is the research setting, even though too many shortcomings do not suggest its clinical application in diagnosis(15). Regarding the association between occluso-postural features and clinical symptoms, the literature shows poor predictive rate of occlusal features for TMD symptoms(16-17). Also, it must be considered that myogenous TMD pain could be responsible for muscle tone and postural adaptations, so the information renders less valuable. Moreover, even the most recent systematic literature reviews did not comply with the use of irreversible occlusal therapies for TMD treatment and/or prevention(18-20). Despite the numerous amounts of papers concluding that studying dental occlusion is not a key factor in the TMD diagnosis. Occlusal features are neither found to be associated with TMD(21) nor with muscle disorders(22), even though they are the way through which muscle forces get transmitted to the various structures of the stomatognathic system(23). Also, the presence of occlusal abnormalities in patients with TMD could be due to joint degeneration and/or remodelling leading in an occlusal shift(24). Data from randomized controlled studies suggest that in healthy subjects the play of an occlusal interference leads to a deterioration of the EMG activity of the masseter muscles(25) and doesn’t majorly affect pressure pain thresholds(26). Furthermore, subjects with a TMD history seemed to respond differently to iatrogenic occlusal interferences in comparison with the subjects who had no history of previous TMD(27). Besides, an acute experimental occlusal alteration cannot be compared with a clinical diagnosis of the presence of a ‘non-ideal’ dentition which the patient gradually adapted over the years(28,29). Temporomandibular disorders have a multifactorial etiology and there is no single factor causing it thereby deriving weak associations between occluso-postural factors and TMD as described by few authors in their study(30,31). The role of occlusion in the etiology of TMD have well established concepts in field of prosthetics and orthodontics, since wrong occlusion on restored/treated dentition has the potential to lead to iatrogenic trauma(32,33). To conclude, a mechanical approach to TMD management by ways of irreversible occlusal treatments, which are recommended on the basis of diagnostic assessments of patients with TMD, should be discouraged from a scientific viewpoint and also condemned from an ethical viewpoint(39). Owing to the poor knowledge on TMD etiology(34-37), the treatment for TMD treatment is based on symptoms management by reversible and non-invasive treatments(40); most patients suffering with TMD symptom are good responders to unspecific treatment regimens, due to symptom fluctuations and and placebo effect(41,42).

**Diagnostic reliability of technological devices:** Practically, to be useful clinically, the instrument should have repeatability and technical efficacy, accuracy to measure the main pathological marker (i.e. presence vs absence of disease) renders the validity of the instrument. The main pathological marker is pain in the field of TMD. The quest to determine the association between clinical symptoms (e.g. pain evoked with palpation) and instrument efficacy lead to development of better recognizing measures, such as magnetic resonance imaging(43,44), for accurate diagnosis(45,46). The same concept applies on clinical efficacy of sEMG, KG and postural platforms, which have internal validity. Many authors showed that these techniques have a low accuracy to distinguish amongst patients with TMD and asymptomatic subjects(47-49). Their involvement as diagnostic or even treatment-planning tool in patients with TMD can be justified owing to greater false positives, almost up to 80% for various parameters (e.g. sEMG values at rest, all postural platform variables and all kinesiographic parameters)(50-51). Despite this, the literature also projected that sEMG they usage can be relied in the clinical setting. According to the pain adaptation model

and(50-51), motor units recruitment are affected negatively and maintaining normal physiological functioning causes reduction in maximum muscle force. Standardized approaches under controlled experimental conditions allowed recording accurate measurements(52), with valid values of sensitivity and specificity for sEMG values at the time of maximum clenching(50). Standardized sEMG in laboratory settings showed a sensitivity of 86% and a specificity of 92% to discriminate between patients with TMD and those with pain in the neck but they cannot identify asymptomatic subjects(52-54). Those two studies assessed respectively an asymmetry index of the body sway area on postural platforms applied in controlled laboratory settings(55), and few clinical parameters for the trunk postural analysis on the sagittal plane(55). Therefore, numerous
studies, even if positive outcome were claimed on the use of postural platforms even though not substantiated by their own study (52-54), discouraged the use of clinical postural assessment and posturographic devices in the field of dentistry (56-59).

**Conclusion**

To conclude, there is no evidence substantiating association between occlusal and postural features, and it is quite evident that TMD pain is unrelated to the existence of measurable occlusopostural abnormalities. Therefore, the employment of instruments and techniques aiming to measure occlusal, electromyographic, kinesiographic or posturographic abnormalities can’t be justified in the evidence-based TMD practice.

The use of devices to assess dental occlusion and body posture have to be restricted to controlled research settings. Only then, hypothesis-tested clinical revelations can be drawn. From an ethical viewpoint, all medical professionals involved in the management of patients with TMD have to recognize their role of care-providers taking care of the patients’ interests within the boundaries of evidence-based medicine.

**Ethical Clearance:** Not required since it is a review article.

Dermatoglyphics in Orthodontics: A Review

G. Nidhya Varshini¹, M.S. Kannan²

¹Post Graduate Student, ²Professor and Head of the Department, Department of Orthodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

Abstract

The word dermatoglyphics is basically a greek word meaning derma=skin, glyphae = carve. It is the scientific study of friction ridges on the palmar and plantar surfaces of hand and feet. Fingerprints are usually formed at the 13th to 19th week of an embryo. It is revealed 6 months after birth. They remain constant, except for the change in their sizes. Embryological development of oro dental structures occurs around the same time. Hence many studies were done to establish the association between dermatoglyphics and dental and skeletal malocclusions. In developing countries with a large population, the simplicity of dermatoglyphic technique and its inexpensiveness warrants its continued use as a diagnostic tool. When combined with other clinical and investigative features dermatoglyphic study can serve to strengthen a diagnostic impression and can be used as a useful screening device.

Keywords: Dermatoglyphics, Finger prints, Hypodontia.

Introduction

The history of dermatoglyphics goes back through centuries when Chinese used it as a means of fortune telling. Ancient Indians believed that the presence of ten whorls destined a person to be an emperor.

In 1684, Nehemiah Grew, a physician, published the first description of the epidermal ridges making distinct patterns while recording fingerprints. These “innumerable little ridges of equal width and distance, and everywhere running parallel one with another,” contain the pores of the sweat glands. Grew also described them as “ellipticks” and “triangles.” After which, another paper was published in Amsterdam of a brief account in Bidloo’s (1685) Anatomia Humani Corporis. After a couple of years, a comparable description was given by Malpighi in De Externotactusorgano. After a long time, in 1823, Purkinje, described nine types of patterns (or varieties of curvature) on the fingers.

However, Galton in 1892 carried out the first systematic study. Initially, the value of fingerprints for personal identification was studied, for their uniqueness and constancy. He was the first to study dermal patterns in families and racial groups. It was further elaborated and improved by Sir Edward Richard Henry of Scotland Yard for identifying criminals. And they are increasingly used in anthropology, medicine, and genetics. Dermatoglyphics, as Harold Cummins of Tulane University, named the study of epidermal ridges in 1926, cuts across all these disciplines.

For many years, evidence has accumulated, which suggest that fingerprint patterns are determined by heredity. Yet qualitative analysis and other features of fingerprint patterns such as form and direction led to inconclusive results. In 1950, Cherrill published a paper on fingerprints and diseases. As a result of examination of the hands of decomposed cadavers over a long period, he noticed that the muscles and skin of the left-hand exhibit signs of greater decomposition than the right. Cherill’s work was followed by Fang’s “A note on a-b ridge count and intelligence.”
During the 1950s, the most relevant paper to appear was Walker’s, “The use of Dermal Configurations in the Diagnosis of Mongolism” (1957), which extended the knowledge of dermatoglyphics in this condition and attempted to quantify dermal configurations for use as a meaningful diagnostic tool.

In the past 50 years, a lot of work has been done on various aspects of dermatoglyphics and developmental disorders, to name a few: on rudimentary palms of infants damaged by Thalidomide. “A dermal configurations in the diagnosis of Down syndrome; “Unusual dermatoglyphic associated with major congenital malformations;” Palmar and digital dermatoglyphics in Congenitally deaf subjects.

**Morphology:** Cummins and Midlo\(^3\) classified various pattern types on fingertips as:

1. Arch
2. Loop
3. Whorl
4. Composites.

**Fig 1:** Three basic patterns of fingerprints

1. Loops: Ridges entering from a side and exiting from the same side is a loop. All loops have one delta. Loops were divided into single loop or double loop.
2. Whorl: Has at least two deltas and a type line. One ridge must complete the circuit. Ridge can be spiral, oval, or any variant of a circle. The whorl was further sub-classified into symmetrical and spiral whorls.
3. Arches: They do not have a type line, deltas, or cores. Simple arch is the simplest and constitutes ridges extending from one side of the print to the other side at the center of the pattern, thus forming a wave-like structure. The tented arch is similar, but rises sharply in the center, causing a thrust/spike, or the ridges meet at an angle less than 90 degrees\(^4\)

**Use of Dermatoglyphics in Dentistry:**
Dermatoglyphics is used in dentistry to determine oral pathology like oral clefts, dental caries, and submucous fibrosis\(^4\). The different patterns of fingerprints like plain loop, double loop, arch with loop, plain whorl, double whorl, arch with whorl, plain arch, tented arch and central pocket loop have an important role in determining the degree of dental caries with increase in whorls a person is more prone to dental caries while less number of loops decreases a person’s susceptibility to caries\(^5\). Increased whorls, higher total finger ridge count and higher interdigital radial and ulnar loops are characteristics of caries. In case of cleft lip and palate, there is high incidence of arches, double loops and ulnar loops.

**Method of Recording Dermatoglyphics:**

**Ink Method:** This is one of the most widely used method. The various required equipment are printer’s ink, a roller, a glass or metal inking slab, a sponge rubber, and good quality paper.\(^6,7\)

**Faurot Inkless Method:** In this method, commercially available patented solution and specially treated, sensitized paper are used.\(^7\)

**Photographic method**

It is based on the total internal reflection. \(^8\)

**Transparent adhesive tape method:** In this method, a dry coloring pigment is applied to the skin and is lifted off with the transparent adhesive tape.\(^9\)

**Special method:** This helps in studying the correlation between the epidermal patterns and the underlying bone structures.\(^9\)

**Numerical method:** In this method, an algorithm of images of fingerprints is used

**Dermatoglyphics in Orthodontics:** Kharbanda et al.,\(^10\) in 1982, conducted a study on 25 North Indian males by with true mandibular prognathism which was confirmed with cephalometric Down’s analysis. They compared this with the dermatoglyphic findings of individuals with Class I occlusion and craniofacial pattern. They stated in their study that the craniofacial
skeletal Class III pattern was associated with an increase in arches and ulnar loops at the expense of whorls on all digits except digit II, there was an increased frequency of whorls and radial loops, and an increased frequency of carpel loops on interdigital area of palms.

Lakshmi conducted a study in 1989, where they studied the fingerprint patterns of twenty patients with hypodontia and compared with those of twenty normal males and 20 normal females. The frequency of whorls and arch patterns was more compared to that of the loop patterns in individuals with hypodontia as compared to normal females. An increased frequency of whorls and decreased frequency of loops and arch patterns were found as compared to normal males.

In 1997, the study was conducted by Reddy et al. where dermatoglyphics was used to predict and compare Class I, Class II division 1, division 2, and Class III malocclusion. The study revealed that increased frequency of arches and ulnar loops and decreased frequency of whorls were associated with craniofacial Class II division 1, division 2, Class III malocclusion was associated with an increased frequency of arches and radial loops with decreased frequency of ulnar loops.

A study was undertaken by Trehan et al. in 2000 to analyze and compare the dermatoglyphic patterns of patients with normal occlusion and various classes of malocclusion. The study showed an association of increased frequency of radical loops and arches with Class I and Class II division 1 malocclusions. Furthermore, an association of an increased frequency of whorls with Class I and Class III malocclusion was seen when compared to normal occlusion.

A study was conducted by Reddy et al. in 2013 in an attempt to compare the dermatoglyphic patterns of individuals with normal occlusion and various classes of malocclusions. Particular predictive occurrence of patterns was not found to be associated with each group, but some of the fingerprint patterns such as twinned loops were seen with an increased frequency in Class II malocclusions and radial loops were absent in Class III malocclusions.

In 2019, a study by AlShahrani, to assess correlation of dermatoglyphic pattern with quantitative palatal anatomic parameters measured using three-dimensional scanning of dental casts and to explore the possibility of utilizing these to predict future occurrence of malocclusion.

**Conclusion**

In can be concluded from the above studies there is a co-relation between ridge patterns and malocclusion. However, dermatoglyphics can only be used as a screening method but not the diagnostic method because, numerous other factors such as ethnic and racial variations, congenital, environmental and other local factors can also influence the development of malocclusion.

Application of Resonance Frequency Analysis in Orthodontics: 
A Review

R. Padmavati¹, A. Arif Yezdani²

¹Post Graduate Student, ²Professor & Director, Department of Orthodontics and Dentofacial Orthopedics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Chennai, Tamil Nadu, India

Abstract

The success of mini implants depends on primary stability followed by secondary stabilization. Resonance frequency analysis has been used to assess the primary stability of implants used in dentistry. There is a paucity in the literature regarding its use in orthodontics. This review attempts to showcase the efficiency and reliability of resonance frequency analysis for assessing stability of orthodontic implants.

Keywords: Mini implants; resonance frequency analysis; primary stability.

Introduction

Primary stability results from mechanical interlocking of implant threads with cortical bone and secondary stability develops from regeneration and remodeling of bone and tissue around the implant post insertion. The combined effects of primary and secondary stability determine the total clinical stability of an implant.¹

There are different method to measure the stability of mini-implants. The most widely reported approach is measurement of maximum insertion torque during insertion for which precise torque sensors are commonly used. Periotest device is yet another equipment used for measuring stability. It works on the principle of capturing the damping characteristics of a mini-implant. This is accomplished by percussing the implant head with a small pestle that will rebound at a specific speed depending on implant stability. During contact, a piezoelectric crystal inside the head of the pestle is deformed, thus creating an electric impulse that reveals the duration of contact. This time based information is converted to stability expressed as Periotest values. This method first developed to measure tooth mobility, was introduced to implant dentistry by Bragger et al. ²

In 2000, the Osstell device³ (Integration Diagnostics AB, Göteborg, Sweden) was introduced for monitoring dental implant status. When a detection device is used for resonance frequency analysis (RFA), stable coupling between the SmartPeg transducer and implant is needed. A transducer suitable for the size and structure of a particular mini implant may be difficult to obtain. The main advantage of RFA over traditional method such as torque assessment is the ability to perform measurements without changing or disrupting the mechanical characteristics of the bone-implant interface⁴ making it the most appropriate method to monitor the stability of implants throughout their clinical application.

This review of literature focuses primarily on the efficiency and reliability of resonance frequency analysis in measuring the primary stability of orthodontic mini implants.

Method

A Pubmed search for articles relevant to the topic “Resonance frequency analysis in orthodontics”, was done using MeSH terms –“Orthodontics”, “Resonance Frequency Analysis”. The search was limited to the
period January 2005 to September 2019. 86 abstracts were perused out of which 19 articles pertinent to the topic were selected for the review.

Discussion

RFA is considered to be the gold standard noninvasive method for measuring the clinical stability of dental implants immediately after placement. One of the method to check the primary and secondary stability of implant is measuring the peak insertion and removal torque values. Disadvantage with this method is that it can be done only during insertion and removal of the mini implant. Orthodontic mini-implants differ from prosthetic dental implants with respect to size, design, surface characteristics, insertion method and insertion sites due to which the results of RFA measurements are significantly affected. To assess mini-implant stability several authors tried various method to make the smart peg compatible with the mini implant head.

Meredith et al 5 described the resonance frequency analysis using Osstell device. Osstell devices have been manufactured since 1999 by the Integration Diagnostics Ltd. Company (Sävedalen, Sweden). Several generations of this device have followed one another for implant stability measurement like Osstell, Osstell Mentor and OsstellISQ. This device uses transducers that are connected to the implant. One difficulty that is encountered is the connection between the mini implant and the SmartPeg. The transducers (SmartPegs) produce a lateral force on the fixed components and the system shift is then measured. Thus, RFA measures the stiffness and deflection of the implant-bone complex 5. The value obtained by Osstell is automatically translated into an index called Implant stability Quotient (ISQ), ranging from 1 to 100 with 100 being indicative of highest stability value (Fig 1). It also allows stability to be evaluated over time.

Yu yusu et al 6(2009) performed a study regarding RFA for mini implants used adhesive fixation of a magnet to the mini implant’s head. The results suggested that RFA might work for mini implants. However, it should be noted that the bonding strength between the transducer and the implant could be affected by factors such as acrylic resin thickness, moisture contamination, or available bonding area. Moreover, it is still unknown whether similar results could be obtained with different adhesives. Veltriet al 7 soldered the SmartPeg over the implant head using an abutment. However, this method was not suitable as the soldering process might affect the magnetism property of the SmartPeg.

In a study by Ureet al 8, the SmartPegs were screwed into the head of the mini implants and tightened with finger pressure. Screwing the Smart Peg into the head of the mini implant and unscrewing it after the recordings may have contributed to the high failure rate, because all of the failures occurred while attempting to unscrew the Smartpeg.

A study done by Nienkemper et al 9 have found a strong correlation between Periotest values and RFA and they have suggested that RFA is a feasible measurement method for orthodontic mini implants. Nienkemper et al 10,11 modified the SmartPegs to fit with the inner screw thread of orthodontic mini-implants. Therefore, it
would be desirable to use RFA to evaluate orthodontic mini implants as well. Because of the sensitivity of this measurement technique, a stable, solid, and reproducible connection must be ensured to make it work. However, this screw coupling cannot be made on the mini implant head as the head of the mini implant is used for various mechanics purpose, and moreover, the head of the mini implant is small to provide a screw coupling. To meet all the requirements of an ideal connector, Hosein et al. described a universal adaptor (MISPA) that fitted with multiple mini-implant designs without altering the implant itself. However further clinical trials are required to check its efficiency and accuracy. Suzuki et al. in his study, to evaluate the possibility of using RFA to assess the stability of miniscrew implants made a custom connector to allow the attachment of the transducer to the head of the miniscrew implant head. Tseng et al. used a RF analyzer (Implomates, BioTech One, Inc., Taipei, Taiwan) in many of his studies in which the mini-implant’s head was impacted by the tapping rod of Implomate.

Conclusions

- RFA is a reliable method for measuring orthodontic mini-implant stability provided there is adequate bonding strength between the transducer and the implant.
- It could be effectively used for clinical evaluation of current stability and stability-related loading of mini-implants in order to reduce the failure rate of mini implants.

Role of Respiration and Malocclusion: A Review

Sowmya Mohan Kumar¹, D. Amudha², M.S. Kannan³

¹Post Graduate Student, ²Tutor, ³Professor and Head of the Department, Department of Orthodontics, Sree Balaji Dental College And Hospital, Bharath Institute Of Higher Education and Research, Chennai

Abstract

Prevalence of Malocclusion has been increasingly reported. A proper diagnosis of the etiological factor is crucial to achieve a successfully completed treatment. Malocclusions have peculiar distribution of occurrence. This can be attributed to the geographical condition, developmental anomalies or habits that are acquired over time. A thorough investigation of the malocclusion, the reason for its development and others factors that could influence the treatment outcome should be analysed before starting any procedure. This review article specifically analyzes the role of respiration and how its alterations can result in the particular type of malocclusion. A proper understanding of the basic anatomy and physiological process, guides in clinical correlation of the aberration. Furthermore, other additional diagnostic method to assess the qualitativeness and quantitativeness of the type of respiratory disorder will aid in accurate diagnosis and various treatment modalities that can be included to eliminate this etiological factor in intercepting the malocclusion. Dentists maybe the first healthcare professionals to have contact with a mouth breathing child. Thus early detection and need for appropriate treatment can be made possible when there is a series of tests that can be implemented to assess the need for management.

Keywords: Malocclusion, Gingivitis, Periodontitis.

Introduction

Nasal breathing is a key factor that influences the growth and development of the orofacial complex by aiding proper functioning of the oral cavity. Ideal cycle of normal respiration includes cleansing, humidification and moisturization of the inspired air.

Any obstruction or congestions of the upper respiratory tract may negatively impact the most optimal respiratory tract. This switch from nasal to oral breathing leads to serious consequences. They have a negative impact on the developing orofacial region and often result in other symptoms such as sleep disorders, such as frequent waking-up, nocturia, difficulties falling asleep. Chronic muscle tension around the oral cavity could result in the widening of cranio-vertebral angle, posterior position of mandible and narrow maxillary arch. Among dental alterations the most common are class II malocclusion (total or partial) with the protrusion of the anterior teeth, cross bite (unilateral or bilateral), anterior open bite and primary crowded teeth. Apart from malocclusion, chronic gingivitis, periodontitis, candida infections and halitosis are frequently present in mouth-breathing patients.

Mouth breathing is defined as the habitual respiration through the mouth instead of the nose which can be either Obstructive, Habitual or Anatomical type. There are various factors that contribute to this of which commonly seen ones are Nasal Obstruction that includes hypertrophy of nasal turbinates due to allergies, chronic respiratory infections, pollution or hot and dry climatic conditions, Pharyngeal Lymphoid tissue hypertrophy such as tonsillitis, adenoids enlargement. Other conditions associated with it are Intranasal defects – deviated nasal septum, allergic rhinitis, nasal polyps.
genetic predisposition, short hypotonic lip, Obstructive sleep Apnoea syndrome or habitual.

Therefore, it is necessary to intervene early on these aetiological factors of malocclusion to prevent its development or worsening and, if already developed, correct it by early orthodontic treatment to promote skeletal growth.  

Basic Anatomy and Physiology: Breathing is defined as pulmonary ventilation, wherein there is a movement of air between the atmosphere and the lung alveoli. It involves 2 events: inspiration and expiration.

The airways are subdivided into conducting zone (airways) and respiratory zone. The conducting airway carry the air in and out of the lungs. It comprises of the following: the nose, the nasopharynx, larynx, trachea, bronchi, bronchioles and terminal bronchioles. Orthodontists can influence and bring about changes if the derangement is around the nasopharynx region.

Respiratory need are the predeterminant of the posture of the jaws and the tongue. An altered respiratory pattern (mouth Breathing) could change the position of the jaw, head and tongue. Thus the mandible and tongue are lowered, head extended, and face height would increase, posterior teeth would supraerupt. The mandible tends to rotate downward and backward, opening the bite anteriorly and increasing the overjet giving the descriptive appearance of adenoid facies.

Clinical Correlation of Applied Anatomy: Mouth breathing habits are frequently associated with orthodontic problems. In the nasal area, the lack of ventilation leads to an underdevelopment of the maxilla: lateral and sometimes anterior cross bites appear. In the buccal area, the need of maintaining the mouth opened induces a new postural position of the mandible which alters the pattern of growth of the mandible (“long face”). The functional context of the buccal praxis is also altered: low or protruded tongue, deviant swallowing, troubles of speech. The treatment of this pathological context needs a pluridisciplinary approach where the otorhinolaryngologist, the dentist, the orthodontist and the speech pathologist have to play an important role. In the orthodontic fields, we have to carry out an orthopedic treatment (rapid maxillary expansion, facial masks) to normalize the growth of the maxilla before the orthodontic treatment.

The prevalence of posterior crossbite is higher in mouth breathing children than in the general population. During mixed and permanent dentitions, anterior open bite and class II malocclusion were more likely to be present in mouth breathers. Although more children showed these malocclusions, most mouth breathing children evaluated in this study did not match the expected “mouth breathing dental stereotype”. In this population of mouth breathing children, the obstructive size of adenoids or tonsils and the presence of rhinitis were not risk factors to the development of class II malocclusion, anterior open bite or posterior crossbite.

Felcar et al 1 found absence of sealed lips in 58.8% of mouth breathers, and sagging and hypofunction of the orbicularis oris muscle were considered causes of lack of lip seal in 67% of mouth breathers. Absence of sealed lips suggests the presence of vertical and sagittal facial discrepancies, inadequate lip length, increased lower facial height, abnormal breathing function, and altered lip tonicity. Increased lower facial height, a characteristic of the dolicho facial type, in

The most prevalent malocclusions found in the mouth-breather group were atresic palate and anterior open bite. Several studies have confirmed the close relationship established between teeth, supporting tissues and the functional activity of the neuromuscular system. When abnormal pressure of muscles interferes in facial growth, it can determine the appearance of a malocclusion. The tongue can take a low and forward position, which is common in the presence of hypertrophic palatine tonsils as an attempt to increase posterior airway space and ease breathing. The low position of the tongue decreases internal pressure in the upper arch, increasing the external pressure of perioral muscles and causing an atresic palate. Because imbalance can cause anatomical and functional changes, proper balance between bones, muscles, and dental structures is essential.1

Postural problems were noted to be significantly more common among children with mouth breathing syndrome, thus highlighting the need for early interdisciplinary treatment2 he principal etiologic bases of MBS are mechanical obstruction of the upper airways (adenotonsillar hyperplasia, inferior turbinates hypertrophy and nasal septum abnormalities), inflammatory diseases (allergic rhinitis) and congenital malformations with craniofacial deformities. In chronic mouth breathing air reaches the lungs via a shorter and easier path. This can lead to changes in respiratory rhythm with deglutition of air, which causes abdominal
distension and flaccidity, compromising thoracic expansion and pulmonary ventilation. Changes to muscle strength balance have also been observed, in addition to effects on growth and development, caused by poor respiratory mechanics and function.

Mouth breathing children with snoring tend to have a more convex profile than non snorers. Clinical examination can reveal lips to be apart, deep breathing, hoarseness of voice, malocclusion.

**Method of Diagnosing Disorders of Respiration:** Reliable way to quantify the extent of mouth breathing is to establish how much of total airflow goes through the nose and how much goes through the mouth, which requires special instrumentation to simultaneously measure nasal and oral airflow. For the average individual, there is a transition to partial oral breathing when ventilatory exchange rates above 40-45 L/min is reached. At maximum effort, 80 or more of air is needed. At rest, a minimum of 20-25 L/min is present but heavy mental concentration or even normal concentration leads to increased airflow and transition to partial mouth breathing.

COMMONLY USED clinical testing method include:

1. Mirror test
2. Butterfly test – Massler and Zwemmer
3. Water holding test
4. Rhinomanometry
5. Cephalometrics

Cephalometric variations include considerable backward and downward rotation of the mandible, increased overjet, increase in the mandible plane angle, a higher palatal plane, and narrowing of both upper and lower arches at the level of canines and first molars thereby predisposing to clockwise rotation of the mandible with disproportionate increase in anterior lower vertical face height and decreased posterior facial height.

Use of EEG to find if mouth breathing is acquired as a learned habit: Continuous mouth breathing results not only morphological deformations but also poor learning outcomes. A study was conducted to investigate the changes in brain activity during mouth breathing while the participant simultaneously performed a cognitive task using electroencephalography (EEG). Mouth breathing showed different brain activity patterns, compared to nose breathing. The reason for this change seems to relate to the decreased oxygen saturation during mouth breathing, suggesting that when cognitive abilities are required, mouth breathing can act as one of the variables that cause different outcomes in brain activities.

Three dimensional morphological changes associated with mouth breathing: Mouth-breathing children have significantly reduced inter-molar width, palatal volume, and surface, and substantially increased palatal height, leading to different developmental patterns of the palatal morphology.

Lingual and Maxillary Labial Frenuloplasty with Myofunctional Therapy as a Treatment for Mouth Breathing and Snoring: A case report explores the case of a three-year-old girl with mouth breathing, snoring, noisy breathing, and oral phase dysphagia that was successfully treated with lingual and labial frenuloplasty as an adjunct to myofunctional therapy. Within four days of the procedure, the patient had stopped snoring and demonstrated complete resolution of open mouth breathing. The patient was also observed to have increased compliance with myofunctional therapy exercises. This report highlights the effectiveness of surgical interventions to improve the efficacy of myofunctional therapy in addressing open mouth posture and low tongue resting position.

Clinical Recognition of Mouth Breathing
These guidelines can be used to examine children and aid recognition of mouth breathing

Do you:

- Sleep with your mouth open? () YES () NO
- Keep your mouth open when you are distracted? () YES () NO
- Snore? () YES () NO
- Drool on your pillow? () YES () NO
- Experience excessive daytime sleepiness? () YES () NO
- Wake up with a headache? () YES () NO
- Get tired easily? () YES () NO
- Often have allergies? () YES () NO
- Often have a stuffy nose and/or runny nose? () YES () NO
- Have difficulty in school? () YES () NO
- Have difficulty concentrating? () YES () NO

3. Breathing tests

The child must be sitting. At least two tests should be performed.

a. Graded mirror test

After the second output of air on the mirror, mark the halo area with a marker (Fig 1).

(Low nasal flow: up to 30 mm; Average nasal flow: 30-60 mm; High nasal flow: above 60 mm)

b. Water retention test

Place water in the patient’s mouth (approximately 15 ml) and ask him/her to hold it for 3 minutes.

c. Lip seal test

Seal the patient’s mouth completely with a tape for 3 minutes.

4. Training to eliminate the habit of mouth breathing

Training should be performed at home on a daily basis until the child is able to return to nasal breathing.

Lip seal test

Seal the child’s mouth with masking tape when he/she is distracted or focusing his/her attention on another activity. Progressively increase the time each day until the child is able to breathe only through the nose for, at least, two consecutive hours.

Treatment and Management Considerations:

Once diagnosed, early intervention of respiratory disorders is required. Treatment considerations should include age of the child, appropriate ENT examination, timing of the treatment. Treatment should aim at eliminating the cause by surgical management (septoplasty, tonsillectomy, removal of enlarged adenoids), local medication, rapid maxillary expansion in cases of constricted maxillary arches. Habit interception can be achieved by physical exercises (deep breathing in the morning and at night), lip exercises (extending the upper lip, lower lip exercise, playing a wind instrument, holding of celluloid strip or metal disk, maxillothoracic myotherapy (macacay activator), oral screen, oral shield appliance, monobloc activator, chin cap.

Conclusion

Orthodontists are perhaps, one amongst the most earliest the diagnose respiratory disorders during their routine clinical examination. Respiratory disorders and malocclusion are like double edge swords. Disorders of one will lead to the defective development and functioning of the other. An early diagnosis and intervention will intercept the problems and can be managed non surgically. Mouth breathing, in short, may contribute to the development of orthodontic problems but is difficult to indict as a frequent etiologic agent. It is important for the entire health care community (including general and pediatric dentists) to screen and diagnose for mouth breathing in adults and in children as young as 5 years of age. If mouth breathing is treated early, its negative effect on facial and dental development and the medical and social problems associated with it can be reduced or averted.

A Beginner’s Guide to Surgical Treatment Objective: An Orthodontist’s Point of View

Diana Ashok¹, Thulasi Ram E.², Kannan M.S.³

¹Post Graduate, ²Senior Lecturer, ³Head of Department, Department of Orthodontics and Dentofacial Orthopedics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

Abstract

Visualising the result of any proposed treatment, not only guides us in each part of the journey toward the final result but also to assess if the treatment objectives are met. Any adverse effects can be easily determined, before the start of the treatment, and necessary alterations to the treatment plan can be made. Various method in which the result of an orthognathic surgery can be visualised are – overlay tracing, template tracing, cephalometric prediction tracing, computer prediction, feasibility mock surgery, etc. How to carry out these predictions are discussed in detail in this article.

Keywords: Surgical treatment objective (STO), Cephalometric prediction tracing, feasibility mock surgery, template tracing, dolphin imaging, 3D cephalometric analysis.

Introduction

The lateral cephalogram’s advent is one of the milestones in orthodontics. It paved the way of better understanding, diagnosing and ultimately treating the underlying dentofacial anomaly.

A lot of contributions have been made by various authors, like Tweed’s diagnostic triangle in 1954 which gained a lot of attention. Following him, various other cephalometric analyses were proposed by Steiner’s, Mc Namara, Down’s. In 1960, Rickett proposed a method of predicting growth with the help of serial cephalograms taken at different points of time, over a period of time. Hold away in 1983, stated the importance of the soft tissue parameters in the orthodontic treatment, and suggested a VISUALIZATION of the treatment objective (VTO) – to have an idea as to how the outcome of the treatment would affect the profile of the patient.

This method of visualization, led to the development of a cephalometric prediction tracing by Epker and Fish, which gave a mental image at the outcome for a surgical intervention. In 1985 – Larry Wolford, introduced the term – “Surgical Treatment Objective(STO)”, which is basically a visualization of the outcome of an orthognathic surgery prior to the start of treatment, to better assess the end result.

Types:

The prediction can be for
1. Orthodontic and surgical use
2. Surgical use

The Orthodontic and Surgical VTO is the discussed further in detail in this article. Surgical VTO is more important from an Oral and Maxillo-Facial Surgeon’s point of view.

Orthodontic Surgical VTO: When a malocclusion is too severe to be corrected by only orthodontic interception, the patient might need a surgical correction, it involves an interdisciplinary approach where the orthodontist and the oral surgeon work together as a team in achieving the best treatment results for the patient.

When surgery is planned in the treatment, it is adviceable to perform the surgery earlier on in the...
treatment, as the precision achieved by fixed appliance in orthodontics is better than that of the surgery. There will be rapid tooth movement 3 months Post-Surgery, due to the inflamed bone and there is early improvement of the facial appearance, which aids in better patient compliance.

Two–Patient Concept: Epker and Fish, came up with something called as the “TWO PATIENT CONCEPT”. A mock surgery was performed in the patients casts and the new set of casts were treated as a second patient. The mock surgery helps the Orthodontist to assess with a Pre – Surgical Orthodontic phase is required or not. If the Mock surgery is carried out after a Pre-Surgical Orthodontic Phase is over, it helps the orthodontist assess if any other corrections need to be made prior to surgery or if the Clinical situation presented before him, at the end of surgical phase (with the help of mock surgery) can be handled and tackled by him, in the Post Surgical Orthodontic Phase.

Another method of applying this two patient concept, is with the help of Cephalometric Prediction Tracing. Various method of Cephalometric prediction can be carried out and the Prediction obtained at the end can be treated as a Second patient. Now the task is to simply start with patient one and reach the results of patient two. So it becomes easier to envision and tackle the complicated malocclusion involving surgery.

Various Method of Cephalometric Prediction: For decades, Cephalometric prediction was done by hand, manually, by taping acetate sheets to radiographs. In this method the angles were measured directly with the help of protractor, ruler, divider, etc. Then came into play the Computerised method, in which the landmarks can be directly digitised with the help of an electronic pen or a crosshair cursor. For indirect digitization, a scanner or a digital camera captures the image and stores in the computer’s memory.

Manual Method

The first manual method used to predict a mandibular surgery was given by Cohen(4). In this method he demonstrated the soft tissues changes by carrying out the usual cephalometric tracing of maxilla, maxillary teeth, followed by the tracing of the lower face. Then another tracing of only the mandible and the lower face was done and cut out. He used divider to record the amount of Mandibular movement and he slid the cut out section over the original section to mock the surgery. Another tracing was done with the new position of the mandible and the soft tissue changes were observed.
A similar method of Overlay tracing was given by Mc Neil (5), in which he oriented the patients casts to the post surgical position and that helped determine the amount of posterior movement of the overlay.

Henderson (6) proposed a method of using the patient’s profile photograph with a transparency of 1:1 superimposed over the Cephalometric tracing in order to better understand the soft tissue changes. The photographic prediction method was also advocated by Hohl at al (7).

The method of surgical-orthodontic cephalometric soft tissue prediction tracing for mandibular advancement, maxillary superior repositioning and combined maxillary and mandibular surgery was proposed by Fish and Epker (8). The authors believed that the three method explained by them would suffice to predict any Orthognathic surgery.

**Computerised Method:** The computerised method, involves digitising the cephalometric tracing and landmarks or to save the image digitally and carry out the tracing on the computer, virtually. There are numerous softwares available which can carry out the Cephalometric Prediction tracings (9). The first computer software was developed by Bhatia and Sowray (10), where they used graphics to mimic the outcome of the surgery.

Later on many softwares were introduced and used by various authors like, Harradine and Burnie (11), Walters and Walters (12), Freihofer (13), etc.

Currently there is a wide variety of computerized cephalometric software systems for orthognathic surgery prediction. Quick Ceph was the first commercially available software for orthognathic surgery prediction. The Quick Ceph Image (Quick Ceph Systems, San Diego, California) it is designed for Macintosh computers. It permits a wide range of functions based on a 28-point digitization. When orthodontic and surgical movements are simulated, horizontal and vertical changes are recorded by the computer. The soft tissue adjusts automatically according to predetermined ratios. The majority of these ratios are derived from Wolford et al. (1,14).

The various other softwares available include, The dentofacial planner, Vistadent, Orthodontic Treatment Planner (OTP), Orthognathic Prediction Analysis (OPAL) (15), Dolphin Imaging Software (16), etc.

**Video Imaging:** More recently, the introduction of computer software programs with video imaging by Sarver et al. (17), surgery has greatly facilitated and improved the communication of the final predicted esthetic outcome and allowed the clinician to rapidly analyze, plan, perform the simulated surgery.

True vision image processing system (TIPS) (18) is a software that superimposed the patients profile image, captured from the video imaging, over the cephalometric prediction to better visualise the soft tissue changes. Another video imaging software was given by Grubb (19) where the patients study casts data and Cephalometric data can be fed onto the computer and various analysis are carried out by the computer software.

The purposes of calibrating the cephalogram to the profile video image are to: (a) relate the underlying hard tissue to the soft tissue, (b) allow quantification of movements needed for occlusal correction and aesthetic ideal to be achieved, (c) allow realistic movements to be planned and, (d) permit the treatment plan to be designed as close as possible to the patient desires.

Video Imaging poses as a major addition to the contribution of computers towards Orthognathic Surgery treatment planning. However, there are also some errors encountered with the use of softwares in Superimposition of facial images and Cephalometric radiographs (20).

The 2D views have limitations such as Head positioning errors, rotational errors, etc. It particularly gets tricky when it comes to planning complex surgeries such as in patients suffering from various syndromes, cleft lip and cleft palate, asymmetry, deviated chin etc. (21,22)

**Three Dimentional Prediction Method:** Nowadays, with the advent of various imaging facilities that can capture the patient’s hard and soft tissue details in 3D, it has become more easier to predict the outcome of the treatment, in a three dimentional manner. The various three dimentional imaging facilities available are the Computed Tomography (CT), Cone Beam Computed Tomography (CBCT), and Magnetic Resonance Imaging (MRI).

The data obtained from these diagnostic imaging can be fed to the computer and the 3D cephalometric softwares available can be used to carry out the various prediction tracings (23), mock surgeries etc.
The software uses graphic interpretation and mocks the soft tissue changes almost flawlessly, by adapting the soft tissue profile of the patient obtained from the diagnostic imaging. This customised prediction, better enables the visualization for both the clinician as well as the patient who is undergoing the surgery. Surgeons can benefit from performing mock surgeries, osteotomies on the software, to determine and plan the accuracy of their osteotomies.

The first complete 3D model for prediction of orthognathic surgery developed by Nakasima et al., which can be adjusted to the patient’s head from cephalograms, 3D stereophotographs and dental casts. The fusion model replaces the need for model surgery, since the virtual head can be used to design a surgical wafer, which can be used as a surgical guide.

**Conclusion**

Surgical treatment objective, is a systematic approach towards visualising the end result of surgery, as a part of treatment planning, to better enable both the Surgeon as well as the Orthodontist, to work hand in hand towards the benefit of the patient. The various method of predicting or mocking a surgery available were given in this article. It is upto the clinician to choose wisely which method to employ bearing in mind the limitations of each each technique. Each method has its owns perks, like being cost effective, simple, quick and easy. It is also noteworthy to mention that the clinicians be mindful in experimenting with various method available in order to choose the method that works best for them.

The Relevance of Nose in Achieving Aesthetic Outcome in Orthodontic Treatment: A Review

Thailavathy V. 1, Niha Naveed2, Kannan Sabapathy3

1Reader, 2Post Graduate, 3Professor and Head, Department of Orthodontics and Dentofacial Orthopedics, Sree Balaji Dental College & Hospital, BIHER

Abstract

The nose being the centre of the face and one of the most striking facial features influences the aesthetic outcome of orthodontic therapy. This topic has not received as much emphasis as it should. The nose plays an important role in every aspect of orthodontic therapy such as the diagnosis, treatment planning and post treatment prognosis. Most of the patients treated orthodontically are growing patients. Many a times, both the orthodontist and patient may be satisfied with the facial appearance at the end of orthodontic treatment. But as the growth of the nose continues till about the age of 16, the facial appearance may change.

Keywords: Facial esthetics, Nose, Orthodontics, Growth, Rhinoplasty.

Introduction

Orthodontic treatment has as its goal to achieve a balanced facial profile. A balanced facial profile has been recognized as one of the most important goal of orthodontic treatment because consciousness of beauty or physical attractiveness of patient’s face has a major psychosocial effect on acceptance and perceived success in society. Facial harmony in orthodontics is determined by the morphologic relationships and proportions of the nose, lips, and chin. The nose dominates the middle portion of the face and is in close harmony with lips and chin as it defines the characteristic facial appearance of an individual. Nose serves as a main guideline while planning orthodontic treatment. Although the functionality of the nose has been given importance, not much importance has been given to its contribution in maintaining a balance in facial esthetics. This article focuses on the importance of the nose in orthodontic diagnosis and treatment planning to achieve facial esthetics. The examination of the nose, its growth potential and changes occurring with orthodontic treatment have been elaborated in this article.

Examination of the Nose:

The upper face on frontal and profile examination is dominated by the nose, which is an area that has not been emphasized in orthodontic training. There is a great deal of orthodontic literature on the subject but it has not gotten the attention from orthodontists it deserves. An orthodontist should include examination of the nose in routine extra-oral examination procedures.

Profile Examination:

Radix: It is referred to as the root of the nose. On profile, this is orthodontically referred to as the soft-tissue nasion. It would be unacceptable to remove the dorsal hump in this type of nose because it would result in a nose with excessive tip projection. Recommended rhinoplastic treatment includes augmentation of the nasofrontal angle with nasal septum or ear conchacartilage grafts.

Nasal Dorsum: One third to one half of the nasal dorsum is called the bony dorsum because it is formed by the confluence of the two nasal bones. The nasal dorsum is the area of the nose that gets the most attention and recognition from patients. The removal of an over projected dorsal hump is one of the most common rhinoplastic procedures. Although dorsal hump removal is a commonly performed procedure, it is not uncommon to see patients who exhibit a lack of dorsal projection, or a saddle deformity. Because it is often a result of traumatic injury, it has also been termed as boxer’s nose. Recommended augmentation procedures include autografts, homografts, and implantation.

Nasal Tip-The nasal tip is part of what is often
referred to as the anterior nasal lobule. The supratip break is described as the area just cephalic to the nasal tip where the lobule meets the dorsal portion of the nose. On anesthetic nose, a slight depression is present on the supratip, which should be more pronounced in the female than the male.\[^9\][\[12\]

Goode’s method is used to evaluate nasal projection to nasal tip ratio. The vertical axis is from nasion to the alar groove. Horizontal line is from ala to the tip. Nasal projection should be 60% of nasal length. This is expected as a ratio with ala-tip nasion-tip equalling 0.55-0.60.\[^{13}\]

**Columella:** The columella is the portion of the nose between the base of the nose (subspinale) and the nasal tip. It comprises of the cartilaginous nasal septum and membranous septum. The angle formed where the columella meets the central upper lip is the columellar-labial angle; its position is determined partially by the caudal border of the septum and the nasal spine, as well as the anterior surface of the premaxilla and teeth. The soft tissues contributing to the formation of this angle are skin, muscle (mainly depressor septi nasi), and some fat and fibrous tissue.\[^{14}\]

**Nasolabial Angle:** The nasolabial angle measures the inclination of the columella in relation to the upper lip. The nasolabial angle should be in the range of 90 to 120 degrees. Its morphology is a function of several anatomical features.\[^{15}\]

**The anteroposterior position of the maxilla:** Procumbency of the maxilla tends to produce an acute nasolabial angle. Maxillary retrusion tends to produce an obtuse nasolabial angle.

**Maxillary procumbency.** Maxillary procumbency often contributes to an acute nasolabial angle. This skeletal problem may be camouflaged dentally with extraction of first premolars and orthodontic retraction of the anterior teeth in both adults and adolescents with extraction of first premolars and orthodontic retraction of the anterior teeth.\[^{17}\]

**The vertical position and projection of the nasal tip:** The high nasal tip tends to produce obtuseness to the nasolabial angle, whereas a low position of the nasal tip contributes to an acute nasolabial angle. Rhinoplasty can modify both of these problems.\[^{18}\]

**Soft-tissue thickness of the maxillary lip:** The thin upper lip contributes to a flat nasolabial angle, and lip augmentation is indicated. Procedures for this correction include injecting cosmetic fillers into the lip. These tend to be temporary solutions. Cheiloplasty with lip plumping may also be recommended. The thick maxillary lip creates an acute nasolabial angle. Reduction cheiloplasty can correct this but tends to be an unpredictable procedure.\[^{19}\]

**Frontal examination:**

**Alar Base Width:** The width of the alar base should be approximately the same as the intercanthal distance, which should be the same as the width of an eye.\[^{20}\] If the intercanthal distance is smaller than an eye width, it is better to keep the nose slightly wider than the intercanthal distance. In the growing patient, there is a little fluctuation in the alar width in females after age 14, and in males there is a significant spurt from ages 11 to 13. The width of the alar base is heavily influenced by inherited ethnic characteristics.

**Columella:** The columella is located between the nasal tip and the base of the nose. It is divided into three segments: the anterior lobula, the intermediate (narrower portion of the columella), and the basal (wider portion of the columella at the base of the nose) segments. The segments are approximately equal in dimension.\[^{14}\]

**Nasal tip:** On frontal view, the nasal tip should have four defining points. If any of these points are not in the correct position, it should be determined which is out of position and how can it be improved. The nares should be barely visible when the head is in natural head position. There is a “gull in flight” contour to the base of the nose, and the columella is slightly lower than and parallel to the ala when viewed in any direction. Tip refinement techniques may be performed through intranasal or extranasal approaches.\[^{21}\][\[22\]][\[23\]][\[24\]

**Nasal dorsum:** The nasal dorsum should be outlined by two slightly curved divergent lines extending
from the medial supraciliary ridges to the nasal tip defining points. This contour describes the desirable curvature from the brow to the nasal tip, and its width is determined by the skeleton of the external nose. The external nose resembles a pyramid, with the upper half being comprised of bone and the lower half of cartilage. Narrowing of the nasal dorsum is performed routinely in cases of dorsal hump reduction but may also be narrowed if the width of the dorsum is undesirable. [9][10][11]

**Growth of the Nose:** The orthodontist should keep in mind the age and growth factors inherent in the face of the individuals. It must also be remembered that these changes have to be harmonized with many variations that will take place, regardless of orthodontic treatment to the end that a desirable result is achieved. During treatment planning, the orthodontist must take into consideration the nose, its growth potential and most important its shape changes in analysis of facial profile. Numerous papers [25][26][27][28] have been published regarding nasal growth and its contribution to the development of the facial profile. Nevertheless, this is a topic that has not received as much emphasis as it should.

Several other studies have documented the downward and forward growth of the nose. [25] [29][30] [31] Manera and Subtelny [27] studied 46 serial headfilms from the Bolton-Brush sample, representing ages 10 to 16. Included in the sample were subjects of various angle classifications: 20 class I subjects, 22 class II subjects, and 4 class III subjects, none of whom had undergone orthodontic treatment. This study confirmed Subtelny’s documentation of the downward and anterior growth of the nose and indicated a general tendency for girls to have slightly more nasal growth than boys during the early period of adolescence.

Genecov et al [32,34] tested not only for sexual dimorphism but also for potential differences between angle classifications I and II. The data analysis collected in this study was for both sexes and angle classes to show similar amounts of soft-tissue growth from ages 7 to 12, but for a considerable dichotomy to occur between the sexes from ages 12 to 17. The females demonstrated equal, if not slightly greater, amounts of nasal projection at age 7 and experienced slightly more growth coincident with the adolescent growth spurt. Nasal projection in the females remained virtually constant from ages 12 (generally after the adolescent growth spurt) to 17.

Posen [33,35] found that in the normal child the nasal bones, as measured from nasion to rhinion, increased in length in an orderly, linear fashion between the ages of 3 months and 13 years. After a short period in which little additional growth was noted, the nasal bones showed added increases in length at 15 years and again at 18 years of age. He stated that what appears to be a pleasing and harmonious facial profile at 13 years may be radically changed by the age of 18 years.

**Changes in Nose with Orthognathic Surgery:** Orthognathic surgery alters the position of the maxilla and mandible, and consequently changes the nasal shape.

Alar base cinching is a rhinoplastic technique to correct this. With rhinoplasty performed simultaneously with maxillary osteotomy, the nasal reaction to maxillary surgery is addressed at the time of surgery, rather than having the patient endure unesthetic nasal characteristics for the period of 6 to 12 months required before a secondary rhinoplasty can be considered. In addition, the patient undergoes one surgical experience instead of two. [36][37][38]

Repositioning the maxilla inferiorly causes both the alar base and columella to move downward, overlying tissues to become thinner, and nasolabial angle to become more obtuse. [38][39]

Advancement of the maxilla results in tip of the nose being moved forward and slightly upward. The alar base will enlarge, and depression in supratip area will get accentuated. [40][41]

Although maxillary setback is a rare procedure, it has been found to decrease the projection of tip of the nose. Mandibular surgeries were seldom found to change the appearance of the nose. [41]

**Conclusion**

Over the years, improvement of facial esthetics has been the key objective of orthodontic treatment. Facial harmony in orthodontics is the outcome of the morphological balance of the nose, lips and chin. The nose being the most prominent structure when visualising the face, has been found to greatly influence orthodontic treatment outcomes. It is clinically important for the orthodontist to understand the changes of the nose that occur not only with orthodontic treatment but also the amount and direction of growth expected after completion of treatment.

Breastfeeding and Early Childhood Caries: A Review

Aarthi J.¹, Hema R.²

¹Reader, Department of Pedodontics, ²Student, Sree Balaji Dental College & Hospitals, BIHER, Velachery Main Road, Pallikaranai, Chennai

Abstract

Breast milk is the first and foremost nutrition a child receives. The enormous benefits of breast feeding have been well documented over the years. However its association with early childhood caries (ECC) has been a constant subject of debate. The etiology of ECC is multifactorial thus posing a difficulty in attributing the risk towards a single factor. The increased duration and frequency of breastfeeding along with poor dietary habits and oral hygiene practices have been reported as contributing factors for ECC. Certain constituents of breast milk have an inhibitory effect on Streptococcus mutans, the major organism implicated in the initiation of ECC. Awareness of ECC and its preventive strategies should be emphasized to young mothers along with the importance of nutrition obtained from breast milk and the benefits of breast feeding. This review is a consolidation of various factors that have been conferred as being associated with breast feeding and ECC.

Keywords: Breastfeeding, Early Childhood Caries, Risk factors, Nutrition.

Introduction

Early childhood caries (ECC) is defined as presence of one or more teeth decayed teeth (cavitated or non-cavitated lesions), missing teeth (due to caries), or a filled surface on any primary tooth of children under the age 6 years. Any sign of caries in children younger than 3 years of age is indicative of severe early childhood caries (S-ECC) [¹]. An Analytical study revealed the prevalence of ECC in India to be 49.6%. Andhra Pradesh was found to have highest prevalence of ECC with 63%, and Sikkim had the lowest prevalence with 41.92% [²]. The main risk factors in the development of ECC can be categorized as microbiological, dietary, and environmental. The major contributing factors responsible for development of ECC are improper feeding practices, familial, socioeconomic background, lack of parental education, high sugar intake, lack of access to dental care, lack of oral hygiene, lack of fluoride exposure, and enamel defects [³,⁴]. ECC has been reported to affect the quality of life of children physically, mentally and emotionally. This includes pain, trouble in sleeping, eating hard foods, hot or cold food [⁵].

Early Childhood Caries ans it’s Risk Factors: Early childhood caries is a multifactorial disease produced by interaction of three factors such cariogenic microorganism, cariogenic diet and susceptible host over a period of time. Harris et al. 2004 has reported risk factors for ECC into 3 categories: socio demographic, diet, oral hygiene, bacterial flora and breast/ bottle feeding. In this systematic review, duration and frequency of breastfeeding, nocturnal breastfeeding, breastfeeding to stop baby crying at night and breastfeeding at 12-18 of months of age were reported as possible risk factors for early childhood caries. However researchers have found difficulty in establishing a clear relationship between ECC and breastfeeding. Some authors recommend cessation of breastfeeding at around 12th month of life, as soon as the infant can able drink from a cup. The association was attributed to a certain pattern of consumption such as ad libitum breastfeeding, prolonged and frequent breast feeding at night which could result in...
accumulation of milk on the teeth. This combined with lack of oral hygiene and reduced salivary flow produces decay. In contrary to this mechanism of breastfeeding is different than drinking from a bottle. A breastfeeding child draws milk by compressing the nipple against the palate with soft peristaltic motion. In contrast, a bottle fed child uses a much more powerful sucking motion of lips and cheeks in a “piston-like” motion to compressed the bottle nipple [6]. Valitis et al. observed a moderate correlation between breastfeeding and ECC. But however the quality of studies was categorized to be poor and inconsistent.

**Content of Human Breastmilk:** Human breast milk is a complex matrix with a composition of 87% water, 3.8% fat, 1.0% protein, 7% lactose [7], casein (2.3mg/ml) [8]and lactoferrin (2.6gm/L) [9] which varies in colostrum (~7g/L) and mature milk (~1g/L) [10]. Human breastmilk is an infant’s first and foremost diet which contains highly nutritious substances essential for the growth of child. Oral health care professionals have constantly raised concern over the effect of human breastmilk on dental health. The presence bacterial biofilm which contains elevated levels of Streptococcus mutans has been associated with dental caries. The principal sugar found in human milk is lactose. The Nutritional components include whey and casein proteins, palmitic and oleic acids providing the fat. Non-nutritional components include anti-infectious and anti-inflammatory agents, growth factors, and prebiotics. Bioactive factor of human milk contains several immunologic components [11] of which IgA antibodies help in inhibiting the growth of several micro-organisms [12, 13, 14]. Another important bioactive factor is Lactoferrin which chelates with iron and making this essential nutrient inaccessible to invading microorganisms, thereby limiting its growth [15,16]. Also Lactoferrin has strong bactericidal action against Streptococcus mutans and plays a significant role in the innate defense mechanisms against pathogens [17,18,19]. Thus the bioactive components of breast milk have protective action against Streptococcus mutans. This is in concordance with the findings of Grenby et al. [20], Rose et al. [21], Aimutis et al. [22] and Allison et al. [23] who described that the components in milk namely lactoferrin, lysozyme, albumin, peroxidase have an inhibitory effect against S. mutans and S. sorbinus. Lactose present in human milk is fermentable by S.mutans, however not to the same degree as sucrose. Allison et al [23] conducted a study on various concentrations of human breast milk samples and macronutrients such as lactose, casein, lactoferrin and IgA. Human breastmilk samples demonstrated an increase in biofilm formation at dilutions of 1:10, 1:20, 1:40. Lactoferrin and IgA decreased biofilm formation significantly. Lactose had no effect at average breast milk concentration but increased biofilm formation at its lowest concentration and casein significantly increased biofilm formation at higher concentration.

**Studies on Breastfeeding and Early Childhood Caries:** Various studies have been reported to investigate the association between breastfeeding and early childhood caries. Of which Matee et al. [24,25], Wendt et al. [26], Vachiraropisanel et al. [27] have inferred is a significant association between early childhood caries and breastfeeding. However various other reports suggest that there is no association between breastfeeding and Early Childhood Caries [28-36].

**Guidelines on Breastfeeding by American Academy of Pediatrics (AAP):** American Association of Paediatrics recommends “exclusive breastfeeding for about 6 months, followed by continued breastfeeding as complementary foods are introduced, with continuation of breastfeeding for one year or longer as mutually desired by mother and infant”[38].

**Policy Statement by American Academy of Pediatric Dentistry (AAPD) for Dietary Requirements:**

**The AAPD recommends:**

- Breast-feeding of infants provide general health, nutritional, developmental, psychological, social, economic, and environmental advantages
- Also it significantly decreases the risk for a large number of acute and chronic diseases.
- Breast-feeding of infants prior to 12 months of age is recommended to ensure the best possible health and development.
- However, breast feeding greater than 7times a day has been reported to be associated with increased risk of ECC. AAPD recommends that oral hygiene measures to be initiated immediately after the eruption of first tooth [39].

**Conclusion**

Over the years enormous research has been conducted in early childhood caries and its various associated risk factors. This has enabled in devising
preventive strategies towards the same. However one factor that remains a myth is the effect of extended breastfeeding on primary teeth. Policies on breastfeeding by various academies suggest an exclusive breastfeeding for first 6 months of the infant in order to ensure complete health and development. First tooth erupts at the age of 6 months. Breastfeeding when continued after this point along with other dietary supplements has been reported to be associated with ECC.

However diet is a confounding factor when analysing the association between breast-feeding and caries”. More cohort studies to establish the association between ECC and breastfeeding are necessary.

Effect of Music on Pain and Anxiety in Pediatric Dental Patients

Ramya Chellammal M.1, Ponnudurai Arangannal2, Jeevarathan J.3, Aarthi J.4, Amudha S.4, Vijayakumar M.5

1Post Graduate Student, Department of Pedodontics, 2Professor and Head of the Department, 3Professor, 4Reader, 5Senior Lecturer, Sree Balaji Dental College & Hospital, BIHER, Pallikaranai, Chennai

Abstract

Dental anxiety and pain management in pediatric children is always challenging. Management of Pain and anxiety are the utmost concern for a paediatrician in order to achieve patient cooperation which plays an essential role in the success of the treatment. Interventions aimed at improving the health and wellbeing of children may also cause pain and anxiety. Inadequate pain control during medical procedures can have long-term detrimental effects, especially among very young children. Hence this review article aims at determining the effect of music on pain and anxiety in pediatric dental patients.

Keywords: Anxiety, Pharmacotherapy, Behaviour.

Introduction

Management of Pain and anxiety are the utmost concern for a paediatrician inorder to achieve patient cooperation which plays an essential role in the success of the treatment. Interventions aimed at improving the health and wellbeing of children may also cause pain and anxiety. The Children’s Dental Health Survey in 2013 found that 21% of 5-year-olds and 17% of 8-year-olds were reported by their parents to be anxious about visiting the dentist. In older children, dental anxiety was found to be higher with 76% of 12-year-olds and 64% of 15-year-olds reporting either moderate or severe dental anxiety when visiting the dentist (HSCIC 2015). Inadequate pain control during medical procedures can have long-term detrimental effects, especially among very young children.(1) The goal of behaviour management techniques practiced by the paediatric dentist aims to establish communication and an element of trust with the child patient. Various behaviour management techniques are proven to be successful, but attitude of parents and some dental practitioners towards these techniques have changed, and this is the reason why new non invasive techniques which are more effective and more acceptable to the parents are being used. Many parents feel that pharmacological method of managing their child are undesirable due to perceived medical risks.

Music as a Distraction: Music is an alternative treatment option which is being used in different medical fields to meet the psychological, physiological and spiritual needs of the patient. Music has the potential to obviate or decrease the need for pharmacotherapy.(2) Suitable music have proven to have a strong influence on human brain waves which leads people into state of deep relaxation. Music can ease pain and anxiety by moving conscious thought away from the symptoms. According to the gate control theory of pain, pain receptors act together to send pain signals to the brain, therefore distractors such as music can block certain pain pathways and diminish the amount of perceived pain.4 Studies have proven that musical intervention decreases surgical stress, induces relaxation, decreases blood pressure, heart rate and respiratory rate during an operation with local anesthesia. Musical distraction (MD), defined as the use of music as an adjuvant therapy in the treatment of behavioral disorders. MD leads the child to focus on the audio by listening in

e-mail: drapdurai66@gmail.com
order to avoid the perception of aversive stimuli, such as the micromotor or turbine, thereby reducing levels of DA. This technique is effective, especially in patients with moderate anxiety. However, there is great heterogeneity between studies, showing much variability in clinical scenarios, forms of application, types of music and method of delivery. Based on these studies, it is suggested that MD be used with other distraction techniques for best results. There is a distinct difference between music administered by medical or healthcare professionals (passive music listening) than with those of trained music therapist (active music therapy). Brusia termed music listening as the receptive type of music experience whereby the clients listens to music and responds to the experience silently, verbally or in anathor modality and Music therapy has “a systematic process of intervention wherein the therapist helps the client to promote health, using music experiences and the relationships that develop through them as dynamic forces of change.”

**Effects of Music on the Clinical Setup:** Spintge in his review of music in operating theatres focuses extensively on the use of music to moderate stress and anxiety. He coined the term Anxioalgolytic Music (AAM) to refer to this practice, and given the individual differences of response, suggests self-chosen music as the most effective way of defining the musical material listened to, and notes that using headphones (where possible) reduces the impact of the music on staff. This does make staff-patient communication more difficult, although in noisy settings may help mask irritating or anxiety-inducing environmental sounds for the patient. Music played over loudspeakers has both positive and negative effects on operating room staff: it can disrupt effective communication, but can also produce a calm working environment. What is clear is that music is being used in perioperative settings, and despite the practical issues that arise, may be an effective intervention alongside more traditional approaches to chronic or situational anxiety when undergoing procedures.

Music’s impact on our physiological and cognitive state is far from straightforward. Reactions to music are highly individual and context dependent, varying with personality, experience, surroundings, age, taste and cultural background. Some generalities apply however, and certain pat-terns of musical structure (and associated lyrical content) may have predictable impacts on listeners, and there are conventional as well as more individual associations between styles and individual pieces of music, so it may be possible to predict and therefore prescribe music as a psychobiological treatment. Nonetheless, such predictable responses are elusive: for example, a piece of music might have a generally relaxing effect on most patients (due to its intrinsic musical structures), but the opposite effect on one patient who had first heard it in a shopping mall during an armed robbery. Visualise emotional responses to the external environment along two dimensions, one related to valence (the cognitive interpretation of the emotion from positive to negative) and the other its level of activity (high or low arousal).

**Effect of Music on Dental Anxiety:** Marwah et al. (2005) conducted a randomised controlled trial; this study included 40 children aged between 4 and 8 years old who were divided into three groups: control group (no music), instrumental music group and nursery rhymes group. Each child had a screening visit, an oral prophylaxis visit, a restorative visit and then an extraction visit. The children’s anxiety was measured using the Venham’s picture test (VPT), the Venham’s clinical anxiety rating scale (VCRS), pulse rate and oxygen saturation. The results showed that the VPT scores were not significantly different between the three groups and the pulse rate was not significantly different between the control group and the two music groups. However, the VCRS scores and pulse rate in the instrumental group were significantly less than in the nursery rhyme group. Overall the study found that instrumental music was more effective at reducing dental anxiety than nursery rhymes.

In a more recent randomised controlled trial by Jindal and Kaur (2011), 30 children aged between 4 and 8 years old were randomly divided into two groups, a control and a music group. Each child had four visits which increased in their invasiveness. The child’s anxiety levels were measured using the VPT before and immediately after each appointment. The levels of anxiety were found to be greatest in the third and fourth visits as the invasiveness of the procedures increased. Interestingly, the reported anxiety levels were significantly reduced in the music group. Similarly, Singh et al. (2014) in a randomised controlled trial found that listening to patient selected music significantly decreased intra-operative anxiety compared with the no music control group in 60 children aged between 6 and 12 years old undergoing dental extractions. Physiological anxiety measurements were recorded using a pulse oximeter and blood pressure monitor. In addition, self-reported
anxiety measurement using the VPT was also used. The study showed that systolic blood pressure, pulse rate and VPT scores were all significantly reduced in the music group. In contrast to the above studies, several others have shown that music is not an effective tool to reduce dental anxiety in paediatric patients. Aitken et al. (2002) concluded that music did not result in a reduction in pain, anxiety or uncooperative behaviour during dental procedures in children aged between 4 and 6 years old. The children were not given a choice of music to listen to which the authors’ recognised could have prevented the child from fully benefiting from the music as it was not familiar to them; however 93% of the patients who listened to the music said that they enjoyed listening to it. In addition, the patients included in the study were relatively young at 4–6 years old compared with other studies. It may be that older children are more likely to benefit from the effects of music. In another study by Gupta et al. (2017), 60 patients aged between 3 and 7 years old who required treatment under local analgesia were divided into three groups: a control group, an upbeat music group and a relaxing music group. In the first visit all the children had restorative treatment following an inferior alveolar nerve block in one quadrant. At the following visit approximately 2 weeks later, the children wore headphones; the music groups listened to music and for the control group no music was played. For both visits, anxiety was measured using the VPT pre and post-operatively, a visual analogue scale post-operatively to assess the child’s perceived pain and heart rate was measured using a pulse oximeter before treatment, during local analgesia and at subsequent 5 min intervals. The child was also filmed and their behaviour assessed using the North Carolina Behaviour Rating Scale. The study concluded that music did not significantly reduce pain, anxiety or disruptive behaviour. There was a wide variation across the studies in the type of music (folk, lullabies and classical) and how it was delivered (recoreded, live) and the mode of delivery (direct headsets, audiovisuals).

**Conclusion**

Music has been shown to influence both the biological and psychological aspects of anxiety and acts as an aid for distraction from painful experiences and there is a growing body of evidence to support its use alongside or instead of traditional interventions within the clinical setting.

Mixed Dentition Analysis Procedure: A Review

Keerthika A., Jeevarathan J., Ponnudurai Aranganna, Vijayakumar M., Amudha S., Aarthi J.

1Post Graduate Student, Department of Pedodontics, 2Professor and Head of the Department, 3Professor, 4Reader, 5Senior Lecturer, Sree Balaji Dental College & Hospital, BIHER, Pallikarani, Chennai

Abstract

As the child's dentition changes from primary to permanent dentition there are a number of changes that happens in the oral cavity of the child. This intermediate stage of transition is known as Mixed dentition stage and lasts from 6 years to 12 years. The identification and measurement of these changes is of great importance in preventing, managing and treating future dental as well as skeletal malocclusions. Over the years several tests and analysis have been done to analyse these changes. The aim of this paper is to analyse the existing literature on various mixed dentition analysis and also to spot light on the recently developed mixed dentitions and primary dentition analysis.

Keywords: Mixed dentition analysis, Primary dentition analysis, Nance analysis, Hixon Oldfather analysis.

Introduction

Mixed dentition lasts from 6 years to 12 years of age, mixed dentition can further be divided as early mixed dentition (6 years – 9 years) and late mixed dentition (9 years – 12 years). There are a lot of changes that happens during the transition of primary to permanent dentition. Moorrees investigated; by measurements on dental casts of 184 North American children of Arch length reduces 2 mm to 3 mm from 10 years to 14 years when primary molars are replaced by premolars. [1]. Malocclusion which is in dormant condition in the deciduous or mixed dentition period usually, surfaces after the eruption of permanent successors. A majority of children will be benefited if such developing malocclusion can be diagnosed and treated early. [2] One of the first analysis was done by G.V. Black, in 1897; he determined the average mesiodistal crown widths of all primary and permanent teeth. [3].

He found that permanent incisor and canine teeth were larger than their predecessors, whereas premolar teeth were smaller. He concluded that measurement of un erupted permanent canines and premolars on radiographs was more accurate than estimation by measurement of the primary dentition.

Since then a lot of analysis has been done in various parts of world. All these analysis used three approaches to achieve the purpose. The first approach employs direct measurements of the teeth from radiographs with or without the use of prediction formula. [3,6] The second method utilizes prediction tables based on measurements of other erupted permanent teeth. The third method involves a combination of previous two method, i.e. the use of prediction tables in association with. Measurements of erupted and unerupted teeth [7]. Six generally used mixed dentition analysis is reviewed in this article, namely:

e-mail: dr_rathan@rediffmail.com
Various types of analysis:

Hays Nance analysis: Nance in 1947 did an analysis to estimate the space required for permanent canines and premolars using erupted permanent incisors. He measured the maximum mesiodistal width of each permanent incisor (maxillary and mandibular incisors on the cast), Using a brass wire (0.010 inch) measured the arch perimeter. Measure maximum mesiodistal width of unerupted permanent canine, first and second premolar from radiograph. [4]

In 1993 Nanda revised Hays Nance procedure, he changed, added few points. Nanda advised to perform Huckabas analysis to the radiographic value of measured unerupted premolars to minimize the error. He also has asked to perform cephalometric analysis (tweeds analysis) as it allows for correction of protrusion of mandibular incisors. [8]

Advantage-Minimal error, Performed with reliability, Allows analysis of both arches. Limitation-Time consuming, Need to do cephalometric analysis

Ballard and Wylie analysis: Ballard & Wylie conducted studies to examined the casts of 441 individuals who had permanent incisors, canines, premolars and first molars fully erupted. The correlation coefficient between the sum of the mesio-distal widths of the mandibular incisors and that of the canines and premolars was +0.64. They gave the formula as

\[ x = 9.41 + 0.527y \]

In which \( x \) = sum of mesio-distal widths of canine and premolars, and \( y \) = sum of mesio-distal widths of the mandibular incisors. They found that the average error using this formula was 0.6 mm, or 2.670, and concluded that this equation was of some value in the prediction of the combined width of unerupted mandibular permanent canine and premolar teeth. [9]

Hixon and Oldfather analysis: In 1958 Hixon and Oldfather published a method for prediction of the mesiodistal widths of the mandibular canines and premolars in mixed-dentition patients. They based their prediction method on measurements taken from participants in the Iowa Facial Growth Study. They measured the maximum mesiodistal width of each permanent incisor (each quadrant on the cast). From radiograph measured maximum mesiodistal width of unerupted first and second premolar. Added the mesiodistal widths of incisors and premolars from each quadrant compare in Hixon and Oldfather predication table the corresponding value in the predication table is the value of space estimated for permanent canine, first and second premolar. Advantage-Coefficient of correlation is 0.87 or 75 percentile [10]

Staley & Kerber in 1980 undertook to revise the work of Hixon & Oldfather in an attempt to determine whether an improved equation could be found. They used the same method, measuring the mandibular central and lateral incisor in one quadrant on casts and the first and second premolar teeth in the same quadrant on radiographs. Both authors examined a sample of 57 subjects selected from the longitudinal records of the Iowa Facial Growth Study, and another sample of 53 subjects selected from the records of patients in the Department of Orthodontics at the University of Iowa.

Staley et al. found that results were improved by using separate equations for males and females, but Hixon & Oldfather made no allowance for gender in their calculations, they developed a regression equation. The equations were all similar but the correlation coefficients were higher and the standard errors lower than those reported by Hixon & Oldfather. The standard errors were in the range 0.43-0.45, and that of Hixon & Oldfather 0.57. This could be because Hixon and Oldfather utilized a smaller sample of only 41 subjects. The absolute error was approximately 0.2 mm smaller than the original of Hixon & Oldfather. Staley & Kerber used computers for their calculations, and heliosdial calipers reading to 0.05 mm instead of Boley gauges that read to 0.1 mm. From their equations a modified prediction graph was developed, as shown in Fig. 1.

**Fig. 1.** Hixon & Oldfather prediction graph, as revised by Staley & Kerber. $1 + 2 + 4 + 5 = \text{sum of mesio-distal widths of erupted mandibular central and lateral incisors, and of mandibular first and second premolar teeth in one quadrant measured on a radiograph}$

$3 + 4 + 5 = \text{predicted sum of mesio-distal widths of unerupted mandibular canine and premolar teeth in same quadrant}$

**Moyers analysis:** Moyers\textsuperscript{[11,12]} produced a table giving the predicted mesio-distal widths of maxillary and mandibular permanent canines and premolars on the basis of permanent mandibular incisor widths, using data obtained from an unspecified number of North American white children. The analysis allowed for the space required for tooth alignment and retroclination of the labial segment, if necessary. It was claimed that this analysis was accurate at the 50% probability level when used by experienced clinicians and at the 75% level by beginners. Moyers advised caution in using any analysis, as none was able to compensate for the biological variation in individuals during the transition from primary to permanent dentition. Advantage-high accuracy, most used of all analysis. Disadvantage-needs prediction chart, analysis was done in limited sample size and the exact ethnicity of the population was not mentioned.

**Tanaka and Johnston Analysis:** Tanaka & Johnston\textsuperscript{[13]} in 1974 studied dental casts of 506 orthodontic patients in Cleveland area and produced simplified equations for determining the space required for unerupted permanent canine and first and second premolar in each segment:
(i) Sum of widths of maxillary canine and premolar teeth = half sum of width of mandibular incisors + 11.0 mm.

(ii) Sum of widths of mandibular canine and premolar teeth = half sum of width of mandibular incisors + 10.5 mm.

**Huckabas radiographic method:** Huckaba in 1964 gave formula relating the measures of erupted teeth to their radiographic images in order to obtain the proportional dimensions of unerupted teeth, to reduce the radiographic error due to elongation etc., as follows:

\[
\frac{\text{X-Ray MD width of deciduous}}{\text{X-Ray MD width of the permanent}} = \frac{\text{Real MD width of deciduous}}{\text{Real MD width of the permanent}}
\]

**Boston university analysis:** A recent analysis which was presented by Gianelly in Boston university [13, 14], he used all primary erupted teeth to find out and is as follows: Mesiodistal widths of permanent mandibular canines and premolars = MDW of primary mandibular canine + 2 (MDW of primary mandibular first molar).

The main disadvantage of all this analysis is that they have been done in one particular population their reliability when used in other populations is very less.

**Discussion**

Gardner [15] compared the accuracy of four mixed dentition analyses (Nance, Tanaka & Johnston, Moyers, and Hixon & Oldfather) by examining the casts and radiographs of 41 North American children selected from the orthodontic department at the University of the Pacific, San Francisco, and from an orthodontic practice in Palo Alto, California. Casts and radiographs taken before treatment (in the mixed dentition stage) and after the eruption of permanent teeth were examined. All four method displayed high correlations between predicted and actual arch length and between predicted and actual sum of widths of mandibular canine and premolar teeth, as shown in

Table 3: Correlation coefficients between predicted and actual arch length and between predicted and actual sum of mesiodistal widths of mandibular canine and premolar teeth (from Gardner, 1979)

Bolton [16], and discovered that the values for the Indian children were very different from those of Tanaka & Johnston 0.625 Ballard & Wylie ~ Hixon & Oldfather ~ 0.648 0.64 0.69 Caucasian children, from which they concluded that there were racial discrepancies in tooth size, and therefore that data collected from one ethnic group were not transferable to another.

In a systematic review conducted in 2013 by Mariana de Aguiar [17] to see the Applicability of Moyers analysis in mixed dentition, the main clinical problem that was found to exist in the review was at 75%, the predicted values underestimate the real values, in which case there will not be enough space to properly align the teeth. When the values overestimate the real values, it means that there will be more space to accommodate the posterior teeth, which is not considered a real clinical problem. The systematic review concluded that Moyers mixed dentition analysis should be used carefully, because, in the majority of the articles examined, its accuracy regarding probability level at 75% was poor.

In a systematic review conducted in 2011 by Nghe S. Luuet al [18] analyzed the validity and reliability of mixed dentition analysis method from 39 articles they concluded that all modalities had validities correlated in the positive direction, but we found no difference in terms of overall validity between modalities. The predictions based on the combined study-model/radiographic method had the least variable overall validity. Predictions based on the radiographic method had more variable overall validity, and predictions based on the study-model method had the most variable overall validity. Polymorphisms based on ethnicity, jaw, sex or side of mouth did not appear to have any meaningful influence on the validity of MDA method. They found that any given MDA approach will lead to either over
prediction or under prediction of the combined widths of three teeth (un erupted canines and premolars) in a quadrant of less than 2 mm with correlation coefficients that tend to be greater than 0.6.

**Conclusion**

Mixed dentition analysis is of great importance in predicting is the space available is adequate or will more space be required and also how to manage the space. One should always remember that these analysis gives us information only about the dental malocclusion and not the underlying skeletal conditions (if any present). also since all of these analysis were done in specific population, to substantiate these analysis for the population throughout the world vast studies with larger sample sizes have to be conducted.

Abstract

One in seven of the population of the world is highly anxious about undergoing dental treatment and requires careful and considerate management by dental practitioners. The interaction between the dentist, dental health team and the patient can reveal the presence of anxiety, fear, and phobia. In such situations, subjective evaluation by interviews and self-reporting on fear and anxiety scales and objective assessment of blood pressure, pulse rate, pulse oximetry, finger temperature, and galvanic skin response can greatly enhance the diagnosis and enable categorization of these individuals as mildly, moderately, or highly anxious or dental phobics. Formulating acceptable evidence-based therapies for children is essential, or else they can be a considerable source of stress for the dentist.

Keywords: Sedation, Anxiety, Fear, Phobia.

Introduction

The management of acute pain and anxiety in children undergoing therapeutic and diagnostic procedures outside the operating room has developed substantially in the past few decades[1,2]. The widespread availability of noninvasive monitoring, short acting opioids and sedatives, and specific opioid and benzodiazepine antagonists has enabled clinicians to administer sedation safely for procedures in diverse settings. This paper presents a review of a number of pharmacological (oral) techniques that can be used in the dental clinic or surgery in order to assist anxious individuals obtain needed dental care.[3]

Sedation is defined as the use of a drug or combination of drugs to depress the CNS, thus reducing patient awareness of their surroundings. Depending on the degree of CNS suppression, the sedation may be conscious, deep, or general. Sedation does not control pain, and consequently does not eliminate the need for the use of local anesthetics. Sedation is a continuous process that exists from minimal to deep in a dose–response manner. This continuous process can be divided into levels with characteristics that have been used to design several subjective sedation scales.

Sedatives or Anesthesia?: Variations the use of drug combinations including propofol with potent opiates by non-anesthesiologists in the future will continue to force us to examine the question as to where deep sedation ends and general anesthesia begins. According to the ASA/JCAHO/AAP criteria[4-10], the distinguishing characteristic between these two entities is the presence or absence of a response to repeated painful stimuli. Whereas most studies involving sedation do not describe the condition of sedated patients adequately enough to determine the sedation level of the patient, there is no doubt that many of the regimens used in emergency departments and ICUs around the country are evolving into recipes for brief general anesthesia rather than sedation. In light of the fact that the difference between these two states can be subtle (patients can go in and out of a given state quite rapidly) and that there is no practical way to police this practice, any effort to limit anesthesia by non-anesthesiologists for brief procedures in children is doomed to failure. In terms of promoting
safety and generally good sedation delivery, pediatric patients will be better served by advocating for standards anesthesiologists have successfully used to improve the safety of anesthesia care by 10-fold over the last 20 yr \(^{(9,10)}\). Specifically, all providers of deep sedation should be able to rescue patients from side effects of general anesthesia, as mandated by the JCAHO. To do this, anesthesiologists need to demand that high standards are met by these individuals. These should include, but not be limited to, the following: (a) There should be defined competencies in terms of airway, and these skills should be demonstrated in clinical practice or simulation setting; (b) Knowledge of disease entities that impact sedation and anesthesia should be documented; (c) Familiarity with sedation drugs—doses, side effects, and contraindications, reversal drugs, and rescue medications should be documented; (d) Intraprocedural monitoring should be used, optimal method for monitoring ventilation as well as oxygenation (pulse oximeter); (e) All equipment required for emergency interventions such as masks, airways, suction, and ventilation bags must be present for each sedation, and they must be regularly checked and accounted for; and (f) Sedation systems must have a quality improvement program that examines its own outcomes on a continuing basis.

**Indications:** Four main considerations for oral sedation in children are anxiety, medical and behavioral, and treatment complexity. Children with special needs (mental retardation, autism, mental illness, traumatic brain injury) and clinical situations can be indicated for pharmacological management.\(^{[12, 13]}\) Factors to be considered prior to pharmacological management:

1. Risks involved with pharmacological management when compared to behavioral therapies
2. Appropriate evidence-based selection of drugs for pharmacological management
3. Extent of the patient’s dental needs and severity of anxiety
4. Patient’s cognitive and emotional needs and personality
5. Practitioner skill, training, and experience
6. Proper equipment and monitoring
7. Cost of the procedure.

According to the American Society of Anesthesiologists, patients should be classified as category ASA I (mentally and physically healthy) or ASA II (only mild systemic disease, which does not result in any functional limitation), in order to be considered a candidate for sedation

**Sedative–hypnotic agents:**

**Chloral Hydrate:** One of the oldest drugs, oral chloral hydrate has a well-established safety profile.\(^{[15-17]}\) Chloral hydrate has no analgesic properties, and its use is now mainly restricted to diagnostic imaging, particularly in children under three years of age.

**Benzodiazepines:**

**Midazolam:** Most commonly used for sedation in children and adults during procedures.\(^{[18-27]}\) This short-acting benzodiazepine can be administered by multiple routes. It provides potent sedation, loss of memory, and anxiolysis and is preferred over the longer-acting diazepam and lorazepam. Benzodiazepines provide no analgesia, and for painful procedures midazolam is commonly administered with an opioid. Caution must be exercised when using benzodiazepines and opioids together, since the risks of hypoxia and apnea are significantly greater than when either is used alone. The effects of midazolam can be reversed with the antagonist flumazenil. Barbiturates have been used for pre-induction of anesthesia for over 30 years and have an extensive safe

**Barbiturates:** Barbiturates have been used for pre-induction of anesthesia for over 30 years and have an extensive safety profile.\(^{[15,16]}\) They are widely regarded as the drugs of choice to facilitate diagnostic imaging in children three years of age or older. Though lacking analgesic properties, they provide effective immobilization and can be delivered by multiple routes. Intravenous pentobarbital and rectal methohexital and thiopental are the most extensively studied barbiturates used for procedural sedation.\(^{[31-36]}\)

**Present sedation guidelines in pediatric dentistry:**

**Reimbursement:** The continued improvement of pediatric sedation practice depends on the involvement of qualified professionals. This involvement can only be done if there is proper reimbursement. Unfortunately, reimbursement depends on economic status of the child’s family, insurance companies and state medical reimbursement schedules. In India there are not many schemes that cover these aspects of dentistry; hence this would be one area which will need analysis and improvement.
Conclusion

Providing sedation to children is an area of rapid change marked by evolving standards. This article gives brief dosage regimens which can be clinically administered by dental health team, without difficulty. Role of pedodontist and his team is little known and appreciated as far as oral sedation for dental procedure is concern. It is of importance at this time that pedodontists and dental health team use their established identity as professionals who can also provide oral sedation with a proven track record of clinical practice, training, and safety in this field is optimized. However anesthesiologists will be the ultimate experts in this field.

Passive Immunization Against Streptococcus Mutans

Madhumitha M.1, Vijayakumar M.2, Ponnudurai Arangannal3, Jeevarathan J.4, Amudha S.5, Aarthi J.5

1Post Graduate Student, Department of Pedodontics, 2Senior Lecturer, 3Professor and Head of the Department, 4Professor, 5Reader, Sree Balaji Dental College & Hospital, BIHER, Pallikarani, Chennai

Abstract

Dental caries is an irreversible microbial disease of the calcified tissues of teeth, which is characterized by demineralization of inorganic portion and destruction of organic substance of the tooth which often leads to cavitation. It is a multifactorial disease. Among the various microorganism Streptococcus mutans considered to be chief etiological agent. Immune therapy against this microorganism to curtail this widespread disease has gained interest. Passive antibody administration has also been examined for effects on indigenous mutans streptococci. Passive immunotherapy is of interest due to its many advantages. This review briefs on passive immunotherapy.

Keywords: Dental caries, Immunotherapy, Streptococci.

Introduction

Dental caries is one of the most common and widespread disease in humans1. Dental caries is an infectious, irreversible, microbial disease of the calcified tissues of teeth, which is characterized by demineralization of inorganic portion and destruction of organic substance of the tooth which often leads to cavitation2. It is a multifactorial disease caused by interaction between four principal factors the host (saliva and teeth), the micro flora, the substrate (diet) and the time1. Various microorganism – Streptococcus mutans (S.mutans), lactobacillus sp., Actinomyces sp. are involved in caries formation. Chief etiological agent as reported by most studies was Streptococcus mutans. Caufields(1993) monitored oral cavity levels from birth up to 5 years to analyze window of infectivity2. He noted that initial acquisition of S.mutans was from 19-31 months. With age maternal dose of a child varies which leads to variation in MS level. Children exposed to modest maternal challenge have approximately 50% bacterial colonization and children exposed to high maternal levels have 90% colonization. With high maternal level and exposure to dietary sucrose, initial dental colonization with MS occurs at young age. Therefore, window of vaccine opportunity is from 12-18 months2.

Caries Vaccination: Introduced by William Bowen, 1969. Whole cell S.mutans were injected in Macacafasicularis monkeys, showed successful result against caries. Thus earlier whole cell of the bacteria was used to induce immune reaction.3 At present, antigenic components of S. mutans are used to induce immune response4. The caries vaccine targets the initial stages of dental plaque formation by acting on

a. Aggregation of bacteria before colonization
b. Inactivation of enzymes
c. Blockage of surface receptors

Antigenic Components of S. Mutans5:
• Adhesin (Antigen I/I/SAI/II/PAC)
• Glucosyl transferase
• Glucan binding proteins
• Dextranases

Corresponding Author:
Vijayakumar M., MDS

e-mail: drvijaypedo6@gmail.com
Adhesin (ANTIGEN I/II/SAI/II/PAC): Adhesin are found in S.Mutan cell surface. Regions associated with adhesion are the alanine rich region is the salivary binding regions. Mechanism of action: Active immunization with AG I/II (or) Passive immunization with IGY antibodies target salivary binding domain and block adherence of S.Mutans to saliva coated hydroxyapatite [Brady etal, 1992-1993] and induce cellular aggregation [Liljemarketal, 1981].

Glucosyl Transferase: These are enzymes of S.Mutans involved in glucan production. It has a sucrose binding domain and glucan binding domain. Glucosyl transferase of S.Mutans binds with sucrose forms and forms glucans and formed glucans are released into saliva. It slowly gets incorporated into initial salivary pellicle and promote selective adherence of bacteria which then colonizes human teeth and promote plaque formation. There are 3 forms of glucosyl transferase that provides multiple binding sites for accumulation of S. Mutans, promoting plaque formation. They are as follows:

- Glucosyl transferase 1: Water insoluble glucan synthesis enzyme (2,1,6 glucose residue)
- Glucosyl transferase S: Water soluble glucan synthesis enzyme. (2,1,6 glucose residue)
- Glucosyl transferase S-1: Water soluble and water insoluble glucan synthesis enzyme

Mechanism of action: Antibodies inhibit the functional activity of enzyme (Kruger etal 2004) and affect synthesis of glucans (Taubman etal 1995)

Glucan Binding Proteins: Following are the types of glucan binding proteins:

- Glucan binding protein –A (hydrophobic, thus bond with water soluble glucan)
- Glucan binding protien-B (hydrophobic only induce protective immune response)
- Glucan binding protein- C.

Antibodies act by blocking Glucosyl binding protein type B and thus reduce sucrose dependent adherence of S.Mutan to tooth surface.

Dextranases: It is an enzyme produced by S.mutans and plays a major role in dental plaque formation. Mechanism of action of vaccine is to prevent bacterial adhesion to plaque by inhibiting the enzymes.

Types of Passive Immunization: Passive immunization involves passive or external supplementation of the antibodies. Passive immunotherapy includes 6, 7, 8:

- Bovine milk antibodies
- Monoclonal antibodies
- Plant antibodies
- Egg yolk antibodies

Though bovine milk antibodies, monoclonal antibodies, plant antibodies have been found to decrease S.mutans count in dental plaque as well as reduction in caries lesions, egg yolk antibodies, now called immunoglobulin Y antibodies has attracted attention only in the last two decades.

- Monoclonal Antibodies: Monoclonal antibodies to S. mutans cell surface antigen I/II have been investigated. The topical application in human subjects brought a marked reduction in the implanted S.mutans. Thus, by bypassing the system, less concern exists about the potential side effects.

- Bovine Milk and Whey Antibodies: Systemic immunization of cows with a vaccine using whole S. mutans led to the bovine milk and whey containing polyclonal IgG antibodies. This was then added to the diet of rat (Inoculated with S.mutans MT8148R) which showed decrease in S.mutans colonization. Antibodies Inhibit surface antigenI/II and Glucosyl transferase enzyme.

- Transgenic Plant Antibodies: The production of monoclonal antibodies in plants has been described in a number of patents. This involves the assembly of monoclonal antibodies in transgenic tobacco plants [4] and the generation of secretory antibodies in plants. Recombinant plant monoclonal antibodies were tested in human subjects for preventive immunotherapy.

- Egg Yolk Antibodies: Egg yolk antibodies, now called immunoglobulin Y (IgY) was discovered in the late 1800s, alternative possibility of producing antibodies has attracted attention only in the last two decades. Egg farming can be switched over as antibody farming for prophylactic and therapeutic applications in human and veterinary medicine, in counter bioterrorism and also for diagnostic purposes. Chicken antibody is financially viable with sustainable availability and huge quantity of
antibody is obtained from hens, approximately a total potential harvest of 20 g total IgY/year of which 1–10% is expected to be antigen specific. Eggs of avian origin may be used as an antibody source and purification procedures such as water dilution method are simple, cheap and nontoxic. There is apparently no systemic immune response with respect to orally administered antibodies. Immune complexes containing IgY do not activate the mammalian complement system and do not interact with mammalian Fc and complement receptors that could mediate inflammatory response. The use of IgY for passive immunization has been studied extensively demonstrating its effectiveness in preventing or treating infectious diseases.

Passive antibody administration has also been examined for effects on indigenous mutans streptococci. Mouthrinses containing bovine milk (Filler et al., 1991) or hen egg yolk IgY (Hatta et al., 1997) antibody to S. mutans cells led to modest short-term decreases in the numbers of indigenous mutans streptococci in saliva or dental plaque. Experimental passive immune protection could also be achieved with antibody to GTF (Hamada et al., 1991) or GbpB (Smith et al., 2001). Thus, topical or dietary administration of immune reagents with specificity for epitopes on these proteins may also have potential human application. Filler et al conducted experiments on passive immunization and showed that passive immune protection can be achieved with antibodies to GTF or GBPs mouth rinses containing bovine milk or hen egg yolk. Childers et al reported that the antibody to S. mutans cells lead to a modest, short-term decrease in the number of Streptococci mutans in saliva or dental plaque.

**Conclusion**

As most of the approaches against dental caries are of treatment in nature which is quiet expensive, the dire need for new alternative and potential preventive approaches for challenging the cariogenic bacteria has been universally accepted and now the focus is on active and passive immunotherapy. Absolute safety should be ensured with respect to immunotherapy as dental caries is not a life threatening one. Newer approaches are focused on the application of passive immunotherapy and successful passive immunization may ride over active immunization which seems to have more risk than benefits. Further advances to make immunization against caries practical will depend upon clinical trials aimed at establishing whether the findings from animal experiments can be transferred to humans.

Challenges in Shortcomings of Caries Vaccination: An Insight

Madhumitha M.1, Vijayakumar M.2, Ponnuduraiarangannal, Jeevarathan J.4, Amudha S.5, Aarthi J.5

1Post Graduate Student, Department of Paedodontics, 2Senior Lecturer, 3Professor and Head of the Department, 4Professor, 5Reader, Sree Balaji Dental College & Hospital, BIHER, Pallikarani, Chennai

Abstract

Background: Dental caries is an infectious microbiologic disease of the teeth and is one of the most common diseases in humans. It is a multifactorial disease caused by interaction between four principal factors-the host (saliva and teeth), the microflora, the substrate (diet) and the time. Targeting the microbial factor of the disease, researchers have been developing vaccination to protect the caries prone children and adults. Immunization includes active and passive immunization. Vaccines should be safe and effective. This article gives an insight into the shortcomings and challenges of caries vaccinations.

Keywords: Caries vaccination, active immunization, passive immunization.

Introduction

Dental caries is one of the most prevalent oral disease formed by the interaction of 4 factors namely: The host (saliva and teeth), the microflora, the substrate (diet) and the time. Among the various microorganism that are responsible for caries formation and progression, the main causative agent for initiation is Streptococcus mutans.1,2 At present there are various caries prevention method of which developing vaccination against S.mutans has been of greater interest among researchers for past few decades.3,4

In late 1969, the modern era of vaccination began with intravenous immunization experiments conducted by William Bowen on animals. Earlier whole cell S. mutans were found to be used for vaccination2. At present virulent factors of bacteria are used to induce immune response.5

Methodology

Articles from the year 2000-2015 were searched from the online databases (PUBMED, Cochrane, Science direct, Google scholar) and by hand search. Search terms used were disadvantages, shortcoming, drawback, caries vaccine, dental caries vaccine, dental vaccine, vaccination, oral microflora, oral microorganism. Out of 25 articles, 11 articles that gave description of the drawbacks of various vaccination against oral microflora were included.

Shortcomings of Caries Vaccine: All vaccines, even if properly manufactured and administered, seem to have risks. Active immunization has shortcomings
due to reasons stated below. The most serious is that sera of some patients with rheumatic fever who show serological cross-reactivity between heart tissue antigens and certain antigens from haemolytic Streptococci. Experiments from antisera from rabbits immunized with whole cells of S. mutans and with a high molecular weight protein antigen of S. mutans were reported to cross react with normal rabbit and human heart tissues. Polypeptides (62-67 KDA) immunologically cross-reactive with human heart tissue and rabbit skeleton muscles myosin are found in the cell membrane of S. mutans and Streptococcus rattii. On the other hand, demonstrations showed that rabbit antiserum to high molecular weight, Todd-Hewitt broth components reacted with monkey cardiac muscle with S. mutans coated with medium components. Heartcross-reactive antibodies do not develop in rhesus monkeys or rabbits immunized with purified Ag I/II from S. mutans. It is possible that increased production of heart-reactive antibody in rabbits immunized with mutans streptococci results in injury of heart tissue as a consequence of binding of this low molecular weight Streptococcal polypeptide. Because of the potential of Streptococcal whole cells to induce heart reactive antibodies, the development of an sub-unit vaccine for controlling dental caries has been of intense research interest. Glucosyltransferase was also tested for cross-reactivity with human heart tissue and the results were negative. Further research showed that the C-terminal part of Ag I/II contains an epitope, which is cross-reactive with human IgG. Although the clinical significance of this observation is unknown, it appears that this potentially harmful epitope should be excluded from a caries vaccine. The human IgG cross-reactive region is also present in other mutans streptococci such as Streptococcus sanguinis as well as in non mutans streptococci. Also usage of animal has been a concern for animal welfare teams. Bulk production of vaccination is not efficient and was costly.

Passive immunotherapy overcame many of the disadvantages of active immunization. Few other risks of this immunization are stated below. Transgenic plant antibodies due to its nicotine content may cross react and is harmful. Also passive immunity is obtained only for a shorter period of time and hence places the need for repeated vaccination and these booster doses also needs patient compliance.

**Conclusion**

Active and passive immunization strategies, which target key elements in the molecular pathogenesis of mutans Streptococci, hold promise. Integrating these approaches into broad-based public health programs may yet forestall dental caries disease in many of the world’s children, among whom those of high risk might derive the greatest benefit.

Along with established method of caries prevention, caries vaccines have the potential of making a highly valuable contribution to disease control. In the meantime, basic research on the mode of action of caries vaccine and the search for new, economical, efficient bulk production. Procedure of Active and Passive Immunization to work against pathogenesis of S. mutans in oral cavity holds promise. In order to make it feasible on human, more of clinical trials are required primarily on experimental animals. The main aim of vaccine should be long term prevention from dental caries, as the disease is gradual developing process. The vaccine should be safe and effective. Caries vaccine if successful tested on humans could be a valuable immunomodulator as compared to other caries preventive measures.

Turner’s Syndrome Manifestation with Generalized Periodontitis: A Case Report

J. Bhuvaneswarri

Professor, Department of Periodontics, Sree Balaji Dental College & Hospital, BIHER, Velachery Main Road, Pallikaranai, Chennai, Tamilnadu, India

Abstract

The knowledge of these syndromes is essential as they can influence the prognosis and management of periodontal disease. Syndromes associated with periodontium are a rare entity. Hence clinical diagnosis is very important. This case report is about turners syndromes with generalized aggressive periodontitis.

Keywords: Turner’s Syndromes, Systemic conditions, periodontitis.

Introduction

Henry Turner was the author who described seven young girls with the triad; sexual infantilism, webbing of the skin of the neck and elbow deformity\(^1\). Additional features also found by Turner were retarded growth and low hairline. He believed the underlying reason for the clinical symptoms being a result from a defect in the anterior pituitary gland called it has Turner Syndrome (TS).

Turner syndrome is caused by complete or partial X monosomy. The incidence of Turner syndrome is approximately 1 in 2000 among live female infants. Different karyotypes are associated with varying phenotypic expression. The most prevalent karyotype in patients with Turner syndrome is 45, X monosomy. The Xq isochromosome is associated with autoimmune disorders but not congenital abnormalities. Women with the ring X chromosome are less likely to display congenital abnormalities but are more likely to have spontaneous menses and cognitive disability. Women with Turner syndrome also can have a mosaic pattern with additional Y chromosome material (45,X/46,XY).\(^1,2,3\)

Many studies have reported systemic disorders and their relationship with periodontal disease. There are many underlying factors related to immune, endocrine and connective tissue. These alterations are associated with different pathogenesis and syndromes that cause periodontal disease either as a primary manifestation or by aggravating a preexisting condition to local factors\(^4,5\).

Case Report: A 19 yr old came to our department with a complaint of mobile teeth for the past one year. On clinical examination her records revealed karyotyping was done revealed it’s a case of trisomy 21 [Turners syndrome], patient is short stature, Amenorrhea, hypogonadism.

On intra oral examination pocket depth of 7mm is recorded in right & left upper molars, grade III mobility in upper 11, 12, 21, 22, high arch palate, deposits are minimal. Radiograph revealed extensive bone loss in all the quadrants. RCT was done in 11.

A full mouth flap surgery was planned, patient was put under regular oral prophylaxis, scaling and root planning was done and patient was under doxy cycline & metronidazole treatment.

After non-surgical phase, a full mouth flap surgery was done. Patient was reviewed after a month, 3 month & 6 months. Prosthesis was restored in 12, 11, 12, 22.
Case Report:

Preoperative:

Fig: Post Operative

Discussion

Periodontitis is a chronic bacterial infection of the supporting structures of the teeth. The host response to infection is an important factor in determining the extent and severity of periodontal disease. Systemic factors modify periodontitis principally through their effects on the normal immune and inflammatory mechanisms. Several conditions may give rise to an increased prevalence, incidence or severity of gingivitis and periodontitis. In many cases the literature is insufficient to make definite statements on links between certain syndromes and periodontitis and for several conditions only case reports exist.[5,6,7] Microbial dental plaque is the initiator of periodontal disease but whether it affects a particular subject, what form the disease takes, and how it progresses, are all dependent on the host defenses to this challenge. It is important to be familiar with the special management required for these patients, in which the dental treatment can affect the underlying cause of the disease.

Down’s syndrome is characterized by the appearance and behavior of the patients, oral manifestations are, gingival hyperplasia can occur secondarily due to mouth breathing, poor hygiene, and local irritating factors. The gingivitis which progresses to generalized periodontitis, which starts in the deciduous dentition and affects the permanent dentition.[8,9].

Conclusion

It is well established that many systemic conditions and their effects on the periodontium. Future studies are needed to assess the role of systemic conditions and its affect in periodontal disease, and mechanical factors which play a role in increasing susceptibility to periodontal disease.

Evolution of Mechanical Debridement and its Concepts

S. Deepa¹, Savithra Rathinasabapathy², D. Dhivyadarshani¹

¹Senior Lecturer, Sree Balaji Dental College and Hospital, BIHER, Chennai,
²General Practitioner, United Kingdom

Abstract

The field of periodontics has evolved over the period of years in classification, etiology and management of the periodontal disease. Biofilms are spatially and functionally organized, and environmentally heterogenous, enabling organisms to co-exist that appear incompatible with one another. Dental plaque is a classic example of both biofilm and microbial community. As the concepts of the etiology of the disease kept evolved, so did the management strategies.

Keywords: Periodontics, Dental plaque, Biofilm.

Introduction

Historical perspective- etiology of periodontal disease: During 1880-1930 researches found that four distinct groups of microorganisms as possible etiologic agents - amoeba, spirochetes, fusiforms and streptococci.

In mid 1930s there was a decline in the interest in microorganisms. Some constitutional defect like trauma from occlusion was considered as etiology and bacteria were believed to be secondary invaders.

In late 1950s, once again bacteria were considered as possible etiology in tissue destruction. Per nonspecific plaque hypothesis more the plaque, more the periodontal disease.

As per specific plaque hypothesis only certain type of plaque containing specific bacteria are particularly pathogenic ¹.

Current concepts of pathogenesis of periodontal disease: Biofilms are spatially and functionally organized, and environmentally heterogenous, enabling organisms to co-exist that appear incompatible with one another. Dental plaque is a classic example of both biofilm and microbial community ³.

As per Ecologic plaque hypothesis ⁴, in health, biofilm composition is relatively stable in a state of dynamic equilibrium and in balance with steady state low level immune/inflammatory response. Presence of red complex species (P.gingivalis, T. forsythia and T.denticola) were commonly found in advanced periodontitis associated with deep pocketing ⁵. Periodontitis is an inflammatory disease initiated by the oral microbial biofilm it is the host response to the biofilm that destroys the periodontium ⁶.

The objective of periodontal debridement ²:

- Disruption and removal of the subgingival biofilm. Treatment should aim to disrupt the biofilm and removal as much of it as possible.
- Creation of biologically acceptable root surface that is smooth and free of plaque retentive factors
- Resolution of inflammation.

Mechanical Professional Cleaning-Definitions ⁸:

SCALING is instrumentation to remove dental plaque and calculus from the surface of a tooth, from the surface of a tooth apical to the gingival margin accumulated in periodontal pockets, or from the surface coronal to the gingival margin (MeSH, introduced 1991).

Root Planing: It is a technique of using hand instruments to remove the softened cementum, to achieve hard and smooth root surface, usually carried out by quadrant, around 45-60 minutes per quadrant ⁷ and using Local anesthesia, referred to as scaling and root planing (SRP) or quadrant scaling and root planing (QSRP).

ROOT SURFACE DEBRIDEMENT (RSD) is the removal or disruption of dental deposits and plaque...
retentive dental calculus from tooth surfaces and within the periodontal pockets space without deliberate removal of cementum (MeSH, introduced 2011).

**Full Mouth Disinfection** is a specific technique that was proposed by a group of researchers who compared full mouth instrumentation within a 24-hour period and quadrant by quadrant instrumentation utilizing chlorhexidine gluconate extensively.\(^9\)-\(^{10-11}\)

**Full Mouth Ultrasonic Debridement (FMUD)** is a full mouth treatment carried out at one session, utilizing ultrasonic instrumentation alone and a debridement (conserving tooth structure) technique.

How the changes in concepts of etiology changed the treatment modalities?

**Scaling and Root Planing—Hand instrumentation:**
As calculus was considered as irritant, the goal of the periodontal treatment was to completely get rid of calculus.

In 1953 edition of Glickman’s Clinical periodontology textbook, the use of scalers is described to remove calculus deposits and to smooth the tooth surface by the removal of softened necrotic cementum.\(^12\)

In 1980s studies identified that endotoxin was present in the outer surface of cementum in teeth affected by periodontal disease.\(^13\) Removal of the endotoxin creates a root surface that is more biologically acceptable and compatible with wound healing. Usage of curettage was reduced as pain was associated in the procedure and studies eventually proved that the outcome of SRP with curettage is the same as that of SRP alone.\(^14\) During 1985-90 studies identified that endotoxin did not penetrate significantly into the cementum.\(^15\) During 1990-1991 further studies concluded that the therapeutic benefits of periodontal instrumentation are derived from the removal of the plaque rather than cementum or calculus.\(^16-17\)

Deliberate removal of cementum by SRP is no longer warranted or justified, and more gentle and conservative approach of RSD should be implemented in daily periodontal practice.\(^18\)

**Ultrasonic instrumentation—Root Surface Debridement:** Ultrasonic scaler facilitates biofilm disruption and endotoxin flushing, but with preservation of cementum. Ultrasonic scalers have vibrating tips which operate at frequencies of between 18 and 45kHz by using the conversion of electrical energy to mechanical energy.

Ultrasonic instrumentation is an effective method of treating periodontitis and provides similar clinical improvements compared to the other method of periodontal therapy.\(^19\)

Kieser’s research group introduced the term RSD which is a light touch, gentler form of instrumentation to promote plaque removal, yet with preservation of cementum.\(^22-23\) He proposed that periodontal therapy should be performed in a pragmatic, staged approach adopting RSD.

**Daily oral health care routine—commitment from the Patient:** Maintenance of periodontal health following therapy includes a lifelong supportive care consisting of daily removal of the microbial plaque by the patient, supplemented by professional care in an individually designed programme. The patient should be advised to use appropriate aids and technique. A soft brush, an interspace brush, interdental tooth brushes or tooth picks are recommended in periodontal patients.\(^25\)

In periodontal treatment, the importance of self-performed plaque control is frequently acknowledged but often underestimated.\(^26\)

**Discussion**

Early days plaque, calculus, endotoxin, and endotoxin impregnated cementum are considered to be the etiological factor in periodontal disease which lead to the management strategies involved scaling and root planing. The use of manual instrument to remove the epithelial lining of pocket wall, and cementum removal under Local anaesthesia and by quadrants, had unwanted side effects like dentine sensitivity, patient discomfort, and toxic effects of LA.

Studies then revealed the role of plaque as biofilm and microbial community and the host response releasing anti-inflammatory mediators which played major role in the tissue destruction in periodontal disease. This modified the treatment strategies which concentrated more on biofilm disruption rather than aggressive removal of cementum.

Studies proved that full mouth ultrasonic debridement without LA over an hour duration produced the result comparable to manual instruments under LA over 4 visits each an hour duration (QSRP). Self-
performed plaque control measures plays a vital role in maintaining the health of the periodontium. Educating and motivating the patient forms an important part of the treatment plan as this is the crucial factor influencing the outcome of the periodontal therapy.

**Conclusion**

As the concepts regarding the etiopathogenesis of periodontitis changed, its treatment modalities to remove plaque and calculus also evolved to reach the contemporary concepts.

**Ethical Clearance:** Not required since it is a review article.

Study Outcome of Bone Regeneration Using Bone Grafts: A Case

Sajid. T. Hussain

Reader, Department of Periodontology, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamilnadu, India

Abstract

Bone grafts play a major role in the regeneration of bone. So they are a very important factor in the regeneration of bone particles. Bone molecules have been impacted in those bone substitutes which play a major role in the formation of bone. Bone loss is a common problem in dental field due to increased compressive forces on the tooth structure which causes distortion and tension. Dentistry today is more towards regeneration and access towards regaining lost structures and tissues.

Keywords: Bonegrafts, Substitutes, Alloplasts, Autografts.

Introduction

Bone loss is one of the most common problem seen in the field of Periodontics. So the advent of artificial bone substitutes have made bone repair more eventful and easy. Bone loss is a common problem in dental field due to increased compressive forces on the tooth structure which causes distortion and tension. Dentistry today is more towards regeneration and access towards regaining lost structures and tissues.

Case History: The aim of this case report was to enhance the bone level by the substitution of bone grafts.

Materials and Method

A patient named Mr. Yoganand aged 40 years had come to the Department of Periodontics, Sree Balaji Dental College, for getting his infected gums treated. On X-ray it was found that there was loss of bone in the mesial aspect of 21. Pt was given medications and advised scaling and root planning initially. Later he was advised for a flap surgery and bone grafting.

Pre-op Probing

The patient is checked with all the periodontal indices and then taken up for further management and surgery. The case history is taken and the patient is further proceeded for surgical treatment.
Discussion

Whether bone grafts need to be placed was debatable but later it was confirmed that bone grafts need to be placed\(^4\). Bone grafts play a major role in the regeneration of bone materials and they are placed in the mesial aspect of 21. These grafts are placed and sutured with simple interrupted sutures. After that patient is given medications and recalled after a week for review\(^5,6\).

Conclusion

Flap surgery with bone grafting has been recommended as treatment of choice for gum infection and bone loss in the mesial aspect of 21.

Ethical Clearance: Not required since it is a case report.

Chronic Periodontitis and Hypertension: A Systematic Review

Bagavad Gita Jayaraman¹, Nilofer Farjana², Keerthana S.A.³

¹Professor, ²Post Graduate, ³Post Graduate, Sree Balaji Dental College and Hospital, BIHER, Chennai

Abstract

Aim: To conduct a systematic review evaluating associations between periodontal disease and hypertension.

Method: A MEDLINE literature search of papers published between 2000 and March 2016 was conducted. Cross-sectional studies, prospective studies and nested case-control studies that studied the association between periodontitis and hypertension formed the mainstay of this literature review. This systematic review was conducted on the guidelines of the Cochrane Systematic Reviews and the conclusive evidence was based on the Canadian task force on preventive health care guidelines.

Results: A total of 21 articles were searched for relevancy, determined by article title, abstract and full copy, resulting in a yield of 17 studies that met our inclusion criteria. 1) There is a fair evidence (II-2 Grade B recommendation) for an association between chronic periodontitis and blood pressure with OR of 2.93 (95% CI:1.25-6.84) but the association becomes stronger when restricted with those with hypertension or taking anti-hypertensive medications: OR = 4.20(95% CI:1.28-13.80). 2) A good evidence (I, Grade A recommendation) that intensive periodontal therapy decrease cardiovascular risk scores (Framingham) at 296 mm (1.53% F 1.20% (95% CI 1.05-2.24, P = .0290) and 2.00% F 1.42% (95% CI 0.98-4.09, P = .0568).

Conclusions: With the available literature we conclude that,

1. There is a fair evidence for an association between chronic periodontitis and hypertension.

2. Intensive periodontal therapy reduces the systemic inflammatory markers and systolic blood pressure imminently at 6 months after the end of periodontal treatment.

Keywords: Chronic periodontitis; Hypertension; Reactive oxygen species.

Introduction

Inflammation is now proved to be associated with all stages of coronary artery disease, from atheroma up to thrombus formation. Chronic periodontitis is a constant source of inflammation, with pro inflammatory cytokines being released from host bacterial interaction. This systematic review highlights how periodontal intervention can possibly reduce morbid outcomes of untreated and uncontrolled hypertension like acute myocardial infarction.

Background: Hypertension is the most prevalent cardiovascular disease affecting over 30% of the adult population globally. Untreated or uncontrolled hypertension is a fore-runner for morbid cardiovascular fatalities like atherosclerosis and myocardial infarction. It may also lead to target organ damage such as left ventricular hypertrophy and disruption of renal functions⁴⁰.

Periodontitis is a chronic inflammatory disease of the supporting structures of the teeth, caused by a plethora of gram-negative anaerobes⁶. The progressive attachment and bone loss eventually leads to loss of the tooth when untreated. The disease is associated with an abundance of host and bacteria-derived pro inflammatory cytokines such as IL-1 β, Tumor Necrosis Factor α and C Reactive Proteins²⁴,³¹.

Possible mechanisms linking chronic periodontitis and hypertension

1. Inflammation: The systemic inflammatory response
that may accompany periodontal disease has been proposed as one link between periodontal disease, hypertension and its cardiovascular ill-effects.\textsuperscript{25,26} A direct bacteraemia with far-reaching systemic effects is another possible mechanism\textsuperscript{12}.

Recent pathogenetic models suggest inflammatory mechanisms and endogenous related vasoactive substances to be responsible for hypertension.\textsuperscript{5,30} (Fig 1). Activation of endothelial cells by inflammatory cytokines promotes a proatherogenic phenotype with increased expression of proinflammatory factors and loss of the antithrombotic, growth-inhibitory, and vasodilator properties of the endothelium, including a decrease in the biological activity of nitric oxide.\textsuperscript{9}

2. **Oxidative Stress:** Periodontitis is associated with endothelial dysfunction in subjects without cardiovascular risk factors, as well as hypertensive patients, through a decrease in Nitric Oxide bioavailability.\textsuperscript{14} Oxidative stress in turn is implicated in the development of hypertension, since reactive oxygen species may be regarded as mediators of vasoconstriction and vascular inflammation, and bioavailability of nitric oxide is strongly related to the redox state.\textsuperscript{12}

3. **Obesity:** A well-known risk factor for developing cardiovascular disease is obesity, which is also associated with chronic periodontal disease.\textsuperscript{8} A high cholesterol diet increases the proliferation of junctional epithelium and alveolar bone resorption exacerbating periodontitis and periodontitis causing impaired glucose tolerance resulting in diabetes, obesity and cardiovascular disease. Thus periodontitis is a dual risk factor for hypertension.

4. **Periodontal disease and hypertension:** Data derived from the 3rd National Health and Nutrition Examination Survey (NHANES III) on almost 12,000 adult dentate participants to examine associations between periodontal disease measures and BP levels showed that a positive linear relationship between systolic BP and increased severity of periodontitis was identified in middle-aged subjects.\textsuperscript{10} This hypothetical association has been termed as Dental hypertension\textsuperscript{15} by Tsioufs et al. The severity of target organ damage due to hypertension such as left ventricular hypertrophy has also been associated with severity of periodontitis.\textsuperscript{34} Periodontal disease and its effect on the risk of pre-eclampsia\textsuperscript{6,7,8,23} and stroke\textsuperscript{3,13,17} have been studied extensively with varying results. Serological evidence by Pussinen et al.,\textsuperscript{27} and a case-control study by Grau\textsuperscript{13} pointed towards chronic periodontitis being an independent risk factor for ischemic stroke.

### Method

**Objectives:** This systematic review sought to answer the following questions:

a. Are healthy patients with chronic periodontitis at a higher risk of developing hypertension?

b. Does periodontal intervention in hypertensive patients improve blood pressure levels?

**Study Eligibility Criteria:** Longitudinal studies, randomized control trials, nested case control, case-control studies and cross-sectional studies that studied the association between chronic periodontitis and hypertension, and randomized interventional cohort studies, which assessed hypertension control in chronic periodontitis patients.

**Data Sources:** All abstracts in English language with hypertension as the outcome and periodontal disease as the predictor variable were searched in Google scholar and PubMed. Indexed specialty Journals were also hand-searched. The entire search period extended from January 2000 to March 2014.

Patient population included volunteers attending dental clinics and pregnant women attending obstetric clinics. Other subjects were those were formed part of various health projects like the NHANES III, Health Professionals Follow-up Studies, Oral Conditions, And Pregnancy study, The OralInfections and Vascular Disease Epidemiology Study (INVEST) and Puerto Rican Elderly Dental Health Study studies, Oral Conditions And Pregnancy study.

Patient population comprises of males and females in the age range of 45 to 60 years. There were 3 classes of patients, Patients with generalized chronic periodontitis, Patients with severe, primary, non-responsive (refractory) arterial hypertension or enrolled for treatment of hypertension and Healthy individuals without hypertension or chronic periodontitis.

**Study Selection:** Two reviewers assessed studies for inclusion in the review. Data were abstracted by one reviewer and reviewed for accuracy by another author. To rate the quality of the studies, levels of bias were
assessed using Cochrane’s risk of bias assessment tool. At the end, the articles that had a high risk of bias were eliminated.

**Stage I:** Independent electronic search by 2 reviewers yielded 50 article abstracts.

Application of exclusion criteria and discussion led to the exclusion of 8 titles.

**Stage II:** Independent analysis of abstracts of the 40 selected titles by the investigators. Application of exclusion criteria and discussion led to exclusion of 23 abstracts.

**Stage III:** Independent analysis of full text of the 21 selected abstracts by the investigators. Using the Risk of Bias Assessment tool by Cochrane, we eliminated 4 articles, which had a high risk of bias. Final number of articles included for analysis were 17. The details of the 17 studies selected

Characteristics of study participants, study size, PICOS variables, were noted on a chart by one reviewer and crosschecked

**Data Extraction:** Both reviewers did data extraction from the selected articles. One reviewer extracted the data and the other checked the extracted data.

**The Data Included:**

- Characteristics of trial participants (such as age, type and severity of periodontitis)
- Objective of the study
- Variables used in periodontal assessment
- Controlling for confounding factors.
- Type of intervention (where applicable)
- Outcome values
- Odds Ratio

**Validity Assessment:**

**Risk of Bias in Individual Studies:** This was performed based on Cochrane Risk of Bias Assessment tool. Sequence generation, allocation, blinding of participants, personnel and incomplete outcome data were assessed for each study. It was done at the study and outcome level of each study.

**Results**

Study selection: All English articles with the key words, periodontitis, hypertension, oral hygiene and tooth loss from Google scholar, PubMed and hand searching of indexed period ontology journals were searched independently by both reviewers.

Confounders for the study contributing to bias have also been tabulated for each study.

Risk of bias of each study and, if available, any outcome-level assessment was done.

Summary of evidence based on periodontal parameters, periodontal intervention, pre eclampsia, stroke and sub gingival microflora are tabulated in Table 4. All the selected studies were short-listed only after risk of bias assessment using the Cochrane ROB assessment tool.

**Discussion**

In this systematic review, the evidence for an association between chronic periodontitis and hypertension has been searched from cross-sectional data, cohort studies and a few interventional studies. The association was assessed also by secondary outcomes such as pre- eclampsia and stroke susceptibility.

Associative studies showed conflicting results ranging from no association to stronger association in known hypertensives. Clinical findings associated with periodontitis were studied, such as deep periodontal pockets and gingival bleeding were significantly associated with high blood pressure. Secondary outcomes of hypertension showed positive associations with chronic periodontitis too. Periodontal bacterial burden as assessed by the sub gingival micro flora have also been proved to have an impact on the risk of development of hypertension and pre-eclampsia. Pre-eclampsia and stroke were associated with chronic periodontitis than in those with a healthy periodontium. Non-surgical periodontal therapy, along with Oral Hygiene Instructions significantly reduces the cardiovascular risk evident after 16 months of intervention. In a cross-sectional study periodontal disease informs of pathological periodontal pocket is found associated with the raised diastolic blood pressure.

Interventional periodontal therapy has shown a reduction in blood pressure levels. The number of
interventional studies is limited and more RCTs with good study design are needed to conclude on any interventional effect. Table 4 shows the summary of evidence in the selected studies.

The available literature evidence has input from cross-sectional, case-control, nested case-control, cohort, and prospective interventional cohort studies. These drawbacks indicate the dire need for more longitudinal randomized control trials with intervention in clearly defined populations with uniform case definitions.

Studies designed on the following lines will considerably fill in the lacunae in the available literature:

- Well-defined and uniform case definitions of periodontitis, including the influence of the severity of the disease on hypertension.
- Longitudinal studies in healthy individuals with periodontitis and the absence of other risk factors.
- Randomized controlled interventional trials addressing the impact of chronic periodontitis on hypertension.

Conclusions

The quality of evidence and grades of recommendations were done based on the Canadian task force on preventive health care. Based on that we have made the following conclusions: 1) There is a fair evidence (II-2 Grade B recommendation) for an association between chronic periodontitis and blood pressure with OR of 2.93 (95% CI: 1.25-6.84) but the association becomes stronger when restricted with those with hypertension or taking anti-hypertensive medications: OR=4.20(95% CI: 1.28-13.80). 2) A good evidence (I, Grade A recommendation) that intensive periodontal therapy decrease cardiovascular risk scores (Framingham) at 296mm (1.53% F 1.20% (95% CI 1.05-2.24, P = .0290) and 2.00% F 1.42% (95% CI 0.98-4.09, P = .0568). 3) There is a fair evidence to support the Canadian Recommendation of PHE (Periodic Health Examination) in our study to improve’s people general health and longevity.

Ethical Clearance: Not required since it is a review article.

Clinical Efficacy and Anti-Inflammatory Property of Curcumin in Periodontal Disease: A Systematic Review

Sindhuja S.¹, J. Bhuvaneswarri², Dr. Mohan Valiathan², Dr. Bhaskar J.²

¹Post Graduate, ²Professor, Department of Periodontics, Sree Balaji Dental College and Hospital, BIHER, Chennai

Abstract

Periodontitis is a chronic inflammatory condition, caused by bacteria, that leads to the destruction of supporting tissues around teeth, resulting ultimately in significant morbidity as a result of infection, pain and tooth loss. Curcumin, from the root of the turmeric plant Curcuma longa, is an extended pseudo symmetric polyphenol. In recent years, in vitro and in vivo research has suggested that curcumin has anticarcinogenic, antiviral, antioxidant and anti-inflammatory effects. The aim of this review is to systematically evaluate the clinical efficacy and anti-inflammatory property of curcumin in periodontal disease. An electronic search was carried out using the keywords ‘curcumin’, ‘periodontal’ and ‘periodontitis’ via the PubMed/Medline, ISI Web of Science and Google Scholar databases for relevant articles published from 2009 to February 2019.

Keywords: Curcumin, Periodontal, Periodontitis, Inflammation.

Introduction

Periodontal disease is considered as an infection that involves both inflammatory and immune responses, which leads to increased pocket depth, clinical attachment loss, as well as destruction of alveolar bone and cementum.¹ Treatment modalities to resolve periodontal inflammation can be surgical or nonsurgical periodontal therapy based on the severity of periodontal destruction. Nonsurgical therapy includes both mechanical and chemotherapeutic method to minimize or eliminate microbial biofilm which is the prime etiological factor of gingivitis and periodontitis. Systemic use of antibiotics can interfere with normal body systems and may cause several side effects. The local administration of antibiotics or antimicrobials appears to be an effective means of eliminating these adverse reactions.² Hence the aim of this review is to systematically evaluate the therapeutic potential of curcumin in periodontal therapy.

Curcumin is a plant-derived dietary spice with various biological activities, including anticarcinogenic and anti-inflammatory effects.³⁴ Its therapeutic applications have been studied in a variety of conditions, including rheumatoid arthritis, colon cancer and depression. The anti-inflammatory properties of curcumin seem to be mediated by modulation of the activity of signaling pathways and transcription factors, especially nuclear factor-jB (NF-jB), activating protein-1 (AP-1) and MAPKs⁵. Besides its anti-inflammatory properties, curcumin has also been shown to improve wound healing by increasing collagen deposition, angiogenesis and the density of fibroblasts, reducing the radiation-induced delay in wound repair. Natural curcumin (diferuloylmethane) is a hydrophobic polyphenol composed of a mixture of three curcuminoids: curcumin, demethoxycurcumin and bisdemethoxycurcumin with various biological activities reported.⁶⁷

Primary Objective Question: To review current literature, analyze the efficacy, anti-inflammatory properties of curcumin in periodontal disease.
Criteria for Selection of Studies: The inclusion criteria for this study were:

1. articles published from 2010-2019,
2. original studies published in English language,
3. animal and human studies,
4. cell culture studies,
5. interventional studies

The exclusion criteria for the study were:

1. historic reviews,
2. letter to the editor,
3. case series and reports,
4. non clinical trials.

Search Methodology: An electronic database was carried out using the keywords ‘curcumin’ and ‘periodontal therapy’ via the Pubmed/Medline and Cochrane databases for relevant articles published from 2009 to 2019.

Results

Search Results: Following the removal of the duplicate search results, the primary search results resulted in 13 articles in total. Articles were excluded based on title and abstract. Hence remaining 11 articles were read completely for eligibility. Two studies were human studies and remaining were animal trials as listed in table.

Human Studies: The number of subjects ranged from 20-30. In one study, curcumin and chlorhexidine gel was applied in the contra lateral disease sites at baseline and 15 day and clinical parameters like CAL, PPD, gingival index and plaque index were recorded and CFU were assessed microbiologically (Maha MA. Nasra et al 2017). In another study, the clinical efficacy of Cur in-situ gel and the effect for 3 months in refrigerator was investigated through the determination of probing depth, plaque index, and bleeding index at baseline and 1 month after application (Anitha V Rajesh et al in 2019). The general characteristics of human studies are given in table.

Animal Studies: All the animal studies done were in vivo prospective studies (ref). The number of animals used as subjects ranged from 10-60. In one study (Guimaraes et al in 2011) periodontal disease was induced by placing cotton ligatures around both lower first molars. In study done by Correa MG et al in 2016 periodontitis was induced by tying a silk suture as a ligature around first molars. In all other animal studies (Morgana R Guimaraes et al in 2010, Muna S Elburki et al in 2014, Elburki MS et al in 2016, Fabiana Almeida et al in 2018) periodontal disease was induced by injecting LPS into gingival tissues. The followup period ranged from 15-25 days. The general characteristic features of animal studies are provided in table.

Assessment of Parameters: In animal studies (Guimaraes MR et al in 2011., Morgana R Guimaraes et al in 2011., Correa MG et al in 2011., Elburki MS et al in 2016., Fabiana Almeida et al in 2018., Munalburki et al in 2014). In first study, Guimaraes MR et al in 2011 Micro CT analysis, stereometric analysis were assessed. In second study, Morgana R Guimaraes et al in 2011 Micro CT analysis, stereometric analysis were assessed. In third study, Correa MG et al in 2016 Immunoenzymatic assay was assessed. In fourth study, Fabiana Almeida et al in 2018 Micro CT analysis, stereometric analysis were assessed. In fifth study, Elburki MS et al in 2016 ELISA, Western blot were assessed. In sixth study, Munalburki et al in 2014 Micro CT analysis, ELISA, Immunoblotting were done.

In human studies (Maha MA. Nasra et al 2017, Anitha V Rajesh et al in 2019). In first study, Maha MA. Nasra et al 2017 parameters like clinical attachment level, pocket probing depth, plaque index and bleeding index were assessed at baseline and after 1 month of surgery. In second study, Anitha V Rajesh et al in 2019 plaque index, bleeding index, clinical attachment level and pocket probing depth were assessed at baseline, 15 days and after 1 month of surgery.

Outcomes of the Selected Studies: Results from all 6 studies show that using MF is effective in reducing bone loss and improving outcomes of periodontal treatment (ref).

In Animal studies (Maha MA. Nasra et al 2017, Anitha V Rajesh et al in 2019), the results indicated the efficacy of 1% curcumin in reducing both clinical parameters and microbial load in patients with chronic periodontitis. Curcumin treated wounds had increased TGF-B1 which enhances wound healing which may be responsible in the gain in attachment following its use in periodontal therapy. It possess similar mode of action as non steroidal anti-inflammatory drugs like aspirin, but...
also has an advantage that it selectively inhibits the synthesis of prostaglandins and thromboxane while not affecting the synthesis of prostacyclin.

**Discussion**

**Human Studies:** All the human studies reviewed showed a reduction in the clinical parameters which is due to the anti-inflammatory effect of curcumin. In a study conducted by Maha M.A et al in 2017, the reduction in bleeding might be due to the resolution of gingival inflammation after scaling and root planning. Another study conducted by Anitha V et al in 2019 showed a significant difference at 30 days for curcumin over chlorhexidine in reducing the microbial and clinical parameters evaluated. This shows that curcumin could be a viable alternative to chlorhexidine in adjunctive use in periodontal therapy.

The human studies show that curcumin reduces the inflammatory mediators and causes shrinkage by reducing inflammatory edema and vascular engorgement of connective tissues (Rastogi et al., 2012). Other properties of curcumin such as anti-inflammatory, antioxidant, anti microbial, hepatoprotective, immunostimulant, antimutagenic properties may also help in the improvement in clinical and microbiologic parameters following use as an adjunct in periodontal therapy. Another mechanism by which curcumin reduces inflammatory changes is by promoting the migration of epithelial cells to aid in re-epithelialization.

**Animal Studies:** All the animal studies reviewed showed that Curcumin produced a significant reduction on the inflammatory infiltrate and increased collagen content and fibroblastic cell numbers. Curcumin potently inhibits innate immune responses associated with periodontal disease, suggesting a therapeutic potential in this chronic inflammatory condition.

In the **first study** conducted by Morgana R Guimaraes et al in 2011 investigated the effect of curcumin on the expression of pro-inflammatory mediators and host response in an LPS model of periodontal disease. It was found that administration of curcumin by oral gavage completely blocked PGE2 expression and produced a dose-dependent inhibition of IL-6 and TNF-a levels in the gingival tissues. The suppression of pro-inflammatory cytokines by curcumin was accompanied by a marked reduction of the inflammatory process verified by the stereometric analysis. These changes may be due, at least partially, to the dose-independent inhibition of NF-kB activation in the gingival tissues of curcumin treated animals LPS-induced activation of NF-kB in the gingival tissues was inhibited only with the lower dose of curcumin and also curcumin produced a significant reduction on the inflammatory infiltrate and increased collagen content and fibroblastic cell numbers. In the **second study** conducted by Guimaraes MR et al in 2011 demonstrated that intragastrically administered curcumin effectively reduces inflammation and connective tissue breakdown in this experimental periodontitis model. This effect has been explained, at least in part, by the inhibition of IL-6, PGE2 and TNF-a expression, as a result of the modulation of NF-jB activation.

In the **third study** conducted by Correa MG et al in 2016, The administration of resveratrol and curcumin, alone or in combination, appeared to enhance the levels of IL-4, whereas resveratrol alone, and not curcumin, reduced the levels of IFN-c. It is noteworthy that although no significant difference was found in the amounts of IL-1b when resveratrol and curcumin were used alone, a trend toward lower levels of IL-1b in these groups was observed when compared with the control group. Resveratrol administered alone led to reduced loss of alveolar bone in experimental periodontitis when compared with placebo. The administration of curcumin alone lead to reductions in bone loss when compared with placebo. It also caused significant reduction in inflammation-mediated destruction of periodontal soft tissues and bone. In the **fourth study** conducted by Fabiana Almeida et al in 2018, oral administration of CMC 2.24, but not curcumin, significantly reduced inflammatory bone resorption and the number of osteoclasts in the proximity of the alveolar bone. On the other hand, curcumin, but not CMC 2.24, significantly inhibited apoptosis in the gingival tissue and also of osteocytes, both in the presence or absence of inflammation. In the **fifth and sixth studies** conducted by Muna S Elburki et al in 2014 & Elburki MS et al in 2016, showed that the administration of CMC 2.24 to diabetic rats with endotoxin-induced periodontitis: (i) significantly suppressed local/alveolar bone loss and also tended to reduce the severity of systemic bone loss (diabetes associated osteoporosis); (ii) attenuated the severity of local and systemic inflammation by reducing cytokine levels (IL-6 and IL-1b); and (iii) reduced pathologically elevated levels of MMPs (MMP-2, MMP-8 and MMP-9), and their activation, both locally in the gingiva and systemically in the circulation and in skin.
Curcumin increased the levels of newly synthesized (salt-soluble) collagen and decreased the proportion of the older (insoluble) collagen in skin of diabetic rats.

In general, chemically modified curcumin (CMC2.24) is more soluble than curcumin in water-based vehicles and this compound has three zinc-binding moieties that are able to inhibit matrix metalloproteinases, which are essential in the degradation of connective tissue, including bone tissue. The increased bioavailability of CMC2.24 may be at least partly responsible for the attenuation of bone resorption; however the decrease on the osteoclast numbers observed in CMC2.24-treated animals suggest an effect on osteoclast differentiation. Moreover the chemically modified curcumin appears to have additional benefits by reducing the impact of this local inflammatory disease on systemic biomarkers of the host without (apparently) negatively affecting the mediators of constitutive connective tissue turnover.

**Conclusion**

Curcumin has a long history as a traditional herbal medicine and has established anti-inflammatory properties in animals following systemic administration. This compound is particularly interesting for therapeutic applications because its anti-inflammatory and antiproliferative effects are potent, occurring at micromolar concentrations. However longer term studies in models of experimental periodontitis might be required to elucidate their effects more clearly. This could lead to the development of more effective prevention approaches for periodontitis in humans.

Periodontal Status among Residents of Dhideer Kuppam Slum in Chennai

Anita M.¹, Vidhya Rekha U², Sadhana K.³
¹Reader, ²Senior Lecturer, ³Senior Lecturer, Dept. of Public Health Dentistry, Sree Balaji Dental College and Hospital, BIHER

Abstract

Oral health is an integral component of general health and is essential for a person’s comprehensive well-being. The current outlook towards oral health has broadened beyond the concept of just good teeth and has evolved to encompass freedom from chronic pain, the absence of oral and throat carcinoma, oral sores and birth defects such as cleft lip and palate, freedom from periodontal diseases, tooth decay, tooth loss and many other diseases and disorders that affect the mouth and oral cavity.

Keywords: Oral health, cleft lip and palate, Oral sores.

Introduction

Every person is entitled to live a healthy life irrespective of socioeconomic status, caste, religion or ethnicity¹. A quarter of Chennai’s 4.5 million population lives in the slums ²,³. The inhabitants work as fishermen, auto drivers, daily wage labourers, painters, electricians, house keepers and most of the womenfolk work as house maids⁴. As per the Government of India, a slum is “a compact area of at least 300 in population or about 60 – 70 households of poorly built, congested tenements in an unhygienic environment usually with inadequate infrastructure and lacking proper sanitary and drinking water facilities”⁵. If these were to be the material defects, repercussions lie in the form of poor health often leading to slum epidemics.

A wide health disparity exists between populations in upper and lower socioeconomic status. Primary and preventive health care is the most important means whereby the health sector with intersectorial coordination, can close the health gap and improve the health status of the population⁶. This in the dental context implies early detection and prompt intervention of oral diseases.

Keeping in mind the paucity of data on periodontal status of slum dwellers in Chennai, an attempt has been made to determine the periodontal status among residents of Dhideer Kuppam slum in Chennai.

Aim: To determine the periodontal status among residents of Dhideer Kuppam slum in Chennai.

Materials and Method

Chennai is the capital city of Tamil Nadu. It has an estimated population of over 8.05 million (2009) making it one of the largest urban agglomerates in India³. A cross-sectional descriptive study was conducted in Dhideer Kuppam, a slum in Chennai for assessing oral health status and treatment needs.

Inclusion criteria and exclusion criteria: Only those subjects who are permanent residents of Dhideer Kuppam were eligible to participate in the study.

Those who were unavailable at home for enrolment in the study even after three consecutive visits to their homes and those who were not willing to participate were excluded from the study.

Approval and informed consent: Ethical approval was obtained from the Institutional Review Board. Informed consent was obtained from all the participants and minors were examined only after obtaining consent from their parents or guardian.

Sample size estimation: The sample size was calculated on the basis of the prevalence (P) of dental caries (57%) among residents of an urban slum in West Bengal¹⁰. The Q value (100-P) was 43% (100-57) and
allowable error (L) was set at 10% of P [10% of 57 = 5.7]. The required sample size (N) was 290. As a cluster sampling technique was employed, final sample size = 290 \times 1.4 (Design effect) = 406 subjects.

**Survey methodology:** After a brief introduction on the purpose and intent of the study, examination was conducted by a single examiner who had been trained through a series of clinical training sessions at the Department of Public Health Dentistry, Sree Balaji Dental College, Chennai. Demographic information was collected followed by clinical examination. All instruments were sterilized by autoclaving. Only completely filled forms were considered for analysis.

**Clinical examination:** Dental examinations were conducted under natural light by means of mouth mirror and a periodontal probe which conform to World Health Organization (WHO) specifications. Data were recorded according to the WHO assessment form 1997.

**Statistical analysis:** Data were entered in Microsoft Excel spreadsheet and analyzed using SPSS software. Pearson’s chi-square was used to test if the differences for various parameters between males and females were statistically significant. Trend Chi-square was used to test the relationship between periodontal condition, loss of attachment and prosthetic needs with age.

**Results**

Table 1 depicts the distribution of study subjects by age and gender. The study sample consisted of 531 individuals of which 218 (41.1%) of the respondents were males and 313 (58.9%) were females. The study subjects were between the age group of 5 and 76 years.

Table 2 represents the prevalence of periodontal condition among the study subjects. The prevalence of periodontal disease among the study subjects was 75.1%. The change in periodontal condition across the age groups was very highly significant p=0.000. Periodontal disease increased in prevalence with increasing age. Difference in the prevalence of calculus among the gender was found to be statistically significant (p=0.024), with a higher prevalence among the females. The prevalence of shallow and deep pockets among the gender was found to be statistically significant, p=0.031 and p=0.000 respectively, with higher prevalence among the males.

Table 3 depicts the sextant wise prevalence of periodontal condition among the study subjects expressed as mean number of sextants per person. Mean number of healthy sextants per person was maximum in the 20 – 24 year old males (3.2). Gingival bleeding,

In the present study, prevalence rate of periodontal disease among the study population was 75.1%. This was found to be higher than that observed by Doifode VV et al\(^\text{13}\) (2000, Nagpur) where the prevalence rate was 34.8%. This difference in the prevalence rates may be because of the broad categorisation of socioeconomic status and the various components which may differ in different geographic areas. Attached with it are habits and behaviour which affects the prevalence of oro-dental diseases. Usually, higher prevalence of dental disorders is reported in lower socioeconomic strata\(^\text{24}\). That may be due to lower educational status, primitive idea about oral hygiene and non availability of preventive and curative facilities.
In a study conducted by Meghshyam Bhat et al\textsuperscript{21} (2008, Karnataka) the maximum number of subjects scoring healthy periodontal status as per CPI was found to be in the younger age groups and the number gradually decreased as age increased. This is in agreement with the findings of the present study.

In the present study, none of the 15-19 year age group subjects had shallow pockets. Deep pockets were most prevalent in the 65+ age group females (55.6%). However, Arvidson et al\textsuperscript{8} (1990, Bangladesh) found that the prevalence of shallow pocket among 18 year old urban slum dwellers was 34% and that deep pockets were most prevalent (42%) among the 35-44 years age group. This difference in prevalence rate could be because of differences in the study setting.

**Conclusion**

In conclusion, the present study highlights the fact that the prevalence of oral diseases among the residents of Dhideer Kuppam slum is high. A comprehensive understanding of the magnitude of the public health problem would enable effective planning of interventional measures.

Oral Hygiene Status, Dental Caries Experience and Treatment Needs among Psychiatric Outpatients in Chennai, India

Anita M.¹, U. Vidhya Rekha², Sadhana Kandavel²

¹Reader, ²Senior Lecturer, Dept. of Public Health Dentistry, Sree Balaji Dental College and Hospital, BIHER

Abstract

Objective: To assess the oral hygiene status, dental caries experience and treatment needs among psychiatric outpatients in Chennai.

Basic Research Design: A cross-sectional descriptive study was carried out on patients receiving care at the Outpatient Wing of The Department of Psychiatry, Stanley Medical College and Hospital, Chennai. A cluster sampling technique was employed.

Participants: The study sample consisted of 159 male and 145 female psychiatric patients.

Main Outcome Measures: Oral hygiene status, Dental caries experience and Treatment needs.

Results: Among the male subjects; 9 (5.6%), 75(47.2%) and 75(47.2%) had good, fair and poor oral hygiene, respectively. Among the female subjects; 9(6.2%), 87(60%) and 49(33.8%) had good, fair and poor oral hygiene, respectively. The overall mean DMFT among males and females was 7.8±0.52 and 8.01±0.50, respectively.

Association between age and DMFT score was found to be statistically very highly significant \(X^2 = 54.64, \text{df} = 4, \ p = 0.000\). The association between gender and DMFT score was found to be statistically not significant \(X^2 = 3.73, \text{df} = 1, \ p = 0.053\). Prevalence of dental caries in the study population was 83.55%.

Conclusion: The oral hygiene status of psychiatric outpatients is poor. Dental caries experience and treatment needs are high.

Keywords: Oral hygiene status, Dental caries experience, Psychiatric outpatients.

Introduction

Illness, whether physical or mental may lead to deterioration in self care and have an adverse effect on the holistic wellbeing of the individual. Among the unique population groups, people with psychiatric disorders deserve special attention. The term psychiatric illness is used to describe clinically recognizable patterns of psychological symptoms or behavior causing acute or chronic ill health, personal distress or distress to others.ⁱ⁶

Psychiatric illness is a continuum ranging from minor distress to severe disorder of the mind or behavior.³,¹³

Routine dental health care for institutionalized psychiatric patients are provided within many of the large institutions, but only a small portion (2.35%) of psychiatric patients are users of mental health services.¹⁰ A vast majority of adults with mental illness live in the community.¹⁴

About 2-5% of India’s population suffers some form of mental or behavioural disorder. 10-15% of those attending general health facilities have a common mental disorder. Among the states of India, Tamil Nadu has the maximum number of mental health institutions. Yet, the population is so vast and diverse that majority of mentally ill patients are still treated as community dwelling outpatients.⁶
Materials and Method

Study Design: A cross-sectional descriptive study

Study Area: Four government administrated facilities cater to the treatment needs of community dwelling psychiatric outpatients in Chennai. This study was conducted at Stanley Medical College and Hospitals, which is one of the four facilities.

Inclusion criteria:
- Subjects who had been diagnosed with psychiatric illness at least 5 years ago.
- The patient must be currently receiving treatment for the psychiatric illness.

Exclusion criteria:
- Those who are not stable to give informed consent.
- Those who are not willing to participate in the study.

Approval and informed consent: Ethical approval was obtained from the Institutional Review Boards of Stanley Medical College and Hospital.

Informed consent was obtained from all the participants and minors were examined only after obtaining consent from their parents or guardian.

Sample size estimation: The sample size was calculated on the basis of the prevalence (P) of periodontal disease (98.1%) among psychiatric patients in Davangere. The required sample size was 128 subjects.

Sampling methodology: A cluster sampling technique was employed. A list of Government administrated psychiatric outpatient facilities in Chennai was obtained from the Department of Health and Family welfare, Government of Tamil Nadu. One hospital was selected from the aforementioned list by simple random sampling using lottery method.

The study sample consisted of 159 males and 145 females. Among the study population; 87, 78, 75 and 64 subjects were diagnosed with schizophrenia, mood disorder, organic brain damage and other psychiatric illness respectively. All willing, eligible participants within the cluster were enrolled into the study, yielding a total sample of 304 individuals.

Survey instrument: An operator administered pre-tested questionnaire, specially designed for this purpose was used. Demographic information, information about diagnosis and duration of psychiatric illness and current medications were obtained from the hospital medical records. Information about oral hygiene practices and frequency of brushing teeth were obtained by interviewing the patient. Oral hygiene index-simplified and dentition status and treatment needs index were recorded.

Clinical examination: Dental examinations were conducted by a single examiner who had been trained through a series of clinical training sessions at the Department of Public Health Dentistry, Sree Balaji Dental College and Hospital, Chennai. After recording the questionnaire, dental examinations were conducted in supine position under natural light by means of mouth mirror and a CPI probe. Instruments were sterilized using standard protocol. Only completely filled forms were considered for analysis. The intra examiner reliability was calculated using the data obtained by re-examination of first and eleventh subject of each day after scheduled number of subjects were examined for the day (K=0.81).

Statistical analysis: Data was entered in Microsoft Excel spreadsheet and analyzed using SPSS (Version 15) software. Chi-square test, Trend Chi-square test, Linear regression analysis and Post Hoc Tukey test were employed.

Results

The study sample consisted of 304 psychiatric outpatients. 159 (52.3%) of the respondents were males and 145 (47.7%) were females. The study subjects were between the age group of 18 and 71 years. Among males; 57 (36%), 12 (7%), 54 (34%) and 36 (23%) were diagnosed with schizophrenia, mood disorder, organic brain damage and others, respectively. Among females; 30 (21%), 66 (46%), 21 (14%) and 28 (19%) were diagnosed with schizophrenia, mood disorder, organic brain damage and others, respectively.

Among the 304 study subjects, 89% cleaned their teeth by themselves and 11% cleaned their teeth with the help of an assistant. All the subjects who cleaned their teeth with the help of an assistant did so once a day. Among the study subjects who cleaned their teeth themselves,
86% cleaned the teeth once a day, 10% cleaned twice a day and 4% were irregular in cleaning teeth.

Linear regression analysis showed that DMFT scores were significantly higher in those who brushed their teeth with assistance, than in patients who brushed their teeth themselves (t = 2.78, p = 0.006).

Table 1 describes the distribution of study subjects based on oral hygiene status. Among 159 male subjects; 9 (5.6%), 75 (47.2%) and 75 (47.2%) had good, fair and poor oral hygiene, respectively. Out of 145 female subjects; 9(6.2%), 87(60%) and 49(33.8%) had good, fair and poor oral hygiene, respectively.

Among males, the maximum number of subjects having good, fair and poor oral hygiene were found in the 20-29, < 19 and > 50 years age group, respectively. Among females, the maximum number of subjects having good, fair and poor oral hygiene were found in the < 19, 20-29 and > 50 years age group, respectively.

Trend Chi-square test was performed to determine the pattern of OHI-S score variation across the age groups. It was found that as age increases, OHI-S score also increased [X² = 5.352, p = 0.021]. The association between age and OHI-S score was found to be statistically significant [X² = 2.561, p = 0.015].

ANOVA test performed to test the relationship between age groups and DI-S score [F = 32.260, p = 0.000], CI-S score [F = 24.428, p = 0.000] and OHI-S score [F = 37.560, p = 0.000] was found to be statistically very highly significant.

Table 2 depicts the distribution of study subjects based on oral hygiene status. Among the study subjects, 13(8.17%) males and 12(8.27%) females were caries free. In both males and females, the maximum number of caries free subjects were found among the 30-39 year age group. Highest mean DT was found among the 40-49 year age groups with males and females having a mean ± SD of 7.29±3.27 and 7.50±1.91, respectively. Highest mean MT was found among the > 50 year age groups with males and females having a mean ± SD of 6.91±5.57 and 7.46±6.82, respectively. Highest mean FT was found among the < 19 year age group among females (2.00±0.50) and in the 20-29 year age group among males (1.09±1.01). The overall mean DMFT among males and females was 7.8±0.52 and 8.01±0.50, respectively.

Association between age and DMFT score was found to be statistically very highly significant [ X²= 54.64, df = 4, p = 0.000]. The association between gender and DMFT score was found to be statistically not significant [ X²= 3.73, df = 1, p = 0.053]. Prevalence of dental caries in the study population was 83.55%

Table 3 illustrates the distribution of study subjects based on diagnosis and caries experience. Post Hoc Tukey test performed to test the association between the diagnostic subdivisions of psychiatric illness and DMFT score revealed that Schizophrenia was significantly more strongly associated with dental caries experience (p= 0.015) than mood disorder, organic brain damage and others. Mood disorder was more strongly associated with dental caries (p = 0.023) than organic brain damage and others but to a lesser degree than Schizophrenia.

Table 4 depicts the age wise treatment needs among the study subjects. Highest requirement for one surface fillings, two surface fillings and crown were in the 40-49 year age group with the mean ± SD being 3.99±0.48, 2.03±1.00 and 0.99±0.35, respectively. Pulp therapy was most needed in the 30-39 year olds with the mean ± SD being 0.96±0.20. Maximum number of extractions were required in the >50 year age group with the mean ± SD being 5.72±3.57.

Discussion

Apathetic nature, poor diet and xerostomia inducing medications predispose psychiatric patients to significantly higher risk of dental diseases. Routine dental health care is provided to institutionalized psychiatric patients. However, only 2.35% of psychiatric patients are users of mental health services.10.

Age of the participants in this study ranged from 18 years to 71 years. The inclusion of a wide array of ages facilitated the assessment of disease trends across the age groups. Among the study subjects; 87, 78, 75 and 64 were diagnosed with schizophrenia, mood disorder, organic brain damage and other psychiatric illnesses respectively. These diagnostic subdivisions were considered in this study because they are most commonly associated with the occurrence of dental caries.5,7,9,10.

Mean OHI-S score in our study was 3.05±1.17. This is similar to the findings of Manish Kumar et al (2006)9 where the mean OHI-S score was 3.3. However, it was found to be lower than the mean OHI-S score (4.2) obtained by Angelillo et al (1995)1 in Italy. In our study, Trend Chi-square test showed that as age increases OHI-S score increases. Similar findings have been reported by Angelillo et al (1995)1, Kenkre et al(2000)5 and Manish Kumar et al (2006)9.

DMFT scores were significantly higher in partly helpless patients than in patients who brushed their teeth without assistance. A similar observation was made by Angelillo et al (1995)1. Mean DT in our study (5.05) is higher than the findings of Lucchese C et al (1998)8 and Ramon T et al (2003)11 where the mean DT was 2.1 and 2.3 respectively. DMFT scores increased with increasing age which is in accordance with many other studies (Angelillo IF et al, 1995; Kenkre AM et al, 2000; Lewis S et al, 2001; Lucchese C et al, 1998; Manish Kumar et al, 2006; Ramon T et al, 2003)7,8,9,11. Mean DMFT score in our study is 7.91. This is lower than that observed by Lewis S et al (2001)7 in South Wales (19.1) and Ramon T et al (2003)11 in Israel (26.74). However, in the study by Manish Kumar et al (2006)9 in Davangere, the mean DMFT score was 0.92. This vast discrepancy may be because the water source of Davangere has a fluoride concentration of 1.5 to 2 ppm.

The percentage of caries free subjects in our study (8.3%) is lower than that reported by Kenkre AM et al (12%)5 and Manish Kumar et al (67.8%)9.

In this study, caries experience was maximum among those diagnosed with schizophrenia followed by those with mood disorder. This is in agreement with other studies (BorgeHede, 1988; Persson K et al, 2009)2,10. Reasons for this may be the level of disability these illnesses cause and the medications given. Highest requirement for one surface fillings, two surface fillings and crown were in the 40-49 year age group, which is in accordance with other studies (Lewis S et al, 2001; Lucchese C et al, 1998; Manish Kumar et al, 2006)7,8,9.

Conclusion

Thus, results of this study show that psychiatric patients have extensive dental diseases, many of them requiring complex treatment. However, prevention should be the main objective because patients with advanced psychiatric illness are often anxious and uncooperative for extensive curative therapy.

A Survey of Teething Beliefs and Related Practices among Child Healthcare Workers in Chennai City, India

Vidhya Rekha U.¹, Anita M.¹, Sadhana Kandavel¹

¹Dept. of Public Health Dentistry, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

Abstract

Purpose: To determine the perceptions and related practices among the dentists and doctors regarding teething and its associated symptoms in Chennai.

Materials and Method: This was a cross sectional study which consisted of 140 child healthcare workers which included dentists and doctors in the hospitals and clinics in Chennai.

Results: Out of the 140 dentists and doctors, a total of 134 dentists and doctors believed in the systemic signs and symptoms of teething in children. Among which 66(49.3%) doctors and 68(50.7%) dentists believed in teething problems. The source of teething beliefs included 22(15.7%) on books, 55(39.3%) on local myths, 58(41.4%) on personal experience and 5(3.6%) on other sources (school and workshop acquaintances). The teething symptoms which were manifested by the children were vomiting 69(49.3%) ranked first in the third column, fever 65(46.4%) which ranked second in the first column is believed to be associated with teething, Irritability 62(44.3%) ranked second in the second column and followed by Gum redness 52(37.1%). The most common drugs which were prescribed by the doctors and dentists were, paracetamol 133(95%) and antibiotics 96(68.5%).

Conclusions: Most of the dentists and doctors do believe in the signs and symptoms caused during the eruption of teeth in children. They also prescribe drugs for those symptoms.

Keywords: Tooth eruption, teething symptoms, teething beliefs.

Introduction

Is there really a relation between teething and symptoms like fever, diarrhoea, etc.? If symptoms are present are drugs required for it?

Right from Adam and Eve or, more precisely, from Cain and Abel, infants have been teething, and for almost a long time, teething has been a myth and medical opinion. But, despite extensive discussion of teething, very less evidence-based medical information is available. And so, even today, debate continues in the medical literature about the association with teething of specific symptoms, such as fever, diarrhea, etc.

Teething is associated with increased biting, drooling, gum rubbing, sucking, irritability, wakefulness, ear rubbing, facial rash, decreased appetite for solid foods, and mild temperature elevation. But some other researchers like do not agree to this belief of teething and its symptoms. They found no association between teething and temperature or other symptoms, including drooling, sleep disturbance, diarrhea, or rashes. “There can be no excuse for ascribing fever, fits, diarrhoea, bronchitis, or rashes to teething,” wrote the BMJ in 1975.

Pediatricians often contribute to the mythology of teething. Swan reported in 1979 on 50 infants who had been admitted to the hospital with a chief complaint by
the parents of “teething” and whose presenting symptoms included fever, irritability, diarrhea, respiratory distress, poor feeding, and convulsions(1).

The local and systemic manifestations in children ages 0 to 3 years seen in the baby clinic of the Araçtuba Dental School, UNESP, São Paulo, Brazil, gave data as responded by parents on primary tooth eruption and the predominant manifestation was gingival irritation (85%), while the least frequent symptom (26%) was a runny nose(3).

Carlos Alberto Feldens, investigated the occurrence and management of teething symptoms during the first year of life and associated factors. The results showed Teething symptoms reported in 73% of the children analyzed (273/375). The symptoms most frequently reported were irritability (40.5%), fever (38.9%), diarrhoea (36.0%) and itching (33.6%). Dentists had little influence on the management of symptoms and self-medication to relieve them was a common practice. The risk of reporting teething symptoms was higher for children from nuclear families (p=0.040) and for children from families with higher income (p=0.040)(4).

Tooth eruption has been held responsible for a variety of systemic manifestations in infants. The association between teething and irritability, increased salivation, sleep disturbance, fever, diarrhea, and loss of appetite remains unclear because the onset of these disorders may simply coincide with the teething. Moreover, some of these signs and symptoms may imply more serious conditions. Thus, the aim of this prospective longitudinal study was to investigate the association between tooth eruption in infants and a range of signs and symptoms of teething while minimizing the limitations found in previous studies.

**Materials and Method**

The study was cross sectional, where a total of 140 questionnaires were given to child healthcare workers including dentists and doctors in Chennai. The questionnaires were filled by the professionals and returned to the author at the same day.

The biographical data of the child healthcare worker was elicited in the first part of the questionnaire which included name, age, gender, address, profession, number of years in practice.

The following information like the perception of teething by the healthcare professional, source of teething belief, signs and symptoms related to teething and drugs prescribed for teething were given in the second half of the questionnaire. The teething symptoms were given in a tabulated form in which the order of symptoms was ranked as 1, 2, and 3.

The data were analyzed using STATA for windows. The analysis included frequencies and cross tabulations.

**Results**

The study consisted of 140 child healthcare workers in Chennai who returned their questionnaires on the same day. 89 were male and 51 were female.

Table 1 shows that there were 71 doctors and 69 dentists in which 66 (49.3%) of the doctors and 68 (50.7%) of the dentists believed in teething problems.

Table 2 shows that of 66 (49.3%) dentists and 68 (50.7%) doctors who believed in teething problems, 23 (44.2) doctors and 29 (55.8%) dentists and believed that all children had teething problems. Whereas 45 (54.9%) doctors and 37 (45.1%) dentists believed that only some children had teething symptoms.

Table 3 shows that the source of teething beliefs included 22 (15.7%) on books, 55 (39.3%) on local myths, 58 (41.4%) on personal experience and 5 (3.6%) on other sources (school and workshop acquaintances).

Table 4 shows that out of the 140 respondents 28 (46.7%) doctors and 32 (53.3%) dentists = stated that they prescribed drugs for teething in children.

Table 5 shows vomiting (69 (49.3%) ranked first in the third column, fever 65 (46.4%) which ranked second in the first column is believed to be associated with teething. Irritability 62 (44.3%) ranked second in the second column followed by Gum redness 52 (37.1%).

Table 6 shows that the most common drugs which were prescribed by the doctors and dentists were, paracetamol 133 (95%) and antibiotics 96 (68.5%).

**Discussion**

Teething has long been the subject of superstition, speculation, and opinion, but little research. It is important for the healthcare professional as well as the parents to know about teething and its beliefs whether it is true or not. In Nigeria most of the parents believe in teething symptoms and 82 children died after the administration of a teething mixture “Mr. pikin”(5).
There is a wide knowledge about the beliefs which parents have on teething symptoms which their children have but there is less study on whether the healthcare workers also agree to it and prescribe drugs.

There is an interesting possibility that may be related to teething symptoms which is a result from undiagnosed herpetic gingivostomatitis. Herpes infections often occur in the second six months of life when infants are losing maternal antibody and at the same time they often present with the same symptoms ascribed to teething. But the signs and symptoms were significant on the day of eruption and 1 day after eruption. Therefore, it is not possible to predict eruption through the observation of signs and symptoms because there were no associations with the day before eruption. Thus, health professionals involved in the care of infants should seek other causes before attributing severe signs and symptoms to teething. Australian health professionals, on the whole, believe that many systemic symptoms can be attributed to teething, although pediatricians were less likely than other health-care professionals to subscribe to that belief.

An article in the consumer magazine Working Mother in September 1993 quoted a pediatrician as saying, “When a tooth is pushing through the gum, it leaves an opening through which viruses can enter the body. Also, during teething, youngsters tend to put fingers and toys into their mouths. This increases their chances of getting a virus that might cause fever or diarrhea.”

A study done in Royal Children’s Hospital, Parkville, Australia did not confirm the expected strong associations between tooth eruption and a range of teething symptoms in children 6 to 30 months old. Such beliefs may preclude optimal management of common patterns of illness and behavior in young children. Almost all parents, the majority of nurses, and many physicians believe that teething is associated with the appearance of symptoms, most of which are minor and relate to discomfort rather than physical illness, but a substantial minority still ascribes potentially serious symptoms to teething.

Normal developmental phenomena make interpretation of research on teething more challenging. Between 2 and 3 months of age, the salivary glands of infants begin functioning and contribute to constant drooling, which parents may misinterpret as a manifestation of teething. Moreover, infants of this age can put their hands in their mouths, which also is subject to parental misinterpretation. Another normal developmental event that parents may assume erroneously is a symptom of teething is the night waking that occurs around 8 or 9 months of age, when infants develop a sense of object permanence and call out to their parents at night. Irritability and fussiness, another symptom often ascribed to teething, can result from a variety of medical or behavioral issues. If the parent or physician quickly attributes irritable behavior to teething, medical illness or behavioral-development issues may not be appropriately acknowledged or addressed.

In this article most dentists and doctors believed in teething signs and symptoms and they also prescribed drugs according to the symptom. Most of the dentists and doctors had believed in teething symptoms from their personal experience however, some are due to local myths too.

Therefore from all the previous studies and this study, there is no accurate proof for the relation between tooth eruption and the symptoms which the child has at that time. There may be an underlying infection for the appearance of the symptoms. Normally at the age of 6 months the first tooth erupts and at the same time the child’s maternal antibodies decrease. At this period the some children also starts crawling and they become more susceptible to all the microorganisms and infections. So most of the parents correlate teething with the infections caused due to other reasons as do the healthcare workers. The use of drugs for the symptoms of the infection can be given. But some kind of teething mixtures can also cause morbidity.

### Conclusion

This study shows that most of the dentists and doctors do believe in the signs and symptoms caused during the eruption of teeth in children. Their beliefs were not based on any medical evidence but on their personal experience. The drugs should be prescribed for the symptoms of the underlying infection and not for teething.

A Comparative Study to Determine the Wettability of Different Impression Materials

S. Chandrakala1, Ganesh Ramesh2, Sanjna Nayar3

1Post Graduate Student, Sree Balaji Dental College and Hospital, BIHER, Chennai, 2MDS Professor, Sree Balaji Dental College and Hospital, BIHER, Chennai, 3Ph.D., MDS. Professor and Head, Department of Prosthodontics, Sree Balaji Dental College and Hospital, BIHER, Chennai

Abstract

Background: Wettability of impression materials is essential to obtain a void-free cast. The purpose of this study was to evaluate the wettability of the impression materials immediately after setting and also to determine the change in wettability after 24 hours.

Materials and Method: Four impression materials were selected among which two were hydrocolloids and two were elastomers. Fifteen samples of each were experimentally tested immediately and 24 hours after sample preparation. Data obtained were subjected to t-test and analysis of variance for statistical comparisons at a 5% level of significance.

Results: The contact angle values were recorded immediately and 24 hours after setting. Lesser the contact angle value more the wettability of the impression material. The changes in wettability with respect to time were statistically analysed and it showed a statistically significant difference between the materials both immediately and after 24 hours.

Conclusion: Within the limitations of the study, Elastomers showed better wettability when compared to the hydrocolloids at both time interval and they have negligible time dependant change. Newly introduced cream alginate showed better wettability at both time intervals equivalent to the elastomers and can be considered for usage.

Keywords: Wettability, Elastomers, Gypsum.

Introduction

Dental impression materials are used to generate a negative replica of the dental hard and soft tissues. They are an essential part of many dental procedures including the creation of crowns, bridges, and dentures. Typically, the impression is used to create a model of the dental tissues, for example, in the Plaster of Paris or dental stone, thus creating a long-lasting, stable, direct 3D replica of a patient’s oral tissues.

The interaction of impression material and the gypsum slurry is important in the fabrication of a void-free die. The interaction is determined in part by the hydrophilic or hydrophobic nature of the impression material. The hydrophilicity of the impression materials is critically crucial to wet the hard and soft tissues in the mouth and to create accurate impressions and casts.

During making the impression, the material needs to flow and adhere to the tooth structure and periodontal tissues that may be wetted by blood, saliva, and water. Only when the impression material is hydrophilic, can water be displaced and can the material ideally adhere to these surfaces.

Besides being dimensionally and chemically stable in the presence of gypsum, an impression material
should possess surface properties that allow it to be easily wet by a standard mix of gypsum. Inadequate wetting of an impression results in the incorporation of air bubbles and voids in the casts. These voids are often located in critical areas of preparation, such as margins and retentive grooves, which makes the die stone cast unacceptable for further use.

Considering the impact of hydrophilicity on accurate die casting\(^3\), inadequate wetting results in gypsum casts and dies producing pits and voids\(^4\) located in critical areas such as margins, pinholes, and retentive grooves\(^5\). Hydrophilic materials have 2 major aims:

1. To enhance wetting and spreading on moist oral tissues, and
2. To ensure better wettability by water containing slurries of dental stone

Wettability, the ability of a liquid to spread over the surface of a solid. The wettability of a surface is usually determined by measuring the magnitude of the contact angle formed between a drop of liquid and the surface in question. The contact angle is the angle between the surface of wetted solid and a tangent to the curved surface of a drop at the point of contact.

The contact angle between a solid substance and a liquid depends on the nature of the solid surface and the energy of the liquid surface commonly called the surface tension (units mN/m = dynes/cm)\(^6\). Most importantly, contact angle measurements can be used to examine the surface reactivity of the surface interface between a solid and a liquid\(^7\,^8\).

**Materials and Method**

**A. Selection and Manipulation of Materials:** Four different dental impression materials that are commonly used were selected and used for the study.

- Alginate
- Cream alginate
- Polyvinyl siloxane
- Polyether

**B. Die Preparation:** A square-shaped acrylic block of dimension 3×3 cm was prepared using cold cure acrylic resin and was used as the die to determine the wettability. The die has uniform thickness and dimension with a polished surface above which a glass slab is used to press the impression materials to obtain a uniformly flat surface on all sides.

**C. Sample Size:** Four impression materials were selected among which two were hydrocolloids and two were elastomers. Alginate and cream alginate from hydrocolloids and light body vinyl polysiloxane and polyether from elastomers were used for the study. Fifteen samples of each material were experimentally tested immediately and 24 hours after sample preparation.

**D. Sample Preparation:** Each material was manipulated as per manufacturer’s instruction and evenly spread over the die and a glass slab is placed over the impression material for an even polished surface. The whole assembly was kept undisturbed for the setting time suggested by the manufacturer.

After the adequate setting time, the material was separated from the die. Thus, prepared samples were measuring 3×3cm in dimension. Similarly, all 60 void-free samples, 15 samples of each impression material were obtained. In between the time of observation, the samples were stored at normal room temperature.

**Figure 1: Impression material samples (15) to determine wettability A. Alginate; B. Cream Alginate; C. Vinyl PolySiloxane Light body; D. Polyether**

**E. Contact Angle Measurement:** Wettability of impression materials was evaluated by determining the contact angle formed between the drop of an aqueous solution of calcium sulfate dihydrate and the impression surface. Contact angle values were obtained using a horizontal profile projector. The sample was placed over the horizontal profile projector above which a drop containing 0.4ml of an aqueous solution of calcium sulfate dihydrate
was placed on the flat surface of the sample using a micropipette. The profile projector is adjusted accordingly to measure the angle formed between the droplet and the impression surface.

The measurements were recorded immediately after sample preparation and the same procedure was repeated exactly after 24hrs of sample preparation. Both the readings were statistically analyzed and the change in wettability with time was evaluated.

**Figure 2: Determining wettability of impression material using horizontal profile projector**

**Experimental Findings:**

**Wettability-Immediate:** The wettability values taken immediately after sample preparation showed that cream alginate is the most easily wettable when compared to the other impression materials studied. Contact angle value that is least shows better wettability and highest shows least wettability.

**Figure 3: Comparing wettability of impression materials immediately after sample preparation**
Wettability–After 24 Hours: The wettability values taken 24 hours after sample preparation showed that cream alginate is the most easily wettable when compared to the other impression materials studied. Contact angle value that is least shows better wettability and highest shows least wettability. Poly ether showed an increase in values which indicated that there is a decrease in wettability after 24 hours.

**Figure 4: Comparing wettability of impression materials 24 hours after sample preparation**

**Wettability Comparison:** The wettability changes evaluated showed that cream alginate and polyether showed wettability changes which increased by time at later stages, whereas alginate and polyvinyl siloxane showed changes that decreased by time.

**Figure 5: Comparing wettability changes of impression materials**

The mean value of all the four impression material taken for wettability is provided in the table given below.

**Statistical Analysis:** The readings were recorded, tabulated and subjected to analysis of variance for comparisons at a 95% probability accuracy level with 0.05 as the level of significance.
Results and Interpretation

The t-test results comparing the immediate results after sample preparation of hydrocolloids showed that there is a statistically significant difference between the materials but with the time difference of about 24 hours, there is no statistically significant difference between the materials. The t-test results comparing the results of both immediate and 24 hours after sample preparation of elastomers showed that there is a statistically significant difference between the materials.

The ANOVA results comparing the results of both immediate and 24 hours after sample preparation of all four impression materials showed that there is a statistically significant difference between the materials.

The contact angle value that is least shows better wettability and highest shows the least wettability. The wettability values taken immediately after sample preparation showed that cream alginate is the most easily wettable when compared to the other impression materials studied. The wettability values taken 24 hours after sample preparation showed that cream alginate is the most easily wettable when compared to the other impression materials studied. Polyether showed an increase in values which indicated that there is a decrease in wettability after 24 hours. The wettability changes evaluated showed that cream alginate and polyether showed wettability changes which increased by time at later stages, whereas alginate and polyvinyl siloxane showed changes that decreased by time.

Discussion

There are many rigid, thermoplastic or elastic materials available for recording impressions in dentistry. Hydrocolloids are commonly used for removable prosthesis and elastomers for fixed prosthesis. The study was planned to compare the properties of materials available in the market so that it will provide a fair idea about any improvements in relation to its wettability.

Surface tension is the contractile force within the liquid that causes the formation of drops and resists spreading over a solid surface.

Wetting of a surface is the degree of spread of a drop over the solid surface. The advancing contact angle is a measure of the wettability of a surface by a particular liquid. The greater the angle, the greater the risk of entrapment of air on the surface that may result in voids in the impression or dies. Wetting the impression surface by die stone is important because the contact angle of water placed on the impression material has been shown to be related to the number of bubbles formed in the dies poured from the material.

The contact angle is the angle formed between the surface of the wetted solid and a line tangent to the curved surface of the drop of a liquid at the point of three-phase contact. When water is the contacting liquid, solids with contact angles less than 90° are called hydrophilic and solids with contact angles more than 90° are called hydrophobic. Contact angles of liquids on impression materials have been measured by many investigators using water, gypsum and aqueous solutions of CaSO₄.

The hydrophobicity can be explained by the material’s chemical structure, which consists of hydrophobic, aliphatic hydrocarbon which does not mediate with water molecules surrounding the material. In contrast, few materials are hydrophilic in nature because of their chemical structures containing a functional group that attracts and interacts with water molecules through hydrogen bonding.

Actual contact angle values variations resulted due to a number of factors from sample preparation to measurement techniques. When die stone slurries were used to wet specimens for contact angle measurements, the size of the slurry drop (water/powder ratio) presumably affects the rheology of the slurry and causes variations in the contact angle analysis. Therefore, to eliminate the effect of these variables equal-sized droplet of 0.4ml of an aqueous solution of calcium sulfate dihydrate was used for the study.

There are three method to measure the contact angle (in vitro): Sessile drop, captive bubble, and Wilhelmy balance method. All three method give different measurements for the same material tested. The nature of the liquid drop (water/slurry of gypsum) also makes the difference because the contact angle formed at the solid-liquid interface is a result of the interfacial tension, which changes depending on the attractive forces between the molecules in the liquid and the solid. In this study, we have used the SESSILE DROP method to determine the contact angle formed with the impression surface and it is the most commonly used method to determine the contact angle.

The wettability of the impression materials evaluated during the study showed that the new material cream alginate exhibited the least contact angle values
thereby indicating better wettability compared to the other materials including elastomers. This also proved that the casts obtained from cream alginate would have more chances of being void free compared to the other materials.

Many studies indicated that immersion in disinfectant solution altered the wettability of impression materials. Direct comparison with studies in the literature was not possible because of the variations in the technique of measuring contact angle, type of material tested and concentration of the disinfectant used\textsuperscript{12}

It has been proposed that the disinfectant treatments are found to alter the surface chemistry of an impression material that may change the hydrophilicity of the impression material. The disinfection of dental impression particularly the hydrophilic ones such as polyether is a concern. However, iodophor holds promise as an effective disinfectant for Impregum soft without affecting its wettability property\textsuperscript{13}.

**Limitations of the Study:** The results of this in-vitro investigation should be viewed cautiously because laboratory testing cannot exactly replicate clinical situations. Wetting of impression material depended on surface energy of the impressed surface. Proteinaceous surfaces of prepared teeth and oral soft tissues had lesser surface energy than the surface free energy of the die.

**Clinical Significance:** To obtain an impression with accurate details of the teeth and oral structures, the property of the impression material to be used is important. The contact angle is one of the factors, which plays a significant role in determining the nature of the impression material and to obtain an accurate cast. Void free cast is essential for a perfectly fitting prosthesis.

**Conclusion**

**Within the limitations of the study:** Wettability of hydrocolloids and elastomers were analyzed by placing a 0.4ml drop of an aqueous solution of calcium sulfate dihydrate over the prepared sample and placed under the horizontal profile projector. Contact angle values were determined and statistically analyzed. The Contact angle value that is least shows better wettability and highest shows least wettability.

Elastomers showed better wettability when compared to the hydrocolloids at both time interval and they have negligible time dependant change. Newly introduced cream alginate showed better wettability at both time intervals equivalent to the elastomers and can be considered for usage.

**Ethical Clearance:** Not required since it is a review article.

Comparative Evaluation of Four Factors in Gingival Retraction Using Three Different Gingival Retraction Techniques: In Vivo Study

R. Gururaj1, S.R. Jayesh2, Sanjana Nayar3

1Senior Lecturer, 2Professor, 3Professor and Head, Sree Balaji Dental College and Hospital, BIHER, Chennai

Abstract:

Aim: To evaluate and compare four factors in gingival retraction using three different gingival retraction method (Retraction Cord, Magic foam retraction Cord and Laser gingival troughing). Vertical and horizontal gingival displacement, hemorrhage control and time taken for performing each method were evaluated.

Materials and Method: 30 patients requiring fixed partial denture with two abutments were selected for the study. Following tooth preparation, three gingival retraction systems were used on the prepared abutments randomly, such that each combination was repeated ten times with overall n value being 60. Williams probe was used to measure sulcus depth before and after retraction. The horizontal sulcular width was measured indirectly by making impressions and measuring them under stereomicroscope. Hemorrhage scores were recorded immediately after removal of the retraction system. The time taken for each method was recorded in seconds. All results were recorded, tabulated statistically, analysed and interpreted.

Conclusion: From the results of the present study, following conclusions were drawn; 1) The depth and width or lateral displacement were more with retraction cord than with the other two method. 2) Hemorrhage control was best with magic foam, followed by laser with cord retraction having more haemorrhage. 3) Least time taken for gingival retraction was with Laser method, followed by magic foam, while retraction cord method consumed maximum time.

Keywords: Gingival retraction, retraction cord, magic foam, LASER.

Introduction

Tooth-supported fixed dental prostheses are routinely used in prosthetic dentistry to replace missing or decayed teeth for aesthetic as well as functional purposes.

Several factors affect the success and durability of restorations. Marginal integrity is one of the important factors, which contribute to the success of cast restorations. The restoration can survive in the biological environment of the oral cavity, only if the margins are closely adapted to the finish line of the preparation. In general, the type of impression making, setting characteristics, material flow, temperature, humidity, mixing, disinfection and pouring time have effects on the final accuracy of the indirect restorations. Supra-gingival margins are contributory in periodontal health maintenance, but do not provide ideal aesthetics.

So in most cases in aesthetic zone, margin of restoration is placed sub-gingivally. In tooth supported and implant supported fixed prosthesis, impression making requires accurate record of the prepared finish line area, especially in cases where the prepared finish line is located at same level as gingiva or sub-gingivally.

The gingival finish line should be clean and accessible during impression making, allowing adequate flow of the impression material over it. Gingival sulcus must also be wide enough. Accurate impression is usually achieved with the sulcular width of 0.15 to 0.20 mm.1 If the sulcus width is less than this value, the resultant thickness of the impression in this area will be too less so, impression material will not be able to resist against the rupture and deformation, thereupon the impression’s marginal accuracy is reduced. The primary factor in defective recording of marginal details is compromised gingival displacement technique.
A survey of literature revealed that there are divergent opinions regarding different techniques for gingival displacement. So, the present study is proposed to evaluate four factors of three gingival retraction techniques namely retraction cord, magic foam and LASER.

**Materials and Method**

**Inclusion Criteria**

1. Age limit 18-55 yrs
2. Patients willing for fixed partial denture
3. Patients having optimal gingival health
4. Patients with sound systemic health

**Exclusion Criteria:**

1. Patients with gingivitis
2. Patients with periodontitis
3. Patients with any systemic disease

Partially edentulous patients seeking fixed partial denture treatment visiting our department were screened, examined and evaluated.

Out of them those with minimum two abutments (posterior abutment and anterior abutment) which were periodontally sound and near ideally placed in the arch were selected for the study. Patients with missing first molar and second premolar were selected for the study.

A thorough scaling and polishing was done to enhance the gingival condition in indicated cases.

**Tooth preparation was made on chosen abutments:** Following tooth preparation, three gingival retraction systems were used on the prepared abutments randomly, such that each combination was repeated ten times with overall n value = 60. For example, in the first subject, retraction cord and magic foam cord were used for two prepared abutments, in the second subject magic foam and Laser were used and in the third subject laser and retraction cord was used for gingival retraction. The same order was followed for all the thirty subjects, so that all the three retraction systems were compared with each other in group of two for ten times.

The time taken for placement of each retraction system was recorded in seconds.

Smooth rounded measuring tip was used to measure sulcus depth before and after retraction. The horizontal sulcular width was measured indirectly using elastomeric impression material made before the retraction procedure and after the retraction procedure and then was examined under stereomicroscope.

Hemorrhage scores were recorded immediately after removal of the retraction system. The hemorrhage scores were as follows: Shoulder finish lines were prepared at the gingival crest level. Pre displacement impression was made with addition silicone material using two stage double mix technique to measure the initial sulcus width. The impressions were examined under magnification, void free and streak free impressions alone were included in the study. Upon removal, the impressions were rinsed under running tap water and disinfected by immersing in 5.25% sodium hypochlorite solution for 10 minutes.

The retraction cord of adequate size/width and length was cut and looped around the prepared tooth. Cord packing was started from the mesial interproximal area by gently pushing the cord into the sulcus. After 5 min the cord was removed.

The magic foam cord cartridge was attached to the auto mixing gun and then the mixing syringe with intraoral tip was placed into the gingival sulcus and gingival retraction material was applied all around the tooth. After injecting the retraction material the corresponding comprecap was placed on to the abutment to push the material deep into the gingival sulcus. After 5 min, the comprecap with the set retraction material attached to it was removed from the patient’s mouth.

Zolar Diodelaser (810nm) with the initiated fiber tip having a diameter of 400 microns was programmed for...
gingival retraction at 0.8 watt power with a frequency of 25 kHz in continuous mode. The retraction area was cleansed with 3% hydrogen peroxide and rinsed with light spray of water and dried with air, then the initiated fiber tip was placed into the sulcus just inside the crest of gingiva with very light pressure and moved around the tooth in small paint brush stroke.

All the results were recorded, tabulated, statistically analysed and interpreted.

**Results**

The mean values of time taken in performing the procedure using Retraction cord, Magic foam and LASER were 252.15 secs, 85.75 secs and 56.20 secs respectively. The mean values of width of the gingival sulcus obtained using retraction cord, magic foam and LASER were 0.33mm, 0.19mm and 0.31mm respectively. The mean values of depth of gingival sulcus obtained using retraction cord, magic foam and LASER were 1.43mm, 0.815mm and 1.245mm respectively. There was statistically significant association (chi square test) between depth, width, time and hemorrhage with the method employed in the study. There was a negative correlation between the hemorrhage score and the method of retraction. There was positive correlation between depth and time with respect to method of retraction. (Spearman rank Ratio.) There was a statistically significant association between the method and all variables including duration, hemorrhage, width and depth based on Kruskal-Wallis test.

Time taken for application of LASER and Magic foam retraction system was significantly (P<0.05) less compared to time taken with retraction cord. The amount of vertical gingival retraction obtained by using retraction cord and Laser retraction systems was significantly (P<0.05) higher than magic foam cord retraction system. The hemorrhage control with the magic foam system was found to be better than hemorrhage control with the other two retraction systems used in the study.

Laser and magic foam cord retraction systems were found easier in placement compared to retraction cord. Laser gingival troughing can be considered more effective among the three retraction systems used in this study, as it has taken less time and was easier in placement, obtained good amount of retraction and induced minimal bleeding on removal compared to retraction cord.

Discussion

Clinical success of fixed prosthodontic restorations depends, to a large extent, on the accuracy of final impression. A good quality impression is influenced by appropriate location of the finish lines, abutment’s periodontal health and a dry field, in addition to the inherent accuracy of the final impression material. Modern impression materials used in Prosthodontics
possess high accuracy of recording tissue details. Nevertheless, treatment protocol necessitates displacement of gingival tissues to expose and record the gingival finish lines on the prepared tooth surface. Thus, gingiva must be displaced temporarily to make an acceptable impression.²

The aim of gingival retraction is to allow access atraumatically for the impression material beyond the finish line margin and to create space for adequate thickness of impression material in gingival sulcus region so that it can better withstand the tearing forces encountered during removal of impressions.³

The present study has been designed to evaluate three different systems of gingival retraction i.e. 1) retraction cord soaked - a conventional technique 2) Magic foam cord and 3) Laser gingival troughing.

Results revealed that the depth and width or lateral displacement were more with retraction cord than with the other two method. Hemorrhage control was best with magic foam, followed by laser with cord retraction having more haemorrhage. Least time taken for gingival retraction was with Laser method, followed by magic foam, while retraction cord method consumed maximum time. The results were statistically significant.

The maximum depth and width achieved with retraction cord in the present study is similar to the studies of Ankit gupta⁴ et al(2013) and Phatale⁵ et al. Similarly, results of haemorrhage control are also in conformity with the results of Ankit gupta⁴ et al in 2013 and Phatale⁵, et al. Time taken for the procedure of the gingival retraction was least with Laser. This is in conformity with the results of study of Manjeet Dawani⁶ et al (2016). Abdel Gabbar⁷ and Aboulazm compared mechanochemical method with laser tissue displacement. They found that the laser resulted in less hemorrhage and less inflammation with a faster and painless gingival healing. The present study is also in agreement with the study conducted by Vamsi Krishna CH⁸, Gupta N, Reddy KM in which diode laser was used for lateral displacement of gingiva on 20 abutment teeth at three specific sites where they found gingival retraction which ranged from 230µm – 670µm, closer to the thickness of sulcular epithelium and which was greater than the limit of minimum retraction of 200µm. The procedures were carried out within less time and a considerable improvement in patient comfort was reported⁹,¹⁰.

The present study reveals that all three retraction systems are reasonably acceptable as per the results, as all three provide retraction more than the minimum amount of retraction (0.22 mm) required for any fixed partial denture impressions¹¹,¹²,¹³.

Clinical implications of the study: The results of the present study suggest that for adequate lateral and vertical displacement. The retraction by cord method can be used. For best hemorrhage control Magic foam cord can be used. When clinician has less time for chair side work, using laser for gingival retraction will be beneficial. These corollaries can be extrapolated from the results of the present study.

Limitations of the study: Though all possible care was taken to standardize all aspects of the study, every patient’s physiology may have differed and hence the response of the gingiva to the retraction material could have varied from patient to patient. Different gingival biotypes (thick and thin) and different age groups might have contributed to variations¹⁴.

Scope for further studies: A larger sample size with more n value in different areas of maxillary and mandibular dental arches can be undertaken and more data could be utilised for evaluation. Also there is a need for histological analysis of the effect of gingival retraction materials on the soft tissue.

Conclusion;

Marginal integrity of the fixed dental prosthesis requires accurate impression of the prepared finish line. If the prepared finish line is adjacent to the gingival sulcus, gingival retraction techniques should be used to decrease the marginal discrepancy between the restoration and the prepared abutment. Accurate marginal fit of the restoration in the prepared finish line of the abutment is required for therapeutic, preventive and aesthetic purposes. Impression materials by themselves do not contribute to gingival retraction. If the finish line of a tooth preparation is located sub-gingivally or epi-gingivally, a temporary gingival deflection is needed before impression is made. This is a critical step in order to obtain a precise duplication of the prepared tooth for the technician to fabricate the prosthesis.

Hence forth, from the results of the present study, following conclusions were drawn;1) The depth and width or lateral displacement were more with retraction cord than with the other two method. 2) Hemorrhage
control was best with magic foam, followed by laser with cord retraction having more haemorrhage. 3) Least time taken for gingival retraction was with Laser method, followed by magic foam, while retraction cord method consumed maximum time. LASER gingival retraction could be considered more effective among the three retraction systems used in this study, as it has taken less time and was easier in performing, attained good amount of retraction and induced minimal bleeding compared to stay-put retraction cord.

Disinfection Techniques for Dental Impressions: A Review Article

Sanjna Nayar¹, Sanket Jadhav²

¹Professor & Head of Department, ²First Year, Post-Graduate, Department of Prosthodontics, Sree Balaji Dental College & Hospital, BIHER, Chennai

Abstract

Statement of Problem: Dental impressions are infected with various types of micro-organisms e.g. Hepatitis B, C, HIV, Mycobacterium, Herpes simplex, Ebola etc. In order to prevent their spread through dental impression it is important to sterilize the impression just after removal from patient’s mouth. Numerous method to disinfect impressions have been described in literature having their own advantages, disadvantages and effects on impression material. To enhance the knowledge of a dental health care workers about impression disinfection, a structured literature review of the current disinfection techniques has been carried out.

Material and Method: One electronic database (PubMed) was searched through in November 2019. The term “dental impression disinfection” was chosen. The titles and abstracts were screened and the studies which performed “disinfection techniques in dentistry” were selected.

Conclusions: Cross infection control is very important aspect of clinician and patient safety. It is the responsibility of the dentist to make appropriate choice of disinfection method for different impression materials.

Keywords: Disinfectants, disinfection techniques, dental impressions, sterilization, cross-infection.

Introduction

The importance of cross-infection control cannot be overemphasized. Disinfection and sterilization method are used to achieve disinfection and sterility of the medical and surgical instruments. In order to avoid the spread of pathogens from patients to patient, patient to health care personnel and health care personnel to patient, it is the duty of the health care policies makers to allocate the appropriate method of cleaning, disinfection and sterilization for various surfaces and instruments.¹ Cleaning is the removal of all foreign material (e.g. blood, saliva, debris) from objects while decontamination is the removal of pathogenic micro-organisms from objects. Disinfection is the process that eliminates many to all pathogenic microorganisms on inanimate objects except bacterial endospores. While sterilization is the complete elimination of all micro-organisms including spores.

Disinfection can be divided into three categories according to their efficacy. High level disinfection involves bacterial spore inactivity along with other microbial forms. Intermediate level disinfection involves destruction of microorganisms like tubercle bacilli but not able to kill spore. Low level disinfection possesses narrow antimicrobial activity.

(Dental impressions are categorized under semi-critical objects in dental practice and require high level disinfection or sterilization. Twenty years before sterilization in an autoclave will compromise the dimensional accuracy of the impression hence it is not feasible. Until 1991, the recommended procedure for disinfection of impression was rinsing under running water with which only 40% of...
bacteria, viruses and fungi were removed and potential for transmission of microorganisms remains there.\textsuperscript{3,8,9} In recent times, a pre wash of the impression with running water is advocated first to cast off all particles, blood and saliva prior to active disinfection procedure.\textsuperscript{10}

Disinfecting dental impressions should be routinely followed in the dental office and dental laboratory. However, many of the dental professionals in private clinics, hospitals, dental schools and prosthetic laboratories are not following the required protocols for impression disinfection.\textsuperscript{11,12}

Hence, it is of utmost importance to create awareness in dental professionals who are involved in any process of handling, transportation, processing and storage of the dental impressions. The objective of this literature review is to provide knowledge about various techniques of impression disinfection along with their mechanism of action and necessary guidelines for their usage.

**Disinfectant Solutions:**

**Sodium hypochlorite:** It provides intermediate level disinfection and has a broad-spectrum antimicrobial activity. It is very useful disinfectant with advantages including fast bactericidal activity, ease of use as it is soluble in water, relatively stable, nontoxic at use concentrations, low cost, non-staining, nonflammable and colorless. Disadvantages include irritation of mucous membrane, less efficient in organic environment and metal corrosive.\textsuperscript{13} According to one study, alginate impression disinfected with spray method using 1% NaOCl did not show any severe dimensional changes or surface roughness of stone model that were fabricated from that impression.\textsuperscript{18} However, in another study impression disinfection by immersion method with 0.5% NaOCl for 15 min exhibited small dimensional change.\textsuperscript{19}

**Glutaraldehyde:** A high-level disinfectant and is available in alkaline, neutral and acidic forms.\textsuperscript{5} It is a broad-spectrum chemical agent with fast killing capability. It is also called chemo sterilizer. If it is used in proper concentration and specialized equipment, it can destroy all types of micro-organisms including bacterial and fungal spores, tubercle bacilli and viruses.\textsuperscript{16} It is a colorless liquid with pungent odor. Although it is considered as the best disinfectant for cold sterilization of medical equipment, it also has many health hazards including irritation to skin, eyes and respiratory tract. It is a sensitizer of skin and respiratory tract, so special precautions are needed while using it e.g. wearing butyl or nitrile gloves, closed system for solution handling, exhaust ventilation of the places of handling and keeping the temperature of the solution low as it will reduce the airborne concentration of the solution.\textsuperscript{17}

**Iodophors:** These halogens provide low to intermediate level disinfection. These are bactericidal, mycobactericidal and virucidal. It is also fungicidal but requires more contact time. These are mainly used as antiseptics rather than disinfectants. These are not sporicidal and cause staining of fabrics. They are not flammable. They have irritating effect on mucous membrane.\textsuperscript{20,21}

Disinfectant capability of iodine is neutralized due to presence of organic material on any surface.

Hence, more frequent application of disinfectant is required for complete disinfection.\textsuperscript{3} According to one study, 30 min exposure to 0.1% povidone-iodine did not cause remarkable distortion of polysulfide and polysiloxane impression material.\textsuperscript{5}

**Alcohols:** These provide intermediate level disinfection and include isopropyl alcohol and ethyl alcohol. Isopropyl alcohol is normally used as antiseptic. Medical surfaces can also be disinfected with isopropyl alcohol. Ethyl alcohol is more potent in bactericidal than bacteriostatic activity. It is also tuberculocidal, fungicidal and virucidal for enveloped viruses as well.\textsuperscript{14,20,22,23} Alcohols are contraindicated for impression disinfection because they can cause surface changes of impressions.\textsuperscript{3} They are also not suitable for disinfection of denture bases consisting of non-cross-linked resins.\textsuperscript{24}

**Phenols:** Complex phenols are classified as intermediate level disinfectants. These are also known as protoplasmic poisons. At low concentration, they cause lysis of rapidly growing e.coli, staphylococci and streptococci. They possess antifungal and antiviral properties as well.\textsuperscript{23} These are commonly used in mouthwashes, scrub soaps and surface disinfectants. Ideally not recommended for impression disinfection as simple phenols are low level disinfectants. They are incompatible with latex, acrylic, rubber and cause acute toxicity as well.\textsuperscript{3,4}

**Chlorhexidine:** It is an intermediate level disinfectant and antiseptic. It has broad spectrum of activity and also used as preservative. It is commonly used in hand washes and oral products. It is bactericidal,
virucidal and mycobacteriostatic. Its activity depends on specific pH, hence presence of organic matter declines its action.\(^{23}\)

2% chlorhexidine has shown activity against S. aureus, E. coli, B. subtilis, but no antifungal activity was seen in agar diffusion test at low concentration. 0.2% chlorhexidine disinfectant solution can be used as water substitute in alginate mixing. Impression can also be immersed in chlorhexidine solution and it causes effective disinfection.\(^{25}\) According to one study, 1.0 g/L chlorhexidine solution can be used to produce self-disinfecting alginate impression material for clinical use. In this way, it has shown antimicrobial activity and did not cause any changes in dimensional accuracy, flow ability and setting time of irreversible hydrocolloid impression material.\(^{26,27}\)

**Ozonated water:** Ozone is an inorganic gaseous molecule. Its chemical formula is O\(_3\). It is less stable than O\(_2\) in lower atmosphere.\(^{3}\) It has antimicrobial, anti-hypoxic, analgesic and immunostimulatory activities.\(^{28}\) It is used for disinfection of water lines, oral cavity and dentures. It is also used as prophylactic agent before etching for the placement of restorations.\(^{29}\) Ozonated water can also be used as impression disinfectant. According to one study, aqueous ozone is more biocompatible than other disinfectant solutions e.g. chlorhexidine, NaOCl, H\(_2\)O\(_2\). Ozonated water can reduce the number of microorganisms on the surface of irreversible hydrocolloid impression materials and by increasing time of immersion more effective disinfection can be achieved.\(^{28}\)

**Other Techniques:**

**Microwave irradiation:** Microwaves cause disruption of cell membrane integrity and cell metabolism which ultimately leads to microbial death.\(^{3}\) Microwaves are simple to use, low in cost and provide good disinfection. Dentures are being disinfected with microwaves and are found better disinfected than NaOCl. Impression disinfection can be done by microwave irradiation. With no changes in physical properties of impression material, Polyvinyl siloxane impression material can be disinfected with microwaves.\(^{30}\)

**Cast disinfection:** Microorganisms are found on dental cast as well. These dental casts can be a medium of cross infection between patients and dental health care workers. Therefore, it’s necessary to disinfect dental casts.\(^{7}\) The American Dental Association recommends various method for cast disinfection. These include use of disinfectant spray, immersion in disinfectant solution, and incorporation of disinfectant in stone at the time of mixing.\(^{31}\) Immersion in 0.525% NaOCl did not cause any changes in dimensional accuracy, surface detail quality and compressive strength.\(^{32}\) Microwave irradiation can also be used for cast disinfection. Dental cast can also be sterilized.\(^{3}\)

**Sterilization of impression:** Various method are available for sterilization of impressions e.g. exposure to UV light, steam autoclave, ethylene oxide gas autoclave, and radiofrequency flow discharge etc.\(^{3}\)

**Discussion**

In dental practice, cross-infection control is of utmost importance but impression disinfection is still widely neglected.

**The proper criteria for impression disinfection involve:**

- The most suitable method (spray or immersion).
- Appropriate application (time of contact).
- Periodic check for efficacy.\(^{33}\)

The factors to be considered for any disinfection protocol for dental impression are effectiveness, chemical stability and efficacy of the disinfectant solution. The disinfection procedure should not alter the dimensions and surface details of the impression and resultant cast.\(^{32,34}\) It has been proven that the most effective method of reducing the burden of micro-organisms from impression surface is chemical disinfection. Spray disinfection and immersion disinfection are the two method of impression disinfection. However, immersion is the most reliable method because all surfaces of impression and tray come in contact with disinfectant solution. But immersion is not the method of choice for hydrocolloids material as they are extremely hydrophilic.\(^{3,34}\)

UV rays can be used for disinfection of water supplies, laboratory equipment, dental headpieces, dental impression and implants. In one study, while comparing UV ray’s disinfection with Glutaraldehyde and NaOCl, UV rays exhibited maximum efficacy.\(^{36}\)

The factors affecting the efficacy of NaOCl include concentration and life of solution, pH, temperature and contact time with the impression surface. According to
Fahimeh et al, the compatibility of disinfectant solution with impression material should be assessed prior to disinfection procedure. Any compatible disinfectant solution should not cause any alteration on the surface detail reproduction.37

Although some chemical disinfectants cause dimensional changes in impression surface, these changes are not expected to alter the clinical performance. This is why, chemical disinfection is considered the most harmless form of impression disinfection. 2% glutaraldehyde had exhibited more dimensional changes than 5.25% NaOCl in immersion disinfection procedure.38

The American Dental Association’s revised guidelines recommend chemical agents that are virucidal, bactericidal and sporicidal. These chemical agents are chlorine compounds, phenols, iodophors, formaldehyde and glutaraldehyde. Immersion in NaOCl at concentration of 1:10 (0.525%) is advised for 10 minutes. Samra and Neiman investigated the effects of glutaraldehyde, phenol, iodophors and chlorine compound immersion disinfection procedure on set stone cast. The results of this study showed that a 0.525% NaOCl least affected the cast with regard to compressive strength, surface changes, surface hardness and chemical reactivity.32

The Japan Prosthodontic Society has recommended the alginate impression in either 0.1-1% NaOCl solution for 15-30 min or 2-3.5% glutaraldehyde solution for 30-60 minutes. But immersion in glutaraldehyde for more than 30 min has shown dimensional changes and altered surface quality of the resultant cast.19

Ethylene oxide gas autoclaving has shown significant structural changes of heavy and light body addition silicone impression material. Sterilization of dental stone cast has shown improved mechanical properties but decreased compressive strength. Addition or condensation silicone impression materials can be sterilized in steam autoclave without remarkable changes in dimensional accuracy.3

**Conclusion**

Cross infection control is very important aspect of clinician and patient safety.

It is the responsibility of the dentist to make appropriate choice of disinfection method for different impression materials.40

Impression disinfection can prevent spread of infection from dental clinic to dental laboratory technicians, patients and dental auxiliaries.

Impression Materials: A Comparative Review of Impression Materials Most Commonly Used in Prosthodontics

Sanjna Nayar¹, S. Chandrakala²

¹Professor and Head, ²Professor, Department of Prosthodontics, Sree Balaji Dental College and Hospital, BIHER

Abstract

Impression materials are used to record intraoral structures for the fabrication of definitive restorations. Accurate impressions are necessary for construction of any dental prosthesis. The relationship between static and mobile oral structures must be reproduced accurately for an optimum cast. Making a cast in gypsum materials from an impression of dental anatomy aids dentists in designing and constructing removable and fixed prostheses. The accuracy of these final restorations depends greatly on the impression materials and techniques. Accurate impressions depend on identifying the applications that do or do not fit each material’s characteristics. Materials used without adequate knowledge of their characteristics can impair a successful outcome. Often, the choice of impression materials depends on the subjective choice of the operator based on personal preferences and past experience with particular materials.

Keywords: Impression materials, Gypsum, Hydrocolloids.

Introduction

Ideal Characteristics of Impression Materials:
An ideal impression material should exhibit certain characteristics in the clinical and laboratory environment. Clinically, it should produce an accurate impression secondary to its adaptability to oral structures, have a consistency that is dimensionally stable to resist tearing but results in an atraumatic removal, set within a reasonable amount of time, demonstrate biocompatibility to include a hypoallergenic nature, and have a reasonable cost per use. In a laboratory setting, it should be dimensionally stable for accurate pouring of multiple casts and should not affect dimensional accuracy upon disinfection [¹–⁴]

Common Impression Materials Used in Restorative Dentistry: Impression materials that are currently popular include hydrocolloids, addition silicones, polyethers, and polysulfides. Some of the older impression materials (eg, zinc oxide eugenol impression paste, impression plaster, and impression compound) are still used in certain applications but are limited in use because they cannot be removed past undercuts without distorting or fracturing the impression [³].

Depending on the manufacturer, many of the materials are available in cartridges for automixing and tubes or containers for hand spatulation. The automixing products require no mixing pads or spatulation, and training in their use is less time consuming. There may be less waste of material associated with automixing and providing a more bubble-free mix resulting in more accurate casts. Accessories such as intraoral tips, mixing tips, and various types of tray systems are also important when weighing the advantages and disadvantages of the delivery systems of impression materials.

Criteria used in evaluating impression materials:

Properties and handling characteristics: The hydrophilic versus hydrophobic nature of materials is discussed as it relates to flow characteristics, which result in more bubble-free impressions. In recent years, dentists have turned toward using polyvinyl siloxanes and polyethers because of their improved physical and
mechanical properties\textsuperscript{[1,5–7]}. These properties include improved dimensional accuracy, stability, wettability, excellent elastic recovery, flexibility, ease of handling, tear strength, ability to produce multiple casts from one impression, and superior ability to reproduce detail.

**Dimensional Accuracy:** Elastomeric impression materials such as polyvinyl siloxane, polyether, and polysulfide, the dimensional accuracy is usually time dependent, with greater dimensional accuracy occurring immediately after polymerization is complete but declining as the impression is stored for extended periods of time \textsuperscript{[5,7–9]}. Polyvinyl siloxane and polyether impression materials remain dimensionally accurate for 1 to 2 weeks \textsuperscript{[5,7,8]}. Poly- sulfide impression material is dimensionally accurate if poured within 1 to 2 hours of making the impression \textsuperscript{[5,7]}. Practitioners should take this characteristic into consideration when selecting impression materials given the time available to the practitioner to pour casts during office hours.

Presence of moisture results in impressions with voids or pitted surfaces, and the detail reproduced is inferior. This result has been reported even with the new “hydrophilic” polyvinyl siloxane impression materials. These hydrophilic polyvinyl siloxanes have improved wettability \textsuperscript{[1,4,19,20]}, and they are only clinically acceptable under dry conditions \textsuperscript{[17]}. The hydrophilization of polyvinyl siloxanes is enhanced with the incorporation of nonionic surfactants. They have a hydrophilic part and a silicone-compatible hydrophobic part. These surfactants act through a diffusion transfer of surfactant molecules from the polyvinyl siloxane into the aqueous phase. The surface tension of the liquid is changed, and increased wettability results \textsuperscript{[2]}. When using polyvinyl siloxanes, moisture control is critical to ensure success for predictable clinical impression making. Because of their hydrophilic nature, using polyether and polysulfide impression materials is more compatible with the inherent moisture present in mucosal tissues \textsuperscript{[1–3,9]}.

**Dimensional Stability:** The dimensional stability of an impression material reflects its ability to maintain the accuracy of the impression over time \textsuperscript{[2]}. These materials should have low shrinkage upon polymerizing and remain stable, which allows them to be poured days after making the impression. High impression dimensional stability materials usually can be poured within 1 to 2 weeks after the impression is made and still produce an accurate cast \textsuperscript{[2,3,5,8]}. Materials with high dimensional stability are the polyethers and polyvinyl siloxanes, in contrast to alginate, which has a low dimensional stability. The polysulfides distort over time \textsuperscript{[14]}. Because many dentists send their impressions to a laboratory to be poured, this characteristic should be considered when choosing an impression material \textsuperscript{[2,8]}.

Rigid impression materials require less support from trays. They distort less on pouring and make good bite registration materials \textsuperscript{[2,8]}. They work well for implant impressions, in which posts must be transferred accurately \textsuperscript{[8]}. They would be detrimental in making full arch impressions of periodontally compromised or mobile teeth. Polyethers and some polyvinyl siloxanes fall into this category.

**Wettability (or flow characteristics):** Wettability of an impression material relates to the ability of the material to flow into small areas \textsuperscript{[2]}. Impressions that wet the teeth well displace moisture and result in fewer voids. Materials with a high wetting angle do not flow easily into small crevices and are poor candidates for use in fixed prosthodontics. Materials with a low wetting angle flow extensively. Water is the ideal example of a material with a low wetting angle. Wettability results in fewer voids and less entrapment of oral fluids, providing more accurate impressions \textsuperscript{[2,4]}.

**Elastic Recovery:** A set impression must be sufficiently elastic so that it will return to its original dimensions without significant distortion upon removal from the mouth \textsuperscript{[2]}. Polyvinyl siloxane has the best elastic recovery, followed by polyether and polysulfide \textsuperscript{[2,8]}.

**Flexibility:** Flexible impressions are easier to remove from the mouth when set. Polyethers tend to be the most rigid impression materials \textsuperscript{[2]}. Polyvinyl siloxanes are fairly stiff, and depending on the viscosity of the material, they flow readily to capture areas of detail \textsuperscript{[8]}. Clinical studies have shown that the viscosity of the impression material is the most important factor in producing impressions and dies with minimal bubbles and maximum detail \textsuperscript{[2]}. Accuracy of the impression is also affected when the percentage of deformation and the time involved in removing the impression are increased. In these instances, permanent deformation occurs relative to the type of elastomeric impression material used \textsuperscript{[2,8,14]}. Alginate would be considered the most flexible of the impression materials, whereas polyethers would be considered the least flexible.

**Ease of Handling:** Working times can be varied
with respect to standard-set versus quick-set impression materials as prepared by various manufacturers [8]. Various viscosities and flow characteristics are also made available per individual manufacturer formulations.

**Tear Strength:** The tear strength of an impression material relates to how resistant a particular material is to tearing after setting [11,12]. Polyethers are considered to have the highest tear strengths, whereas hydrocolloids have relatively low tear strengths [2,3]. Polysulfide impression materials have a high resistance to tearing but stretch and do not recover completely elastically [2,14].

**Contact angle (and ability to reproduce detail):** Impression materials with low contact angle enable dental stone to flow easily, and relatively bubble-free casts are produced. Materials with high contact angle require more careful pour technique and attention to produce accurate casts [2]. Polyvinyl siloxane materials may require surfactants to lower the contact angle before pouring casts. Hydrocolloids, polyethers, and polysulfides have relatively low contact angles.

**Miscellaneous:** In addition to these criteria, the following criteria should be considered: how well a material is tolerated by patients, obtaining the best results for the least amount of expense, and occurrence of minimal changes when in contact with disinfection chemicals. Materials such as hydrocolloids, polyethers, and methacrylates may require specific disinfection protocols to prevent distortion of the material after setting [2,11–13].

**Summary:** Dentists have relied on impression materials for various uses, including fabricating dental prostheses, serving as temporary liners, and serving as bite registration materials. The materials that have received a lot of attention because of their physical and handling properties include the irreversible hydrocolloids, polyethers, and polysulfides.

The polyvinyls (addition silicones) and the polyethers account for a major portion of the market used as impression materials in fabricating fixed partial dentures, removable appliances, and implant prostheses. The hydrophilic addition silicones and polyethers flow easily, result in fewer retakes, and produce more bubble-free casts when used under appropriate guidelines. The polyvinyl siloxane materials are intrinsically hydrophobic (water repellent) by nature, so they must be made hydrophilic by adding surfactants. When these surfactants come into contact with moisture, it has to migrate to the surface, which prevents the hydrophilicity from fully developing during working and setting times and can result in voids and inaccurate impressions. A dry field is critical for their use. Polyether is hydrophilic by nature of its chemical makeup, and moisture does not interfere as much with achieving void-free impressions.

The condensation silicones, polysulfides, and irreversible hydrocolloids have qualities that make them more sensitive with respect to handling considerations and mix-and-pour techniques because they exhibit more changes over time after setting, which may affect accuracy in detail reproduction. The polyvinyls and polyethers are more stable to deformation after setting has occurred. All have specific protocols for disinfecting that must be followed to prevent distortion of the material before pouring casts; however, the polyvinyls seem to be most impervious to different disinfection protocols.

Management of Xerostomia and its Impact on Dental Caries: A Review

Lakshmi S. 1, Sanjna Nayar 2

1 Post Graduate Student, 2 Professor and Head, Department of Prosthodontics, Sree Balaji Dental College and Hospital, BIHER, Chennai

Abstract

Many elder groups have been studied to determine their frequency of dry mouth complaints and their salivary flow rates. To appreciate these it is first necessary to understand two related concepts. First, complaints of dry mouth (or xerostomia) may not reflect reduced salivary function may instead reflect dehydration or other systemic conditions. Therefore studies that only examine the complaints of dry mouth will not reflect the true risk for oral diseases in the population. Second, it is very difficult to determine values for normal salivary function. Other studies suggest that salivary flow rates in elders are related to the number of medications they take on a regular basis, time number of systemic disorders they report, and the length of time for which they consume the drugs.

Keywords: Dry mouth, radiation therapy, saliva, xerostomia.

Introduction

Xerostomia (dry mouth, oral dryness, and mouth dryness) is considered a complex condition that affects several stomatological functions and can be caused by hyposalivation with consequences such as oral lesions, alterations of taste, feeling of thick saliva, chewing problems, dental caries, dental demineralization, periodontal disease, salivary gland infection, cervical caries, fungal infections, and others. Etiology seems to be multifactorial where both local and systemic factors would participate. Although xerostomia may occur frequently in the general population, proper diagnosis and treatment planning has to be done.

Based on the etiology, the xerostomia can be classified as true xerostomia (xerostomia vera, primaria), caused by the malfunction of the salivary glands and pseudo xerostomia or symptomatic xerostomia (xerostomia spuria, symptomatica), which is described as the subjective sensation of oral dryness, despite normal secretory function of the salivary glands. The xerostomia, as a symptom, is more common in older populations, but its causes are not related to aging. It has been shown it is related to some specific diseases, drugs, or therapies associated. The dry mouth (xerostomia) sensation has a higher incidence on individuals over 60 years old up to three times higher than on younger adults.

The most severe conditions with effect on the salivary flow are SS and radiotherapy in the head and neck area, with the prevalence of xerostomia in almost 100% in these cases. These conditions are characterized by a progressive loss of secretory cells, and thus a progressive decline in saliva production. Less severe conditions may be dehydration, smoking, and inflammation or infection of the salivary glands. In older people, the most common cause of xerostomia is the use of medications because the vast majority of the elderly are being treated with at least one drug that causes salivary hypofunction.

Drugs most commonly associated with xerostomia are: - antidepressants (particularly tricyclic antidepressants); - Selective Serotonin Reuptake Inhibitors (SSRIs), particularly when combined with...
benzodiazepines; - Diuretics, antihypertensive drugs and angiotensinconverting enzyme inhibitors (ACE inhibitors), - oral hypoglycemiant, - acetylsalicylic acid (ASA), -iron supplements. Let us not forget that drugs with the most intense xerostomizing effect are also the most widely and frequently used (treatment of metal disorders and cardiovascular diseases).

Many medicines can cause dry mouth, including drugs used to treat obesity, epilepsy, hypertension (diuretics), diarrhea, urinary incontinence, asthma, and Parkinson’s disease.

**Treatment:** Treatment design to alleviate dry-mouth symptoms should be personalized to the individual patient, based on available treatment. The treatments of xerostomia can be classified into the following categories: (1) patient education, (2) prevention, (3) symptomatic treatment, (4) systemic and topical salivary stimulants, and (5) regenerative and gene therapies. Patient education Patients should receive detailed information about the potential causes of dry mouth and the potential sequelae of impaired salivary secretion, such as dental caries, candidiasis, and mucosal complications. Therefore, patients should be encouraged to have preventive oral health care such as dental hygiene habits and regular dental visits. Another palliative action to minimizing symptoms and preventing oral complications is water intake, drinking water frequently, and remaining hydrated is an important treatment for symptoms of dry mouth.

Preventive therapies Pharmacological interventions for the prevention of radiation-induced salivary gland dysfunction have been studied. The use of chemical radioprotectors represents an obvious strategy to improve the therapeutic index in radiotherapy. However, the vast majority of these are either too weak in terms of radioprotection, too toxic, or without any apparent mechanisms to ensure selective normal tissue protection. The sulphydryl compound amifostine (WR2721; 2-[3-(aminopropyl) amino] ethylphosphorothioic acid), is an oxygen scavenger that may protect salivary glands from free-radical damage during radiation therapy without attenuation of the anti-tumor effects in many experiments performed. Amifostine has been approved for prevention of xerostomia, in head and neck squamous cell carcinoma patients undergoing radiotherapy.

**Discussion**

Bakke et al, have reported that xerostomia was higher in women than in men in all age groups. There was higher prevalence of xerostomia with increasing age in both sexes and it was more frequent at night than during daytime. They concluded that the dramatic increase of xerostomia between age 50 and 75, especially amongst 620 women, needs to be considered in the management of this age group.

A recent systematic review that included randomized controlled trials suggested that the drug amifostine prevents the feeling of dry mouth in people receiving radiotherapy to head and neck (with or without chemotherapy) in the short- (end of radiotherapy) to medium-term (3 months after radiotherapy). However, amifostine has adverse effects such as nausea, vomiting, hypotension, transient, hypocalcemia, and allergic reactions. Then, the benefits of amifostine should be weighed against its high cost and side effects. Another cytoprotective compound described in literature is the bioactive factor Keratinocyte growth factor18.

Gambon et al, reported that the application of citric acid might be increased risk of caries, as a consequence of the erosive action of these agents over the dentin.

Anneroth et al, reported that the use of chewing gums can cause similar bad effects. In order to avoid demineralising effect on the human dentin, the use of spray format allows a direct contact with the oral mucosa, and combined with a suitable concentration (as the stimulant effect on saliva production), could reduce the demineralising potential of chewable products.

Da Mata et al, indicated that Gustatory stimulants of salivary secretion with fluoride, xylitol and lower acid content maintain similar salivary stimulation capacity while reducing significantly the dental erosion predictive potential.

**Conclusion**

The dental practioners have difficulty in diagnosis and treatment of dry mouth. Diagnosis of xerostomia may be based on evidence obtained from the patient’s history, an examination of the oral cavity and/or sialometry, a procedure that measures the flow rate of saliva. Xerostomia should be considered if the patient complains of dry mouth, particularly at night, or of difficulty eating dry foods such as crackers.

Osseodensification in Dental Implants: A Review

Bhuminathan Swamikannu1, Kalyani Ramkumar Sadhana2, Sanjna Nayar3

1Professor, 2Post Graduate Student, 3Professor and Head of the Department, Department of Prosthodontics, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education and Research, Chennai, India

Abstract

Background: Primary Implant Stability of dental implants is an essential factor for achieving successful osseointegration. The quality of bone is one of the most crucial factors that affects primary implant stability. Sufficient bone to implant contact [BIC] is an essential criterion for biomechanically stable dental implant.

Osseodensification, a recently developed technique has been at the forefront of evolutionary changes in osteotomy site preparation in implantology. This technique involves low plastic deformation of bone that is created by rolling and sliding contact using a densifying bur that is fluted such that it densifies the bone with minimal heat elevation. This technique has been proposed to help in better osteotomy preparation, bone density and increases primary implant stability.

Method: A literature review was done to analyse the osseodensification procedure, its advantages over conventional osteotomy on bone density and primary implant stability.

Conclusion: Densifying drills [Densah] for bone osseodensification resulted in undersized osteotomy compared to conventional drills. It also resulted in improved bone density and increase in percentage bone volume and bone to implant contact, thereby improving implant stability.

Keywords: Implant Stability, Bone Density, Osseointegration, Osseodensification, Osteotomy.

Introduction

Osseointegration is the formation of a direct interface between living bone and the surface of a load-bearing prosthetic implant. Osseointegration is crucial for implant stability which determines the long-term success of dental implants.1 Primary stability is achieved when there is no micro movement of implant in its completely seated position.2

Standard drills used during osteotomies are made to remove bone to create space for implant placement. A new concept for osteotomy called osseodensification has been at the forefront of changes in surgical site preparation in implantology, developed by HuwaisS.3 Osseodensification does not excavate bone tissue. It is carried out with densifying burs to increase bone density as they expand osteotomy site.4

Primary Stability: Bone density, surgical protocol, implant thread type, and geometry are the factors involved in improving primary stability of dental implants. The maintenance and preservation of bone during osteotomy preparation leads to enhanced primary mechanical stability enhanced Bone to Implant Contact, thereby enhancing the implant secondary stability.2

Method to Increase Primary Stability: Many surgical techniques were developed to increase the implant primary stability in bone with low density. A method to increase the primary stability that is widely used is the under-preparation of the implant bed, which is achieved by using a one or more size smaller as the last drill than selected implant diameter.

In the presence of poor bone quality, 10% undersized implant bed preparation is sufficient to enhance primary stability whereas, additional decrease does not improve primary stability values.5,6

Studies on stepped osteotomy of implant bed, which is another variant of the under-preparation method, have reported greater implant stability in terms of insertional torque than conventional osteotomy in soft bone.2
Summers RB described the use of osteotomes to condense bone in case of low bone density. Stavropoulos A et al., reported good primary stability of implants using bone condensation technique.

Osseodensification is a newer technique of preparation of the implant bed, to develop a condensed autograft surrounding the implant, which enhances implant stability.

Rationale of Osseodensification:
Osseodensification involves the usage of proprietary densifying burs (Densah burs) that allows allow bone preservation and condensation through compaction autografting during osteotomy preparation thereby increasing the peri-implant bone density, and the implant mechanical stability.

Higher degrees of primary stability due to physical interlocking between the bone and the device, faster new bone growth formation due to osteoblasts nucleating on instrumented bone that is in close proximity with the implant.

Bur Technology: Specially designed Densah burs runs at a speed of 800-1500 rpm, precisely cut bone in the clockwise direction and densify bone in a non-cutting counter clockwise direction combined with copious irrigation which aids the surgical procedure during implant placement.

They have lands along with negative rake angle that work in a non-cutting action. They have a cutting chisel edge and a tapered shank so that when entering deep into the bone, they expand the osteotomy preparation smoothly compacting the bone in the peripheral area.

Advantages:
Compaction auto grafting: Osseodensification maintains the bulk of bone by condensation and compaction which results in higher bone to implant contact.

Enhances bone density: Osseodensification burs allow preservation of bone and condensation through compaction autografting, thereby increasing the peri-implant bone density, and the implant mechanical stability.

A study conducted by Huwais S and Meyer EG confirmed that the osseodensification technique increase primary stability, the percentage of bone at the implant surface and bone mineral density. They also concluded that, by reserving bulk bone, healing process would be accelerated due to bone matrix, cells and biochemicals maintained and autografted along the osteotomy surface site.

Residual ridge expansion: Studies shown that narrow bone expands along with osseodensification thus facilitating for placement of implants with larger diameter and also avoiding fenestration and dehiscence.

Increase in residual strain: The bouncing motion helps to create a rate dependent stress to produce a rate dependent strain, and allows saline irrigation to gently pressurise the bone walls. These together facilitate increased bone plasticity and bone expansion.

Increase in Implant Stability: Huwais S concluded that, the densah™ bur technology facilitates ridge expansion with maintained alveolar ridge. He also concluded that, despite compromised bone anatomy, osseodensification preserved bone bulk and promoted a shorter waiting period to the restoration.

Contra Indications: Osseodensification does not work with cortical bone as cortical bone is a non-dynamic tissue which lacks plasticity. Densification of xenografts should be avoided because they behave biomechanically different than the bone tissue, as they have only inorganic content and they just provide the bulk without any viscoelasticity.

Discussion
Lahen B et al., in their study examined the effect of osseodensification on the primary stability and early osseointegration of implants. They concluded that drill design positively influence the osseointegration when utilised in both clockwise and counter clockwise directions is a result of densification of autologous bone debris at the bone walls.

Trisi P et al., in his animal study concluded that the osseodensification technique demonstrated the ability to enhance implant primary stability and maintained implant secondary stability, and increased the bone-volume percent around dental implants inserted in low density bone in respect with conventional implant drilling procedures.

Lopez CD et al., in their study assessed the biomechanical and histological effects of osseodensification surgical instrumentation in a spine
model animal study and concluded that this technique can potentially improve the safety and success rates of bony drilling at all sites of low bone density and limited bone volume.\(^8\)

**Conclusion**

With the introduction of densah burs, making osseodensification possible, not only reduces treatment time but, also gives a successful implant outcome. Osseodensification is a promising concept which creates an autograft layer of condensed bone at the periphery of the implant bed with the use of densah burs that rotate both in clockwise and counter-clockwise direction, thereby enhancing implant stability and success.

Peek a Polymer Material Feasible for Dental Implant Body/Implant Fixture: A Systematic Review

Sanjna Nayar¹, Monika D.²

¹Professor and Head, ²Post Graduate Student, Department of Prosthodontics, Sree Balaji Dental College and Hospital, BIHER, Chennai

Abstract

Based on the available research on PEEK materials, to find that whether PEEK material has favourable properties and can enhance Osseointegration, so that they can be utilize as dental implant body/fixture.

Appropriate selection of the implant biomaterial is a key factor for long term success of implants. The biologic environment does not accept completely any material so to optimize biological performance, implants should be selected to reduce the negative biologic response while maintaining adequate function. This review makes an effort to summarize peek implant bio material.

Results: Initially, the search resulted in 106 papers out of which 19 articles were excluded due to irrelevant titles and abstracts. Independent screenings of the abstracts were done to identify the articles related to the question in focus Eighty Seven studies were selected out of which 31 articles were further excluded due to Articles and studies related to PEEK as implant abutments, or implant restoration were excluded. Finally, 21 articles were included in the review.

Keywords: PEEK, Osseo integration, Ceramics, Polymer.

Introduction

Dental implants are today a viable and mainstream alternative to the conventional removable and fixed dental prostheses. In line with the growth and mainstreaming of this treatment form, the science of biomaterials, specifically implant materials is also evolving rapidly.¹,²,³ Among various dental materials and their successful applications, a dental implant is a good example of the integrated system of science and technology involved in multiple disciplines including surface chemistry and physics, biomechanics from macro-scale to Nano scale manufacturing technologies, and surface engineering⁴,⁵.

Materials Used for Dental Implants: In the long history of dental implants, several materials have been tested such as metals, alloys, ceramics, polymer based materials, glasses, and carbon⁶,⁷,⁸, the characteristics required for the manufacturing of dental implants are biocompatibility, bio functionality, availability, together with the capacity to Osseo integrate, as defined in the previous paragraph. Availability refers to the handiness of the fabrication and sterilization techniques of the implants⁹.
Ancient Era (through AD 1000): Implants are traceable to ancient Egyptian and South American civilization. There is a skull form pre Columbian era in which artificial tooth is carved with dark stone. Albucasis de condue Arabian surgeon, credited with a written paper of transplants as a means of replacing missing teeth10.

Foundational period (1800-1910): This era is the beginning of End osseous oral implantology. Maggiolo in 1809 used gold in the shape of the tooth root. In 1887 Harris reported the use of teeth made of porcelain into which lead coated platinum posts were fitted. In 1890, Zamenski reported the implantation of teeth made of porcelain, gutta-percha, and rubber and in 1898 R.E payne places silver capsule in the tooth socket. In the early 1900’s lambotte fabricated implants of aluminium, silver, brass, red copper, magnesium, gold and soft steel plated with gold and nickel11.

Dawn of the modern era (1935-1978): In this era, synthetic polymers, ceramics and metal alloys started replacing the naturally derived materials because they have better performance and more predictable results than the natural ones.

Strock anchored a vitallium screw within bone and immediately mounted it with a porcelain crown. He was the first one to achieve an implant survival for 15 years11,12.

Types of Prosthetic Implant Biomaterials:
Materials used in dental implantology can be broadly categorized in two different ways13, 17

1. Based on the chemical composition of the material; and
2. Based on the biological response of the material.

From a chemical composition standpoint, the relevant materials may be classified as:

- **Metals** are elements that are crystalline when solid; many metals are characterized by opacity, ductility, conductivity, and a unique luster.
- **Ceramics** are hard, brittle, and heat and corrosion resistant materials made typically of metallic elements combined with oxygen or with carbon, nitrogen, or sulphur.
- **Polymers** are compounds of high molecular weight derived either by the addition of many smaller molecules or by the condensation of many smaller molecules with the elimination of water, alcohol, or the like. These materials are relatively inert to biodegradation and have certain properties that are similar to soft tissues.

From a biological response standpoint, the relevant materials may be classified as:

- **Bio tolerant** materials are those that are not necessarily rejected when implants are placed into living tissues but are surrounded by a fibrous layer in the form of a capsule.
- **Bioinert** materials allow apposition of bone on their surface leading to contact osteogenesis.
- **Bioactive** materials also allow the formation of new bone onto their surface but ion exchange with host tissues leads to the formation of a chemical bond, along with the interface (bonding osteogenesis). A recent development is the development of “biomimetic” materials, which are new tissue engineered materials designed to mimic specific biologic processes and help optimize the healing or regenerative responses of the host microenvironment. These materials can be any combination of the chemical and biodynamic activity categories, depending on the therapeutic strategy and the type of host tissues.12

This systematic review was undertaken to evaluate the experimental, animal, and clinical studies done on PEEK materials to find that whether PEEK material has favourable properties and can enhance osseo integration, so that they can be used for dental implants.

Eligibility Criteria:

Types of Studies: The review included laboratory research studies, in vitro studies that using cells from human or animals and in vivo studies on animals. Studies published on English language between 2014 and 2019 with various evaluation method for osseo integration and osteoblasts proliferation. Letters, reviews and abstracts were excluded.

Study selection

Inclusion criteria for the selection were:

- Articles included related to PEEK materials and their applications in dental implants as implant body/implant fixture.
- All clinical, experimental, and animal studies and were included in the review.
Exclusion criteria for the selection were:

- Articles not related to PEEK and their applications in implants were excluded.
- Articles and studies related to PEEK as Implant abutments, or implant restoration were excluded.
- Articles not available in abstract form.

Discussion

PEEK is a high performance semi-crystalline thermoplastic polymer, which combines its very good strength and stiffness with an outstanding thermal and chemical resistance—e.g., against oils and acids. Being colourless and endowed with an elastic modulus close to that of the bone, PEEK is a viable option for dental implant manufacturing. However, PEEK alone is generally bio inert and is not conductive to cell adhesion\(^{13}\). Ti is the main material for use in dental implants. During mastication there may be overloading of the jaw bone because of remarkable difference in the modulus of elasticity of bone (≈1-30 GPa) and Ti (110 GPa), which causes major problem to the associated implants. In such situation, PEEK (elastic modulus 3-4 GPa) can be contemplate extremely encouraging because of their aesthetic and functional properties. When compared to Ti, PEEK possessed compound structure, which allows optimizing the dispensation of masticatory forces surrounding the implant\(^{14,15}\).

PEEK has been applied as an implant material in the implant body, abutment, and superstructure. Applications in the implant body have been limited to bench tests, and there is no report on its application to the mandible as the implant body. Lee et al. reported, if PEEK is used as a dental implant body, it may exhibit lower stress shielding than Ti due to the closer compatibility of the mechanical properties of PEEK and bone\(^{16,17}\).

Rust-Dawicki et al. compared the in vivo mechanical strength of the bone interface of titanium-coated and uncoated PEEK dental implants. There was no significant difference in bone contact or new bone growth between 4 and 8 weeks in the two groups. At 4 and 8 weeks, the coated specimens had significantly higher percentages of bone contact\(^{18}\).

Xu et al. developed CFR-PEEK-Nano hydroxyapatite with micro-/Nano-topographical structures by modifying them with oxygen plasma and sandblasting the surface. The aim was to enhance osteogenesis as a potential bioactive material for bone grafting and bone tissue engineering applications with enhanced biocompatibility and osseointegration\(^{19,20,21}\).

According to Sano H et al. and Sandler J et al. the tensile properties of PEEK are also analogous to that of bone, enamel, and dentin. Thus, this material can exhibit less stress shielding effect compared to titanium, and it can be considered as a good substitute material\(^{22}\).

Kurtz et al. For example, incorporation of carbon fibres to increase the elastic modulus up to 18 GPa and thus the elasticity of this material might reduce the distal torque and the stress on the abutment teeth. When reinforced with fibre, PEEK can reduce stress shielding when compared with traditional metallic implants\(^{23,24}\).

Guyer et al. reported PEEK implants appear to be limited in Osseo integration potential because of the fibrous soft tissue forming along the implant-bone interface\(^{25}\).

Results showed that in vitro initial cell adhesion and proliferation on the Nano-FHA reinforced PEEK composite were improved. In addition, higher alkaline phosphatase activity and cell mineralization were also detected in cells cultured on PEEK/Nano-FHA bio composites, especially for rough PEEK/Nano-FHA surfaces. For in vivo test, the newly formed bone volume of PEEK/Nano-FHA group was higher than that of bare PEEK group based on 3D micro computed tomography and 2D histomorphometric analysis\(^{26,28,29}\).

Johansson et al. reported a significant improvement of early bone integration for PEEK implants coated with Nano sized HA. The results may be of clinical interest for early loading applications, but further studies are required to statistically verify the results and to improve the extended effect of the coating. The finding of a BIC advantage for HA-coated PEEK was similar to this study, which also showed a significantly higher BA for HA-coated PEEK after 3 weeks\(^{30,31,32}\).

A special effect of n-TiO\(_2\) on the composite surface was also observed. Bioactivity evaluation of the Nano composites revealed that pseudopods of osteoblasts preferred to anchor at areas where n-TiO\(_2\) presented at the surface. This study also showed that the surface roughness of n-TiO\(_2\)/PEEK composites played a prominent role in promoting cell attachment and regeneration of new bones. Our study suggests that n-TiO\(_2\)/PEEK composites utilize the attractive bioactivity of n-TiO\(_2\) as well as the outstanding mechanical properties of PEEK, and could
be a potential substitute for metal implant material in orthopaedic and dental applications.

Bioactivity evaluation of the Nano composites revealed that pseudopods of osteoblasts preferred to anchor at areas where n-TiO$_2$ was present on the surface. In in vivo studies, the bone volume value of n-TiO$_2$/PEEK was approximately twice as large as that of PEEK ($P < 0.05$). Vivid three-dimensional and histologic images of the newly generated bone on the implants further supported our test results. The main limitation is Very limited clinical trials have been done using PEEK as dental implant.

**Conclusion**

Surface modification of PEEK seems to enhance the cell adhesion, proliferation, biocompatibility, and osteogenic properties of PEEK implant materials. PEEK had also influence the biofilms structure and reduces the chances of peri implant inflammation. Very limited clinical trials have been done using PEEK as dental implant, so it is too early to conclude that PEEK can replace Ti implants in future. Although PEEK and its derived are currently being evaluated in vivo and in vitro, further investigations and definitive clinical evidence on their safety are necessary. Since the Osseo integration of PEEK and its derived are not always a straightforward biological process, experimental modulations of the surface are mandatory to achieve the highest possible grade of Osseo integration. Further research and more number of controlled clinical trials on PEEK implant is required in near future long-term studies in animal models will be pursued to evaluate in vivo effects.

The Effect of Using the McCarthy and Merle Instructional Models on Some Physical Abilities and Skills in Basketball and Football

Emad Toma Radi¹, Mentdhar Hussen Sabt¹, Iman Hamad Shihab²

¹Lecturer, ²Assistance Professor, Mustansiriyah University, Faculty of Basic Education, Department of Physical Education and Sport Sciences, Baghdad-Iraq

Abstract

The research included the introduction, the importance of the research and the aim of the research to

1. Preparation and implementation of special educational units using the McCarthy and Merle model in improving some physical abilities and offensive skills of basketball and football.

2. Recognize the effect of using the McCarthy and Merle models in some physical abilities and offensive skills in basketball and football.

The sample was chosen by the deliberate method of students of the Faculty of Physical Education and Sports Sciences University of Mustansiriyah for the academic year 2018-2019, the number of (58) students and the sample was divided into two experimental groups. The first experimental group uses (McCarthy model) and the second experimental group uses (Merle model) And conduct the application of the implementation of the model McCarthy and Merle and applied educational units and the number (6) educational units for each mathematical Valley and then conduct the tests after.

The most important conclusions is the effectiveness of educational units prepared by researchers using the models McCarthy and Merle in some physical abilities and offensive skills of basketball and football.

Keywords: McCarthy, Merle instructional models and physical abilities.

Introduction

In light of the great scientific and cognitive advancement in the fields of life, information is now being published at the time of its birth. In this scene, all teachers should take advantage of this reality to advance the educational process at all levels of its educational institutions has become obligatory for the teacher of physical education in various stages of study from kindergarten to university care and development towards the correct performance of sports skills as much as given to take care of the level of achievement and development and use Modern method and learning models based on the basic learning theories, is still the dominant characteristic of teaching and up to the present time is the use of teachers to method and method of teaching based on memorizing the matter and memorization of scientific material and The process, which is poor pre-planning of the method used in the teaching of a particular concept by the teacher, which makes teaching follow a similar pattern in most lessons intended to provide students with the largest amount of information and concepts, at the same time shows the lack of interest in linking them in a way that creates a state of integration and balance Among them in the structure of the learner and therefore these concepts and ideas remain dispersed in the minds of students and his exposure to forgetfulness as well as misunderstanding them.
The view of the teacher as a suitable teaching environment that achieves good learning is that the teaching model is a mini-embodiment of a field of teaching to produce a quantity of outputs. The model includes relationships between the collection of elements in the form of steps and classroom practices and is based on theories. Many modern teaching models have been designed in the developed world because of their impact on the capabilities of the human mind. Organized efforts have begun to teach and employ these models of designing programs that meet the learner’s needs and seek to correlate between educational attitudes, characteristics, needs, and abilities. Each learner, and through technological development in general, and technology of teaching and learning in particular has become the pairing of technology and educational models a necessity for learners and practitioners of all educational processes at all stages of university education to raise the level of efficiency of the process and products. 2

This model in the McCarthy educational model. This model in the quartet learning cycle is continuous with some constant, that all students should be taught in accordance with the patterns of this model and that it fits all stages of education and model (Merle) educational, which was presented as a result of their great effort and built on basic assumptions Subject to testing and application within the classroom or outside the classroom and found that the goal of teaching is to help students to collect positive examples of the concept and respond to it by symbol or reference or name, and that the acquisition of concepts is to classify the characteristics of the concept and attributes in the same way that the tide Through the introduction of the definition and then provide evidence until the learner conduct taxonomic behavior. 3

Research Objectives:
1. Preparation and implementation of special educational units using the McCarthy and Merle model in improving some physical abilities and offensive skills of basketball and football.
2. Recognize the impact of the use of typical McCarthy and Merle in some physical abilities and offensive skills of basketball and football.
3. Identify which model is best at improving some physical abilities and learn offensive skills in basketball and football.

Research methodology and field procedures:

Research Methodology: Use the experimental method: The sample was (122) male and female students and distributed to (5) people. The sample was chosen in a deliberate way (58) students from the original community. The sample was divided into two experimental groups, the first experimental group (29) using (McCarthy model) Division (b) and the second experimental group (29) using (Merle model) Division (c) by lot and thus the sample formed 47.54% The skills of basketball and football take the first stage Second to the homogeneity of some variables (length, weight, age) as shown in table (1).

Table 1:

<table>
<thead>
<tr>
<th>Variables</th>
<th>Mean</th>
<th>SD</th>
<th>Median</th>
<th>Skewness</th>
</tr>

</tbody>
</table>

Table (1) shows that the sample is homogeneous and distributed naturally because the torsion coefficient is confined between (±3).

Research tools and equipment: (Tape measure, Medical balance, People, Stopwatch, Basket balls, Footballs, Basketball, Stadium, Football goal, chalk, Whistle, laptop, Electronic, Calculator, Adhesive tape with different colors and Medical balls).

Tests used for research:
1. Test explosive power of the arms (throwing the medical ball on the chair/distance): 4
   Purpose of the test: to measure the explosive power of the arms
2. Test the characteristic power of the speed of the legs (bend knees and extend them in 10 seconds). 5
   Purpose of the test: to measure the characteristic power at the speed of the two men
3. Thoracic Passing Test (Accuracy of Goal Scoring/Score). 5
   The purpose of the test/measure the accuracy of the scroll (passing of the bra).
4. The test of loop shoot scoring (Measuring loop shoot scoring/Sec.). 5
   Purpose of the test: Measuring loop shoot scoring.
5. Passing test: the test and the hand-bounced on the wall for 20 seconds. Purpose of the test: Know the measurement of passing accuracy.

6. Test quench ball inside the box measurements (2 m × 2 m). Purpose of the test: To measure the accuracy of stopping the ball in all parts of the body accept the arms.

Pretests: The researchers conducted the pretests in the sports hall of the Faculty of Physical Education and Sports Sciences, Mustansiriyah University, The physical tests and football tests were conducted on 13/11/2018 and then the basketball tests were conducted on 14/11/2018.

Application of educational units: Before launching the modules, the researchers conducted two modules introducing the modules in the McCarthy and Merle models. The researchers then applied the proposed modules in the first experimental group.

1. Notes: (Interpretation): Where educational method are used to help the process of learning a skill such as passing bra basketball and then processing.
2. Thinking (Expansion) After perception the student works on making decisions and prefers the simulation system to learn directly
3. Active experimentation (applied. Presentation) Conduct applied exercises or exercises similar to playing for the learner’s skills while trying to learn another skill such as scoring and then.

The second experimental group works with the Merle model and works according to the steps.

1. The principle of activation: It is the presentation of general information about the skill and explain and take out a model and ask questions.
2. Principle of evaluation: Here is the introduction of the student in the preparation of public and private, provided and physical exercises collectively.
3. Principle of application: The exercises are explained in the form of stations and the application of each station and the teacher observing their application.
4. The Principle of Integration: Here students are discussed about the contents of the unit of instruction skill.

The educational modules which lasted (5 weeks) were carried out by two units per week and each chest passing skill with physical variables under study (2 units.) With physical variables and skills are applied by college curriculum. Where the units are implemented on 18/11/2018 and completion of the implementation of 25/12/2018 according to the time allocated to the skill by the teacher of the subject.

Posttests: It was conducted on 26-27/12/2018, for physical and basketball and foot skills.

Statistical means: The statistical bag (SPSS) was used to process the search results.

Results and Discussions

From table (2) the application of the four steps model McCarthy educational model that helped students to improve physical variables and offensive skills basketball and football and contributed to the two models in the impulse and motivation of learners to participate in harmony in classroom attitudes This gave them enough space to think about the intrinsic features inherent between the examples belonging to the concept of skill and the non-belonging examples common mistakes, and the awareness of the relationships among them, and strengthened the learners a sense of confidence and the ability to conclude, and to be a productive learning effective, and this is confirmed by the educational literature To provide students with the opportunity to rely on themselves to know the common characteristics of exercises and examples belonging to the concept of skill, and examples not belonging to the skill and make them a focus of the learning process in contrast to the traditional method based on the teacher’s.

The McCarthy model is a learning that has a better sense of retention than any other learning.

The introduction of activities and exercises for the use of concepts and the active participation of learners in these exercises led to the enhancement of the concept and its application and use in new educational situations later. As well as the correction of errors during the performance feedback in the McCarthy model and informing learners of the correct performance or the correct answer to the activities and skills they have contributed to increase the effectiveness of learning and raise the adequacy of the students of the first experimental group, and agrees with the views of (Bruner) who emphasizes that the learner must repeat Organize the concepts or information of the content to be learned and integrate it with what has already been learned in its mental structure and then have a new organizational structure that reveals something by doing activities and activities that further consolidate.

The application of units came regularly and tidy according to the gradient from easy to difficult and part to all and thus works with the cooperation of learners where the application of exercises given during the units came with the capabilities of learners, which were given in the form of cooperative groups and the transition from one exercise to another based on the performance of the previous exercise This is part of the requirements of the model that the McCarthy model works on the opportunity to learn within different groups and this develops the spirit of cooperation and teamwork skills.

The student moves in this from active experimentation to sensory experiences and blends the learner’s understanding with his individual experiences and works to apply them in practice, (develops previous
experiences and information and updates this information in a modern way, and uses ideas in multiple forms to allow students to discover the meanings and concepts of teamwork and apply them). The teaching method of McCarthy model works to raise the level of effective lesson planning from the planning, implementation and evaluation by the teacher according to the model steps (the presence of the method or method is an excellent area for planning and teaching active and effective methodological materials).  

The teaching according to McCarthy model, which works to increase the motivation for learning among learners and the different motivation among them, which led to their rush to learn the skills of basketball and football self and in cooperation with the group and it works on the spirit of cooperation and collective solidarity between the same group to work in a cooperative spirit in order to reach the goal Please with all enthusiasm and optimism and excellent morale and get rid of the monotony and the traditional constrained context of kinetic performance so that the teaching method McCarthy model works on the participation of learners in order to reach a good performance and work on the carrot and attract the attention of the You know to learn through the educational process (the educational model that allowed the appropriate educational environment and allow the learner the opportunity to self-learning and to activate the cycle in the learning process).  

By interpreting the results, the researchers demonstrate the effectiveness of McCarthy’s model in improving some of the physical abilities and offensive skills of basketball and football applied to students who sought to help learners, as well as the application that motivated and motivated students to encourage a spirit of cooperation and understanding between them and the teacher.  

Conclusions

1. Effectiveness of McCarthy and Merle model to improve some physical abilities and offensive skills of basketball and football.

2. The effectiveness of educational units prepared by researchers using the models McCarthy and Merle in some physical abilities and offensive skills of basketball and football.

3. Demonstrated that the use of teaching method McCarthy model has a role in learning some physical abilities (explosive power of the arms, the power characteristic speed of the two men) and basketball offensive skills (chest passing and loop shoot scoring) and skills (suppression, passing) football.

4. The second experimental group improved the Merle model in some physical abilities and offensive skills of basketball and football.

Objective Evaluation of Shooting Skill Performance According to the Interim Objectives for the Junior Players in Handball

Haider Shakir Mizher¹, Abdulrahman Nasir Rashid²

¹Assist Prof., ²Prof. Dr. University of Diyala, Iraq

Abstract

Shooting skill is considered as the separating point between loss and winning. In addition, the offensive playing planning and skills, in all its types, will be useless if they are not ended and crowned with successful shooting on goal. What’s more, the sports educators agree on the idea saying that the practice of sports, in whatever their levels may be, needs clear objectives with specified specifications.

In order evaluate the training curricula, on the basis of what has been mentioned issues and based on the great significance and the relationship between evaluation and objectives; the two researchers objectively used the interim objectives in evaluating the shooting skill without the interference of the handball trainers subjectivity.

The objective of the study are setting interim objectives for the junior players in the performance of the shooting skill in handball and using interim objectives objectively, evaluating the junior player’s performance of shooting skill in handball.

The sample of the study were selected from the handball junior players. They were (20) players.

The study has come up with the following results, the mean of the previous test was (18.2), and whereas the mean of the first interim test was (20.7).The mean of the second interim test was (23.3). While the mean of the posttest was (26.1)

Keywords: Objective evaluation, shooting in handball and interim objectives.

Introduction

Evaluation is a process that includes giving judgments on the values of things, persons and objects in order to improve, modify and develop them. The duty of evaluation includes: programmers, curricula and method of teaching and training and the issues related to teaching and training the motor skills and in all games and sports activities.

The basic skills in handball are considered as the basic substrate of the game. One of the most important of these skills is shooting skill. The team whose players perform this skill well has the capacity to defeat the opponent team. Shooting skill is also considered as the separating point between loss and winning. In addition, the offensive playing planning and skills, in all its types, will be useless if they are not ended and crowned with successful shooting on goal.¹

Therefore, the trainers spend long time in training the shooting skill to make the players master it. The successful trainer or teacher always seeks implementing processes of assessment and evaluation in order to get knowledge of the play’s or the learner’s level of progress; and also to know the impact of training or teaching on that level. Each programmer, whether training or teaching, has specific objective and assessment and evaluation are those tools that both achieve the objective.

The sports educators agree on the idea saying that the practice of sports, in whatever their levels may be, needs clear objectives with specified specifications. In other words, all the processes of teaching, training and competing are in need of objectives because practice without objective is like moving one objects in the space without the power of gravity, then no one knows the starting point nor the horizon of end. Therefore, building objectives has wide range of space in the processes
of teaching and training, then achieving superiority, reaching the achievement and the best performance setting out from the idea that the objective is the final behavior that can be noticed and assessed and predicted that the learner can do after undergoing the educational situation.2

To evaluate the training curricula, on the basis of what has been mentioned issues and based on the great significance and the relationship between evaluation and objectives; the two researchers objectively used the interim objectives in evaluating the shooting skill without the interference of the handball trainer’s subjectivity.

By the following up of the two researchers, their experiences as handball players and trainers and their conversations with some handball trainers and players, There are two questions have grown up in the researchers.

How do the handball trainers evaluate the shooting skill performance of their junior players?

Do the handball trainers use interim tests to know the level reached by the players in the shooting skill?

Objectives of the study:

1. Setting interim objectives for the junior players in the performance of the shooting skill in handball.
2. Using interim objectives objectively to evaluate the junior player’s performance of shooting skill in handball.

Methodology

Method followed and study sample: Choosing the method of study is one of the important issues in implementing the procedures of the study. It is the problem of the study that specifies the type of method used in achieving solution and treatment to the problem. Thus, the two researchers used the descriptive method with the scanning style, for its suitability to the nature of the problem and aims of the study.

Whereas the sample is “ the part that represents the community of the study or the model on which the researcher do most of his work. That sample should be characterized by a main condition that is the capability of generalizing its results on the original group from which it has been selected.” Thus, the sample of the study were represented by the handball junior players of the specialized school. They were (20) players.

Means of collecting information:

- Arabic and foreign resources.
- Internet.
- Notice.
- Personal interviews made with some experts and specialists.
- The form of identifying the interim objectives (Houdale Stone 1993).
- Data inserting form.

Devices and Tools used in the Study:

- Two electronic timers (Sewan) made in Germany.
- Chinese (hp) laptop computer.
- Two Japanese (Sony) digital cameras.
- Two (NIKE) whistles.
- Ten standard hand balls.
- Standard handball court.

Method of specifying the interim objectives: In order to specify the interim objective of each player, it should implement the following:

1. Do three attempts of the test.
2. The mean of the three attempts should be counted.
3. The mean should be subtracted from best record the player did.
4. The result in step three should be added to the best record done by the player and the resulting number should be considered as the medium range.
5. The result in step three should be added to the medium range to achieve the targeted range either future interim objective on which the player should work to achieve.

Tools Used: Handball, handball goal drawn on the wall (3 × 2) m and then divided into nine rectangles to measure the accuracy of shooting and draw a line on the ground (9) m away from the goal as in Figure (1).

Performance Method: The player is shooting from behind the line step by step, taking into account the following:
A- Shooting of the rectangles (9, 7, 3, 1), which represent the angles of the goal, which dimensions (100 × 60) cm get four degrees.

B- Shooting rectangles (8, 2), which represents the area above the head of the goalkeeper and between his feet, which dimensions (100 × 60) cm receive three degrees.

C- Shooting rectangles (6, 4), which represents the extent of the arms of the goalkeeper, which dimensions (100 × 80) cm obtain two degrees.

D- Shooting rectangle (5) represents the area of the chest and the trunk of the goalkeeper, which dimensions (100 × 80) cm obtain one degree.

E- If the ball goes out the player gets zero.

F- Each player performs ten shoots for one attempt only.

**Fig. (1): Shooting skill test**

**The application of tests:** The researchers applied the skill test correction in the closed hall of the club of Diyala/Iraq as follows:

1. Pre-test at the beginning of the experiment on 1-9-2019
2. First interim test two weeks after the start of the experiment on 15-9-2019
3. Second interim test two weeks after the first progress test on 29-9-2019
4. After the test after two weeks of the second interim test on 13-10-2019.

**Statistical means:** The researchers used the following statistical method:

- Analysis of variance 2-L.S.D Test

**Results and Discussions**

Discussions

It is clear from the tables (1) (2) and (3) that the results show that the post-test has surpassed the results of the first and second preliminary tests in the skill of handball correction and these results coincide with the great importance of the role of the interim goals that were applied to the sample. During the interim goals form, which includes some statistical steps that give the player an indication of the next goal to be achieved and this gives us a clear impression and perception on the subject of goals in sports as the topic of the interim goals is one of the most important topics has been addressed by researchers and scientists of its importance and reached through the results. According to scientists, the concept of goal is to achieve a special level of progress in the performance of a work and is usually determined within a special time. Goal Setting is also one of the most important guidance and guidance that the athlete should pay attention to. A goal is intended to achieve a certain level of progress or mastery in a work within a specified period of time, the goal focuses on achieving a certain level of performance or record a certain number in a race and this progress or improvement will be within a specific time unit. For a period of one to three months or after (20) units of education or training or during a period that may reach two years. The role and importance of setting goals in sports reinforced the conviction of many sports workers, whether they are trainers or teachers, who are always looking for ways and mechanisms to help them succeed in their educational or training tasks away from traditional patterns that are not linked to the aspects of education and training psychological factors. Among them the motivation therefore put a number of benefits achieved by the process of setting goals during sports practice, namely:

- Improve performance and quality of practice.
- Clarify expectations.
- Help to get rid of boredom to make education and training more challenging.
- Increase self-motivation.
- Develop a sense of pride, satisfaction and self-confidence.

The researchers, through their presence and proximity to the research sample when applying the interim goals, have noticed that the members of the sample were experiencing moments of enthusiasm and impulsivity when they are conducting the interim tests and were asking those on the tests to know the percentages of their development and what is required to achieve in the next tests so we can say with great confidence that the impact of interim tests on the motivation of the players was very large and this is proved by the results of the dimension, and the motivation and its role and its impact on learning and training that the motivation function includes three dimensions:

1. Liberate the emotional energy inherent in the organism that provokes a particular activity or this
applies to the theoretical motives of the process of acquiring skills and modification of patterns of behavior.

2. Dictates that individuals respond to a particular situation with neglect of other situations as dictated by the way to act.

3. Directing the behavior of a particular destination
   This is linked to the two previous functions, it is not enough that the organism is active but must direct a specific destination.

Conclusions

1. Results of the post-test are superior to the results of the first and second pretest and interim tests.

2. Effectiveness of developing the objective method in the objective way used by the researchers in developing the skill of correction

3. The level of performance of the players in the correction skill escalated from one test to another.

Significance of Differences in the Performance Momentum Power of Arms, Legs, and the Accuracy of Shooting in Handball According to Normal Weight Categories for Junior Players

Haider Shakir Mizher
Assist. Prof. Dr. University of Diyala, Iraq

Abstract

Basic skills are considered to be the first basis in handball. One of the most important basic skills is shooting skill. Therefore, it should be trained on and mastered to let the team guarantee ending attacks successfully. The variable of momentum power is in the first rank in the order of the physical capacities in handball. Coaches are well aware of the idea of developing the skillful performance is related to developing physical capacities especially momentum power. The weight of the player is considered as one of the most important physical measures that affects sports performance. The increase of mass of the body (weight) of the player is regarded as one of the muscles capacity obstacles because it is an overload burden (resistance) to both power, speed and performance in the sports activities field that require conducting fast and strong movements as happens in in handball. The problem of the study lies in our ignorance to the role of normal weight and weight categories that are far from it; whether increase or decrease in the performance of momentum power of (arms and legs) and the accuracy of shooting of Junior handball players. Whereas the aims of the study were:

• Knowing the performance level of momentum power (arms and legs) and the shooting accuracy for junior handball players.

• Knowing the differences in the performance of momentum power (arms and legs) and the accuracy of shooting for the junior handball players according to their classification into particular weight categories.

While the sample of the study was represented by (20) junior handball players in the province of Diyala.

The study came up with the following results:

• There is no incorporeal significance differences between the two categories of the weight in the arms and legs momentum power and shooting accuracy.

• The increase found between the two categories of weight compared to the normal weight wasn’t great, but it was normal and within the requirements of handball game.

Keywords: Significance, differences, momentum power and shooting accuracy.

Introduction

The basic skills are considered as the basis in handball. It is also considered as the basic factor to achieve winning in matches. They have a main part in training. Coaches spend long time to get them achieved. One of the most important of these skills is shooting. Therefore, it should be trained on and mastered to let the team guarantee the successful end of the attacks. If a team failed to score a goal, this means that all the teams’ efforts, of helping the player to be in the shooting position, went in vain. In addition to losing the ball and the change of the team from offensive to defensive position. This may be negatively reflected on the spirits
of the players and their performance. Which, eventually, leads the team to lose the match.\(^1\)

The variable of momentum power has the first rank in the order of the physical capacities in handball. Coaches fully understand that the performance skillful improvement is related to developing physical capacity, especially momentum power, because it has a great and principal role in strengthening parts of the body and growing groups of muscles that have principal role in the speed of playing. Because handball player needs the most of his power in the shortest period of time. Thus he will have the ability to shoot powerfully, quickly and jump highly. While in the position of weakness, the player will not be able to master shooting skill, jumping passing to the colleague. League passing to the weakness, the player will not be able to master shooting needs the most skillful performance, because it is the basic factors in developing performance.\(^2\)

Body measurements are considered as the most important specifications of practicing sports activities; because they contribute to perform various basic skills and physical abilities in handball. Player’s weight is one of the most effective variables in sports performance because the increase in the weight of the player is considered as one of the muscles capacity obstacles because it will be additional burden (resistance) on power, speed and performance in the sports activities field that demands conducting quick and powerful movements as it often happens in handball (height and weight (often plays important roles in the success of performing some sports games and activities that are practice days important roles in the such. In this study, the researcher wants to recognize the role of weight of the handball players in performing momentum power and the accuracy of shooting. In that, players are divided in weight category according to whether they are near or far from the normal weight within agreed percentage and depending on the ideal weight and according to the statistical equation for this purpose and here lies the importance of the study, Weight is considered as the most body measurements used in the scientific studies. Thus it is possible that it can be beneficial as one of the physical growth measurement. It is scientifically proved that there is a link between weight and the performance of physical skill and abilities. In some sports activities, increasing in weight is something demanded, while it is considered as an obstacle. g demanded, while it is considered as element. It is scientifically proved that there is a link between and here lies the importance of

the study red as one of the muscles capacity orbs be considered as a valid reference of fatigue.\(^3\)

It is important to know the difference between the ideal weight and the normal weight. The first one is what the individual should, accurately, be it should be in accordance with the height. While the latter is a peek to the specified deviation, the increase or decrease in particular percentage Depending on such percentage, weights of the players are classified into particular weight categories. The problem of the study lies in the idea that we do not know the role of the normal weight and the weight Categories that are far away from it, whether increase or decrease in the performance of the momentum power and the accuracy of shooting for the Junior handball players.

**Objectives of the Study:**

1. Knowing the performance level of momentum power (arms and legs) and the shooting accuracy for junior handball players.

2. Knowing the differences in the performance of momentum power (arms and legs) and the accuracy of shooting for the Junior handball players according to their classification into particular weight categories

**Method of the Study:** Choosing the method of study is one of the important issues in implementing the procedures of the study. Thus, the researcher used the descriptive method of the scanning style, for its suitability to the nature of the problem and aims of the study. While the sample of the study was represented by the junior players of the specialized school in the province of Diyala in handball. They were (20) players.

**Tools and Means used in the study to collect information:**

- Arabic and foreign resources.
- Data processing form.
- Chinese laptop (hp).
- Handball.
- Standard handball court.
- Medical weight scale.
- Measurement ribbon.

**Tests of the Study:**

First, Momentum power test for the arms (pushing medical ball with three Kg weight).\(^4\)
Name of the test. Pushing the medical ball with three Kg weight from the standing position.

**Aim of the test:** Measuring the momentum power of the arms.

Description of the performance. The tested stands behind the first line, pushes the ball forward as strong and fast as he can (momentum power of arms).

Account the score. Each tested is given two attempts, the best of which is recorded the distance is counted by meter

**Second,** Testing the momentum power of the legs (wide leap from stable position):\(^5\)

Aim of the test measuring the momentum power of the legs.

**Tools:** Measurement ribbon, chalk, level floor in order not to let the tested slip. Drawing a line on the floor (start line).

**Method of performance:** The tested stands behind the start line with his legs slightly opened swings the two arms forward backward and backwards, with arched knees to the middle, the trunk should be put forward until he reaches the starting position of swimming. From this position, arms should be swing forward powerfully with stretching legs as the stretching of the trunk. Pushing the floor with the feet powerfully in an attempt of jumping forward as further as he could.

**Measurement:** The distance of the leap is measured from the starting line-up or without touching the floor. The tested is give two attempts the best of which is recorded.

**Third,** Shooting skill tests:\(^6\)

Objective of the test: Measuring the accuracy of Shooting.

**Tools used:** Handball, handball goal drawn on the wall (3 × 2) m and then divided into nine rectangles to measure the accuracy of shooting and draw a line on the ground (9) m away from the goal as in Figure (1).

**Performance method:** The player is shooting from behind the line step by step, taking into account the following:

G- Shooting of the rectangles (9, 7, 3, 1), which represent the angles of the goal, which dimensions (100 × 60) cm get four degrees.

H- Shooting rectangles (8, 2), which represents the area above the head of the goalkeeper and between his feet, which dimensions (100 × 60) cm receive three degrees.

I- Shooting rectangles (6, 4), which represents the extent of the arms of the goalkeeper, which dimensions (100 × 80) cm obtain two degrees.

J- Shooting rectangle (5) represents the area of the chest and the trunk of the goalkeeper, which dimensions (100 × 80) cm obtain one degree.

K- If the ball goes out the player gets zero.

L- Each player performs ten shoots for one attempt only.

**Fourth,** body measurement for the individuals of the sample:\(^7\)

- **Age:** Age data were collected by the direct interview between the researchers and the sample of the study (question and answer) data were recorded in a special form.

- **Height:** The height of all the individuals of sample, who are (20) players, was measured with a metal ribbon fixed on the wall and it’s pointed by the ruler and the player should bare footed. This is so, because we need to measure the height accurately and record it in a special from.

- **Weight:** The weight of the players was measured by an electronic scale. The normal weight of sample players bodies were specified by using the following equation:\(^8\)

\[
\text{The normal weight} = \text{the actual weight – the ideal weight/the ideal weight } \times 100
\]

Using this equation, the percentage mean of increase and decrease was concluded, the percentage was (20-30\%) as an increase or decrease from the normal level. While the normal weight was specified in the percentage of (10\%). The normal weight of all the individuals of sample was concluded according to the following steps:

1. Concluding the ideal weight of each player from special standard table, by which the ideal weight of each player is concluded. This table includes three variables (age, weight and height). In that, each height has an ideal weight in front of it starting from (150) cm and ending in (188) cm. Knowing that this table is for the ages (24) and under.
2. The height and the weight of all the individuals of sample were measured and the equation of the ideal weight was applied using the standard table of the ideal weights.

3. According to step two results the normal weight of all individuals of the sample of the study was concluded. They were categorized into two categories:

A. The first category: includes those individuals whose weights decrease in (10%) from their normal weight. And those are people whose weights have normal increase.

B. The second category: includes those individuals whose weights increase (10%) of their normal weights. Those are called the weight category of (10%) percentage increase, Table (1).

Applying the tests: The researcher applied his tests and measured the momentum power of arms and legs and the accuracy of shooting on the junior handball players who were (20) players. That was on Tuesday and Wednesday 1st and 2nd of October.

Statistical Means: Mean for the identical samples, torsion coefficient, standard deviation and T-test.

Discussions

Table (2) results showed that all the torsion coefficient of momentum power of arms and legs and the accuracy of shooting of handball is limited between (3-) and (3+). This indicates that these results distributed normally. While the results of table (3) showed that T values in all tests were not referent, therefore; there are no incorporeal reference differences between the two categories of the weight in all tests. The reasons behind that is the average of weight increase of the players over the normal level was not great. In that the number of the players in the first category, normal weight, was (9). Players who have increase over the normal weight in (10%) were (11). This means that the real increase happened in the weights of players, was important and necessary. This is so, because the nature and specialty of handball needs strong muscles players that help them in the matches to do the skills, especially shooting and other physical abilities especially the arms and legs momentum. The improvement in the strength of the muscles leads to improvement in the performance level from (8-12) time compared to the athletes who only use the tactical skills. In accomplishing the achievements in the sports games. Here we may have a reality that most researchers emphasized on it is not the increase of weight that makes a burden in all times, but in some sports games like handball; the logical and understandable increase is considered as a necessary issue during the performance, and this what emphasized the momentum power is influenced by the weight.

Conclusions

• There is no incorporeal reference differences between the two categories of the weight in the arms and legs momentum power and shooting accuracy.

• The increase found between the two categories of weight compared to the normal weight wasn’t great, but it was normal and within the requirements of handball game.

Effect of Healthy Training According to Lactic Threshold to Develop Performance Tolerance (Defensive and Offensive) and Some Functions of Blood and Liver for Young Football Players

Fadhil Daham Mansour¹, Khalid Mohammed Ridha², Ahmed Murtada Abdulhussein²

¹Assist. Prof., University of Wasit, ²Lecturer, ³Assis. Prof., University of Kerbala, College of Physical Education and Sport Science, Iraq

Abstract

Anaerobic threshold is barrier between oxygenic action and non-oxygenic action and work is characterized by high intensity and difficulty which causes accumulation of lactic acid in blood and muscles that exceeds ability to get rid of it, which causes pressure on work of body and its inability to continue, then decrease in performance, so researcher prepared exercises according to anaerobic threshold to increase capabilities of players to face causes of tiredness and continue to perform for long time. Research problem concerned with decrease of players performance and their inability to continue to play for a long time in competition without appearance of fatigue. Study aims to prepare drills according to anaerobic threshold to hold out pressure of high-performance level and some functional indicators of blood and liver. Researcher used empirical method that suits with nature of problem. Sample of research identified about (18) young players from Wasit football club and then divided them into two groups (empirical and control group), and he used statistical method like statistical program SPSS to treats search results (AM, standard deviation, Independent sampling codes, interrelated sampling codes). researcher concluded that exercises according to anaerobic threshold contributed to develop performance level which is reflected positively on functional indicators of blood (red and white blood cells, and cortisol), while there was no change in level of liver functions to harmonize training loads with functional abilities of players. researcher recommends dependence on results of tests as indicator and guidebook to regulate training curriculum.

Keywords: Defensive, Offensive, Training, Develop Performance, Blood and Liver.

Introduction

Work of trainers is always aimed at improving performance components of athletes. Thus, sports training is a pivotal and basic process to enhance their physical, skill and planning capabilities according to requirements of specialized activities.

Which is a major goal of work of trainers, which is reflected positively on level of performance of athletes, as it raises level of efficiency to perform its functions, which reflects positively on level and nature and output of sports performance, which is sought by athlete and athlete. Development and high level of athlete and achieving achievement depends greatly on harmony and harmony between physical, functional and functional aspects of body of player and this harmony and harmony does not come normally or coincidence, but adoption of trainers and specialists on scientific planning in proper organization of training and application in form that best results positive to raise level of work and efficiency of work of body of athlete to continue to perform distinctive for a long time without exposure to fatigue. Level of performance in football depends mainly on training and physiological factor as it comes in forefront to influence level of performance, which is closely related to training process and vocabulary, which urges adaptation to body’s vital organs and their ability to resist fatigue. Lactic threshold represents boundary between oxygenation and non-oxygen. Work is characterized by high intensity and difficulty, which causes an increase in accumulation of calories burning waste and a rise in level of lactic acid in muscle and blood beyond ability to get rid of it, state of fatigue and low level of performance, As game of football is characterized
by lack of stability in performance throughout time of
game efficiently without falling down level as changing
attitudes of game and change effort of athlete and to raise
capabilities and capabilities of body of player in a way
that enables them to continue to perform for a longer
period needs to train in proportion to Which requires
efficiency of energy required in accordance with system
of production of energy prevailing is Lactic system,
both at level of defense or attack, which takes an upward
curve in difficulty of performance in view of high level
of competition, As a result of training in all its types and
in all energy systems, changes in level of blood or liver
functions have a clear effect on nature of work of body.

Football is one of games that is characterized by
its performance of constant change and instability.
This means adopting its performance on more than one
system for producing energy and continuing work for a
long period of time. anaerobic energy system is lactic at
most times of game and leaves no residue in muscle or
blood which causes fatigue.

**Research Areas:**

1. Human Field/Players of Alsharqia Youth Football
   Club/Wasit Governorate.

**Research Methodology:** Researcher used
experimental method to suit nature of problem. Experimental approach defines it as a “deliberate and
acceptable change of conditions defined as an accident
and observation of resulting changes in incident itself
and its interpretation (1).

**Society and sample research:** Research community
is determined by players of Eastern football club (18)
players divided into two groups (experimental and
control) with design of equal groups with tribal and
remote tests. Experimental group is trained in accordance
with exercises prepared by researcher while training
control group according to curriculum prepared by
coach, And importance of finding homogeneity among
members of study and to avoid factors that affect results
of experiment and to enable researcher to re-variance
to experimental factor has been adopted measurements
for variables (length - weight - age - training age) and
using value of torsion coefficient of Mispronounce all
indicated that it achieved curve equinoctial ranging from
(± 3) which shows good distribution of sample as shown
in Table (1).

**Means of collection of information and devices
used:** In order to achieve research objectives, researcher
used tools and tools that enable him to obtain information
and data required to solve research problem.

**Arab and foreign sources and references:** Physical
and biochemical tests and measurements, device of
weight and length,Electronic stopwatch Japanese type
Casio - Number (3),Football yard, Soccer Balls Number
(15), Plastic figures - Number (30), Tube keeping blood
contains EDTA, Yapit device for checking serum –
German, Blood measuring device Blood coulter, On step
American-made.

**Pre-Tests:** Researcher carried out tests and pre-
test measurements of blood withdrawal by assistant
medical staff of laboratory of Dr. Muntader al-Saidi on
Wednesday, 28/6/2017 and for groups (experimental and
control). physical test (carrying defensive and offensive
performance) was conducted at (4) 29/6/2017 for sample
of research on stadium of Wasit Sports Club, and in light
of results of tribal measurements, vocabulary of exercises

were placed on threshold of anaerobic differential, which will be applied to experimental group as control group exercises according to curriculum prepared by coach.

**Main experience:** After studying many sources and references in field of sports training and physiotherapy, researcher prepared appropriate training according to lactic threshold, which is based mainly on anaerobic energy system, which is characterized by high intensity and less than maximum using high intensity training and repetitive training as training method. Performance of football is characterized by a repetition of performance, diversification of exercises and adoption of competitive and exciting exercises to increase motivation and desire of players and their training. Training modules prepared by researcher included exercises using different types, metal tracks, barriers, speed training for different distances, as show below:

**Remote tests:** After completion of training program, researcher conducted post-tests on Saturday, 2/9/2017 after completion of training program, where blood was drawn to sample of research at 10 am by medical staff assistant to Dr. Muntader al-Saidi, (Carrying defensive and offensive performance) on Sunday, 3/9/2017 at 3 pm at stadium of Eastern Sports Club. Researcher has done that conditions of remote tests, whether blood extraction or physical testing (carrying defensive and offensive performance) same conditions as tests of tribal sample of research.

**Statistical means:** After completion of implementation of training vocabulary and conduct of remote tests, data obtained by researcher were processed using SPSS program. In following statistical method: AM - Standard division SD - torsion coefficient - test for interrelated samples - independent sample tests).

**Results**

Presentation and analysis of results of tribal and remote tests of functional blood and liver indicators and carrying out defensive and experimental performance of experimental group.

degree of freedom (16) and differences level (0.05)

Table (4) shows results of remote tests of research variables of two groups (experimental and control). In WBC variable we found that experimental mean in experimental group was (7.85) and SD(1.18), while mean of control group (6.82) and SD(1.09) and extraction of calculated value of (2.71), With a score of (16) and a significance level of (0.05) indicating a significant difference in post-test and for benefit of experimental group.

In RBC variable, mean of experimental group was (5.90) and SD(0.38), while control mean of control group (5.52) and SD(0.17) and value of calculated value of (4.22) (12.2) at freedom level (16) and significance level (0.05) indicating a significant difference in post-test and for benefit of experimental group.

In Hb variable we found that experimental mean in experimental group was 14.9 and SD(0.74), mean of control group (14.26) and SD(0.59) and calculation of calculated value of (2.78) (12.2) at freedom level (16) and significance level (0.05) indicating a significant difference in post-test and for benefit of experimental group.

In GOT variable we found that mean of experimental group was (28.80) and SD(1.89) while mean of control group (29.7) and SD(2.11) and extraction of value of (t) calculated (1.32) (12.2) at degree of freedom (16) and level of significance (0.05) indicating that there is no significant difference between two groups (experimental and control).

In GPT variable we found that experimental mean in experimental group was (16.100) and SD(1.256) while mean of control group (17.37) and SD(1.8) and extraction of calculated value (t) of (0.295) (12.2) at degree of freedom (16) and level of significance (0.05) indicating that there is no significant difference between two groups (experimental and control).

Discussion

By examining results of post-test of experimental and control groups as shown in Table (4), we find that there is a significant difference between tests of two groups in variable (WBC) and for benefit of experimental group which means that exercises prepared by researcher according to Latakian threshold, In a timely manner contributed to positive results and increase in size of white blood cells as well as good training age enjoyed by members of research sample helped increase activity of white blood cells, and this is confirmed by Abdul Rahman Abdul Hamid, “increase in activity and
effectiveness of white blood cells have a correlation age of training for athlete as well as appropriate period for that (1).

In RBC variable we find that there is an improvement in level and role of this variable because it is related to tolerance component, which took a lot of space in exercises because football player is in great need of endurance in performance because endurance is base of anaerobic abilities because performance training muscle helps to extract more oxygen and therefore ability to work for a longer period of time. Kamal Jamil-Rabadi, citing (Aklom, 1972), points to an increase in blood volume (1).

In biochemical variables (GoT, GpT) for two groups of research before and after exercises, we find that results are not significant and this means that these variables did not encounter any defect in performance of its role as a result of exposure to training as it is dependent on safety of liver cells and called enzymes Liver, Liver, which arises from special tissues in liver, heart and muscles and at a normal level ranging from (0 - 41) IU/L, level of these enzymes (GoT, GpT) increases in event of a specific defect and physical effort to add burdens on these devices and deductions in endurance exercises and increase burden when there is a defect in formation of training loads, and since exercises that were subjected to members of research sample is Therefore, these enzymes have no problems in performance of their functions and thus found that their forgetfulness is normal in body of athlete, which indicates no significant differences between two groups of research because “high physical activity intensity accompanied by muscle fatigue in muscle, which is evident in pain in muscles and level Technical performance is related In one aspect of extent of change in level of these enzymes and damage in muscle fiber accompanied by an increase in some enzymes with a high specialization such as enzyme (GoT, GpT) (2).

In variable Cortisol Cortisol, we find that there is a significant difference in tests of dimension of two groups of research and for benefit of experimental group and attributed researcher this preference because members of experimental sample were subjected to exercises ranging between high and below maximum, causing physical effort affecting organs of body and cortisol increases during effort Physical “is to provide glucose consumed during physical effort, whether from sources of carbohydrate or non-carbohydrate for provision of energy necessary for muscle work during competition effort, which imposes on athlete a physical effort leads to occurrence of Physiological responses and this is required by neuromuscular compatibility during physical effort (3).

Cortisol is an important component of energy saving during physical and skillful physical activities, as in game of football. Cortisol is increased as a result of high physical exertion and “increased during violent sports activities as it helps to speed metabolism of energy sources (1).

Conclusions
Exercises contributed to increase performance and economy with effort and energy of players, which was reflected on other variables.

Prevalence of Malnutrition in Community-Dwelling Egyptian Elderly

Gehan Refat Mohamed Hefnawy

Assistant Professor, College of Applied Medical Science, Nursing Department, Jouf University, Saudi Arabia, Faculty of Nursing, Geriatric Nursing Department, El-Minia University, Egypt

Abstract

This study aimed to assess Egyptian elder’s nutritional status and determined effect of chronic diseases on elder’s nutritional status. Tools of the study; (1) Socio-demographic & medical data, (2) assessment of the top ten chronic diseases among Egyptian elders, and (3) Mini-Nutritional Assessment (MNA®) screening tool. It’s a prospective, cross-sectional study. The studied sample was 345 Egyptian elders. According sample age (M± SD = 68.06 ± 7.708). They live in the Beni-Suef governorate. The results mentioned that thirty-nine percent of subjects were less than 75Yrs, sixty-two had one chronic disease or more. Twenty percent had hypertension while 0.6% had Alzheimer’s disease. The study shows more than one-third (39.1%) of elders were at risk of malnutrition while about one-quarter (22.9%) were malnourished. There aren’t statistically significant differences between age and nutritional status (P-Value ˃ 0.005). While there is a positive relationship between the presence of chronic diseases in Egyptian elders and their risk of malnutrition with statistically significant differences (P-Value ≤ 0.005). Egyptian elderly had unsatisfactory nutritional status, they need an educational program about therapeutic nutrition according to their health conditions

Keywords: Malnutrition, Elders, Mini-Nutritional Assessment (MNA®).

Introduction

Number of elderly persons is growing rapidly in the world. The global number of elders were 524 million in 2010.1 According to the World Health Organization, it is estimated that there will be approximately 1.2 billion elderly people in 2025, and this figure will reach 2 billion by 2050, about 80% of them living in developing countries.2

The U.S. Census Current Population Report, the older population in the USA were ≥ 65 years will almost double from 43.1 million in 2012 to 83.7 million in 2050.3

Nutrition is an important aspect of health in persons 60 years and above. Malnutrition in the elderly is often under-diagnosed. Malnutrition and risks of malnutrition in the elderly population may have various undesirable results, as prolonging hospital, increasing care costs, decreasing quality of life and increasing mortality rate.4 Careful nutritional assessment is necessary for both the successful diagnosis and development of comprehensive treatment plans for malnutrition in this population.5

Underweight and overweight elderly people (BMI < 19 and BMI > 25, respectively) frequently have a loss of muscle mass, a compromised immune system and have increased complications and premature death.6

Older adults are especially exposed to malnutrition, which often goes undetected and increases the risks of illness and death. The nurse plays a key role in prevention and early intervention of nutritional problems.6

The Mini Nutritional Assessment screening tool is an effective, easily administered tool designed to detect people who have malnutrition or at risk for developing it.7,8

The current study aimed to assess Egyptian elder’s nutritional status and determined effect of chronic diseases on elder’s nutritional status.

Patients and Method

Design: It’s a prospective, cross-sectional study.

Setting of the Study: This study was carried out in geriatric’s clubs in the Beni-Suef governorate in Egypt.

Exclusion Criteria: Elders with cancer diseases were excluded as a group with higher malnutrition risk.

Ethical Consideration: An official approval letter was obtained from the Dean of Faculty of Nursing in Minia University and delivered to the administrator of geriatric’s clubs in the Beni-Suef governorate in Egypt. To get the necessary approval to conduct the study. This letter included permission to collect the necessary data and explain the purpose and nature of the study. Verbal consent was gotten from patients before their sharing in the study.

Data Collection: The data were collected from the beginning of May to the end of September 2019.

Tool of data collection: Researcher developed a structured interview questionnaire based on the review of literature, it consists of three parts;

Tool (1): Socio-demographic and medical data include; (age, sex, level of education, source of income, presence of chronic diseases………).

Tool (2): Mini-Nutritional Assessment MNA® screening tool is used to evaluate the nutritional status of elderly people. The MNA® can be completed in about 15 minutes, published in 1994 by Guigoz, et al. 9

Method of Data Collection: The Mini Nutritional Assessment MNA® screening tool, consisting of a screening phase and an assessment phase.

(a) The screening phase; used as a short form to find patients at risk of malnutrition. It consists of six items: a food intake item, two anthropometric parameters (recent weight loss and body mass index), and three general parameters about mobility, physical and emotional stress, and neuropsychological.

(b) The assessment phase; include anthropometric measure (calf and upper arm circumference), general questions about lifestyle, medication, and mobility, dietary related questions about number of meals, food, and fluid intake, and mode of feeding, and subjective assessment about personal view of health and nutritional status.

The Mini Nutritional Assessment scores of both phases distinguish between elderly person with adequate nutrition (MNA score ≥ 24), at risk of malnutrition (MNA score 17.5-23.5), and protein-calorie malnutrition (MNA < 17).

Statistical analysis: Study data were analyzed using the SPSS 9. Qualitative data were styled as numbers and percentages and quantitative data styled as mean and standard deviation. Qualitative variables were compared by using chi-square test. Comparison between distributed items done through using ANOVA test. Concerning the correlation between quantitative variables was analyzed by calculating the Spearman correlation measurement. Statistical tests of two-sided variables considered significance was set at p < 0.05.

As regard to socio-demographic and medical data of the studied sample, it was found that 60% from them ranged from sixty years to less than seventy-five, 54.2% from them were men, 49.3% were illiterate, 47.2% from villages, 48.7% had one chronic disease and 13.3% had more than one chronic disease.

![Fig. (1): Distribution of top ten chronic diseases among Egyptian elders (n= 345)](image1)

Figure one shows the top ten chronic diseases found in the present studied sample, it was found that 20% of them had hypertension, 17.1% had diabetes, 8.1% had hypertension & diabetes, and 3.2% had romantics diseases, while only 0.6% had Alzheimer’s disease.

![Fig. (2): Total scores of elders’ nutritional status (n= 345)](image2)
Figure two shows the nutritional status of the studied sample, it was found that more than one third (38.0%) were normal and 39.1% at risk of malnutrition while about one quarter (22.9%) of them were malnourished.

*P value ≤ 0.05 = significant differences

Table (2), shows that about two-thirds (64.6%) from Elders with one chronic disease are malnourished while only 19.0% from elders without chronic diseases are malnourished. It shows statistically significant differences between the presence of chronic diseases in Egyptian elders and their nutritional status with statistically significant differences (P-Value ≤ 0.005). While there aren’t statistically significant differences between age and nutritional status (P-Value > 0.005).

It was found that, 44.3% of elders who stay in the nursing home and 36.7% from elders in villages, while only 19.0% from elders in the city are malnourished significant differences between elders’ address and their nutritional status (P-Value ≤ 0.005). While there aren’t statistically significant differences between the level of education of the studied sample and their nutritional status (P-Value > 0.005).

**Discussion**

The present study aimed to assess the nutritional status of the Egyptian elders and to determine effect of chronic diseases on nutritional status.

The current study estimated the top 10 chronic diseases affecting elderly people, it found hypertension is the 1st disease followed by diabetes. This result agrees with Ward and Schiller, 2014 study concerning hypertension while disagreeing with them concerning diabetes which arranged as the 4th disease in elders people.

Our study results confirm that 38% of elders people in Beni-Suef governorate were well-nourished, 39.1% at risk for malnutrition and 22.9% had malnutrition. It’s in the same way of study of Abdelrahman and Elawam, 2012 which found, 44% from Egyptian elders in urban areas were well-nourished, 41.5% at risk of malnutrition and 14.5% were malnourished. Also, the current study agrees with the study of Rashmi, et al., 2015 with a slight difference in percent. They found out of the total of 360 Indian elderly persons, 15% were malnourished and 55% were at risk of malnutrition.
And also, our study results found no relation between the level of education and malnutrition in Egyptian Elders. This disagrees with studies of Abdelrahman and Elawam, 2012\textsuperscript{11} and De Silva, et al., 2017\textsuperscript{13} which found the negative relationship between the level of education and nutritional status.

The current study found that, Egyptian elders living in rural areas suffering from malnutrition. This result agrees with studies of De Silva, et al., 2017\textsuperscript{13} in Sri Lanka and Tamang, et al., 2019\textsuperscript{14} in Nepal which noted that elderly persons living in rural areas had malnutrition more than those in urban. This may be due to low income of elders who live in the village.

**Conclusion**

Egyptian elderly had unsatisfactory nutritional status, more than one-third were at risk for malnutrition and about one quadrant was malnourish. There are statistically significant differences between number of chronic diseases in elderly persons and his/her nutritional status (P-Value $\leq 0.005$). This reflects the persistent need for an educational program about therapeutic nutrition according to their health conditions.

**Limitations:** A limitation of this study is the cross-sectional design, no conclusions can be drawn in line with the cause-effect model. Besides, the study was conducted in one governorate, so its findings could not be generalized to other settings of Egypt.

Abstract

Dengue hemorrhagic fever (DHF) is still a public health problem in the world, including Indonesia. This study aims to determine the relationship of ecological, epidemiological factors with the endemicity status of DHF in Makassar City in 2013. This study used a cross-sectional study design. A sample of 14 sub-districts in Makassar City, South Sulawesi Province, was categorized based on the endemicity status of DHF. Sampling using exhaustive sampling. Data collection is done through secondary data analysis, observation, and documentation. Data were analyzed using the Mann Whitney test. The results showed that the ecological factors associated with the endemicity status of DHF in Makassar City were population density (p <0.05), while the rate of larva free, rainfall, and occupancy density was not related to the endemicity status of DHF (p> 0.05). Therefore, more attention needs to be paid to districts with high population densities and the need to establish trends in the spread of dengue cases based on ecological factors to determine areas prone to dengue fever and their treatment priorities.

Keywords: Dengue Hemorrhagic Fever (DHF), Endemicity, Ecology

Introduction

Dengue hemorrhagic fever (DHF) is still a public health problem in the world, including Indonesia. DHF is an infectious disease caused by the dengue virus and transmitted by the Aedes aegypti mosquito.¹ Around 2.5 billion inhabitants live in dengue-endemic countries, and there is a population at risk of DHF affected by 70% who live in Southeast Asian and Western Pacific Countries. Since 2000, the dengue epidemic has spread to new areas, and in 2003 there were eight countries reporting dengue cases, one of which was Indonesia.²

DHF is an endemic disease in several regions of South Sulawesi, including Makassar City. The number of dengue cases in Makassar City has increased from 223 cases in 2010 to 452 cases in 2012.³

In terms of epidemiology, in addition to host factors and agent factors, environmental factors also influence the incidence of DHF, so an ecological approach to DHF epidemiology is needed in different geographical conditions. Several studies have concluded that ecological factors are related to the epidemiology of DHF. These ecological factors include vectors, climate, topography, and human ecology.⁴

Research related to DHF eco-epidemiological analysis in India found that the main factors affecting DHF outbreaks are climate factors, namely rainfall, temperature, and relative humidity.⁵ Temperature variations that affect variations in efficiency Ae. aegypti is one of the important factors that influence the variation of DHF events.⁶ The existence of environmental
differences, such as differences in vegetation and differences in the presence of predator vectors, also affect the differences in entomological parameters associated with dengue events.\(^{(7)}\)

Analysis of the endemicity status of dengue fever in a region can be associated with disease determinants, which include environmental, geographic and demographic factors. The difference in ecological and geographic conditions in an area also influences the pattern and type of disease, as well as the epidemiology of DHF. Based on the background description, the researcher is interested in studying the relationship of ecological, epidemiological factors with the endemic status of DHF in Makassar City in 2013. By obtaining information on ecological factors related to the DHF endemicity status, it is hoped that DHF control activities can be planned more efficiently and effectively adjusted with the state of the area.

**Method**

This study is an analytic study with a cross-sectional study design to identify environmental factors that are epidemiologically suspected to be directly or indirectly related to the endemicity status of DHF. This research was conducted in Makassar City, South Sulawesi Province, Indonesia. The target population in this study is the eco-epidemiological data and the incidence of DHF in each District/Kelurahan in Makassar City. Exhaustive sampling technique is used for the sampling of this study, namely, 14 districts in Makassar with endemicity and non-endemicity status of DHF in 2010-2012.

The data used in this study are secondary data in the form of dengue case data, climate data, population density data, larvae free data, and base maps of the study area, each obtained from the Health Office, the Meteorology and Geophysics Agency, the Central Statistics Agency, Bakosurtanal, Department of Spatial Planning and Regional Planning Agency of Makassar City area. Data collection is done through secondary data analysis, observation, and documentation. Data were analyzed using the Mann Whitney test to assess the relationship between ecological factors and the endemic status of DHF.

**Results**

**The incident Dengue Hemorrhagic Fever**

Graph 1: Distribution of Dengue Hemorrhagic Fever Cases in 14 Districts in Makassar City in 2010-2012

Graph 1 shows the distribution of dengue cases in Makassar City, which tends to decrease every year. In 2010, the highest incidence of DHF occurred in Rappocini District (12 cases), and the lowest was in three districts namely Mariso, Makassar, and Ujung Pandang District (no cases). In 2011, the highest incidence of DHF occurred in Rappocini District (15 cases), and the lowest occurred in two districts namely Bontoala District and Ujung Tanah District (1 Case). In 2012, the highest incidence of DHF occurred in Biringkanaya District (17 cases), and the lowest was in Ujung Pandang District (no cases).

**DHF Endemicity Status:** Table 1 shows that the sub-districts in Makassar are more dominant with DHF endemic (78.6%).

*Mann Whitney Test

Table 9 shows that the mean rank of larval free numbers in non-endemic DHF areas is higher than in endemic DHF regions. Mann Whitney test results obtained p-value = 0.239, so it was concluded that there was no relationship between larval free rates and DHF endemicity status in Makassar City. Based on rainfall, the mean rank value in DHF endemic regions is lower than in non-endemic DHF regions. Mann Whitney test results obtained p = 0.464, meaning there is no relationship between rainfall and the endemic status of dengue in Makassar City.

The mean rank of population density in non-endemic DHF areas is higher than in endemic DHF regions. Mann Whitney test results obtained p-value = 0.039, so it was concluded that there is a significant relationship between population density with the endemic status of DHF in Makassar City. Based on residential density, the mean rank value in non-endemic DHF areas is lower than in endemic DHF regions. Mann Whitney test results obtained p-value = 0.406, meaning there is no relationship between the density of occupancy with the status of endemicity of dengue in Makassar City.

Discussion

The results of this study indicate that the distribution of dengue cases in Makassar City from 2010 to 2012 tends to decrease every year. Nevertheless, the subdistricts in Makassar City were more dominant in DHF endemic (78.6%), out of a total of 14 districts. Makassar City is a region with a high level of endemicity based on the endemicity level category stated by Marjuki in his research in Malang, which is an area where in the last three years in a row there were more than ten cases/deaths due to DHF. (8)

Based on the results of the Mann Whitney test, it was concluded that ecological factors significantly related to the endemicity status of DHF in 14 districts in Makassar City were population density. The results of this study are in line with research in Denpasar, which states that there is a relationship between population density and the incidence of DHF. (9) This finding is also in line with the results of research in Venezuela which found that population density is positively correlated with the level of DHF endemicity in a region. (10) A denser population will facilitate the transmission of DHF, especially in urban areas, because mosquito flying distances are estimated at 50 to 100 meters. (11) Female mosquitoes can fly as far as two kilometers, but the normal ability is about 40 meters. In densely populated areas with high mosquito distribution, the potential for virus transmission increases and tends towards the formation of an endemic area.

Larvae free rate is the percentage of houses/buildings not found larvae. Free larvae numbers and house index better illustrates the extent of the spread of mosquitoes in an area. The higher Larvae free rate value in an area shows that the incidence of DHF is lower. Research in Medan and Gorontalo found that the presence of larvae inside or outside the home was significantly related to the incidence of DHF. (12, 13) But the two studies are not following the results of this study, which found that there was no relationship between ABJ and DHF endemicity status. The difference in the results of this study can be caused by the number of study samples that are too small. Also, based on ABJ percentage data obtained from the Makassar City Health Office, it can be seen that almost all districts have ABJ percentage values above 80%; even many districts with endemic status have ABJ percentages above 90%. This means that other factors affect endemicity status in each sub-district because even though most of the houses (> 80%) are declared larvae-free, DHF still occurs. So it can be said that there is no significant relationship between the percentage of ABJ with the incidence of DHF.
Similar to larval free numbers, the results of this study also concluded that there was no relationship between rainfall and DHF endemicity status in Makassar City. This study is not in line with research in Thailand, which found that there was a relationship between rainfall and the incidence of DHF.\(^{(14)}\) The difference in the results of this study can occur because the influence of rainfall varies according to the amount of rain and the physical condition of an area. Too much rain will cause flooding, and too little rain will cause drought, resulting in the temporary movement of mosquito breeding sites, so that vector breeding will decrease. Towards the rainy season or the transition, the season is marked by the least frequency of rain, so that there is a puddle of clear water long enough to be a habitat for dengue virus carriers, the Aedes aegypti mosquito.

Dwelling density can facilitate the transmission of DHF from person to person. However, in this study, no relationship was found between occupancy density and DHF endemicity status. This is in line with research conducted in Surabaya which also found no link between the incidence of DHF with occupancy density.\(^{(15)}\) There is no relationship between the density of occupancy and endemicity status of dengue fever can be caused by knowledge and attitudes of urban residents who are better towards a disease and the increasing number of health facilities that are spread evenly and easily accessible by the community, so that if there are family members who suffer from dengue disease then members other families will immediately seek treatment before the disease is transmitted to other family members.

**Conclusions**

This study concludes that the ecological factors associated with the endemicity status of DHF in Makassar City are population density, while the variable rate of larvae free, rainfall, and occupancy density is not related to DHF endemicity status.

Therefore, more attention needs to be paid to districts with high population density and the need to establish trends in the spread of DHF cases based on ecological factors to determine areas prone to DHF as well as to see the achievement of DHF disease prevention programs. Also, it is hoped that there will be an increase in regional-based health problem analysis to make it easier to determine priority priorities and more appropriate preventive measures.

Abstract

Introduction: Until now construction sector is still dominant contributors on workplace accident (WA) in Indonesia. However, there is a limited report analysing the causal factors. Demographic characteristics and work environment are suspected factors to be responsible on this condition.

Objectives: This study aimed to analyse the factors associated with WA occurrence on high building (hotel) construction.

Method: This research has been conducted on 105 workers at a high building construction in Samarinda by one of Indonesian largest construction company. Factors observed were age, working experience, level of education, working time, adherence to a standard operating procedure, health and safety knowledge, health and safety attitude, level of noise, lighting at a workplace, and work fatigue. Cramer’s V test and odds ratio were applied to see an association between the WA occurrence and the factors as well as their level.

Results: During the 11 months construction, 58 WA occurrence were recorded. It is about 55.2% of the whole number of workers. Age \((p=0.000)\), working experience \((p=0.000)\), working time per day \((p=0.001)\), adherence to SOP \((p=0.000)\), lighting exposure \((p=0.03)\) and health and safety knowledge \((p=0.000)\) showed significance correlation on the WA occurrence.

Conclusions: Construction sector is still high risk work sector in Indonesia. Demographic characteristic (age, working experience and health safety knowledge) and working environment (working time, adherence of SOP, lighting exposure) are essential factors need to be considered to overcome the WA occurrence in high building construction.

Keywords: High building, hotel, workplace accident, work environment, Samarinda.

Introduction

Construction sector plays an essential role in the economy of a country because its significant contributions to the gross domestic product.¹ ³ However, it belongs to a high-risk job in developing countries cause of its high rate of workplace accident (WA) contribution.⁴ ⁶ ⁷ The construction WA are quite high in Malaysia,⁴ Thailand,⁸ Uganda² and Iran.⁸ Similarly, the construction sector in Indonesia is the highest contributors to WA with the number of 32% compared to other sectors.¹⁰ Manufacturing, transportation, forestry, mining industries, and other sectors, were accounted for 31.6, 9.3, 3.8, 2.6, and 21%, Several factors related to WA in construction are an inadequate in providing resources for safety and operational procedure, unsafe act, failures in constructed site management, age of workers, work experience, gender, length of service, work location, and climatic zones, workers’ negligence, failure too bey work
procedures, work at high elevation, operating equipment without safety devices, poor site management, harsh work operation, low knowledge and skill level of workers, failure to use personal protective equipment and poor workers attitude about safety, and poor safety culture.\textsuperscript{8,11} Construction factors associated to reduce the WA occurrence in the construction sector in developing countries, including Indonesia. This study aimed to analyse the factors associated with WA in construction sector. This finding is advantageous to overcome the problem by identifying and evaluating the parameters associated with WA in high building construction.

**Material and Method**

This research was conducted from Dec 2017 until Oct 2018 at a high building (hotel) construction in Samarinda by one of the largest Indonesian construction companies. Proportional random sampling was applied to get a total of 105 respondents with various duties of work. The hotel has 12 floors, one semi-basement, 174 rooms, five meeting rooms, a ballroom, a town hall restaurant, a swimming pool, a gym, and a spa counter.

Age, working period, education level, working time, occupational health and safety (OHS) knowledge and attitude were measured by questionnaires.\textsuperscript{17,18} Work fatigue was measured by IFRC’s Subjective feelings of fatigue.\textsuperscript{19,20} The adherence of standard operating procedure standard operating procedure (SOP) and WA was measured by interview and direct observation. The level of noise exposure and lighting at the workplace were measured by sound level and lux meter, respectively. Cramer’s V and odds ratio\textsuperscript{21,22} were applied to analyse the correlation and the association level between the WA occurrence and its related factors.

**Results**

The construction workers are most young (17-41 years, 82.80%). Senior and Seconadry High School (70%) are the dominant education background level of the workers. Many workers (63.81%) have working experience of 1-8 years (Table 1). Number of workers (62.86%) have working time of more than 8 hours per day, 65.71% adhered to SOP, 16.19% exposed to noise above threshold limit value 85 dB, 69.52% with work with illumination <100lux, 56.19% have good OHS knowledge, 86.67% showed favourable OHS attitudes and 69.52% have experienced moderate fatigue (Table 1).

During this study, number of WA occurrence accounted at 55.2%, in which most occurred during the day (37%). WA types often took place were hit by a hammer and punctured by spikes with the number of 20.0 and 17.1%, respectively (Table 2.)

**Discussion**

**Association between demographic characteristics and WA:** Age and working experience are often used as hypotheses in analysing of WA, several studies reported different results on young and elder workers of dimensions of incidence, severity, type of accident and type of injury. In this study, which the worker is dominated by young workers shown that age and working experience were significantly related to WA. This result is inline with previous studies.13,14,20,23,24

By levelling of age and working experience to 2 categories (young workers: 17-41 years and elder workers: > 41-63 years; Low work experience: 1-16 years and high work experience: > 16-26 year), the young workers and low working experience workers have twice and 3 times higher on WA risk compared to those elder and high work experience workers, respectively. This study are in accordance with previous study, which reported that young workers were found to be accidents due to carelessness and lack of experience, although physically have a higher reaction and agility.24 The working time of > 8 hours per day run the WA risk of 1.5 times higher than the less working time. Long working time will lead to work fatigue and will have an impact on occupational accidents.25,26

Level of workers education affects the perceptions of workers’ OHS, which later affected on OHS behaviour and incidence of occupational accidents.21 However, in this study, the education level of workers isn’t associated with the WA.

**Association between the working environment and WA**

**Adherence to the SOP:** The results prove that workers compliance to SOP associated with WA. This result emphasises the previous study that the most significant contributor to the cause of the WA is risky behaviour. One type of unsafe behaviour in the workplace is ignoring SOP.28 The workers who disobey work procedures have a risk of experiencing WA 12 times more than SOP-compliant workers.

**Noise exposure and lighting at the workplace:** In this study, most respondents (83.3%) were exposed to noise but still below the threshold limit value (TLV) (85 dB for 8 hours per day). Many studies have concluded that noise exposure reduces the listening ability, lowers alertness and ultimately increases hearing loss and occupational injury risks.29,30 However, in this study, noise exposure isn’t significantly related to occupational accidents; this is probably due to only a small proportion (16.2%) of respondents exposed to noise over the threshold value.

It is found that lighting in the workplace is significantly related to WA. The results of this study reinforce previous research that concluded physical factors at the workplace such as noise, vibration, light, thermal climate and radiation are not merely mean that it will only affect an individual physically but can also have a significant impact on wellbeing and comfort, performance and the risk of an accident.31 The workers, who didn’t expose to light at the TLV, have risk to WA 1.5 times higher than those exposed to light at TLV.

**OHS knowledge and attitude:** Respondents’ knowledge of OHS was mostly good (56.2%), and statistically significant with workplace accidents. This result reinforces previous research that the knowledge of OHS has a significant effect on safety performance. Knowledge are variables that need to be analysed in work behaviour because of its powerful influence on work behaviour, which can affect individual perception, risk assessment, and decision making.32,33 The workers with low OHS knowledge are at risk of WA experiencing 6 times higher than those with high OHS knowledge.

Attitudes of workers toward OHS at work mostly favourable (86.7%), but no associated with the occupational accident. As revealed previously, the attitude was one part of the individual factors influencing risky behaviour and accidents on construction sites. Workers who have been trained and have proper knowledge of his work but still decided to commit unsafe acts, won’t be free of workplace accidents unless they change their attitude.34-36

**Work Fatigue:** Most construction workers experienced mild work fatigue (69.5%), but statistically wasn’t related to workplace accidents. Previous research concluded that occupational fatigue is a potential hazard in the workplace that affects the decreased ability to think logically and decrease the response to danger, and this can lead to workplace accidents,25,35,37 but in this study, it wasn’t proven yet.

**Conclusions and Recommendations**

WA in high building construction in Indonesia, was high as 55.2% of workers had experienced with WA.
62.9% of the WA occurred during the night shift. Age, working experience, working time, adherence of SOP, lighting in the workplace, and knowledge of OHS were associated significantly to the WA incidents. These findings highlight that construction management should give more attention to demographic characteristics and work environment to improve the safety work in high building construction in Indonesia.

Developmental Initiatives for Person with Disabilities: 
Appraisal on Village Based Rehabilitation of 
Amar Seva Sangam

K.M. Ashifa

Asst. Professor, Department of Social Service, Faculty of Health Science, Istanbul Gelisim University- Istanbul

Abstract

Disability is the type of impairment. Person with disabilities is the people who are physically and mentally affected with some of the impairment whether it may be partial or temporary. It significantly distresses a person’s life happenings and might be current since birth or else arise during a person’s period. Formation of Self-Help Groups is a major approach used to facilitate target population work as a single unit with greater bargaining power. Disabled persons are giving various developmental initiatives to uplift their livelihood. Factually, people with disabilities partake mostly remained on condition that for concluded resolutions that separate out them, such as housing organizations and special schools. Policy consumes now a days removed in the direction of public and educational insertion, and medically intensive solutions have given mode to extra collaborating method recognizing that people remain disabled by eco-friendly issues as fine as by their bodies. This study developmental initiative among person with disabilities was chosen by how they are facing problems in the society, their livelihood needs and how they are excluded from the society. This study aims to identify the needs and their difficulties that are faced in the society and helps to solve them. This study also reveals the exclusion of person with disabilities in the current scenario. This study finally helps to solve the problems of the disabled and provides some developmental initiatives for the livelihood.

Keywords: Disability, Livelihood, Development, Initiatives.

Introduction

Disability is an impairment that might be intellectual, growing, knowledgeable, mental, physical, and sensory or around grouping of these. It significantly marks a person’s life actions and might be existing from birth or happen through a person’s generation. Factually, people with disabilities partake mostly remained on condition that for concluded resolutions that separate out them, such as housing organizations and special schools. Policy consumes nowadays removed in the direction of public and educational insertion, and medically intensive solutions have given mode to extra collaborating method recognizing that people remain disabled by eco-friendly issues as fine as by their bodies. Nationwide and worldwide inventiveness – such by way of the United Nations Standard Rules on the Equalization of Occasions of Peoples with Disabilities– partake combined the human rights of people with disabilities, concluding in 2006 with the implementation of the United Nations Convention on the Rights of Peoples with Disabilities (CRPD). Replies to disability have altered since the 1970s, provoked mainly via the self-organization of people with disabilities, and through the rising propensity to get disability as a human rights problem. Exclusion of any type disconnects individuals from social relations and puts a limit on their full participation in the activities that are assigned by society according to norms and conventions.

Disability: Conceptual Frame: According to World Health Organization’s International Classification of impairments, disabilities, and handicap impairment is defined as a disturbance affecting functions that are essentially mental (memory, consciousness) or sensory, internal organs (heart, kidney), the head, the trunk or the limbs. Disability is a restriction or inability to perform an activity in the manner or within the range considered normal for a human being, mostly resulting from the impairment. Handicap is the result of an impairment.
or disability that limits or prevents the fulfillment of one or several roles regarded as normal, depending on age, sex and social and cultural factors.\(^{(1)}\)

**Causative Factors:** Disability is a major cause of social exclusion and it is both the cause and consequence of poverty (Department for International Development, 2000)\(^{(2)}\). The World Bank studies contended that half a billion people with disabilities are undeniably amongst the poorest of the poor\(^{(4)}\) and are estimated to 15 to 20 percent of the poorest in developing countries\(^{(3)}\). Study projected that the motor disability counts the second highest percentage of disability, it is perhaps the most neglected as it is often felt that this group does not need any special care or attention like the other categories (viz. visual, mental, hearing impaired) and thus characterized as an underrepresented group in the disability movement\(^{(10)}\). The causes of disabilities mainly vary according to different age groups, although there are differences between males and females\(^{(6)}\). It is also important to note that the causes of disability differ according to the type of disability, regions and other background characteristics a person belongs to\(^{(8)}\).

**Review of Literature:** Seventy million people in India cannot step out of their homes because of an inaccessible physical infrastructure and transport system, thus reducing them to families for sustenance and are a burden on society. Accessible infrastructure will enable people with disabilities to get education, employment, and dignity\(^{(7)}\). Access to public transport, toilets, hospitals, government offices, public spaces like parks, educational institutions, places of worship are still inaccessible\(^{(15)}\). The areas like education, teaching aids, books in Braille and interpreters for the hearing and speech impaired are still not available to large sections of the disabled\(^{(9)}\). According to Rao, while disability causes poverty, it is also possible that in a country like India, poverty causes disability\(^{(14)}\). The combination of poverty and disability results in a condition of “simultaneous deprivation.”\(^{(10)}\)

According to Harris-White, this is a syndrome that sets up barriers to the participation of persons with disabilities in the normal routines and activities of the community, including regular schooling\(^{(13)}\). The unreliability of data on the educational participation of children with disabilities is marked- both in terms of estimates in the school going age group and indeed the numbers actually attending school\(^{(12)}\). Not more than 4 percent of children with disabilities have access to education\(^{(11)}\).

A majority of the disabled resides in rural areas where accessibility, availability, and utilization of rehabilitation services and its cost effectiveness are the major issues to be considered\(^{(17)}\). Despite reservation for persons with disabled in employment, the employment rate in India is relatively low compared to that of the all-India working age population, with great variations across gender, the urban/rural sectors and states\(^{(13)}\). Persons with disability suffer from both social and material disability. The society, which is caught up with uniformity, cannot see people with differences with the same eye\(^{(12)}\). For the 40-60 million people with mental and physical disabilities in India, discrimination and stigma are daily occurrences. In a country where social standing including through marriage is crucial, having a disability often means being relegated to the bottom of the pile\(^{(10)}\). Problems of Women with Disability Women and girls with disabled are of all ages, all racial, ethnic, religious, and socioeconomic backgrounds and sexual orientations; they live in rural, urban and suburban communities\(^{(5)}\). Women and girls live at the corner of disability and womanhood with two multiple barriers to achieving their life goals\(^{(8)}\). While many women derive enormous strength, resilience and creativity from their multiple identities, they also face the consequences of discrimination\(^{(9)}\). They are seen imperfect, incomplete, inferior, asexual, and non-productive and denial recognition as women and human beings\(^{(8)}\).

**Objectives of the Study:** This study is made to profile initiatives of Amar sevasangam which is the Amar Seva Sangam is a premier institution in the field of Disability Management in the country, to assess the effectiveness developmental initiative for person with disabilities by Amar Seva Sangam and to analyze the role of village based rehabilitation to enhance the livelihood of person with disabilities.

**Method of Study:** Both qualitative and quantitative method is used. Survey method was used for the study. In order to gather information on the effectiveness of Amar Seva Sangam researcher conducted survey among the person with disabilities. A focus group discussion has conducted and self help group’s members to get improvement for growth factor on availability, accessibility, flexibility and reachability of government policies and development of Amar Seva Sangam. The researcher used two types of tools for data collection; they are Interview Schedule and Focus Group Discussion format.
Result and Discussion

The study on the developmental initiatives of person with disabilities has been carried in Amar Seva Sangam. It also covers the various developmental initiatives that are undertaken by the state and central government and the organization in which they implement that policies and programmes for them. It shows the various measures that are undertaken for the person with disabilities through the organization. The respondents were having busy schedule in their work which made their availability for data collection very difficult.

Developmental Initiatives: It indicates the effectiveness of developmental initiatives by Amar Seva Sangam for the development of person with disability. Majority of the respondents (55 percent) opined that Amar Seva Sangam is giving equipment disable people and 73 percent of them opined that they are getting periodical training and training for livelihood among person with disability (based on the opinion of 78 percent). 54 percent of the respondents are aware of their rights and they are also aware of various welfare schemes and policies for the better livelihood among the person with disability. According to the responses of 83 percent and 80 percent of the respondents they are being safe and free from exploitation and abuse and also getting Barrier Free Environment respectively. Participation in social gathering and recreational activities is common phenomena, it based on the opinion of 64 percent of the respondents.

Role of Self Help Group for development of person with disability: It indicates the role of village based rehabilitation of person with disability especially based on the activities of Self Help Group. Majority of the respondents (79 percent) aware of developmental initiatives and 68 percent are involved in the advocacy activities. 52 percent are opined that they not availed loans and because of the conventional fear in loans. But 41 percent are availed loans and 43 percent are saying yes for appreciation of repayment of loans. According to the opinion of 54, their jobs are supporting for their and also activities in Self Help Group also support for personality development of its members. Economic aspects of the women soap opera viewers. 78 percent of the respondents preferring to watch serial because of luxury interiors. 65 percent of soap opera viewers have greediness to get a luxurious life as like serials. 77 percent have an inferior feeling once seeing the luxurious life in serials. 69 percent are attracted by the urban city life which shown in the serials rarely. 82 percent of them have spendthrift attitude due to regular watching of serials and self motive aspects in serials is very rare, according to the opinion of 82 percent of the respondents.

A structural text modeling was developed based on the opinion raised during focused group discussion among the person with disability in order to analyzing effectiveness of developmental initiatives of Amar Seva Sangam towards the availability, accessibility, reachability and flexibility of initiatives. There are many initiatives are taken by Amar Seva Sangam which was very accessible and available to the disabled in which they are involved very much. The Vocational training organized by the organization are very much accessible, flexible, available and also reachable to the needy. The representation in group of disabled people are very much eager to develop participation and involvement in activities, which was accessible, flexible, available and reachable and it help them to implement new plans and programmes. Amar Seva Sangam are giving loans generating self employment and it leads to transparency.
by means of accessible, flexible, available and reachable of initiatives. Amar Seva Sangam was very helpful for them in getting many benefits given by government and number of persons getting rehabilitation which was more accessible, flexible, available and reachable. The disabled people participation was very high in group activities and the Amar Seva Sangam very much appreciate the involvement. Based on the opinion of the respondents the equipments, aids and appliances are accessible, flexible, available and reachable to the disabled people. Amar Seva Sangam was providing training and developments for disabled people for their livelihood programmes and Introducing new plans and schemes for welfare. Medical camps for needy, periodical training programmes and loan facilities for generating self employment were the regular phenomena of Amar Seva Sangam. It showed the effectiveness of Amar Seva Sangam activities are very much accessible to target group, it is available for purpose, flexible according to the situation and also reachable to right hands.

Conclusion

Disability is not mutually agreed, similar to gender; it is collectively collected from universal truth. The major causes of disability contain a contact at individual; interpersonal, relations and community levels. The researcher carried out an elaborate study on various factors related to disabilities, its causative factors, cognitive factors, various policies by government and developmental initiatives of Amar Seva Sangam especially village based rehabilitation. The study was conducted in four main blocks of Thirunelveli district. The study revealed that disabled people are not aware of the government policies and programmes due to bureaucratic corruption and lack of support from the government officials. So the government policies and programmes for person with disability were not much accessible, available, and also not reachable to the needy. The study further analyzed the effectiveness of Amar Seva Sangam’s developmental initiatives and it is revealed that, developmental activities of Amar Seva Sangam have been very effective and appreciable in sustainable developmental aspects to enhance the livelihood of the person with disabilities than government implementations. So this study helps in promoting effectual actions for obstacle of disability and for remedy of the disable people to develop.

Study the Composition of Fatty Acids in Blood Serum Parts During the Fasting Month (Ramadan)

Mohammed A.H. Alobeady1, Raghad A.A. Al Hialy2

1Asst. Professor; 2Lecturer, Chemistry Department, College of Education for Pure Science, University of Mosul

Abstract

This study dealt with the measurement of several variables in the blood serum for a group of people in the case of fasting (Ramadan) for (14-16) hours, where the blood serum was withdrawn from people during daylight hours after fasting (5-8) hours and then follow the same people after (15) days of fasting and then after (25) days as well as blood serum samples were collected for the same people one month after the end of the month of Ramadan and the age of people ranged between (19-80) years and both sexes (males and females) are healthy people and do not suffer from any apparent disease. The study focused on measuring the percentage of fatty acids in the three segments separated from serum (cholesterol ester, triglyceride and phospholipids) which were separated by thin layer chromatography and then the esterification of the separated fatty acids was carried out using (BF3/methanol) method. Percentage of fatty acids (SFA, MUFA and PUFA) using a capillary gas chromatography device The results of this study indicated a significant increase in the percentage of saturated fatty acids, a non-significant decrease in the percentage of monounsaturated fatty acids, and a non-significant decrease in the percentage of polyunsaturated fatty acids in The serum cholesterol ester portion of the fasting group compared with the control group The results of this study indicated a significant increase in the percentage (SFA), a non-significant decrease in the percentage (MUFA), and a non-significant increase in the percentage (PUFA) in the Tricyclic serum for serum group The results of this study showed a significant increase in the percentage (SFA), a significant decrease in the percentage (MUFA), and a significant non-significant decrease in the percentage (PUFA) in the serum phosphate fat portion of the fasting group compared with Control group.

Keywords: Fatty acids, cholesterol ester, fasting, saturated fatty acid.

Introduction

This study was designed to identify the effect of fasting on the level of chemotactic variables and the percentage of fatty acids in serum. Fasting is an integral part of many religions in terms of the pattern, duration and limits of fasting that differ between different religions [1], and fasting in biochemical conditions is to refrain from eating calories for (12-14) hours (2). Ramadan is the ninth month of the Islamic calendar during this month and it is expected that all healthy adult Muslims, males and females abstain from foods, liquids, oral medications and smoking from dawn to sunset and this type of fasting is addressed in our study, which lasts (29 to 30 days) [3] Fasting affects many metabolic processes in the human body and physiological indicators return to normal after the end of the month of fasting, indicating the safety of fasting for healthy people. [1] The human diet is a complex mixture of reactive components that cumulatively affect health [2], and fast e An excellent model of how dietary modifications affect lipid profile [3]. Studies have shown beneficial changes in serum on chemotactic variables in terms of high variables (HDL) and low variables (TG, TC, LDL) that are considered to be the main risk factors For coronary heart disease and cerebro vascular disease [4] diet modification (fasting) is a treatment for hyperlipidemia and is also taken in conjunction with drug therapy in people with coronary heart disease risk. Fasting also affects the percentages of fatty acids in the three parts of the blood serum, as this effect is positive and the percentage of fatty acids with different varieties is balanced in the three parts of the blood serum. [1].

Materials and Method

Blood samples were collected for healthy people who were fasting after a period days and then follow
up the people themselves after (20) days of fasting and control group where the samples were collected for the period (17/5-16/6 (2018), where (5) milliliters of blood was withdrawn for each person and then the samples are left for Serum is separated. After that, the serum divided into two parts.

Section 1: Measurement GLU, TC, HDL, LDL, TG, PL by Kits and VLDL was theoretically calculate.

The second section kept in freezing at (-18)°C until the start of the analysis of fatty acids.

The percentage of fatty acids of the three parts of the serum (CE, PL and TG) was measured after the separation of each of the three parts using (TLC) technique. These parts are distributed on the used silica gel plate resulting from the separation of serum components blood using a solvent system consisting of (hexane/ether/formic acid) in percentages (2:20:80) (V/V/V).[5]

The fatty acids are then re-esterified for each of the three previously separated parts using BF3/Methanol (16%) [6], and then diagnosis and analysis of the percentage of fatty acids for each part using standard models.

Percentage of fatty acids: The serum fatty acid content of the above three components was estimated by means of injecting (1) micro-liters of the model prepared for measurement in the (CGC)[7] Figure (1) shows the graph resulting from the analysis and measurement of the ratio of (23) fatty acid standard using the device (CGC).

Statistical Analysis: The results were analyzed for the levels of chemotherapeutic variables (Glu, TC, LDL, HDL, VLDL, TG and PL) as well as percentage analysis of fatty acids in the three segments separated from serum lipids. Blood using t-test for groups of equal number and different totals to compare the results of people fasting with the control group in general, where the acceptable probability level is (P> 0.05)[8].

Results and Discussion

The results of this study showed a significant decrease in (Glu) concentration in the fasting group compared with the control group. This may be attributed to lower calorie intake during Ramadan compared to other months as well as the nature of muscular effort and sleep during fasting month. [9] The results indicated a significant decrease in (TC) concentration in the fasting group compared to the control group. This is consistent with several studies that indicated this decrease during fasting. Insulin sensitivity. The results also indicated a significant increase in (HDL-C) level in the fasting group compared to the control group. This corresponds to several studies in the case of fasting. The role of hepatic lipase, which controls the level of (HDL-C) and during fasting, is an increase in the effectiveness of hepatic lipase which leads to an increase in the level of this type of cholesterol during the fasting period and low level of (TC) [10]. This study indicated a significant decrease in (LDL-C) level in the fasting group compared with the control group. This corresponds to a number of studies that indicated the possibility of (LDL-C) level during the fasting period[11]. There was a significant decrease in the (TG) in serum in the fasting group compared with the control group. This can be due to the nature of food intake during the fasting period as the concentration of this type of fat depends on the level of neutral triglycerides, which are directly related to the food [12]. (LDL/HDL) is
an important clinical indicators to diagnose the risk of disease Cardiovascular \[13\]. The increase or decrease in this ratio is an indication of the progression of metabolic processes within the normal level and the normal ratio should be less than 3.3 \[14\]. The ratio (TC/HDL) refers to this ratio The risk of developing cardiovascular disease and its probability of occurrence is more specific than the total cholesterol level of serum \[15\]. The results of this study indicated a significant decrease in this percentage of the total fasting compared with the control group, and the ratio (TG/HDL) This is one of the important indicators on the occurrence of atherosclerosis and the higher this percentage increased the probability of developing atherosclerosis \[16\]. The results of this study showed a significant decrease in this ratio in the fasting group compared to the control group. This indicates the usefulness Fasting affecting the insulin level The results of this study indicated a significant decrease in (PL) in the fasting group compared to the control group. The hepatic lipase enzyme is effective during fasting, leading to increased lipolysis in general and phospholipids in particular \[17\] all results shown in Table (2).

**Fatty acids in the cholesterol ester:** The results of this study showed a significant increase in the percentage of (SFA) for the fasting group compared with the control group. A significant decrease in the percentage of (MUFA) for the fasting group compared with the control group. There was a significant decrease in the ratio of (PUFA) to the fasting group compared to the control group as shown in Fig. 2 and Table 3. Lipid triglycerides in adipose tissue (ATGL) that oxidize and metabolize fats, especially cholesterol ester and triglycerides in adipose tissue \[18\] [19]. Located in For food with their serum levels and give an indication of the usefulness of fasting in affecting the proportion of fatty acids of all kinds in this part of the blood serum \[20\] [21].

* Mean±SD

**Fatty acids in the triglyceride:** The results of this study indicated a significant increase in (SFA) for the fasting group compared with the control group as . This may be due to insulin sensitivity during the fasting period. There is an inverse relationship between insulin sensitivity and fatty acid level \[22\]. This is due to the effect of fasting on a number of specific enzymes. By removing saturation and elongation which plays an important role in increasing . This may be due largely to food intake in addition to The effect of fasting on enzymes that regulate lipolysis \[23\] which leads to the formation of a greater percentage of polyunsaturated fatty acids through increased fat oxidation and de-saturation of some short-
chain acids and converted to long chain (PUFA) and this corresponds to a number of recent studies in the field of fasting.\textsuperscript{[24]} The percentage of fatty acids indicates and its installed in triple part of the serum in general to the amount of fatty acids within the existing food intake, as the proportion of fatty acids in this part of the blood serum are highly correlated associated with the nature and the amount of fatty acids present in the intake of food during the fasting period.\textsuperscript{[25]}

**Fatty Acids in the Phospholipids:** The results of this study indicated a significant increase in the (SFA) of the fasting group compared with the control group. This may be due to the role of the liver during the fasting process as the liver plays an essential role in the formation or demolition of this type of phospholipids by controlling the amount of (SFA) entering or exiting the blood serum to the liver, which affects the percentage of this type of acid as the process of demolition of fat increases during the fasting period and the liver plays a major role in this process\textsuperscript{[26]} and to The presence of a significant decrease in the level of fatty acids This may be attributed to the fact that fasting affects the body mass rate in the first stage by activating the activity of the enzyme lipoprotein lipase and thus affecting the rate of formation of triglycerides. The results of this study indicated that there was increase in the percentage of fatty acid (22: 2n6) of serum dimple, fasting group compared with the total. This can be attributed to insulin sensitivity, which in turn affects the action of desaturating enzymes, since the action of these enzymes is closely related to The results of this study indicated that there is a variation in the percentage of fatty acids in this part of the blood serum compared ester cholesterol and triglycerides, which is consistent with many studies in this area. As the proportion of fatty acids in this part of the blood serum\textsuperscript{[27]} It is an indication of the importance of fasting by increasing compatibility and hepatogenesis of both (SFA), especially fatty acid (16: 0) and (PUFA) n: 3, as phospholipids are a good vector for recycling fatty acid of fatty proteins it promotes the health of the body through the redistribution and transmission of fatty acids between different parts of the serum.\textsuperscript{[28]}

**Conclusions**

1. The study indicated a significant decrease in serum(TC) level in the fasting group compared to the control group, which indicates the usefulness of fasting in reducing the risk of high serum cholesterol. High serum cholesterol leads to an increased risk of heart disease and atherosclerosis.
2. The study indicated a significant rise in (HDL) level and a significant decrease in LDL level. This proves the role of fasting in controlling metabolism in general and fat metabolism in particular. The body fats fat during fasting as a major source of energy during the fasting period and then the body returns to normal after breakfast.
3. The study indicated the effect of fasting on the level of fatty acids (PUFA/MUFA/SFA) in the three parts of the serum where the effects were different from high percentage of fatty acids and low percentage of (MUFA). The multicomponent compared with control groups demonstrating the role of fasting in influencing the metabolism of all types of fatty acids in different parts of the serum.

Effects of Paan Dependence and the Attitude-Social Influence-Self Efficacy (ASE) Model on Paan-Use Cessation Intention among Bangladeshi Women

Park, Hye Ok¹, Kim, Young Im²

¹Graduate student, Dept. of Nursing, Korea National Open University, ²Professor, Dept. of Nursing, KNOU

Abstract

Background/Objectives: This study aimed to identify the factors influencing paan-use cessation intention (PUCI) among Bangladeshi women to obtain basic data for the development of paan-use cessation (PUC) programs.

Method/Statistical analysis: 173 Bangladeshi women participated in the study between May and June 2019. Data were analyzed using descriptive statistics, chi-square, factor analysis, t-test, and logistic regression analysis.

Findings: Among participants, 54.3% had PUCI. Factors influencing PUCI were attempt at PUC in the past year, recognizing the need for education on PUC, PUC attitude, and secondary dependence motives.

Improvements/Applications: Customized PUC programs should be developed based on Bangladesh women’s demographic and paan-use characteristics, actively encouraging attitude formation related to PUC.

Keywords: Chewing tobacco, tobacco dependence, tobacco use cessation, intention, Bangladeshi women.

Introduction

Paan refers to betel quid chewing. It is estimated that approximately 10-20% of the global population use paan. Bangladesh has very high paan-use rates, in particular, showing higher rates among women than men.

Paan is known to be highly addictive, and contains nicotine, harmful substances and carcinogens, having a negative impact on pregnancy and childbirth. Therefore, paan use among Bangladeshi women affects not only their own health but that of the following generation, which highlights the urgent need for PUC.

Existing studies on paan use in Bangladesh have focused on identifying paan use rates, harmfulness of paan, and demographic characteristics related to paan use, which demonstrates that paan, unlike cigarettes, is socially accepted in Bangladesh.

Previous studies on smoking have shown that smoking-cessation intention plays an important mediating role, eventually leading to actual smoking cessation. Smoking-cessation intention in Trantheoretical model (TTM) is a predictor of success in smoking cessation. Thus, the more smoking-cessation intention, the more likely people intend to attempt to stop smoking. From this perspective, it is important to identify the level of paan dependence, PUCI, and factors influencing such intention for successful PUC among Bangladeshi women.

The ASE model is suitable for identifying health-promotion-related behaviors and intentions for such behaviors and has been used for studies on smoking-cessation intention and areca nut chewing among Taiwanese adolescents and college students as well as predicting the intention to quit school. Based on these studies, the effectiveness of the ASE model has been adequately validated.

This study aimed to establish basic data for the development of PUC programs and measures to promote PUC among Bangladeshi women.
The specific objectives were to:
1. Identify paan dependence, ASE model factors, and PUCI among Bangladeshi women.
2. Identify PUCI according to the general characteristics of participants (demographics and characteristics related to paan use and cessation).
3. Identify associations of PUCI with ASE factors and paan dependence.
4. Identify the factors influencing PUCI.

Materials and Method

This study involved a descriptive study of Bangladeshi women who used paan aiming to identify the influence of paan dependence and ASE model factors on PUCI.

Theoretical Framework: To determine potential factors influencing PUCI, general characteristics included demographics showing differences regarding paan use rate\textsuperscript{[12]} as well as paan use, which dependence increases with use\textsuperscript{[2]}, and PUC characteristics influencing PUCI.

Panan dependence represents desire and repeat of paan use, classified as positive dependence motives (PDMs): loss of control/craving and etc., and secondary dependence motives (SDMs): affective enhancement and etc.\textsuperscript{[13]}.

In the ASE model, attitude refers to making a positive or negative assessment for PUC\textsuperscript{[7]}. Social influence contains both social norms, modeling and social support from their families or peers for PUC\textsuperscript{[14]}. Self-efficacy refers to the confidence that an individual can perform PUC\textsuperscript{[15]}. Meanwhile, PUCI refers to the willingness to quit using paan in the near future; in the present study, this was assessed with “I will quit paan sometime in the future,” which was answered as “yes/no.”

Research Participants and Data Collection: Participants in this study were women aged 18–59 years using paan for at least 6 months in the impoverished region of Dhaka. The required sample size was calculated with G*Power 3.1, based on a significance level of .05, statistical power of .95, and effect size of .15. Considering a drop-out rate of 20\%, questionnaires were distributed to 192 women. Excluded containing invalid responses, as a result, 173 questionnaires were used in the final analysis. Data were collected between May and June 2019 using a self-report questionnaire. Participants provided written informed consent. For illiterate participants, the questions were read to them by a local interpreter.

Instruments: This study used a structured questionnaire. Permission of each instrument was obtained from each corresponding researcher, which was revised and supplemented for application to paan in this study and was rated on a 5-point scale.

Variables related to paan use and cessation: The study used six items related to paan use and seven related to PUC, which were revised and modified from Global Adult Tobacco Survey (GATS) Bangladesh 2009\textsuperscript{[16]}.

Panan dependence: The Oklahoma Scale for Smokeless Tobacco Dependence (OSSTD)\textsuperscript{[13]} with 23 items was used, which are divided into two major categories: PDMs and SDMs. The reliability of the instrument as measured by Cronbach’s $\alpha$ was .93 and .96 in a previous study\textsuperscript{[13]} and this study, respectively.

ASE factors related to PUC

Attitude. The attitude instrument in a previous smoking-cessation intention study\textsuperscript{[7]} was used with 16 items. Some items were scored reversely. Higher scores indicate a more positive attitude toward PUC. Cronbach’s $\alpha$ was .65 and .64 in a previous study\textsuperscript{[7]} and this study.

Social influence. The social influence instruments was used in previous studies\textsuperscript{[7,11]} with six items: two for social norm, modeling, and social support, respectively. After data collection, factor analysis was performed. The component analysis of subdomains showed that social influence could be divided into two components; thus, excluded social norms, only the four items in modeling and social support were used. Higher modeling scores indicated more PUC models around the participants and higher social support scores indicated greater support for PUC. Cronbach’s $\alpha$ was .65, .86 and .61 in previous studies\textsuperscript{[7,11]} and this study.

Self-efficacy. The self-efficacy instrument was used in a previous study\textsuperscript{[7]} with 12 items. Higher scores indicated higher self-efficacy regarding PUC. Cronbach’s $\alpha$ was .83 and .94 in a previous\textsuperscript{[7]} and this study.

Data Analysis: Collected data were analyzed using SPSS 23 version with descriptive statistics, t-test, chi-square, factor analysis, and logistic regression analysis.
Results

The mean paan dependence (PDMs+SDMs) score was 3.62 (SD=1.19). The mean score of attitude was 2.89 (SD=0.54), while the mean self-efficacy score was 2.47 (SD=1.24). And, 54.3% had PUCI (Table 1).

The mean age was 38.26 years and 74.6% were unemployed (Table 2). There were significant differences in PUCI by general characteristics; age ($\chi^2=9.60, p=.022$), education level ($\chi^2=11.93, p<.001$), frequency of paan use ($\chi^2=13.13, p<.001$), period of paan use ($\chi^2=9.55, p=.023$), average paan use per day ($\chi^2=17.16, p<.001$), age at first paan use ($\chi^2=7.49, p=.024$), having attempted PUC in the past year ($\chi^2=29.66, p<.001$), and need for PUC education ($\chi^2=12.65, p<.001$).

In Table 4, the logistic regression model using the Backward: Likelihood Ratio (LR) method was significant \(\chi^2=75.68, \ p<.001\). The odds of having PUCI was 7.85 times higher when PUC had been attempted in the past year; 5.49 times higher for participants who recognized the need for PUC education; and 2.88 times higher when the mean score for PUC attitude had increased by 1 point. On the other hand, a 1-point increase in SDMs led to a 0.61 odds increase, indicating a lower likelihood of having PUCI.

Discussion

This study was to identify the factors influencing PUCI among Bangladeshi women with a focus on paan dependence and the ASE model.

Regarding the general characteristics, almost half were aged 40 years and over and had lower SES, and over 60% had not received regular education and had no occupation with similar results to paan-use studies in Bangladeshi women\(^\text{[5,16,12]}\) and in Malaysians (mostly Indians)\(^\text{[17]}\). And, approximately 20% was under 18 years at first paan use, which indicates that paan use started at an early age\(^\text{[2]}\) because of seeing family members use paan\(^\text{[6]}\) and became a long-term habit, recognizing paan use as a positive behavior\(^\text{[18]}\).

As for four significant factors of PUCI in the logistic regression analysis, PUC education needs to be provided for individuals who have previously attempted PUC in exploring the reasons for failure in previous attempts and promoting success through stress management\(^\text{[6]}\) and image training for coping with enticement and intimidation from other paan users.

Recognizing the need for PUC education reflects the desire of participants to obtain accurate information about paan. Low awareness and knowledge about paan could act as motivating factors that make it easier to use paan\(^\text{[7]}\), thus, educational activities regarding paan-use risk\(^\text{[6]}\) must be provided in considering the education level and targeting those aged 30-39 years showing the highest PUCI.

More negative attitude toward PUC results in lower PUCI. Therefore, in Bangladesh, where is liberal about paan use\(^\text{[6]}\), long-term and repetitive education is more ideal than short-term, single-session education for enhancing PUC attitude.

Regarding SDMs, in particular, choline in areca nut, an ingredient in paan, excites the parasympathetic nerves to slow tension and induces a euphoric feeling\(^\text{[2]}\), and in zarda, an ingredient in paan, the nicotine content more than doubles that in typical cigarettes\(^\text{[3]}\), thus, a higher frequency of paan use increases paan dependence, making PUC even more difficult. Therefore, it is important to start PUC education as early as possible, even before paan use, and to immediately target paan users with a shorter period and a lower frequency of use.

Meanwhile, to increase self-efficacy, as not shown a significant factor, it is important to acquire skills to prevent re-use of paan where paan use is typically consumed\(^\text{[6]}\), along with identifying helpers with positive reinforcement. Moreover, social influence was not also an influencing factor because paan use in Bangladesh is in strong community-based bonds. Therefore, a group approach considering sociocultural aspects is recommended over an individual approach\(^\text{[5]}\).

This study is significant because it was the first study conducted in Bangladesh to analyze PUCI among Bangladeshi women focusing on paan dependence as well as ASE model factors regarding PUC. The high paan use rate and dependence among our participants re-emphasize the need for future systematic studies in Bangladesh. However, because the participants in this study were residents in an impoverished region, the paan-use rate may have been high consistent with previous studies\(^\text{[5,12]}\), thus, it may be difficult to generalize the findings to other regions, and further studies including participants from other areas are needed.

Conclusions

Despite relatively high PUCI, close most participants did not attempt to quit. Having attempted PUC in the past year, recognizing the need for PUC education, positive attitude toward PUC, and lower paan dependence were significant factors influencing PUCI. Therefore, there is the need for systematic education and promotion of tolerant social awareness about paan use based on a sociocultural approach. Moreover, it is important to develop customized PUC programs that reflect the characteristics of paan users.

Analysis of Biscuit Nutrition Material with Addition of Morning Flour (Moringa Oleifera) from Different Treatments

Putu Candriasih¹, Mardiani Mangun¹, Bohari²

¹Lecturer in Department of Nutrition, Poltekkes Kemenkes Palu, ²Lecturer in Department of Nutrition, Faculty of Public Health, Tadulako University, City of Palu, Indonesia

Abstract

This study aimed to analyse the content of macro and micronutrients in flour and biscuits with three treatments. This research is a quantitative study with an experimental method of 3 treatments of wheat flour and moringa leaf flour. The results of macro nutrient of moringa leaf flour showed water content of K1 = 6.58%, K3 = 10.28%, K4 = 10.31%. Energy of K1 = 382.48 kcal, K3 = 367.00 kcal, K4 = 369.83 kcal. Carbohydrate of K1 = 43.12%, K3 = 40.78%, K4 = 40.40%. Protein of K1 = 29.82, K3 = 31.78%, K4 = 33.18%. Fat of K1 = 10.08%, K3 8.63%, K4 8.39%. Micronutrient substances namely vitamin C of K1 = 2.66 mg, K3 = 4.51 mg, K4 = 11.19 mg, vitamin B12 of K4 = 0.09. Iron of K1 = 20.90 mg, K3 = 18.14 mg, K4 = 13.34 mg. Zinc of K1 = 3.22 mg, K3 = 3.33 mg, K4 = 3.53 mg. The results of macro nutrient analysis of moringa biscuits showed water content of BK4.1 = 8.84%, BK4.2 = 4.12%, BK4.3 = 6.77%. Energy of BK4.1 = 485.83 kcal, K4.2 = 495.32 kcal BK4.3 = 458.50 kcal. Carbohydrate of BK4.1 = 58.83%, K4.2 = 58.04%, BK4.3 = 58.81%. Protein of BK4.1 = 9.82%, K4.2 = 11.16%, BK4.3 = 11.52%. Fat of BK4.1 = 23.47%, K4.2 = 24.28%, BK4.3 = 19.02%. Micronutrient substances namely vitamin C of BK4.2 = 1.58 mg, Iron of BK4.1 = 8.22 mg, BK4.2 = 9.53 mg, BK4.3 = 13.39 mg. Zinc of BK4.1 = 2.16 mg, BK 4.2 = 3.59 mg, BK 4.3 = 7.72 mg. It can be concluded from nutrient content analysis, the high nutrient content moringa leaf flour was 6 months stored moringa leaf flour because of low water content. While the macro nutrient content of the 3 biscuit treatments was almost the same while the highest micronutrient of iron and zinc was found on biscuit with wheat flour and Moringa flour ratio of 1:1.

Keywords: Macro nutrient, Micro nutrient, Biscuit, Moringa leaf flour.

Introduction

Moringa (Moringa oleifera) is a plant that has been known for centuries as a multi-use plant, nutrient dense and can be used as medicine¹. Most frequently studied moringa species is moringa oleifera and has gained much recognition for their high nutritional value in the form of rich minerals, such as calcium and iron which are essential for growth and development².

Moringa contains 46 powerful antioxidants that protect the body from free radicals, 18 amino acids (8 essential amino acids) needed by the body to build new cells, 36 anti-inflammatory compounds, and 90 natural nutrients such as vitamins and minerals. In the beginning, many people did not believe that there is multipurpose plant that has so many nutrients and medicinal properties, even has better content than other food sources³.⁴.

Moringa is a plant that thrives in Indonesia with various benefits which contains high protein, β-carotene, vitamin C, minerals especially iron and calcium⁵. Nutrients in moringa leaves except for vitamin C have increased in quantity when dried and then processed into powder. Moringa oleifera has great potential for use as a natural preservative and nutraceutical in the food industry⁶.
Research into the influence of giving Moringa oleifera biscuits to hemoglobin (Hb) status in pregnant women shows that there was a significant difference between the groups with biscuits (60 g) and the control group (p≤0.05). Giving Moringa biscuits per day to pregnant women with anemia as an alternative to overcome the problem of malnutrition and anemia in pregnant women. Moringa leaves are a good medicinal plant during pregnancy and postpartum. Biscuits are a popular food, by adding Moringa leaf flour to the process of making biscuits, good for health biscuits can be produced. Moringa leaves contain high protein, vitamins and minerals.

The study was conducted on cakes made from a mixture of Moringa stenopetala (MLP) leaf powder with wheat flour for breastfeeding mothers who lack iron. MLP and wheat flour are mixed in a ratio of 0:100, 5:95, 10:90, 15:85 and 20:80 by using a simplex mixture lattice design and consumption of 100 g cookies per day, so as to meet 53.6% of RDA of nursing mothers. In general, this study showed that T5 (20% MLP mixed) contains higher amounts of Fe, Zn, Ca and P.

Based on these results the manufacture of Moringa leaf flour for biscuits uses heat and food composition table. So to find out the overall nutritional content, it is necessary to do further analysis of the macro and micro nutrient content in biscuits by using Moringa leaf flour from two treatments namely with sunlight and oven. Based on this background, the study aimed to analyze the macro and micro nutrients in flour and biscuits with three treatments.

**Method**

This type of research is a quantitative study with a randomized block design experimental method (RBD) with three treatments. This research was conducted in three stages, the first stage was Moringa leaf flour production, the second stage was Moringa Biscuits production and the third stage was nutrient analysis. Moringa leaf flour production was performed with 2 treatment, the first treatment was that Moringa leaves were blanched then dried (K1). The second treatment was Moringa leaves were blended and then aerated at room temperature (K2), moringa leaf flour which has been stored for > 6 months (K3). Biscuits were made from flour with all nutrients from nutrient analysis, namely K2 flour. Biscuits were made in 3 treatments. The first treatment was that biscuits were made with a ratio of 2:1 between flour and Moringa flour, second treatment was 3:2.5 ratio of flour and Moringa flour, third treatment was 1:1 ratio of flour and Moringa flour.

**Results and Discussion**

Nutrient content analysis was performed at the Saraswanti Indo Genetech (SIG) Laboratory Bogor. There were several analytical method used in this study namely, the water content analysis with SNI 29732011 method point A.3, carbohydrate analysis with 18-8.9/MU/SMM-SIG method, protein analysis with 18-8-31/MU/SMM-SIG. Weibull method.

Table 1 shows that the macro nutrients of water, energy, carbohydrates and fats in the moringa leaf flour which was dried in the sun compared to those that was aerated were almost the same. Whereas the Moringa leaf flour which was stored for >6 months had lower water and protein content. While the levels of Energy, carbohydrates and fat was more than new Moringa leaf flour. The protein content of moringa leaf flour is very good. Moringa (Moringa oleifera) thrives in tropical and subtropical regions. This plant is rich in nutrients more than other plants and should be able to be a potential source of vegetable protein, but in reality it has not been utilized maximally.13

Table 2 shows high level vitamin of the Moringa leaves which were aerated at room temperature as well as vitamin B12 while iron levels were lower than the others. 6 months stored moringa flour had lower levels of vitamin C, but higher iron content, but zinc levels were lower than new Moringa leaf flour.

Biscuits were made using moringa leaf flour which was blanched and aerated at room temperature (K2). Biscuits were made with 3 treatments. First biscuits with the code BK2.1 are biscuits made with the ratio of wheat flour and moringa leaf flour of 2:1, biscuits with code BK 2.2 which are biscuits made from wheat flour and Moringa leaves with a ratio of 3:2.5, Biscuits with code BK 2.3 which are biscuits made with a ratio of wheat flour and Moringa flour of 1:1.

Table 3 shows the results of macro nutrient analysis of Moringa Leaf Biscuit in 100 gram samples

Table 4 shows that the higher the ratio of moringa leaf flour used to make biscuits, the higher iron and zinc.

Another result of the study on the influence of Moringa oleifera biscuit on the hemoglobin (Hb) status of pregnant women showed that there were significant differences between the treatment and control groups after the intervention (p ≤0.05). By giving five pieces (60 g) of Moringa biscuits per day as an alternative to overcome the problem of malnutrition in pregnant women, especially to increase Hb levels. Moringa leaves are medicinal plants for pregnancy and postpartum.

In table 3 shows the lowest water content, this shows the results of very crispy biscuits. The low water content of biscuit that is too low will result in biscuits that are charred and biscuit colors that are too dark, whereas if the water content is too high then the resulting biscuits have a structure that is not too crunchy and will trigger rapid changes in flavor during storage.

Acceptance test was conducted on Biscuit A with a ratio of Moringa flour and flour that is 1:1 while Biscuit B with a ratio of 3:2.5 between flour and Moringa flour.

The result of acceptance test on aroma, texture, flavor and color, showed Biscuit B product was the favorite with a ratio of flour and Moringa which is 3:2.5 with code of BK 2.2.

Conclusion

Based on the analysis of macro and micro nutrients in moringa leaf flour showed that moringa leaf flour which is made by blanching and aerated at room temperature had the highest value of nutrients. Vitamin C and vitamin B12 levels were still present even though the amount was small. The results of the analysis of macro nutrients in biscuits showed that higher Moringa leaf flour, the lower energy and fat content. The higher Moringa leaf flour used, the higher tiron and zinc content. But the organoleptic test results showed that the biscuit preferred by respondents was biscuit BK.2.2.

Role of Community Based Programmes for Active Ageing:
Elders Self Help Group in Kerala

R.A. Rasi¹, K.M. Ashifa²

¹Asst. Professor, School of Social Work, Marian College, Kuttikanam (Autonomous), Kerala, ²Asst. Professor, Department of Social Service, Faculty of Health science, Istanbul Gelisim University, Istanbul-Turkey

Abstract

Ageing is an inevitable process in human life. It is primarily considered as a physiological phenomenon but an individual’s economic, psychological and social areas can affect by the ageing process. Old age population has been growing at an unprecedented rate all over the world. It is true that people live longer because of improved nutrition, sanitation, medical advances, health care, education and economic well-being. In this context there is a felt need to develop new strategies to ensure the welfare and need of old age population. Community based programmes which are easily accessible to elderly can lend a hand for the welfare and long term care of the elderly. Elders Self Help Group (ESHG) is a community based organization of older people above 60 years aimed at improving living conditions for elderly. The need for different type of community based programmes designed exclusively for the welfare of elderly has been indicated by the findings of the present research. The Elders Self Help Group can facilitate the active ageing among the elderly and the pillars of active ageing such as participation, health and security can be strengthened.

Keywords: Active aging, well-being, social security, participation.

Introduction

Old age population has been growing at an unprecedented rate all over the world. Increases in longevity in life, decline in fertility and mortality rates have contributed the population ageing phenomena. Labelled as Graying Nation, with over seven percent of its population above sixty plus segment, India will carry the bulk of burden of caring the elderly population. The size and percentage share of India’s elderly population has increased from 7 percent in 2001 to 8.30 percent in 2011 and projected to increase 10.70 percent in 2021(3). South India has shown a significant increase in elderly population and Kerala is leading with 10.56 percent in 2001 and 11.93 percent in 2011. It is predicted that the number of elderly in Kerala will reach 15.09 percent of the population in 2021(4). In this context the concerns and issues of elderly are multifaceted. A series of development such as weakening of traditional joint family system, more chance in women employability and inability to extend care due to geographical distance between the children and parents created new challenges in the care of elderly. Disability and impairments among the elderly is a cause of concern for elderly as it adversely affected their independence and autonomy. Morbidity, which has higher incidence among the elderly, will cause an increasing burden to the elderly themselves and to their families also. The problem of sensory impairment, orthopedic hazards, dementia, depression, alzheimer’s along with other lifestyle diseases exacerbate the situation even more deeply. In addition women are having a longer life span than men and the number of elderly women in the state is higher when compared to men lead them to a highly vulnerable group among the elderly(2).

The community based programmes are pursued in areas where traditional forms of aid are not yet possible. Different community based programmes like ESHGs, Senior Citizen Clubs, Pensioner’s Union and Community Policing provides care and support to the elders. ESHG is a community based organization of older people above 60 years aimed at improving living conditions for elderly. It is a group of 10 to 20 active elderly who organize themselves. The groups meet four times every month and unite for the care and support of its members. ESHG ensures the mechanism for social support in the community through facilitating activities and delivering services for sustainable livelihood(6).
The ageing process has already begun in Kerala at a much faster rate than anticipated and increasing trend reveals the need for special attention. The emergence of nuclear family system, increasing longevity, high rate of migration to middle east countries, the changing attitude towards the older ones and traditional caregivers, mainly women, are increasingly taking jobs have been affected the life of older generation (1). The morbidity, which have higher incidence among the elderly, will cause an increasing burden to the elderly themselves and to their families. So these two vulnerabilities, natural vulnerability due to health problem and imposed vulnerabilities due to social background will turn out to be a major cause for concern in Kerala (7). The Kerala model development has been appreciated all over India. The standard of living, health, literacy and education are being compared to the development world (10). At the same time social security and welfare measures for the elderly are not on par with the developed countries. As the number of older people continues to increase and traditional social structures break down, families and policy-makers will increasingly need to look for other options. In this context there is a felt need to develop new strategies to ensure the welfare and need of old age population. Such a situation community based programmes which are easily accessible to elderly community can lend a hand for the welfare and long term care of elderly (11).

**Review of Literature:** The part reveals the different dimensions of ageing and its factors. Case studies on elderly in Kerala stated that people who are regularly engaged themselves in mentally challenging activities like reading are less likely to develop dementia in later stage of life. The contribution of elderly towards child-care and this could be a subject of interest to a demographic or socio-economic and who are physically active are much more likely to live longer than those without. The mental and physical activities among the elderly should be encouraged and discouraged due to health aspects (8). The community context is crucial in ageing process and three major reasons. First, inequalities in the spacial distribution of ageing population require attention to how community context shapes and shaped by residents. Second, meeting the service needs of our ageing population requires attention to the natural and planned community contexts in which people age and to which they move. Third, growing popular and scientific interest in the concept of social capital and in social inequalities in health requires integration and response from gerontological theories, researchers and practitioners (12). The abuse and neglect of elderly is not taken-up as a problem by community. The observation of World Elder Abuse Awareness Day concern the rising incidence of extreme violence, neglect, rape, bulgury, homicide affecting elderly across the state. Sensitization programmes are conducted effectively by some of NGOs related to the groups such as street plays at the bus stops and railway station as part of the elderly abuse awareness programme. Migration of the younger generation leaving their parents has compounded the issue of neglect. The scope of community based social service was reviewed in the report of WHO. Community centres for elderly are regarded as ideal locations for social services because of their convenience, familiarity and accessibility. The guide urged the need of improvement in existing social service systems. One of the best examples described in the guide regarding community based programme is issuing identity card for elderly in Mexico City for getting access to lower prizes and some free services. The community based programmes have significant role among elderly in Kerala because of the significant increase in elderly population. In this context the review emphasized the need for a comprehensive study on community based programmes and it is noted that study on ESHGs in Kerala is scanty. Therefore the present study has been undertaken to examine the community based programme through ESHGs.

**Objectives:** The present study attempts to analyse the role of community based programmes in active ageing. This study examine activities of ESHGs and involvement of aged in this group as one of the community based programmes.

**Methodology**

The study conducted among the 98 ESHGs in Kollam district under the initiative by Help Age India and implemented through Quilon Social Service Society (QSSS) as part of post tsunami extended response project at Kollam and Alappuzha districts. Repeated interview sessions and sustained efforts were taken to overcome to complete the data collection. Simplified situational examples have been used for eliciting information instead of direct method.

**Result and Discussion**

The active ageing is analyzed with the community based programme in the present study. Three pillars of active ageing namely participation, health and security
were associated with membership and activities studied by ESHGs. The formation of ESHGs and its activities integrates elderly with the community in democratic way of expression. The ESHGs work under a three tier system which allows the members to disseminate the duties and responsibilities effectively. Activities carried out by the community organization reveal that active ageing process is evident among the ESHG members.

ESHG member’s status on age and sex pattern, literacy level, marital status, assets and income reveals their socio-economic conditions. The present study revealed that female elderly outnumbered male elderly and is substantially agree with the NSSO 60 round data that elderly females were outnumber than males both in rural and urban areas in all parts of south India. Female elderly participated in the ESHG activity fairly well when compared to males. These findings is readily acceptable with the literature that the participation in different programmes by elderly men shows decreasing level but among the elderly women it shows an increasing effect (13). The high participation level of young old compared to the other two categories is evident in the study. The elderly maintained the ESHG records in a proper manner. The incidence of widowhood has been revealed among ESHGs member, the study revealed that widowhood did not resist them from the participatory process and they joined the community based organization without any hesitation. ESHG members undertook their activities independently. Irrespective of age classification as young old, old-old and oldest old the elderly remains a very good level of ADL. It enabled the elderly to associate with community based programmes at different levels of constraints and difficulties.

ESHG organized health care services not only to their own members but also to others in the neighbouring community. Medical outpatient services, pain and palliative and home care service are offered by ESHG members. The members of ESHG offered health friendly social service to the needy people and this components also assisted active ageing among the elderly. The medical out-patient programmes under ‘Vayomithram’ plan by government of Kerala has a significant role in offering medical consultation and distribution of medicines at free of cost. ESHGs even coordinated the activities at the Kollam coastal area. The members of the ESHG are using the medical out-patient programmes during that time and used to take the doctor to the nearby bed ridden patients. The pain and palliative care services has been offered by the group members to the bed ridden and needy people through medical out-patient programmes. The ESHG members offer space and other amenities for conducting the medical out-patient programme. The elderly are more conscious about their health through their active effort and involvement in the prevention and reduction of the disease.

The ESHG became instrumental for getting the pension as they collectively sent the application through federations and submitted memorandum for getting the needy elderly. Those who are not getting the old age pension sought the help from ESHGs and village level federation. Majority of the elderly are living with their spouse or children. The elderly living alone and living with relatives are few in number. It shows the traditional practices of care offered by the grown-up children are prevailing. The loneliness, depression and anxiety may be avoided at certain extend by living with children and spouses. Majority of the elderly are getting care on time from the family members. It further reveals that 29 percent of the elderly received care only after repeated prompting and 8 percent of them are getting delayed care. Proper care at right time ensures the security of elderly. It enables the elderly to live actively and add more years in their life. The activity of daily living under different aspects such as personal hygiene, eating, dressing and undressing, controlling urinary and fecal discharges and transportation shows that ESHG members are fully independent to do their own and it reveals their ability to be active in old age. ESHG members used their group for getting financial assistance to their family in the form of loan. The elderly took loan from the group at a very low percent of interest and help their family. The members offer mental and physical support to the group members by offering help in maintenance, cleaning, preparing food at functions and celebrations. It revealed the sense of belongingness among the ESHG members and towards the family. Majority of the ESHG members (67 percent) are not supporting the old age institutions. It revealed that a majority of elderly like to remain in their own home with their family members. They feel the sense of security through the non-institutionalized settings.

**Recommendations:** The concept of ESHGs should be popularized and new groups will be setup irrespective of societal classification. The government should give financial assistance to the ESHGs. The regularity and payment of old age pension should be monitored effectively through community based organizations. World Elder’s Day and World Elder Abuse Awareness
Day, should be observed by educational institutions with support of elderly organization to create awareness on importance of elderly among youth and children. Setting up of geriatric wards, separate beds, medical officer with experience in geriatric care in all governmental hospitals and ensure separate queues for elderly are the rights for elderly. Ensure a proper monitoring mechanism with the help of community based organizations in district level for the effective implementation of these programmes.

Establish multipurpose utility centre and adult day care centres for elderly in grama panchayat level will help the elderly to come and share their issues and problem in a common ground. The elderly organizations can run the centres with the help and support of common public. A toll free number should set-up for getting immediate assistance and support for elderly. Some states have already implemented toll free number for elderly and it should come up at national level for an emergency support system. Constitution of maintenance tribunal and appelot tribunals at district level and appointment of counsellors for settling the disputes amicably is the provision comes under Senior Citizen (Maintenance, Care and Protection) Act-2007. Most of the states are not implemented it properly and it is a felt need of elderly to set-up the tribunals exclusively for them.

Conduct awareness programmes and melas for popularizing active ageing process among the elderly. It should be conducted at village level to convey the message in ground level for the common public. Service of mobile medical unit comprised of doctor and pharmacist at panchayat level will help the bed ridden, poor and destitute elderly. Integrate subjects related to ageing in school curriculum to eliminate generation gap and getting awareness on problems and issues faced by elderly. New professional courses should come-up exclusively on gerontology and it will increase the scope ageing studies in a progressive way. Establish a research centre for ageing and related studies. As the number of elderly is alarmingly high in the state, the research centre may act as the back bone for framing policy, programmes and research for the welfare of the elderly. Implement pain and palliative care exclusively for elderly population. It should be a multi-disciplinary team comprised of trained health care professionals, social worker, local leaders and youth representatives. Provide support and incentives for agencies that are offering home help service and respite care for the elderly. Introduce geriatric nursing courses at medical colleges for availing specialized trained nurses in care and support for the needy elderly. Design lifelong learning and life skill education programmes for the elderly through ESHGs and community based organizations.

Conclusion

The present study analysed the active ageing process through community based programme. The study revealed that ESHG can facilitate the active ageing among the elderly and the pillars of active ageing such as participation, health and security can be strengthened through ESHGs. The need for different type of community based programmes designed exclusively for the welfare of elderly has been indicated by the findings of the present research. It is a fact that the percentage of elderly population in Kerala is alarmingly high and the social security system alone cannot address the elderly issues and problem in a comprehensive way. The support from community and family is very much essential for the care and support of elderly. In this context, the innovative practices like Elders Self Help Group will help the elderly remain active and add more productive years in their life.

Molecular Detection of Bacterial Etiologies Causing Meningitis in Pediatric Patients in Taif City, Saudi Arabia

Reem Ayedh Al Shahrani
Researcher and Teaching Assistant, Department of Biology, College of Sciences, University of Bisha, Kingdom of Saudi Arabia

Abstract
Bacterial meningitis is prevalent in pediatric populations worldwide and associated with mortality and neurological complications in tropical and subtropical regions. This study aimed to evaluate in-use clinical diagnostic approaches against two PCR method in detection of bacterial pathogens implicated in pediatric meningitis in Taif city (Saudi Arabia). The tested PCR method were real-time and multiplex polymerase chain-reaction (RT-PCR and mPCR). One hundred and fifteen CSF samples were collected from suspected pediatric patients with acute meningitis admitted to Taif children’s hospital between January and December 2016. Bacterial identification and antimicrobial susceptibility testing were performed by the automated BD Phoenix™ identification and susceptibility testing system. Culture-based detection identified Citrobacter freundii (in one sample) and Salmonella spp. (in one sample). However, molecular detection by PCR approach of 113 culture-negative samples identified; N. meningitidis, (A serotype), H. influenzae (2-strains), and S. pneumoniae (19A and 23F strains). PCR-based detection approach is more efficient in microbiological diagnosis of bacterial etiologies in CSF specimens.

Keywords: Polymerase chain reaction, Bacterial meningitis, Phoenix system, children.

Introduction
Bacterial meningitis (BM) is a life-threatening inflammation of the meninges and the sub arachnoid apace triggered by bacteriaor bacterial products reaching the meninges1,2. Globally, BM is an important cause of mortality and morbidity especially in tropical and subtropical regions. Up to 25% of meningitis cases in Asia and Africa result in neurological sequelae such as deafness, loss of vision, cognitive impairment and epilepsy2. Such complications can be avoided by early diagnosis and administration of antimicrobial chemotherapy3.

Prior application of vaccination programs, about 90% of BM infections in children were caused by Streptococcus pneumoniae, Haemophilus influenzae type b (Hib), and Neisseria meningitides3. Additionally, other bacterial species such as Streptococcus agalactiae, Listeria monocytogenes, and Escherichia coli are also implicated in BM in children4,5. Pneumococcal meningitis (caused by S. pneumoniae) is more common in children <5 years of age, while meningococcal meningitis (caused by N. meningitidis) is more frequent in elder children6.

In laboratory, conventional culture of CSF specimens is the gold standard approach for BM diagnosis. CSF examination is critical for the diagnosis of all types of meningitis. Gram smear of CSF will mostly reveal the presence of bacteria with sensitivity range from 65% to 80%7,8. On the other hand, CSF culture can be negative in children who received antibiotics prior to CSF collection and examination9. Various nucleic-acid amplification assays have been developed to detect infecting pathogens in BM. Multiplex PCR and real-time PCR techniques have shown substantially higher rates
of detection than culture method especially in patients who had previously received antibiotic treatment. The purpose of this study was to evaluate the effectiveness of application of the RT-PCR and PCR techniques for the concurrent identification of *Haemophilus influenzae*, *Streptococcus agalactiae*, *Streptococcus pneumoniae* (Hib), and *N. meningitides* in CSF specimens collected from suspected bacterial meningitis in children.

**Materials and Method**

**Patients and samples:** Pediatric patients suspected of BM admitted to Taif children’s hospital, Kingdom of Saudi Arabia, were subjected to physical examination with or without lumbar puncture between January and December 2016. The diagnosis of BM was based on clinical presentation consistent with the World Health Organization (WHO) clinical measures of suspected meningitis disease. A total of 115 CSF specimens were further included for detection of bacterial agents.

**Bacterial detection and antimicrobial susceptibility testing:** Bacterial detection and antimicrobial susceptibility testing were performed by the automated BD Phoenix™ 100 Microbiology system (Becton Dickinson, USA) according to manufacturer’s instructions. The tested antibiotics were; amikacin, ceftazidime, etrapenem, meropenem, ceftriaxone, aztreonam, ampicillin, amoxicillin, ciprofloxacin, levofloxacin, tigecycline, ceferoxim, cephalothin, amikacin, cefoxitin, and gentamicin.

**PCR diagnostic approach:** One hundred and thirteen culture-negative specimens were subjected to PCR-based diagnosis of the most common bacterial pathogens implicated in pediatric meningitis. The targeted pathogens and their specific primers are listed in table 1. Bacterial DNA was extracted by QI Aamp DNA mini Kit (Qiagen, Germany) according to manufacturer’s instructions. The purified solution of 5-10 µl of DNA was utilized as a specimen for PCR. Settings of PCR protocols for identification of BM agents were followed as previously published. Serotyping of *S. pneumoniae* and *N. meningitidis* was conducted for the two CSF specimens. The two specimens were found to belong to 19A and 23F serogroups (Fig, 2). *N. meningitidis* isolate belonged to the A serogroup. *S. agalactiae* was not detected in any sample.

**Efficacy of PCR:** The effectiveness of PCR was evaluated against the gold standard test (culture). PCR tests were found very efficient to screen out negative patients with 95% accuracy. However, PCR predictive value positive was low (58.33%) because PCR only targets the agents of whose primers have been included in the test.

**Results**

**Demographic data of cases:** A number of 115 pediatric CSF specimens from suspected bacterial meningitis between January and December 2016. The demographic data of cases is summarized in table 2. Children age ranged from 1.4 to 8 years (4.17±1.71 years).

**CSF cell count:** The differential cell count in CSF specimens ranged from 2 to 8% for neutrophils (3.21±1.43%) and from 15-65% for lymphocytes (30.81±15.58%). Detailed differential cell count in the specimens is summarized in table 3. No significant difference in cell count was found between age groups.

**Identified bacterial species and susceptibility testing:** Only two specimens of CSF (1.74%) revealed positive bacterial growth detected by BD Phoenix™ 100 Microbiology system. The detected bacteria were *Citrobacter freundii* and *Salmonella* spp. In terms of antimicrobial susceptibility testing, *Salmonella* isolate was susceptible to nearly the whole antibiotics utilized in the Taif children’s hospital excluding ceferoxim, cephalothin, amikacin, cefoxitin, and gentamicin, while *Citrobacter freundii* was insusceptible to fluoroquinolones, carbapenems and aminoglycosides, but showed sensitivity to all tested cephalosporins.

**Statistical analysis:** Data were entered and processed by Microsoft Excel 2016 (version 16.0.06769.2017, Redmond, USA). Descriptive statistics and confidence intervals were calculated by normal approximation method. Chi square test was employed to test for difference between groups.

Discussion

The overall prevalence of bacterial etiologies was 6.09% detected by culture-dependent (Phoenix system) and culture-independent (PCR) approaches. Such low prevalence was also reported from Iran (6.8% and 2.9%)\(^\text{18,19}\), and Nepal (7.2%)\(^\text{20}\), and Switzerland\(^\text{21}\). The detected bacteria by Phoenix system were *Citrobacter freundii* and *Salmonella*, two aerobic gram negative rods increasingly recognized to cause BM in immuno compromised individuals, or after traumatic experience\(^\text{22}\). The low recovery rate associated with culture method was also reported in a study in Tehran (1.5%)\(^\text{12}\), China\(^\text{23}\), and Switzerland (7.27%)\(^\text{21}\). These observations are most likely resulted from intake of antibiotics prior to CSF culture\(^\text{24,25}\).

Culture-negative specimens (n=113) were subjected to PCR-based analysis. A total of five cases were found positive (4.42%). These observations are in consistent with previous report from Iran (6%)\(^\text{26}\). The detected bacteria were the most commonly reported causes of bacterial meningitis\(^\text{22}\). These species were *H. influenzae*, *S. pneumoniae*, and *N. meningitidis*. Children<5 years with BM are mostly caused by *S. pneumoniae*, where as *N. meningitidis* are frequent in older children\(^\text{22,27,28}\).

Hajj and Umrah are well-known Islamic pilgrimages that have been accompanied by outbreaks of meningococcal diseases\(^\text{15,29}\). The serotypes 19A and 23F of *S. pneumoniae* have been identified in China\(^\text{30}\), Sri Lanka\(^\text{31}\), and India\(^\text{32}\). On the other hand, *H. influenzae* type b remains a major cause of BM in developing third-world countries\(^\text{28,33}\).

A worth noting point is that PCR is not an alternative for culture approach for laboratory detection of pathogens involved in BM. The most apparent reason for such limitations is that addition of primers specific for all potential BM pathogens is not practically feasible\(^\text{21,34}\). PCR approach has more efficacy in detection of bacterial etiologies in culture negative samples. More studies are recommended to address other bacterial and viral causes of pediatric meningitis in Saudi Arabia.

Ultrasound Guidance for Introducing Spinal Anesthesia through Paramedian Approach Versus Landmark Guided Technique During Lower Limb Surgeries, Randomized Controlled Trial

Sohib Mohamed Galal1, Dina Zakaria Mohamed2, Ahmed Zaghloul Fouad2

1MD, 2Assistant Professor, Anaesthesia and SICU and Pain Management, Cairo University, Cairo, Egypt

Abstract

Introduction: Ultrasound imaging skills are appreciated for improving the safety of different puncture techniques supported with the fact that the advances in imaging quality have significantly improved our understanding of neuroaxial Sonoanatomy (1). Today, ultrasound imaging has been used to assist or guide central neuroaxial blocks (2).

Objectives: To identify the value of using the ultrasound guidance in applying spinal anaesthesia when compared with the conventional landmark guided approach, regarding the duration of applying the anaesthetic technique and incidence of associated common complications.

Design: Randomized controlled trial.

Method: 178 patients scheduled to undergo elective lower limb surgeries under spinal anaesthesia in El Kasr Al- Aini Hospital, Cairo University were enrolled in the study. Patients were randomly assigned into landmark guided control group in which 89 patients received landmark guided paramedian spinal anaesthesia and ultrasound group in which 89 patients received real time ultrasound guided paramedian spinal anaesthesia.

Results: The mean numbers of puncture attempts, levels and needle redirections between the control group and ultrasound group were 1.61±0.83 vs. 1.12±0.36 (P value 0.013), 1.15±0.36 vs. 1.06±0.25 (p value 0.018) and 2.68±2.75 vs1.94±1.93 (p value 0.021) respectively. Also the duration recorded during applying the anaesthetic procedure for the control group and ultrasound group were 136.4±83.2 vs. 138.3±63.4 (P value 0.001) correspondingly.

Ultrasound guided group of patients showed significant lower incidence of bloody puncture and paraesthesia after engaging the needle through the dura.

Conclusion: Ultrasound guiding although it took longer duration in application but improved the ease of introducing spinal anesthesia, reduced the number of puncture attempts, number of puncture levels, number of needle redirections, and incidence of complications.

Keywords: Ultrasound, Spinal anaesthesia, Guidance, Landmark, Neuroaxial.

Introduction

Spinal anaesthesia is a wide spread popular method of anaesthesia, used for most of the orthopaedic surgical procedures involving the lower limb (1).

Spinal anaesthesia remains the first choice in such surgeries because of its dense block, rapid onset, low infection risk as from catheter placement in cases of epidural, avoidance of serious complications that may be associated with airway management during general anaesthesia, in addition to other benefits associated with central neuroaxial blockade (e.g. decreased incidence of blood loss, thromboembolism and wound infection) (2).
Spinal anaesthetic block failure among experienced anaesthetists reported to be not more than 1%\(^{(3)}\), however such incidence could be higher in a training environment due to the inability to predict technical difficulties or placing needle accurately with any of the landmark-based techniques. This may lead to multiple needle attempts, block failure, discomfort, poor patient satisfaction and occurrence of complications\(^{(4)}\).

Such failure may be related to improper technique, inexperience (of the unsupervised trainee especially), and inability to appreciate the need for a meticulous approach\(^{(5)}\).

Minimizing the incidence of failure is an important pre-requisite for gaining the benefits of spinal anaesthesia, and to prevent the potential pitfalls\(^{(3)}\).

The use of ultrasound guidance for performing regional anaesthesia is a relatively new and evolving concept, though it was first reported in 1980\(^{(6)}\).

Ultrasound allows real time imaging of neural structures, without either staff or patient exposure to radiation.\(^{(7)}\) Ultrasound-imaging skills are valuable for enhancing the safety of different puncture techniques especially with the developments in imaging quality that have significantly improved our understanding of the Sonoanatomy of the lumbar spine.\(^{(8)}\)

Today, ultrasound imaging has been used to assist or guide central neuroaxial blocks if an interlaminar window that permits passage of sound waves into the vertebral canal can be identified, the same window will permit passage of a needle into the epidural or intrathecal space\(^{(9)}\). This coupled with real-time imaging of the needle passage to the required sites should permit high-quality and low-risk regional anaesthesia.\(^{(10)}\)

It was reported that ultrasound guided epidural needle insertion had reduced the number of puncture attempts\(^{(11-14)}\), reduced the need for multiple levels puncture\(^{(12-14)}\) and improved patient satisfaction during the procedure\(^{(13)}\) for these advantages it was recommended by the National Institute of Clinical Excellence (NICE) in the United Kingdom to recommend that ultrasound guided epidural blocks should be routinely used.\(^{(15)}\)

Our aim in this study was to investigate efficacy and safety of ultrasound guided paramedian sagittal neuroaxial approach in providing spinal anaesthesia for lower extremities surgeries in comparison to the conventional landmark guided approach.

**Discussion**

In this study we found that real time ultrasound guided spinal anesthesia, decreased the number of puncture attempts, number of puncture levels, number of needle redirections, and incidence of complications.

Unfortunately no previous randomized controlled trials were done to attest the real time guided technique in order to compare its role in improving the quality of applying spinal anesthesia with the conventional blind method through and to the best of our knowledge; our study is the first randomized controlled study to compare real time ultrasound technique to conventional manual palpation blind method.
Lee PJ et al (19) who tested real-time ultrasound guided spinal anesthesia in the prone position for 10 patients undergoing knee arthroplasty in an effort to positively attain CSF through this approach, they reported successful spinal anesthesia in all applicants; and they recorded that nine patients needed only one attempt to acquire CSF. A weakness of this study was the small number of patients involved, the lack of a control group and the need for prone positioning of patients for that technique which was problematic.

This trial support our findings, as we demonstrated that ultrasound guided technique group of patients when compared to the control group showed significant lower number of puncture attempts (1.12±0.36 vs 1.61±0.83), lower number of puncture levels (1.06±0.25 vs 1.15±0.36) and lower number of needle redirections (1.94±1.93 vs 2.68±2.75).

In the current study ultrasound guided group of patients significantly showed lower incidence of bloody puncture and paraesthesia after engaging the needle through the dura. In accordance with our study, the meta-analysis (20) concerned with the use of ultrasound as a preprocedural guidance, concluded that ultrasound imaging reduced the risk of traumatic procedures with a risk ratio of 0.27 (95% confidence interval 0.11 to 0.67, P=0.005) with an absolute risk reduction of 0.059 and reduced the odds of a traumatic procedure (0.28 (0.13 to 0.61), P=0.001).

Contrary to our study findings; Arzola et al (21) results differed from our study and most of the supporting studies; they attested using ultrasound preprocedural screening in aiding the introduction of epidural catheters in female patients going for normal labor, they found that ultrasound use didn’t improve the ease of lumbar epidural catheter, there was no difference in median (interquartile range, IQR) epidural insertion time between the ultrasound and palpation groups [174 (120 to 241) versus 180 (130 to 322.5)]s, respectively; P=0.14], the number of interspace levels attempted and needle passes were also similar in both groups; this difference might be attributed to their special population as they selected parturient with easily palpable lumbar spines.

Another study that reported a different finding than ours was conducted by Hayes et al in children (22); they tried to attest the value of using ultrasound scanning in identifying lumbar spaces in children, but they reported no benefit in using ultrasound when compared to manual palpation done by experienced anesthesiologist. This can be explained by the anatomical differences in pediatric population with relatively easy landmarks.

These different results from ours could be attributed for the different nature of the techniques used rather than our real time method and also different reasons for failure in each of them, and so direct comparison is not possible.

Our study had a strength of being done by a single operator with moderate experience in the use of ultrasound, this provides a degree of reliability, that the difference in outcome between the two groups is not due to any difference in operator skills, this also provides the evidence that the use of ultrasound in this procedure is a skill that isn’t hard to acquire.

Effect of Nursing Interpretation and Intervention of Intrapartum Cardiotocography on Pregnancy Outcomes

Hanaa Elsayed Ahmed Shahin¹, Dalal Khalil Eshra², Hesham Salah Eldien Mahmoud³

¹Assistant Professor, Nursing Department, College of Applied Medical Sciences, Jouf University, KSA and Lecturer-Maternal and Newborn Health Nursing Department, ²Professor of Maternal and Newborn Health Nursing, Faculty of Nursing, Menoufia University, ³Lecturer of Obstetrics and Gynecology, Faculty of Medicine, Menoufia University

Abstract

An important goal of intrapartum monitoring is preservation of fetal well-being by early detection and relief, when possible, of those conditions causing fetal distress and adverse outcomes.

The aim: Assess the effectiveness of nursing interpretation and intervention of intrapartum cardiotocography on pregnancy outcomes.

Design: Quazi experimental design.

The sample: Was convenient sample of 120 cases divided into two groups (study, and control) each one is 60 cases (30 low risks, and 30 high risks).

Tools: three different tools namely assessment sheet for the mother in first stage includes all significant data about the mother, intrapartum fetal monitoring assessment will be done using cardiotocography strip, and Apgar score at one and five minutes.

The settings: Shebin Elkom Teaching and University hospitals-Egypt. The main findings were that no statistically significant relations for low risk cases that being handled with cardiotocography and fetal complications. Instrumental delivery and cesarean section rate for low risk cases in the study group is increased than for low risk in control group shows statistical significance difference. There were strong statistically significant relations between high risk fetal heart rate nursing interpretation and Apgar score in the first minute. Statistical significance to total complications during present labor to the mother.

Conclusion: Continuous cardiotocography should recommended for high-risk pregnancies where there is an increased risk of prenatal adverse outcomes. Cardiotocography for low risk is associated with a significant increase in instrumental delivery and caesarean section rates compared with intermittent auscultation.

Recommendations: continuous electronic fetal monitoring should be recommended for high-risk pregnancies where there is an increased risk of fetal compromise.

Keywords: Interpretation, intervention, Intrapartum, Cardiotocography, pregnancy outcomes.

Introduction

External monitoring is conducted using a doppler ultrasound probe to auscultate and count the FHR during a uterine contraction and detect fetal response for 30 seconds afterwards [¹]. It can also be achieved using an internal transducer that is mounted on the maternal abdomen and protected by an elastic belt or girdle in place. Doppler ultrasound is used by the transducer to track fetal heart movement and is attached to an FHR screen [²]. Internal monitoring is carried out by connecting a screw type electrode with a connection to an FHR screen to the fetal scalp. Rupture of the fetal membranes and at least partial dilution of the cervix before the electrode can be placed on the fetal scalp [³].
In low risk patients in the active phase of labor and every 15 minutes in the second stage of labor, the prescribed intermittent auscultation procedure includes auscultation every 30 minutes. Continuous EFM is indicated if irregularities arise with sporadic auscultation and for use in high risk patients. The FHR recordings may be viewed as encouraging, unreassuring or alarming, depending of the tracing pattern\(^2\). Reassuring patterns associate well with a positive fetal result, but patters that are not reassuring. Evaluation of fetal wellbeing with stimulation of the fetal scalp, pH measurement or both is recommended for use in patients with unreassuring patterns\(^5\).

**Significance of the study:** A growing body of evidence indicates that in predicting both good and bad fetal outcomes. Fetal heart rate evaluation may be equivalent to or superior to fetal blood pH calculation\(^6\). Medical professionals are responsible for correctly diagnosing complications and issues during pregnancy\(^7\).

On the basis of all these factors, the researcher found that it is necessary to assess the impact of nursing perception and intrapartum cardiotocography intervention on maternal and fetal outcomes.

**Aim of the study:** Assessing the effectiveness of nursing interpretation and intervention of intrapartum cardiotocography on pregnancy outcomes.

**Research hypothesis:**
1. Accurate and appropriate nursing interpretation and intervention of cardiotocography during labor (first stage) will improve fetal and maternal outcomes.
2. High risk cases that will not handle with cardiotocography during labor (first stage) will have low maternal and fetal outcomes.

**Subjects and Method:**

**Research design:** A quasi-experimental design

**Setting:** University Hospital and Shebin El-Kom Teaching Hospital.

**Subjects:** Convenient sample was used (120). They were divided into two major groups

**A. Study group, includes**

A1. Cases (high risk) that CTG was handled for (30).

A2. Cases (low risk) that CTG was handled for (30).

**B. Control group includes**

B1. Cases (high risk) that CTG was not handled for (30).

B2. Cases (low risk) that CTG was not handled for (30).

**Data collection instruments:**

**A. Assessment sheet for the mother:** This tool consisted of four parts:

- Part I: included the mother’s socio demographic data
- Part II: family history
- Part III: Obstetric history
- Part IV: Data about the fetus using CTG strip and Apgar score

**B. Apgar score**

**C. Cardiotocography strip**

**Validity and reliability:** Validity and reliability of the instrument(A) were done by panel of expertise in the field of Maternal and Newborn Health Nursing and Obstetrics and Gynecology medicine. The instruments were reviewed for simplicity of language, comprehensiveness and understandability. Test-retest reliability was applied by the researcher for testing the internal consistency of the instruments. It is the administration of the same instruments to the same participants under similar conditions on two or more occasions. Scores from repeated testing were compared. The reliability was done by Cronbach alpha coefficient test equal 0.95.

**Pilot study:** The piloting was conducted on 12 of the laboring to test the applicability of the instruments and to estimate the time needed for data collection.

**Ethical Consideration:** Official steps were taken to obtain a permission to conduct the study, with explanation of the purpose and the importance of the study to the centers authorities and approval from ethical committee is taken before gathering data. An informed verbal consent was obtained from all laboring women before participation in the study. Women were assured that their information were confidential and only used for study process. Also the women were informed that the collected data would be used only for the purpose of the present study, as well as for their benefits of the study.
Procedure:

Preparatory phase: Completing ethical formal letters for all needed authorities

Implementation Phase:

1. The data collection of the study took eight months starting 1/12/2017 ending at 31/7/2018.
2. Settings on CTG machines were standardized and indications for fetal monitoring were determined.
3. The procedure was explained to the mother and obtain permission to commence.
4. The woman was given the opportunity to empty her bladder and maintain an upright or lateral position (not supine).
5. CTGs were labeled with the mother’s name, number and date and time of commencement. 8-Maternal heart rate was recorded on the CTG at commencement of the CTG in order to differentiate between maternal and fetal heart rates.
6. A ‘CTG sticker’ has been developed to support documentation because CTG strip used in the patient’s record.
7. Response to the CTG trace were guided by the algorithm, and any abnormalities were documented in the patient’s record and reported to escalate in light of the patient’s clinical circumstances.
8. Based on the interpretation of the CTG strip, nursing action and management took place.
9- According to the action the researcher attending with the mother during caesarean or normal delivery to evaluate the outcomes on the mother and the fetus

Evaluation: Evaluation was accomplished by determining type and mood of delivery. Complications during and after delivery to the mother were evaluated. The newborn is received and Apgar score is made.

Statistical Data Analysis: Data was statistically analyzed using statistical package for social studies (SPSS. Inc, Chicago, IL, USA) version 20 on IBM compatible computer.

Results

![Figure 1: Antenatal Maternal Risk Factors of CTG for Study Grou](image)

Cases with history of previous cesarean section reaching about two fifth of cases (42.7%). The lowest percent was to intrauterine infection (4.4%).
Figure 2: Intrapartum Fetal Risk Factors of CTG of the Study Group.

Displays that about one third of the cases were with suspicious fetal heart rate on auscultation (30.3%). Meconium staining, post term pregnancy had (24.2%) and (15.3%), premature fetus and multiple pregnancy had the same percent (13.5). As regard to oligogydrominos, it has the lowest percent(5%).

Shows no statistical significance related to perineal or cervical tear, and immediate vaginal bleeding. Instrumental delivery and cesarean section rate for low risk cases in the study group is increased than for low risk in control group and shows statistical significance difference (p<0.01).

Discussion

Regarding to indications of cardiotocography vaginal birth after cesarean section (VBAC) there were nine cases did not have indications to cesarean section on admission rather than they were being previous cesarean section and more than two third of them were being delivered normally without any complications to neither fetus nor the mother. One third have been delivered cesarean section due to no cervical dilatation response, or development of signs of fetal distress.

Malene and Andersen et al.,[8] reported that a pathological cardiotocogram should lead to particular attention on threatening uterine rupture but cannot be considered a strong predictor. [9][10] are all reported that planned VBAC is a clinically safe choice for the majority of women with a single previous lower segment caesarean delivery.

There were no significant differences in fetal outcomes from using intrapartum CTG for low risk cases compared with fetal outcomes for control group. On the same line[10][11] stated that organizations and stakeholders like the World Health Organization and the International Federation of Gynecology and Obstetrics (FIGO) recommend that intermittent auscultation (IA) should be used to monitor (low-risk) pregnancies during labour. Also,[11][12] reported that the evidence does
not support routine use of antenatal EFM for low-risk pregnant women.

Regarding to high risk cases there is significance difference in using CTG versus intermittent auscultations for high risk cases in concern to fetal outcomes. Supported result by as incidence of fetal distress, moderate-thick meconium stained liquor and neonatal intensive care unit (NICU) admission was significantly more frequent among patients with ominous test results compared with equivocal or reactive test results on admission. Incidence of vaginal delivery was more common when the test was reactive.

Apgar score at (1min) after birth between 4 -5 at 5 minutes had normal fetal heart rate pattern, and about one eight had nonreassuring fetal heart rate pattern, and about one third had abnormal fetal heart rate pattern. Apgar score 5 minutes after birth ≤ 3 were 1%, 9% and 13% respectively. Supported results by showed that there were no association between Apgar scores at one minute and acidosis.

Intervention rate in our study showed that the rates of both operative vaginal delivery and caesarean section were significantly increased with the use of CTG compared with intermittent auscultation for low risk. For this effect was more pronounced if only those deliveries for presumed ‘fetal distress’ were considered. This was Support by who reported that CTG had importance in detection of fetal distress with low Apgar score (P <0.001).

It was obviously clear that the research hypothesis were accepted.

**Conclusion**

- Cardiotocography should be recommended for labor for high-risk pregnancies where there is an increased risk of prenatal adverse outcomes.
- Low risk pregnancy recommended to be monitored by intermittent auscultation.
- Cardiotocography for low risk is associated with a significant increase in instrumental delivery and caesarean section rates compared with intermittent auscultation.

**Recommendations:** Continuous electronic fetal monitoring should be offered and recommended for high-risk pregnancies where there is an increased risk of fetal compromise.

The Use of Walnut Tree Bark Powder as a Teeth Whitener

Ausama Abbas Faisal¹, Maher Ahmed Abed², Abbas I. Hussein³

¹Lecturer, University of Anbar, College of Medicine, Department of Biochemistry, ²Lecturer, University of Anbar, College of Agriculture, Department of Food Science, ³Lecturer, University of Anbar, College of Dentistry, Department of Prosthodontics, Iraq

Abstract

The chemical changes that may occur with carious destruction of enamel lead to unacceptable appearance of teeth. For males and females the appearance of teeth is of most importance, therefore they should take care with their teeth. The cleaning and whitening processes are expensive and may be harmful for enamel of teeth, so this research includes the whitening of teeth by using natural product containing toothpaste. The powdered bark of walnut tree has been used as whitening material in four forms and these are tested on 40 volunteers with stained teeth in dentist clinic. The four products were powder only. Powder mixed with toothpaste, condensed aqueous extract and granules of the product. The percentage of the powder in the paste was 5%, the mixture is homogenized by using mortar and pestle and the pH is tested and calibrated by pH meter to 6.5 which is the acceptable medium for mouth and is included the normal range of saliva pH. The product is examined by brushing gently for two minutes after the brushing for same period by toothpaste without the powder. Walnut bark contains high quantities of minerals particularly manganese, and contains important subgroup of polyphenolic compound called ellagitannins which have antibacterial effects and antioxidant properties. The differences before and after brushing with powder were highly significant.

Keywords: Toothpaste. Walnut bark. Teeth whitener.

Introduction

Enamel is the most mineralized part in the body, leading to form thin, very hard, translucent layer and calcified tissue that cover the crown of the tooth¹. The thickness and the hardness of enamel vary from tooth to other and from person to other one. The hardness of enamel is explained by its composition from inorganic materials 95-98% calcium and phosphate ions that form hydroxyapatite crystals (fig. 1)²,³. These crystals also contain trace minerals like strontium, magnesium, lead and fluoride. Enamel contains specific proteins called enamelines which tend to bind hydroxyapatite crystals⁴. Enamel is permeable so the fluids can move and diffuse. This permeability may affect the density and the hardness of enamel by demineralization which is the loss of calcium and phosphate ions when pH decreases less than 5.5 so the oral medium becomes acidic⁵.

The binding of fluoride ions with apatite occurs by filling the hydroxyl vacancies or by displacing hydroxyl ions. Because of the high charge density presents on fluoride ions, theses ions close and fit with calcium ions in the triangles of apatite leading to stabilize the crystal structure⁶. The binding of carbonate occurs by replacing calcium or phosphate ions, and the replacement depends on the development of crystal⁷.

![Figure 1: Crystal structure of hydroxyapatite](source.png)
ions incorporation have a positive synergistic effect on hydroxyapatite by increasing acid solubility of apatite mineral[10]. Chloride, sodium and lead may be present in the structure of apatite[11]. Organic materials are also present in a low concentration in the structure of enamel in a form of small peptides and amino acids distributed in the mature tissues[12]. Enamel also contains a distinct type of protein called enamelin which comprises 10% of the total enamel protein and involved in amelogenesis[13,14]. Mutation in the gene ENAM that is responsible for enamelin formation can cause amelogenesis imperfect[15].

**Materials and Method**

All reagents used were of high purity. The samples are the walnut tree bark. The bark pieces were collected and rinsed with distilled water three times and dried in oven at 40°C. The bark pieces after drying were powdered by stainless steel grinder three times until fine powder was produced. The powder is stored in a polyethylene container until use. The practical procedure included four parts: the first part is the aqueous extraction of the sample by continuous extraction using soxhlet for 24 hours, the extract is condensed by rotary evaporator then used as a crude extract in the whitening process. The second part is the mixing of powder with ordinary toothpaste and packaging the mixture to be examined. The third part is the formation of granules by mixing the powder with toothpaste and drying the mixture then convert it to granules. The fourth part is the use of powder only. The four products were tested on 40 volunteers in dentist clinic and the teeth were imaged before and after the whitening. The whitening effect of the products has been tested by two ways once by brushing and the second way by using micro motor device at 10000 rpm with soft brush. Three of products showed good results of whitening except the condensed extract, the others have a high effect of whitening. The highest effect of whitening was for the powder only without additives but have not favorable and pungent taste and the pH cannot be controlled easily. The effect of powder containing toothpaste was high and the pungent taste is reduced and the pH can be easily controlled. The effect of granules was less than the powder containing toothpaste despite the granules was made by mixing with toothpaste, this can be explained according to the consistency of the product. The two ways of whitening showed the same results this means that there is no effect for the mechanical cleaning and the brushing is easier. The whitening persists for two months for those that keep care the teeth (fig. 2). The brushing period was three minutes and the results were for one use only. The effect of whitening may be explained by the presence of carbonates, sodium, potassium, calcium, phosphorus, magnesium, iron, cupper, manganese, and zinc ions in the bark of walnut tree, all of these ions and molecules involved in the structure of hydroxyl apatite of the enamel and aid in demineralization process of enamel. Magnesium ions are located in the surface of the apatite crystal which has a stabilizing effect on the apatite lattice. Magnesium and carbonates have a synergistic effect by their incorporation to the hydroxyapatite lattice and by the ability to increase the acid solubility of apatite mineral. The structure of the plant also contains important compound called ellagitannin which is polyphenolic compound and sever antioxidant and has antibacterial effect. This product whitener is natural has no chemical compound which make it distinct over the other whiteners.

**Results and Discussion**

The effect of whitening for the four productswas examined in a dentist clinic by two ways the first one by brushing and the second by micro motor device at 10000 rpm with soft brush. Three of products showed good results of whitening except the condensed extract, the others have a high effect of whitening. The highest effect of whitening was for the powder only without additives but have not favorable and pungent taste and the pH cannot be controlled easily. The effect of powder containing toothpaste was high and the pungent taste is reduced and the pH can be easily controlled. The effect of granules was less than the powder containing toothpaste despite the granules was made by mixing with toothpaste, this can be explained according to the consistency of the product. The two ways of whitening showed the same results this means that there is no effect for the mechanical cleaning and the brushing is easier. The whitening persists for two months for those that keep care the teeth (fig. 2). The brushing period was three minutes and the results were for one use only. The effect of whitening may be explained by the presence of carbonates, sodium, potassium, calcium, phosphorus, magnesium, iron, cupper, manganese, and zinc ions in the bark of walnut tree, all of these ions and molecules involved in the structure of hydroxyl apatite of the enamel and aid in demineralization process of enamel. Magnesium ions are located in the surface of the apatite crystal which has a stabilizing effect on the apatite lattice. Magnesium and carbonates have a synergistic effect by their incorporation to the hydroxyapatite lattice and by the ability to increase the acid solubility of apatite mineral. The structure of the plant also contains important compound called ellagitannin which is polyphenolic compound and sever antioxidant and has antibacterial effect. This product whitener is natural has no chemical compound which make it distinct over the other whiteners.
Figure 2: Images of some volunteers teeth before and after whitening.
Figure 3: Cromascop used to compare between teeth before and after whitening

Conclusions

From the results and the period of whitening, the powder of walnut tree bark is a useful material for teeth whitening and has antibacterial effects because the presence of polyphenolic compounds. The paper discusses and treats important problems for males and females which can be solved in other expensive and harmful ways. The principle of this research depends on the use of natural products instead of chemicals so this whitener is safe to use.

Determination of Dyspnea in Mechanically Ventilated Patients

Masouda Hassan Abd El-Hamid Atrous1,2, Khaled Mohamed Al-Sayaghi3

1Collage of Applied Medical Sciences, Nursing Department, Jouf University, Kingdom of Saudi Arabia,
2Critical Care and Emergency Nursing Department, Faculty of Nursing, University of Alexandria, Egypt,
3Critical Care and Emergency Nursing Department, Nursing Division, Faculty of Medicine and Health Sciences, Sana’a University, Yemen

Abstract

Background: Although dyspnea is the most common suffering and devastating symptom in the mechanically ventilated patients (MVPs), it is not routinely measured.

Aim of the study: To assess dyspnea and factors contributing to it in MVPs.

Design: A descriptive research design

Settings: Intensive Care Units of Alexandria Main University Hospital.

Subjects: Forty critically ill conscious adult MVPs

Tool of data collection: Dyspnea assessment tool used to collect the data.

Results: 55% of the study sample had dyspnea and 86.4% of dyspneic MVPs had moderate to intense level of dyspnea.

Conclusion: Dyspnea is present in more than half of the MVPs. Moderate to intense dyspnea is more frequent in MVPs.

Keywords: Dyspnea, Mechanical ventilation, Modified Borg Scale.

Introduction

Dyspnea is a subjective experience of breathing discomfort described as air hunger, heavy breathing or choking.1,2 It is a common and often debilitating symptom that affects up to half of patients admitted to acute tertiary care hospitals and 25% of patients admitted to acute tertiary care hospitals seeking care in ambulatory settings.3,4 Presence of dyspnea is a strong predictor of patient’s clinical course and mortality and neglecting it cause suffering, complicate and extend length of stay, and counterbalance physiological benefits in terms of clinical outcomes.4,5,6 Therefore, mechanical ventilation which is a commonly used technological treatment in ICUs,7 aims to maintain adequate oxygenation, alleviate the patient’s respiratory symptoms, reduce the work of breathing (WOB), and improve patient comfort.1,6

However and at the same time, patients on MV may experience distressing symptoms such as anxiety, dyspnea, pain or discomfort, confusion, agitation, and sleep disturbances.8 In other words, dyspnea can persist, reappear, or re-increase after the initiation of MV. This can reveal many complications (such as pneumothorax, pneumonia, cardiac failure, anemia, etc.), air leaks, increased airway resistance, decreased lung compliance, inappropriate ventilator settings, anxiety and pain.6,9 Therefore, dyspnea could be used as a useful clinical management tool for the MVPs.6

The critical care nurses had an essential role in providing patient-centered care to maintain oxygenation and ventilation adequacy, breathing comfort, and patient-ventilator synchrony.\textsuperscript{(10)} Responsibilities of the critical care nurse related to ventilator management may vary among acute care settings, but no doubt the nurse is the “first-line manager” challenged with MVPs related problems.\textsuperscript{(9)} Therefore, it is very important that they should do their best effort to develop their knowledge and skills needed for effective management of MVPs.\textsuperscript{(9)}

As dyspnea is the most suffering and devastating symptom.\textsuperscript{(11)} A patient-centered approach of nursing care should include routine assessment for dyspnea using an appropriate instrument.\textsuperscript{(5, 9, 12)} Unfortunately, dyspnea is still not routinely assessed in critically ill patients, except during patient weaning from MV.\textsuperscript{(6)} During the last decades, manufacturers and researchers increase their attention on the patient-ventilator interactions.\textsuperscript{(13)} However, dyspnea has not been studied to any great extent in MVPs.\textsuperscript{(6)} In general critical care nurses have a sense of security that, because the patients are supported by the MV, they are receiving adequate ventilation and they are not suffering from dyspnea; however, in fact, dyspnea is common and more frequent problem in MVPs. In addition, there is a knowledge gap in the understanding of dyspnea in those patients. Therefore, this study aimed to assess dyspnea in mechanically ventilated patients.

\textbf{Materials and Method}

\textbf{Design:} A descriptive research design was used to assess dyspnea in MVPs.

\textbf{Sample:} A convenience sample of 40 critically ill conscious patients above 18 years old intubated and attached to MV for more than 24 hours.

\textbf{Settings:} Casualty and general ICU of Alexandria Main University Hospital.

\textbf{Instrument:} Dyspnea assessment tool used to collect the data and was developed after reviewing the related literature.\textsuperscript{(5, 6, 9, 14)} It consisted of two parts. The first part consisted of the patients’ characteristics, MV parameters and the respiratory distress manifestations associated with dyspnea. Arterial blood gases (ABG), peripheral oxygen saturation (SpO\textsubscript{2}) vital signs, anxiety, pain level, blood hemoglobin level (Hb) were also assessed. The second part of the tool consisted of the dyspnea scale. The Modified Borg Scale (MBS)\textsuperscript{(5, 15)} was used to assess dyspnea in MVPs. It is a 12-point scale (0, 0.5, 1–10) with numbers corresponding to descriptions regarding the amount of dyspnea, with no dyspnea rated as 0 and worst maximal dyspnea rated as 10.

\textbf{Data collection:}

The patient’s characteristics and health relevant data were recorded. The manifestations of respiratory distress associated with dyspnea, were continuously observed.

If any abnormality in breathing dynamics was present, dyspnea assessment was done by asking patients first “do you have trouble breathing”. If the answer was yes, then they were asked to rate the intensity by telling the patients the items of Modified Borg Scale (MBS) and ask them to select the dyspnea level. Finally, mechanical ventilation settings, vital signs, Hb level, ABG and SpO\textsubscript{2} were assessed and documented. Pain and anxiety were also assessed by visual analog scales (10-cm VASs to evaluate anxiety (“no anxiety” to intolerable anxiety”) and pain (“no pain” to “intolerable pain”).

\textbf{Data Analysis:} Patient were categorized according to the dyspnea as “present” or “absent” and therefore defining two groups of patients. The patients groups were compared using Wilcoxon rank sum tests for quantitative variables and the Fisher’s exact test for qualitative variables. A multiple logistic regression with a backward stepwise model selection was used to identify factors independently associated with dyspnea. All tests were two sided, and p values < .05 were considered statistically significance. The statistical analyses were performed using SPSS version 17.

\textbf{Results}

Result of this study shows that more than half of the study sample had dyspnea (55%) and the mean age of dyspneic patients was 53.39 ± 17.0. The majority of the study sample (77.5%) was males (90.9% of them were dyspneic). One half of the study sample suffered from pulmonary disorders and 59.1% of them had dyspnea. The mean score of dyspnea modified Borg scale was 6.0 ± 1.8 and this reflect the moderate to intense level of dyspnea. This table also shows that there was significant difference between dyspneic and non dyspneic patients in term of hemoglobin level.

Findings of current study revealed that 31.8% of the dyspneic patients had fever, 27.3% of them had pain and 63.6% of them had anxiety. Dyspneic patients exhibited
abnormalities in breathing dynamics (using of accessory muscle) while, non dyspneic ones did not exhibit any abnormality in breathing dynamics. Also dyspneic patients were more attempting to sit up in bed, had higher respiratory rate(RR), higher HR, higher systolic blood pressure (SBP) and diastolic blood pressure (DBP), lower Hb level, lower SpO₂, lower FiO₂%, lower Vt, lower flow rate, lower PEEP, higher PS, and higher PAP than non dyspneic patients. There were statistically significant differences between dyspneic and non dyspneic patients regarding RR, HR, SBP, DBP, Hb level and SpO₂. It was observed that dyspneic patients were on assist control ventilation (ACV) mode and PSV mode while, non dyspneic patients were on biphasic positive airway pressure (BIPAP), synchronized intermittent mandatory ventilation (SIMV), and continuous positive airway pressure (CPAP) modes and there were statistically significant differences regarding ventilator modes, PAP in dyspneic and non dyspneic patients.

Also it was found that 86.4% of the patients had moderate to intense level of dyspnea. Of those 50% had moderate dyspnea and 36.4% had intense dyspnea. There were statistically significant differences between dyspnea intensity level (mild, moderate and severe dyspnea) regarding abnormalities in breathing dynamics, RR, HR, SBP, and PAP.

**Discussion**

Poor patient–ventilator interaction causes discomfort and dyspnea. Optimizing patient comfort is a main concern in the ICU and relieving immediate suffering is indeed a natural mission of all caregivers. Therefore, the aim of this study is to assess dyspnea in MVPs.

Regarding the presence and intensity level of dyspnea in MVPs, the findings of this study highlight that dyspnea is more frequent in MVPs and our result revealed that more than half of the study sample had dyspnea and the majority of them experienced moderate to intense level of dyspnea. This may be related to assessment of dyspnea in MVPs is neglected due to safety feeling of critical care nurses that MV provide support to patients attached to it. In addition, lack of knowledge and skills related to dyspnea in MVPs. These findings are consistent with Bissett et al and Twibell et al findings who reported that patients had moderate and high levels of dyspnea during MV. On the contrary, Decavèl et al and Merchán-Tahvanainen et al results which revealed that MVPs had low to moderate levels of dyspnea.

In relation to the characteristics of the study sample, one half of the sample diagnosed with pulmonary disorders. This may be due to that the majority of subjects were adult male and more than one third of them were elderly. This may be due to smoking history and aging which affecting on the lung volume. As people are older, their lung functions start to decline (Veljković, 2019).

In our study, Dyspneic and non dyspneic patients did not differ significantly in term of patients’ diagnosis. This may be due to presence of many factors which contribute to dyspnea in MVPs. This result is in agreement with Schmidt et al. (2011) who found that intensity, characteristics and prevalence of dyspnea did not depend on the cause of respiratory failure and this result suggests that dyspnea may be caused by pathophysiology of disease. Indeed, patients with pulmonary disorders reported dyspnea that is may be related to the hyperinflation-induced volume restriction as in COPD patients.

Mechanical ventilation and critical illness induce great anxiety and distress in hospitalized patients. Anxiety and pain may increase dyspnea by stimulating ventilatory drive. We found that there were no statistically significant differences between dyspneic and non dyspneic patients regarding anxiety and pain in MVPs. This may be due to MVPs may be unable to communicate their distress, anxiety and pain. It was reported by Schmidt et al that pain and anxiety were more frequent in dyspneic than in non-dyspneic MVPs and dyspnea was significantly associated with anxiety.

As hemoglobin is a common generator of dyspnea, and at the same time there was an association between anemia and failure of weaning from MV. So, it is of most importance to assess hemoglobin level and correlate it with dyspnea in MVPs. Dyspneic patients had lower hemoglobin level than non dyspneic patients and there was statistically significant difference between dyspneic and non dyspneic patients in term of hemoglobin level. Multivariate analysis showed that there was no significant association between dyspnea and hemoglobin. This is similar to Schmidt et al. (2011) who found that that there was no association between dyspnea and hemoglobin.
Ventilatory settings might be involved in the genesis of dyspnea, in addition to ventilatory mode. In the present study, dyspneic patients were usually on ACV and PSV modes and there were statistically significant differences regarding ventilator modes, PAP in dyspneic and non dyspneic patients. This may be due to higher respiratory rate in ACV which increase inspiratory efforts and hence increase work of breathing. Schmidt et al (6) reported that ACV was the principle cause of dyspnea and found that the ACV mode was independently associated with dyspnea.(17)

Regarding Pressure support ventilation, there were no statistically significant differences between dyspneic and non dyspneic patients. This may be due to that the mean pressure support in dyspneic patients is to some extent similar to non dyspneic patients. On the contrary, Vaporidiet al (2019)(26) who found low pressure support levels have also been associated with a sense of excessive inspiratory effort and there was a trend toward more dyspnea in those who received a pressure support ventilatory mode with a pressure support level < 15 cmH2O.(6)

Other factor may contribute to dyspnea in MVPs is a low tidal volume. We found that there was no statistically significant difference between dyspneic and non dyspneic patients in relation to tidal volume. This may be also related to small variations in the value of the tidal volume in the dyspneic and non dyspneic patients. This is against Rauxet al (2019)(27) found that low tidal volumes were associated with air hunger.

Moreover, the inspiratory flow is among the ventilator settings that may be lead to dyspnea. Our findings indicate that dyspneic patients had a lower inspiratory flow than non dyspneic patients. This may be due to that ventilator flow rate is not adjusted to match the high respiratory demands of critically ill patients. Also there was no statistically significant difference between dyspneic and non dyspneic patients in the term of inspiratory flow. These findings are consistent with Schmidt et al (6)and Binks et al (2017)(28) findings that an inspiratory flow below 1 l/sec equates to a risk of generating dyspnea.

Conclusion

It can be concluded that dyspnea is present in more than half of the MVPs. Moderate to intense dyspnea is more frequent in MVPs. Assessment of dyspnea in the MVPs is feasible and applicable.

Ethical Clearance: The Research and Ethical Committee of the Faculty of Nursing, Alexandria University approved the study, and an ethical clearance was issued. Permissions were requested from hospitals’ management and unit’s managers. Participation in the study was voluntary and an informed written consent was obtained from patients after explaining aim of the study. The right to refuse to participate or to withdraw from the study was emphasized to patients. Confidentiality of participants was maintained.

Duplex Ultrasound for Carotid Arteries Must be Done as Screening for All Patients with Coronary Artery Surgery Regardless of Age Group and Risk Factors

Samer Makki Mohamed Al-Hakkak¹, Firas Shaker Mahmoud Al-Faham², Mundher Mudhafar⁴, Ali Najeh Al-Awwady¹

¹Department of Surgery, Faculty of Medicine, Jabir Ibn Hayyan Medical University, Najaf City, Iraq
²Department of Surgery, Faculty of Medicine, Kerbala University, Kerbala City, Iraq

Abstract

Aim: Routine utilizes of Doppler ultrasonography in the clinical examination of the patients for carotid artery stenosis varies according to the age groups. In the present work, predictive level of age groups and co-occurrence risk factors are examined in terms of the necessity of Doppler ultrasonography to be routinely used in the examination of the carotid artery in isolated coronary and associated with carotid artery surgery.

Material and Method: 86 patients underwent carotid endarterectomy in our center between April 2016 and June 2018. Thirty-eight (44.18%) of these patients had been detected during the screening before the coronary artery by-pass graft surgery, whereas 48 (55.82%) were patients referred from the neurology clinic because of severe carotid artery stenosis. Retrospectively reviewed of all patients in terms of gender and age group, as well the existence of hypertension, diabetes, and smoking. Division of patients into two groups: those < 65 years age (Group 1) and those equals 65 and over (Group 2).

Results: Thirty-one (36%) of the patients that underwent carotid endarterectomy was < 65 years’ age (Group 1). Fifteen (17.4%) of these patients were those that would undergo coronary bypass surgery. When the patients had submitted isolated and concomitant carotid artery endarterectomy were evaluated in terms of risk factors, hypertension and diabetes were found significantly higher in group one as compared to group two (p<0.05).

Conclusion: Our opinion Doppler ultrasonography should routinely use together with physical examination in the preoperative evaluation of the patients with coronary artery disease in order not to underestimate such critical carotid artery stenosis that would require surgical intervention.

Keywords: Carotid artery, Doppler ultrasonography, Coronary artery surgery, age, risk factors, endarterectomy.

Introduction

Today, cerebrovascular accident (CVA) is the 3rd leading cause of mortality, second in deaths related to cardiovascular diseases and first in neurological deaths. 80% of CVAs are ischemic and 20% are hemorrhagic. Carotid artery stenosis (CAS) is present in approximately 50% of those who are diagnosed as ischemic CVA’s ¹. Ischemic stroke; is one of the most common prolonged hospitals stays post coronary artery bypass graft (CABG) surgery and the lethal complications that lead to a patient loss ². Critical CAS or occlusion has been shown in the majority of patients with CABG who developed perioperative stroke ³-10. Critical CAS was reported in 36% of patients who will...
As known, patients with CAS who have become symptomatic, refer to neurology clinics and are diagnosed by the examinations. Patients with atherosclerosis who are neurologically asymptomatic and at constant risk for CVA are checked for carotid system integrity, especially in healthcare institutions where they are referred for other atherosclerotic diseases like coronary artery disease or peripheral vascular disease. Some centres are suggesting that pre-CABG carotid artery screening should be performed in diabetic patients for <65 and all patients ≥65 years old ages. It has been observed that the tendency is in this direction in many centres. So, the objective of this study was to investigate the incidence of CAS in patients undergoing CABG and determine the age as a risk factor related to critical carotid stenosis.

**Material and Method**

Between April 2016 and June 2018, 91 carotid endarterectomy procedure was performed for 86 patients. Sixty-five of them were male and 21 females. Five patients had bilateral (4 males, 1 female patient) critical CAS. Of these, 38 (44.19%) patients were diagnosed on the pre-operative assessment before the coronary bypass surgery, and 48 (55.81%) patients were referred from the neurology clinic for the reason of symptomatic CAS. On the carotid Duplex ultrasound, if there is ulceration with more than 50% stenosis, or any 70% or more stenosis on the common or internal carotid artery were considered as critical CAS as recommended in the guidelines. These patients underwent a carotid artery system, digital angiography examination and determination of the same criteria were considered surgical indications. Colour Doppler-angiography compatibility was determined as 98%. There were two groups, aged less than 65 years (Group 1) and 65 years and older (Group 2) and they were retrospectively investigated for coronary artery disease, sex, diabetes mellitus (DM), hypertension (HT) and smoking.

**Results**

The patients who underwent carotid artery endarterectomy, 31 (36.04%) were in group 1 and 55 (63.95%) in group 2. Of Group 1 patients, 15 (17.44%) were diagnosed by Carotid Doppler ultrasonography during preoperative preparation for CABG and 16 (18.6%) of them were referred from the neurology clinic as shown in (Table 1). According to this; on preoperative scans for CABG, 38 patients diagnosed with critical CAS, 15 of them were <65 age (Group 1) patients. As a result, 39.47% of the patients (15/38) with CAS who are diagnosed with pre-CABG carotid artery screening were younger than 65 years old. When the two groups of patients were examined in terms of risk factors, DM and HT rates were significantly higher in group 1 compared to group 2 (p <0.05) (Table 2). According to this, in group 1, 44.4% of patients had DM and 63.5% had HT whereas, in group 2, this rate was determined as 29.4% and 42.2%, respectively. The patients who referred to the neurology clinic evaluated for coronary artery disease (n:48). Twenty-one of them had the critical coronary artery disease, 11 of them treated by PTCA-stent (Percutaneous transluminal coronary angioplasty) procedure, and the remaining referred for CABG. Carotid and coronary surgical procedures were performed in the same session or different sessions according to the severity of coronary lesions. Patients who were referred from neurology clinic for Carotid Endarterectomy and who diagnosed as critical CAS on pre-CABG screening were compared in terms of risk factors. According to this, regardless of age group, DM and HT were significantly higher (p <0.05) in pre-CABG patients. Then who were referred from the neurology clinic (Table 3). In patients diagnosed with CAS on pre-CABG screening, DM was detected in 45.5% and hypertension in 63.5% and patients referred from neurology clinic this rate was determined as 26.3% and 42.2%, respectively. When the age groups and referral centres were compared; there was a statistically significant difference in group 1 and group 2 in the incidence of DM and HT in patients who referred to the neurology clinic. The incidence of DM and HT were significantly higher in group 1. Whereas there was no statistical difference in risk factors between age groups in patients diagnosed with critical CAS on pre-CABG screening. On pre-CABG screening patients DM and HT risk factors have been already high for all ages. As a result, there was no difference for critical CAS between groups in pre-CABG screening (Table 4).

Figure 1: Age group rates and risk factors distribution of patients undergoing carotid artery endarterectomy (DM: Diabetes Mellitus, HT: Hypertension).
Discussion

Stroke risk incidence is 1-2% in coronary artery bypass patients with no pathology in the carotid artery system, whereas stroke risk is 14% in patients with stenosis in the carotid arteries. Carotid lesions cause cerebral hypo-perfusion and stroke because of stenosis, thrombosis or particle embolization due to plaque rupture in the perioperative and early postoperative period. In this study, the level of necessity of Colour Doppler ultrasonography of the carotid artery system during the preparation of patients before coronary bypass surgery was investigated. In some studies, the age limit was determined as 60 or 65 for routine pre-CABG carotid artery screening by Doppler ultrasonography was recommended. In the study of Ascher, routine Carotid-Doppler ultrasonography screening before coronary bypass surgery is recommended in patients older than sixty years, unless they have at least two risk factor: DM, HT and smoking. Cornily et al. have considered patients with cerebral or peripheral artery disease, carotid murmur, presence of DM and/or over 70 years as risky, and recommend carotid artery system imaging in this group of patients. Durand et al. suggest routine carotid system Doppler ultrasonography scan because of increased risk over 65 years old, and in patients under 65 years old Doppler scan should be done if there is a murmur in the carotid artery system with CVA history.

Another study, it has been stated that this is troublesome and not necessary, therefore there is no reason for routinely carotid artery screening for all age groups. At, our centre, carotid artery Colour Doppler screening is performed routinely in all patients who are preparing for CABG. All patients who have critical stenosis on carotid Doppler ultrasound are referred for vertebral and carotid artery CT angiography, and treatment options are determined according to these results. Our aim is; to update this issue because younger patients are frequently referring to undergoing either coronary artery bypass surgery or carotid artery endarterectomy. Carotid Duplex screening is generally determined according to the age limit of 60 or 65 years, so we have examined all the patients regardless of their age. In this study, 36% (31 of 86 patients) of the patients who underwent carotid artery endarterectomy were under 65 years old. And also among patients with critical CAS who referred for CABG surgery lower than 65 years constitute the high rate of 39.47% (15 of 38 patients).

When we compared the risk factors according to both age groups and referral centres together; we saw that the rate of DM and HT were significantly higher in <65 years who referred from neurology centre. But on the dark side of the moon; yes, the rate of risk factors was higher than group 2 but; almost 1/2 of the patients were non-DM and non-HT. In the statistical tests, DM and HT are more frequent risk factors for CAS in <65 age, however, this does not mean that there is no CAS in this population who has no DM or HT. As shown in (Table 2) and (Table 5), DM and HT are not detected in almost
half of the patients in <65 years old group. Patients <65 years old 55.6% had no DM and 36.5% had no HT. For this reason, the selection of patients under the age of 65 according to the presence of DM leads to the fact that more than 50% of this group cannot be diagnosed and missed. Therefore, routine screening criteria should be the same for both age groups. In patients over 65 years old, carotid colour Doppler ultrasonography screening is routinely recommended for patients without risk factors such as DM and HT. This recommendation should also apply to the <65 age patient group. Critical arterial stenosis can be detected in colour Doppler screening of the carotid artery system and atherosclerotic thickening can be detected at a considerable level even if not at the surgical margin. By knowing the level of CAS before the coronary artery surgery, even if not at the surgical level; indirect stroke risks could be reduced such as selecting the side of central vein catheterization to avoid trauma to the diseased carotid artery.

**Conclusion:**

Stenosis of the carotid artery was more common in patients with DM and HT. However, there is a substantial mass of non-diabetic and non-hypertensive patients who are treated surgically for critical CAS. We believe that, in the preoperative evaluation of CABG patients, colour Doppler ultrasonography should be routinely taken plus to the physical examination to avoid missing the critical CAS that we have encountered in the <65 age group patients.

The Changes of Seminal Fluid Parameters Following Laparoscopic Varicocelectomy Versus Open Varicocelectomy

Jassim Mohammed Auib Al Taha¹, Raisan Mahdi Shorama Al Jabery²

¹Working in Al Fayhaa Teaching Hospital, ²M.B.Ch.B. F.I.C.M.S. General Surgery, Working in Al Fayhaa Teaching Hospital, Al Askary Street, Basra, Iraq

Abstract

A varicocele is defined as a dilated pampiniform plexus, the network of small veins responsible for venous drainage from the testicle and deep tissues of the hemiscrotum. Two types of operative procedures were applied, i.e. laparoscopic varicocelectomy (LV) and open inguinal varicocelectomy (OIV). The aim of the present study is to compare LV and OIV regarding seminal fluid parameters following surgery. A prospective, comparative study conducted on 110 men with infertility and varicocele. Patients divided into 2 groups viz. LV group (n=50), OIV group (n=60). The LV group consist of 35 and 43 individuals with unilateral and bilateral varicocele, respectively. Similarly, OLV group showed 15 and 17 individuals with unilateral and bilateral varicocele, respectively. Grades of the varicocele in LV group was found to be 19 and 31 in unilateral and bilateral varicocele, respectively. Similarly, OLV group showed 22 and 38 individuals with unilateral and bilateral varicocele, respectively. An improvement, i.e. increased in the semen volume and sperm count while decreased in the abnormal sperm morphology were found to be more in the laparoscopic surgery as compared to the open inguinal surgery. LV is the technique requiring skills and experience. It is a same-day surgery procedure, resulting in rapid recovery, cost savings, and is well accepted by the patient compared to open varicocelectomy.

Keywords: Laparoscopic varicocelectomy, Varicocele, Open inguinal varicocelectomy, sperm count.

Introduction

Nowadays, the fertility is declining worldwide, with a rate of 25% among couples. The male contribution in declining fertility is conservatively at approximately 45%¹. While there are multiple causes in the male, one major cause is varicocele¹. The American Society for Reproductive Medicine and the American Urological Association have found that varicocele causes infertility. A varicocele is defined as a dilated pampiniform plexus, the network of small veins responsible for venous drainage from the testicle and deep tissues of the hemiscrotum. This plexus is contiguous with the ipsilateral gonadal vein, which drains into the renal vein on the left and directly into the inferior vena cava on the right. As a result of leakage, there is a backflow of renal blood down these veins. This renal reflux results in toxic damage to both spermatogenesis and male hormone production by the Leydig cell². The incidence of varicocele can vary between 19% and 41%. Varicoceles occur in approximately 15% of the general male population but are more common (25%-35% prevalence) in infertile men and are the most common physical abnormality in infertile men. Varicoceles typically develop during puberty³.

Various mechanisms have been proposed to explain infertility in men with varicocele⁴. These include hypoxia, stasis, testicular venous hypertension, elevated testicular temperature, increase in spermatic vein catecholamine, and increased oxidative stress. Also, the testes are damaged in varying progressive stages.
over time. There are hyperthermia, testicular shrinkage and atrophy, sperm membrane damage, spermatogenic arrest, Sertoli cell destruction, and germinal epithelial sloughing. In its earlier subclinical stages, varicocele is diagnosed by Doppler ultrasound, whereas in its later more advanced clinical stages, the swollen veins become palpable. The condition is bilateral, but may appear to manifest unilaterally.

When medically indicated for clinically significant varicoceles, many treatment options have been used over time. Varicocelectomy is by far the most commonly performed operation for the treatment of male infertility. The indications of varicocelectomy for clinically significant varicoceles includes infertility, particularly with impaired semen parameters or sperm quality etc. The surgical approach (high retroperitoneal, inguinal, subinguinal) is the gold standard in treatment of varicocele, where its aim is to ligate internal and external spermatic veins with preservation of the vas deferens and lymphatic vessels. In addition to open surgical approaches; laparoscopic surgery and radiologic embolization method are also used. The retroperitoneal high ligation technique, known as the Palomo approach utilises a horizontal incision medial to the anterior superior iliac spine. This approach enables identification of the internal spermatic vein before extensive branching, which theoretically could reduce the recurrence rate. This approach can be performed with or without arterial ligation. The laparoscopic intraperitoneal approach utilises a transperitoneal intra-abdominal approach, which offers several advantages including increased efficiency for bilateral surgery and relatively short operating times over open varicocelectomy. The approach involves placement of laparoscopic ports in the abdomen, identifying the inguinal ring and the spermatic cord contents, and selectively ligating the gonadal veins, whilst leaving the arterial blood supply intact. At this level, only one or two large veins are present and, hence, a fewer number veins are to be ligated. In addition, the testicular artery has not yet branched out and is often distinctly separate from the internal spermatic veins. LV is generally performed transperitoneally, but extra- or retro-peritoneal approaches have also been described. The persistence/recurrence rate of LV is in the range of 6–15%. With this background the aim of the study is to compare laparoscopic varicocelectomy and open varicocelectomy regarding seminal fluid parameters following surgery.

Material and Method

This was a prospective, comparative study conducted on 110 men with infertility and varicocele in Al Fayhaa teaching Hospital in Basra between May 2015 to September 2017. Patients divided into 2 groups viz. LV group underwent LV (n=50), OIV group underwent open inguinal varicocelectomy (n=60). The informed consent was taken from the patients before enrolled in the present study.

All patients evaluated for the other causes of infertility and seminal fluid were analyzed for the various parameters pre and post operative (3 months) procedure. The seminal fluid was evaluated for the semen volume, sperm count (million/ml), progression motility (%) and their morphology (% Abnormal form).

Inclusion Criteria:
1. Men aged 20-35 year varicocele grade 2 and 3
2. The female partner has normal fertility
3. Abnormal seminal parameters

Exclusion criteria: Patients varicocele and coexisting cause of infertility.

Statistical Analysis: Results were presented as mean ± standard deviation (SD). One way analysis of variance (ANOVA) and Dunnett multiple comparison test was done to estimate the statistical significance.

Results

In the present study, patients with infertility and varicocele was treated with two ways, i.e. LV (LV, n=50) and open inguinal varicocelectomy (OLV, n=60). LV group consist of 35 and 43 individuals with unilateral and bilateral varicocele, respectively. Similarly, OLV group showed 15 and 17 individuals with unilateral and bilateral varicocele, respectively.

Semen parameters before and 3 months after surgery for LV and OLV are shown in the Table 3. The semen count was comparable in the both LV and OLV operated patients as compared to the before surgery. The sperm count found to be increased in the LV group (p<0.001) than the OLV group as compared before surgery count. Percentage progression motility was found to be increased in both the surgery. However, non-significant improvement was occurred in the LV group. The percentage morphology was decreased in the LV group as compared to the preoperative parameter.

Discussion

In the inguinal approach (also known as Ivanissevich approach), an incision is made in the groin above and lateral to the ipsilateral pubic tubercle and extending laterally along the skin lines of the inferior abdominal wall. The external oblique fascia is sharply incised to expose the spermatic cord covered with the cremasteric fibers, which, along with the external spermatic fascia, are incised to provide access to the vascular structures within. Generally, the vas deferens along with its artery, vein and lymphatic vessels, should be identified and preserved. Venous structures, including the internal spermatic veins, cremasteric veins, external spermatic veins, gubernacular veins and periarterial veins (venae comitantes), have all been described to be part of the body of varicoceles and should be identified and dissected for ligation. Any arteries and lymphatic vessels should be clearly identified and preserved to avoid complications. The inguinal approach is a traditional surgical dissection in familiar anatomy, but the inguinal canal dissection requires fascial incision and increases the risk of pain...
and hernia formation, as well as inadvertent damage to the ilioinguinal nerve.

The subinguinal (Goldstein) approach has gained popularity as a safe and effective operation. Incision of the open subinguinal varicocelectomy is made at the level of the external inguinal ring to allow delivery of the spermatic cord without dividing any muscle or fascia of the abdominal wall. Benefits include a shorter recovery and less pain than the inguinal approach (probably due to the lack of fascial violation). However, all vessels branch out at this low level, resulting in a higher number of vessels, each of a smaller diameter, to be dissected. Thus, optical magnification is strongly recommended when performing a subinguinal varicocelectomy. Disadvantages include a longer operative time, presumably due to the slightly less intuitive anatomy. Due to a high rate of testicular artery damage and/or hydrocele formation, the scrotal approach is a historical operation that is rarely employed in the modern era and has been replaced by safer and more reliable approaches. In the present study also, the improvement i.e. semen volume, sperm count and abnormal sperm morphology were found to be more in the open inguinal surgery as compared to the laparoscopic surgery.

Although open varicocelectomy is commonly performed under general or spinal anesthesia on an outpatient basis, in selected patients, it can be performed under local/regional blockage with or without intravenous sedation. Conventional open varicocelectomy is associated with a wide range of variation in the surgical outcomes. Complications, occurring at a rate of 5-30%, include hydroceles, inadvertent arterial ligation, testicular atrophy, injury to the vas deferens, epididymitis, hematoma and wound infection. The recurrence/persistence rate, at 10–45%, is also significantly higher than other treatment options.

In order to understand changes in seminal fluid parameters post open varicocelectomy, various researchers has explored the correlation. In a study by Abdel-Kader et al. subinguinal varicocelectomy with loup magnification was successfully performed in 91 patients, with no intra-operative complications. After surgery, followup has been done for 7 months to perform semen analysis. Despite considerable changes were noted in sperm concentration, there wasn’t statistically significant difference in percentage of motility and normal sperm morphology post-varicocelectomy. In our study, the laparoscopic surgery operated patients showed increases in semen volume, sperm count, reduce sperm abnormality etc.

In another study by Al-Ghazo et al. the changes regarding preoperative and postoperative total sperm motility counts and spontaneous pregnancy rate were evaluated. Surgical varicocelectomy improves the total sperm motility counts in patients and improves the spontaneous pregnancy rates. In a retrospective study by Shamsa et al. evaluation of four parameters (sperm analysis, fertility, early ejaculation and spontaneous abortion among spouses) in relation to varicocele and varicocelectomy during a 13-year period was done. A total of 1,711 patients with varicocele underwent varicocelectomy by high inguinal method (251 cases), subinguinal method (1,375 cases), scrotal method (34 cases), and subinguinal method with local anesthesia (38 cases). Sperm count, motility and morphology increased three months post operation along with improvement in pregnancy rate, early ejaculation, and scrotal pain.

Efficacy of varicocelectomy and its influence on semen parameters, particularly sperm count, motility and morphology has been determined by Chhabra et al. in a study population of 50 men with varicoceles who had both preoperative and postoperative semen examination done. Macro and microscopic assessment of semen samples was carried out according to WHO guidelines. The surgical approach used for varicocelectomy was inguinal. Significant improvement in semen parameters viz sperm counts/ml, sperm counts/ejaculate and sperm motility were observed after varicocelectomy. Preoperatively, men with Grade III varicoceles had lower sperm counts and sperm motility, but significant improvement was observed post-operatively compared to men with Grades I and II varicoceles. In a study by Cakiroglu et al. comparison of preoperative and postoperative sperm parameters such as sperm count, motility, and morphology in patients with normal sperm concentration with teratozoospermia and asthenozoospermia has been done on 106 patients. The sperm motility of patients with normospermia showed a significant improvement postoperatively. In a retrospective study by Leonardo et al. to evaluate the improvement of seminal parameters after surgery of varicocele in 232 patients, 18 to 37 years old; it was observed general improvement of the seminal parameters (concentration, motility and morphology) to 150 of patients (64.65%) and another prospective study of 123 patients diagnosed with primary infertility with varicocele by Shabana et al. semen analyses were
completed preoperatively and 6 months postoperatively. Microscopic subinguinal varicocelectomy was done in all cases. Patient demographics, pre- and postoperative clinical data (varicocele grade and semen parameters) were statistically analyzed. Semen parameters were found to be improved after varicocelectomy. Complications of laparoscopic varicocelectomy, occurring at an overall rate of 8–12%, include air embolism, inadvertent arterial division, genitofemoral nerve injury, hydrocele, intestinal injury and peritonitis. Hydrocele, secondary to lymphatic congestion after accidental ligation of the lymphatic vessels, is the most commonly encountered post-operative complication. When the lymphatics are not intentionally identified and preserved, the post-operative hydrocele rate can be as high as 40%. Technically, with the optical capacity of laparoscopes at close distance to the tissues, magnification at 10–20x can be achievable, allowing skillful laparoscopic surgeons to visualize and spare lymphatic vessels using similar microsurgical principles and techniques as in microsurgical varicocelectomy. To further facilitate the identification of lymphatics, various authors described techniques of scrotal infusion of blue dyes (patent blue V, isosulfan blue or methylene blue) that could result in a significant reduction of the post-operative hydrocele LV should only be performed by experienced laparoscopic urologists. Other disadvantages of the procedure include the high cost, need of general anesthesia in all cases. The study by Chen et al. showed the feasibility and successful results of treating the varicocele using the video laparoscopic approach because of its bigger vascular vessels. The 4000 patients were treated for both left and right varicoceles. No morbidity and mortality were encountered in the study, with little likelihood of recurrence of the condition. The semen profile was improved, including a decreased sperm DNA fragmentation rate and successful pregnancy favor.

**Conclusion**

LV is the technique requiring skills and experience. It is a same-day surgery procedure, resulting in rapid recovery, cost savings, and is well accepted by the patient compared to open varicocelectomy. The important feature of the surgery is the degree of magnification obtained through the video laparoscopy, enabling a complete and thorough bilateral ligation of the testicular veins, without risk of injury to the testicular artery. In the present study, an improvement, i.e. increased in the semen volume and sperm count while decreased in the abnormal sperm morphology were found to be more in the laparoscopic surgery as compared to the open inguinal surgery.

Impact of Food Allergy on Adolescent’s Quality of Life

Azza I. Ismail1,2, Mohammed Y. Abdel Hamid3

1Assistant Professor, College of Applied Medical Sciences, Jouf University, KSA, 2Lecturer of Pediatric Nursing, Faculty of Nursing, Suez Canal University, Egypt, 3Assistant Professor of Home Economics, Faculty of Education, Suez Canal University, Egypt

Abstract

Background: Food allergy is a major problem in both developed and developing countries and seems to increase over the past 10–15 years. Due to the incomplete understanding of the effects of food allergy on health-related quality of life (HRQL) among adolescents. This study aimed to identify the impact of food allergy on adolescent’s quality of life.

Method: In this cross-sectional study, 144 adolescents aged 12–18 years who objectively-diagnosed having food allergy were included. Adolescents were interviewed and completed questionnaire sheet consisted of two parts, the first part for personal data and the second part included questions about types of allergic foods, signs and symptoms and complications of allergy, also they completed specific food allergy quality of life questionnaire-teenager form.

Results: Shows that, the average score of the food allergies scale is (167.93), which is in the high range. The average quality of life measure for adolescents is 105.42 degrees, which is considered a low level of quality of life as a whole. There is a negative correlation between food allergies in adolescents and the quality of life dimensions at the level of significance p= 0.05, which highlights the importance of the current study.

Conclusions: The present study concluded that food allergy has a high impact on the quality of life of adolescents and there are negative correlations between adolescent food allergies and the quality of life from all dimensions.

Keywords: Adolescents, Food allergy, Quality of life, Health-related quality of life.

Introduction

Food is a crucial part of our lives; it is necessary to stay alive and it is an integral part of our cultural identity. Food allergy is an adverse reaction to the immune system that occurs shortly after exposure to some food.1,2 In developed countries, food allergy has increased and can have a dramatic impact on the quality of life as it causes fatal reactions.3,4 Around 4-6% of children and 2.3% of teenagers are diagnosed with food allergy, are allergic to one or more foods and have dietary restrictions that impair their quality of life.5

Food allergy can be fatal, and teens are at the highest risk of death due to food allergy.6 Symptoms may include swollen lips, tongue, or eyes; itchiness, rash, or hives; nausea, vomiting, or diarrhea; coughing, heavy speech, or swallowing disturbance; wheezing or breathing difficulty; dizziness, fainting, or loss of consciousness, change of mood, or confusion. Food reactions can range from mild to severe enough to be fatal (i.e. anaphylaxis).7,8 Quality of life (QoL) can also be characterized as well-being that is determined by both objective and subjective factors in many areas of life that are considered important in one’s culture and time.9

Fatal reactions3,4 Around 4-6% of children and 2.3% of teenagers are diagnosed with food allergy, are allergic to one or more foods and have dietary restrictions that impair their quality of life.5

Though the health-related quality of life (HRQL) has three components: personal, psychological and physical\textsuperscript{[10]}. Evidence has shown that allergic diseases have a negative impact and deteriorations on the health-related quality of life of in children. Pediatric research suggests that food allergy can affect various aspects of (HRQoL) for children, adolescents, and their families as the risk of allergic reaction limits children in their autonomous social activities\textsuperscript{[11]} more often absent from school and less self-confident \textsuperscript{[12]}.

**The Aim:** The aim of the present research was to identify the impact of food allergy on adolescent’s quality of life.

**Research Question:** What are the effect of food allergy on adolescent’s quality of life?

**Subject and Method**

**Design:** Descriptive cross-sectional design used in this research

**Setting:** primary schools (six grade), preparatory and secondary schools of El Kassasen City, Ismailia Governorate, Egypt. And from faculty of nursing and education (first-year students) Suez Canal University, Egypt.

**Sample:** A random selection of 144 adolescents who have already been diagnosed with food allergy (12-18) years.

**Tools of data collection:**

**Tool (1):** Structured questionnaire sheet

**Part (I):** Socio-demographic data about adolescents and their parents.

**Part (II):** Questions about the type of food that causes allergy, signs and symptoms, complications, and allergy effects on educational achievement and family.

**Tool (2):** Food allergy quality of life questionnaire-teenager form\textsuperscript{[12]} was used. The questionnaire consisted of (64) questions distributed on three axes reflecting the quality of life dimensions (physical aspects, health aspects, and social relationships within and outside the family).

**Validity:** The tools were revised by three experts in pediatric nursing and community health nursing for clarity, relevance, applicability, and comprehensiveness.

**Pilot Study:** A pilot study was conducted on 15 adolescents.

**Procedure:** The data was collected during the second semester of the 2017-2018 academic year. Oral affirmative consent was obtained from adolescents after explaining the aim of study, each adolescent was interviewed individually in order to fill the research tools which take about 30 to 40 minutes.

**Statistical analysis:** The data was then imported into the statistical analysis program of the Statistical Package for Social Sciences (SPSS version 18). The SPSS software used to calculate the arithmetic mean, the standard deviation, the frequencies, the percentages, the coefficient of Pearson correlation, the variations between the measures using the T-test, and the one-way calculation using the F test.

As shown in table (1) near two-thirds of study sample (62%) have an allergy to only one food. While 7% have an allergy to three types of food. Most of the sample (79.3%) have an allergy to strawberry followed by 60.3% have an allergy to mango. While the minority of them (8.6%) have allergy to wheat. All adolescents (100%) had respiratory complications due to allergy, followed by dermatological, gastrointestinal and anaphylaxis (90.2%, 68.3%, and 56.1%) respectively.

**Significance at level 0.05

Seen from the table (3) that, there is a negative correlation between food allergies in adolescents and the quality of life from all dimensions at the level of significance 0.05, which highlights the importance of the current study.

Discussion

The current study found that over two-thirds of adolescents were girls and that less than two-thirds of adolescents were allergic to one food while less than 10% were allergic to three foods. These results in contradiction with[12] who studied “developed self-administered food allergy quality of life questionnaire for adolescents”, and found that less than two-thirds of adolescents were allergic to three and more food types. More than three-quarters of adolescents are allergic to strawberry, mango, and milk, respectively, in the current study. This is distinguished from[13] who studied “Interpretation of commercial food ingredient labels by parents of food-allergic children” and found that more than half, more than one fifth and less than ten percent of adolescents were allergic to soy protein, peanut, and milk respectively. On the other side[14] who studied “Food allergy in adolescents and adults” found that nuts and seafood were the main cause of adolescent’s food allergy. From the author’s point of view these variations may be due to differences in location, community or habits.

All adolescents reported respiratory problems in the current study, the majority of them had dermatological complications, more than two-thirds had gastrointestinal complications and more than half had anaphylaxis.
These findings are confirmed by [1] who found more than four-fifths of adolescents suffered from respiratory complications and more than two-thirds of adolescents had dermatological complications. The results of the study also showed that cardiac complications were the least common insignificantly more than one quadrant, and this is contrary to [1], who found that just under half of the adolescents had cardiovascular complications. From the point of view of the author, cardiovascular problems may occur due to accidental or careless adolescents and their families regarding food types that can cause allergy, careless reading of food ingredients and individual differences in food reactions.

The current study showed that all aspects of quality of life are affected by food allergy with an average of more than one-third for physical aspects, health aspects and social relations, and overall quality of life. Such findings were consistent with [12,15] who found that more than one-third of children with food allergy had an effect on school attendance and were socially isolated and had worse overall health. These results also supported by [16,17,18] all of these studies reported worse physical function, school, and social limitations and general health. Moreover [15] who found that children with nut allergy had poorer total HRQL.

The current study showed a negative correlation between adolescent food allergy and quality of life from all dimensions as physical aspects were -0.19, health aspects were -0.52, social aspects were -0.48 and quality of life were -0.48 in general. Such findings in line with [19] who find negative correlations as r = -0.4 with respect to general health and family activity and supported by [10] as well. However, in accordance with [1,6,12] who also found negative associations between adolescent food allergies and the quality of life from all dimensions as physical functions were -0.29 and general health was -0.31. More about [1] who found a negative correlation between adolescent food allergies and HRQL as a correlation (-.62). From the point of view of the author, this connection is negative due to the overall deficiency of the quality of life among adolescents and it also reflect the sever effect of food allergy on adolescent’s quality of life which highlights the importance of the current study.

**Conclusion**

The present study has shown that food allergy has a high impact on the quality of life of adolescents, and there are negative correlations between adolescent’s food allergy and the quality of life from all dimensions.

**Recommendations:**

1. More researches are needed to clarify gender differences in this field.
2. Further research is needed to highlight the impact of food allergy on the development of children.
3. Food allergy programs to help adolescents deal with their health problems and prevent complications and consequences
4. Program to enhance the socialization of food allergy adolescents

**Source of Funding:** Self

**Conflict of Interest:** Nil

**Ethical Clearance:** The Research and Ethical Committee of the Faculty of Nursing, Suez Canal University approved the study, and an ethical clearance was issued. Permissions were requested from school managers where the study was conducted. Participation in the study was voluntary and an informed consent was obtained from adolescents after explaining the aim of the study. The right to refuse to participate or to withdraw from the study was emphasized to adolescents. Confidentiality of participants was maintained.

The Behavior of Visual Inspection with Acetate Acid (VIA) Test on Women of Childbearing Age in Bima City of West Nusa Tenggara

Adang Bachtiar Kantaatmaja¹, Dumilah Ayuningtyas¹, Sri Windiarti²

¹Department of Health Policy and Administration, Faculty of Public Health, ²Health Reproduction, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

Cervical cancer is the third highest cause of women mortalities in the world; in Indonesia, it was estimated that every one hour one person died. State burden for handling cervical cancer is quite high. The biggest cause cervical cancer is late for early detection. Visual Inspection with Acetate(VIA) method is an effective and efficient method to be applied to countries with low social determinants and limited human resources. This study aims to obtain about the behavior of VIA test on the WCA who have been given counseling and the tendency of relationship among factors affecting. This research is a qualitative study used Rapid Assessment Procedure (RAP) on 14 people informants WCA who have been given counseling about the cervical cancer detection, married, aged 30 - 50 years, reside in Bima City of West Nusa Tenggara. The results show that 1. The decision to do VIA test tends to be influenced by method, process and evaluation of counseling. 2. Counseling on individual method tends to be more effective than mass counseling. 3. Counseling given when midwives provide counseling and IUD KB installation service tends to be more effective because it can be done simultaneously. 4. Counseling about VIA given tends to increase knowledge but does not necessarily change behavior in VIA test. 5. Other factors that tend to influence the behavior of VIA test on WCA who have been given counseling are perception, motivation, and husband support.

Keywords: VIA, WCA, early detection, cervical cancer, qualitative study.

Introduction

Cervical cancer is a major problem for women in developing countries. This disease is the third most common cancer among women worldwide, with the incidence of age standards in 2008 greater than 30/100,000/year in East and West Africa, 26.8/100,000/year in South Africa, 24.6/100,000/year in South-Central Asia, 23.9/100,000/year in South America, and 23.0/100,000/year in Central Africa.¹

In Indonesia, cervical cancer is the second most common cancer in women, with an estimated incidence and standard death rate in the age of 17.3 and 8.2 per 100,000 women per year.² The financial charge for cancer is increasing in developing countries.³ In Indonesia, the fund used for cancer treatment is high, in 2014 to 905 billion Rupiah.⁴ In addition, the diagnosis of cervical cancer has become a great burden for both patient and family. Most cancer patients with advanced stage have low life quality score, that indicates they have a problem. Family should take care of their loved ones dealing with the diagnosis, treatment, and side effects of cervical cancer.⁵

According to Rasjadi, Hartati et al, 2010 ‘Cervical cancer is a malignant tumor that grows in the cervix which is the lowest part of the uterus attached to the top of the vagina. The biggest cause of cervical cancer is infection of HPV (Human Papilloma Virus) which is transmitted through sexual contact. A woman can be
infected with this virus in the teenage years and newly known to have cancer in 20 to 30 years later after the infection spreads.  

Nowadays several methods of screening and early detection of cervical cancer have been known such as pap smear and VIA, VIA enlargement with gynecostasia, colposcopy, cervicography, thin prep, and HPV test. However, the one that suits the conditions in developing countries including in Indonesia is VIA method with the consideration of easy to do, relatively cheap cost, fast, high sensitivity and accurate enough to find abnormalities at the stage of cell disorders (dysplasia) or before pre-cancer. It is recommended to do VIA test for all women aged 30-50 years and women who have sexual intercourse.

Awareness and decision to do early detection is one of the most effective preventive measures. In Indonesia, low early detection is influenced by several factors, including demographic area, continuity of information delivery, and lack of human resources as screening agent, so the hope to find early stage cervical cancer is still difficult. According to (Emilea, ova, 2010) cervical cancer problem in Indonesia is constrained by social condition of society and social economy. Societal societies are related to taboo concept in the norms of society where cervical cancer screening is conducted on sensitive and closed part so it is not easy to encourage and ask women to open and allow the test.

Counseling is one of method to bring information access closer to society, based on Lawrence green theory (1980), access to information is one of the enabling factors that can influence a person’s behavior change. Some preliminary studies mentioned that one of the most influencing factors for a person to do VIA test is the exposure of information. A quite different phenomenon occurs in the field; researchers see quite different phenomena that occurred in the field. Preliminary study conducted in the working area of Female Cancer Program (FCP) Bima, West Nusa Tenggara, based on 2017 coverage report of total 64,215 targets, who have been given counseling as much as 14,918 and who did VIA screening was still very low at 4,433 (30%), find screening result with VIA (+) 254 people, cryotherapy 126, susp Ca cervical 7 people, cervical abnormalities 139 people.

To get the initial picture, the researcher then tried to find information through social media (Facebook) about the description of VIA test in Women of Childbearing Age. From the total of 104 people WCA who is married, 85% who had given VIA counseling about early detection cervical cancer. Only 45% are examining VIA test, 40% have not checked VIA when it can be information about VIA, and 15% have not checked VIA because it has not been able to information about VIA.

This study aims to obtain about the behavior of VIA test on the WCA who have been given counseling and the tendency of relationship among factors affecting.

**Method**

The design of this study is a qualitative method, with RAP research design (Rapid Assessment Procedure) or quick research aimed at obtaining in-depth information about mothers’ decisions for VIA test and trends in the relationship of the factors that influence them. Population of this research was all WCA which have been given counseling of cervical cancer early detection in work area of FCP Bima with 64,215 people. The concepts of sample selection in qualitative research were suitability, adequacy and saturation. The selection of the sample was then based on the inclusion criteria of women of childbearing age who have been given counseling about the cervical cancer detection, married, aged 30 - 50 years. The number of samples in this study was 14 people and for triangulation of data 2 midwives as key informants who had given counseling about cervical cancer early detection were used. The study was conducted in April 2018 in Bima City, West Nusa Tenggara.

Result

Overview Counseling Cervical Cancer: The results of in-depth interviews conducted with informants showed that 6 informants were given counseling during integrated service post, 3 informants at the midwife practice place, and 3 others during social service activity.

The statements of all informants above were justified by the midwife as a key informant that the counseling about cervical cancer detection by VIA method in its working area was carried out according to integrated service post schedule, during social service activity and also done at the independent midwife practice place.

All informants given counseling during integrated service post it was found the descriptions of the counseling process by showing the pictures, in a busy atmosphere, lack of focus and listening in a hurry. From the 3 informants given individual counseling, it was said that the counseling was clear enough, showed the pictures, was done during the consultation of family planning issues and the development of their children and was not in a hurry. Similar things were found in 3 other informants who said that the counseling was quite clear, showed pictures, listened somewhat in a hurry because of the crowded queue.

Statement from WCA informants about counseling method was justified by midwives as key informant that “The counseling during integrated service post was still done in the yard where the integrated service post joined with other integrated service post activities. The counseling used the back sheet of cervical cancer early detection, with limited time because midwives who worked down to the field were only 2 people and must perform VIA test after giving counseling”.

All informants who have been given counseling about cervical cancer early detection bVIA method (12 informant) said there was no specific evaluation from midwives after counseling. Follow-up contact with the midwives according to informants occurred during the VIA test. The statement from the informants was justified by the midwife: there has been no specific post-counseling evaluation conducted, especially for WCA who did not directly do VIA test. Follow-up was still limited to the participants who wanted to check by providing VIA test service, then if the VIA result was positive or suspicion of any abnormal, the referral to the hospital for follow-up would be done.

Knowledge Overview of VIA: In-depth interviews conducted to the informants who have been given counseling either have done the VIA test or not, which about the knowledge overview of VIA and purpose of check VIA. From 12 informants as many 9 informants have good knowledge by saying that “VIA test was a check to determine the cancer in the uterus by using acetate acid”. While the 3 informants still have less good knowledge by saying that “VIA test was a test to determine whether there was a disease or not in the uterus”. Statements from all above informants were justified by midwives that VIA test was a test by inspection to know whether there was pre-cancer lesion in the cervix.

Behavior of VIA Test: From 6 informants who conducted VIA test after being given counseling, that all stated “did VIA test for the first time”. The reasons why informants did VIA test were different, the informant (P1) said that “VIA test was done because of complaints on the utility part such as vaginal discharge, irregular menstruation”, while the informant (P3) said that “doing a VIA test was because of the fear of incident experienced by an artist”. The informants (P4, P5) said that doing a VIA test at the same time during the installation of the spiral contraceptive device (IUD), while the informant (P6) did do VIA test because it was requested by the husband while accompanying the consultation.

From 6 informants who did not do a VIA test after the counseling was obtained, the informants (P7, P8, P9) by saying that “did not do VIA test because they were still afraid and embarrassed that their utility part needed to be opened in front of many people”. The informant (P10) said that after being given counseling, there was a willing to do VIA test but it did not happen because of menstruation, while the informants (P11, P12) said they did not do VIA test because there was an important matter. Informant (P10, P11, P12) who are unable to check VIA at the time of extension do not go back to the midwife or Puskesmas to check the VIA because there is no contact back.

Discussion

Health education including counseling is a planned series of lessons, based on logical theories and to equip individuals, groups and communities to influence others, obtain information and skills to make quality health decisions in order to improve healthy living standards and wellbeing society. To obtain optimum
results counseling should pay attention to various aspects such as the method, the tools, the background and the needs of the audiences. Cervical cancer early detection counseling tends to be more effective to be done by individual method; this is in line with the theory: according to Notoatmojo, this health counseling method is more used to foster new behavior or someone who has become interested in a behavior change or innovation. The basis of this individual approach is used because everyone has different problems or reasons in connection with acceptance or new behavior.\textsuperscript{10} If due to limited human resources and time for individual counseling, it should be chosen a method that can combine elements of education, counseling, involvement of family roles and continuous evaluation such as the Wish and Drive method which is a method that has more value than conventional learning method, because this method is a method that combines education and counseling, seeks to generate perception, motivation of respondents in doing cervical cancer early detection by involving external support and by using various stimulation.\textsuperscript{15}

In counseling early detection of cervical cancer tend to be more effective if done by individual method, this is in line with the theory, according to Notoatmodjo (2013) this individual health counseling is better used to foster new behavior or someone who has become interest in a behavior or innovation. The basis of this individual approach is used because everyone has different problems or reasons in relation to the acceptance of a new behavior.\textsuperscript{10}

Due to the limited human resources and time for individual counseling, it should be chosen a method than can combine elements of education, counseling, involvement of family roles and continuous evaluation, which combines education and counseling, seeks to generate perceptions, respondent motivation in early detection of cervical cancer by using various stimulation.\textsuperscript{15}

**Conclusions and Recommendations**

Research on the behavior of VIA examination concluded as a bit: a). Counseling about VIA given tends to increase knowledge but does not necessarily change behavior in VIA test. b). Counseling by using individual counseling method tends to be more effective than mass counseling. c). Post-counseling evaluation is very important to be done by the midwife to inventory any participants who have not done VIA test in order to be followed-up. d). Counseling given when the midwife provides counseling and IUD KB installation service tends to be more effective because it can be done follow-up. e). Other factors that tend to influence the behavior of VIA test on WCA who have been given counseling are perception, motivation, and support from the husband.

Research on the behavior of VIA examination recommend as follows: a). Post-counseling evaluation is very important to be done by the midwife to inventory any participants who have not done VIA test in order to be followed-up. b). Related limited human resources and time for individual counseling, it should be chosen a method than can combine elements of education, counseling, involvement of family roles and continuous evaluation, which combines education and counseling, seeks to generate perceptions, respondent motivation in early detection of cervical cancer by using various stimulation.

HIV and Zonke-bonke Syndrome in Mthatha Region of South Africa: Case Reports

Meel B.

Research Associate, Faculty of Health Sciences, Nelson Mandela University, Port Elizabeth 5117

Abstract

Background: South Africa is described as an African rainbow nation, not only in the color of its population, but also in the mixture of HIV infection. Three varieties of HIV infection have been distinguished: HIV-1, HIV-2, and a combination of the two. This is a matter of concern.

Objective: To highlight the problem of HIV-1 and HIV-2 (combined) infection in the Mthatha region of South Africa.

Case History: The first four cases of HIV-1/2 mixed infection were reported within a period of one year (2009). These cases were reported at Sinawe Center when people were examined after being sexually assaulted. HIV screening tests were carried out for HIV infection. Four patients were found to be positive for both HIV1 and 2. Surprisingly, one was a child of eight years old. Multiple sexual partners who were involved at some or other time with West Africans who harbored type 2 HIV could be the cause of this mixed infection. This kind of promiscuous behavior with multiple partners is called “Zonke-bonke syndrome”. The history, mode of transmission of HIV infection, and the consequences of mixed HIV infections are discussed in this case report.

Conclusion: HIV-1 and HIV-2 (mixed) infection occurs in the Mthatha region of South Africa. It is a matter of serious concern.

Keywords: HIV type 1 and 2, promiscuous behavior, multiple partners.

Introduction

South Africa has one of the highest rates of sexual assault in the world, as well as one of the highest prevalence rates of HIV infection. In Transkei young people are allowed to engage in free sexual experimentation. Young women actively seek partners who are willing to spend money and often initiate relationships with older men. The girl goes out and positions herself in a place where she knows she will encounter men. They do not see themselves as victims. This is all about power and authority, with teenage boys and girls involved in these relationships on an unequal footing. The “sugar daddy or mommy” is in a better position and is therefore able to entice the young girl or boy into a relationship. Even those who talk about it are reluctant to be identified because “people will think we are doing these things” Although everyone agrees it is common practice, cross-generational relationships are not often addressed in HIV/AIDS prevention campaigns, despite growing awareness that they are driving much of the epidemic.

HIV-2 infections are predominantly found in Africa. West African nations with a prevalence of HIV-2 of more than 1% in the general population are Cape Verde, Côte d’Ivoire (Ivory Coast), Gambia, Guinea-Bissau,
Mali, Mauritania, Nigeria, and Sierra Leone. Other West African countries reporting HIV-2 are Benin, Burkina Faso, Ghana, Guinea, Liberia, Niger, São Tomé, Senegal, and Togo. Angola and Mozambique are also African nations where the prevalence of HIV-2 is more than 1\%.\textsuperscript{4}

Differentiating between HIV-1 and HIV-2 infection is the first step to understanding HIV transmission, epidemiology and pathogenesis in geographical areas where both viruses circulate.\textsuperscript{5} HIV is a highly variable virus, which mutates very readily. This means there are many different strains of HIV, even within the body of a single infected person. Both types (HIV-1 and HIV-2) are transmitted by sexual contact, through blood, and from mother to child, and they appear to cause clinically indistinguishable AIDS. However, it seems that HIV-2 is less easily transmitted, and the period between initial infection and illness is longer in the case of HIV-2. Worldwide, the predominant virus is HIV-1 and generally, when people refer to HIV without specifying the type of virus, they will be referring to HIV-1. The relatively uncommon HIV-2 type is concentrated in West Africa and is rarely found elsewhere.\textsuperscript{6} HIV-2 is intrinsically resistant to nonnucleoside reverse transcriptase inhibitors. Therefore, it is mandatory to discriminate between HIV types before initiating antiretroviral treatment. Guinea-Bissau has the world’s highest prevalence of HIV-2 and HIV-1/HIV-2 dually infected individuals.\textsuperscript{7} The purpose of these case reports is to highlight the problem of HIV1 and HIV-2 (combined) infection in this community (Transkei), and to create awareness among health care professionals about its management.

**Methodology**

This is a retrospective study done in Sinawe Center over year (January to December, 2009). This unit is part of Nelson Mandela Academic Hospital and caters for a population of about 400 000 in the OR Tambo municipality area. All cases of rape and sexual assault are reported to this center. It is now a ‘One Stop Center’, providing multidisciplinary management of victims of rape and sexual assaults. It is open from Monday to Friday from 08:00 to 16:00. On weekends and after hours, victims are examined in the Accident and Emergency section of Nelson Mandela Academic Hospital. It is the policy of the center to provide HIV testing after counseling to all victims of sexual assault and rape. Blood for HIV screening is taken with the consent of the victims. Results are later confirmed by ELISA test in the laboratory. HIV1 and HIV2 (combined) infection has been found in four cases presented to the center for examination. Post-exposure prophylaxis was started at the beginning of 2003 and is offered to all victims except those who report later than 72 hours after the incident.

**Case History 1:** AM, a 19-year-old female, presented with a history of sexual assault by a known person, her boyfriend’s cousin. It happened in the morning hours. She was with her boyfriend, who was intoxicated in his aunt’s home in the guest room. The perpetrator pushed open the door, entered the room, and dragged her outside the bedroom. She tried to resist but the perpetrator assaulted her. He forcefully undressed her and raped her. He used a condom.

The victim had a boyfriend who worked in Cape Town and they had consensual sex in August 2008. She wanted sex, as she had met her friend again after a long time, but he was drunk. The perpetrator took advantage of her. The victim had multiple injuries, such as lacerations on her left knee and bruises on her left hand and back.

On genital examination, an old ruptured hymen was found, with fresh tears in the 9 o’clock position. There was increased friability with bruised introitus. A rapid test was reactive to both HIV1 and 2. HIV Ag/Ab combination assay was reactive, suggestive of both HIV antibodies and antigen (p24).

**Case History 2:** PM, a 26-year-old single woman, lived 40 km from Mthatha. A known person sexually assaulted her on 26.03.2009. This happened in the perpetrator’s bedroom at Qumbu. She was talking to a colleague. The perpetrator showed her a knife and pinned her to his bed. She had a boyfriend and had consensual intercourse about two weeks before. She had two children of nine and four years old.

On genital examination, there was no sign of any injury. There was increased friability, but no whitish discharge was visible. A rapid test was reactive to both HIV1 and 2. HIV Ag/Ab combination assay reactive was suggestive of both HIV antibodies and antigen (p24).

**Case History 3:** The police brought in BB, an 18-yearold female, with a history of sexual assault, on 10.04.2009. She was a learner in standard 10. She was waiting for transport to go to an Easter church service. Four unknown men approached her and asked her name.
One of them started assaulting her, dragged her into nearby bushes and raped her. He robbed her of R15. BB had a boyfriend and had consensual sex on 20-03-2009. She had two earlier boyfriend as well. They did not use a condom. She was menstruating at the time. No injury was identified. She was counseled about an HIV test in January, but she tested negative. HIV screening test was conducted on 10-04-2009 at Sinawe Center, and she was found to be HIV positive for both HIV1 and HIV 2. She had had only one boyfriend in the last three years.

**Case History 4:** IT, an eight-year-old learner, was referred from Ngangelizwe Health Center with a history of being sexually abused by a known eight-year-old boy on 03.04. 2009 at about 15:00. Her grandmother brought her to Sinawe Center on 24.04.2009. Her mother lived in Johannesburg. She was coming from school, and on the way she was overpowered by the perpetrator, who raped her. Counseling and reassuring therapy were given.

During examination it became obvious that the child was scared of her mother. There was a yellowish, offensive dark, vaginal discharge and a ruptured hymen was found. Pus swabs were taken for microscopy and culture. A gram stain showed on microscopy gram-positive cocci, yeast cells with neutrophils. Culture revealed klebsiella pneumoniae extended spectrum ß-lactamase producer and proteus mirabilis. A rapid HIV test found her to be positive for both types HIV-1 and HIV-2.

**Discussion**

These cases are believed to be the first evidence of HIV-2 infection in this region. No similar cases have been found in literature reported in South Africa. These reports provide important information that justifies expanded efforts to initiate and develop a program for HIV-2 screening in this region. Mthatha (Umtata) was the capital of the former Republic of Transkei. The Mthatha region is the least developed of the former black homelands. It is a region where the majority of workers go to earn their living in far-flung richer areas of South Africa. This has contributed directly to the spread of HIV in the rural areas of South Africa.

The most important cause of HIV transmission is poverty. Older men, who use their power and money in return for sex from younger women, are among the drivers of the HIV and AIDS infections in this region. Several studies have shown that there was a positive correlation between HIV prevalence and poverty globally, especially in sub-Saharan Africa. The rate of infection is increasing. Research organizations dealing with testing and counseling say it is not only men but women, too, who are out to attract younger partners. The fact is that older, affluent professionals, previously thought to be at low risk of HIV infection, are increasingly becoming vulnerable to infection because of risky sexual behavior with younger partners.

Changes in sexual behavior among the wealthy have led to a worrying swell in HIV and AIDS infections among those who had previously been considered at low risk. Several behavioral factors have been aligned to this development, among others inter-generational sex, where older, affluent men and women are having sex with the higher-risk younger group. It is arrogance, not ignorance, which is contributing to the spread of HIV infection. In the United States (US), HIV-2 infection was diagnosed in 1987. Since then, the Centers for Disease Control and Prevention (CDC) have worked with state and local health departments to collect demographic, clinical, and laboratory data on people with HIV-2 infection. Of the 79 infected people, 66 were black and 51 were male. Fifty-two were born in West Africa, one in Kenya, seven in the US, two in India and two in Europe. The region of origin was not known for 15 of the people, although four of them had a malaria-antibody profile consistent with residence in West Africa. AIDS-defining conditions had developed in 17, and eight died. Similar information is not known in the Transkei area, but nationals of almost all African countries reside in South Africa. There should be a screening system in place before they immigrate to South Africa. These case counts represent minimal estimates because the completeness of reporting has not been assessed. Although AIDS is reported uniformly nationwide, the reporting of HIV infection, including HIV-2 infection, differs from state to state according to state policy. Hardly any estimates are available in South Africa despite the fact that the incidence of HIV-2 infection is increasing.

Because epidemiologic data indicate that the prevalence of HIV-2 in the US is very low, CDC does not recommend routine HIV-2 testing at US HIV counseling and test sites or in settings other than blood centers. However, when HIV testing is to be performed, tests for antibodies to both HIV-1 and HIV-2 should be obtained if demographic or behavioral information suggests that HIV-2 infection might be present. The first victim in the current study reported that her boyfriend, who could have been the source of infection with HIV-2,
was working in Cape Town. The second case was that of a multipara young woman who had a history of having multiple sexual partners, one of whom was a West African. The third victim was a schoolgirl who had a relationship with a boyfriend without using a condom. Most surprising was the case of a child (case 4) who was only eight years old and had been sexually abused. She had a history of having a foul-smelling discharge from the vagina. This was noticed by her grandmother. The perpetrator could be a close relative of this child, as the mother was staying in Johannesburg.

Among all HIV-infected people, the prevalence of HIV-2 is very low compared with HIV-1. However, the potential risk of HIV-2 infection in some populations may justify routine HIV-2 testing for all people for whom HIV-1 testing is warranted. The decision to implement routine HIV-2 testing requires consideration in view of the number of HIV-2-infected persons whose infection would remain undiagnosed without routine HIV-2 testing, compared with the problems and costs associated with the implementation of HIV-2 testing. The development of antibodies is similar in HIV-1 and HIV-2. Antibodies generally become detectable within three months of infection. Since 1992, all US blood donations have been tested with a combination HIV-1/HIV-2 enzyme immunoassay test kit that is sensitive to antibodies to both viruses. This testing has demonstrated that HIV-2 infection in blood donors is extremely rare. All donations detected with either HIV-1 or HIV-2 are excluded from any clinical use, and donors are deferred from further donations.

Little is known about the best approach to the clinical treatment and care of patients infected with HIV-2. Given the slower development of immunodeficiency and the limited clinical experience with HIV-2, it is unclear whether antiretroviral therapy significantly slows progression. Not all of the drugs used to treat HIV-1 infection are effective against HIV-2. In vitro (laboratory) studies suggest that nucleoside analogs are active against HIV-2, though not as active as against HIV-1. Protease inhibitors should be active against HIV-2. However, non-nucleoside reverse transcriptase inhibitors are not active against HIV-2. Whether any potential benefits would outweigh the possible adverse effects of treatment is unknown. Monitoring the treatment response of patients infected with HIV-2 is more difficult than monitoring people infected with HIV-1. Viral load assays used for HIV-1 are not reliable for monitoring HIV-2. Response to treatment for HIV-2 infection may be monitored by following CD4+ T-cell counts and other indicators of immune system deterioration, such as weight loss, oral candidiasis, unexplained fever and the appearance of a new AIDS-defining illness. More research and clinical experience are needed to determine the most effective treatment for HIV-2.

In conclusion, there is lack of knowledge regarding HIV-2 infection in the Mthatha region of South Africa. It needs surveillance study to know the population infected with HIV-2. This will help in the management of patients as well as curbing the infection at grassroots levels. Physicians caring for patients with HIV-2 infection should be empowered to initiate antiretroviral therapy after discussing with their patients what is known, what is not known, and the possible adverse effects of treatment. Continued surveillance is needed to monitor HIV-2 in the population, since its further spread is possible. Programs aimed at preventing the transmission of HIV-1 may also help to prevent and control the spread of HIV-2.

**Ethical Consideration:** Prior consent for HIV testing was obtained from all the victims of sexual assaults. Their names and identity were kept confidential and were not divulged to anybody. The author has also taken ethical permission for collecting case history and publication (approved project No. 4114/1999) from the Ethical Committee of the University of Transkei, South Africa.

Prevalence of Hearing Loss among Former Mine Workers of the former Black Homeland of the Transkei, South Africa

Meel B.

Research Associate, Faculty of Health Sciences, Nelson Mandela University, Port Elizabeth 5117

Abstract

Objective: To study the prevalence of loss of hearing among the retired mineworkers of the Transkei region of South Africa.

Method: Between May 1997 and May 2011, 2 027 ex-mineworkers were examined at the Benefit Examination Clinic, which is located in the Chest Section of Umtata General Hospital (UGH), the teaching hospital of the University of Transkei Medical School in the Eastern Cape province of South Africa.

Results: Hearing loss was indicated by 219 (54%) of the respondents, of whom 72 (33%) were between 40 and 59 years of age. Of the 182 (45%) of workers who had worked for between 10 to 19 years in the mines, 40 (22%) indicated experiencing a loss of hearing. A strong association between hearing loss and years spent mining was detected.

Conclusion: Many (54%) of the ex-mine workers from the Transkei were found to be afflicted with hearing loss. Such a health problem demands much attention from occupational hygienists and the compensation authorities.

Keywords: Noise, hearing loss, mineworkers, occupational health, compensation.

Introduction

Noise exposure, which is the commonest preventable cause of hearing loss in both developing and developed countries, causes much of the global burden of disability. More than 20 million people in the United States have some type of hearing impairment, with at least half of those cases probably being due to noise exposure. A survey conducted from 1985 to 1988 in the Australian New South Wales coal industry showed that 41.5% of underground coal miners had a compensable level of NIHL. Therefore, there is a great need to reduce the levels of NIHL among mineworkers. Noise is one of the commonest of all occupational hazards. The progress of NIHL is insidious, in that it develops gradually, staying largely unnoticed until it is discernible as a handicap. The harmful effects of noise exposure vary according to the level of exposure endured, as well as the individual susceptibility to it. An auditory system that is exposed to noise might undergo reversible auditory alterations that are not detected by the method normally employed for testing hearing.

Occupational hearing loss is a common work-related problem, which result from an offending workplace agent. As there are different preventable causes of occupational hearing loss, physicians should remain alert to the development of such a problem. By assessing employees’ hearing, it can be determined whether the preventative measures are effective. In order to minimise the costs involved and the amount of time taken off work, such testing can be effectively carried out in the workplace, as long as certain conditions are met.
Interviews conducted in the past with men with NIHL have revealed their lack of awareness that exposure to excessive noise can harm their hearing. Most men interviewed were unwilling to acknowledge, or denied, their hearing problems. Interviews with the spouses of men with NIHL showed that the husband’s hearing loss often caused misunderstandings and irritation within the family, which had a negative impact on the couple’s relationship. The group rehabilitation programme referred to in this article, which was designed for men with NIHL and their spouses, is intended to provide psychosocial support and adequate information relating to NIHL and practice in the use of effective coping strategies. A professional approach to treating men with NIHL involves taking a patient-centric global perspective on the patient, encouraging him to identify, describe and acknowledge problems related to his impaired hearing. Such a patient needs professional help for coping with his hearing-related problems. In identifying and solving such problems, family involvement is important and vital. 

All mining companies have been requested to perform baseline-hearing tests on all current mineworkers. Such testing will enable an equitable apportionment of the awarding of claims for hearing deterioration to be made between the previous and successive employers. The implementation of NIHL baselining has increased the awareness of the need to continue to implement measures aimed at preventing the development of NIHL among mineworkers.

In industrial environments, where workers are exposed to high noise levels, which are likely to induce hearing loss, hearing conservation programmes must be implemented. In South Africa, as in many other countries, the implementation of such programmes is a legal obligation on employers. Where engineering methods are aimed at reducing ambient noise levels to below the prescribed level fail to do so, personal protection method should be used. Under such circumstances, audiometry may serve as a valuable tool for monitoring the effectiveness of environmental and personal control method.

The Transkei is a former black homeland to which most mineworkers from the area returned home when they became disabled. Insufficient attention has, so far, been paid to the needs of retired mineworkers who have hearing loss, which is recognised as a major problem in the mining industry. The objective of the present study was to estimate the prevalence of NIHL among former mineworkers who were exposed to noise in the underground mines, as well as to correlate their years of working underground with their age.

**Method**

Between May 1997 and May 2011, 2 027 retired mineworkers were examined at the Benefit Examination Clinic, a clinic located in the Chest Section of Umtata General Hospital (UGH), the teaching hospital of the University of Transkei Medical School in the Eastern Cape province of South Africa. The retired mineworkers presented themselves voluntarily for examinations related to compensation claims for their lung-related conditions.

A questionnaire with 17 direct questions was distributed among 677 randomly selected ex-mineworkers. The clinical records of the mineworkers were numerically arranged from 1 to 2 027, with every third record being selected as that of a designated participant in the study. Each designated participant was sent the questionnaire (see Appendix 1). The questionnaire, which was in the local Xhosa language, was returned by 480 of the designated participants. Of the responses, 74 (11%) were incomplete. The data from the completed questionnaires, which numbered 406 (60%) in total, were compiled and analysed using the Epi 6 Info computer program.

**Results**

In the current study, 60% of the mineworkers were aged between 40 and 59 years (see Fig. 1). Hearing loss was indicated by 220 (54%) of the respondents (Table 1). Of those experiencing hearing loss, 73 (33%) were between 50 and 59 years of age (Table 1). Those who had worked between 10 and 19 years on the mines numbered 183 (Table 2), of whom 91 (41%) indicated experiencing hearing impairment (Table 2). A strong association was noted between hearing loss and years spent in mining, with \( p < 0.05 \) (Table 1). However, no association was found between hearing loss and the different age groups (Table 2), pulmonary tuberculosis (Table 3), and compensation claims (Table 4) in the current study.
Discussion

In the mining industry, the worker often accepts noise as an inevitable part of his working conditions. However, the existence of such noise concerns the occupational hygienist, due to the various health risks that it holds. NIHL is by far the most common health risk with which the industry has to contend.  

In the current study, 60% of the ex-mineworkers were between the ages of 40 and 59 years (see Table 1). During a period of about 20 years from 1967 onwards, 128 575 mineworkers were certified as having acquired occupational diseases. The actual number of mineworkers who have contracted such diseases is certainly much higher, due to their under-assessment among migrant workers who have returned to their rural homes in any one of several labour reservoirs in South Africa, as well as in the neighbouring countries. Practically nothing is known about the fate of those with a certified occupational disease.  

In the current study, 220 (54%) of the mineworkers indicated some degree of hearing impairment (see Table 1). Demko (2003) reported that 90% of coal mineworkers had a hearing impairment, compared to 9% of the general population. Developing a hearing impairment in coal mining is comparable to contracting black lung in such mining, or to developing a stiff-silicotic lung, or PTB, in gold mining. PTB is curable, while NIHL is a lifelong permanent disability. Some mineworkers were compensated for having contracted PTB but have been awarded very little compensation for having developed NIHL. Steps have been taken to control the level of dust in mines, but no steps seem to have been taken to control noise. Noise has been underrated as a health risk, due to its being insidious and not considered as life-threatening. NIHL is a chronic disease that detracts from the quality of life of those suffering from it. Despite innovations in the mining industry, some mineworkers are still required to drill blast holes underground, which, by generating noise, is an ongoing hazard to such workers.  

Noise is one of the most pervasive health hazards in mining and results in the development not only of NIHL, but of serious physical, emotional, psychological, and social problems in their families. In the current study, of those mineworkers who were found to have impaired hearing, 73 (33%) were between the ages of 40 and 59 years (see Table 1), hence falling in a productive age group. For most of the families concerned, such individuals are the sole breadwinners. Disabled mineworkers find it difficult to get alternative work in the poverty-stricken areas in which they live.

In the current study, 183 (45%) of the respondents were found to have worked in the mines between 10 to 19 years (see Table 2). About half (91) of those subjects indicated a hearing impairment (see Table 2). Apart from the greater intensity of the levels of noise endured, the duration of the exposure to noise was found to be almost 5 to 10 times higher than average in cases of hearing impairment. It is well documented that hearing loss due to noise exposure progresses more rapidly during the first 3 to 5 years exposure, then levelling off almost parallel with the normal presbycusis (age-related hearing loss) curve. The median hearing loss experienced by those workers exposed to 105dB is expected to be about 25dB after the first 5 years, but only about 7dB after the following 5 years. Hetu (1979) formulated two predictions for populations at risk. For noise exposure at 85dB, a significant loss is likely only to be detected at about 25dB after the first 5 years, but only about 7dB after the following 5 years.  

Table I. Association between age groups with hearing among ex-mineworkers of the Transkei (n=406)
detected. For a noise exposure of 95dB, a significant loss is likely to be measurable after 1 year in less than 10% of workers. Only after another 4 years is it likely that a deterioration of another 10dB in all the affected workers might be detected. A survey of Canadian workers found that the average decrements in the hearing threshold were in the order of 1dB per year at 1000Hz and 1.5dB at 4000Hz. A non-exposed control population showed an average annual loss of 0.5dB per year among participants. Younger subjects (<30 years) showed higher decrements, in the order of 3dB per year at 4000Hz when exposed to excessive noise.

A survey of Canadian workers found that the average decrements in the hearing threshold were in the order of 1dB per year at 1000Hz and 1.5dB at 4000Hz. A non-exposed control population showed an average annual loss of 0.5dB per year among participants. Younger subjects (<30 years) showed higher decrements, in the order of 3dB per year at 4000Hz when exposed to excessive noise.

In the current study, there is a strong association between hearing loss and years spent in mining. Therefore, the length of exposure to the noise in the mines appeared to be the most important single risk factor for the development of NIHL (p < 0.05) (see Table 2). However, no association was established between the different age groups of mineworkers, PTB, compensation claims and hearing loss (see tables 2 to 4). The current preliminary study has no explanation for such a lack of association.

Exposure to excessive noise is the major avoidable cause of permanent hearing impairment worldwide. In developed countries, such exposure is at least partially the cause of impairment in more than one-third of those with such impairment, with, in many countries, its being the most frequently encountered compensatable occupational hazard. According to the Occupational Health and Safety Administration (OHS), between 5 and 10 million Americans are at risk of developing NIHL, due to their exposure to sounds louder than 85dB on a sustained basis in the workplace. In Africa, despite the levels of exposure to noise in the mining sector being high, the awareness of hazards among employees, employers and the public is low. Most countries on the continent do not have effective NIHL prevention programmes in place. There is a need for strict regulatory control requirements, enforcement policies, and measures, including an increase in the use of hearing protection devices in the workplace. A study conducted by Joy and Middendorf showed that noise exposure reduction was accompanied by an increase in shift length, as represented by dosimeter sample duration. For coal miners exposed above the permissible exposure level, the use of hearing protection devices increased from 61% to 89% during the said period.

Hearing loss, due to presbycusis, is eventually present in most individuals. Occasionally, a physician is asked to assess the percentage of hearing loss experienced due to noise exposure, as distinct from the percentage due to other causes. The diagnosis of NIHL should rarely be made on the basis of the audiometric pattern alone. Information about the level of noise exposure should be a part of the diagnosis. What percentage of presbycusis is a consequence of a lifetime of socioacusis, and how much is due solely to the physiologic aging process, is still a matter of contention. By means of the age correction of audiograms, such instruments can be used to assess the proportion of hearing loss due to the noise-induced permanent threshold shift. The age correction of audiograms should be considered appropriate for compensation assessment purposes in the current situation, in those cases where mineworkers have failed to claim during the stipulated timeframe (<1 year). The mineworkers in South Africa, especially in the Transkei region, are not currently claiming what is due to them on account of their NIHL status, as they are illiterate and lack the appropriate facilities for making such claims.

The International Labor Organization (ILO) advocates the monitoring of the health of all workers exposed to noise (with 85 dB being given as the warning level and 90 dB as the danger limit value). A pre-employment audiogram should be used to determine the
baseline record of the workers concerned, who should all undergo periodic medical examinations to detect any signs of occupational disease or any abnormal sensitivity to noise. As the reliability and validity of audiometry in the industry in South Africa is currently questionable, under the Machinery and Occupational Safety Act, 1983 (Act No. 6 of 1983), the Chief Inspector of Factories may require employers in specified activities to arrange audiometric testing to be conducted on workers exposed to excessive amounts of noise.

The Chamber of Mines in South Africa, which was established over a century ago, has not yet been able to reduce the noise levels in mines. Such a failure is despite the fact that the World Health Organization programme for the prevention of deafness and hearing impairment is concerned with developing and promoting strategies for the prevention of hearing impairment and deafness.

Despite the limitations on the current study, it has provided a baseline picture of the prevalence of hearing impairment among mineworkers in the Transkei.

Conclusion

As most (54%) ex-mineworkers living in the Transkei suffer from NIHL, the attention of both the relevant occupational hygienists and the compensation authorities is urgently required in this regard.

Metabolic Disturbance in Women with Polycystic Ovary Syndrome and its Impact on Bone Turnover

Rana Ali Hamdi¹, Ammar Adil Jasim¹, Safana Ali AL-Rawi²

¹Department of Biochemistry, College of Medicine, University of Baghdad, ²Ministry of Heath

Abstract

Background: Insulin resistance and abdominal obesity are main characteristics of polycystic ovary syndrome, women with this syndrome at high risk for prolong term metabolic disorders. Obesity, insulin resistance, and hyperinsulinemia affect the hormones that control calcium homeostasis. Lower levels of serum vitamin D and higher levels of serum parathyroid hormone were found in women with polycystic ovary syndrome. However, high levels of parathyroid hormone can reduce bone mineral density and increase bone turnover.

Objectives: The present study aimed to measure the parameters of bone metabolism including parathyroid hormone, calcium, and phosphorous in serum of women with polycystic ovary syndrome and compare their levels with healthy controls. Also, investigate the possible impact of metabolic alterations in polycystic ovary syndrome on bone turnover.

Material and Method: This case-control study included 82 women from 20 to 37 years of age. All women were selected from Infertility Center in Baghdad Teaching Hospital during the period from 1 June 2019 to 30 August 2019. Women were divided into two groups: group (1) involved 42 women with polycystic ovary syndrome and group (2) involved 40 healthy women (act as controls). Each Serum specimen was analyzed for the measuring of parathyroid hormone, calcium, phosphorous, fasting insulin, fasting glucose, and homeostasis model assessment of insulin resistance (HOMA-IR).

Results: Significantly higher serum levels of parathyroid hormone, calcium, fasting insulin, and fasting glucose with lower levels of serum phosphorous in women with polycystic ovary syndrome as compared with healthy women. In addition, significant positive correlation was found between serum parathyroid hormone and waist circumference (r=0.609, p=0.00001) as well as between serum parathyroid hormone and HOMA-IR (r= 0.781, p=0.00001).

Conclusion: The metabolic disturbance found in polycystic ovary syndrome tend to support the relation between this syndrome and defective bone metabolism. High prevalence of obesity and high levels of insulin, HOMA-IR, and parathyroid hormone were found in women with this syndrome which in turn affect bone turn over. Thus, women with polycystic ovary syndrome are at risk for the development of metabolic bone disease.

Keywords: Polycystic ovary syndrome, parathyroid hormone, bone turn over.

Introduction

Polycystic ovary syndrome (PCOS) is a common endocrinopathy among female between 18 and 44 years of age¹. It characterized by high androgen levels, menstrual abnormalities, and multiple immature follicles seen by ultrasound ². Insulin resistance (IR) and abdominal obesity are
main characteristics of this syndrome, PCOS women at high risk for metabolic disorders.

Obesity, IR, and hyperinsulinemia affect the hormones that control calcium homeostasis. Lower levels of serum vitamin D and higher levels of serum parathyroid hormone (PTH) was found in obese people as well PCOS women. However, high levels of PTH can reduce bone mineral density and increase bone turnover. In bone, PTH stimulate calcium release from the large stores contained in the bones by enhancing bone resorption (a process of bone degradation by osteoclasts). It has been shown that PTH has an indirect effect on osteoclasts via binding to nearby osteoblasts. High PTH levels enhance expression of receptor activator of nuclear factor-κβ ligand (RANKL), which interacts with its receptor (RANK) on osteoclast precursor cells causing stimulation and formation of osteoclasts, which ultimately stimulate bone degradation. According to previous information, the present study aimed to measure the parameter of bone metabolism including PTH, calcium, and phosphorous in women with PCOS and compare their levels with healthy controls. Also, investigate the possible impact of metabolic alterations in PCOS on bone turnover.

**Material and Method**

This case-control study included 82 women from 20 to 37 years of age. All women were selected from Infertility Center in Baghdad Teaching Hospital during the period from 1 June 2019 to 30 August 2019. Women were divided into two groups: group (1) involved 42 women with PCOS and group (2) involved 40 healthy women (act as controls).

Women with PCOS were diagnosed according to Rotterdam criteria in the availability of two or three following criteria: oligoovulation and/or anovulation, clinical and/or biochemical hyperandrogenism, and polycystic ovaries detected via ultrasound.

Women with hyperprolactinemia, androgen secreting tumors, Cushing’s syndrome, congenital adrenal hyperplasia, and impaired thyroid, renal, and liver functions were excluded from the present study.

Each Serum specimen was analyzed for measuring PTH by enzyme linked immunoassay (ELISA) using kit provided by (Euroimmun, Germany), fasting serum insulin by ELISA kit (Monobind Company, USA), and fasting serum glucose, calcium, phosphorous by spectrophotometer using kits supplied by (Human Company, Germany). In addition, homeostasis model assessment of insulin resistance (HOMA-IR) calculates the IR according to following equation:

\[
    \text{HOMA-IR} = \frac{\text{Fasting plasma glucose (mg/dL)} \times \text{Fasting plasma insulin (μU/mL)}}{405}
\]

Women considered to have insulin resistance when HOMA-IR equal to or more than 2.5.

The body mass index (BMI) of each woman was calculated as weight in kilograms per height in square meter. Normal weight women when BMI (18.5-24.9 kg/m²), overweight women when BMI (25-29.9 kg/m²), and obese women when BMI ≥30 kg/m². Waist circumference (WC) also was estimated by measuring the midpoint between the lower border of the rib cage and the iliac crest, which provide a practical information about abdominal lipid accumulation and related disease. Central obesity was considered when waist circumference of women equal to or greater than 88 cm.

**Statistical Analysis:** Data analyses were performed by using computer facility of SPSS-20 (Statistical Package for Social Science – version 20). The results were presented as numbers, range, mean, and standard deviation (SD). Student-t test was used to assess the significance of difference between two independent means. Also, the correlation between two quantitative variables was assessed by using Pearson correlation with t-test for determining the significance of correlation. Statistical significance was detected when the p value was equal to or less than 0.05.

**Results**

Significant increase in mean value of BMI, WC, fasting serum insulin, fasting serum glucose, HOMA-IR in women with PCOS as compared with healthy controls as demonstrated in Table 1.

Significant positive correlations were found between PTH and WC (r=0.609, p=0.00001) as well as between PTH and HOMA-IR (r=0.781, p=0.00001) in women with PCOS as shown in Figure 1 and 2, respectively.

Figure (1): Significant positive correlations between PTH and WC (r=0.609, p=0.00001) in women with PCOS.
Discussion

This study was planned to investigate the impact of the metabolic modifications in PCOS on serum PTH which in turn affect bone metabolism. The results found that women with PCOS had higher levels of PTH as compared with healthy controls. Also, serum PTH levels positively correlated with both waist circumference and HOMA-IR in PCOS women.

In this context, parathyroid hormone is a peptide hormone important in the regulation of calcium homeostasis through its effect on bone turnover\textsuperscript{15}. Women with PCOS had significantly higher PTH levels compared to healthy women\textsuperscript{5}. PCOS patients are at high risk of IR. Insulin resistance in turn has been correlated with high PTH amounts\textsuperscript{16,17}. It is assumed that insulin has anabolic impact on bone. It decreases the capacity of PTH to stimulate protein kinase C in bone formation cells and suppress bone degradation\textsuperscript{18}. Moreover, insulin act to stimulate collagen synthesis by osteoblasts (cells responsible for the bone synthesis and mineralization)\textsuperscript{18}.

Some evidence showed that insulin may act to enhance osteoblast differentiation\textsuperscript{19}. However, high levels of insulin and IR in PCOS women causing deterioration of bone mineral density and impaired bone turnover\textsuperscript{20}.

Wang et al.\textsuperscript{21} found that insulin influences both the expression RANKL via MG63 osteoblast and osteoclastogenesis. These effects similar to PTH action\textsuperscript{21}. So, increased insulin levels influence the osteoclast recruitment and differentiation via impairment of the RANKL signaling pathway (RANKL is a molecule identified to have a major role in osteoclastogenesis and bone remodeling process)\textsuperscript{21}. Another study by Huang et al. which showed that diminished in the number of tartrate resistant acid phosphatase-positive cells after adding of insulin to the ex vivo osteoclast cell culture. Therefore, it is probable that elevated insulin levels in women with PCOS could bind to insulin receptor in osteoblast leading to decrease bone formation and influence bone degradation\textsuperscript{22}.  

Figure (2): Significant positive correlations between PTH and HOMA-IR ($r=0.781$, $p=0.00001$) in women with PCOS.
Likewise, calcium homeostasis is linked with obesity and metabolic syndrome. Modifications in both vitamin D and PTH amounts occur due to increased body fat content. In addition, PTH itself may enhance adiposity due to the physiological elevation of PTH associated with increase intracellular calcium ion amounts, which in turn enhance accumulation triglyceride in adipose tissue via its role in the control of both lipogenesis and lipolysis.

Conclusion

The metabolic disturbance found in PCOS tend to support the relation between this syndrome and defective bone metabolism. High prevalence of obesity and high levels of insulin, HOMA-IR, and PTH were found in women with this syndrome which in turn affect bone turnover. Thus, women with PCOS are at risk for the development of metabolic bone disease.

Active Learning Practices for First-grade Science Teachers and their Relationship to Students’ Successful Intelligence

Ban Mohammed Kareem¹, Ghadah Shareef Al-Sheikh¹, Abbas Hussein Mugir¹

¹Department of Higher Education, College of Basic Education, University of Babylon, Babylon, Iraq

Abstract

The paper aimed to identify the active learning practices of the teachers of science for the first grade and their relation to the successful intelligence of their students. The descriptive approach was used to suit the nature of the study. The researcher presented the study tools to a group of experts and arbitrators for the purpose of verifying the validity of the research tools. The data were also statistically processed using Holistic equation, arithmetic averages, standard deviations, The results of this study found that active learning practices were weak, while successful intelligence was medium. Results showed a statistically significant positive correlation between active learning practices among science teachers and between In the light of the previous results, the researcher recommended several recommendations, including the preparation of training programs for teachers of science in general and for the first grade teachers in particular the average of active learning practices and the need to hold seminars for science teachers to identify successful intelligence and provide a classroom environment that works on development.

Keywords: Active Learning-Science Teachers-Successful Intelligence.

Introduction

In view of what the Ministry of Education in Iraq aspires to keep pace with the educational system and the elements of the educational process for the progress made whether in the role of the teacher or the role of the learner through the use of teachers educational practices focused on making the student the focus of the educational process and active-active with the intelligence and abilities The researcher finds the need to reveal the level of active learning practices among the teachers of science and the level of intelligence in their students and the relationship between active learning and successful intelligence. Therefore, the problem of research can be formulated by the question: Is there a correlation between active learning practices The teachers of science and the successful intelligence of their students? The current era has witnessed great development in all aspects of life. We reflect this development in the field of education and teaching method¹. Moreover, teachers do not care about strategies used with students in learning and accordingly, they follow certain modes of teaching and thinking that encourages auto-memorization². As education is a social necessity and enjoys a value and importance because it has a practical effect in all societies and educational institutions ³. There are several modern teaching method and strategies that pay attention to the learners and deem them as the focus of the education process. The education process has been shifted from the dependence on the teacher to dependence on the learner’s themselves, with minimal contribution of the teacher as a director in the education process⁴. Modern education has to keep up with the tremendous developments that happened in all aspects of life, so the teacher is no longer just a teacher but a learner of knowledge, the learner has an important role in the process of education and learning, and the teacher became organizer and guide of those processes⁵. Teachers have to choose method, strategies and teaching method which are intended to reach the aim in educational programs, the selection of these things
depends on the suitability of the students’ characteristics, needs, the nature of the academic content, educational aims and the available financial and human means as the use of modern strategies was not accidental, but came in response to the needs of the educational system to achieve its objectives. Hence, teaching concept indicates the intentional and regulated process by which the teaching elements (teacher, learner and material) interact, and which is done according to pre-planned procedures aiming at fulfilling desirable destinations and ends. The process of teaching science is fertile ground in information, facts, concepts, skills and educational values towards the students in the intermediate stage, which may contribute to the improvement of the level of students’ achievement in science, but recently showed a lot of educational and scientific data such as previous studies and conferences towards the educational process

In the current period, the information technology revolution has started at a rapid and rapid pace in the technological field, which still leaves clear imprints in the lives of individuals and reflects broad challenges in all areas of life. Science has played a major role in change and scientific development. It has brought with it the interest of educationalists and their partners in the hands of innovation, development, and modernization in terms of content, teaching method and teaching aids. In this sense, it is the responsibility of teachers to choose the method, strategies and teaching method intended to achieve the goal to be achieved in programs. Some experts in the field of science teaching believe that the method of teaching the dominant sciences and the sciences, The traditional method is often effective in achieving the goals of science teaching, and effective science education can produce effective independent learners who are able to organize their everyday life, be productive, cooperative and have the ability to make good decisions. The teacher in general and the science teacher, in particular, should be able to have all the modern method and teaching practices to choose the appropriate educational situation. The successful middle school teacher is especially able to make the student involved in the educational process. Not a passive recipient. This can only be achieved by activating active learning within the classroom, which makes the learner the focus of the learning process, participating in achieving his or her learning goals, making him active in the classroom, practicing experimentation, and conversing with the discussions within him. Which makes the learner the focus of the educational process and makes him an active, active and participatory, has a role in the management of the educational process in terms of identifying some of the activities that address and commensurate with the wishes and potentials, and this type of learning is based on learning by practice and participation and research and exploration, P. In the classrooms, today’s learners are faced with the problem of teaching them with learning and teaching practices that do not match their mental abilities. This leads to a lack of learning. At the same time, these learners and their teachers may reach the conclusion that they have a lack of learning ability and the fact that many of them have amazing abilities to learn if taught in a way that suits them, and Sternberg believes that this claim was reached only through one case is that the success of many learners in certain circumstances and failure In other circumstances, Sternberg developed the theory of successful intelligence for the order. This is done only through the development of a set of teaching and assessment method and practices to help learners reach their maximum potential and success in life. Successful intelligence is one of the key cognitive processes that can outweigh information and knowledge in facilitating the adaptation and uncontrolled of individual resources and resources within the context of the learner in different life situations, whether these resources are in the form of information, experiences or tools available in the learner’s daily life situation. The learner’s ability to achieve the goals according to certain criteria or special within the social and cultural context in which the learner, that is, the learner sets goals and works to achieve them in line with the social and cultural context, which is the ability to achieve success in life by the expression of personal standards within the social context, The intellectual of the learner and consists of successful intelligence (analytical intelligence, practical intelligence, and creative intelligence).

There are previous studies similar to the current research variables: Al-Rawashdah and Walid (2015). The degree of active learning practice in science classes in the primary classroom in the North Eastern Bedouin schools in Jordan. And the study (happiness and Dalal) 2018 Degree of the practice of primary school teachers of active learning elements from the point of view of mentors and managers in Kuwait City. And Ahmed, Nahla (2016). The relationship between the intelligence of three-dimensional and mental alertness among middle school students. The study (Zoubi, Ahmed) 2016 The relationship between the assessment of successful intelligence and its practice in the education of private school teachers Jordan.
Methodology

The researcher used the descriptive (associative) approach as the appropriate method for the purpose of research aimed at identifying the active learning practices of the first-grade middle school teachers and their relation to the successful intelligence of their students. The sample of the research was randomly selected by 13% of the research community. The sample of the teachers was 15 teachers and the sample was 42% of the research community. (1691) Students for the purpose of collecting data To answer the study questions and achieve their objectives, the researcher prepared a note card to observe the active learning practices after reviewing the previous studies and literature concerning active learning if the observation card consisted of (40) Which includes (9) paragraph and field (implementation), which includes (23) paragraph and area (calendar) (High, high, medium, low, very low). The researcher presented a note of active learning practices in their initial form on a group Of teachers specialized in the field of teaching method and the quality of education in various Iraqi universities to express their views on the clarity and integrity of its formulation and has been modified in accordance with their observations. The researcher also prepared a successful intelligence test to measure the successful intelligence of first-grade students. The Sternberg test, which was prepared for the secondary stage, consisted of (36) multi-choice questions on the three abilities of successful intelligence (analytical ability, practical ability, creative ability) With (10,14,12) question, respectively, the researcher presented the test with instructions to a group of professors specialized in teaching method in different Iraqi universities and according to the opinions and observations, the researcher modified the test.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Conclusion

The results showed a positive correlative relationship at the level of significance between the active learning practices of the science teachers and the successful intelligence of their students Pearson correlation coefficient (0.67).

Ethical Clearance: All experimental protocols were approved under the Department of Graduate Studies - Method of Teaching General Sciences, Faculty of Basic Education, University of Babylon, Iraq and all experiments were carried out in accordance with approved guidelines.

Comparison the Tensile and Transverse Strength between the Biostar Machine Sheets and Heat-Cure Acrylic Resin

Mohammed Abdul Sattar Al Segar1, Weal Abdul Razzaq Al-Waeli1

1B.D.S.-M.Sc. Orthodontic, Middle Technical University, College of Health & Medical Technology, Prosthodontic Department

Abstract

The Biostar foils (Duran®) used a substitute material to the heat cure acrylic in splint therapy. Dentists often prefer to make and deliver a splint shortly (1 to 2 hours) rather than having them fabricated in a laboratory when treating temp or mandibular joint disorders patients. The Duran® became widely used and popular, the wear resistant and strength of the splint materials are the most important properties that improve the splint therapy. The study compared the tensile and transverse strength of the (Duran®) Biostar foil and heat-cure acrylic resin. 40 samples were constructed in total, 20 samples for heat cure acrylic resin and 20 samples for Biostar foils. The result showed Duran sheets have the greatest mean values of transverse strength and tensile strength compared to heat cured resin

Keywords: Splint therapy, Biostar foils, Acrylic, Duran.

Introduction

Duran® is used as occlusal splints, and it is a kind of Biostar foil occlusal splint after construction. Generally, Occlusal splints can be constructed from several materials and could be partially or completely coverage for maxilla or mandible. Acrylic resins are reasonably hard materials which could be easily adjusted and are durable enough to serve as a protective night guard. As well, the use of Vacuformed vinyl splints is useful but has some limitations[1]. They are characterized by improved physical characteristics such as volume stability, good form, and low sensitivity to moisture. In addition, these materials are easy to use and save time. The dental assistant can use such materials in the clinic to make splints that can be used immediately after processing and that are suitable for patients[2]. Duran® is a hard-elastic, highly transparent plates, odorless, of 1.27 g/cm³ density (ISO 1183) and water absorption about 0.2% after 24h at 23°C, bond to acrylic, can be used in many applications (i.e. bite guards, retainer splints, invisible retainers, temporary crowns and bridges). Duran® is made from Polyethylenterephthalat-Glycol Copolyester (PET-G)[3]. Poly methyl methacrylate (PMMA) polymers were introduced in the markets as dental materials in 1930s[4]. This study compared the transverse and tensile strength between heat cured acrylic resin and Duran® Biostar foil.

Materials and Method

Heat cure acrylic resin (Spofadental, Czech Republic) and Biostar sheets (Scheu, Germany were used to evaluate tensile and Transverse strength. 

Biostar (Duran®) specimen preparation: One sheet of the Duran® foil was selected (of 3mm thickness) and placed on the pressure chamber of a Biostar machine and clamped it tightly by a special ring to prevent any movement then heat the foil by setting the code according to the instructions. When the machine has been operated, the temperature began to rise until it reached to the required temperature of 220°C by an infrared heater until the foils reached the working temperature and can be plastified, such as Figure(1) then heater is removed, and the pressure chamber (with foil) is closed down and clamped down tightly, the Pressurized air is blown down over the foil to further distribute the thermoform material and it remain over it until the cooling phase ended, finally evacuation of pressure and opening the machine cover was done. By using a permanent pen a rectangular shape has drawn over the processed foil of required dimensions for transverse strength test (65 mm
length X 10mm width X 3 mm thickness) which later has been cut by a special Biostar bur to obtain the specimens, no finishing needed for these specimens(Figure 2). For tensile strength test, the permanent pen has also drawn over the processed foil. Also, these specimens would be used as a plastic pattern for the construction of the heat-cure samples.

Heat-cure Specimen Preparation: Heat-cure samples were constructed using plastic patterns with dimensions of (65mm length X 10 width X 3 mm thickness) for transverse strength(5). As well, plastic patterns with dimensions of (75mm length X 12.5 width X 3 mm thickness) were used for tensile test(5). The lower portion of dental flask was separated with a Vaseline, and then filled with creamy stone according to the manufactured instructions (i.e. 30ml/100mg). After stone has set, the stone surface and metal patterns were coated with separating medium. Next, the upper half of the flask was placed on lower portion and then filled with stone. Then the flask was left to set for one hour before opening. The flask was opened and metal strips removed from the mold carefully (figure 3).

The acrylic powder and liquid were mixed according to manufacturer’s instructions (24g: 10 ml). When the mixture reached the dough stage, It was packed in the mold, and the two halves of the flask were put in contact and placed under the hydraulic press and then in a flask clamp. The flask was cured in water bath machine according to manufacturer instructions. Following curing, the flask was taken away from water bath and left to cool. The acrylic samples were removed from the flask, finished and polished (figures 4 and 5).

Tensile Strength: The instron testing machine was used for tensile strength test. The applied force was 100kg with cross head speed (0.5) and chart speed (20 mm/min). The recorded force was recorded in kg and then converted into (N)(6).

The values of tensile strength were calculated by the following formula (7).  

$$T.S. (N/mm^2) = \frac{F}{A}$$

Where:

- The T.S represents the tensile strength
- The letter F represents the Force at failure (N).
- The letter A represents the section area at failure (mm).

Transverse strength:  

Testing Procedure: The transverse strength of acrylic and Duran resin samples were measured on an instron testing machine by three points bending (figure 7). Each specimen was positioned at each end of 2 supports. The constant cross head speed was 2mm per min and the applied load was (50 kg). The transverse strength values (N/mm²) were measured by the following formula(8).

$$S. = \frac{3P. I}{2bd^2}$$  Where the letter S. = Transverse strength.

The letter P represents the Maximum force.

The letter I represents the distance between the supports.

The letter b represents the specimen width.

The letter d represents the specimen width.

Results

The results showed that Duran sheets have the greatest mean values of transverse strength and tensile strength compared to heat cured resin as demonstrated in table 1. There were, however, no significant differences between Duran and heat cured resins in terms of both tensile and transverse strength (P> 0.05) as illustrated in table 2 and figure 8.

This study compared the transverse and tensile strength of two different materials (Duran® Biostar foil and heat cured acrylic resin). The results of this study showed that the Duran® material has the greatest mean value of transverse strength because of the modification of the poly(ethylene terephthalate), which is considered as the main component of the Duran by Glycol, leading to better enhancement in the mechanical properties(9). Another reason might be that the Duran was a thermoplastic material of fine particles and this material is ready to use just after remolding by high temperature and pressure. This might had a direct impact on the flexural strength. Our result was in agreement with (Emco)(9) and (cheric)(10) who found that transverse strength of Duran 88.30 N/mm² and tensile strength of Duran is 51.60 N/mm². The high values of tensile strength and transverse in specimens at 100psi might be related to first, higher pressure with elevated temperature with concentration of reinforcement of acrylic resins causes increase tensile strength and transverse strength, second prevention of
the porosity and water sorption which leading to increase tensile strength and transverse strength. This agreed with Craig and Powers(7); Brauer(11); Anusavice(12) and McCabe(13).

**Conclusion**

The current study concluded the following points: Duran® showed a highest value of tensile strength and flexural strength, and that mean this type of splint material is recommended for short time use in patients suffer from acute pain and/or dysfunction. Duran biostar is considered as the first choice material used as removable orthodontic retainer because of their suitable mechanical properties.

Are Emergency Services the First Place of Diagnosis for Juvenile Pregnancies?

Sema Avcı1, Bulut Demirel2

1MD, Emergency Department, Amasya University Sabuncuoğlu Şerefeddin Research and Training Hospital, Amasya, Turkey 2MD, Emergency Department, Ankara Atatürk Research and Training Hospital, Ankara, Turkey

Abstract

Objectives: Child marriage is a situation that varies based on the country and region in which it is found, and it is the name given to marriages under the age of 18. We aim to learn in the study we planned of the places where juvenile-child pregnancies are first diagnosed.

Method: The study was conducted over the health data in the Kars province, found in eastern Turkey, between the dates of January 2012 and January 2017, and approval was obtained from the provincial health directorate.

Results: 260 pregnancies were detected under the age of 18. The age, place of residence, upon which referral the diagnosis was made of the pregnant women, the health institution and department that made the request, and the reason for examination were recorded. 142 of the patients (54.6%) come from rural regions.

Conclusions: All healthcare professionals, primarily emergency care doctors, must be educated about juvenile pregnancy, and social programs must be organized to monitor pregnant juveniles.

Keywords: Juvenile pregnancy, emergency, marriage.

Introduction

Child marriage is a situation that varies based on the country and region in which it is found, and it is the name given to marriages under the age of 18. 700 million women around the world are being married as children, and a third of this number are under the age of 15. This situation is often seen in regions where marriage is almost a necessity and where extramarital pregnancy-sexual relationships are not accepted. At the same time, these regions are noted as being low socio-economic regions, for example, while this rate is observed as 4% in the United States and 2% in the United Kingdom, it rises up to 62% in Niger. South Asia (48%) and Africa (42%) are the higher rates, and Turkey is around 15%. The reason for this can be seen as the relatively strict implementation of laws. In short, juvenile-child marriages and pregnancies are a multidisciplinary subject that concerns families, healthcare workers, educators, state officials, and youths themselves.

Pregnancy develops as a natural result of juvenile-child marriages seen in a certain proportion in developed nations. Even if the situation of pregnant juveniles-children due to socio-economic depression, traditional perspectives and lifestyles, and focusing on causal situations is the subject of numerous studies, they are not issues that enable consensus. Although pregnancies are seen at younger ages, according to a study, the mortality rate in pregnancies between the ages of 15-19 was three times greater than pregnancies between the ages of 20-24, and complications like premature birth, low birth weight, and fistula are frequently encountered. With awareness campaigns, legal regulations, and the efforts
of human rights advocates, this rate generally tends to decrease.\textsuperscript{13}

In the situation of a pregnancy with this severe of results, medical care is also in a position to be attentive. Juvenile-child marriages and pregnancies are hidden from government records due to legal necessity or government records remain insufficient. For this reason, the place at which the diagnosis of pregnancy is given might be the place at which health services are received for the first and maybe the last time throughout the juvenile-child pregnancy. Therefore, by enabling the healthcare professionals and necessary infrastructure at the health centers that most provide diagnoses, both the diagnosis of pregnancy won’t be delayed and may be relatively protected from complications. We aim to learn in the study we planned of the places where juvenile-child pregnancies are first diagnosed.

**Method**

The study was conducted over the health data in the Kars province, found in eastern Turkey, between the dates of January 2012 and January 2017, and approval was obtained from the provincial health directorate. 260 pregnancies were detected under the age of 18. The age, place of residence, upon which referral the diagnosis was made of the pregnant women, the health institution and department that made the request, and the reason for examination were recorded.

The parameters were analyzed with SPSS 15.0 for Windows version. In the descriptive statistics of continuous variable, average and standard deviation were stated with numbers and percentages. The significance of difference between the groups was evaluated with chi-square test. In the analysis of normally distributed parameters, parametric tests were used. In the analysis of not normally distributed parameters, non-parametric tests were used. In comparison of binary groups, Mann Whitney U test was used. For the groups more than two, Kruskall Wallis test was used. p<0.05 value was accepted to be statistically significant.

Suspicion and observation of pregnancy (22.69\%), general medical examination (21.92\%), irregular menstruation (10\%), and upper abdominal pain (8.46\%) were among the most frequent health institution referrals.

**Discussion**

Poverty and inability to reach health services are an important factor in the referrals to emergency services.\textsuperscript{14,15} It is greater, especially in regions of low socioeconomic levels, due to availability and...
convenience of the use of emergency services and lack of advance financial demand in most regions.\textsuperscript{14,16,17} Another problem in regions with low socioeconomic levels is juvenile pregnancy, and the rate of involuntary pregnancy among women referred to emergency services is greater compared with other pregnancies.\textsuperscript{18} When these two factors are combined, the referral of undiagnosed juvenile pregnancy to emergency services in regions with lower socioeconomic levels is more likely. Our study found emergency services to be, at 43.5\%, the first place where juvenile pregnancy is diagnosed. In a study conducted in a region similar to that in which we conducted our study, one-third of juveniles referred to emergency services become pregnant within one year.\textsuperscript{19} Therefore, referrals of juveniles to emergency services should be evaluated for suspicion of pregnancy or for future potential of pregnancy.

The literature qualifies women between the ages of 15–44 as fertile and specifies that suspicion of pregnancy must be prioritized.\textsuperscript{20} But our study found that there are diagnosed pregnant women under the age of 15. It is obvious in regions with low socioeconomic levels that suspicion of pregnancy must be kept within a wider age range.

The rate of pregnancy at the age of 17 was the most common, with 68.1\%. The reason for this value can be interpreted as marriage at the age of 17 being allowed in certain situations with a court decision and as an increase in religious marriage, referred to as “imam marriage” as age progresses, in countries in which the study was conducted.\textsuperscript{21,22} In the region where we conducted the study, however, the proportion of only religious marriage being held was 11\%, consanguineous marriage was 40.1\%, and arranged marriages, the highest rate, was 66.2\%.\textsuperscript{21} At the same time, child abuse outside of religious-official marriage is found with young mothers or having a young mother, and this creates a vicious cycle and increases and increases the risk for juvenile pregnancy.\textsuperscript{23,24} Apart from this, that the religious values of religiously married individuals is prioritized and birth control being considered sacrilegious according to most Muslims are also risk factors.\textsuperscript{25} Another factor, however, is that women who carry a risk of pregnancy in adolescence refrain from going to hospital checkups, despite the special policies of hospitals.\textsuperscript{15}

The diagnosis of pregnancy being 95\% at state institutions is another indicator of the socioeconomic level of this population. According to 2015 data, 19\% of outpatient clinic examinations and 12\% of emergency examinations were conducted at private hospitals; our study, however, found this rate to be lower among juvenile pregnancies.\textsuperscript{26}

When examinations are organized based on ICD codes, it is seen that most applicants have pregnancy-related diseases. But abdominal pain and the general request of the examination is greater than 30\%. Similarly conducted studies have shown that pregnant juveniles are referred to emergency services, reporting their symptoms related to pregnancy.\textsuperscript{19} Therefore, all physicians, especially emergency services physicians working in regions with low socioeconomic levels, must be educated and informed about juvenile pregnancy. No matter how often pregnancy is detected at the first two referrals with a rate above 90\%, it can be considered that the subject mortality is insufficient when there is such high juvenile pregnancy. Another reason for this rate is thought to be the classes that physicians represent being different from that region of society, and pregnancy under the age of 15 might be though of as taboo or impossible by physicians.\textsuperscript{27,28}

**Conclusion**

In regions where epidemiological studies and socioeconomic levels are low and where juvenile pregnancy is seen frequently, all healthcare professionals, primarily emergency care doctors, must be educated about juvenile pregnancy, and social programs must be organized to monitor pregnant juveniles.

Physostigmine in Hyoscyamus Niger Intoxication: Is it an Antidote Myth?

Bulut Demirel¹, Sema Avci²

¹MD, Department of Emergency Medicine, Ankara Atatürk Research and Training Hospital, Ankara, Turkey,

Abstract

Introduction: Hyoscyamus niger intoxication (HNI) is usually seen in children and its diagnosis is based on history and clinical symptoms. Approach to intoxication: physostigmine therapy is an alternative to general approach in the treatment of intoxicated patients. However, physostigmine is a generally accepted antidote; it is not always accessible in every region or place. This retrospective study aimed to evaluate HNI cases in which physostigmine were not administered. The study examined the clinical outcomes, the follow-ups after discharge, and the laboratory analyses in order to see the impact of presence and absence of physostigmine administration in the treatment of HNI.

Method: 27 patients who presented to the hospital because of HNI intake were included in the study. Laboratory values, hospitalizations and outcomes of the patients were recorded. Patients’ clinical status and admissions to E.R. in the following three-month period after the discharge were examined by having contact with the patients.

Results: Although blood values of all the patients were in the normal reference ranges, direct bilirubin and ALT values were higher in the patients hospitalized to intensive care unit. Stomach lavage was applied to all patients and supportive care was started. Any complications including death, intubation and mechanic ventilation were not developed in the patients. All the hospitalized patients were discharged in four days. After the discharge, all the patients were contacted and questioned about whether they had any admissions to E.R., and had any complications or not. It was seen that none of them had a hospital admission associated with HNI.

Concerning the findings in our study and the literature in which patients were not administered physostigmine, we can state that instead of administering physostigmine in HNI patients, applying supportive toxicology approach is more accurate.

Keywords: Intoxication, pediatrics, antidote.

Introduction

Intoxication from herbs is one of the major intoxication reasons in rural areas and at a great scale affects children.¹ Hyoscyamus niger (HN) is a kind of herb whose root, leaves and fruits include alkaloids such as atropine, scopolamine and hyoscyamine, and which is a herb from solonacea family and is named in variant ways in different languages (Henbane, Stinking nightshade, Khurasani ajwain). It is known as “Batbat out” in our region.²,³ This plant, which has a two-year life cycle, has 50-60 cm height and usually grows up at rocky and rough fields.⁴ Every year in spring and summer, it causes accidental intoxications in children.⁵ HNI, which causes paralysis of parasympathetic nerve
system because of the alkaloids that it includes, results in memory disorders named as central anticholinergic symptoms, hallucinations, ataxia, hyperpyrexia, dry skin, flushing, tachycardia, mydriasis and a decrease in intestinal.\textsuperscript{6,7} Hyoscyamus niger intoxication (HNI) can be diagnosed with the help of those obvious symptoms and the history of the case. The treatment includes stomach lavage, supportive care and physostigmine therapy in selected cases. Even though HNI is commonly seen around the world, physostigmine, the antidote for the treatment, does not have that much prevalence.\textsuperscript{8} This study evaluated the outcomes of patients who did not have physostigmine administration, their hospitalization period, their laboratory findings, and their additional symptoms which occurred during the three-month period after the discharge. Although any patients were not administered physostigmine but were given standard supportive care, death or any complications were not observed. There was seen no death or complications when supportive care was administered to uncomplicated HNI patients instead of the recommended therapy physostigmine.

**Material and Method**

This study examined the findings of 27 patients who presented to E.R. in Kars Harakani State Hospital between the dates January 2017 and January 2018, and who were diagnosed with HNI. In the protocol of Kars Harakani State Hospital in herbal intoxications the image of the herb is shown to the patients and the local name of the herb is confirmed by the patients. The parameters were analyzed with SPSS 15.0 for Windows version. In the descriptive statistics of continuous variable, average and standard deviation were stated with numbers and percentages. The significance of difference between the groups was evaluated with chi-square test. In the analysis of normally distributed parameters, parametric tests were used. In the analysis of not normally distributed parameters, non-parametric tests were used. In comparison of binary groups, Mann Whitney U test was used. For the groups more than two, Kruskall Wallis test was used. \( p<0.05 \) value was accepted to be statistically significant. Parameters which belong to the patients; their age, symptoms, clinical findings, laboratory findings, treatment protocols, hospitalization status, complications and outcomes were evaluated. They were also contacted to learn about whether they had an admission to any medical institution or not during the three month-period after their discharge.

**Results**

Table 1: Includes demographic parameters, symptoms and findings of the patients. As displayed in the table, classical HNI (atropine intoxication) is seen in all patients. The age of the patients ranges from 2 to 15.

The average hospitalization duration of the patients was 1.1 (1-2) days. The average hospitalization in the intensive care unit was 2.2 (1-4) days. The duration of the hospitalization in the intensive care unit was longer than the hospitalization period in the clinic (\( p<0.022 \)).

All patients were applied gastric lavage and administered intragastric activated charcoal suspension and intravenous fluid (1500 ml/m2/day, 1/3 saline solution). The patients with agitation and convulsion were treated with diazepam (0.25 mg/kg/dose).

Even though the first blood results of the patients were in the normal reference ranges, direct bilirubin and ALT levels were found to be higher in the normal reference ranges in the patients hospitalized to the intensive care unit (respectively \( p=0.047, p=0.023 \)).
One patient with mild symptoms refused to have medical care so he was discharged from the hospital after taking his written consent. However, the follow-up after the discharge was done.

Of the patients, only two had a hospital admission in the following three-month period after the discharge. One of those patients were diagnosed with urinary system infection, the other one underwent an operation because of acute appendicitis. Both of those patients’ admissions were not associated with HNI.

Discussion
