All the patients had typical symptoms. After HNI was clinically confirmed, intoxication was diagnosed as it is stated in the literature.9 HNI and intoxications with other herbs may affect the health in a negative way. For that reason, gastric decontamination, gastric lavage, activated charcoal application were recommended to be applied to the intoxicated patients as the first step of the treatment. Our hospital’s protocol includes 1 mg administration of activated charcoal to 1 kg, so the treatment of the patients was performed in this way. Higher dosages of activated charcoal were given to HNI patients in a study in the literature. However, the study showed similar rates of death and complications to our study results. In other words, it displayed that administration in higher dosages did not affect the process of the treatment much. For that reason, we think that the dosage of the activated charcoal in our treatment is convenient.9 Besides, children with active vomiting have a risk of aspiration, and children with diarrhea have a risk due to the ready-made drugs that contain sorbitol. For that reason, high doses should be cautiously used.10 On the other hand, for the reason that atropine and alkaloids decelerate both gastric passage and lavage, both lavage and the use of activated charcoal are recommended. Ipeka syrup should not be definitely used.11,12 For that reason, our all patients were administered gastric lavage and activated charcoal.

Physostigmine is a safely used agent which is an antidote of atropine and similar alkaloids. It also antagonizes both the central and the peripheral effects of atropine and similar alkaloids.13-15 Physostigmine has mild effects such as vomiting.16 Physostigmine is gradually administered as infusion when symptoms start to disappear or until cholinergic effects start to appear. When anticholinergic findings such as tachycardia, somnolance, coma and respiratory arrest develop without any contradiction, physostigmine administration is recommended.17,18 Despite of being a specific antidote, every health institution does not have physostigmine with various reasons.9

Even though, of our 27 patients, 22 had tachycardia (81.48%), 20 had somnolance (74.07%), physostigmine was not administrated. In spite of this, all the patients were discharged from hospital at the end of the 4th day. In the literature in a study performed in the same region, patients with tachycardia and somnolance were not administered physostigmine and all of them were discharged from the hospital without any sequela in 48 hours.9 In an earlier study in which 216 HNI cases were examined, all the patients including the ones in coma were given supportive care and all of them came around without any sequela at the end of the 3rd day.19 In another study performed on 31 cases in the same region, all the patients who were not administered physostigmine were discharged from the hospital without any sequel.20 HNI was discussed in only one of those studies as it was discussed in our study.9 In cases reported in Canada, two elderly patients with HNI were watched to come around without physostigmine administration.8

In our study, the patients were given follow up after their discharge. They were also contacted to learn about whether they had an admission to any medical institution or not during the three month-period after their discharge from the hospital.

Of our patients, only two were learned to have hospital admission during the following three-month after their discharge; one of those two patients was diagnosed with urinary system infection; the other one underwent an operation because of acute appendicitis. Both of those patients’ admissions were not associated with HNI. In the earlier studies, there is not information about the patients’ clinical status after the discharge.

Even though laboratory values of the all patients were in the normal reference ranges, ALT and direct bilirubin levels were found to be significantly different. As those values were in the normal range, we do not think that it has a clinical significance.

Additionally, we saw that hospitalization duration in the ones in intensive care unit was longer than others. The reason of this can be thought as more severe cases were taken to intensive care unit. However, in the earlier studies, the differentiation of the patients according to the departments they were hospitalized was not done.9,19,20
As a result; even though physostigmine is recommended to be administered to HNI patients with dyspnea and in coma, our study in the light of the literature showed that convenient supportive care without physostigmine provided perfect outcomes on both HNI patients and HNI patients with dyspnea and in coma.

Differences in Consumption of Flavonoid Phytochemicals toward Total Cholesterol and LDL-Cholesterol Levels in Dyslipidemia and Non-Dyslipidemia Groups of Minangkabau Ethnic Women

Hermita Bus Umar¹, Diah M. Utari²

¹Faculty of Public Health, University of Indonesia, West Java, Department of Nutrition, Health Ministry Polytechnic of Padang, West Sumatera, Indonesia, ²Departement of Public Health Nutrition, Faculty of Public Health, University of Indonesia, West Java, Indonesia

Abstract

Introduction: Dyslipidemia is the primary risk factor for cardiovascular disease. Prevalence of dyslipidemia in Indonesia is still high, which is related to lifestyles such as unhealthy diet. Flavonoids are one type of phytochemical that is abundant in fruits, vegetables, nuts, and flavors that have a preventive effect on degenerative diseases.

Purpose: To determine differences in flavonoid phytochemical consumption of total cholesterol (TC) and low-density lipoprotein cholesterol (LDL-C) in dyslipidemia and non-dyslipidemia groups of Minangkabau ethnic women.

Method: The study design was comparative cross-sectional, examination of lipid levels of TC and LDL-C was carried out to determine dyslipidemia status. Subjects consisted of 72 women with dyslipidemia and 74 women with non-dyslipidemia. Interviews on food consumption used a food consumption frequency questionnaire (semi-quantitative food frequency questionnaire).

Results: The mean TC and LDL-C were higher in the dyslipidemia group, there was an inverse correlation between flavan 3-ols, flavones, flavonols, antocyanidins and isoflavones with TC and LDL-C. There were significant differences in flavonols and antocyanidin consumptions among the dyslipidemia and non-dyslipidemia groups (p < 0.05).

Conclusion: The flavonoid consumption can improve dyslipidemia status (TC and LDL-C).

Keywords: Dyslipidemia, flavonoid, total cholesterol, low-density lipoprotein cholesterol.

Introduction

Dyslipidemia is a disorder of lipid metabolism which is characterized by an increase or decrease in lipid fraction in plasma, which is the primary risk factor for cardiovascular diseases such as coronary heart disease.¹,² The prevalence of dyslipidemia in Indonesia is still high, based on the 2013 National Basic Health Research survey results, that prevalence of dyslipidemia in people over 15 years old obtained total cholesterol (TC) above normal at 35.9%. Low-density lipoprotein (LDL) is not optimal at 60.3%. Based on sex, LDL cholesterol (LDL-C) in females is higher than in males.³

The cause of dyslipidemia consists of factors that cannot be modified such as age, sex, family records, and modifiable risk factors including food intake. Unhealthy
diet is associated with abnormal lipid profiles such as increases in LDL-C and TC which can be at risk for cardiovascular disease. From various studies, a high-fiber consumption from vegetables, fruits, nuts, and seeds⁴⁻⁹, consumption of antioxidant vitamins and flavonoids are related to the reduced risk of cardiovascular disease¹⁰⁻¹³.

Food phytochemicals are commonly found in plant foods such as fruits, vegetables, grains, and tea. Consumption of flavonoids is consistently associated with protection from chronic diseases, including cardiovascular disease, cancer, and neurodegenerative diseases. A large group of phytochemicals is polyphenols, mostly consisting of flavonoids which are secondary metabolites of plants found in cereals, vegetables, fruits, flavors, and spices.¹⁴⁻¹⁷

In recent years, flavonoids have been recognized as compounds with a strong biological activity which also play a role in the prevention of chronic diseases including cardiovascular diseases.¹⁸ Food flavonoids have biological effects, such as anti-oxidant and anti-inflammatory properties. Flavonoid types such as flavan-3-ols and proanthocyanidins have been associated with a reduced risk of cardiovascular disease by increasing the release of endothelial nitric oxide and inducing vasodilation.¹⁷ Several epidemiological studies have found a relationship between flavonoid intake and lower risk of cardiovascular disease. Flavonoids can also prevent damage and oxidation of LDL.¹⁸ This study aims to determine the differences in flavonoid phytochemical consumption toward TC and LDL-C levels in the dyslipidemia and non-dyslipidemia groups of Minangkabau ethnic women.

Materials and Method

The design of this study was a comparative cross-sectional study, which compared phytochemical consumption between groups with dyslipidemia and non-dyslipidemia. The study was conducted on Minangkabau ethnic women in Koto Tangah District, Padang City, West Sumatra Province, Indonesia. Prior to the study, screening lipid levels (TC and LDL-C) was carried out to determine dyslipidemia status. The number of samples in each group were 72 women with dyslipidemia and 74 women with non-dyslipidemia. The inclusion criteria consisted of women aged 20-44 years who came from Minangkabau ethnic based on the ethnicity of their parents coming from the Minangkabau tribe without any mixed marriages with other ethnic groups; exclusion criteria were women who were pregnant, suffering from chronic diseases (heart disease, diabetes mellitus, and kidney disorders), and those taking anti-cholesterol medicines regularly.

Data collection included interviews, and laboratory tests, namely examination of TC and LDL-C levels. Interviews on food phytochemical consumption used a semi-quantitative food frequency questionnaire (FFQ) in the last three months. The dyslipidemia status was determined based on the National Cholesterol Education Program (NCEP) Adult Treatment Panel III classification guide, which is a total cholesterol level of > 200 mg/dl and/or an LDL cholesterol of > 130 mg/dl. A database for Indonesian food composition was in accordance with the Indonesian Food Composition Table in 2017, while a flavonoid database was added from USDA. Data processing of consumption patterns applied the modified Minang cuisine FFQ program and the 2007 Nutri Survey program. The independent t-test and Mann Whitney were taken to determine differences in the average consumption of flavonoid phytochemicals in the dyslipidemia and non-dyslipidemia groups. Pearson’s and Spearman’s correlation tests were used to determine the relationship between phytochemical consumption with TC and LDL-C. The results were stated statistically significant if the two-way test got p-value ≤ 0.05.

Results

Of the number, the total of those who met the inclusion criteria and were willing to voluntarily participate in the study were 146 people consisting of 72 people as the dyslipidemia group and 74 people as the non-dyslipidemia group. The normality test showed that TC and LDL-C levels were normally distributed. The mean TC and LDL-C levels in both groups can be seen in Table 1.

Table 1. The Mean TC and LDL-C Levels of Minangkabau Ethnic Women

</tr>
</tbody>
</table>

Based on the lipid fraction in Table 1, the mean TC and LDL-C levels in the dyslipidemia group were higher than the non-dyslipidemia group.
Table 2 shows the average consumption of flavonoids in the non-dyslipidemia group was higher (117.7 mg) than the dyslipidemia group (107.27 mg), except in the flavanones class. Statistically, there were significant differences in the average consumptions of flavonols and anthocyanidin between the two groups (p-value < 0.05). However, overall, there was no difference in flavonoid consumption between the two groups.

Table 3 shows that there is a match between the theory and the results of the study, namely an inverse correlation between the consumption of phytochemical flavonoids with TC and LDL-C, except for flavanones. Statistically, there is a significant relationship between flavonols with TC and LDL-C, while flavones are associated with LDL-C.

**Discussion**

A study conducted on four ethnic groups in Indonesia found that the prevalence of dyslipidemia in the Minangkabau ethnic group was higher than that of the other. Another study stated that consumption pattern of Minangkabau ethnic likely uses coconut milk as a source of saturated fat, but also uses various flavors and spices which are a source of antioxidants.

Antioxidants can be obtained from various food phytochemical sources, one of which is from abundant flavonoids found in vegetables, fruits, flavors, and spices. Based on its chemical structure, food flavonoids are generally categorized into the main subclasses: flavonols, flavones, flavanones, flavan-3-ols, anthocyanidins and isoflavones. Many epidemiological studies show that food flavonoids are associated with lower incidence of degenerative diseases such as cardiovascular disease. Flavonols shows a protective effect against type-2 diabetes in the Framingham Offspring cohort study, and anthocyanidins, flavan-3-ols, flavones and flavonols individually are associated with lower mortality caused
by cardiovascular disease in the Cancer Prevention Study II Nutrition Cohort.\textsuperscript{21,22}

In this study, the mean TC and LDL-C was higher in the dyslipidemia group. Flavonoid consumption in the non-dyslipidemia group was higher than the dyslipidemia group, except for flavanones whose consumption was almost the same between the two groups. The types of flavonoids with the highest average consumption in both groups were flavanones whose main source in this study were citrus fruit. Most types of Hesperetin and Naringenin flavanones are found in citrus fruit.\textsuperscript{14} The mean isoflavones are also high in the non-dyslipidemia group, which in this study the main source is mainly from tofu and tempeh. Isoflavonoids are a very distinct subgroup of flavonoids. Isoflavonoids are mostly found in soybeans and other leguminous plants.\textsuperscript{14}

Table 2 shows that, statistically, there are differences in the consumption of flavonoids in the flavonols and antocyanidin groups in both groups (p-value < 0.05). In this study, the flavonols group with the highest average was from quercetin flavonoids found in lettuce, and from the onion, garlic, and turmeric flavors; while, kaempferol flavonoids are obtained from spinach. Flavonol intake is found to be associated with a variety of health benefits that include antioxidant potential and a reduction in the risk of vascular disease.\textsuperscript{14} Quercetin and its derivatives can prevent oxidative damage in various systems, including those with clear relevance to atherosclerosis.\textsuperscript{24}

The most consumed group of antocyanidin is delphinidin flavonoids obtained from eggplant. Qui et al reported that anthocyanidin supplements (160 mg) compared to the placebo group given for 12 weeks improved LDL and HDL levels from 120 subjects with hypercholesterolemia.\textsuperscript{17}

Overall, the average consumption of flavonoids was 112.56 ± 37.16 mg, which results are higher compared to other studies on antioxidants in Minang cuisines with an average consumption of flavonoids at 105.0 ± 48.0 mg.\textsuperscript{11} In this study, there was no difference in total flavonoid consumption in both groups, which were also supported by previous studies.

In this study, there were significant differences in phytochemical consumption in the flavonols and antocyanidin groups with dyslipidemia. From the fraction of the lipid profile, there was an inverse correlation between consumption of flavonoids with TC and LDL-C levels, meaning that increased consumption of flavonoids was associated with lower TC and LDL-C levels.

A study conducted between Mediterranean and non-Mediterranean groups found no significant difference in the average total flavonoid intake between non-MED countries (373.7mg/day) and MED countries (370.2mg/day) observed. In non-MED areas, the main contributors were proanthocyanidins (48.2%) and flav-3-ol monomers (24.9%) and the main food sources were tea (25.7%) and fruits (32.8%). In the MED region, proanthocyanidins (59.0%) are by far the most abundant contributors and fruits (55.1%), grapes (16.7%) and tea (6.8%) are the main food sources. This study showed similar results for total food flavonoids intake, but a significant difference in the intake of flavonoids, food sources and some characteristics between MED and non-MED countries.\textsuperscript{25}

A study conducted on Japanese women found that total flavonoid intake was inversely correlated with plasma TC concentration (TC) ($r = -0.236$, $P <0.05$) and plasma LDL-C concentration (LDL-C) ($r = -0.220$, $P <0.05$), the main source of flavonoid is onion and the isoflavone is tofu.\textsuperscript{22} A population study in Australia also show an association between consumption of flavonoids and the risk of coronary heart disease.\textsuperscript{23}

At the molecular level, flavonoids can contribute to the reduction of the risk of coronary heart disease by affecting oxidation of LDL, fat plaque, and hypercholesterolemia.\textsuperscript{22} Studies in Haitian-American and African-American ethnic groups show that increased consumption of flavan-3-ols and flavanone is associated with lower LDL in the group with no diabetes.\textsuperscript{17} Flavonoids from old garlic extract flavor can reduce TC and LDL-C by 5-10% in hypercholesterolemic patients.\textsuperscript{24}

A meta-analysis study shows that turmeric and curcumin which contain a high level of flavonoids have an effect on decreasing LDL-C and TC levels.\textsuperscript{25} A study shows that orange juice (750 mL/day), which was also high in flavonoid level, improved blood lipid profile in hypercholesterolemic subjects.\textsuperscript{26} Naringenin-type flavonoids given in supplement form during the 8-week trial were found to reduce LDL concentrations by 17% in the hypercholesterolemic group compared with the healthy control.\textsuperscript{17}

**Conclusion**

There are differences in the consumption of...
flavonoids for the flavonols and antocyanidin groups in the dyslipidemia and non-dyslipidemia groups of Minangkabau ethnic women. The consumption of flavonoids is inversely correlated with TC and LDL-C levels, then it can be concluded that consumption of flavonoids can improve the status of dyslipidemia (TC and LDL-C). The next researcher is suggested to analyze the flavonoid phytochemical consumption directly through blood test.

Histological Assessment of Anti-inflammatory Effectiveness of 940 Nanometer LLLT on Carrageenan Induced Arthritis in Temporomandibular Joint in Wistar Albino Rats

Ali Imad Al-Khassaki¹, Jamal Noori Ahmed¹, Ammar Saleh Al-Allawi²

¹Department of Oral Diagnosis, College of Dentistry, University of Baghdad,  
²Alimamain Alkhazimain Medical City, Baghdad, Iraq

Abstract
Low level laser therapy is very promising method to treat temporomandibular joint disorders, the aim of this study was to assess the effectiveness of different energy density of 940nm diode laser, 120 Westar albino male rats (250g weight, three months old) were used in this study, divided randomly into four experimental groups; negative control group injected with saline, positive control group injected with carrageenan solution with no treatment, study group injected with carrageenan and treated with 171J/cm² LLLT group, and study group injected with carrageenan and treated with 74J/cm² LLLT group, animals were euthanized in day;1,3, and 7, histological slides obtained and examined under light microscope for assess acute and chronic inflammatory infiltrations. It was concluded that LLLT using 74J/cm² energy density had a very efficient anti-inflammatory effect.

Keywords: Anti-inflammatory, effectiveness, carrageenan, arthritis.

Introduction
Temporomandibular disorder can be defined as the clinical conditions involving the masticatory muscles, temporomandibular joint, or both of them¹. Temporomandibular disorder affects important percentage of the population in general and many of these disorders have an inflammatory component² many types of non-surgical treatments are usually used to treat TMDs to improve and enhance function and to reduce or cure symptoms³ such as physical therapy⁴, drug therapy⁵, various types of occlusal splints⁶, acupuncture ⁷ and low level laser therapy³ which is very promising method to treat TMDs³⁵⁸. Low-level laser therapy (LLLT) is the treatment that utilize light-source of a single wavelength (laser), with low power that will not generated heat in tissue so act with reaction which is non-thermal and photochemical⁹. Most studies in LLLT recommend using laser systems in the red to infrared spectrum of light⁵ biostimulation, which is a stimulatory effect of laser light on biochemical and molecular processes that normally occur in tissue, such as healing and repair. Examples of this are pain relief, wound healing, and collagen growth. Biostimulation increases circulation, collagen, and osteoblastic and fibroblastic formation, which initiates healing¹⁰. Some “biostimulation” is actually a matter of inhibition. Relief of acute pain requires inhibition of neural activity, and even though the patient feels “stimulated,” the pain response has actually been inhibited¹¹. Carrageenan is a sulphated mucopolysaccharide which has been used in the rat for inflammation models: footpad inflammation or paw edema model¹², air pouch model¹³, and to induce acute arthritis¹⁴, either alone or in conjunction with other agents¹⁵ and in the enhancement of inflammatory arthritis in other models¹⁶. Carrageenan causes well documented inflammatory effects after injection in joint¹⁷, thus it was chosen to induce arthritis in this study. The aim of this study was to evaluation of the effectiveness of 940nm LLLT on carrageenan induced arthritis as anti-
inflammatory agent in Wistar albino rats TMJ, using two different energy density (171J/cm² and 74J/cm²).

**Materials and Method**

**Subjects:** Following approval by the Committee of the college of Dentistry of the University of Baghdad, 120 male Wistar rats (150-200g) obtained from the animal house of the higher institute of infertility diagnosis and research assisting production of the University of Al-Nahrain were used in this study. Animals kept in acrylic cages lined with wood chips and maintained at 24 °C in a day/night light cycle with limitless access to food and water. Procedure was carried out in the animal house during light period of the day from 8:30 a.m. to 12:30 p.m.

**Method**

**Preparation and calibration of laser device:** Epic X diode laser device and deep tissue handpiece were used in this experiment, the handpiece was covered with tin foil diaphragm with central 10mm radius circular opening, the tin foil diaphragm was used to cover and protect eyes and ears from laser beam.

**Formation of the experimental groups:** Animals were randomly assigned to four experimental groups as following:

- Negative control group: injected by normal saline into TMJ area and applying deep tissue handpiece with 0 J/cm².
- Positive control group: injected with carrageenan solution into TMJ area with and applying deep tissue handpiece with 0 J/cm².
- LLLT with 171 J/cm² group: injected with carrageenan solution into TMJ area with and applying deep tissue handpiece with 171 J/cm².
- LLLT with 74 J/cm² group: injected with carrageenan solution into TMJ area with and applying deep tissue handpiece with 171 J/cm².

Injection of saline and applying 0 J/cm² were made to ensure that all animals undergo the same circumstances and stressful procedures.

**Carrageenan Injection:** Freshly prepared 1% carrageenan solution was made by dissolving carrageenan powder (Modernist, USA) in normal saline (Pioneer Co. IRAQ). The animals were anesthetized by inhalation of Diethyl ether (stab/BHT, Netherlands) in close plastic container then hair on TMJ area were removed using hair removal cream and plastic spatula. The postero-inferior border of the left zygomatic arch was palpated and a needle of an insulin syringe was inserted immediately below this point and then advanced in the anterior direction until reaching the postero-lateral aspect of the condyle. Then, 50 µL of the carrageenan solution was injected into the left TMJ²,⁵,¹⁸,¹⁹

**LLLT Procedure:** Low level laser therapy procedure was made transcutaneously in one contact point facing the central position of left TMJ, immediately after carrageenan injection while the animal is under anesthesia, using diode laser device (Biolase epic X, USA) and deep tissue handpiece (Biolase epic, USA), using wavelength 940 nm, spot radius 10mm, irradiation time 90 second and energy density for first experimental group was 171J/cm² and 74 J/cm² for the second experimental group, the procedure were repeated every 48 hours for the next seven days (four session of irradiation).

**Histological Procedure:** Ten animals of each group were euthanized using over dose of ketamine hydrochloride, on day 1,3 and 7 after initial injection of carrageenan solution, head decapitated and skin removed, the area of temporomandibular joint was cut using surgical disk, then kept in formalin foe 24 hours for fixation of tissue followed by storing in formic acid for 48 hours to decalcify the hard tissue, finally mount in paraffin wax, cut in microtome then stained using H&E stain to be examined under light microscope²,⁵.

**Histological Analysis:** Histological analysis was done by two examiners, blindly, under light microscope with magnification power of 400X, scoring for chronic and acute inflammatory cells of five randomly selected areas on each slide,

Scoring criteria as following⁵,²⁰

0 Absent or very few inflammatory cells

1. **Mild:** average number less than 10 inflammatory cells
2. **Moderate:** average number 10-25 inflammatory cells
3. **Severe:** average number greater than 25 inflammatory cells

**Statistical Analysis:** Data were analyzed using SigmaStat for Windows version 4.0 build 4.0.0.37,
Systat, USA. and the figures were made using Microsoft office 2016. Comparison between study groups were made using one-way ANOVA and multiple post hoc comparisons were performed using the Tukey test. A probability level of less than 0.05 was considered to indicate statistical significance.

Results and Discussion

A cute inflammatory cells analysis: First autopsy of rat TMJ was taken after 24 hours from induction of inflammation by carrageenan, second one at day three and the last at the end of the experiment at day seven. All study groups showed sever to moderate infiltration of acute inflammatory cells except negative control group which was injected with normal saline instead of carrageenan solution (Figure 1), statistically highly significant differences between study groups when compared using one-way ANOVA in day one and day three (P<0.001), this differences continued but to lesser extend in day seven of the experiment with significant differences and P=0.011. Post hoc analysis was done to reveal the differences between each pairs of study groups, the results for day one showed highly significant increasing in positive control, 171J/cm² LLLT group and 74J/cm² and when compared to negative control and P values were <0.001 in all three comparisons, which indicate severe acute inflammation in these groups, but there was significant decrease in acute inflammatory scoring of 74J/cm² LLLT when compared to positive control which meant the inflammation was much lower in former (P= 0.036), regarding 171J/cm² LLLT group there was non-significant decrease in the score when compared to positive control group (P=0.072) and the acute inflammation was non-significantly suppressed in this group. Day three post hoc analysis showed that acute inflammatory scoring was still highly significantly higher in all study group compared to negative control group with P value <0.001 indicating that acute phase inflammation still active 96 hours after initial induction. Although there was significant acute inflammation in LLLT group treated with 171J/cm² and 74J/cm² but there was highly significant decrease in the scoring when compared to positive control group (P=<0.001) indicating a good suppression of acute inflammation in these group at this stage. Last day of the experiment 192 hours after carrageenan solution injection the histopathological picture dramatically changed, acute inflammatory scoring differences were decreased in all groups, inflammation were still obvious to some extend in positive control and 171J/cm2 LLLT groups and when compared them with negative control group there were statistically significant increasing with P value 0.021 for the former and 0.014 for the later.

Analysis chronic inflammation score: Analysis of chronic inflammatory scoring was done using one-way ANOVA, there were statistically high significant differences among all study groups in all days of the experiment and the P value <0.001, thus post hoc analysis was performed to distinguish the differences among each pairs of the study groups in every day of the experiment. Post hoc analysis of day one of the experiment revealed highly significant increasing in chronic inflammatory cells infiltrations in all study groups when compared to negative control group (P =<0.001), comparing positive control group with 171J/cm² LLLT group showed highly significant increasing in chronic inflammatory cells in 171J/cm² LLLT group (P value =0.001), comparison of positive control group with 74J/cm² LLLT group there was non-significant differences (P value =0.235), similar non-significant differences between both LLLT treated group (P value =0.234). Comparison the data of negative control group with other study groups in the third day revealed highly significant increase in chronic inflammatory cells infiltration in positive control, 171J/cm² and 74J/cm² LLLT group, both LLLT groups showed highly significant increase in chronic inflammatory cells infiltration when compared to positive control group. Picture of the seventh day had major changes (table 3.29), negative to positive groups comparison still maintain the statistical differences but to lesser extent (P value= 0.017) thus the chronic inflammatory cells infiltration was still significantly higher in positive control group, comparing 74J/cm² LLLT to negative control group showed non-significant differences (P=0.376) which meant suppression of chronic inflammation in this group, interestingly unexpected highly significant increase in the scoring of 171J/cm² LLLT in comparing to negative control and 74J/cm² LLLT group (P= <0.001) and similar significant increase in comparing to positive control (P =0.048) which meant sever chronic inflammation in this group. Chronic inflammatory cells analysis for the seven day can be summaries in figure (2), negative control group as it was expected maintain baseline scoring through the experiment, all other groups showed increasing from day of induction till day three with more intense and earlier chronic infiltration in both LLLT group then the inflammation start to suppress from this point to the end of the experiment in 74J/cm² LLLT group as
well as in positive control group, while 171J/cm\(^2\) LLLT group maintain the chronic inflammation till experiment ending. Induction of arthritis was made using the most common method used to evaluate the effects of different types of treatment protocols on inflammatory arthritis which is induction of arthritis using carrageenan solution injected directly into TMJ, carrageenan is polysaccharide obtained from sea weed, it have potent pro-inflammatory effect in animal joint when injected into the joint space\(^{21}\), previous studies had proof the carrageenan effectiveness in arthritis induction in TMJ of rats\(^{18,19,22,23}\). As it was expected there was sustained level of chronic inflammation in 171J/cm\(^2\) LLLT group until the last day of the experiment when compared to positive control group, and this can have explained by the new invasion of inflammatory cells from skin burns which effect most of rats in this group\(^{29}\), or might be due to exceed the critical window of biostimulation to bio-inhibition\(^{30,31}\).
Conclusion

The results of this study demonstrate that LLLT using 74J/cm² have a very powerful anti-inflammatory effect on TMJ induced arthritis.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of oral diagnosis, College of Dentistry, University of Baghdad, Baghdad, Iraq and all experiments were carried out in accordance with approved guidelines.

The Impact of the Method of Teaching the Mediator Different Speed and Mental Training to Teach Some of the Offensive Skills for Beginners in Handball

Manaf Majid Hasan¹, Omar Ahmed Mosleh¹, Fouad Hammad¹

¹University of Anbar, Faculty of Physical Education and Sports Sciences, Iraq

Abstract

The aim of this study is to compare the effect of the teaching method (the explanation and the typical presentation) carried out by the control group and the method of the mediator according to the speed of presentation of the motor model and mental training conducted by the pilot group in the education of beginners.

The experimental method was used to design the two groups of pre-and post-test tests. The study was conducted over a period of five weeks. After processing the data of the pre and post measurements, the results were obtained. The most important results were: The presentation of the motor model along with the mental training results in superior learning for beginners as a result of the use of the video presentation with different operating speeds of performance, providing learners with an ideal mental vision and integrated mental training before they go to the playroom to apply it practically.

Keywords: Teaching method, technological medium, speed training, mental training, and handball.

Introduction

We all aspire to reach the beginner learner to the best level of knowledge and skills and requires that continue to search for the best teaching method that fit the capabilities of learners and their needs and the content of education and its objectives, “The adherence to one method or method of learning may not achieve all the objectives and the existence of variance in the level of individual differences And the difference of learners in the ability and comprehension on the perception and perception of motor performance “¹ and that the best method of teaching are that are very influential and leave the impact of learning in the learner and make it involved and interacting in the educational process, recalling,”A positive only if the learner or interactive“².

It is noticeable in our work as teachers that we do the dynamic model or to show it using video, the performance is fast and negatively affects the formation of the first image of the learner to hide the fine details, the novice gets a mental image is incomplete and does not achieve the main purpose in education.

In our review of the teaching literature in the Faculty of Physical Education - Anbar University we found missing rings in teaching using the method of order (explanation and presentation of the model) and the model is presented by the same teacher and in the best case is used video tutorial and the speed of the normal presentation, which is equal in how fast the performance of the model from In both cases, the speed of motor performance exceeded the perceptions of junior learners with no interest in mental training, which reflected negatively on the levels of learners when evaluating them. The researchers suggested an assessment of the levels of learners for the last three years and after obtaining them officially from the results of the evaluation were divided between the six official levels of assessment (acceptable, intermediate, good,
very good, excellence) and the largest dispersion ratio (mean - acceptable - average).

The importance of the research is to suggest a method of teaching the different technological medium as well as mental training as a new contribution to teaching as well as in solving the problems of teaching mentioned above.

**Research aim:** To identify the effect of the method of teaching using the technology of different speed and mental training and compare its results in a way teaching the matter (explanation and presentation of the model).

**Hypothesis:**
1. There were significant differences in favor of post measurements of control and experimental research groups.

2. There are significant differences in favor of the results of the experimental group using the different speed and mental training technology.

**Research Methodology:** The researchers used the experimental approach.

**The research sample:** A random sample of (35) non-practicing students of the handball game from the second stage in the Faculty of Physical Education-Anbar University for the academic year 2017-2018 (23 of Division A - 12 of Division B) by 58.333% of the total research community (60) Learned.

**Table (1). Shows the amount of dispersion in the levels of the second stage students in the handball course**

* Moderate (±3)

**Tests used:**

1. Push a medical ball for the farthest distance to measure the explosive force of the arm
2. Vertical jump of stability to measure the explosive force of the upright legs.
3. Test the numbered circuits to measure your compatibility in the handball.
4. Test the accuracy of the shoot of the jump to measure accuracy.
Procedures of the experiment:

Pre Test: Carried out during the period from 11-18/2/2018 recorded homogeneity data and evaluate the pre performance of the main research variables

Execute the experiment: Control group: The Spectrum of Teaching Styles introduced by Muston and Ashworth" method was used over a five-week period with two teaching units per week (90 minutes).

Experimental group: The technological medium used the different speed to display the kinetic model to the Gantt training program over a period of 5 weeks and two learning units per week (90 minutes).

Post-test: Was carried out in the period 18-21/4/2018 and recorded the data of performance evaluation skills and the same method of pre testing.

*Morality below error level (0.05) in front of the degree of freedom (23-1 = 22)

Table (3) and (4) show that there are significant differences between the evaluation of the pre and post performance of the control group as well as the experimental group and the evaluation of the post-performance of both groups.

The positive results of the effectiveness of both method in teaching are attributed to the fact that each method of teaching has its administrative and organizational aspects and its tools that influence the teaching and motivating the learners. the learners interact with each other according to their ability and inclination to accept the appropriate method in education. They are all aimed at improving the learner’s level and imparting the experience and practical knowledge of the that “method and method of teaching are very important in the educational process and that these method and method affect the speed of learning and the degree of saturation in learning". and agree with the results of the research that the method of teaching physical education “regulate the interaction of learners in educational situations to acquire educational and educational experiences related to the goals of physical education”.
and also agree with the view in “The successful method of teaching is to reach the desired goal and achieve the purposes of the lesson with the least time and effort and the most appropriate means”.

* Moral and below error level (0.05) in front of the degree of freedom (23 + 12-2 = 33)

Table (5) shows that there are significant differences in the evaluation of the post-performance between the control and experimental groups and in favor of the results of the experimental group for the large arithmetic mean of their research variables. Thus, the hypothesis of alternative research was achieved: “There are significant differences in favor of experimental group results using the different speed and mental training medium”.

Table (6) show that Effect size of the teaching method of the control group (0.22-0.65) means that (22-65%) of the effect on the teaching of the search variables is explained by the effect of the order method (explanation and typical presentation) The ratio is not explained by strange factors. It is clear from the same table and shape that Effect size of the experimental group teaching method (0.50-0.90) means that (50-90%) of the effect on the teaching of the search variables is explained by the effect of “The remainder of the ratios are unexplained and due to strange factors and the observed effect size data finds a significant increase in the proposed method And his superiority”.

The researchers attributed the positive results of table (5) and (6) to the method of teaching the experimental group to the effectiveness of the administrative and organizational aspects. The effective tools harnessed the available resources for teaching in accordance with the content of the lesson and the requirements of the educational situation and the needs, tendencies and attitudes of the learners. (0.70X) (0.30X). It provided a clear, meaningful and integrated picture of the parts of the skill and its sections. The learner was able to understand the small parts of the skill and to connect them to each other and to form the correct motor image of the performance. Where he confirms whenever the information provided with meaning and purpose has diminished the need for repetition to save them and the division of information displayed becomes a catalyst to increase the learner’s capacity to address them and absorbed through the organization of such information.
The positive results of the method of teaching the experimental group are attributed to the good organization and implementation of mental training in terms of the time it is given and the number of times it is implemented in proportion to the learner’s need to take the right mental perception and training, thus strengthening and strengthening the mental motor program to show in the form of the correct motor behavior of the performance when performing it that mental training is one of the method used in the educational process of motor skills, which affect positively through the effectiveness of mental training factors in relaxation and training through observation, thus proved an unquestionable success in raising the level of Disease. The results also agree with the reference that “mental training is closely related to learning in general and in the field of learning locomotion in particular, where mental training adds a cognitive aspect of performance in terms of seeing the full performance and then recall the image to return it fully or fragmented and training to correct Performance or increased arousal for optimal performance “."12

Conclusions
1. The effectiveness of both the teaching method (explanation and presentation model) and the method of teaching using the medium different speed of the presentation of the motor model and mental training in the education of beginners some of the offensive skills in handball.
2. The emergence of a difference in the results of the evaluation of the post-performance of the control and experimental research groups and for the benefit of the pilot that uses the mediator according to the speed of presentation of the model and motor mental training.
3. The method of teaching using the mediator is different than the speed of presentation of the motor model and the proposed mental training in the differential difference in the size of the positive effect.

Abstract

Ischemic stroke may happen in different combinations of clinical ailments and these residues represent a major problem. Reactive oxygen species (ROS) have been shown to act a main action in cerebral ischemia-reperfusion injury (IRI). Where reperfusion is defined as the action of restoring the flow of blood to an organ or tissue after a heart attack or stroke. Diverse therapeutic effects have been substantive for Rosmarinus Officinalis (Rosemary). In addition, it has been offered that Rosmarinus Officinalis has covering impact versus I/R stimulate cerebral damages to diverse organs. For this cause, it sounds conceivable that the administration of Rosmarinus Officinalis might keep the brain versus the ischemia reperfusion injury. The study included knowledge the chemical components of the Rosmarinus Officinalis leaves in the watery extract and determine whether Rosmarinus Officinalis prevents ischemia-reperfusion induced stroke. Thirty rats were divided into three groups as control Group 1, IRI group Group2, and Rosmarinus Officinalis treatment group Group3. All animals underwent stroke for 30 min followed by 60 min period of reperfusion. Animals were internal infused with only 0.9% saline solution in group 2. Rats in group3 received Rosmarinus Officinalis (1 mL/kg) for two weeks with the same diet intraperitoneally, before ischemia and before reperfusion. We were the estimation of the biochemical parameters: Blood samples were taken from the rats. Serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), lactate dehydrogenase (LDH) oxidative stress levels of nitric oxide (NO) and lipid peroxidation (LPO) and blood was used for the estimation of enzyme immunoassay: Interleukin-8 (IL-8), tumor necrosis factor Alpha (TNF-α), interleukin-1β (IL-1β). The results showed that the extract contains several species. The levels of enzymes and Oxidative stress in group3 were significantly lower than those in the group2. Our results suggest that Rosmarinus Officinalis treatment protects the rat brain against ischemia-reperfusion induced Cerebral injuries.

Keywords: Rosmarinus Officinalis, Ischemia/reperfusion, Cerebral injuries, Oxidative stress, Antioxidant.

Introduction

Ischemia disease remains the leading cause of death world-wide, intracerebral stroke is most common type of stroke, accounting for almost 87% for all stroke. The goal of therapy of ischemia is to improve the blood flow (Reperfusion), that reperfusion is 50-70% after injury occur normally.2 Reperfusion the type of treatment depend on type of stroke either by procedure called an endovascular (physical removal of a large blood clot), or a mechanical thrombectomy, using wire-caged device called a stents retriever to remove the large blood clot and thrombus disruption using stents. Medical treatment with recombinant tissue plasminogen activator that given intravenously is only FDA-approved drug thrombolytic treatment for acute ischemic stroke therapy. Tissue plasminogen activator only used within three hours of having stroke, but recent studies have long that time window of tissue plasminogen activator thrombolysis treat to 4.5 hours after injury time onset.3 Patients in

last year’s, so many clinical trial for patients that need embolotomy surgery by stent retrievers done in US and the result was benefit to patients in all that lead us to use this type of treatment widely in clinic in future. However, there something called reperfusion injury, despite we want the reperfusion to reoccure and oxygen restoration but it that happen very rapid many cause effect on brain function and lead to harmfull effect on brain, that worse in certain type of stroke, the reperfusion injury was significantly, has been clearly reveal from both experiential studies and clinical guide damage effect of reperfusion injury after stroke. For example, the infract volume clearly increased during 6-24 hr., in rat model of stroke with middle cerebral artery occlusion, subsequent the start reperfusion compared continual occlusion, which is a firm evidence of reperfusion injury following stroke.6

Therapeutic properties of herbs have been traditional applied in the therapy of different human’s illness and therapeutic characteristics and their pharmacological have been related to various chemical components particular from their raw extractor. Specially chemical constitutive of antioxidant action can be found in high concentration in herb and can be responsible for their barring effects in different degenerative diseases, including cardiovascular, neurological and cancer, diseases. So, the antioxidant properties of herbs have prolong academic usage applications in humane verdure sponsorship.7

Since common medical therapy have side effects, especially in association with their long-term use, and have high costs enjoined on these patients, trend towards traditional and alternative treatments is increasing. A major amount of investigate has been done on plants to test their effects on oxidative stress.8 Rosemary (Rosmarinus officinalis), plant belongs to the Lamiaceae family is an aromatic herb that is utilized as a food additive.9 Although this plant is mostly known for its antioxidant properties in medicine, it possesses anti tumorigenic, anti-inflammatory, antidiabetic, anticancer, antiproliferative, and neuroprotective effects, as well.10 Various studies have shown that rosmarinus officinalis is a mediator of apoptosis and inflammatory activities. It has a diversity of properties, including expectorant, antispasmodic and diuretic11 rosemary inhibits the production of free oxygen radicals, lipid peroxidation (LPO) and suppresses inflammation.12

### Materials and Method

**Plant Material:** The purpose in this treatise was to fluid watery offprints from Rosmarinus officinalis L. The desiccated rosemary blades were gained from (Baghdad, Iraq).

**Chemical detection of the plant components:** The aqueous extract of rosemary was prepared by using the chemical compounds which were listed at Table 1. These listed compounds were glycosides, phenolic compounds, tannins, saponins, resins, proteins and flavonoids.13

**Experimental Design:** At experimental project research were used thirty (Wister) rats with weight 200-230g which were kept at standard circumstances. These rats were prevented from eating and water for 24hours before the surgery was achieved on rats under tested. These rats were spilted to 3 sets which were nourished the same nourishment: sham group (Group 1), IRI group (Group 2), and IRI with aqueous extract of Rosmarinus Officinalis handling combination. All these sets of rats were doped by giving amount of 40-50 mg/kg of thiopental sodium. Watery extract of Rosmarinus Officinalis was granted to the rats of treatment set type, prior IRI of a potion with a concentration of 1 mL/kg by intraperitoneal track.

**Surgical Procedure:** The tested cerebral ischemia caused by obstruction of the two carotid arteries for 30 mins. Reperfusion was entered by releasing the cord sweetly for duration of 60mins. In control rats group proliferated anesthesia, skin incision and separation of the arteries without subsequent ligation of vessels. All surgical procedures were carried out under general anesthesia [intra introduction of thiopental sodium at a dose of 40-50 mg/kg]. During ischemia, the animal’s body temperature was maintained at normal levels (37°C) using warm table lamp. After, decapitation of rats was used to study.14

**Biochemical analyses:**

a. Heart enzymes: Plasma was used to measure ALT, AST and LDH as indicative parameters of heart function. The plasma activities of ALT, AST and LDH were estimated by commercially available kits using an autoanalyser [aerose® Abbott Laboratories, Chicago, IL].

b. Oxidative stress indices: The left hemisphere was used to detect nitric oxide (NO) measured as total...
nitrite\(^{15}\) and lipid peroxidation (LPO) as Thio Barbituric Acid Reactive Substances.\(^{16}\) IL-8, TNF-\(\alpha\), IL-1\(\beta\) levels were measured using commercial enzyme immunoassay kits (Endogen, Woburn, MA, USA).

**Results**

The chemical components tests of the hydrous extracts of rosemary are listed in Table 1, which were showed that carbohydrate, saponins, proteins, tannins, flavonoids and various phenolic compounds are leaves components.

**Table 1: Qualitative chemical analyses for aqueous extract of Rosmarinus Officinalis leaves**

As it was expected, ischemia reperfusion for the group (I/R) led to rise producing of the oxygen free radicals which has been recorded in ischemic reperfused heart and led to tissue harm as indicated by boost percent of concentration for AST, ALT, beside of LDH (in the I/R set). With the compare to the percent of concentrations or levels for AST, ALT, and LDH in the Rosmarinus Officinalis, it showed curing set recorded lower standards of LDH, ALT than those in the ischemia reperfusion set. They were significantly senior in the ischemia reperfusion set than those in the control type. The gained results are illustrated as shown at Fig. 1.

![Fig. 1: Showed enzymes of Heart at control set I/R and I/R+Rosmarinus Officinalis, rats (n=10, mean± SD)](image)

AST: Aspartate aminotransferase enzyme; ALT: refer to alanine-aminotransferase; LDH: refer to Lactate–dehydrogenase. Significances with controls: is *\(P<0.01\).

As it is clarifying by rising of the levels for the oxidative exertion for LPO and NO (Fig. 2) whilst oxidative stress standards for LPO and NO in the Rosmarinus Officinalis curing set were recoded decreasing to be lower than those in the ischemia reperfusion kind. Ischemia reperfusion group showed increasing in the levels of oxidative stress of LPO and NO with the comparison of their levels at control group.

![Fig. 2: Showed the Oxidative overwork in control group, I/R and I/R Rosmarinus Officinalis, rats (n=10, mean± SD)](image)

NO: nitric oxide, LPO: lipid peroxidation. Significances contra controls: *\(P<0.01\).
The results which were on recorded in Figure 3 clarified that blood IL-8, TNF-α and IL-1β standards in remedy set (Group 3) were remarkable lower (p<0.001) than their levels in I/R set.

**Discussion**

The first part of this study is to evaluate the qualitative chemical analyses of the aqueous extracts (Table 1). These are quite similar to that reported by Martinez et al.\(^{17}\) The second part of the work involves study the influence of Rosemary extract on Cerebral Ischemic. The results of this estimation revealed that pretreatment with Rosemary extract significantly decreased the blood–brain barrier permeability disruption and injuries, and more importantly, relieved brain infarction and neurological deficit scores after focal ischemia reperfusion.

Results demonstrated *Rosmarinus Officinalis* could protect Cerebral injuries in a rat. Furthermore, it also decreased cognitive deficits induced by ischemia.

Oxidative strain is one of the more remarkable mechanization that engaged in pathogenesis of ischemic injuries and results in blood–brain barrier disruption and neuronal death.\(^{18}\) It has also been reported that Rosemary extract decreases LPO and OH radical, and H\(_2\)O\(_2\) activities in rat serum, brain, liver, kidney and heart tissues.\(^{19}\) Based on the mentioned proofs, it can be said that Rosemary extract has strong antioxidant properties,\(^{20}\) even more than the phenolic compounds.\(^{21}\)

The data showed that the administration of Rosemary extract caused to an effective betterment of cerebral edema, as well as of neurological scores, over and above, too it is ambidextrous to successfully attenuate blood–brain barrier permeability which in turn lead to the rebate of brain infarction. Consequently, Rosemary extract safeguard with blood–brain barrier limited disruption by acute Cerebral ischemic through limiting intracranial pressure, brain infarction,, restoring energy and cerebral blood flow.

Recent studies have showed that the phenolic components from Rosmarinus officinalis L. reduce oxidative stress.\(^{22,23}\) Brain inflammation has newly emerged as an important role in the pathogenesis of Cerebral Ischemic injury.\(^{24}\) It shown that ROS extract can prevent or decrease of phosphorylation of MAPKs, then blocking NF-kB activation, and ultimately decreased expression of Cyclooxygenase-2 and iNOS.\(^{25}\) Similarly, pro-inflammatory enzymes, leukocytes activities and mediators such as TNF-α, IL-1β, and NO were suppressed by Rosemary extract during inflammation.\(^{26}\)

**Conclusion**

The present investigation demonstrated that brain infarction tolerance induced by Rosemary extract pretreatment leads to a prevention or reduction of ischemic stroke lesion. Therefore, Rosemary extract could markedly improve stroke outcome. Based on the mentioned proofs, cerebral ischemic tolerance induced by Rosemary extract can be useful as a practical therapeutic in related other diseases.

The Effectiveness of National Early Warning Score (News) as Predictor of Mortality in Heart Failure Patients in Emergency Department

Srikandi Puspa Amandaty1, Siswanto2, Asti Melani Astari2

1Nursing Master Program, Faculty of Medicine, University of Brawijaya, 2Lecturer in Faculty of Medicine, University of Brawijaya

Abstract

Introduction: Heart failure is one of the global health problems for society characterized by a high mortality rate, increased hospitalization and rehospitalization. National Early Warning Score (NEWS) is one who has the EWS development of physiological parameters include pulse rate, systolic blood pressure (SBP), respiratory rate, body temperature, level of consciousness (AVPU), oxygen saturation and the use of supplemental oxygen in the range of 0-3 on each parameter.

Objective: This study aimed to analyze NEWS effectiveness as a predictor of mortality of heart failure patients in the Emergency Department (ED) of General Hospital of Dr. Slamet Martodirdjo Pamekasan.

Method: This study using observational analytic design with prospective cohort approach. The respondents in this study were 64 patients in quota sampling. The research instrument is observation sheet. ROC analysis and multivariate used multiple logistic regression test.

Results: ROC test showed that NEWS has value of p=0.000 and AUC of 0.856 which describes NEWS can be a strong predictor related mortality in heart failure patients with CI of 95%, sensitivity value of 0.85 (85%) and specificity of 0.818 (81.8%). Logistic regression analysis explained the SBP became independent variables that most associated with mortality of heart failure patients with Exp(B) of 10.208 which describes the high score of SBP has greater risk 10.208 times to death compared with a normal score of SBP after controlled by SPO2.

Conclusion: NEWS is an effective predictor of mortality of heart failure patients.

Keywords: National Early Warning Score, heart failure, mortality, ED.

Introduction

Heart failure is one of the global health problems for society characterized by a high mortality rate, increased hospitalization and rehospitalization1. Patients with heart failure who have the condition decompensation come with a return visit to the installation of emergency and have high rates of hospitalization, resulting in an increase in health care costs2. WHO (2016) recorded more than 17.5 million people in the world die of cardiovascular disease3.

Based on data from basic medical research in 2013, the prevalence of heart failure are diagnosed by a doctor or symptoms by 0.3%, or about 530 068 people, with a prevalence of heart failure is based on the highest diagnosis in Yogyakarta (0.25%), followed by East Java (0.18%), while the prevalence of heart failure in North Sulawesi (0.14%), the prevalence of heart failure...
increases with age and the highest prevalence occurs at age 65-74 years (0.5%) and are more prevalent in urban areas.

The treatment of patients with heart failure remains a problem for doctors and nurses in the ED, in terms of setting priorities, monitoring and assessing on an ongoing basis on the condition of the patient, and provide support to patients and families in a limited time. One of strategy for detecting deterioration of non-trauma patients in the ER is the implementation of Early Warning Score (EWS). National Early Warning Score (NEWS) is one of the development of EWS by the Royal College of Physicians that have physiological parameters include pulse rate, systolic blood pressure, respiratory rate, body temperature, level of consciousness (AVPU), oxygen saturation and the use of supplemental oxygen in the range 0-3 on each parameter. NEWS recommended to assess patients in acute pain conditions. Currently there are limited studies that address the application NEWS in heart failure patients in the ED. EWS research in the ED just focused on predicting mortality and referral to the ICU and the study was conducted retrospectively.

Based on preliminary studies, the number of visits a patient in the ED of General Hospital of Dr. Slamet Martodirdjo Pamekasan in 2017 as many as 15,689 patients, while in 2018 until September as many as 111.276 patients. Heart failure among the 10 major diseases in the ED in 2017 until 2018. Interviews with ED nurse that there are some patients with heart failure who suddenly experience worsening and nurses require early detection system to predict the deterioration of the patient so that they can be addressed early and prevent death. Therefore, this research needs to be carried out.

Methodology of Research: This study used observational analytic design with prospective cohort approach. The respondents in this study were 64 patients in quota sampling. The research was conducted in the ED of General Hospital of Dr. Slamet Martodirdjo Pamekasan. The research instrument is observation sheet. ROC analysis and multivariate used logistic regression test.

Research Result

Table 1 shows the highest NEWS is 13 and the lowest is 0 with the average value is 6.83. The oldest respondent is 85 years old and the youngest is 25 years old with an average of 58.25 years old. A maximum systolic blood pressure on patients is 261 mmHg and the lowest is 95 mmHg with an average of 154.36 mmHg. The maximum heart rate of patient is 149 and lowest is 53 with an average of 97.36. The maximum respiration rate on patient is 40x/minute and the lowest is 16x/min with an average of 27.02x/min. The highest temperature of the patient is 38.5°C and the lowest is 34.9°C with an average of 36.5°C. The maximum oxygen saturation of patient is 100% and the minimum is 77% with an average of 94.69%.

Table 2 describes the gender of the respondents have an equal number of male and female with each number of 32 people. The survive respondents in this study were 44. The most respondents with alert awareness level were 58 people. The most respondent that use oxygen were 61 people.
Table 3 shows the NEWS has a value of p=0.000 and the AUC of 0.856 which describes NEWS can be a strong predictor related to mortality in patients with heart failure.

Table 4. Cut off Point, Sensitivity and Specificity

Table 4 shows the cut off point of NEWS is at a point 6.5 which means that the detection of mortality of heart failure patients in the score of 6.5 with the sensitivity of 0.85 and specificity of 0.818. The sensitivity of 0.85 indicates the NEWS ability clinically to generate positive value or their mortality of heart failure patients by 85%. The specificity of 0.818 showed NEWS ability clinically to produce a negative value or the patient’s life in case of heart failure by 81.8%.

Table 5. The results of multiple logistic regression test between the scores of systolic blood pressure (SBP), respiratory rate (RR), temperature, oxygen saturation (SPO2), level of consciousness (AVPU) and use of oxygen to mortality in heart failure patients in the ED

Table 5 shown the final results of the multiple logistic regression test indicate the calculated value Exp (B) systolic blood pressure is 10.208, the value of Exp(B) of SPO2 is 2.886 and the value of Exp(B) of the level of consciousness (AVPU) is 1.741. Based on the results of this analysis, the variables SBP became independent variables that associated with mortality of heart failure patients with Exp(B) value of 10.208 which describes high score of SBP has greater risk of 10.208 times to the death compared with a normal score of systolic blood pressure (SBP) after being controlled by oxygen saturation (SPO2).
Discussion

The results of this study indicate that the NEWS is effective in detecting the occurrence of mortality in heart failure patients in the ER. Based on Table 5.4 shows that NEWS has the Area Under the Curve (AUC) of 0.856 (0.741-0.971), which means NEWS can be a strong predictor related mortality. Furthermore, the cut off point values of NEWS obtained at a point 6.5 which means that the detection of mortality of heart failure patients in the score of 6.5 with the sensitivity of 0.85 and specificity of 0.818. Supported by the positive predictive value of 0.68 indicates clinically NEWS ability to generate positive value or their mortality of heart failure patients by 68%.

According to the study results Alam et al., 2015 with a prospective design, explained NEWS as a good predictor of death with AUC value 0.768 (0.618 to 0.919). Powered studies Smith et al., 2012 retrospectively say that NEWS is an effective predictor to detect unexpected death compared with 33 EWS others with mean AUC value of 0.894 were strong (Smith et al., 2012). The study by Pimentel et al., 2018 retrospectively to detect mortality in patients in the ER told NEWS has a value of 0.862 which means strong AUC as a predictor of mortality. The purpose of NEWS including the assessment of acute illness, clinical deterioration detection, and enable timely clinical response. NEWS should be used for a preliminary assessment of acute illness and for further monitoring of patients during hospital stay. By NEWS regularly noted, the clinical response of patients can be identified when there is a potential patient’s clinical deterioration and the need to obtain clinical care. Likewise Scoring NEWS will provide guidance on patient recovery and re-stabilized, thereby reducing the frequency and intensity of clinical monitoring to discharge patients.

NEWS has seven physiological parameters include heart rate (HR), systolic blood pressure (SBP), respiratory rate (RR), body temperature, level of consciousness (AVPU), oxygen saturation and the use of supplemental oxygen in the range of 0-3 on each parameter. On multivariate analysis, obtained the variable component of the NEWS of the most influential is the component of systolic blood pressure (SBP) with Exp (B) 10 208 which describes score SBP high 10 208 times greater risk of death compared with a score of SBP normal after being controlled by the oxygen saturation (SPO2).

Blood pressure is one of the hemodynamic parameters were simple and easy to do measurement. According to Jones & Hall (2006), high blood pressure (hypertension) is an important risk factor for cardiovascular disease. The results showed that patients with systolic blood pressure of 261 mmHg highest and the lowest was 95 mmHg with an average reach 154.36 mmHg. The study results Britton et al., 2009 says there is an increased risk of heart failure by 35% among subjects with systolic blood pressure of 130-139 mmHg compared to subjects with normal systolic blood pressure of 120 mmHg. However, systolic blood pressure low (hypotension) an assessment of the worsening of the acute illness of the most significant because of hypotension may indicate compensation blood circulation due to a decrease in the volume of cardiac output, heart failure or heart rhythm disorders, and the effects of blood pressure lowering drugs. Low systolic blood pressure (<120 mmHg) at admission showed a worse prognosis. In the scoring system NEWS hypotension condition is given a higher assessment scores (a score of 1 and 2) than hypertension <200 mmHg given a low score (a score of 0). Described in severe hypertension (systolic blood pressure ≥200 mmHg), can occur as a result of the pain experienced by the patient but it is important to consider the impact of acute disease or be exacerbated by severe hypertension and selection of clinical measures.

Furthermore, oxygen saturation is a powerful tool for the assessment of pulmonary function and cardiac integrated. Measurement of oxygen saturation is one of the non-invasive procedure using pulse oximetry are routinely be used in the clinical assessment of acute illness but are still rarely included in the EWS system. Because the measurements are considered practical, the oxygen saturation is considered as an important parameter in NEWS. On the condition of heart failure with shortness of breath conditions can cause a decrease in oxygen saturation of the patient. In the study Sittichanbuncha et al., 2015 says that the oxygen saturation including predictors of mortality. Oxygen saturation has a negative correlation with prehospital mortality. In the results in Table 5.1 oxygen saturation values obtained for heart failure patients when entering the ED is 77-100%. There are still patients with heart failure had oxygen saturation below 94%. Studies have shown that the lower the patient’s oxygen saturation owned by the increased risk of death in patients. Each 1% increase in oxygen saturation, it will be followed by a decrease in the risk of death by 8%. By observing the oxygen saturation levels will be known needs oxygen delivery. Giving oxygen to patients would increase
survival in patients so it will give good results. Oxygen saturation has a positive correlation with the amount of oxygen supplied which means higher oxygen levels given the higher levels of oxygen saturation.

**Conclusion**

NEWS is effective as a predictor of mortality of heart failure patients in the ED as well as systolic blood pressure (SBP) is the most closely related to NEWS parameters as predictors of mortality of heart failure patients in the ED.

Analysis of Gas H$_2$S Exposure with At Risk Behavior to Workers at XYZ Geothermal Company in 2018

Tri U. Pantyarso$^1$, Zulifli Djunaidi, Dadan Erwandi$^1$, Laksita R. Hastiti$^1$

$^1$Occupational Health and Safety Department, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

The study was conducted in geothermal operations which has been found that the H$_2$S gas exposure was the riskiest. The purpose of this study was to examine the relationship between perceptions, knowledge, attitudes and the ability to avoid exposure H$_2$S with at risk behavior to workers in XYZ geothermal company in 2018. It used cross sectional design from 80 samples which used questionnaire to examine. The results showed that most respondents have good perception, knowledge, attitude and ability to avoid H$_2$S gas exposure, and have good safe behavior on H$_2$S gas exposure. The statistical test shows that there is a significant correlation between perception with P value 0.001 and OR 6.660 (CI 2.151 - 20.623), attitude about the hazard of exposure of H$_2$S gas with P Value 0.000 and OR 13.440 (CI 2.876 to 62.809) While knowledge and ability to avoid danger a significant relationship with risk exposure to H$_2$S gas. The multivariate result showed that attitude gave the biggest influence with P value 0.026 and OR 8,035. It is recommended that the company consistently conduct training and refresh training for workers related to H$_2$S gas exposure, improve the quality of Leadership Accountability activities, and improve the implementation of the BBS (Behavior Based Safety) program and synergize with the RTS (Right To Stop) program where each worker is authorized to stop work if observing any unsafe actions or conditions, and continue to communicate H$_2$S risks to all employees.

Keywords: Geothermal, hydrogen sulfide gas, at risk behavior, risk perception

Introduction

The ILO estimates that around 2.3 million women and men worldwide die from accidents or occupational diseases every year. Worldwide, there are about 340 million occupational accidents and 160 million work-related victims each year$^1$. In Indonesia, the number of work accidents in Indonesia is still high. Up to the end of 2015 there were 105,182 work accidents. Meanwhile, for cases of severe accidents that resulted in death there were 2,375 cases of the total number of work accidents$^2$.

Geothermal company XYZ’s geothermal steam field began operating in 1994 and continues to make efforts to make its operations safe for humans, the environment and assets. One of the hazards that are a priority in controlling hazards in XYZ is the risk of H2S gas exposure because the risk is the most dangerous, naturally occurring or in the production process. The company has carried out engineering controls, administrative controls, and protection of personal protective equipment (PPE) while protection by eliminating and substituting the risk of H$_2$S exposure cannot be done considering that H$_2$S is naturally present in geothermal activity. Company records, during January 2014 - December 2017, there were 4 cases of nearmiss related to H$_2$S and one of the factors that is always concluded as root cause is failure to identify the danger of H$_2$S when the work is done. Identification failures can be in the form of individual failures or failure of existing procedures to anticipate H$_2$S hazards. Based on the Observation Report and Right to Stop (RTS) data, it was shown that unsafe acts were still observed (more than 10%) in various activities that could potentially cause H$_2$S gas exposure during January 2015 to December 2016 (65 from 644 observations in 2015 and 40 from 322 observations in 2016).
The purpose of this study was to find out the description of the relationship of unsafe acts of employees of the XYZ geothermal company related to the risk of H$_2$S gas exposure and the factors associated with the risk of H$_2$S gas exposure to workers.

**Method**

This type of research is descriptive analytic with cross sectional research, where the independent variables include perceptions, knowledge, attitudes and ability to avoid the danger of H$_2$S gas exposure and the dependent variable at risk behaviors.

**Results**

The occupational health and safety management system used in the XYZ company is named the Integrated Geothermal Operations Management System (IGOMS). IGOMS consists of 4 elements, namely: Leadership Commitment, Management System Cycle, Standard and Expectation and Audit Review and continual improvement.

The company encourages leaders to monitor the implementation of the Managing Safe Work Program (MSW) as often as possible. Some of the activities carried out related to this leadership accountability include:

1. Leadership Engagement (LE), carried out by the leader group and the level above and the level engineer.
2. Leadership Safe Guard Verification (LSV). This activity is carried out by Middle Management (Team Manager up) against safeguards installed on production equipment to ensure all safeguards are installed and functioning.

Risk control for H$_2$S gas exposure is one of the processes in Incident/Injury-Free Operations (IFO). In this element there are several critical processes related to occupational safety and health in the company, including Managing Safe Work (MSW), Motor Vehicle Safety (MVS), Repetitive Stress Injury Program (RSIP), and Industrial Hygiene.

To ensure that geothermal operations do not cause the release of H$_2$S gas in high concentrations into the air, the company strictly monitors H$_2$S concentrations at some critical points contained in the production process. One of them is the cooling tower which is one of the latest production equipment from the operation of geothermal power plants.

H$_2$S hazard management by elimination and substitution cannot be done because H$_2$S is one of NCGs that are naturally present in nature. Some engineering designs used to control H$_2$S exposure for workers and the environment include the following: Material, Flash tank, Gas Removal System, Alarm System, Blower and active ventilation.

Administrative control refer to the main H$_2$S management standards to provide guidelines and requirements for reducing H$_2$S exposure among risky workers, with following: MSW, personnel training, specific procedures for high risk activities, portable gas detection, maintenance, tested and calibration and emergency management & preparedness.

The company has provided personal protective equipment, as the last protection against the dangers of H$_2$S gas exposure, to all employees, as well as visitors to the workplace. Some of the PPE provided by the company related to H$_2$S exposure are as follows: Air breathing equipment provided (SABA) and Self-contained breathing apparatus (SCBA).

The results of respondents’ risk perception using 9 psychometric paradigms are 1) The majority of respondents (66.7%) have a good paradigm by accepting voluntarily the risk of exposure to H$_2$S in these jobs; 2) Based on the immediacy of effect paradigm, most responses (70.4%) have a good paradigm; 3) The majority of responses (87.0%) have a Know to Expose the Risk perception paradigm that is lacking in risk exposure; 4) The paradigm of knowledge perception on the risk of H$_2$S gas exposure, for less and good categories has the same percentage of 50%; 5) The majority of respondents (70.4%) have a paradigm of perception of Control Over Risk for good risk control; 6) Most of the responses (79.6%) have a less paradigm where the risk faced is a risk that is commonly faced; 7) Most of the responses (94.4%) have a perception paradigm in which the potential risk level only occurs in one or several people; 8) In the paradigm of common-dread psychometry, most respondents (68.5%) have a poor perception paradigm; 9) Most of the responses (68.5%) have a good Severity of Consequences paradigm.

The majority of respondents (47.4%) had less perception and had more high-risk actions. It is found that the P value is 0.001 meant there is a relationship between respondents’ perceptions and at risk behaviors.
Respondents who have less knowledge and have more high-risk actions are as many as 5 people (38.5%) than respondents who have good knowledge and have low-risk actions as many as 18 people (26.9%). There is no relationship between the knowledge of respondents with at risk behaviors (P Value=0.505).

Respondents who had the attitude of accepting danger and having high risk actions were more as many as 21 people (45.7%) than respondents who had a hazard-resisting attitude and had low risk actions namely as many as 2 people (5.9%). There is a relationship between the attitude of respondents with at risk behaviors (P value=0.001).

The respondents who had less ability in avoiding H₂S gas exposure and had more high-risk actions were as many as 3 people (50.0%) than respondents who had good ability in avoiding H₂S gas exposure and having a low risk action that is as many as 20 people (27.0%).

The ability variable to avoid H₂S gas exposure with at risk behaviors is known that the P Value is 0.347, meant there is no relationship between the ability to avoid H₂S gas exposure with at risk behaviors.

The results of Multivariate analysis can be obtained that the greatest influence is the attitude variable with P Value 0.026 and OR 8.035. Respondents who have the attitude of resisting danger are more likely to do good behavior in preventing at risk behaviors after being controlled by perception variables. In predicting at risk behaviors, the ability of the model formed is 71.3%, this means that the attitude and perception variables predict at risk behaviors by 71.3%, R Square values obtained results of 0.294 means that the attitude and perception variables can explain variations in risk measures by 29.4%.

Discussion

The results of this study showed that most respondents had good behavior related to H₂S exposure. This principle requires that all work must be carried out in accordance with the standards at all times, so that there is no tolerance in carrying out the work according to the procedures / work standards that have been determined. This growing attitude of good safety behavior, one of which is influenced by the company’s commitment in implementing a work safety culture through the IGOMS. Provision of safety guard against potential production equipment for H₂S gas exposure, efforts to increase knowledge and awareness of H₂S risk through the fulfillment of workers’ competencies, provision of adequate resources for worker protection, provision of work-step standards, especially for high-risk work and activities are some examples of the company’s efforts in cultivating safe working behavior.

Risk perception is a subjective assessment that people make about the characteristics and severity of risk. This phrase is most often used in reference to natural hazards and threats to the environment or health. The results of perception analysis using 9 psychometric paradigms, obtained the results of the majority of respondents have had a good perception of jobs that have the potential to H₂S exposure in activities in geothermal operations. Perceptions of each respondent were lacking in the perception paradigm of Known to Expose of Risk, Newness, Chronic-catastropic, and Common-dread.

Most respondents behave safely in the face of the danger of H₂S gas exposure in activities that have the potential to cause H₂S gas exposure in the workplace (well maintenance, confined space, routine inspections around the well pad and Power Generation Facility (PGF)), as well as maintenance of production and injection wells.

The existence of good perception and knowledge can influence a person to decide the attitude of resisting danger. With the support of a good ability to avoid danger, the person will eventually be able to perform safe behavior. There are several reasons why this at risk behavior is still found in work at geothermal operations. In addition, the involvement of all workers in the implementation of Right To Stop (RTS) to stop dangerous actions observed through the Behavior Based Safety program must also be improved. One of the things that needs to be emphasized is more effective supervision when carrying out high-risk work.

It is found that most respondents had a good perception of the dangers of H₂S gas exposure. Perception can be formed because of the influence of experience, beliefs, facilities and socio-culture. From work period of the respondents, they had worked at the company for at least 5 years. So that during this period, the respondents had gained sufficient experience and knowledge regarding the risk of H₂S gas exposure. These experiences and knowledge were obtained from several sources including the communication culture of the reported incident/nearmiss / observation report. Most
respondents have good knowledge about the dangers of \( \text{H}_2\text{S} \) gas exposure. Knowledge is obtained through the learning process. Knowledge can be obtained through various trainings that have been followed.

The majority of respondents who have poor knowledge will take at risk behaviors compared to respondents who have good knowledge and have less behavior. There is no significant relationship between knowledge and behavior. In the high knowledge category, more respondents who were categorized as low unsafe behavior, and in the low knowledge category, there were more high unsafe behavior. That is, a high level of knowledge does not guarantee that someone will behave safely.

The majority of respondents who refused the danger would take a safe action. This indicate that the majority of respondents who have an attitude to accept the danger of \( \text{H}_2\text{S} \) gas exposure. This shows that most respondents have a good attitude in the face of the danger of \( \text{H}_2\text{S} \) gas exposure in the workplace. Risk perceptions are weakened if risk is chosen voluntarily, but strengthened if forced. The acceptance of this voluntary risk from the results of field observations is because the company has positively demonstrated its commitment in \( \text{H}_2\text{S} \) control efforts, from the beginning the company operated.

Most respondents showed good ability to avoid the danger of \( \text{H}_2\text{S} \) gas exposure based on the results of this study. They also have good ability to avoid the danger of \( \text{H}_2\text{S} \) gas exposure and have expertise in carrying out the activities needed. Training that is appropriate for the work will also support the ability of workers.

There was a small percentage of respondents still lacking ability to avoid the danger of \( \text{H}_2\text{S} \) gas exposure based on this study. Some respondents have the ability to avoid \( \text{H}_2\text{S} \) gas exposure is that there is a phobia of certain conditions. In addition, it is necessary to keep a safety briefing in the form of communicating JSA (Job Safety Analysis) which involves supervisors and workers before carrying out activities that have the potential to be exposed to \( \text{H}_2\text{S} \) gas, so that workers are confident in controlling hazards when the work is done.

The Multivariate analysis found the variables that have the most influence are attitude variables on \( \text{H}_2\text{S} \) gas exposure. Geothermal workers who have the attitude of resisting danger are more likely to do good behavior in preventing at risk behaviors after being controlled by perception variables. These prove that even though the company has implemented safety procedures well, workers’ attitudes and perceptions are important variables that must always be maintained, so that at risk behaviors related to \( \text{H}_2\text{S} \) gas exposure in geothermal operations can be minimized and even eliminated. The workers consider the risk of \( \text{H}_2\text{S} \) gas exposure to be a risk of having a low severity. One of the things that needs to be improved is to build awareness of the risks due to exposure to \( \text{H}_2\text{S} \) gas.

**Conclusion**

The company has made efforts to control occupational safety and health and environmental protection, by applying the IGOMS. Risk control for exposure to \( \text{H}_2\text{S} \) gas is one part of Managing Safe Work Process, as one of the processes contained in IGOMS.

The majority of respondents have had a good perception of jobs that have the potential to \( \text{H}_2\text{S} \) exposure in activities in geothermal operations. Most respondents have a good perception, knowledge, attitude and ability to avoid risks about the dangers of \( \text{H}_2\text{S} \) gas exposure. There is a significant relationship between perceptions and attitudes about the dangers of \( \text{H}_2\text{S} \) gas exposure and at risk behaviors which also means the acceptance of this research hypothesis. The results of the Multivariate Analysis showed, of all the variables studied in this study, attitude variables were the variables that most affected the at risk behaviors of exposure to \( \text{H}_2\text{S} \) gas in geothermal operations.

Safety Critical Element Methodology in an Oil and Gas Company

Deddy Fernando WH1, Zulkifli Djunaidi1, Mila Tejamaya1
1Department of Occupational Health and safety, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract
Barrier systems are used to protect humans and assets from hazards. These barrier systems may be classified as either active or passive barrier systems, and as physical, technical or human/operational barrier systems. Safety Critical Elements (SCE) are part of these barrier systems to protect against major hazardous events such as fire, explosions, collisions, etc. SCEs prevent, control, mitigate and facilitate safe evacuation from the identified major hazards. However, there is no clear methodology to define which systems or equipment are SCE and what to do after SCEs are declared.

This study aimed to develop a specific methodology for implementing SCEs in an oil and gas company. The methodology involved risk assessment, major hazard scenario development, SCE identification, establishing a performance standard, developing maintenance, inspection and testing plans, implementing assurance activities and, finally, issuing a key performance indicator.

The results of this methodology can provide guidance for defining SCE systems and equipment and what to do after these SCE systems are established.

Keywords: Barrier system, Safety Critical element, Major accident

Introduction
The petroleum industry is facing risk from major accidents, i.e., accidents with major consequences, that can cause multiple fatalities and/or massive oil spills (1). Many concepts, programs and assessments have been developed to reduce risk to personnel, assets and the environment from these hazards. Safety Critical elements (SCEs) were specifically developed to protect against major hazards. SCEs form barriers to protect personnel, the environment and assets from a major hazardous event. SCEs prevent, control, mitigate and facilitate safe evacuation from the identified hazards. SCEs are defined as those parts of an installation or an operational organization whose failure could cause or contribute substantially to a major accident (2). These barrier systems may be classified as either active or passive barrier systems and as physical, technical or human/operational barrier systems (3). Because SCEs play an essential role in assurance activities (maintenance, inspection and testing), SCEs must be in place to continuously demonstrate that they remain fit for their purpose during an installation’s entire life.

To implement SCEs for a vast inventory of assets and activities, management efforts should focus on the installation elements that are the most critical to safety, with the objective of minimizing the risk of a major accident hazard (MAH). These critical elements should be designated as SCEs.

Systems and equipment that are designated as SCEs should be treated differently than other systems and equipment. The critical nature of SCEs means that their maintenance must be the highest priority, ranked above that of any other system or equipment. SCEs’ performance must meet required standards, and SCEs should be monitored using dedicated indicators. These processes should be implemented in any company that designates SCEs.
This study focused on SCE methodology. After defining SCEs, a step-by-step implementation process is discussed. There is little research that specifically discusses the methodology of SCEs. Most research has focused on barrier management systems; SCEs are part of these systems, such as the PETROMAKS Innovation project found in SINTEX report A 26845. Gasco company is a leading oil and gas producer in the UAE that has published a methodology for SCE implementation, but this is the only paper that discusses SCE methodology.

**Method**

The proposed methodology was developed as a guideline to implement SCEs. This research involved a literature review and an observational process. As stated above, there are few sources specifically related to SCEs, as most studies discuss barrier management, of which is SCEs are part.

Gasco company has published an example method in the Society of Petroleum Engineers (SPE) journal. In this method, the identification of SCEs is not integrated into the guidelines. The equipment or systems that are defined as SCE have been previously defined$^{[9]}$. DNV proposed that risk assessment is part of SCE implementation$^{[9]}$, since this step covers hazard identification, risk analysis and risk evaluation.

The implementation of SCEs should start with identifying hazards that have major consequences. These major hazards are identified and their risks are assessed through risk assessment and major risk register. These steps are mandatory and are a main reason why SCEs are needed.

**Risk Assessment, Major Scenario Development, SCE Identification**

Risk assessment is intended to identify, establish and describe barrier functions and to specify the properties of an individual barrier’s elements$^{[6]}$. In this paper, risk assessment specifically refers to risks that are generated by flammable, toxic and/or explosive substances. These risks concern personnel, the public, the environment and the integrity of the installation.

Gasco company implements risk assessment to identify major hazards; appropriate measures are developed separately and are not included in the SCE methodology. DNV proposed that identifying SCEs should be done via risk assessment. This step is important, since identified major hazards have serious consequences and specific SCEs against these hazards should be established.

Below is a list of scenarios (Typical) for Major Accident Hazards in offshore and onshore platforms. This list is taken from output studies such as Hazard identification (Hazid), Major Accident Hazard Register, dropped object study, ship collision study, etc.

- Platform Impairment
- Dropped Objects
- Fire & Explosions
- Generic failure: corrosion, vibrations, erosion, mechanical failure, weld defects
- Human Error
- Liquid carryover due to control valve failure
- Overpressure
- Pollution
- Segregation of drain system
- Ship collision
- Vent blockage

**Establishment of performance standards**

A performance standard is a statement that can be expressed in qualitative or quantitative terms, as appropriate, of the performance required of a safety critical element in order to ensure the safety and integrity of the installation$^{[9]}$. Once the key safety equipment or systems have been identified as SCEs, it is necessary to define the functions required to perform and confirm whether the actual equipment and systems can consistently and continuously perform these functions. That process is defined in the performance standard.

According to the Health and Safety executive report (safety case, 2005), safety critical elements should be verified through a suitable scheme. This scheme should be dependable and effective when required and perform as intended$^{[7]}$. DNV strongly proposed that performance standards should be established for safety critical elements$^{[6]}$. 
SCE Assurance Means

SCE assurance activities must be designed to continuously demonstrate that SCEs remain fit for their intended purposes during their entire service life. This process will confirm that the SCE requirements are being met and that the results are recorded and assessed. SCE procedures should be continuously improved as part of a Plan-Do-Check-Act (PDCA) process.

SCE Key Performance Indicator

Key Performance Indicators (KPIs) are used to monitor SCEs’ integrity. The measured results should be tracked against a performance indicator target. Tolerability levels for the degree of acceptability performance against those indicators should also be set. An Action Plan is needed in case there are any issues that may affect SCEs’ integrity.

It is recommended that facilities determine which barriers are most critical for managing major incident risk then select suitable leading and lagging KPIs for each critical barrier

Results

The proposed methodology for SCEs is illustrated below.

Safety Critical Element Methodology:

Risk Assessment → Major Scenario Development → SCE Identification → Performance Standard → Maintenance, Inspection & Testing Plan → Assurance Activities → Integrity KPI

Risk assessment and Major Scenario Development Process:

Hazard Identification → Major Scenario Development → Preliminary Risk Assessment → Detailed Risk Analysis → Risk Evaluation → Risk Register

Performance Standard Assurance Process, SCE Assurance, SCE Key Performance Indicator:

Define SCE Functional Requirement → Define SCE Design Assurance → Define SCE Operational Verification → SCE Measuring Point → Maintenance Plan → Operational Integrity Assurance & Verification → Develop Integrity Reporting → Execute SCE action plans

Discussion

Risk assessment, SCE Identification & Major Hazard scenario Development Process

First, risk assessment is used to identify any risk that is associated with major hazards. A major hazard is defined as any hazard that generates a consequence level of 4 to 5 to people, the environment and assets. The risk is then ranked using a risk matrix. The risk matrix may differ from one company to another. In this case, the risk matrix was a 5x5 table.

Preliminary risk assessment is for conservatively establishing a scenario to be studied in detailed risk analysis. Two methods are commonly used for preliminary risk assessment: simplified method and rigorous method. Detailed risk analysis reconfirms the risk associated with the major scenarios identified in the preliminary risk assessment. The main tasks of this step are to quantify the frequency of events and hazards outcomes, estimate probabilistic damage and present the scenario risk results of the risk matrix.

Risk evaluation is implemented to assist the decision-making process based on the results of risk analysis. This step involves comparing the level of risk with the acceptance criteria. A risk register, or Major risk register (specified for risks related to major hazards), should be created. This register contains a summary of the results of the risk assessment for all identified major risks, as well as a list of all existing risk reduction measures related to major risk.

Performance Standard Establishment and Assurance

Performance standards are key technical requirements to be met by SCEs to ensure they effectively operate on demand, perform as expected and can survive incidents. Performance standards include all the controls that are needed to verify SCEs’ integrity, as well as the minimum performance that should be maintained for each control point through operational and verification activities.

The three criteria of functionality, availability and survivability should cover these main activities:

1. Functionality: To define SCEs’ main functions based on related documents, such as internal documents or any related standards

2. Availability: To ensure the availability of SCEs by maintaining their reliability, which includes managing equipment obsolescence, defining a spare parts’ policy and expediting the procurement process

3. Survivability: To review integrity and design in order to keep SCE’s functions during an emergency

SCE Assurance activities, Maintenance/Inspection & Testing Plan

There are two ways to perform assurance activities: **assurance design and assurance operation**. Equipment should be checked against the initial design; this can be done through external standards, company standards, codes, etc.

After checking the design, the assurance operation should be done. Operational verification consists of compiling the means of assurance operations for all SCE controls (Functionality, Availability and Survivability). This should be performed during daily normal operations and maintenance/inspection. Operational verification consists of onsite and offsite verification. **On-site**
**verification** activities include visual checks, function tests, performance tests and preventive maintenance. **Off-site verification** activities include reviewing related reports (e.g., maintenance reports and inspection reports), work scheduling, stock material availability and data sheets.

**SCE Key Performance Indicators**

The indicators that can be used to monitor SCEs’ performance include:

- Failure of SCE during tests
- SCE Maintenance Backlog
- SCE Inspection Backlog

Below are the equipment or systems identified as SCEs in the oil and gas industry. They are divided into 4 groups: prevention elements, control elements, mitigation elements and evacuation elements. These main functions are used as barriers against major accident hazards as mentioned in METHODS.

1. **Prevention Elements**
   - Collision avoidance system: Navigational aids, Fog Horn
   - Structural Integrity: Jacket
   - Process Containment Integrity: Pressure Vessel & Large Storage Tank, Pipework, Exchangers
   - Pipelines and riser integrity: Pipeline & risers
   - Relief systems: Relief valves/PSV
   - HVAC Systems: HVAC systems and fire dampers
   - Ignition Prevention Systems: Flame Arrestors
   - Crane and lifting equipment: Powered Cranes
   - Corrosion Prevention and monitoring: Corrosion monitoring, corrosion inhibitor

2. **Control Elements**
   - Flammable Gas Detection: Fixed point Gas Detectors, Fixed acoustic leak detectors, Smoke Detectors
   - Fire Detection: Flame Detectors, Fusible loops
   - Fire and gas control system
   - Emergency isolation: ESD system, ESD valves
   - Riser/pipeline ESDV’s
   - Reservoir isolation & containment: Well control facilities, Down hole safety valves
   - Emergency depressurization: Blowdown valves
   - Fire pumps
   - Firewater systems: Diesel day tanks, Deluge system, Firewater monitors, Hydrants
   - Portable/trolley mounted extinguishers: Hose Reels, Portable fire extinguishers

3. **Mitigation Elements**
   - Fire pumps
   - Fire detection: Flame Detectors, Fusible loops
   - Fire and gas control system
   - Emergency isolation: ESD system, ESD valves
   - Riser/pipeline ESDV’s
   - Reservoir isolation & containment: Well control facilities, Down hole safety valves
   - Emergency depressurization: Blowdown valves
   - Fire pumps
   - Firewater systems: Diesel day tanks, Deluge system, Firewater monitors, Hydrants
   - Portable/trolley mounted extinguishers: Hose Reels, Portable fire extinguishers

4. **Evacuation Elements**
   - Fire pumps
   - Fire detection: Flame Detectors, Fusible loops
   - Fire and gas control system
   - Emergency isolation: ESD system, ESD valves
   - Riser/pipeline ESDV’s
   - Reservoir isolation & containment: Well control facilities, Down hole safety valves
   - Emergency depressurization: Blowdown valves
   - Fire pumps
   - Firewater systems: Diesel day tanks, Deluge system, Firewater monitors, Hydrants
   - Portable/trolley mounted extinguishers: Hose Reels, Portable fire extinguishers

**Conclusions**

The present study was aimed at developing a methodology to implement safety critical elements (SCEs), specifically in an oil and gas company. This study involved risk assessment, major development scenario, SCE identification, establishment of performance standards, maintenance, an inspection and testing plan, assurance activities, and a report in the form of a Key performance indicator (KPI).

Applying this method can lead to clear definitions for all equipment/systems defined as SCEs and help ensure these SCEs remain fit during the whole life of an installation.

Safety Leadership Analysis in Construction Contractor Company (Study At Pt X In 2018)

Alfina Hapsari¹, Zulkifli Djunaidi, Dadan Erwandi¹, Laksita Ri Hastiti¹
Occupational Health and Safety Department, Faculty of Public Health, Universitas Indonesia, Depok, West Java, Indonesia

Abstract
The construction industry has a high risk of occupational injury. Throughout August 2017 to February 2018, there had been thirteen construction accidents with three cases of fatality accidents in toll road and rail road projects in Indonesia. Safety Leadership is one of the important components in improving Safety, Health and Environment (SHE) performance. This study examines Safety Leadership Model at the lead position in the project and the operations department of the infrastructure project at PT X as a Construction Contractor Company. This study was a descriptive research with quantitative method based on two main variables of Safety Leadership, those are Leadership Style and Best Practice. Research data obtained from questionnaires, interviews, and observations at PT X’s project location in April - May 2018. This research obtained that Safety Leadership was still weak except The General Manager. This was due to lacks of understanding of SHE policies, communication, consistency and commitment to the implementation of SHE, proactive and initiative action when facing SHE issues. This suggests that company should improve by preparing and implementing Safety Leadership training program for all manager levels as well as maintaining the monitoring of SHE program implementation in the workplace.

Keywords: Safety Leadership; Transformational Leadership; Best Practices

Introduction
Construction industries recorded the most occupational accidents, including injuries and death in all sectors¹. Throughout August 2017 to February 2018, there were thirteen construction accidents including three fatality accident cases of toll road and railway infrastructure projects in Indonesia². Those three accidents causes were man behavior, unsafe workplace and poor management supervision including leadership³. There is relationships between leadership behavior, safety communication and safety performance in construction industry⁴. Safety leadership implementation had proven that safety leadership boosted safety effectiveness in organization. Safety leadership reducing accidents rate whereas promoting safety for all employee and managers and should be applied in all organization levels to ensure a solid commitment for safety.

Method
This study was descriptive research using qualitative method. Primary data was collected by questionnaire which includes Leadership Style (Transformational Leadership) and Best Practice, interview and observation about SHE implementation using unsafe act and condition form. Secondary data was collected was gathered by literature review, such as company records and department’s related documents.

This study was held in Kelapa Gading-Velodrome LRT Project located in Kelapa Gading, Jakarta Utara and Cengkareng-Batu Ceper-Kunciran Toll Road Project located in Tangerang, Banten. The subjects population are General Manager, 2nd Operation Division Manager in 1st General Civil Department and Managers in Project Areas, they are Project Manager, Construction Manager, and Employees of Implementation Unit in Kelapa Gading-Velodrome LRT Project and Cengkareng-Batu

DOI Number: 10.37506/v10/i12/2019/ijphrd/192405
Ceper-Kunciran Toll Road Project. Population had to meet two inclusion criteria, those are: had been have employment status under Kelapa Gading-Velodrome LRT Project and Cengkareng-Batu Ceper-Kunciran Toll Road Project managements and had been worked for a year at least.

Research’s sample was chosen by purposive sampling method. Samples are General Manager, 1st General Civil Department Division Manager, and managers in project area, all Project Managers, Construction Manager, Implementation Unit in Kelapa Gading-Velodrome LRT Project and Cengkareng-Batu Ceper-Kunciran Toll Road Project and Site Officers.

Results

The respondents are 48 men distributed by ages, 52% are 34 years olds or younger and 48% over 34 years olds. Classified by their position, there are 68% worked as Site Officers, 8% as Site Officer Chief, 12% as Construction Managers, 2% as Division Manager and 2% as General Manager. Moreover, grouped by length of working, 20% had been working under five years, 60% about 5-10 years and 20% over 10 years.

The components were studied in Leadership Style are influencing, inspiring, challenging, and engaging. The components were studied in Best Practice dimensions consist of vision, credibility, collaboration, communication, recognition and feedback, accountability and action oriented.

Most of Site Officer Chief and Project Manager had less dominant criteria in influencing component and most of Construction Manager, Division Manager and General Manager included in Dominant criteria. About inspiring component, Site Officer Chief and Project Manager got less dominant criteria, the result for Construction Manager is equal between Dominant and less dominant. Division Manager and General Manager included in Dominant criteria.

Majority of Construction Manager, Project Manager and Division Manager were still low. Otherwise, Site Officer Chief and General Manager classified as Dominant. Likewise engaging components, Site Officer Chief, Construction Manager, Division Manager and General Manager were Dominant and most of Project Manager was still less dominant. Construction Manager earned equal percentage between dominant and less dominant.

In Vision component, all of Site Officer Chief got less dominant rank. In Credibility component, most of Site Officer Chief were in less dominant grade. Construction Manager represented equal percentage between dominant and less dominant. Most of Project Manager, Division Manager and General Manager had been dominant. Most of Site Officer Chief and Project Manager got less dominant in Collaboration. The majority of Construction Manager, Division Manager and General Manager were classified as dominant.

In Communication component showed that most of Construction Manager were in less dominant rank. But, Project Manager had equal percentage of the dominant and less dominant one. Site Officer Chief, Division Manager and General Manager included in dominant.

Most of Site Officer Chief and Project Manager earn less dominant rating for Recognition and Feedback component. Construction Manager represented equal percentage between dominant and less dominant. Division Manager and General Manager had been dominant at this point.

In accountability, most of Site Officer Chief classified as less dominant and most of Construction Manager, Project Manager, Division Manager and General Manager had seen to be dominant.

Most of Site Officer Chief and Construction Manager were less dominant in Action Oriented and most of Project Manager, Division Manager and General Manager who gained Dominant.

</table>

Site Officer Chief, Construction Manager and Division Manager was assessed as less dominant in Transformational Leadership by most of their subordinate perspective. Project Manager and General Manager had been dominant according to their subordinate or work team.

Site Officer Chief and Construction Manager was assumed that they had less dominant capacity in Best Practices variable. While Division Manager had equal percentage of the dominant and less dominant classification. Project Manager and General Manager gained dominant based on their subordinate perspective.
Discussion

Site Officer Supervisors were less dominant in influencing and inspiring aspects, but dominant in challenging and engaging; Construction Managers were less dominant in influencing and challenging, but dominant in influencing and engaging; Project Managers were less dominant in all aspects of Safety Leadership, such as influencing, inspiring, challenging, and engaging. Division Manager was dominant in influencing, inspiring, and engaging, while General Manager was dominant in all aspects.

Leadership Style in the position of leader of infrastructure project in PT X still had no significant effect in SHE implementation. Safety Patrol report and observation conducted on the field, showed the inadequate performance. Each position in infrastructure project of PT X had different dominant aspect related to Leadership Style in workplace. Inspiring is become suggested factor to be improved by the leaders in the infrastructure projects because most of respondents were less dominant in this aspects.

There was a variable which should be improved, that was influencing. This aspects is important because the leaders should influence their subordinate and work team to implement SHE in every work process well. Site Officer Chief should have influencing aspect as the leader of the Site Officers. Project Manager as a supreme leader in a project organization, have to be a role model for all team. There will be optimum engagement and compliance of SHE towards good SHE behavior in workplace.

Challenging aspect of Construction Manager and Project Manager should be improved. Division Manager could be declared as senior manager, so as he should encourage his subordinates to implement SHE in workplace. Engaging aspect of Construction Manager and Project Manager should be developed.

Best Practices of Site Officer Chief, Construction Manager and Project Manager were less dominant. Site Officer Chief were only dominant in Communication aspects. Construction Managers were less dominant in Credibility, Communication, Recognition and Feedback, and Action Oriented aspects, but dominant in vision, collaboration, and accountability. Manager Projects were less dominant in collaboration, communication, recognition & feedback, while they were dominant in best practices components. In other hand, Division Manager and General Manager represented dominant in all variable of Best Practices.

Refer to career path regulation in PT X, employee should be positioned in middle manager and first line manager before become senior manager. For example, Site Officer Chief will be prepared to be Construction Manager, likewise Construction Manager will be projected as Project Manager. Project Manager who had passed through training and development program, would be proposed as Division Manager Candidate, and he could be General Manager in the future.

Weak of Vision of Site Officer Chief was because they had not understand a whole of SHE regulation yet. They did not only communicate to workers rarely also ignore SHE directions when pursued by production deadline and target. One of PT X’s effort to improve worker’s credibility was providing company procedure about emergency, incidence, occupational accident and activities negligence reporting to management. There is inconsistency of Site Officer Chief and Construction Manager SHE performance on the field, especially while there was a forced production demand.

Collaboration by Project Manager and Site Officer Chief were less dominant. Project Manager tried to promote and implicate SHE in every work process. Site Officer Chief as first line manager, were less dominant in collaboration aspect actually. It was known that Site Officer Chief infrequently let in team members in resolve SHE issues. Site Officer Chief assigned team according to head’s instruction directly without any discussion. Communication became the less dominant one of Best Practices dimension on Project Manager and Construction Manager. It was found that they seldom communicated directly with team. Their heavy mobility caused them to be rarely on the field.

There should be improvement about recognition and feedback for Site Officer Chief, Construction Manager and Project Manager. The weak of recognition and feedback was happened because leaders in project assumed that there was no clear punishment mechanism. Reward and performance assessment were limited as reward in weekly safety morning talk. There was no SHE performance indicator for each position. Some respondents stated that SHE performance compliance is a common act. This was not motivated workers to proactive in SHE implementation.
Accountability of General Manager, Division Manager, Project Manager and Construction Manager were dominant because of Top Management’s regulation to obligate SHE Patrol for corporate until project level. Site Officer Chiefs ought to participate in this program but they rarely attend SHE Patrol. Stop Work Action (SWA) regulation by President Director actually could be stimulation to improve Action Oriented. The chairman ensure SWA initiator could not be punished although affect to work completion postponed.

The Site Officer Chief and Construction Manager had not been satisfied most of Safety Leadership aspects yet based on their own perspective and their subordinates perspectives. Differences in self assessment and subordinates assessments in Leadership Style and Best Practices dimension of Site Officer Chief, Construction Manager, Project Manager, and Division Manager indicated over estimate and underestimate of Safety Leadership in themselves. This was because there was no Safety Leadership socialization for all leader and manager levels in project and department.

**Conclusion**

Safety Leadership Model of Site Officer Chief, Construction Manager and Project Manager had been less dominant both in terms Leadership Style and Best Practices. Division Manager had been dominant in almost Safety Leadership aspects, but there were some criteria should be noticed, especially in Leadership Style components. While General Manager had been dominant in all Safety Leadership aspects. Weak Leadership Style and Best Practices caused by lack of comprehension about SHE regulation, communication between leaders and related department, consistency and commitment in SHE implementation including reward and punishmet, and proactive and initiative act while facing SHE problems.

**Suggestions**

This study suggests PT X to develop a cooperation between SHE Department and Human Capital Department. It will be needed for arrangement of Safety Leadership Training and Modul for middle managers and first line managers which contains Leadership Style and Best Practices. The cooperation should be performed for identification and SHE competency analysis in all unit and position. The company should stimulate collaboration between SHE Department and System Development Department to review and create SHE system to support Safety Leadership implementation in workplace.

SHE Department should carry out SHE Sharing which involves production unit, projects and department related, maintain SHE monitoring consistency such as safety patrol and safety meeting by leaders and their team, especially in projects area, and strengthen reward and punishment starting from the project to corporate level.

Influence of Scapular Stabilization Exercises on Asymptomatic Forward Head Posture; A Randomized Controlled Trial

Yasmin M. Safwat¹, Amir N. Wadee², Yasser R. Lasheen², Ragia M. Kamel²
¹Physiotherapy Specialist, El-Sheik Zayed Al-Nahyan Hospital, Cairo, Egypt, ²Department of Physical Therapy for Basic Sciences, Faculty of Physical Therapy, Cairo University, Egypt

Abstract

Objective: The aim of this study was to investigate the influence of scapular stabilization exercises (SSE) on correcting asymptomatic forward head posture (FHP). Methodology: Forty participants aged from 20-30 years with mean (28.72±1.70 years) from both genders were included (21 female-19 male) randomly divided. Study group (A) received SSE and postural correctional exercises (PCE) while control group (B) received PCE only three sessions per week for ten weeks. Cranio-vertebral angle (CVA), and Root mean square (RMS) of muscle activity (EMG) of serratus anterior muscle were measured pre and post-treatment.

Results: Statistical analysis in form of MANOVA showed significant changes within-group at study group (A) in each of CVA, and muscle amplitude of serratus anterior both sides pre and post treatment with (P value =0.000). Also, a significant change within-group at control group (B) with (P value =0.000). The in between-group analysis showed no significant change in pre-value of all variables as (P=0.716, 0.291, 0.217) respectively, post-treatment showed a significant change in CVA as (P=0.000) and muscle activity for serratus anterior muscle showed a significant change of right side as (P= 0.004) while left side showed no significant change (P=0.112) but percent of improvement in study group (A) (R 83.6% , L 54.3%) higher than control group (B) (R 40.5 % , L 29 % ) respectively. Conclusion: SSE is considered as an effective method in correcting FHP in asymptomatic FHP subjects.

Key Words: Scapular stabilization exercises, Forward head posture

Introduction

Forward head posture (FHP) is known as anterior shifting of the cervical spine which occurs with lower neck bone flexion and extension of the upper neck bone and the head¹. Incidence of FHP is about (66%) in healthy subjects between the ages of 20-50 years ². But children and adolescents have shown a high epidemiological prevalence of spine postural deviations ³. Assuming forward posture for long periods, increase the load on neck posterior structures such as ligaments, joints, and muscles, moreover it changes scapular position and movement ⁴.

Serratus anterior and upper trapezius muscles are known as the primary scapular stabilizers. Suitable coupled motions of these two muscles are regarded vital for appropriate scapular movements⁵. Input of Serratus anterior in FHP subjects is lower than healthy ones and the input of upper trapezius in FHP subjects is higher than healthy ones. Therefore, it is very important to restore normal function of these two muscles in order to correct head posture ⁶.

Previous researches have shown that FHP cause shortening of the posterior cervical extensors, weakness of the anterior cervical flexors, and affects position and motion of the scapula ⁷. It is associated with weakness of mid scapular retractor (i.e., Rhomboids, Middle and Lower fibers of trapezius) and shortening of Pectoralis muscles ⁸. SSE correcting position, restoring kinematics of the scapula capable of placing cage of the thorax at the normal central position, restore normal alignment of the neck and correct its awkward posture⁹.

Furthermore, there is a gap in randomized studies investigating the influence of adding scapular stabilization exercises to postural correctional (PCE) on correcting asymptomatic FHP. Therefore, this study was conducted to fulfill it.

**Materials and Method**

This research was performed at the EMG laboratory at the Faculty of Physical Therapy, Cairo University and training protocols were conducted in El-Sheik Zayed Al-Nahyan hospital. The study was conducted during the period of one year from October 2017 to September 2018. The protocol was accepted by Research Ethics Committee of Faculty of Physical Therapy (NO: P.T. REC/012/001628) and registered at Pan African Clinical Trial Registry. ([Registry ID PACTR 201703002094205](https://www.pactr.org/registries/PACTR/10.11485/pactr.201703002094205)).

**Sample size calculation**

It was determined a priori using G*Power (version 3.1.6). Calculation was based on F test, the type I error rate was set at 5% (alpha-level 0.05), and the effect size 0.30 of the main outcome variable obtained from a previous similar study was at 85% power. Considering a 15% drop out rate, the appropriate minimum sample size for this study was 32 subjects. So optimum sample size is 40 subjects with taking percent of drop out in consideration.

**Subjects**

Subjects were recruited from El-Sheik Zayed Al-Nahyan Hospital their ages between 20-30 years old. Sample was chosen from population and allocated randomly by rolling a dice into: Group (A): received SSE and PCE. Group (B) received PCE only. The range of ages from 20 to 30 years with average (28.72±1.70) years. The weight average was (67.05 ±9.32) kg, the height average was (169.07± 10.09) cm and the body mass index average (23.34±1.43) Kg/cm². Figure 1.

**Inclusion and exclusion criteria**

Subjects were asymptomatic FHP with CVA equal or less than 50° and shoulder flexion at least 130 degrees or more. Subjects were excluded if they had a history of cervical spine surgery or cervical spondylosis.

**Outcome measurements**

Neck alignment assessed by measuring Craniovertebral angle (CVA) by photographing (Canon power shot A490, 3.3 optical zoom, 10 mega pixels, China) and activity of serratus anterior muscle was assessed by measuring the root mean square (RMS) by electromyography (Neuro-EMG-Micro, Neurosoft, Ivanovo, Russia).

1. **CVA:**

FHP can be objectively measured by taking lateral photographing, which is a valid and reliable tool. It is the angle between a line passing horizontally by C7 and a line passing from the tragus of the ear till C7. Fix adhesive markers on the tragus and the spinous processes of the C7.

2. **Muscle activity (RMS):**

A two-channel digital electromyogram device was used to assess amplitude of serratus anterior muscle by determining root mean square (RMS). Maximum voluntary isometric contraction (MVIC) was measured.
for three times. Recording electrodes (one active and one reference) were positioned with 2-3 cm between them, and the ground electrode was wrapped around the wrist joints. Shaving was done with alcohol cleaning before the attachment of the electrodes for reduction of skin impedance.

Serratus anterior: the shoulder abducted to 90° and the electrodes were placed vertically along the mid-axillary line at rib levels 6 through 8.

The impedance was checked after the positioning of the electrode to confirm that it was at an acceptable level (<2 kΩ).

Testing protocol:

i. Normalization of resting bioelectric activity

The subject was in a seated position and was asked to perform static contraction of shoulder abduction with the arm at 125° shoulder flexion and neutral shoulder rotation. Resistance was applied manually proximal to the elbow joint. Contraction was maintained for 7 seconds and repeated three times with 30 seconds of rest in between.

ii. Root mean square calculation

Normalized RMS % = EMG amplitude during resting/(average of EMG MAX for the 3 trials) ×100.

Training procedure:

1. SSE:

It is five stages: In supine position, the participant was instructed to relax. In crock-lying position, shoulder flexion to 90° and scapula protraction. In quadruped position, he alternatively lifted up his arms while abducting and flexing it to 125°. In sitting position, a pair of dumbbells (2 kg) was held and lifted them up. Each stage was held for 10 seconds before returning to the starting position and three laps of 10 repetitions. In sitting position, he was instructed to correct his posture in front of a mirror.

2) Postural corrective exercises (PCE):

Strengthening (deep cervical flexors and scapular retractors). And stretching (sub-occipital and pectoral muscles) were performed. Based on a Harman program.

Statistical Analysis

Shapiro- wilk was used to assess the normality of data. All variables were normally distribute (P > 0.05) so parametric test was used (SPSS version 23) (IBM Corp, New York, United States). Mixed MANOVA was used to detect the difference within each group and in between groups. Alpha level (0.05).

Characteristics of subjects:

Data was tested by ANOVA as in table 1.

Discussion

This study was designed to investigate the influence of ten weeks SSE on correcting FHP in asymptomatic subjects through measuring CVA and normalized resting myoelectric activity of serratus anterior muscles. The consequences of the present study showed improvement in the study group for all measured variables in comparison with the study one.

SSE is considered a viable strategy to enhance awkward posture in FHP subjects. Therefore, according to the data analysis in the current study, the results of study group revealed that there was a significant improvement in the values of CVA 34.48% and RMS Serratus anterior (R 83.6% and L 54.3%). As an explanation for this change caused by diminishing the compensatory movement on the muscles that caused by awkward posture by increasing lower trapezius and serratus anterior muscles activities and enhancing the muscles around the neck by scapular stabilization. Moreover, as increment of the lower trapezius muscle activity takes place, a scapular tilt occurs and upper rotation angle diminished through alignment of the scapula. So, the hypothesis cited that SSE together with postural correctional exercises produced insignificant change on FHP in asymptomatic participants was rejected.

Our study results come in agreement with Park who stated that, as actuation of serratus anterior muscle becomes higher, it diminishes upper trapezius muscle actuation and it plays a vital role in scapular rotation and neck straightening. Also, in agreement with our study, Yoon and Lee have stated that SSE have a positive...
impact on CVA, and muscle actuation through correcting muscle imbalances caused by upper crossed syndromes.

In the current study, the significant difference between study and control group post treatment in CVA in favor of study group was attributed to stretch of viscous and plastic elements of the soft tissue which deformed by shortening in anterior and lengthening in the posterior aspect.24

Appropriate contraction and recruitment patterns of muscles require coupling of the serratus anterior muscle with the upper, middle, and lower trapezius muscles, thus resulting in “force couples,” which are regarded as vital for normal scapular orientation and refinement of cervical ROM.7

According to our study, Wegner et al.25 have stated that SSE responsible for positive changes observed in 38 patients with neck problems since of innovation abuse, especially computer usage.

In accordance to our study, Wegner et al.25 have stated that SSE responsible for positive changes observed in 38 patients with neck problems since of innovation abuse, especially computer usage.

According to our data analysis, the results of control group revealed that there was also a significant improvement but less than study group in the values of CVA 19.14% and RMS Serratus anterior (R 40.5% and L 29 %).

This improvement could be attributed to factors such as task familiarity or increased postural awareness,26 or due to direct activation of the deep cervical flexor musculature27 which have a relatively high density of muscle spindles28. Improved cervical kinesthetic senses.29

Therefore, SSE can be regarded as a successful strategy to restore normal posture in FHP subjects through correcting neck and scapula problems.30

The limitations of this study are that we cannot control for the subject’s daily lives. And that the restricted age range of our subject was (20–30 years) affects generalizability. The strengths are: Participants were assigned randomly to both groups. Also, interventions were provided by the same experienced physiotherapist.

**Conclusion**

SSE is considered as an effective method in correcting FHP in asymptomatic subjects.

The Association between the Relative Visceral to Subcutaneous Abdominal Fat Distribution and the Presence of Coronary Artery Atherosclerosis

Mera AS Fahim¹ SamehElKaffas¹, Sameh WG Bakhom², Hossam I Kandil²

¹Lecture, Department of Cardiovascular Medicine, KasrElAiny, Cairo, Egypt, ²Professor, Department of Cardiovascular Medicine, KasrElAiny, Cairo, Egypt

Abstract

Introduction: Distribution of abdominal fat is more detrimental in the pathogenesis of coronary artery atherosclerosis (CAA) than its amount. Purpose: To detect the value of the amount of visceral adipose tissue (VAT) and subcutaneous adipose tissue (SAT), and their distribution by abdominal computed tomography in the detection of CAA as assessed by multi-slice computed tomography coronary angiography (MSCT-CA). Methods: The abdominal muscular wall was traced manually to calculate SAT and VAT areas (cm²) (outside and inside abdominal muscular wall respectively) at L4-L5 in 63 consecutive patients with no risk factors for coronary artery disease (CAD) referred for evaluation of chest pain by MSCT-CA. Results: 40% of the studied patients (n=25) had CAA (Group 1), while the remaining 60% (n=38) had no CAA (Group 2). There was no statistically significant difference between both groups as regards weight, body mass index (BMI), waist circumference (WC), waist-to hip ratio (W/H ratio), VAT area, SAT area, and total fat area. Group 1 patients were predominantly males (53% vs 24%; p=0.023), with statistically significantly increased VAT/SAT area ratio (0.40 ± 0.23 vs 0.29 ± 0.16; p=0.028), and increased age (55.7 ± 7.9 vs 44.0 ± 11.1; p<0.001) as compared to Group 2 patients. Conclusion: VAT/SAT area ratio can be used in the detection of CAA in patients with no CAD risk factors.

Key words: visceral adipose tissue, subcutaneous adipose tissue, multi-slice computed tomography coronary angiography.

Introduction

Obesity is a global epidemic, and it is considered an important cardiometabolic risk factor. The adipose tissue releases into the blood various adipokines responsible for cardiovascular homeostasis. Although, body mass index (BMI) and waist circumference (WC) have been commonly used to assess adiposity, however these anthropometric measures give an incomplete measure of visceral abdominal fat accumulation. This is because BMI does not distinguish fat-free mass from fat mass and can be misleadingly high in a lean, muscular athlete. WC, on the other hand, does not distinguish between the subcutaneous adipose tissue (SAT) and visceral adipose tissue (VAT) compartments. The latter could be differentiated from the former by the use of computed tomography (CT) or magnetic resonance imaging (MRI).

VAT was found to be associated with cardiometabolic risk, more than SAT, and it has been suggested that SAT may even have protective properties. Therefore Kaess et al hypothesized VAT/SAT ratio as a new parameter that can correlate with cardiometabolic risk, which was truly found to predict metabolic risk, even better than BMI and VAT.

Full volumetric analysis of abdominal fat can be substituted with single-slice analysis; with measurements near L4 level having the strongest correlation to volumetric measurements.

Corresponding author: Dr. Mera AS Fahim
Lecturer, Department of Cardiovascular Medicine, KasrElAiny, Cairo, Egypt
Email: mera.fahim@kasralainy.edu.eg
We hypothesized that VAT/SAT area ratio at L4 would most accurately correlate with the presence of coronary artery atherosclerosis (CAD) in patients with no other risk factors for CAA.

**Patients and Method**

Between December 2015 and May 2017, we studied 63 consecutive patients presenting with chest pain, who were referred for evaluation of their symptoms by multi-slice computed tomography coronary angiography (MSCT-CA). Patients with intermediate pretest probability for coronary artery disease (CAD); based on age, gender and type of chest pain, and having no prior coronary intervention were included in our study. Excluded from our study were patients having diabetes, hypertension, dyslipidemia, smokers, or those with positive family history for CAD.

The study was approved by our hospital’s ethical committee, and a written informed consent was obtained from all patients.

**Risk factor assessment:**

All enrolled patients were subjected to full history taking and clinical examination at the time of MSCT-CA including demographic data such as age and gender, presenting symptoms and medical history.

**Basic anthropometric measures of obesity**

BMI was calculated after knowing the weight (in kilograms) and height (in meters) of the patient, using the formula: weight in kg/ height squared in meters. Waist and hip circumferences (HC) were measured using a measuring tape according to the WHO 2008 international guidelines [9]. Then, waist to hip ratio (W/H ratio) was calculated (WC divided by HC). WC was measured at the approximate midpoint between the lower margin of the last palpable rib and the top of the iliac crest. The HC was measured at the widest portion of the buttocks. Subjects were standing with arms at the sides, feet positioned close together, and weight evenly distributed across the feet, while these measurements were taken. The measurements were also taken at the end of a normal expiration, when the lungs are at their functional residual capacity. Each measurement was repeated twice; if the measurements were within 1 cm of one another, the average was calculated. If the difference between the two measurements exceeded 1 cm, the two measurements were repeated.

**Abdominal CT scan:**

Abdominal CT scan was performed in the spinal position at the 4th to 5th lumbar levels in late expiration for measurement of visceral and subcutaneous adipose tissue areas with attenuation ranging from -190 to -30 HU 10. The abdominal cut where the aorta starts to bifurcate into two common iliac arteries was chosen for the evaluation of VAT; which is fat inside abdominal muscular wall, and SAT; defined as fat under skin, but outside muscular wall.

**MSCT-CA:**

MSCT-CA was performed using a 256-slice iCT Philips scanner with a gantry rotation time of 275 ms. To avoid motion artifacts, patients with a resting heart rate (HR) ≥ 60 beats/ min were orally administered 50 mg of atenolol at 60 min before the CT scan. Intravenous contrast followed by 50 ml of saline at a rate of 5 ml/s was power-injected into the ante-cubital vein. Ascending aorta contrast-triggered (160 HU), ECG-gated helical scanning was then performed in a single breath hold. Scanning parameters included heart-rate dependent pitch (0.18), 120 kVp-tube-voltage depending on patient’s BMI, and 650 mA reference tube current. The acquired MSCT-CA data was reconstructed in mid-diastole and at end-systole using 0.6 mm slice thickness, 0.3 mm slice increment, 250 mm field-of-view, and 512 × 512 matrix. If reconstruction from standard phases of the cardiac cycle resulted in un-interpretable segments, additional phases were reconstructed and analyzed. MSCT-CA study quality was graded on a five-point scale ranging from un-interpretable to excellent. Only studies graded as being good (some minor artifact but all coronary segments evaluable) and excellent (no artifact present, all coronary segments evaluable) were included in the study.

Plaque assessment on MSCT-CA was performed by two blinded and independent readers using axial images, oblique multi-planar reformations, and oblique maximum intensity projections. Coronary artery atherosclerosis was defined as the presence of any plaque; with a plaque being any discernible structure that could be assigned to the coronary artery wall, and identified in at least 2 independent planes 11.

**Statistical Analysis**

Data were revised, coded and entered to the statistical package for social science (SPSS) version
Qualitative data were presented as numbers and percentages, while quantitative data as means and standard deviations. Two groups of quantitative data with normal distribution were compared using the Independent t-test. Independent predictors of CAA were assessed using logistic regression analysis. The confidence interval and the margin of error were set to 95% and 5% respectively.

Results

A total of 63 patients (34 males and 29 females) with no risk factors for CAD were assessed over a 17 month period. The mean age of the studied group was 48.6 ± 11.5 years. Obesity measurements of the studied group is described in table 1.

CAA was present in 25 patients (39.7%); while the remaining 38 patients (60.3%) had no CAA. Patients with CAA were older (55.7 ± 7.9 vs 44.0 ± 11.1 years; p value < 0.001), and most predominantly of male gender (53% vs 24%; p value = 0.023). VAT/SAT area ratio was found to be the only obesity parameter statistically significantly associated with the presence of coronary artery atherosclerosis (Table 2).

Discussion

In our study, which was conducted on 63 patients with no CAD risk factors, we found that age, male gender and VAT/SAT area ratio were associated with the presence of CAA.

The association between increasing VAT area and the presence of CAA was close to; but did not reach statistical significance. However, VAT/SAT area ratio was statistically significantly associated with the presence of CAA. This is in concordance with the study done by Bouchi et al, which revealed that patients with type 2 diabetes having the highest VAT areas, and the lowest SAT areas tended to have carotid atherosclerosis when compared to other groups with lower VAT and greater SAT areas. Similarly, another study showed that VAT area was associated with an atherogenic
profile and the development of atherosclerosis, while SAT area had no association with atherosclerosis\textsuperscript{13}. This might be explained by the fact that visceral and subcutaneous adipose tissues are metabolically different, with a stronger correlation between VAT and disturbed glucose metabolism, which could in turn predispose to atherosclerosis\textsuperscript{13}.

The second finding in our study was that age was associated with the presence of CAA. This is in concordance with the literature, as age induces physiological changes in the vascular wall predisposing to atherosclerosis\textsuperscript{14}.

Our final finding was that those having CAA were predominantly males. This may be because CAA develops 7-10 years earlier in males than females, which can be explained by the protective effect of estrogen in premenopausal females against CAD\textsuperscript{15}.

Limitations:

This study had a cross-sectional design, which makes it difficult to determine causal or temporal relationships, because associations are not prospective. All patients were exposed to the extra radiation of abdominal CT. However, CT images were limited to one transverse cut, with minimization of extra radiation. Though, MRI may provide a better resolution of fat depots, with no risk of radiation, however MRI is limited by its expense and the amount of time needed to perform the scan.

Conclusion

VAT/SAT area ratio can be used as an early independent predictor of coronary artery atherosclerosis before risk factor development.

Clinical Assessment of Surgical Outcome of Supratentorial Deeply Seated Gliomas in an Egyptian Tertiary Hospital

Nasser M.F. El-Ghandour1, Hossam Eldin Mostafa1, Waleed Raafat1, Mohamed EL shazly Ghaneim1, Ahmed Mohamed Ali1

1Department of Neurosurgery, Kasr Alainy Medical School Teaching Hospitals, Faculty of Medicine and University Hospitals, Cairo University, Cairo, Egypt

Abstract

Background: Gliomas is a broad category of brain tumor which accounting 33% and comes from Glial cells. Glial cells are the tissue that surrounds and supports neurons.

Method: This is a controlled randomized study. Patients having gliomas in supratentorial areas were evaluated pre-operatively both clinically and radiologically. Operative procedures included tumor biopsy, subtotal resection, near total resection and gross total resection. Postoperatively, patients were evaluated and followed up for about 1 year for their neurological outcome.

Results: Out of the 50 patients who were included in this study; thirty eight patients (76%) had excellent outcomes, five patients (10%) had good outcomes, seven patients (14%) had fair outcomes, and no patient (0%) had poor outcome.

Conclusion: management of gliomas in supratentorial areas still represents a challenge that requires a complex multi-factorial equation in order to achieve an accepted surgical outcome while maintaining proper functional neurological integrity, preoperative neuroimaging, including CT, MRI and a neuronavigation protocol, may be able to maximize the extent of resection and preserve long-term neurological function than using the traditional way of surgery.

Keywords: Supratentorial, Gliomas, Neuronavigation, Neurological Deficits, Outcome

Introduction

It is generally accepted that complete or nearly complete surgical removal of a glioma is beneficial for a patient. The challenge is to remove as much tumor as possible, without injuring brain tissue important to the patient’s neurological function. Traditionally, we open the skull through a craniotomy to insure we can access the tumor and remove as much of it as possible. Image-guided stereotaxy can also be used to deliver different modalities of treatment. Hybrid techniques, in which image based stereotactic localization is used to guide microsurgical resection, are becoming increasingly important in reducing neurologic morbidity and patient length of stay.

Method

1) Patients

In this study, we clinically evaluated 50 patients with brain gliomas. All patients were operated in the Neurosurgery Department of Cairo University Hospitals, Cairo, Egypt along a time interval of one year. We followed very strict criteria in selecting our candidates from the patients who were suffering deeply seated gliomas. Inclusion criteria included any age group, any sex and all supratentorial lesions while exclusion
criteria included any infratentorial tumors, any recurrent supratentorial or residual supratentorial tumors.

II) Data Collection

All candidates provided the necessary data fulfilling our study protocol and were investigated clinically prior surgical interventions then were maintained on a scheduled post-operative follow up visits.

a) History Taking:

Age, gender, occupation, time of initial complaint till the time of presentation, history of any type of tumors the patient suffered from, history of comorbidities e.g. D.M and smoking.

b) Clinical Examination:

All patients were clinically evaluated and examined with special care to the following signs and symptoms: motor deficit, sensory deficit, sphincteric deficit or upper motor neuron (UMN) manifestations.

c) Radiological Investigations:

1) CT of the brain: with and without contrast

2) Brain MRI: (T1W, T2W, and T1W with contrast).

d) Management:

Pre-operative Management

All patients were given the following:

• Antiepileptics: loading and maintenance doses

• Steroids

Patients with lower limb weakness were closely monitored for proper hydration and were given prophylactic dose of short acting anticoagulants.

Operative Management

Skin incisions and craniotomies were fashioned according to the exact anatomical location of the lesions, determined by the pre-operative CT scan & MRI images. Neuronavigation was used in all patients, which were done after patients were anaesthetized and proper head fixation using three-pin Mayfield device after anesthetic scalp nerve block.

Postoperative Management

Patients were given Antibiotics, maintenance dose of phenytoin and tapering doses of steroids. All patients were subjected to a complete postoperative assessment and examination.

Follow up and Outcome

All patients were followed up at intervals of 1 month, 3 month, 6 months and 1 year whenever possible as some patients didn’t show at their scheduled follow up dates. Follow up included detailed neurological examination to evaluate the neurological deficits that the patients already had, and to detect any new neurological deficits the

Patients developed during the follow up period.

Follow up also included radiological evaluation by CT and/or MRI brain with IV contrast to detect tumor recurrence.

By the Karnofsky scoring scale (KPS):

The Karnofsky performance score (KPS) quickly became a standardized tool for expressing such outcome and was adapted for brain tumor treatment studies.(1)

Results

Age:

The median age of presentation in this study was 45.5 years with the youngest patient 4 years old and the oldest 73 years old. The mean age was 42.56 ± 19.6 years.

Presenting Symptoms

The most common presenting symptom was headache in 88%, followed by weakness in one side of the body in 44%, followed by disturbances of consciousness level in 26%, then visual disturbances in 12% followed by seizures in 10%, then speech problems in 6%, followed by frontal manifestations in 2%, followed by increased ICT in 2%.

Radiological Analysis

Regarding hemispheric distribution, thirty one patients had left-sided lesions (62%) and 18 patients had right-sided lesions (36%) and only one patient had midline lesion in the pineal gland (2%). The most commonly involved lobe was the frontal lobe, followed by the temporal lobe, followed by the parietal lobe, followed by the occipital lobe, followed by the thalamus.
**Diameter of the tumor:**

The maximum axial diameter was measured in all axial MRI images T1WI with contrast.

**Surgical Management**

Out of the 50 patients included in this study, regarding the extent of tumor excision, thirty eight had Gross total resection (76%), Seven patients had near total resection (14%), and three patients had Subtotal resection (6%) and two patients had biopsy done(4%).

**Postoperative Complications**

1. Regarding wound infection, three patients (6%) had superficial wound infection, in two patients this superficial wound infection resolved with IV antibiotics and repeated wound dressing for five days. One patient his condition progressed to deep wound infection with the need for surgical debridement.

2. Regarding motor power; four patients (8%) developed motor weakness involving the upper limb in two patients and the lower limb in the other two patients contra-lateral to the tumor in all the patients.

Out of these four patients three originally presented with motor power weakness, three patients (6%) had further deterioration of motor power; This motor power deterioration was transient in one patient (2%) that improved to the pre-operative motor status in one month under physiotherapy, while it became permanent in the other two patients (4%), only one patient (2%) presented preoperatively with full motor power and experienced motor power deterioration.

3. Regarding speech, two patients (4%) had new onset dysphasia, this new onset dysphasia was expressive dysphasia, appeared immediately postoperative& it was transient in these two patients (100%).

4. Regarding seizures, Out of the 5 patients (10%) that originally presented with seizures all patients were operated upon, all of them were controlled on Phenytoin, but another two patients (4%) had post-operative seizure despite adequate dosage and serum therapeutic level of Phenytoin and another antiepileptic drug had to be added.

The 5 patients who suffered from seizures preoperatively had shown marked improvement regarding the frequency and severity of the attacks without any change in their pre-operative anti-epileptic drugs.

Of the 50 patients of our study there were two patients (4%) who were suffering from dysphasia, one of them improved and the other one became aphasic.

There was only one patient (2%) who was suffering from aphasia which improved post operatively.

Three patients (6%) were not suffering at all from speaking difficulties, developed aphasia postoperatively, which was permanent.

One patient (2%) died postoperatively from pulmonary embolism.

**Follow Up:**

During the follow up period, no wound infection was detected, and the patients who had superficial wound infection showed proper healing at follow up, one month after discharge.

Out of the five patients who presented with seizures and operated the seizures were controlled in all of them (100%) in one month postoperative by Phenytoin, while the other two patients, who developed seizures postoperative, required the addition of another antiepileptic medication.

Out of the two patients (4%) who had dysphasia, one patient (2%) recovered to normal within one month postoperative and the other one (2%) deteriorated to total aphasia.

While the patient (2%) who originally presented with aphasia which improved to dysphasia in one month postoperative.

**Outcome:**

Out of the 50 cases which were included in this study we found that according to KPS assessment preoperative and postoperative:

About 37 patients (74 %) regardless of the nature of the tumor had improvements in their KPS postoperatively, About 8 patients (16%) had the same KPS postoperative and finally 5 patients had deteriorations in their KPS postoperative.
Plate 1: A Distribution of symptoms B. Anatomic distribution.

C. Postoperative complication D. Comorbidities present in our study group.

E. Comparison between pre and post KPS F. Comparison between pre and post KPS

IV) case study

Case 1:

58 years old female patient presented with confusion. Then she started to complain from right sided weakness. Imaging showing left parieto-occipital mass of heterogeneous density and patchy areas of enhancement after Gadolinium injection. We achieved Gross total resection and the patient was full motor power after operation.

Plate 2: Case1 A: Preoperative axial flair MRI images.
B: Showing preoperative Coronal T1WI with and without contrast, Sagittal T2WI and T1WI with contrast C: Post-operative axial CT brain without contrast

Case 2:

39 years old female patient presented to us with headache, two weeks prior to admission she suffered from a seizure attack which was controlled on Phenytoin. Imaging showed right temporal space occupying well circumscribed lesion, with ring enhancement after Gadolinium injection. We achieved Gross total resection and the patient was full motor power after operation.

Plate 3: Case 2 A: Preoperative MRI showing Axial cuts T1WI with an without contrast, (b) Preoperative MRI showing Sagittal T2WI, Sagittal T1WI with contrast, (c) Preoperative MRI showing Coronal T2WI,Coronal T1WI with contrast and (d) Preoperative MRI showing Axial T2WI and axial flair images.
Management of Gliomas in Supratentorial region still represents a major conflict and challenge in neurosurgery, as surgical resection of such brain tumors poses significant risks of postoperative neurological impairment.

How to maximally resect the supratentorial lesions without causing neurological deficit is not a simple issue, and most of literature studies in gliomas stated that survival rate is improved mainly by the total tumor resection. Surgical resection of such intra-axial brain tumors in the supratentorial region still poses significant risks of postoperative neurological impairment.

The goals of management in our study especially concerning the goals of surgery were to maintain an adequate quality of life and functional integrity for our patients.

In Willems P. et al study, they were able to achieve GTR in five patients in the standard surgery group and three patients in the neuronavigation assisted group. Unlike our study in which we were able to achieve GTR in 38 patients out of 50. Four patients out of these 38 patients survived only for less than one year and 34 patients were able to survive for more than one year. 7 patients were operated by NTR and 3 patients out of them survived for less than one year. 3 patients were operated by STR who survived for less than one year while the last 2 patients were operated by biopsy and survived for more than 1 year.

In Richard T. et al study, they have mortality rate of 21.7% in their study. They concluded that patient neurological condition was generally improved in the immediate postoperative period after extensive resection, and it was generally worse after partial resection or biopsy. Length of postoperative survival and the quality of survival were much better following extensive resection than following partial resection; these results were similar to our results.

In Sanai N. et al study, they concluded that for newly diagnosed GBM patients, aggressive resection of tumor equates to improvement in overall survival even at the highest levels of resection. These results were consistent with our results regarding the more extensive the resection was, the better the overall survival rate of the patients.

In McGrit MJ. Et al study, They were able to achieve GTR in 38%, NTR in 23% and STR in 39%, they concluded that GTR was associated with delay in tumor progression and malignant degeneration as well as improving overall survival independent of age, degree of disability, histological subtype. So GTR should be attempted when not limited by eloquent cortex.

Unlike our study in which we operated upon not only low grade gliomas, we were able to achieve GTR in 76%, NTR in 14%, STR in 6% and Biopsy in 4% of cases, but similarly we had same conclusion regarding GTR.

In Ius T. et al study, their cases were suffering from newly developed postoperative deficits in 43.7%. They concluded that the extent of resection is the strongest predictor in improving overall survival and delaying tumor progression. Also the use of intraoperative mapping and the overlap of functional data on the neuronavigation system, major resection is possible with acceptable risks and a significant increase in expected overall survival.

These results go along with our study as GTR was associated with better overall survival rates.

In Tanaka S. et al study, Their patients suffered from new persistent neurological deficits in 6.7% and postoperative hemorrhage in 5.7%. They concluded that there are certain factors affecting survival: young age, single lesion, resection, and adjuvant treatment.

In our results, we operated upon 50 cases, with median KPS of 80, only 2 patients in our study were operated upon by biopsy. These patients suffered from worsened Neurological condition in 8%, the pathology of cases included were not only GBM. The same conclusion was resection of as much as safe of the tumor the better the outcome and survival. But our study did not include age as a predictor that affects outcome.

In Bertrand C. et al study, all patients were suffering from high grade gliomas, they concluded that factors most strongly correlated with survival time: Tumor grade, age, seizures as a first symptom, KPS less than 70 and extent of resection. In our study, Male: female patient was 1.4:1, mean age 42.5 years.
Conclusion

The followings are the main conclusion that can be derived from this work:

• Despite the evolution achieved in neurosurgery in the last decade; regarding radiodiagnostic imaging techniques, management of gliomas in supratentorial areas especially eloquent cortical areas still represents a challenge that requires proper solving and adjustment of a complex multi-factorial equation in order to achieve an accepted surgical outcome while preserving proper functional neurological integrity.

• The preoperative clinical and neurological integrity greatly influence the postoperative condition and the KPS of the patient, so that the earlier the intervention done, the better the prognosis we get.

• We tried to use the very variables that had been used in the previous studies and we concluded that each variable apart from the preoperative KPS, had no direct influence on the clinical and neurological outcome, they might affect the survival and also they might collectively affect the outcome but not separately.

• The usage of the new techniques such as neuronavigation whenever possible increase the ability of better tumor localization and more radical resection with better outcome.

Molecular and Bacteriological Method for Identification of Lactose Fermenting Salmonella in Mosul Province

Shababa A. Bahjat1, Manar Fawzi Al-Taee1, Aumama Muafak Al-Hassani1, Owayes Muaffaq Al-Hassani1

1University of Mosul/ College of Science/ Department of Biology, Mosul / Iraq

Abstract

The genus Salmonella consists of more than 2570 antigenic types. Salmonella Paratyphi A, B, C and Salmonella typhi are known to be non-lactose fermenters and the cause of typhoid fever.

The present study aimed to implement molecular (polymerase chain reaction PCR) and routine bacteriological methods to identify 5 Salmonella isolates; 3 clinical and 2 foodborne isolates (obtained from poultry) in Mosul city. Primary biochemical reactions indicated a tentative identification of the bacteria as Salmonella spp. All isolates were identified using selective media (MacConkey, Salmonella-Shigella and XLD agar) in addition to gram stain, and the biochemical tests (Oxidase, Indole, Urease, Citrate utilization, and Triple Sugar Iron agar reaction).

Identification was confirmed using molecular genome with PCR. DNA was extracted directly from each sample and amplified using Salmonella- specific primers.

We hereby report an unusual case of two unusual lactose fermenting strains of Salmonella, one clinical and the others from a poultry sampling. Lactose fermenting Salmonellae cultured on MacConkey agar appeared as pink colonies following a 24 hrs. incubation period at 37 °C. Prolonged incubation (i.e. 48 hrs.) resulted in the appearance of transparent colonies. There were no former reports, as far as we know on such lac+ Salmonella strains in Mosul city.

Isolation of lactose fermenting Salmonellae is critically vital because it could be overlooked or misdiagnosed. Therefore, there is a need of awareness of such unusual Salmonellae that may be misidentified as other members of Enterobacteriaceae (Escherichia coli).

Identification of Salmonellae by Molecular PCR has proved to be a more convenient method that could be completed within 24-36 hrs. as compared to 3-8 days by routine bacteriologic methods.

Key words: Lac +ve, Salmonellae, PCR identification, bacteriological methods.

Introduction

Salmonella spp. is a pathogen responsible for severe foodborne infections and is considered as the second most isolated foodborne pathogens that cause gastroenteritis infections in human after Campylobacter (1-2). There were 94,625 salmonellosis cases in 2015 and 126 deaths in EU [3].

Salmonella genus is a group of foodborne bacteria belonging to the family Enterobacteriaceae The Centers for Disease Control and Prevention (CDC) in UK estimates 1.4 million illnesses each year with 1.3 million cases food-borne infection [4]. Most of these cases can be due to contaminated food and drinking water [5-6].
The genus is prevalent worldwide and is capable of enduring difficult conditions as it is able to survive several weeks in dry environment and several months in water. Today more than 2,570 serotypes have been reported. All serotypes may cause diseases in humans and can be fatal in the elderly immunocompromised and young patients. The World Health Organization (WHO) classifies the genus into two species, *Salmonella enterica* and *Salmonella bongori*. *S. enterica*, can be further classified into six subspecies.[7]

Salmonella often causes serious infections that demand a suitable and effective antibiotic therapy. Among the main source of food-borne outbreaks in humans are contaminated poultry products. Generally, Salmonella are more widespread in poultry and poultry products. The major dissemination paths of salmonellae are trade in animal food products, inadequate cooking of animal food products, and the slaughtering process of meat products. Fish bacteriological safety is another critical and important issue since fish, which is a vital food item in the international trade exported to several countries, may act as a route for Salmonella transmission[8].

Conventional culture methods are usually the “gold standard” for the isolation and identification of pathogenic bacteria. This classical method is known to be sensitive and economical. However; it is laborious and time-consuming. Also, environmental factors, variations in gene expression of microorganisms can occur and may alter the results of biochemical tests.

Salmonellae are normally characterized by being lactose non-fermenters which differentiates them from other species of Enterobacteriaceae.

The general idea that lac+ Salmonella are rare may be true; although these strains result in health problem when an endemic occurs. Lactose-positive (lac+) Salmonella have been known since 1905 [9]. Various reports on the existence of lactose fermenting Salmonella have been recorded worldwide; Brazil [10], United States [11], Sulaimaniya [12], Pakistan [13], and Egypt [14]. Ewing [15] reported that lac+ Salmonella comprised less than 1% of all Salmonella examined at the Center for Disease Control and prevention (CDC). However, the actual incidence may be higher because most laboratories use only enteric plating media which contain lactose and lac+ Salmonella are indistinguishable from *Escherichia coli* on these media. Lac+ colonies would not be picked for further study. Another challenge is that Lac+ strains showed higher degree of antibiotic resistance than lactose-negative Salmonella [14]. Therefore, there is an urge to establish rapid detection and identification methods for these bacteria. Currently molecular identification is applied because of its high specificity, precision, and less time consuming [16].

**Materials and Method**

**Bacterial isolates:** Five isolates suspected to belong to the genus Salmonella were employed in the present work. Three clinical and two isolates from poultry samples.

**Media:**

**Selective media:** The following selective and differential media were used:

*Salmonella-Shigella* (LabM), Hektoen Enteric Agar (oxoid), MacConkey Agar (LabM), Xylose Lysine Deoxycholate agar (LabM).

**Biochemical Tests:**

Primary culture was made directly on MacConkey agar and Salmonella Shigella (SS) agar, Hektoen Enteric Agar and XLD agar, incubated aerobically at 37°C. After 24 hours incubation, the isolated lactose and non-lactose fermenting colonies were inoculated on Triple Sugar Iron agar (TSI) and identified by colonial morphology, gram staining and biochemical testing, (catalase test, oxidase test, indole, methyl red, Voges-Proskauer, citrate and urea tests. Colonies with TSI result of K/A or A/A H2S+ve and negative urease, oxidase, and indole test were chosen for further molecular identification [17-19].

**Genomic analysis:**

The extraction of Salmonella genome was performed according to the instructions by the manufacturer of the Genomic DNA purification kit (Promega) [20]. Concentration and purity of the extracted DNA was measured using the Nano drop.

Master reaction mixture was prepared for each PCR reaction by mixing DNA with the specific primer and the premix components inside a 0.2 ml eppendorf tube (supplied by Promega Company, USA). The reaction volume was brought up to 25 microliter (µl) using
distilled water.

In order to detect the presence of 16srRNA gene loci (rrn), 100 Nano gram of template DNA was added to the primer of the specific gene (supplied by alpha company) and the pre-mix components.

Forward (5’-GCAACG CGA AGA ACC TTA CC-3’)
Reverse (5’-GGT TAC CTT GTT ACG ACT T-3’)

Results and Discussion

Biochemical tests:

Inoculating a single selective medium is rarely adequate for gathering evidence or information on cultural characteristics, some of which may grow better or produce more typical colonies on one medium than on the other. In the present study, four selective media were inoculated; SS agar, XLD agar, Hektoen enteric agar and MacConkey agar. Five isolates were suspected as Salmonella spp. by conventional methods following a series of biochemical tests as shown in table (1).

Table (1) also demonstrates biochemical characteristics of Salmonella isolates [1-3] on all selective media with or without H2S production Hydrogen sulfide production on different agars including SS, and TSI (triple sugar iron) agars is usually one of the main biochemical criteria for identification of pathogenic Salmonella strains [21]. All isolates produced black colonies and/or black precipitate on one or more media except isolate no. (2). Sakano [21] had also obtained four Salmonella non- H2S producers out of 95 poultry meat samples. Furthermore, a study by Lin [22] indicated that H2S negative Salmonella can be found in meat products in particular chicken, they are seen in all clinical serotypes and they carry virulent plasmid in a similar manner as
H₂S positive Salmonella. Their work also verified that H₂S negative Salmonella could be due to a mutation which renders the non-H₂S-producing Salmonella isolates incapable of utilizing thiosulfate to form the H₂S precipitate. Consequently, misconception is more likely to occur in laboratory and hospitals routine work.

Lac+ Salmonella isolates appeared as colorless colonies on XLD agar plates. XLD medium is used for xylose fermentation, H₂S production, and lysine decarboxylation. Salmonella utilize the sugar xylose and decarboxylate lysine which causes an increase in the pH (alkaline). However, Lac+ Salmonella produce large quantities of acids due to fermentation of lactose and sucrose. Consequently, the pH will not revert to alkaline unless incubation continues for more than 48 hours. Colony morphology on different selective media is shown in fig. (1).

(d) : XLD agar and (e): MacConkey Agar.

All isolates were Indole, and Voges proskauer (–ve). Sample (4) was citrate positive which is typical for all salmonella spp, other than S. typhi and S. paratyphi A. TSI was found to be K/A gas+ H₂S + except for isolate (1) and (3) as the results were A/A gas+ H₂S+ (resembling that of E. coli) and this is expected because of their extraordinary ability to ferment lactose and glucose and the production of excess acids.

The key biochemical test normally used to discriminate Salmonella from other Enterobacteriaceae is lactose fermentation according to Bergey’s Manual (23). Whereas; isolates reported in the current study illustrate the prevalence of lactose fermenting Salmonella in both clinical and foodborne samples. This correlates with a study by + who confirmed lactose-fermenting (Lac+) strains of several Salmonella serovars have been isolated from various foodborne outbreaks as well as different geographical regions worldwide.

Both Lac+ isolates (1) and (3) fermented lactose after 24 hours but turns transparent after 48 hours. These isolates yield a mixture of two types of colonies; dark pink lactose fermenters, and transparent non lactose fermenters both demonstrated similar biochemical tests. One isolated colony was taken and streaked out on the same medium but again it gave the same results as shown in fig. (2). These characteristics agree with the results of Latif [13] who also isolated two types of colonies on crystal MacConkey agar (Lac+ and Lac- Salmonella) from a blood culture of a patient. Latif indicated that Lac+ Salmonella carry the Lac + gene on an extra chromosomal plasmid that they might have acquired either by conjugation or transduction.
The prevalence of lactose fermenting Salmonella in humans have been documented since 1907, there have been various reports such as *S. enterica* serotype Typhimurium, *S. enterica* serotype Orangeburg, *S. enterica* serotype Typhi, and many others, Patrick [24].

Salmonella coexist with many enteric bacteria in the environment which may carry the Lac+ operon on either the plasmid or the chromosome where it may also carry determinants of antimicrobial resistance.

Leonard [25] concluded that the region responsible for lactose fermentation is readily transferable between members of Enterobacteriaceae. Acquisition of the lac+ characteristic by Salmonellae may offer environmental adaptation by these bacteria that enables them to grow in the intestine where lactose is present. Also, it has been confirmed that Lac+ Salmonella are more resistant to antibiotics than the lactose non fermenters strains which validate the significance of isolation and identification of lac+ strains of Salmonella [12].

Some isolates are now acquiring a new Lac region that has a truncated Lac A gene which enables them to use lactose without affecting their invasion ability [25].

As far as we know, lactose fermenting Salmonellae have not been reported before in Mosul city.

**Genomic analysis:**

Total genomic DNA extracted from each sample was utilized for PCR analysis. Reactions revealed that the PCR products for all isolates is identical to those of the reference Salmonella serovars. Results shown in Figure (3) revealed a single band (450 bp) similar in size to the positive control (PCR) products of reference Salmonella serovars.

Conflict of Interest: Nil

Source of Funding: Self-funded

Ethical Clearance: Research was performed according to the regulations of University of Mosul. No human or animal sources were used in the current research.

Abstract

Background: Acne vulgaris, a multi-factorial disease, is considered one of the most common dermatological diseases carrying with it significant psychological disturbance. The mechanisms of inflammation occurring in acne are now a subject of intense investigation. The T-lymphocyte function is altered in AV together with the cytokines produced by T-cell subsets, hence implicated in the immunopathogenesis of AV. The role of T Helper 17 cells (Th17) in the pathogenesis of AV has not been established.

Objective: Study the level of expression of Th17 cytokine (IL-17) in tissue of patients of AV with both inflammatory and non-inflammatory lesions.

Method: 50 patients with AV as well as 30 age and sex matched healthy controls were included. Clinical examination was done and tissue levels of IL-17 were measured by ELISA.

Results: The mean tissue levels of IL-17 were significantly higher in patients than in controls (p < 0.001). A statistically significant relation was found between tissue levels of IL-17 and the type of lesion; where the mean levels of IL-17 were statistically significant in patients with both inflammatory (papules & pustules) and non-inflammatory type (comedones) of AV but was found statistically higher in inflammatory type.

Conclusion: Th17 cells potentially play a role in the pathogenesis of AV. Larger scale studies are required to verify the role of Th17 cells in inflammatory and non-inflammatory types of AV.

Key words: Acne vulgaris – T Helper 17 - Pathogenesis – Inflammatory lesions – Non-inflammatory lesions.

Introduction

Acne Vulgaris, a pilosebaceous unit disease, considered one of the commonest inflammatory diseases affecting most of the population. AV can occur due to internal or external factors like sebum overproduction, disturbed follicular keratinization, inflammation and marked colonization by the anaerobic commensal bacteria Propionibacterium acnes¹.

P. acnes has been suggested to be the main inflammatory response in AV working through innate and adaptive immune mechanisms ². T helper 17 pathway in considered a main contributor to the pathogenesis of AV through increased secretion of interleukin 17³. Although researches are continuous, but the pathogenesis of AV is still not clear.

The aim of this work is to study the levels of expression of IL-17 in tissue of AV patients, and their relation to demographic and clinical disease parameters establishing the role of T helper 17 cells in the pathogenesis of AV and hence possibly offering new targets of therapy.

Materials and Method

Study population

The present study is a case control study and was conducted at Dermatology outpatient clinic, Kasr Al Aini, Faculty of Medicine, Cairo University, after approval of the Dermatology Research Ethical Committee (Derma REC). Written informed consents were obtained from all participants. The study was conducted on 50 AV patients.
Acne patients were excluded if they were suffering from chronic inflammatory or autoimmune diseases, using topical or systemic treatment for acne such as hormonal therapy or isotretinoin 1 month before being enrolled in the study, or if they were pregnant or lactating females. Acne severity was evaluated using the Acne scoring System offered by Lehmann et al. in 2002. This scoring system assesses the acne severity through combing the type of acne lesions (papules, pustules, comedones and nodules), where mild acne is counting ≤20 comedones, or <15 inflammatory lesions or total lesion count <30, while moderate acne is from 20-100 comedones, 15-50 inflammatory lesions or total lesions count from 30-125, and for severe acne the comedonal lesions should exceed 100, total inflammatory lesions >50, >5 pseudocysts, or total lesion count >125.

Laboratory work

2mm punch biopsy was taken from lesional skin (face) of acne vulgaris (both comedonal and inflammatory) from each patient. Five milliliters of local anesthesia were injected in the biopsy site beforehand. The skin biopsy was stored in an empty test tube at -80°C for measuring the tissue level of IL-17 by ELISA technique.

Statistical Analysis

Data were statistically described in terms of mean ± standard deviation (± SD), median and range, or frequencies (number of cases) and percentages when appropriate. Comparison of numerical variables between the study groups was done using Student t test for independent samples in comparing 2 groups when normally distributed and Mann Whitney U test for independent samples when not normally distributed. Comparison of numerical variables between more than two groups was done using Kruskal Wallis test. For comparing categorical data, Chi square (X²) test was performed. Exact test was used instead when the expected frequency is less than 5. Correlation between various variables was done using Spearman rank correlation equation. p values less than 0.05 was considered statistically significant. All statistical calculations were done using computer program SPSS (Statistical Package for the Social Science; SPSS Inc., Chicago, IL, USA) release 15 for Microsoft Windows (2006).

Results

This study was conducted on 50 patients (20 males and 30 females) with acne vulgaris and 30 normal subjects who served as controls. Twenty four patients had non-inflammatory type of AV (comedones) (48%), and twenty six patients had inflammatory type (papules & pustules) (52%). Degree of AV according to acne grading system offered by Lehmann et al. in 2002 varied from mild in fourteen patients(28%), moderate in twenty five patients (50%) and severe in eleven patients (22%). The course of the disease varied from stationary course in eleven patients (22%), progressive course in thirteen patients (28%) and recurrent disease in twenty six patients (52%). Duration of disease ranged from 1 month to 72 months with mean of 45.43 ± 55.91 months. Twenty eight patients had negative family history of AV (56%), while only twenty two patients had positive family history (44%) (table 1).

Discussion

Acne vulgaris (acne) is a common inflammatory disease typically associated with the adolescents 4. When compared to other dermatologic conditions such as psoriasis, which is characterized by more severe physical symptoms, acne has been associated with more negative psychosocial and social influence 5.

The pathophysiology of AV is multifactorial. Disturbed hormonal activity, sebum over production, increased follicular keratinization, overgrowth of Propionibacterium acnes (P. acnes), and different cascades of inflammatory events 6.

P. acnes is recognized by the innate immune system via Toll-like receptor 2 (TLR2) 7, causing hypersecretion of inflammatory cytokines, including IL-8 and IL-12. Also the adaptive immune response contributes to the inflammation in acne, leading to recruitment of activated T helper 1 (Th1) lymphocytes to early lesions of AV 8.

The purpose of our study is to elucidate the role of Th17 cytokine (IL-17) in the pathogenesis of AV, as previous studies in these respects are few and unclear. Our study showed that the tissue level of IL-17 was significantly higher in patients with AV than healthy controls as supported by Agak et al., 2014 who found IL-17 producing cells in acne lesions. They also revealed that P. acnes is a main promoter of IL-17, IL-22 and IL-17- associated genes in human peripheral blood mononuclear cells (PBMCs) 9. Kelhälä et al., 2014 also found that the main culprit cytokines IL-17A and IL-17F were significantly increased in lesions of acne at mRNA and protein level which supports our study, as well 10.
Interestingly, a positive correlation was found between the mean tissue levels of IL-17 and severity of AV but wasn’t significant statistically which needs larger scale studies for more verification.

IL-17A and IL-17F are the main cytokines for neutrophils activation and can affect various cell types including keratinocytes, endothelial cells, monocytes, fibroblasts to express pro-inflammatory cytokines IL-6, TNF-α, IL-1β, nitric oxide, matrix metalloproteinases and chemokines (GM-CSF, G-CSF, CXCL1, CXCL8, CCL2, CCL7, CCL20) \(^{11}\).

Keratinocyte proliferation is stimulated by IL-17 via IL-6/STAT3 signaling \(^{12}\). In addition, it is suggested that IL-17 attenuates keratinocyte differentiation \(^{13}\). Hence, homeostasis of follicular keratinocyte is disturbed in acne, as compared to the increased follicular keratinization occurring in psoriasis \(^{14}\).

Together with IL-17A, both Th1 and Th17 effector cytokines, transcription factors, and chemokine receptors are strongly upregulated in acne lesions as proved by Kistowska et al., 2015. They also observed that, in addition to Th17, P. acnes can induce mixed Th17/Th1 responses by promoting the simultaneous secretion of IL-17A and IFN-γ from specific CD4+ T cells in vitro \(^{15}\).

**Conclusion**

The current study sheds the light on the potential involvement of Th17 cells in the pathogenesis of AV. IL-17 represents a therapeutic target that can increase the efficacy of the current treatment regimens for better management of AV. Based on our findings, we can conclude that IL-17 is not only responsible for the start of inflammatory process in AV but also for the perpetuation of the inflammatory cascade. Despite our assumption that IL-17 levels were higher in inflammatory than non-inflammatory lesions of AV, further studies are needed to establish this role.

**Abbreviations**

AV: Acne Vulgaris

P.acnes: Propionibacterium acnes

IL-17: Interleukin 17

TNF-α: Tumour Necrosis Factor Alpha

Evaluation of the Results of Intralesional Bleomycin Injection for Treatment of Haemangioma and Vascular Malformation

1Professor of Plastic Surgery, Faculty of Medicine, Cairo University, Egypt, 2Professor of General Surgery, National Laser Institute, Cairo University, Egypt, 3Specialist of Plastic Surgery, Department of Plastic Surgery, Mataria teaching Hospital, Cairo, Egypt, 4Asissatant Professor of Plastic Surgery, Faculty of Medicine, Cairo University, Egypt, 5Specialist of Plastic Surgery, Nasser Institute Hospital, Cairo, Egypt

Abstract

Aim: is to evaluate the results of intralesional bleomycin injection for treatment of haemangioma and vascular malformation. Indications, limitations, adjustment of dose and results of treatment. Patients and Method: This study was carried out on 40 patients with vascular anomalies; either hemangioma or vascular malformations from both sexes at different age groups. Patients treated with intralesional Bleomycin Injection and treatment response will be evaluated. Results: 26 cases (65%) present significant response which includes complete resolution, excellent and good response; 7 cases (17.5%) presents fair response and 7 cases (17.5%) presents poor response. No cases presents no change or increase in size. Conclusion: Intralesional bleomycin injection (IBI) is a simple, practical and noninvasive method of treatment of vascular anomalies and can considered one of priorities in the treatment of Infantile Hemangiomas and small and medium sized venous malformations.

Key words: Vascular anomalies, Infantile Hemangioma (IH), vascular malformation, Bleomycin and Intralesional Bleomycin Injection (IBI).

Introduction

Term vascular anomaly represents a broad spectrum of vascular pathology, including proliferating vascular tumors and vascular malformations1. Vascular anomalies are confusing due to presence of different types of vascular anomalies, similarity of lesions, and most practitioners use imprecise terminology resulting in inaccurate management2. According to International Society for the Study of Vascular Anomalies (ISSVA), recent classification where divides vascular anomalies into two groups: neoplasms and malformations which provides systematic approach and correlates histopathology with clinical course and therapy3. Hemangiomas and vascular malformations are developmental benign lesions that can occur in any organ4.

Infantile hemangiomas comprise major part of vascular anomalies and the most of vascular tumors. It is composed of rapidly proliferating endothelial cells5. Infantile hemangiomas (IHs) are the most common, benign vascular tumors of infancy, found in 4% to 5% of the population6 with a greater incidence in Caucasians, female, and premature infants7.

Vascular malformations are localized, structural abnormalities of vessels that happen due to developmental defects during vasculogenesis with no sex-predominance, and normal endothelial cell turnover8. Treatment of vascular anomalies is indicated when the lesions become symptomatic by causing functional disturbances, or disfigurement. Several treatment options include: Pharmacologic therapy, surgery, embolization and sclerotherapy9.

Surgery is mainly de-bulking procedure, except for localized VMs that can be totally removed. Surgery and medical treatment have limited success9.
Treatment with sclerotherapy especially lymphatic and venous malformations has advantages including no external scarring and few complications, as compared with surgery. Sclerotherapy causes cell destruction, thrombosis, and severe inflammation. Scarring leads to shrinkage of the lesion. Many sclerosants have been used including doxycycline, sodium tetradecyl sulfate, bleomycin, and OK-432.

Bleomycin induce its effect through two ways: DNA synthesis inhibition and also has sclerosing effect on vascular endothelium. Bleomycin is a valid therapy in vascular anomalies but it has complications too. Muir et al. reported flu-like symptoms, ulceration, cellulitis and temporary hair loss in some cases. Dose-related pulmonary fibrosis is reported in few oncology patients receiving high cumulative doses of intravenous bleomycin. It is reported that the total dose must not exceed 5 mg/kg in adults, or 20 mg in total in infants.

Our Study will evaluate the results of Intral deletion Bleomycin Injection in treatment of Haemangioma and vascular malformation. Indications, limitations, adjustment of dose and results of treatment.

**Patients and Method**

A prospective study was carried between October 2017 and June 2019 (20 months) in Kasr Al-Aini teaching hospitals, Cairo University, Egypt. Forty patients were included presented with haemangiomas and slow-flow vascular malformations from both sexes at different age groups. High-flow malformation, combined malformations and patient with history of previous intralesional sclerosant agent or steroid injection were excluded.

A standardized sheet recording patient’s details included age, sex, weight, and location of lesion, size in square centimeters, bleomycin dose, clinical response and adverse effects were recorded. The response was recorded by serial photography and measurement before, during, and after completion of the treatment.

Dosage regimen used were as follows:

- In children younger than 1 year, the maximum dose per injection is limited to 0.5 to 1 mg/kg and varied according to the size of the lesion.
- In children older than 1 year and adult, a dose of 1 to 15 mg was injected intralesionally per session.

- A single dose of 15 mg per session was never exceeded. The interval between each session was 3 weeks with total times less than 6 times during 6 months therapeutic period with exceptions in large or resistant lesions.

**Method of Intral injection Bleomycin Injection**

In children the injection was performed in general anesthesia and hospitalization was required for a day.

**Direct intral injection**: bleomycin was administered by using a syringe

**Transcutaneous injection** introduced through normal skin, and advanced into the hemangioma or vascular malformation.

**Assessing Response:**

- **Measurement of the lesion’s size**

Lesion size was recorded using “hemispheric” measurements. The regression of the lesion was evaluated according to 0 - 100% scale. An excellent response denotes complete resolution and 76-100% reduction in the size. A good response denotes 51-75% reduction in the size. A fair response denotes 26-50% reduction in the size. Finally, a poor response denotes 1-25% regression and moreover, no change and continued growth of the lesion's size.

**Results**

There were 40 patients treated with IBI. They were 17(42.5%) males and 23(57.5%) females. Their ages at the time of starting treatment was ranging between 4 months and 40 years with a median age of 12.2 ± 10 years. Patients Weights at the time of starting treatment was ranging between 5kgs and 91kgs with a median Weight of 26 ± 20kgs.

The majority of cases are infantile hemangioma 20 cases (50%) then venous malformations 15 cases (37.5%) then lymphatic malformation 3 cases (7.5%) and the least is capillary malformation 2 cases (5%).

Bleomycin average dose was 3 ± 1.4mg per session and ranged from 1.5 to 7.5mg. The Total dose ranges from 7.5 and 75 mg with average 23.6 ± 14mg. Number of sessions ranges between 5 and 12 sessions with average 7 ± 1.6 sessions. The Duration of treatment ranges between 4 and 14 m with average 7 ± 1.6 m.
In the study as regard the response to treatment presented by reduction in size 5 cases (12.5%) presents complete resolution. 14 cases (35%) presents Excellent response. 7 cases (17.5%) presents good response. 7 cases (17.5%) presents fair response. 7 cases (17.5%) presents poor response. No cases presents no change or increase in size. As overall 26 (65%) cases present significant response which includes complete resolution, excellent and good response.

Discussion

Vascular anomalies are now classified into vascular tumors and malformations. With differences in biologic and radiographic behavior, malformations are classified to slow and fast flow lesions. In most patients with IHs, no treatment is necessary because most lesions regress over years without leaving scarring. Infantile hemangiomas of the head and neck especially those giving high proliferation rate and other complications or facial disfigurement had to be treated.

Vascular malformations sub-divided according to vessel type into capillary, venous, arterial and lymphatic malformation. Imaging mainly Doppler US and MRI are basic patient workup. In addition to confirming the diagnosis, they define the extent of the lesion. Different treatment modalities have been described for hemangiomas and vascular malformations, including drug therapy, sclerotherapy, surgery and laser therapy. Sclerotherapy can be used as definitive therapy or can be performed in combination with other procedures such as surgery or laser therapy.

Umezawa discovered Bleomycin as anti-cancer drug in 1966, then it is noticed as effective therapy through intralesional route in lymphatic malformations. Recently it has good results in treating vascular lesions.

Conrad Pienaar et al treated hemangioma with intralesional bleomycin by calibrated dose per session at 0.3 to 0.6 mg/kg. They found that 73% of cases have response more than 75% decrease in hemangioma size. Several studies found that efficacy of intralesional bleomycin for hemangiomas with nearly 56.2% of cases experienced 70% to 100% regression in hemangioma.

Sainsbury et al, 2011 reported 93.3% response rate, a 56.0% response rate was complete with 1.3% recurrence rate; 10.7% give moderate improvement and 6.7% no response. Pienaar et al. reported a mean of five bleomycin injections sessions and mean dosage of 13.6 mg (range, 1.4 to 24.6 mg).

Memon et al used 1.0 mg/ml concentration, though Zheng et al. used a concentration of 2 mg/ml for the venous malformations. They proceeded to four sittings for every case; others used 1-5 sittings, with mean of 3.5 sittings. Bleomycin therapy is in general safe, with reversible complications. They described excellent results, with 96% of hemangiomas cured or substantially reduced. Zheng et al. described success rate of 75-84% for venous and lymphatic malformations. In another series, Hou et al. described 88% cure or substantial reduction in 66 patients.

Our study was carried out on 40 patients with vascular anomalies; either hemangioma or vascular malformation. The Bleomycin injection reports a 12.5% complete resolution, with 52.5% of all patients having a good-to-excellent response, which is comparable to the results in the literature. This study demonstrated a 65% significant response rate of all patients.

In the 20 cases of hemangioma, 17 patients (85%) had clinically good results which is statistically significant with satisfied patient outcomes. 3 patients which had minimal response to bleomycin treatment required secondary interventions; either excision or other therapies. No rebound proliferation occurred
in any hemangioma lesions treated. In our series, the effectiveness of intralesional bleomycin injection as a sole treatment for venous malformations was 53.3% and there was 2 recurrences following treatment of thenar eminence and peri-auricular lesions. The effectiveness of intralesional bleomycin in superficial venous malformations were better than deep or combined forms due to the direct effect of bleomycin before fading away through the draining vessels, dispersion of drug into surrounding tissue with significantly reduced therapeutic effect and may be due imprecise injection and clinical inaccessibility of the deep component of the lesion.

For all lymphatic malformations, 3 cases were treated; a case with microcystic lymphatic malformation had no response. The other two cases were macrocystic lymphatic malformations and show moderate response and require other modalities of treatments. No systemic side-effects of repeated intralesional bleomycin injection treatment experienced, We report that local complications shows as follows: 12 cases (30%) show complications which include Ulceration 8 cases (20%), Hyperpigmentation 2 cases (5%) and Recurrence 2 cases (5%).

Analysis of the data collected shows that cases with better response had lower dosage, number of sessions, total amount and shorter duration of the treatment course with statistically significant difference between both groups. We report that cases with bigger size had poor response as compared to small sized lesions with statistically significant results. Also younger age patients had better response as compared poor response group with statistically significant results.

**Conclusion**

Intralesional bleomycin injection (IBI) was effective and safe in treating vascular anomalies. Our analysis showed that the preferred dose of bleomycin treatment was not more than 1mg/kg or less. In our study, bleomycin was effective in Infantile Hemangiomas than venous malformations. Small and medium sized lesions have better response. Intralesional bleomycin injection (IBI) is a simple, practical and noninvasive method of treatment of vascular anomalies and can considered one of priorities in the treatment of Infantile Hemangiomas and small and medium sized venous malformations.

Improving the Performance of Potato Chips Using Turmeric

Garsa Ali Alshehry
Asst. Prof. Dr. , Food Science and Nutrition Department, College Science, Taif University, Saudi Arabia

Abstract

The current study was achieved to investigate the soaking potato chips indifferent concentrates of turmeric at 4, 8, 12 and 16% levels, and it was separately soaked at 60°C for 6.0 hours and then drying at 50°C for 30 minutes and then baking in a few amounts of sunflower oil. Antioxidant content and activity were determined in turmeric extract; meanwhile, sensory evaluation, color, physico-chemical properties, and texture analysis profile were determined in potato chips.

The results showed that turmeric had contained rich amounts from antioxidants and the highest activity in scavenging free radicals. Moreover, from the potato chips, the results observed that the better color, better crispness and overall acceptability in potato chips soaking in turmeric. The physico-chemical properties found that potato chips drying after soaking caused better moisture loss and it had contained less oil content in all soaked samples. Furthermore, the results from the texture profile analysis confirmed the result obviously the characteristics of potato chips.

From the obvious results, it could be recommended that the baking process of potato chips was soaking in different concentrations of turmeric is acceptability and also it is considered as a healthy alternative to frying could be due to its possibility to supply sensory properties of high quality with the presence of less oil.

Key words: Turmeric, soaking, antioxidant, sensory properties, texture profile analysis

Introduction

Recent research found that the generality of the turmeric activities of turmeric is could be due to curcumin. It has different beneficial characteristics with natural antioxidant activities. Curcumin, as a spice, exhibits most promise as a therapeutic factor

Curcumin had contained three main function groups had contained one diketone group and two phenolic groups. Significant chemical reactions connected with the biological activity of curcumin are most important to oxidation of curcumin, in addition to hydrolysis, dissolution, and enzymatic reactions. All these have a considerable function in different biological activities of curcumin.

In current years, increasing consumer knowledge of the connection between food and health has led to a request for high-quality nutrition to give high healthy. Consequently, making potato chips with less oil and great sensory properties as vacuum frying, low-pressure superheated steam drying, and baking is a prominent method. Between these methods, baking potato is thought carefully about as an alternative to frying could be due to its possibility to make available for use a similar product with no added fat.

The aim of this study was to investigate the effect of soaking potato chips in turmeric solution at different levels 4, 8, 12 and 16%, respectively. The major task of this study was to produce high quality, shiny, lower oil and higher natural antioxidant potato chips.

Materials and Method

Materials

Potatoes (Solanum tuberosum), sunflower oil, turmeric (Curcuma longa) was obtained from local market in Saudi Arabia.
Methods

Phytochemical analysis in turmeric

The total phenolic content (TPC) of the turmeric was estimated by Afroz et al.\textsuperscript{6} and it was determined as mg gallic acid equivalent (GAE)/100 g.

The total flavonoid content (TFC) was estimated by Chang et al.\textsuperscript{7}. The color was measured at 510 nm and it was determined as mg catechin equivalent (CE)/100g.

The total tannin content (TTC) was estimated according to Tambe and Bhambar\textsuperscript{8}. The results were expressed as mg of tannic acid equivalent (TE) per 100 g.

The ascorbic acid content (AAC) was estimated as described by Omaye et al.\textsuperscript{9} and it was determined as ascorbate equivalent mg of AE per 100 g.

Antioxidant radical scavenging in turmeric

ABTS radical cation assay was determined according to Arts et al.\textsuperscript{10}. Ferric-reducing power was measured the ability of the antioxidants to reduce ferrictripiridyltriazine (Fe3+-TPTZ) to a ferrous form (Fe2+) according to Niemeyer and Metzler\textsuperscript{11}. DPPH (1,1-Diphenyl-2-picrylhydrazyl) described by Ravichandran et al.\textsuperscript{12}.

Preparation of potatoes soaking turmeric

The soaking solutions were prepared turmeric powder at 4, 8, 12 and 16 g were dissolved separately in 100 ml distilled water. Potato slices were soaking lasted 6 hours and dried at 50°C for 30 minutes and also, the control potato was soaking in the water at 70°C for 5 minutes.

Baking potatoes chips for lower oil

The dried potato slices was baking in lowering sunflower oil at 180°C for 22 min, this temperature was to lead moisture less than 2% by weight.

Sensory evaluation of baking potato chips

Chips samples were organoleptically examined by twenty trained panelists from the Nutrition and Food Science Department, Faculty of Science, Taif University, the kingdom of Saudi according to Zhang and Zhang\textsuperscript{13}.

Color of baking potato chips

A color image obtained with a digital camera under controlled and defined illumination conditions (D65 illumination in a lightbox. according to Balaban\textsuperscript{14}.

Physico-chemical characteristics of potato chips

Moisture and fat content were estimated by AOAC\textsuperscript{15}. The amylose content and amylopectin was determined by the method prescribed by Hoover and Ratnayake\textsuperscript{16}.

Texture profile analysis of potato chips

Instrumental texture measurements were obtained at room temperature using a Texture Analyzer (CNS Farnell Com, U.K.) immediately up to 1 h after baking potato chips and cooling according to Tuta and Koray Palazoğlu\textsuperscript{17}.

Statistical Analysis

The obtained data were exposed to analysis of variance. Duncan’s multiple range tests at (P ≤ 0.05) level was used to compare between means. The analysis was carried out using the PRO ANOVA procedure of Statistical Analysis System\textsuperscript{18}.

Results and Discussion

Phytochemical analysis of turmeric powder

The results in Table (1) observed that the turmeric powder extract had contained from total phenolic acids, total flavonoids compounds, total tannin, and ascorbic acid were 120.15 mg GAE/100, 155.66 mg CE /100g, 7.70 mg TE/100g, and 0.06 mg AE/100g turmeric, respectively. These results confirmed by Shen\textsuperscript{19} found that the turmeric had contained high amounts from phenolics and flavonoids which as natural antioxidants.

Color of baking potato chips

A color image obtained with a digital camera under controlled and defined illumination conditions (D65 illumination in a lightbox. according to Balaban\textsuperscript{14}.

Physico-chemical characteristics of potato chips

Moisture and fat content were estimated by AOAC\textsuperscript{15}. The amylose content and amylopectin was determined by the method prescribed by Hoover and Ratnayake\textsuperscript{16}.

Texture profile analysis of potato chips

Instrumental texture measurements were obtained at room temperature using a Texture Analyzer (CNS Farnell Com, U.K.) immediately up to 1 h after baking potato chips and cooling according to Tuta and Koray Palazoğlu\textsuperscript{17}.

Statistical Analysis

The obtained data were exposed to analysis of variance. Duncan’s multiple range tests at (P ≤ 0.05) level was used to compare between means. The analysis was carried out using the PRO ANOVA procedure of Statistical Analysis System\textsuperscript{18}.

Results and Discussion

Phytochemical analysis of turmeric powder

The results in Table (1) observed that the turmeric powder extract had contained from total phenolic acids, total flavonoids compounds, total tannin, and ascorbic acid were 120.15 mg GAE/100, 155.66 mg CE /100g, 7.70 mg TE/100g, and 0.06 mg AE/100g turmeric, respectively. These results confirmed by Shen\textsuperscript{19} found that the turmeric had contained on natural antioxidants and the highest total phenolic compounds which play the major therapeutic function.

Tannins are secondary metabolites important which water-soluble plant that has been found to have antioxidant, and antimicrobial activities\textsuperscript{20}.

Antioxidant activity as ABTS, FRAP and DPPH were determined in turmeric powder and the results found that 163.4, 32.6 and 17.31 μg/ml, respectively. These results illustrated that the free radical-scavenging activity could be due to the turmeric had contained high amounts from phenolics and flavonoids which as natural antioxidants.
Antioxidant activities had contained many therapeutic compounds like ascorbic acids possess considerable characteristics that could improve the influences which due to free radicals have been the etiology of several various human ailments.21.

Sensory evaluation of potato chip with turmeric

The results from Table (2) and photo (1) found that no variation between color, texture crispiness, odor and taste in the potato chips soaking in turmeric than the control sample. This may be that the baking potato chips were development and acceptability using turmeric. Texture (crispiness) of chips is a vital criterion that determines the consumers’ acceptance22. The texture is also a major measurement in the evaluation and acceptance of food products and a significant characteristic in determining consumer acceptability of fried foods23. Crispness is often described as one of the attractive textural characteristics of potato chips24.

Color of baking potato chips with turmeric

From the results in Table (3) it could be noticed that higher \( L \) values, lower \( a \), and higher \( b \) values in different potato chips than control. Subjective color scores were related to \( a \) value, with higher subjective color scores tending to coincide with higher \( L \) lower \( a \), and higher \( b \) values. This means that the potato chips soaking in different concentrations from turmeric give a brighter yellow-orange color chip higher \( L \) and \( b \) and lower \( a \) value readings. Crispness is perceived during a collection of different feelings and appears the key texture advantages of dry snack products through the mastication process that, in transformation, is based on break diffusion in crisp substances\(^{25}\).

Color is the greatest significant visual characteristic in the observation of product quality between the various classes of physical properties of foods\(^{26}\). Color is this critical in the acceptance of the product even previously it is consumed\(^{27}\).

Physico-chemical characteristics on potato chips

The results in Table (4) showed that no different significant between potato chips in moisture may be due to soaking potato in turmeric before baking. The results of this study showed that the texture or crispiness of the chips was related to the moisture content of chips. Thus, lowering oil absorption outcomes in elevate crunchiness values for the reason that of decreased moisture retention\(^{28}\).

Meanwhile, in the same Table observed that on significant variation in the amylose and amylopectin in potato chips, the results confirmed that turmeric doesn’t affect on potato chips during baking frying. Jyothi et al.\(^{29}\) found that the C. malabarica starch had contained 25 kg=100 kg amylose content and about 27% starch in variety C. zedoaria. Previous reports found that the amylose content of C. zedoaria starch was 31.3%, these results confirmed our results.

Texture profile analysis of baking potato chips

Table (5) showed that the effect of turmeric at different levels on baking potato chips and the results found that the hardness was slightly increased from 8.20 to 8.10 N. Meanwhile, apparent modulus of elasticity, adhesiveness and compressive energy were slightly significant decreased from 585.7, 0.6 and 2190.1 to 450.4, 0.2 and 1768.7 g/sec, respectively. These results confirmed that the turmeric at different level improvement the quality the backing potato chips. The TPA measure springiness, cohesiveness, chewiness, and resilience are connected with foods flexibility and were considerably reconditioned with the noticed oral processing behaviors.

Adhesiveness indicates the quantity of work required for controlling the attractive power among the surface of the product and the substance with which in contact. This surface controlled on a connected influence of adhesive and cohesive powers.

Values are mean and SD (n = 3); where: Mean values in the same row with the same letter are slightly significantly different at 0.05 levels.

Conclusion

From the results, it could be concluded that the soaking of potato slices in different concentrations of turmeric at 4, 8, 12 and 16% and drying before baking had an influence on the improvement of chips quality and the best sensorial acceptability was noticed in samples. Drying before baking potato chips caused better moisture loss, less oil content in chips, better crispness and overall acceptability in all soaked samples.

Abstract

Background: All over the world, the most common clinically presented valvular heart disease is Mitral regurgitation (MR). Mitral valve repair is considered the surgery of choice for mitral regurgitation.

Aim of work: Evaluation of the early result of mitral repair with flexible and rigid band in non-rheumatic mitral regurgitation.

Patients and Method: Between September 2017 till June 2019, we prospectively reviewing 86 patients who undergoing mitral valve repair with either a flexible or rigid band due to non-rheumatic cause. The mean age of flexible and rigid band group were (48.2±10.2) years and (50.4±10.3) years, respectively. We evaluate all patients after 6 months of surgery.

Results: There is no intraoperative mortality in our study, but according to early mortality there was 2 patient in flexible group and 1 patients in rigid one with no significant differences. There was also no significant differences according to failure of repair.

Conclusions: The early outcomes of Mitral valve repair with rigid or flexible band show good results in our prospective study, in spite of type of band that were used, but there were statistical differences between both groups regarding postoperative left ventricular dimension and function.

Keywords: Mitral regurgitation, mitral valve repair, band and surgery.

Introduction

The most common clinically presented form of valvular heart diseases in adult is mitral valve diseases. In particular, mitral valve regurgitation is most common presented form of mitral valve diseases. The annual incidence of degenerative MV disease in industrialized nations is estimated at around 2% to 3% 1.

MR can be organic or functional mitral regurgitation. Organic MR results from any pathology affecting leaflets and subvalvular apparatus, but functional MR results from left ventricular (LV) remodeling that has led to the dislocation of the papillary muscles and tethering of the leaflets in the presence of a morphologically normal valve 2.

The proper surgery for mitral regurgitation is Mitral valve repair but this surgery becomes more complex in case of rheumatic mitral regurgitation and may have bad results. The long term result can be evident for mitral valve repair in rheumatic heart patient by using long
acting penicillin.3

The most important and critical points in mitral repair are understanding pathology of mitral valve apparatus and mechanism of mitral regurgitation and verifying minor differences between different causes of mitral regurgitation, all these can be achieved by trans esophageal echocardiography 4.

The basic component of mitral valve repair is Annuloplasty. According to Carpentier’s concepts, an annuloplastic device is important for (I) restoring the size and shape of annulus; (II) preventing more annular dilatation; and (III) providing annular support 5.

Many types of annuloplasty devices are present today, rigid, semi rigid and flexible rings, any ring can be used according to the choice of surgeon 6.

Many studies carried out on the two techniques for management of mitral regurgitation each technique has some advantages over the other 7.

In our study we are trying to show which of them is more useful for mitral valve repair in patients with non-ischemic mitral regurgitation.

Patients and Method

This study includes 86 patients with non-rheumatic mitral regurgitation undergoing surgery for mitral valve repair with flexible or rigid annuloplasty device - (43 patients on each group) - attending the Zagazig university hospitals, Egypt and Essen University hospitals, Germany and followed up during the period from September 2017 till June 2019. Patients were randomly sorted into two groups according to a table of random numbers at the time of the operation.

Group A: patients will be subjected to mitral valve repair with flexible band,

Group B: patients will be subjected to mitral valve repair with rigid band.

Patients included in this study are adult patients who have moderate to severe or severe Ischemic, Degenerative, or Congenital mitral regurgitation.

Patients excluded from the study are those with significant mitral valve stenosis. And those who require aortic or pulmonary valves surgery.

After approval of the IRP committee, and a written consent from all patients, patients were subjected to preoperative history taking, clinical examination, and investigations as chest X-ray, echocardiography, cardiac catheterization if needed.

Surgical technique:

Trans-esophageal echocardiography (TEE) was performed in all patients after the induction of anesthesia. All operations were done through a median sternotomy with bicoval cannulation. Cardiopulmonary bypass was done with mild systemic hypothermia (32°C). Myocardial protection was done by antegrade blood cardioplegic solution. The size of annuloplasty device was selected according to the intertrigonal distance. Mitral annuloplasty devices were implanted with 2-0 Ethibond interrupted horizontal mattress sutures. According to the underlying pathology, before insertion of annuloplasty device, another operative technique has been used. After weaning from cardiopulmonary bypass, Mitral repair was reevaluated by using Trans-esophageal echocardiography.

Data collected as Operative time, Cardiopulmonary Bypass time for mitral valve repair, Intraoperative evaluation of mitral valve repair by trans-esophageal echocardiography and follow up data as; postoperative hemodynamic evaluation, Postoperative neurological evaluation, Postoperative Echocardiographic evaluation of mitral valve repair.

All will be presented in a suitable manner and analyzed statistically by SPSS (v 20) package program.

Results

According to demographic data of patients, there was no significant differences between both groups regarding pathology and etiology of mitral regurgitation, the commonest cause in the flexible band group is degenerative, but in rigid band group is ischemic and dilated annulus is the commonest pathology in both groups. There was no significant differences regarding etiology and pathology of mitral regurgitation as shown in table 1.

Preoperative echocardiographic data, as presented in table 2 shows no significant difference between both groups regarding Ejection fraction (EF), Left Ventricular end diastolic diameter (LVEDD), Tricuspid regurgitation (TR) and Left atrial diameter (LAD).

Operative findings as presented in table 3

There was no significant difference between groups regarding technique of repair. The most common technique of repair used in flexible and rigid band groups was Annuloplasty only (22.1%, 27.9%) respectively. There were different sizes of bands among flexible band group patients. The most common band used was pericardial band 32 (46.5%). The only used rigid band was Carpentier-Edwards Ring (100%).

Discussion

Mitral valve repair is the ideal procedure for mitral regurgitation in comparison to mitral valve replacement. All previous surgical studies stated that mitral valve replacement has higher rate of death than mitral valve repair. In this study, the commonest pathology in both band group was dilated annulus but there was no significant differences. In study that was done by David et al., there was prolapsed anterior leaflet in 21% of cases, posterior leaflet prolapse in 28%, bi-leaflet prolapse in 51%. According to Salvador et al., Study there was prolapse of anterior leaflet in 7.7% of cases, posterior leaflet prolapse in 50.7%, bi-leaflet prolapse in 41.6%.

Our study shows that early failure of repair and reoperation of Mitral Regurgitation was lower in the rigid band group, but this difference was statistically insignificant. Among 43 patients who required repair with flexible band, (2.3%) of patients need reoperation, the cause of recurrence of MR was dislodgment of artificial chordae from papillary muscle due to inappropriate surgical technique.

In study performed by chang et al., reoperation and recurrence of MR were higher in the Duran ring group, but this difference was not statistically significant. There were 8 patients who required reoperation, the cause of reoperation in 2 patients was dilated mitral annulus due to abnormal shape of the Duran ring, that caused in improper annular fixation. In study performed by Kanemitsu et al., mortality rate and freedom from reoperation were not significant. The causes of reoperation in three patients were recurrent leaflet prolapse in two and leaflet sclerosis in one.

In our study, regarding early morbidity occurred in our patients, in rigid band group 5 (5.8%) cases were reexplored but there were 2 (2.3%) cases among flexible band group. also there was neurological complications in form of 1 case with left sided hemiparesis and 1 case with brain stem infarction among flexible band group but no neurological complication among rigid band group.

In study performed by Kuntze et al., early morbidity was re exploration for bleeding in 3.6%, postoperative renal failure was 2.1% required dialysis, postoperative stroke in 1.7%. In study done by Salvador et al., early morbidity was re exploration for bleeding was 34% renal failure 9.6%, heart failure was 24%, postoperative stroke 10%. No Intraoperative mortality was found in our study. As regards early mortality (with 30 days of operation) in our study, in flexible band group, 2 cases died (2.3%), 1 case mortality at second day postoperatively occurred due to bleeding, 1 cases mortality at 7th day postoperatively occurred due to heart failure. But in rigid band group, 1 case died (1.2%) at 7 day postoperatively occurred due to cardiac ischemia.

In study performed by Kuntze et al., early mortality was 1.4% due to Congestive Heart Failure (2.5%). Also in study performed by Salvador et al., early mortality was 1% all related to low cardiac output.

In our study, there were no statistical clinical differences between both groups, regarding postoperative pulmonary hypertension and left atrial dimension. But there were statistical differences between them regarding postoperative left ventricular dimensions and function which were significantly improved in flexible band group.

Chang et al., showed that mitral valve Annuloplasty with both rings showed good short term results. There were no statistical differences between the two groups according to the left ventricular function and dimensions.

Conclusions

The early outcomes of Mitral valve repair with rigid or flexible band show good results in our prospective study, in spite of type of band that were used.

Mitral valve annuloplasty with flexible band is better than annuloplasty with rigid band according to left ventricular function and dimensions.

Abstract

Purpose: This work aimed to evaluate the efficacy and safety of intracavernosal injection (ICI) of autologous platelet rich plasma (PRP) for the treatment of erectile dysfunction (ED).

Method: This study included 30 patients (mean age 55.1) suffering from ED for more than 1 year. They were non-responders to oral phosphodiesterase type 5 (PDE5) inhibitors. Before initial therapy by PRP, all patients were subjected to history taking, examination and evaluation of erectile function (EF) using an abridged Arabic version of International Index of Erectile Function (IIEF-5). Additionally, patients were evaluated by Penile Color Doppler Ultrasonography (PCDUS). ICI of PRP was done once per week for 2 months. Follow up of EF and penile hemodynamics included evaluation of patients by IIEF-5 at 1, 2, 3 months and PCDUS at 3 months after initiation of therapy.

Results: IIEF-5 score showed significant improvement at 1, 2 and 3 months after PRP injection. The injections improved the penile hemodynamics on both sides such that, the right peak systolic velocity (PSV), end diastolic velocity (EDV) and diameter of cavernosal artery differed after treatment compared to pre treatment levels (p value 0.012, 0.002 and 0.000) respectively. Also, PRP therapy improved the left side PSV, EDV and cavernosal artery diameter but the difference was statistically significant only in the left cavernosal EDV and cavernosal artery diameter (p value 0.002 and 0.000) respectively. Moreover, the results revealed a significant difference between response to ICI before and after treatment (p value 0.028). Also, the treatment was well tolerated and no major side effects were reported.

Conclusion: ICI of PRP could improve erectile function, penile hemodynamics, response to ICI, patient satisfaction and might be a salvage treatment for patients with severe erectile dysfunction who failed response to medical treatment.

Key Words: Erectile dysfunction, Platelet rich plasma, Intracavernosal injection, International Index of Erectile Function (IIEF-5), penile hemodynamics.

Introduction

ED is a common problem which affects the quality of life. Many risk factors such as age, hypertension, smoking, obesity, dyslipidemia, coronary heart disease, diabetes, and depression increase the prevalence of ED.

Vascular insufficiency is one of the most common causes of erectile dysfunction. Vascular erectile dysfunction may result from endothelial dysfunction which impairs the nitric oxide pathway and decrease the vasodilatation in the penile vessels.
Oral phosphodiesterase type 5 (PDE5) inhibitors are effective therapy for erectile dysfunction while these therapies do not reverse vasculopathy or neuropathy associated with ED. So, we need a new treatment to solve these problems.

Regenerative medicine aims to repair damaged tissues by rejuvenation of cavernous endothelial cells, cavernous nerve, or both to restore nitric oxide bioavailability as a future therapy for curing patients with severe ED and non-responders to PDE5 inhibitors.

Platelets contain many growth factors and cytokines such as platelet-derived growth performance factors.

Platelet-rich plasma (PRP) involves centrifugation of autologous whole blood to extract the plasma with higher concentration of platelets. When platelets come into contact with exposed endothelium within damaged tissues, these growth factors are released and work with tissue-repair mechanisms to promote appropriate wound healing.

Autologous PRP has been investigated in different fields of medicine but there is still limited data regarding the efficacy and safety of PRP injection for the treatment of erectile dysfunction so this work aimed to evaluate the efficacy and safety of intracavernosal injection (ICI) of autologous PRP for the treatment of ED.

Patients and Method

Study Population:

35 patients attended the outpatient clinic of Andrology, Kasr El Aini Hospital, Cairo University. 5 patients dropped out during the study such that 2 patients were afraid of repeated blood sampling and 3 patients lost follow up. This study was approved by Research Ethical Committee of Andrology department, Kasr El Aini Hospital, Cairo University. This work included 30 patients complaining of erectile dysfunction for more than one year and above 40 years. They were non-responders to PDE5 inhibitors. Patients with peyronie’s disease, congenital penile deviation, congenital penile anomalies (hypospadius or epispadius), post traumatic erectile dysfunction and blood dyscrasias were excluded.

After signing an informed consent, all patients were subjected to personal history, sexual history, genital examination, evaluation of erectile function using an abridged validated Arabic version of IIEF-5 before therapy and at 1,2,3 months after initiation of therapy. Also, Pharmaco Penile Duplex Ultrasonography was done using a 7.5 MHz high-resolution linear array transducer (Mindray Z5 ultrasound diagnostic system with color Doppler) following intracavernosal injection of 20 µg prostaglandin E1 (PGE1) before therapy and after 3 months from initiation of PRP injections.

Preparation of PRP:

ICI of autologous PRP was done as sessions (one session every week for 2 months) using the following steps:

(i) Harvested venous blood sample from the patient was accomplished into four 4.5 mL citrate (3.8% sodium citrate)-containing Vacutainer tubes; (ii) blood sample identified with patient specific labels and 2 labels were attached for the returning final preparation; (iii) tubes placed in a sterile transfer box (iv) box opened under laminar flow hood and the tubes centrifuged for 10 min at 1000 rpm at room temperature; (v) After centrifugation, the tubes were removed and sprayed with 70% alcohol and transferred under the laminar flow hood; (vi) The platelets were removed with a sterile 5 ml pipette inserted above the buffy coat. The plasma and platelets were transferred to a new 5 ml Falcon centrifuge tube; (vii) The tube was centrifuged for 15 min at 3500 rpm at room temperature; (viii) The pellet was kept with 2 ml plasma, transferred to a 3 ml syringe and the syringe was closed with a sterile cap to which a patient label was attached and (ix) For each patient, 1ml PRP concentrate was injected in each corpus cavernosum within few minutes after preparation and the patients were observed after the injection for 30 minutes for any complications or side effects.

Before injection of PRP, Sterilization of the skin with alcohol was done to reduce the risk of infection. The intracavernosal injection was performed with 28 gauge needle. The penis was gently stretched in an upright position, and the needle was introduced in a smooth and continuous pattern through the skin, subcutaneous tissue, and tunica albuginea into the cavernous body. The contents of the syringe were gently and smoothly injected into the cavernous body. After injection, the needle and syringe were removed in a rapid fashion and pressure was applied to the injection site for 1 to 2 minutes then massage of the penis was done for 2-3 minutes to distribute the platelet rich plasma in the whole penis.
Statistical Analysis

Statistically analysis of data using program SPSS and calculated as mean ± standard deviation, range, or frequencies and percentages when appropriate. Within group comparison of numerical variables was done using paired t test in normally distributed data and Wilcoxon signed rank test for paired (matched) samples when data was not normally distributed. For comparing categorical data, Chi square (χ²) test performed. Exact test was used instead when the expected frequency is less than 5. McNemar test was performed to compare response.

Results

This study included 30 patients with mean age 55.1(range 42-69). The mean duration of erectile dysfunction was 4.7 years (range 1-15). The average pre PRP IIEF-5 score was 6.5 (range 4-11). The average post PRP IIEF-5 score at 1 month was 7.7 (range 4-17), at 2 months was 9.5 (range 5-24), at 3 months was 10.2 (range 5-24). At the end of this work, selected patients were divided into 2 groups according to the level of improvement in IIEF-5 score as the following:

Group 1: No improvement (No. 20 patients), Group 2: Improvement(No. 10 patients).

This work revealed an improvement of IIEF-5 score at 1, 2 and 3 months after treatment compared to pre-treatment level (Table 1). Also, the 5th question of IIEF-5 which represented satisfaction of the patients revealed statistically significant difference at 2 and 3 months post treatment compared to pre-treatment level (Table 2). In addition, the injections improved the penile hemodynamics on both sides such that, the right peak systolic velocity (PSV), end diastolic velocity (EDV) and diameter of cavernosal artery differed after treatment compared to pre treatment levels (p value 0.012, 0.002 and 0.000) respectively. Also, PRP therapy improved the left side PSV, EDV and cavernosal artery diameter but the difference was statistically significant only in the left cavernosal EDV and cavernosal artery diameter (p value 0.002 and 0.000) respectively (Table 3). Moreover, the results revealed a significant difference between response to ICI before and after treatment (p value 0.028) (Table 4). Also, the treatment was well tolerated and no side effects were reported. Follow up by penile ultrasound after injections to exclude fibrosis.

Discussion

Our results revealed an improvement in IIEF 5 score after ICI of PRP in patients with erectile dysfunction not responding to medical treatment. This may be attributed to the release of growth factors by platelets when they come into contact with exposed endothelium within damaged cavernous tissues.

In the present study, analysis of the results showed a statistically significant improvement in penile hemodynamics on both sides such that, the right peak systolic velocity (PSV), End diastolic velocity (EDV) and diameter of cavernosal artery differed after treatment compared to pre treatment levels (p value 0.012, 0.002 and 0.000) respectively. Also, PRP therapy improved the left side PSV, EDV and cavernosal artery diameter but the difference was statistically significant only in the left cavernosal EDV and cavernosal artery diameter (p value 0.002 and 0.000) respectively. This implies that most of the hemodynamic parameters of the penis improved after PRP therapy. These results could be explained by the effect of growth factors present in platelet rich plasma especially vascular endothelial growth factor (VEGF) on angiogenesis and endothelium. Intracavernous delivery of VEGF-A gene or protein shown to restore erectile function in animal models of vasculogenic ED.

In the present study, there was a statistically significant improvement in response to ICI post treatment compared to pre treatment (p value 0.028). The improvement of ICI response after treatment may be a result of improvement in penile hemodynamics due to platelet rich plasma treatment or the effect of platelet rich plasma on cavernosal nerves regeneration. Our results come in line with a study done by WU CC et al.,
2012\(^9\) to assess the neuroprotective effect of platelet rich plasma injection in corpus cavernosum after bilateral cavernous nerve injury (rat model) and they concluded that PRP injection in the corpus cavernosum increased the number of myelinated axons and facilitated recovery of erectile function in the bilateral cavernous nerve injury rat model.

There were no reported side effects for PRP injection into the cavernous tissue during follow up of our patients. These results were supported by Kim et al., 2011\(^{10}\) who said that the technique is easy to be performed and has no important side-effects.

**Conclusion**

ICI of PRP could improve penile hemodynamics, response to ICI, patient satisfaction, erectile function and might be a salvage treatment for patients with severe erectile dysfunction who failed response to medical treatment.

Abstract

The present study was conducted to evaluate the chemopreventive efficacy and modulatory effects of concanavalin A and D609; either individually or in combination, on some apoptotic markers in Dimethylbenz (a) anthracene (DBMA) induced breast cancer in rats. Breast cancer was induced in adult female albino rats by injection of DMBA (50 mg/kg b. wt.). After 15 weeks, animals and divided into four groups. One group did not receive any treatment and served as a tumor group. The other three groups were injected with concanavalin A (of 20 mg/kg b. wt.) or D609 (50 mg / kg b. wt.) or both components together for a period of 8 weeks. At the end of experimental period, animals of control and treated groups were sacrificed and samples of breast tissues were obtained and prepared for analysis of the apoptotic markers Bcl-2 (B-cell leukemia/lymphoma 2), Bim (BcL2 interacting mediator), Bax (Bcl-2 associated X protein), Caspase 9, and Caspase 3. The results exhibited highly significant changes in apoptotic markers in cancer group as compared to normal control group, mainly represented by the increased levels of Bcl-2 and decreased levels of Bim, Bax and caspases 3 and 9. On the other hand, concanavalin A and D609 treatments induced significant modulatory effects on these markers. They induced significant decrease in Bcl-2 levels and increase in Bim, Bax and caspases 3 and 9 levels in all treated groups as compared to the DBMA-tumor group. These ameliorative changes were highly significant in the group of animals exposed to co-treatment of both materials. To conclude: the present study provides evidence that concanavalin A and D609 enhance apoptotic activity in DMBA-induced breast cancer in rats and suggests that the use of combination of the two therapies is recommended in the treatment of breast cancer.

Key Words: Apoptosis, Breast Cancer, concanavalin A, D609.

Introduction

Breast cancer is the second leading cause of death in women today (after lung Cancer) and it is the most common cancer among women worldwide (23% of all new cancer cases). In Egypt, represents 18.9% of total cancer cases (35.1% in women and 2.2% men)¹.

In general all types of carcinoma are occur in the absence of the suppressor protein P53, so in normal cells the transcription factor and tumor suppressor protein P53 plays a pivotal role in controlling the cell cycle, Apoptosis, Genomic integrity and genotoxic stress ².

Apoptosis (programmed cell death) is an operation that is genetically controlled causing cell death as a result of environmental or developmental signals³. ⁴. Apoptosis can be started throughout two pathways: intrinsic and extrinsic. In the intrinsic pathway, the cell kills itself because of sensing cell stress. In the extrinsic pathway, the cell kills itself as a result of signals from other cells⁵. Each of the pathways induces cell death by

DOI Number: 10.37506/v10/i12/2019/ijphrd/192415
making caspases active, that are proteases, or enzymes, that decay proteins \(^6\). Apoptosis can be promoted by some factors such as Fas receptors \(^7\), whereas apoptosis can be inhibited by some of the Bcl-2 family members of proteins \(^8\).

There are at least two broad pathways that lead to Apoptosis, an “Extrinsic” and an “Intrinsic” Pathway. In both pathways, signaling results in the activation of a family of Cys (Cysteine) Proteases, named Caspases that act in a proteolytic cascade to dismantle and remove the dying cell. The extrinsic pathway begins outside a cell, when conditions in the extracellular environment determine that a cell must die. The intrinsic apoptosis pathway begins when an injury occurs within the cell. The injury could result in necrosis and produce an inflammatory response, but the apoptotic machinery is in place to ensure that the damaged cell is packaged and removed cleanly, in order to prevent inflammation. Apoptosis in Mitochondria is the best known intrinsic apoptosis pathway \(^9\).

The plant lectin Con A is derived from Jack beans is known to cross-link cell surface glycoproteins, there by initiating various cellular responses, including T-cell activation, D609 which targeting sphingomyelin synthase preventing the formation of sphynomyelin in membrane lipid raft and profound defect with impaired CD4+ T cell function with decreased level of II-6 and interferon-\(\gamma\) by Con A injection. D609 could attenuate the formation of ROS and oxidized –PC (OxPC) through its antioxidant/glutathione mimetic properties \(^10\).

The aim of this study is to evaluate chemo preventive efficacy of concanavalin A and D609, either in single or combined treatments, in DBMA –induced breast cancer in rats.

**Materials and Method**

Materials:

1- 7, 12 – dimethylbenz [\(\alpha\)] anthracene (DMBA) with a dose of (50 mg/kg bw) prepared as (120.0 nmol DMBA in 0.2 ml acetone) \(^11\).

2- Concaavalin A (Con A) with a dose of 20 mg/kg (Sigma Chemical) was administered intratumor in 200 microliters of sterile saline according to (12).

3- Potassium tricycle (5.2.1.0) - decan-8-yldithiocarbonate (D609) (50 mg / kg body wt) was prepared in phosphate-buffered saline according to \(^13\).

4- phosphatasebufferd saline (PBS) were dissolved in sterile double distilled H2O at a final concentration of 100Mm Stock solutions were aliquot and kept at 20\(^\circ\)C for long term storage.

All this chemicals were purchased from Sigma Chemicals Company U.S.A.

Animal grouping:

100 female albino rats about 150 – 200 gm. was divided into two main groups:-

2-A: Tumor group. Animals inducted to 1-Normal control group:

Animals (20 rats) (and served as normal control).

2- Inducted group:

80 rats inducted to cancer (breast carcinoma).

Cancer (breast carcinoma) and still without treatment.

2-B: Treated groups: animals receive treatments with different materials and divided into three subgroups:

B-1: receive treatments with Concanavalin A by injection intra tumor for 8 weeks ones per week.

B-2: receive treatments with D609 by injection intra tumor for 8 weeks ones per week.

B-3: receive treatments with Concanavalin by injection intra tumor and D609 by injection intra tumor for 8 weeks ones per week.

**Tumor Induction**

1- The first step was the incitation to tumor by injecting all animals with DMBA intra tumor portion (120.0 nmol DMBA in 0.2ml acetone). The 1st time on the day 30 from birth. Then at the days 50\(^{th}\), 80\(^{th}\) and 110 day with a dose of (50 mg/kg bw).

**Preparation of Tumor Homogenates:**

Tumor homogenates were prepared as follows: rats bearing tumor, with and without treatment, were sacrificed; samples of tumor tissue (5 - 10mm3) were cut weights of the tissues were recorded; and tumor tissues were rinsed with ice-cold PBS (0.01M, pH=7.4), weighed, minced, and then homogenized in PBS (9mL PBS per gram tissue) with a glass homogenizer on ice. The homogenates were centrifuged at 5000r.p.m for
5 min and supernatant was removed and frozen at -70°C. Similarly, normal control rats without tumor and samples of breast tissue (5 - 10 mm³) were treated as above.

BcL2 levels:

The differences between BcL2 levels in Con A, D609 and mix of ConA with D609 groups compared to normal control and Tumor groups were recorded in table (1), and figure (1). These results showed a high significant increase compared to the normal control in the group treated with cancavalin A and D609 (p < 0.000). The mixed treatment group showed non-significant increase compared to the normal control (p < 0.556). The tumor group showed a significant increase compared to normal group. A high significant decrease in all treated groups compared to the tumor group (p < 0.000).

Figure (1): BcL2 mean levels

Bim levels:

The comparisons between Bim levels in Con A, D609 and mix of ConA with D609 treated groups compared to normal control and Tumor group were recorded in table (1), and figure (2). These results showed a highly significant increase in Concanavalin A group compared to the normal group (p < 0.000) and a high significant increase in D609 group compared to the normal control (p < 0.01). The mixed treatment group showed highly significant increase compared to the normal control (p < 0.000). A high significant increase in all treated groups
compared to the tumor group (p < 0.000). There was a highly significant decrease in tumor group in comparison to normal control (p < 0.000).

**Discussion**

It is now accepted that efficacy of chemotherapeutic drug is related to its ability to induce apoptosis; therefore, apoptosis represents a vital target in cancer therapy. In this study chemopreventive efficacy of concanavalin A and D609, was evaluated in DBMA -induced breast cancer in rats. DMBA-induced changes in apoptotic markers analyzed in the present study showed increased anti-apoptotic and decreased pro-apoptotic marker levels compared to control animals (Table1). Enhanced oxidative stress and disruption of tissue redox balance 14 and evasion of apoptosis15. The increase of Bcl-2 concentration and decreased levels of Bax, Bim and caspases 3 and 9 in DBMA-treated animals in this study indicate a principal role of apoptotic pathway dysfunction in breast carcinogenesis.
In this study, caspase-3 and caspase-9 levels were low in DBMA-induced breast cancer in rats. The decreased levels of caspase-3 and caspase-9 expression in breast tumors have been reported in previous studies.

Menget al. (2004) found that breast tumor samples lacked the caspase-3 transcript and caspase-3 protein expression, 17.

Tricyclodecan-9-yl-xanthogenate (D609) has been used as an inhibitor of phosphatidylcholine-specific phospholipase. It impairs proliferation of different cell types, including cancer cells and considered a selective tumor cytotoxic agent. Therefore, this study examined its therapeutic effect in combination with concanavalinA on breast cancer in rats. The results showed that D609 induced changes in apoptotic markers 18, 19.

However, the results of caspases analysis in this study exhibited elevated levels in groups of animals treated with D609 either alone or in combination with concanavalinA treatment. Similarly, it has been also demonstrated that caspase-9-deficiency impairs ceramide-induced apoptosis in Jurkat T cells 20.

Generally, all apoptotic markers investigated in the present study exhibited highly significant changes in group of animals exposed to co-treatment of both concanavalin A and D609 as compared to control or to group treated with each component alone. The results obtained indicate synergistic action of the two components in activation of apoptosis in DMBA-induced breast cancer. Since the therapeutic compounds affect cancer cells at different points in the cell cycle, it was recently reported that the use of combination of different drugs increases the chance that all of the cancer cells could be eliminated 21.

**Conclusion**

In conclusion, the present study provides evidence that Concanavalin A and D609 exert many effects on apoptosis in DMBA-induced breast cancer in rats and suggests that the use of combination of the two therapies is recommended in the treatment of breast cancer.

Hippotherapy versus Traditional Physiotherapy on Gait in Spastic Diaplegic Children

Reham A.A. Abouelkheir1, Mohamed E. Khalil2, Hanaa Mohsen Abd-Elfattah3

1Lecturer at the Department of Physical Therapy for Pediatrics, College of Physical Therapy, Misr University for Science & Technology, Egypt, 2Assistant Professor at Physical Therapy Department, College of Medical Rehabilitation, Qassim University, Saudi Arabia, 3Lecturer at the Department of Physical Therapy for Pediatrics and Pediatric Surgery, College of Physical Therapy, Badr University, Egypt.

Abstract

Objectives: The objective of this review is to determine the effect of hippo therapy on hip angles during stance phase in diaplegic children.

Method: Thirty diaplegic cerebral palsied children of both sexes, ranged in age from 9 to 11 years enrolled in this study. They randomly assigned into two groups of equal number; control group (A), study group (B). Group (A) groups received the conventional neurodevelopmental physical therapy plan for such cases. Whereas group (B) received the same conventional physical therapy program in addition to hippo therapy program for 45 minute. All children were assessed before and after the treatment program by using 2D video based gait assessment system to measure the hip angles during stance phase.

Results: This study showed a statistically significant improvement in both groups by comparing the mean values of all measured variables before and after treatment. There were significant differences between groups A and B in favor of group B with respect to all assessed variables when comparing the post-treatment outcomes.

Conclusion: Our results suggest that hippo therapy program can be included as an alternative therapeutic modality to enhance hip angles in children with spastic diplegia.

Key words: Cerebral palsy, Hippo therapy, Spastic Diaplegia.

Introduction

Cerebral palsy (CP) is a disorder of movement and postural control that results from an insult to the developing fetal or infant brain. The diagnosis of gait varies greatly between patients. As a result of irregular muscle activity or bone loading, secondary impairments can develop over time, such as shortened muscles, which limit the joint range of motion. Both primary and secondary impairments manifest in a pathological pattern of CP gait. Children with CP suffer a high-energy cost when walking as high as three to four times that of non-disabled children. In addition, this cost usually increases with age. Over time, the high energy cost ill cause a deterioration in the act of walking. Regarding the Topographic classification of CP: spastic diaplegic CP children are characterized by hypertonia; the lower limbs are more affected than the upper limbs. Physical problems that face the spastic diplegia include: abnormal gait pattern, poor postural reactions, hypertonia, and deformities. Hippotherapy is a rehabilitation technique that uses equine motion to achieve improvement in different neurological disorders. There are many benefits of horseback riding therapy in CP children included control of hypertonia and improvement of motor control, balance and locomotion.

Method

30 spastic diaplegic children (Twenty boys and ten girls) participated in this study. They had been selected regarding the following criteria: their age ranged from 9 to 11 years, diagnosed as spastic diaplegic CP. spasticity; ranged from grade 1 in the upper limb to 1+ in the lower limb according to Modified Ashworth Scale.
The gross motor development ranged from II to III, according to Gross Motor Function Classification System (GMFCS). All participants could understand & follow orders. They had enough hip abduction to sit with no fixed contractures or deformities of the spine, upper or lower extremities, visual or respiratory disorders. All children’s parents gave their informed consents to have their children participated in the study. They were assigned randomly into two groups: (Group A) 15 children in this group were received a traditional training program as follows: Facilitation of postural mechanism, Proprioceptive training, standing facilitation exercise, gait training activities, up and down stairs and jumping in place. (Group B) 15 children in this group were received a traditional training program given to group A in addition to hippotherapy program (45 minutes/session, 2 session/week for 12 weeks).

For evaluation: Tracker Video Analysis and Modeling Tool (2D video based gait assessment system), it is a free video analysis tool based on the open source physics (OSP) java platform. It is designed to model and analyze object movement in videos by overlaying basic dynamic models directly to the location of videos and extracts. The children walked over 2 meters pathway and a digital video camera (canon) was set up so that it could record the subjects in the sagittal plane on a level tripod, perpendicular to the center of the pathway at a distance of 3 meters. This setting ensured that the calibration area covered the lower limb then the video was analyzed by tracker software.

**Data Analysis**

Mean and standard deviation calculated for all measured variables. Parametric measures (paired and unpaired t-test) used to analyze the mean values of the hip angle before and after the interventions for both groups. Computer program SPSS (version 20) used to analyze data. Statistical tests considered significant if (p < 0.05).

**Results**

In this study, we used tracker software for measuring hip angles during stance phase. The results of this study pre-treatment showed that there were no significant differences between the two groups in all measured parameters and comparison of pre-treatment and post-treatment results of hip angles indicated significant improvements in both groups. Comparison of both groups’ post-treatment results of hip angles indicated significant improvements in favor of group B.

Discussion

This study investigated the effectiveness of hippotherapy program in children with spastic diaplegia that represents the main community of spastic types of CP. This reporting was verified by Yokoshi\(^{10}\) who stated that spastic diaplegia is the main common type of CP accounting for about 44% of CP and about 80% of pre mature infants.

The results of the current study revealed that there was significant improvement in group A and B regarding hip angles with comparison with the pre-treatment results. These findings were supported by McGee, et al.\(^{11}\) in their study who concluded that hippo therapy has a beneficial effect on motor efficiency in cerebral palsy children. Hippo therapy tends to be a therapeutic technique and a way to improve physical outcomes in cerebral palsy children. Hippo therapy is a successful animal-assisted therapy in cerebral palsy children\(^{12}\). The result of the study groups at the end of the treatment period showed significant improvement in hip angles in different gait phases which could attribute to the effect of hippo therapy program help in improvesgait parameters. This finding comes in agreement Kwon et al.\(^{13}\) with who stated that the beneficial effect of hippotherapy on gaitcerebralpalsychildren.

The result of the study groups at the end of the treatment period showed significant improvement in hip angles which may be attributed to the effect of vestibular stimulation over time would enhance sensory integration, standing and walking in individuals with cerebral palsy. These finding support that vestibular stimulation can enhance arousal rates, visual exploratory activity, motor development, balance, and reflex coordination in at-risk infants and developmental retardation disorders\(^{14}\).

The findings of this study provided evidence that good sensory integration involves stimulation of the vestibular, proprioceptive and tactile systems, as a means of exploring new skills. The activities pitched at a level, which stimulates and challenges, but is within the child’s capabilities. The effectiveness of facilitation of sensory integration through the vestibular stimulation is a major component of sensory integrative treatment\(^{15}\).

The horse’s rhythmic symmetrical walking movement could be an important factor, constantly moving the child back and forth across the midline, while the horse’s girth provides the adductor muscles with a gentle, steady stretch. The powerful thrusts of the horse’s legs provide good vestibular and proprioceptive stimulation and body awareness, while regular minor postural changes help the child develop a more normal sense of midline and weight-bearing symmetry.

The findings of the present study revealed that there was a significant improvement in hip angles in the study groups which may be attributed to the effect of hippo therapy that boost the maximum functional potential of a child thus reducing the impact of adductor hyperactivity and weight-bearing asymmetry. These come in agreement with the finding of Benda et al.\(^{16}\).

Conclusion

From the obtained results, it concluded that hippotherapy improve hip angles during stance phase in spastic diaplectic children.

Abstract

Aim: To evaluate the diagnostic value of analyzing the regional longitudinal strain by 2D speckle tracking modality during dobutamine stress echocardiography (DSE) in detecting the culprit disease in either coronary circulation.

Methodology: Prospectively 101 symptomatic patients at intermediate pretest probability for CAD were studied within one month by DSE, followed by coronary angiography. The 3 standard apical views were acquired both at rest and peak stress at an average frame rate of 70/sec. The following indices: longitudinal peak systolic strain (LS), longitudinal peak systolic strain rate (LSRs), and longitudinal early diastolic strain rate (LSRd) were obtained from each segment of the 17 segment model. Regional strain was calculated as the mean of strain parameters of all 10 segments representing the anterior coronary circulation and of the 7 segments representing the posterior coronary circulation separately. Coronary stenosis ≥ 50% was considered significant.

Results: 52 patients had normal or mild CAD, the 49 patients with significant CAD were classified into ACC group n=21, and PCC group n=22. Those with mixed territory disease (n=17) were excluded from final analysis.

At rest, LS & LSRs were significantly lower in PCC than ACC group (-19.46±2.6 vs -21.76±2.5, p: 0.007 and -1.23±0.17 vs -1.49±0.33, p: 0.015 respectively).

At peak stress, all strain parameters were significantly different between the two groups regardless of the involved territory. In Receiver Operator Characteristics analysis, peak stress LS in either ACC and PCC territories showed the largest area under the curve: 0.9 (p<0.001) and 0.88 (p<0.001) respectively. The mean LS at cutoff value of -21% & -20% had 90.5% sensitivity and 88.5% specificity for detecting significant ACC disease, and 81.8% sensitivity and 79% specificity for detecting significant PCC disease respectively.

Conclusion: Baseline regional strain analysis has the potential to detect significant CAD in PCC territory. At peak stress the longitudinal systolic strain can detect significant disease in either coronary territory with high sensitivity and specificity.

Key words: Dobutamine stress echocardiography – 2D speckle tracking – Regional strain analysis – Intermediate pretest probability

Introduction

Dobutamine stress echocardiography (DSE) is a well-validated, non-invasive method for the assessment of myocardial ischemia. But the conventional assessment of wall motion abnormalities (WMA) is subjective...
and relies on assessing the magnitude of myocardial thickening and endocardial excursion, neglecting the longitudinal deformation which is the most susceptible to ischemia.

Myocardial strain and strain rate (SR) are quantitative parameters measured by 2D speckle tracking echocardiography (2D-STE) and can overcome these limitations. They are angle-independent, semi-automated and reproducible.

The integration of the 2D derived global longitudinal strain (GLS) analysis with the conventional DSE protocol resulted in better diagnostic accuracy in the diagnosis of CAD. However, the diagnostic accuracy of regional longitudinal strain analysis during DSE to predict the culprit territory is still unknown.

Method

Study population

This is a prospective observational study conducted on patients presenting to the cardiology outpatient clinic of Cairo University Hospitals for evaluation of myocardial ischemia between April 2015 and February 2017. Symptomatic patients with moderate pretest probability of CAD (based on age, gender and symptoms analysis).

Patients with significant structural heart disease were excluded and also those with suboptimal acoustic windows or persistent arrhythmia to ensure adequate tracking.

All eligible patients were scheduled for DSE with offline STE analysis followed by coronary angiography (CA) within 1 month. Written informed consent was obtained from all patients. The research protocol was approved by the Cairo University Faculty of Medicine Ethical Committee.

Dobutamine stress echocardiography

DSE was performed according to a standard protocol. All studies were performed with an iE33 ultrasound machine (Philips Medical Systems, USA), equipped with the 2.5 MHz S5-1 transducer in the left lateral decubitus with continuous ECG monitoring.

A quad-screen display of equivalent views at each stage was used for analysis. The 17-segment model of the left ventricle was used. Wall motion score index (WMSI) [= sum of all scores divided by the number of analyzed segments] was calculated at peak stress and compared to baseline.

Two-dimensional Speckle tracking

Image acquisition

The apical 4-, 2-and 3-chamber views were acquired at rest and peak stress according to the American Society of Echocardiography (ASE) and European Association of Cardiovascular Imaging (EACVI) recommendations. Patients were asked to hold their breaths for few seconds during image acquisition to minimize translation movement of the heart. Gain, depth and sector width were adjusted to set the frame rate between 60 to 80 frames/sec. One stable well-defined cardiac cycle was acquired for each view and stored digitally for offline analysis.

Image analysis

Each segment of the 17-segment model was analyzed for the following 2D STE derived indices both at rest and at peak stress: (Figure 1)

- Longitudinal peak systolic strain (LS): The maximum negative deflection of the strain before the aortic valve closure (AVC) (%)

- Longitudinal peak systolic strain rate (LSR): The maximum negative deflection of the strain rate before AVC (s-1).

- Longitudinal peak early diastolic strain rate (LSRd): The maximum positive deflection immediately after the AVC (s-1).

Figure 1. Measuring the longitudinal systolic and diastolic strain rate.
Analyzed four-chamber view, the dashed curve represents the mean values of all segments. Point 1 refers to the peak systolic strain rate. Point 2 refers to the early diastolic strain rate. Point 3 refers to the late diastolic strain rate.

Regional strain was obtained by calculating the mean of the longitudinal strain parameters of all segments representing the anterior coronary circulation (ACC) supplied by the left anterior descending artery (LAD): 10 segments; or representing the posterior coronary circulation (PCC) supplied by the right coronary (RCA), left circumflex (LCX) or both arteries: 7 segments.

Patients with significant CAD were classified into isolated ACC territory and isolated PCC territory while those with mixed territory were excluded from final analysis. The mean values of different longitudinal strain parameters of the echocardiographic segments representing either group were compared to the mean values of the corresponding segments in the group of non-significant CAD (control group), both at rest and at peak stress.

Receiver operating characteristics curve (ROC) analysis was done for WMSI and for each strain parameter, to determine the optimal cut-off values that can predict the culprit artery in either territory with good accuracy. The area under the curve (AUC) was calculated: values close to 1.0 indicate high diagnostic accuracy. In all tests, a p-value < 0.05, was considered as statistically significant.

Results

Baseline characteristics

One hundred and one patients completed the study protocol. The mean age was 53 (±8) years, 43.6% were males. According to CA results, 52 patients (51.5%) had normal or mild CAD, and 49 patients (48.5%) had significant CAD. The latter group was further classified into 2: ACC group (n: 21) representing ACC territory disease, and PCC group (n: 11) representing PCC territory disease. Seventeen patients had mixed territorial affection and were excluded from the final analysis.

Diagnostic accuracy of DSE in the ACC & PCC territories

DSE had 90.57% negative predictive value (NPV) and 80% positive predictive value (PPV) to detect significant ACC territory disease; with a diagnostic accuracy of 87.67%. While for PCC territory, DSE had 92.3% NPV and 63.6% PPV to predict significant disease; with a diagnostic accuracy of 87.3%.

WMSI peak stress cut-off value of 1.05 had 62% sensitivity and 81% specificity to detect ACC territory disease (AUC: 0.82, p < 0.001) and 54% sensitivity and 81% specificity to detect PCC territory disease (AUC: 0.80, p < 0.001).
Regional strain analysis

At rest, there were no significant differences between the ACC group and the control in all longitudinal strain parameters while for the PCC, the LS and LSRs were significantly lower than in the normal/mild CAD group.

At peak stress, all patients with the ACC and PCC territorial disease had significantly lower longitudinal strain parameters compared to the normal/mild CAD group except only the LSRd in the PCC group which was only marginally lower than the normal/mild CAD group (Table 1).

ROC analysis of longitudinal strain parameters

Longitudinal peak systolic strain at peak stress had the highest AUC in both ACC & PCC territories (0.9 & 0.88 respectively with p <0.001 for both of them). The corresponding cutoff values to determine the sensitivity and specificity to predict significant CAD in different territories are shown in table 2. Case demonstrating the diagnostic performance of DSE with regional strain analysis is illustrated in figure 3.

Figure 3. Case demonstration of the diagnostic performance of regional strain analysis.

Upper row: Bull’s eye of the 17 segments showing global and regional strain analysis (A) Rest LS of PCC and ACC territories = -18.5% and -20% respectively. GLS= -19% (B) At peak stress: LS of PCC and ACC= -15.9% and -19.3% respectively. GLS=-18%.

Lower row: (C) Right coronary angiography showed subtotal occlusion of the mid RCA. (D) Left coronary angiography showed mid LAD 70% stenosis.

Discussion

The diagnostic performance of the STE-derived strain parameters in the ACC territory was superior to those of the PCC territory. This was concordant to the results of previous studies.\textsuperscript{11,12} As 2D-STE depends on the image quality, the lateral and posterior walls (PCC territory) are usually the most susceptible to drop out and excessive “in and out” motion with subsequent poor tracking, particularly at peak DSE stress with high heart rates. Therefore, the diagnostic accuracy of regional strain analysis of this territory is reduced. Hanekomet et al\textsuperscript{11} reported the same finding; STE strain was feasible and accurate in the ACC territory only. However, in our study, we showed that the mean LS was just more accurate in the ACC territory (sensitivity and specificity: 90.5% & 88.5% respectively), but it could still be applied in the PCC territory with relatively good sensitivity and specificity (81.8% & 79% respectively). This difference in results is because of some differences in the methodology. Hanekomet et al\textsuperscript{11} studied every myocardial segment separately, then chose a single “sentinel” segment with the highest AUC that represented every artery (LAD vs LCX vs RCA). In our study, we divided the heart into two territories from the beginning (ACC vs PCC) including several segments in every territory and avoided the overlap between LCX and RCA -due to dominance- by putting them in one group. Moreover, we included patients with intermediate pretest probability and excluded those with previous MI. On the contrary, Hanekom et al.\textsuperscript{11} included patients with previous CAD and baseline RWMA.

Furthermore, we showed that even at rest, the regional strain analysis may detect significant CAD in the PCC territory, but with modest sensitivity and specificity (72% & 81.8% respectively). A similar finding was shown by Aggeli et al\textsuperscript{12} who studied a similar cohort of patients using the same vendor for 2D strain analysis. The relatively smaller number of myocardial segments in the PCC territory may explain this finding. Minor changes in few segments in response to myocardial ischemia could be easily amplified causing detectable changes in STE strain at rest in this territory.

Conclusion

Regional strain analysis could detect significant CAD in ACC and PCC territories with high sensitivity and specificity at peak stress. At rest, it could detect significant disease in the PCC territory only.

Anterolateral Versus Posterior Approach in Management of Lower Dorsal and Upper Lumbar Traumatic & Pathological Spine Fractures

Mahmoud Ahmed Gomaa¹, Ashraf Abdellatif Osman², Mohamed Khaled Saadeldin³, Mohamed Abdellatif Hussein²
¹Assistant Lecturer, ²Lecturer, Neurosurgery Department, Faculty of Medicine, Fayoum University, Egypt, ³Professor, Neurosurgery Department, Faculty of Medicine, Cairo University, Egypt

Abstract

Purpose: comparing anterolateral versus posterior approach in decompression and stabilization of spine.

Study design: prospective comparative study.

Patients and Method: thirty patients have lower dorsal and upper lumbar spine fractures operated upon in the period from January 2016 to July 2017.

Results: Surgical management of thoracolumbar burst and pathological fractures, Anterolateral approach have not significant superior to posterior approach in terms of recovery neurological function and maintaining normal life activities. Anterior approach was better than posterior approach in rapid improvement of sphincteric control in patients with incomplete cord injury with sphincteric troubles.

Keywords: Thoracolumbar, anterolateral approach, posterior approach, laminectomy, corpectomy.

Introduction

Incidence thoracolumbar spine injuries were about 2% to 7.5% after blunt trauma to the back. 19% to 50% of these injuries have associated neurological deficits. Injuries to thoracolumbar spine could associated with disability.¹

Thoracolumbar spine was transition point between rigid thoracic spine and flexible lumbar spine and predisposed to unique fracture patterns and neurological deficits. Increase prevalence injury at T11-L1 levels than more proximal aspects of thoracic spine or distal lumbar spine.²³

The aims of surgical management of traumatic & pathological spinal fractures are similar: decompression of neural elements, correction of deformities, stabilization of the spine and obtaining tissue for pathology or culture in case of pathological fractures.⁴⁵

In general, surgery for thoracolumbar extradural compressive spine fractures could happen from posterior, anterior or combined approaches.⁶

An anterior approach used primarily for thoracolumbar burst fractures and pathological fractures in where corpectomy and anterior reconstruction required to decompress retropulsed fragments of bone directly off ventral dura or provide immediate reconstruction of the anterior weight-bearing column.⁷

Anterior approaches to pathological infective and neoplastic spine in thoracic and thoracolumbar spine have been described with the advantages of better exposure, allowing more extensive debridement or tumourenbloc excision and better decompression of the cord and more effective bone grafting and biomechanical reconstruction.⁸¹⁰
Patients and Methodology

This study was prospectively conducted on 30 patients with lower dorsal and upper lumbar traumatic and pathological spine fractures operated upon in the period from January 2016 to July 2017 in the Neurosurgery Department, Cairo University and Neurosurgery Department, Fayoum University.

Inclusion criteria:

- All cases of lower thoracic and upper lumbar traumatic and pathological spine fractures.

Exclusion criteria:

- Patients with spine fractures above level of T8 or below level of L2.
- Comorbidities that would prevent an operative procedure.

Patients subjected to thorough history and clinical studies.

Radiological investigations:

- X-Ray thoracolumbar spine with anteroposterior (AP) and lateral views.
- MRI of the thoracolumbar spine.
- CT thoracolumbar spine.

4- Surgical procedures:

Patients were classified in two groups

Group A:

15 patients were operated upon via posterior approach by pedicular screws fixation and decompressive laminectomy.

Group B:

15 patients were operated upon via anterolateral approach by decompressive corpectomy and fusion by grafting and fixation.

5- Postoperative treatment:

Medical treatment:

Antibiotics, analgesics, gastric protecting drugs, I.V fluids.

Physiotherapy:

All patients were referred to physiotherapy.

Bladder training:

All patients were conducted to bladder training.

1. Follow Up and outcome:

a. Full neurological examination.

b. Improvement of back pain were assessed.

c. Post-operative X-ray and CT of thoracolumbar spine.

Results

Table (1) illustrates that there is no statistically significant difference with p-value >0.05 between two study procedures as regards preoperative affection of motor and sphencteric dysfunction and grade of motor paralysis which indicated proper matching between both procedures before intervention.

Discussion

Thoracic and lumbar compressive spine fractures were very prevalent, representing about 90% traumatic spine injuries. Unless contraindicated, MRI should be considered in all cases with neurologic injury.\cite{11-15}

Thoracolumbar burst & pathological fractures could treated via different approaches. Anterior approach offers many outcome such improve canal decompression,\cite{16-17} and exposure of fractured vertebrae, enabling thorough decompression.\cite{18} On the other hand, posterior approach could only support indirect decompression.\cite{19}

Our study included 30 patients complaining of back pain and different degrees of neurological deficits in both lower limbs and sphincteric troubles due to lower thoracic and upper lumbar compressive spine fractures. The patients were classified in two groups: the first group 15 patients with mean age of 38.5 years old and second group of 40.8 years old. In first group, 8 patients were males (53.3%) and 7 patients were females (46.7%). In second group, 9 patients were males (60%) and 6 patients were females (40%). Lin et al mentioned that in their study there were 64 patients with thoracolumbar burst fractures classified in two groups: first group with mean age of 39 years old and second group with mean age of 38 years old. In first group, there were 16 male patients (50%) and 16 female patients (50%). In second group, there were 14 male patients (43.75%) and 18 female patients (56.25%) which is similar to our study.\cite{20}

In contrary to our study, Denisa et al mentioned that in their study of 43 patients with thoracolumbar fractures, patients were classified into two groups: a first group of 27 patients: 19 patients were males (70.3%) and 8 patients were females (29.7%) and a second group of 16 patients: 11 of them were males (68.75%) and only 5 female patients (31.25%) which showing predominance of male gender in Denisa study.\cite{21}

Our study included various levels of fractures, in first group there were: one case with T9 fracture, one case with T10 fracture, one case with T11 fracture, 5 cases with T12 fracture and 7 cases with L1 fracture while in second group 2 cases with T10 fractures, one case with T10-11 fracture, 6 patients with T12 fracture and 4 cases with L1 fracture showing majority of fractures at T12 and L1 levels. Similar to our study, Hitchon et al said that in their study of 63 patients with lower thoracic and upper lumbar spine fractures classified in 2 groups. First group of 25 patients; one patient with T11 fracture, 3 patients with T12 fractures, 12 patients with L1 fracture and 9 patients with L2 fracture and a second group of 38 patients showed one patient with T11 fracture, 13 patients with T12 fracture, 18 patients with L1 fracture and 6 patients with L2 fractures which correlate for majority of injuries at T12 and L1 levels like our study except for presence of L2 fracture in this study which was excluded in our thesis.\cite{22}

In first group, the mean motor power preoperative was 2 and mean motor power in second group preoperative was 1.3. The postoperative results after 3 months showed motor power of 2.5 in first group and 2.1 in second group which showed no superiority of any approach over the other in our study in regaining motor power or ability to walk in paraplegic and severe paraparetic patients which was reported also by Wood et al in their study. On the other hand, there was a significant difference in the outcome of sphincteric function improvement in second group (anterior approach) by decrease in sphincteric dysfunction percentage from 73.3% preoperative to 40% postoperative while in the first group, the improvement of sphincteric dysfunction which was evident in 73.3% preoperative decreased to 53.3% postoperative showing superiority of anterior approach over posterior approach in improving sphincteric dysfunction in early postoperative few months.

Interestingly, although some authors have reported that compared to the posterior approach, the anterior approach provides better decompression of thoracolumbar fractures, which.\cite{22,24}

Correlation between extent of canal encroachment and neurological function were studied; where concerns have raised regarding inadequate spinal canal remodeling after treatment via the posterior approach, no evident between percentage of canal encroachment and clinical symptoms.\cite{25,26} Important purpose of the surgical treatment of thoracolumbar fractures is to
minimize changing in patients’ lives.

Anterior approach associated as better canal remodeling and not greater improvement in Frankel scores or higher incidence of return to normality and recovery of neurological function. (25, 27)

No difference in complication rate between first and second group in our study. Wood et al.24 reported that, 17 “events” in the posterior approach group (6 instrument removal, 2 wound dehiscence, 2 cases of instrumentation/bone failure, 2 urinary tract infections, 2 instrument breakage, 1 deep wound infection, 1 pseudarthrosis and 1 seroma).

In addition, we did not find significant in operative time, blood loss and cost between in 2 groups. Anterior approach has longer operative times due to lack of experience with this approach in first few cases but after many cases there was no significant difference between duration of anterior versus posterior approach. Higher costs were associated with anterior approach due to the special requirements of anaesthesia due to single lung ventilation and the need for titanium mesh or expandable thoracic or lumbar cage.

**Conclusion**

Surgical management of thoracolumbar burst and pathological fractures, the anterolateral approach was not significantly better than posterior approach in terms of significant recovery of neurological function, return to work and maintaining normal life activities. To some extent the anterior approach was better than posterior approach in rapid improvement of sphincteric control in patients with incomplete cord injury with sphincteric troubles. On the other hand, posterior approach was a valid approach with easy preparation and available instrumentation under current causality within few hours from the insult which serves us in emergent cases. Appropriate approach should made cautiously and on a case-by-case basis.

The Early Detection System of Risk Factors on Pregnancy, LaboUR, and Puerperium Women (A Case Study on Midwife Private Practice) in Central Lampung District in 2018

Nanik Yuliwati¹, R. Sutiawan¹

¹Department of Biostatistics and population Study, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

Maternal mortality is a challenge for the public health field across the world, and developing countries account for 99% of maternal deaths globally. It is estimated that 15% to 20% of all pregnant women will experience a high-risk state and obstetric complication. The evidence-based comprehensive guideline provided by the midwife is expected to detect early risk factors for pregnancy, labour, and postpartum before complication occurs. The early detection system through risk factor assessment using the scoring system requires too much time to make being referred to. Risk management cannot be used to be rule for midwives, and pregnant women and their families have not been well enough informed about the mother’s risk requirement. The purpose of this research is to build an early detection system in the midwife private practice of the Central Lampung regency to detect early pregnancy, labour, and post-childbirth to perform risk assessment, to provide risk management as needed, and to design a database of pregnant mothers to be able to produce a report of maternal service. This research uses a prototyping approach as the basis for system development. The early detection system enables midwives to assess the health of pregnant, maternal, and post-childbirth women; perform case management; provide information needed by pregnant women and families; and facilitate midwives in recording and delivering a quality report.

Keywords: Early Detection, Midwife Private Practice, Pregnancy Labour Puerperium, Risk Factors, System

Introduction

It is estimated that in 2016 around 303,000 women in the world died during pregnancy, delivery, and after pregnancy¹. In other words, approximately 830 women died every day due to complications of pregnancy or childbirth¹. Globally, developing countries have accounted for 99% of maternal deaths². The global commitment to reducing maternal and infant mortality is proved through sustainable development, which is referred to as Sustainable Development Goals (SDGs). One goal is to reduce maternal mortality by the year 2030 to 70 instances per 100,000 live births (Sustainable Development Goal 3.1).

Generally, the maternal mortality level in Indonesia is high compared to other Association of South East Asia Nations (ASEAN) countries¹. Maternal deaths in Indonesia are caused by direct factors and indirect factors. The factors of maternal death are preventable if the mother is treated well when managing complications early in pregnancy and during pregnancy. It is estimated that 15% to 20% of all pregnant women will experience a high-risk condition and obstetric complications, which may end anger the life of the mother and fetus if not adequately treated³. Many conditions enable the identification of risks faced through pregnancy and allow for intervention to occur before pregnancy or at the beginning of its period. Proper preparation and effective management during pregnancy can be used to minimise the risk of mortality in mothers and infants⁴.

Midwives, as the most vital component of maternal healthcare, have an important role in reducing maternal mortality. Based on the results of Riskesdas⁵, midwives...
are health workers who provide the most Ante Natal Care (ANC) and delivery assistance labour. The evidence-based report provided by the midwife is expected to be done comprehensively to allow the detection of risk factors in pregnancy, childbirth, and puerperium. This is done to prevent complications by using early treatment\(^{(6)}\). In fact, the recording system used by midwives to indicate maternal health services has not been running well. This conclusion has been reached based on the assessment of the quality of maternal health services in 2012 in 20 districts/cities in Indonesia. The research conducted by the Ministry of Health of Indonesia, World Health Organization, and Indonesian Social Gynecology Obstetrics Association shows that the compliance of health workers, especially midwives, in documenting the results of the examination is still low in 2012\(^{(5)}\). The quality of this maternal health care record triggers the lack of early detection of risk factors in pregnant women.

Consider rephrasing for clarity: Recording the health care provided to mothers has not been optimal, which reduces the early detection of risk factors. Some obstacles in early detection are the complexity in using the mother’s cards and maternal and child health handbook, difficulty using manual documentation, the substantial burden of midwife works, and the time-consuming high-risk pregnancy-risk calculations because they must be calculated manually. Currently, there has not been any risk management for midwives that can be used as a reference in the intervention or prevention of complications. The database used to record pregnant women, delivering mothers, and puerperium mothers uses a manual cohort register. A computerized database is required to store all relevant data and provide quick and easy access to the user to generate required information. The database of high-risk pregnant women can also assist officers in monitoring mothers with risk factors and in facilitating high-risk reporting in real time. Reporting in real time is very useful when making decisions in the community. The development of technology has enabled the improvement of early detection systems for risk factors during pregnancy, childbirth, and puerperium.

**Method**

The system was designed using the System Development Life Cycle (SDLC) using a Rapid Application Development (RAD) model for the prototyping approach. RAD is used because it has a short and fast system development cycle that suits models with limited time\(^{(9)}\). In order to analyse the system needs, a qualitative approach is taken that uses document review, in-depth interviews, and observation.

This system was developed using the reference system proposed by Dennis et al\(^{(9)}\). Prototyping the system design involves four main stages: planning, analysis, design, and implementation\(^{(9)}\). In this study, the system to be built will be limited to a prototype system where the results still resemble the original system. Implementation will be done only in the form of test results of prototype that has been made. Case studies will be undertaken in the private practice of midwifery in the work area of the Public Health Center’s Bandar Jaya and Bumi Nabung district of Central Lampung. Implementation of the research has been conducted from February to June 2018.

**Results**

**Analysis of System Requirements**

Based on the results of in-depth interviews, document review, and observations, current problems found in the system are as follows:

Based on the data provided by informants, the system needs to be made into groups. They are functional needs and non-functional needs, for the long- and short-term. After analysing the current system, it has been determined that the new system should be a website for private midwives to detect risk factors early during pregnancy, childbirth, and puerperium. To see whether the system to be developed is feasible to be implemented, a feasibility analysis must be done by taking into account all existing conditions in Central Lampung District. The system feasibility analysis will be performed using technical, economic, legal, operational, and scheduling (TELOS) criteria.

**The System Design**

The design of an early detection system for risk factors during pregnancy, childbirth, and puerperium must be based upon the identification of the needs of midwives private practice and the ability to recognize opportunities to improve the existing system. This projected application is designed to resemble the current method of early detection by referring to the mother’s card. Mother’s card is used to facilitate the adaptation of midwives to the current system from pre-existing
systems. The new system is designed to provide advice on what should be provided by midwives to patients and the families of patients regarding information for early detection and what to do with regard to high-risk cases experienced by pregnant, maternal, and puerperium women.

The prototype for the early detection system of risk factors is as follows:

1. During pregnancy: Early detection of risk factors during pregnancy is achieved by answering closed questions regarding the 23 question variables that exist. Each variable is assigned a value of 4 or 8. The results of early detection of risk factors during pregnancy are divided into 3 categories: low risk with a score of 2, high risk with a score of 6 to 10, and very high risk if the score value is more than 12. From the results of this early detection, advice will be given to the midwife to do.

2. During delivery: Early detection in delivery is performed using 18 screenings of labour. Currently, screening is done manually using paper. Recording risk factors uses closed-ended questions. Based on the results of a screening, a ‘YES’ answer to a question will lead to a reference for the mother. To facilitate the process of referral, the system menu should provide information for ambulances and regarding the nearest hospital.

3. In puerperium: The early detection system of risk factors during puerperium consists of 8 question variables based on data recorded in the mother’s card. Early detection results appear after closed questions have been answered. The results are in the form of puerperium status: normal or high risk. The system should also provide advice on what midwives can do if the childbirth involves high risk.

4. Concerning mother’s card input: mother’s card is used as the basis of this system. In this system, it is then made prototype of mother’s card online. The system will output a maternal cohort register, ways to detect risk factors.

The following context diagram illustrates the scope of the information system, the entities involved, as well as the incoming and outgoing data regarding the information system process.
Fig. 3: Network Scheme

Based on the above design, the following are some interface designs in the early detection system of risk factors for pregnant, maternity and postpartum women.

Fig. 7: Interface Design of Labour

Fig. 8: Interface Design of Puerperium

Discussion

According to Dennis et al (10), a system should be developed by reasoning why the system should be built and how value will be provided through the system. The absence of a system that enables midwives in private
practiceto identify high-risk cases has become the basis of system-making considerations. Thus, it has been increasing the chances of maternal death. This technology allows early detection to be done quickly and easily.

The completion of clinical data forms, such as the maternal and child health handbook and mother’s cards, will allow systems management data and reporting instruments in a healthcare service will help improve the availability of reliable data to make appropriate decisions, planning and interventions[11]. Current systems are being developed to implement an early detection system for risk factors. In addition, the midwife performing the screening will not require any special qualifications, because the identification of high-risk cases will be performed automatically by the system. In addition, the system will be created using website approach so a midwife can open the system on any platform, such as a smartphone, laptop, tablet, or PC. The system will also assist the midwife to perform case management for at-risk women. Data that has been input will automatically enter the database of pregnant women in MySQL, so it can be recalled when the mother revisits.

The system to be developed will use a mother’s card for midwives who are familiar with the previous manual form. The early detection system will use closed questions to detect risk factors. The inputted data will be stored on the server so am idwife will no longer need to record the results. Midwives can immediately see the results of early detection and view the report after completing the input. Following up with high-risk mothers can be facilitated by drawing data from the database on the next visit. The cost incurred through the use of this application revolves around the cost of internet data packets and papers to print the results of early detection. The system can help midwives to improve the quality of service for mothers and families, the results of screening can assist midwives to facilitate making decisions quickly and accurately.

Conclusions

The conclusions from this study are as follows:

a. An early detection system used by midwives to identify risks is being implemented through out a woman’s pregnancy, delivery, and puerperium health services, but the early detection system has not as expected. Technical factors, behavioural factors, and organizational factors are suspected to be the causes of this problem. An early detection system is needed that would assist midwives in determining the health of pregnant, maternal, or postnatal women.

b. The early detection of risk factors in pregnancy, childbirth, and puerperium facilitates midwives in assessing the pregnancy, childbirth, and puerperium, using the categories of low risk, high-risk, and very high-risk by using assessment indicators on the mother’s card.

c. Pregnant women, women in labour, or women in puerperium who have been screened will be given case management as needed. Management of cases will involve providing information to mothers and families in accordance with the needs of mothers, so it is expected to increase mother and family more care about pregnancy and allow preparation to occur before complications arise.

d. The design of information systems should allow the collection of information into a database of women with risk factors and data facilitate the midwife in recording and providing quality reports.

6. World Health Organization. Pregnancy, Childbirth, Postpartum and Newborn Care : A Guide For

The mucous cells of both species were scattered throughout the gill filament epithelium and mostly localized apically between the pavement cells. Meanwhile, very few mucous cells were rarely observed in the secondary lamellar epithelium. The mucous cells of the Sparus aurata had fine granular light acidophilic cytoplasm. While, those of Oreochromis niloticus lacked the acidophilic cytoplasm or had faintly acidophilic vacuolated cytoplasm.

Histochemically, the granules of mucous cells of Oreochromis niloticus showed strong positive reactivities with PAS as well as, alcian blue pH 1 and pH 2.5. Whereas, these granules in Sparus aurata were PAS positive but, showed a very faint or even negative reactivity with alcian blue.

Ultrastructurally, the cytoplasmic granules of the mucous cells of Oreochromis niloticus were either scattered throughout the cytoplasm or localized in the basal part of the cell and showed some variability in their electro-density. Meanwhile, the mucous granules of Sparus aurata were always distributed all over the entire cytoplasm and showed variable electro-density within the same cell and also between the adjacent mucous cells.

**Key words:** Mucous cells, Ultrastructure, gills, Tilapia Oreochromis niloticus, Sparus aurata, Histological and Histochemical changes.

**Introduction**

Fish are a valuable source of proteins. They have some unique anatomical and physical characteristics that are different from mammals.

The fish gill is multifunctional organ and fulfills several vital functions; mainly dealing with respiration and osmoregulation. The mucous cells contribute to various functions; such as ion and gas exchange, absorption, lubrication and pH balance. However, these mucous cells were termed glycocytes by Chen et al.

None of the available literature was dealing with the normal structure of the gills of Sparus aurata. Moreover, there were a paucity of histological studies have centered their attention to the mucous cells of Oreochromis niloticus.

The present study aimed to investigate the histological, histochemical and ultrastructural features of the mucous cells in the gills of both Oreochromis niloticus as a model of freshwater fish and Sparus aurata as a marine water fish.

**Material and Method**

The total of 10 apparent healthy 20 adult samples of Tilapia nilotica (Oreochromis niloticus) fish from fisheries of the Fayoum city and 20 adult samples of gilthead sea bream (Sparus aurata), were obtained from some private fisheries near the Mediterranean Sea in Port Said, Damietta. This study adhered to ethical requirement to animal welfare in Egypt.
For light microscopic studies; the specimens were fixed in 10% neutral buffered formalin and Bouin’s fixatives. The specimens were processed and embedded in paraffin wax. Sections of 5-7 µm thick were obtained and stained with; Harris haematoxylin and eosin (H & E), Periodic acid Schiff (PAS), Alcian blue pH1.0 and pH 2.5, and Periodic acid Schiff –alcian blue pH 2.5 combination according to Bancroft and Stevens.

For transmission electron microscopy (TEM); small pieces of (1mm) of the gills were fixed in paraformaldehyde-glutaraldehyde in phosphate buffer. Specimens were post fixed in 1 % osmium tetra oxide, washed in 0.1 M phosphate buffer (pH 7.3), dehydrated in ascending grades of ethanol and embedded in Epon araldite mixture. Semi thin sections (1µm) were cut and stained with toluidine blue. Ultrathin sections were cut and stained with Uranyl acetate and lead citrate. Sections were examined with a JEOL 1010 transmission electron microscope at Regional Center for Mycology and Biotechnology Al-Azhar University, Cairo, Egypt.

Results

The gills of both species were formed of rows of primary lamellae or gill filaments. Secondary or respiratory lamellae arose from each filament; including the inter-lamellar regions in-between (Fig.1). In Sparus aurata, the free end of each secondary lamella located close to the free end of the opposite one and might touch it (Fig.2). Generally, a simple epithelium covered the secondary lamellae while, a stratified epithelium covered the gill filaments. The majority of the apical surface was covered by superficial pavement cells. However, chloride cells and mucous cells could be observed among this multilayered epithelium (Fig.3).

Concerning mucous cells, in Sparus aurata, they were scattered singly among the epithelial cells of the inter-lamellar regions or may be observed in small groups of two or three cells. They were usually located apically in the gill filament epithelium among the pavement cells and beside the chloride cells. These mucous cells were larger than the other cells. They appeared ovoid or circular in shape with fine granular light acidophilic cytoplasm and basal flattened or ovoid nuclei (Fig.3). On the other hand, the mucous cells of Oreochromis niloticus lacked the acidophilic cytoplasm or had faintly acidophilic vacuolated cytoplasm (Fig.4). However, in both species such mucous cells became more abundant at the terminal ends of the filaments. Meanwhile, very few mucous cells were rarely observed in the epithelium of some secondary lamellae (Fig.5). In the semi-thin sections, the cytoplasm of the mucous cells was darkly stained with toluidine blue (Fig.6).

Histochemically, the granules of mucous cells of Oreochromis niloticus showed strong positive reactivity with alcian blue pH 1 (Fig.7), alcian blue pH 2.5 (Fig.8), PAS (Fig.9) and alcian blue pH 2.5–PAS combination stains. Whereas, the granules of mucous cells in Sparus aurata showed very faint or even negative reactivities with alcian blue pH 2.5 (Fig.10) and alcian blue pH 1. While, these granules reacted positively with PAS (Fig.11) and alcian blue pH 2.5–PAS combination techniques. Some of the mucous cells displayed mucous secretory granules discharged from their apical surface (Figs.7 and 8). However, no histochemical differences were detected between the mucous cells of the gill filaments and the secondary lamellae.

Ultrastructurally, the mucous cells of Oreochromis niloticus appeared elongated pyramidal or ovoid in shape with basal irregular nuclei. Their cytoplasm revealed the presence of mucous secretory granules of various shapes and sizes. These granules either scattered throughout the cytoplasm (Fig.12) or localized in the basal part of the cell (Fig.13) and showed some variability in their electro-density. However, individual mucous cells were
also demonstrated in the epithelium of some secondary lamellae (Fig.14). Meanwhile, the mucous cells of Sparus aurata were characterized by the presence of numerous mucous granules distributed all over the entire cytoplasm of the cell. Such mucous cells appeared with different sizes and their granules had different shapes and sizes and showed variable electro-density within the same cell and also between the adjacent mucous cells (Fig.15). The nuclei of these cells were ovoid or irregular in shape and basely situated. Some mucous granules were frequently observed discharged from the apical surface of some cells; between the adjacent pavement cells. Such pavement cells were characteristically equipped with apical microridges (Fig.16).

Discussion

In spite of, the presence of numerous mucous cells among the gill filament epithelium, very few mucous cells were rarely observed in the secondary lamellar epithelium. This distribution, on one hand reduces the thickness of the blood–water diffusion barrier, and on the other hand, avoids the particle retention by the produced mucus. Moreover, mucus film may diminish gas diffusion and to avoid this interruption in gas diffusion; secondary lamellae either devoid of mucous cells or possess a very few number. On the other hand, the secondary lamellae have a protective covering of mucous cells in Catla catla. Also, these mucous cells were not only detected in the epithelium of secondary lamellae of Catla catla but also, observed in its core. However, the mucous cells in the secondary lamellar epithelium increase the water blood barrier for respiratory gases diffusion. Furthermore, the mucus protects the secondary lamellar surfaces against toxic and/or infectious agents.

In agreement with Oguz, some the secretory granules of mucous cells of both species were discharged from the cell apical surface between the adjacent pavement cells. Moron et al. described that, thees mucus secretory granules are liberated directly into the environmental water. Furthermore, Samajdar and Mandal noticed mucous cell openings with mucin globules over the
epithelial surface. Diaz et al.\textsuperscript{16} suggested that, the apical microridges of pavement cells prevent the loss of mucus from the gills epithelial surface. However, this mucus secretion is correlated with the increase in salinity\textsuperscript{17}.

Histochemically, the granules of mucous cells of Oreochromis niloticus showed strong positive reactivities with PAS as well as, alcian blue pH 1 and pH 2.5. Whereas, these granules in Sparus aurata were PAS positive but, showed a very faint or even negative reactivity with alcian blue. Adams and Nowak\textsuperscript{18} confirmed that, the mucous cells of Atlantic salmon, Salmosalar L. were most commonly PAS positive and alcian blue negative. However, Bansil and Turner\textsuperscript{19} speculated that the different chemical characteristics of the mucous cells are due to the carbohydrate contents of glycoprotein within their cytoplasmic granules. Also,\textsuperscript{20} may be due to the differences in water and environment conditions. The mucous cells of freshwater Tinca tinca, are generally containing a greater proportion of acid mucins than do marine species.\textsuperscript{21} This acidic glycoprotein could be engaged in the prevention of epithelial damages.\textsuperscript{22} Moreover, the existence of acid mucus over the gill epithelial surface is of crucial importance in freshwater fish, to prevent loss of ions due to the reduced osmolarity of the aquatic milieu\textsuperscript{23}. Also, in a freshwater fish, there is a continuous loss of salts and water gain; the active branchial uptake of sodium and chloride ions becomes crucial for ion homeostasis, and then the presence of neutral glycoprotein could be related to the transport of ions across the gills.\textsuperscript{22}

The histochemical results obtained herein were consistent with the electron microscopic data with regard to the heterogeneity of the chemical composition of the mucus granules and their variation in size and electro-density. Similarly, the mucous cells in Hoplias malabaricus and in Oreochromis niloticus\textsuperscript{24} are characterized by the presence of mucous containing vesicles with variable electron density. According to Diaz et al.\textsuperscript{16}, the variation in size and electro-density of mucus granules is most likely due to the fact that these cells were at different stages of the secretion processes. Furthermore, Banerjee\textsuperscript{25} clarified that, the mucous cells are active cells that respond to environmental changes.

\textbf{Conclusion}

Thus, it can be concluded that, the mucous cells present in the gills of freshwater Oreochromis niloticus differ from that of marine water Sparus aurata fish in their histochemical reactions as well as, their ultrastructural features of the mucus secretory granules. However, this variation may be a mechanism for adaptation to different conditions of the aquatic environment.

Abstract

The Objective of this study was to estimate the Hormones (Ghrelin, and progesterone) gallstone and making liver function test in the patient’s sera and studying the relationship between demographic factors with previous factors. Patients and methods: This study is a probable clinical study in which (100) patients with a gallstone were included in the study. Those patients were (13) males and (87) females; their ages ranged from (17-78) years. While for the control group were collected, from 50 people (31) males and (19) females, their ages ranged from (17-61) years. Serum was obtained by, usual methods and analyzed, for Hormones (Ghrelin and Progesterone) and Liver Function (GOT, GPT, ALP and GGT). Results: The result of the current study shows the mean value was high for (Progesterone) parameters in, patient than the control, with highly significantly different (P<0.005) between, the study group. The result of the current study shows the mean, the value was high, for (GOT.GPT.ALP.GGT) parameters in patients then controls with highly significant different (P<0.05) between study groups. Conclusion: the GD protective effect associated with a high level of Ghrelin in the Serum.

Introduction

Gallstone disease is disease has pathological changes in the digestive, system and the stone are a solid crystalline deposit formed in the gallbladder (10). Bile stones can be, classified according to their chemical composition cholesterol and pigmented, gallstone cholesterol stone is the, highest and spread, of pigment stone (28). Three important mechanisms in the formation of gallstones (cholelithiasis) are cholesterol supersaturation gallbladder, hypomobility, and pro-nucleating or anti-nucleating factors. Through the development, of gallstones, solid mass. of cholesterol, monohydrate crystals, mucin gel, calcium bilirubin and other proteins accumulate crystallise and form gallstones (16). Gallstones are a common problem in all world countries. Percentage infected people are (10-15) % by Gallstones, however only (20) % of infected people have complications such as biliary pain acute cholecystitis, pancreatitis and cholangitis (27). Environmental factors and genetic factors have a significant role in Gallstone formation epidemiological (31). Ghrelin is an endogenous factor of the growth, it stimuli secretion growth hormone in humans (18).

Progesterone is synthesized, from cholesterol, by the descent compound, pregnant, and is the principle, revolving progestin (30). Liver function test is mostly, measured in patients, with liver and biliary tract, disease. Increase activity, of serum enzymes, is, used to sign the pathological, release of an individual, proteins from destroyed, liver cells rather than, to study a particular, function (22). ALT and AST are generally ready in human serum, saliva, cerebrospinal fluid, and bile and it’s not found in urine (26). Gamma-glutamyltransferase and alkaline phosphatase are, sensitive but not particular, to choledocholithiasis because, of their multiple sources. The amount, of their appreciation preoperatively, is that their high increase the, suspicious of the common bile duct (CBD) stone or pathology (24).
has, obstructive disease, alkaline phosphatase is the
first enzyme, to be raised, while if the disease is due to
damage, of liver cells, and the aminotransferases will
be marked. This produces enzyme analysis helpful,
to recognize the disease condition, cholestatic and
hepatocellular, respectively (11). The enzyme is created in
the liver microvilli. Therefore it used as large, marker
for biliary detection obstruction, extrahepatic biliary (12).

Material and Method

Patients:

This study is a likely, clinical study, in which 100
patients, with a gallstone, included in the study. The
study was, started from December 2017 during, March
2018 at the segment, of general surgery in Baquba
Teaching Hospital. Those patients were (13) males and
(87) females; their ages ranged from (17-78) years.

While, for the control, the group were composed,
from 50 people (31) males and (19) females, their ages,
ranged from (17-61) years. Ten milliliters of blood was
composed, into test tubes without anticoagulant. After
coagulation, the blood samples were centrifuged at
(4000 x g) for 10 minutes, and the serum stored on an
ice bath and was used on the same day for the enzymatic
activity assays of the liver function. The residuum
of the sera were stored at -20°C, to be used for other
parameters appreciation. All subjects were required
several factors that have direct influences including
age, gender, family history, date of birth, previous
surgery and former medical. Serum ghrelin level was
determined by using RIA kits in the radioimmunoassay
technique. The levels of GOT and GPT were evaluated,
according to the colorimetric method, respectively (2).
Alkaline phosphatase also, determined according to the
colorimetric method (6) and gamma-glutamyl transferase
determined according to the colorimetric method
(13).

Statistical Analysis

Our Data were analyzed by using, Chi-square (X²)
test for comparative between, percentages. Odd ratio
(OR) and relative, risk (RR) were used to, measure
strength association, between presence factor and
appear happened. The numeric date was described by
(Mean ± SD). T-test used to compare between two
numeric variables, while the F test (ANOVA) used to
differentiate between three numeric variables or more.
Pearson correlation (R) accounted to explain type and
strength, of the relationship between variables. At
significance level is α=0.05 was applied to test (SPSS
v.22 and Graph, pad prism v.6) software used to analyze
data.

Results and Discussion

This study carried, on (100) Gallstone patients from
December 2017 and March 2018 cholecystectomy,
was carried on (100) patients 87(87%) were women,
13 (13%) men. Similar finding has been, observed in
previously, studies Figure (1)

The cumulative prevalence, of GS, increases with age, and the GS average increases by 1% to 3% per annum with the highest rate in the first four contracts of life (5).

1-Hormones and Enzyme:

In the present study, Result of current study shows the mean value, was low for (Ghrelin) parameters, in patients than controls with high significant different (P<0.05) between study groups but the result of the current research shows the mean value was high for (Progesterone) parameters in patient than the control with highly significantly different (P<0.005) between the study group.

The result of the current study shows the mean value was high for (GOT, GPT, ALP, GGT) parameters in patients than controls with highly significantly different (P<0.05) between study groups.

Our results founded that protective influence of GD associated with high level of serum ghrelin concentrations, wherever the chronic ghrelin management is increased body fat content in humans in visceral adipose tissue, Un acylated ghrelin (UAG) and acylated ghrelin (AG) are increase metabolism of the lipid by increasing of the expression of adipogenic genes (20).

However, we approved that there are large facts to be considered Ghrelin stimulates positive energy balance and stimulates obesity in rodents by reducing using of fat. The concentrations of ghrelin are said to decrease in obesity and increase, after weight loss caused by the diet (8).

The current study with Langenberg and his, colleagues agrees that low levels of ghrelin were connected with a higher prevalence of metabolic syndrome, with lower serum ghrelin levels and increased metabolic syndrome (19).

Estrogen receptors and PR have important play a part in gallbladder function through sex hormones (ER and PR) by changing the movement of the gallbladder by adjusting the affinity of the receptors in the gallbladder to octapeptide and carbachol cholecystokinin. Specifically, the presence of public relations in the gallbladder makes them more volatile in the circulation of hormones and their influence on their movement. The inhibitory influence of progesterone on the movement of the gallbladder may include its abnormal movement across multiple signalling pathways, including inhibition of, the L-type calcium channel by cAMP / PKA pathways in the smooth, muscle of the gallbladder to develop gallstones and malignancy (21).

The transaminases enzymes are increased in liver damage, but GOT is also present in skeletal muscle, cardiac muscle and red blood cells. Also, it used as a cardiac sign for example muscle inflammation due to dermatomyositis, GOT are not specific measures at the liver function, but we can use as an indicator in muscle inflammation or damage (25).

Previous research has Assured that the increase in the effectiveness of the enzyme GGT to several times (10-20 years) of the normal state refers to sharp biliary inflammation or obstruction of the bile ducts. As well as the level of the enzyme increase in heart disease cases, diabetes (type II), acute pancreatitis, kidney failure, liver disease and addicts to alcohol consumption. The presence of GGT in cell membranes of the biliary system makes it very critical to diseases of the biliary system, both within the mother and outside the liver so in the case of bile duct obstruction, the enzyme level reaches ten times normal. Studies showed that patients with extracranial cholestasis increased the effectiveness of the extra-liver GGT due to necrosis of the biliary epithelial cells (containing a high concentration of GGT) (1).

The result of the current study shows the mean value was high for (Total Serum Bilirubin, Direct Bilirubin and indirect Bilirubin) parameters in patients than controls with highly significantly different (P<0.05) between study groups.

Measurement of total bilirubin is included plus conjugated and unconjugated bilirubin. Bilirubin is a product from hemolytic. Bilirubin is turbid and combines with albumin and circulates in the blood to the addition of that high concentration drugs (some antibiotics and diuretics) and high fatty acids to unconjugated bilirubin. Hemi is produced from myoglobin (in muscle, mitochondria). The liver does the function of removing unconjugated bilirubin.

The final diagnosis is done by measurement of the direct bilirubin concentration. If direct bilirubin is increased which will results problem in the liver, internal bleeding and hemolysis. If direct bilirubin has a high level but the liver cant secret it outside of the body that associated with several cases such as cancer, hepatitis and cirrhosis. In this study, the mean levels of (DB) showed a significant increase (P<0.001) in patients: group when compared to the control group. That means that all patients in this: a study has the liver disease to interactions with gallstone. This study is contravened with other reviews (4). Which have shown there is no significant difference between liver function tests: and gallstone disease only without another liver disease (14).

3-Differences in Selected Parameters:

Some selected parameters were, detected for patients with gallstones and, control group.

3-1-Age:

The present study shows, non- significant differences, in mean age among all studied groups, among all patients. And all control groups, as well as amonge Male patients and control groups between female patients and control groups.

The result of the current study shows the least, age periods for male, and female patients Was (60 -79) years and high age periods for male and female patients were (40-59 years with non-significant different (P>0.05) among patients, according to sex and age periods.

In terms of age division, the ratio (40-59) contains the highest percentage, and this result agrees with a future randomized study done by Kolla S.B et al. (2004) (24). Also, our finding regarding age is in agreement with a survey conducted by Mohammed S. et al. (2008) (26).

Sex division as a result of our study group had females (87) % and males (13) %, these results are regular with Mohamed S. et al. (2008). In this study also, females were found in the majority which shows that; acute gallbladder inflammation is common in females (23).

The increase in female lithogenicity may be due to the female sex hormone, which activates its compensatory influence by disrupting the emptying of the gall bladder in full particularly during pregnancy reflecting the high level of serum progesterone on the smooth muscle and increase the secretion of bile cholesterol (7).

3-4-Bady Mass Index (BMI):

Obesity is one of the high-risk factors for gallstones.
The most important factor simulating secretion and the concentration of infectious and inhibitory substances is diet and related metabolic disorders. Increased incidence of urolithiasis in the world in recent contracts due to changes in lifestyle, factors that increase, attention to food habits and nutritional cases of stone makers, Body Mass Index was showing a strong correlation with growing risk of stone formation (3).

Result of current study shows the male: percentage is (23.1%) for (<25), (0.0%) for (25) and (76.9%) for (>25) respectively, while the female: percentage is (20.7%) for (<25), (5.7%) for (25) and (73.6%) for (>25) respectively with non-significant different (P>0.05) among patients according to sex and BMI.

Recurrent stones are usually associated with obese and overweight. How does it work? That is unclear yet (29).

A large clinical study showed that big weight gain increases the risk of gallstones. The most probable reason is that the amount of bile salts in the bile has decreased, leading to more cholesterol (15). Because obesity is considered a risk factor, therefore the people must be made body weight is meddled (9).

Ethical Approval: Before the start of the study, it was approved by the ethics committee of university, ministry of education, schools managers, teachers and a written consent from parents of the participating students after detailed discussion with them about the importance if the research and there was no harm for their patient.

Funding: Self-funding

Conflict of Interest: The authors declare that no conflicts of interest.

Prevalence of Stunted Growth among Primary School Children in Egypt

Ali Mohammed El Shafie, Hossam Hegran, Dalia Mounir El-Lahoni, Zein Abdel latiff Omar, Wael Abbas Bahbah, Eman Salah Eladawy

Pediatric Department, Faculty of Medicine, Meniuofia University, Meniuofia Egypt

Abstract

Stunting is an important pediatric problem; it might be the first presentation of underline disease. School age is specific period where’s children undergo rapidly development. So monitoring of the growth among school children with Z score should be mandatory in all schools. Methods: A cross sectional survey was done on students aged (6-11 years) at Egypt. The children were assessed for stunting by clinical examination and anthropometric assessment by Z scores, during April-December 2018. Results: 32170 children were studied. Prevalence of stunting was 15.3%. Boys more stunted (16.7%) compared to girls (13.7%), urban more than rural and average socioeconomic standard. Stunting was lower among (9-10) years while the reverse in (6-8) years. Conclusion and recommendation: Stunting was 15.3% higher among male, urban and (6-8 years) aged. School intervention programs can reduce the stunting problems by early pickup and intervention.

Key words: Children, Egyptian, prevalence, school age, stunting.

Introduction

Childhood short stature is common in family practice. Familial short stature and constitutional growth delay account for most cases, and there are clear guidelines for differentiating these from each other and from less common pathologic conditions.

Although GHD, hypothyroidism, CD and other potentially treatable causes accounted for a considerable percentage of short stature, the majority of children had normal variations of growth.

Stunting is defined as height-for-age z-score equal to or less than (-2 SD) below the mean. It is a well-established child-health indicator of chronic malnutrition.

Stunting is a major public-health problem in low and middle-income countries because of its association with increased risk of mortality during childhood.

So we aimed to determine prevalence of stunting in children in Egypt.

Method

An approval from Menoufia Faculty ethical committee was taken.

A cross section study was conducted in 6 – 11 years children. The sample includes 31270 students. The sample was taken from 9 Egyptian governorates, 6 of them from delta region and 3 from Upper Egypt. The chosen child was with inclusion criteria: Both sexes, Live in Egypt, Apparent healthy and exclusion criteria was: Children below 6 or above 11 years, Children with major medical disorder.

Age and sex were collected in a sheet including height, weight and BMI. If the child suffered from any health problems and families were informed.

The screening was done in the school from 1st April to December 2018.

A written consent form was signed by the managers and authorities in education ministry.
Ethics approvals and a written consents where the study were conducted. The students families were informed about the research also were informed regarding what measurements would undergo and their written consents were to allow their children to participate and there were no invasive maneuvers.

All cases were subjected to:

Clinical history: name, age, sex and residence. Assessment of socioeconomic standard of family with questions about the father’s and mother’s education, occupation and income according to Egyptian families classification.

Physical examination: Height: It was measured by a tape measure permanently fixed to a wall, the head was held firmly at the top of the board. The knees were flattened firmly to fully extend legs. The feet were together and flexed to a 90° angle with the child fully stretched. The child was standing erect with the heels, buttocks, and back of the head against the wall and the arms was down and relaxed.

The data were analyzed by SPSS (statistical package for social science) version 17.0 On IBM computer. We used two types of statistical analysis: Descriptive statistics e.g. percentage, mean and standard deviation and analytic statistics e.g. Chi-square test. P-value of < 0.05 was considered statistically significant.

Results

This tables show that the percentage of the age groups and sex, 6-7 y (30.28%) was higher than 7-8 y (21.68%) and 8-9 y was (18.01%)same as 9-10 y (19.95%) and 10 y < was 10.08% (table 2), according to sex there were 51.62% male, female 48.38% (table 3), according to age the mean was 7.95 ± 1.52. (Table 2)

Tables shows frequency and percentage for area and socioeconomic. according to area, rural and urban (56.79% and 43.21%) respectively( table 5), according to socioeconomic, low, average and high (8.81%, 69.91% and 21.29 %) respectively. (Table 4)

This table show that, very stunted 332 (1.06%), Stunted 4776 (15.27 %), Normal 23540 (75.28 %), Tall 769 (2.46 %) and very tall 237 (0.76 %). (Table 1)

Discussion

Our study showed that, prevalence of stunting (short stature) among the studied group is 15.3%

This is similar to the finding of 16.64% among Kenyan middle-school children, 17.9% among Santal children of Puruliya district in India.

It is high when compared with Turkish children where only 5.7% are stunted. This difference is likely to stem from differential nutritional intake, socioeconomic and cultural differences rather than differences in their genetic potential to achieve maximum height.

This disagrees Roushman et al. the study that done in WHO and NCH on 11 low income countries was 32.6%and 32.6% respectively

Also it is lower than Esfarjaniet al. study who found that, stunting was prevalent among 3.7% of the studied population (n = 3147)

This is disagrees with Mushtaq et al. who aimed to assess the prevalence and socio-demographic correlates of stunting among Pakistani primary school children. A population-based cross-sectional study was conducted with a representative multistage cluster sample of 1860 children aged 5-12 years in Lahore, Pakistan. They found 8% children were stunted, while mild stunting and severe stunting were observed in 18% and 1% children respectively.

Our study revealed that stunting among male (16.7%) was higher than in female (13.7%).

This agrees with El mouzan et al. whose study in Saudia, stunted among males (11.3%) was higher than females (10.5%).

This disagrees with Mushtaq et al. who found stunting was not significantly associated with gender.

The relationship between stunting and gender varied. While some studies demonstrated a higher prevalence among males, others demonstrated a higher among females.

Explanation for the higher prevalence of stunting among female could have been due to the effect of extension of cultural preference for boys at birth.

Our study revealed that prevalence of stunting among urban (16.1%) was higher than in rural (14.6%).

This is consistent with Mushtaq et al. But disagrees with Van de Poel et al. who found higher stunting among rural in Pakistan.

Unlike Zayed et al. in Jordan that confirm stunting was high in rural than urban.

The study found that stunting was high among average socioeconomic standard than higher.

This disagreement with Janevic et al. who reported low socioeconomic status had a more detrimental effect on linear growth than on body weight. Economic inequality is an independent determinant for childhood under nutrition and studies have illustrated that the poor children tend to be at higher risk of being undernourished and restricted growth.

Also agrees with El Mouzan et al. that show improvement in socioeconomic standard decrease stunting in high socioeconomic standard.

Countries with a greater degree of economic inequality tend to have a poor health status than countries with more economic equality. The developing countries remain vulnerable to food insecurity, poor access to health services, under-nutrition and increased morbidity and mortality, and the health and nutritional benefits from economic growth tend to be concentrated only among the economically advantaged population groups.

In the study, stunting was lower among aged 9-10 years while the reverse was among lower age.

This could be due to increased access to food at the older age when the females are culturally involved in the cooking of family-food, and their better nutritional state.

Conclusion and Recommendation

Our study showed that, prevalence of stunting is 15.3%. Prevalence of stunting among male (16.7%) was higher than in female (13.7%). Prevalence of stunting among urban was higher than in rural. Stunting was high in average socioeconomic standard. Prevalence of stunting was lower among aged 9-10 years while the reverse was among lower age. With the help of school intervention programs and ministry of healthy might be the first step in early detection of stunting by yearly recording weight and height the stunted child and give their families information and assurance. Also ministry
of health should help by building programs for detection the causes and the ways for intervention.

**Funding Source:** This article received no specific grant from any funding agency in the public, commercial.

**Ethical Approval:** Before the start of the study, it was approved by the ethics committee of meniuofia university, ministry of education, schools managers, teachers and a written consent from parents of the participating students after detailed discussion with them about the importance if the research and there was no harm for their children.

**Funding:** Self-funding

Serum Adiponectin in Relation to Endothelial Dysfunction and Atherosclerosis in Rheumatoid Arthritis Patients with Renal Dysfunction and Influence on Cardiovascular Risk

Ghada Khalifa\(^1\), Tamer Abdel Tawab\(^1\), Maha Abdelhadi\(^2\), Soha Atef Nasr\(^3\)

\(^1\)Nephrology Department, Theodor Bilharz Research Institute, Egypt, \(^2\)Internal Medicine Department, National Research Centre, Egypt, \(^3\)Clinical Pathology Department, National Research Center, Egypt.

Abstract

Rheumatoid arthritis (RA) is a very common autoimmune disease in the population which leads to progressive destruction of the joints. Cardiovascular diseases are the common causes of death in RA patients. An unfavorable prognosis in patients with RA can be associated with kidney damage. The development of chronic kidney disease (CKD) in RA can be associated with cardiovascular pathology, while renal pathology itself is a risk factor for cardiovascular diseases. Purpose: To evaluate serum level of adiponectin and its relation to endothelial dysfunction and atherosclerosis in rheumatoid arthritis patients with renal dysfunction and prevalence on cardiovascular risk in these patients. Materials and method: This study was done with 52 patients with established diagnosis of RA divided into two groups {group of rheumatoid arthritis (RA) patients with renal dysfunction and group of RA patients without renal dysfunction}. Serum adiponectin level were measured, GFR was calculated. Determination of flow mediated vasodilation was performed and assessment of atherosclerosis and cardiovascular risk. Results: In RA patients with renal dysfunction serum adiponectin level was significantly higher (p<0.05). EDVD was significantly lower (p<0.05) than in RA patients without renal dysfunction. There was increase in cardiovascular risk in RA patients with renal dysfunction. Conclusions: In this study patients with rheumatoid arthritis and more in those with renal dysfunction high adiponectin level was found and in spite of its cardioprotective effect, it has paradoxical effect in these patients with endothelial dysfunction changes and increased cardiovascular risk and mortality with high significant correlation to kidney function.

Keywords: Rheumatoid arthritis; Renal dysfunction; Endothelial dysfunction

Introduction

Rheumatoid arthritis (RA) is a very common autoimmune diseases in the population\(^1\), leads to progressive destruction of the joints. Cardiovascular diseases, primarily ischemic heart disease have been known the common causes of death in RA patients\(^2\).

A bad prognosis in patients with RA can be associated with kidney damage\(^3\). According to different studies, about 57 to 73% have kidney damage in RA\(^4\).

The occurrence of nephropathy in RA is complicated and presenting in various clinical and morphological forms\(^5\).

The development of chronic kidney disease (CKD) in RA is associated with cardiovascular pathology, while renal pathology itself is a risk factor for CVD\(^6\). Biomarkers of subclinical atherosclerosis should be studied in patients with RA to improve the assessment of cardiovascular risk and early prevention\(^7\). From these biomarkers adiponectin which is one of Adipocytokines; (adipocyte-derived cytokines regulating). Recent data proved role of these adipocytokines in the inflammation, immune response and tissue destruction and revealed several links between them and arthritis as in RA patients\(^8\).
Adiponectin, has potent anti-inflammatory properties by inhibiting pro-inflammatory TNF-α, macrophage phagocytic activity production, and myelomonocytic cell proliferation by inducing apoptosis and inducing the production of the anti-inflammatory mediators IL-10 and IL-1 receptor antagonist (IL-1RA). Although adiponectin is a potent driving force of arthritis by stimulating the production of pro-inflammatory and key mediators of destructive arthritis, IL-6 and pro-matrix metallo-proteinase-1 (MMP-1) from RA synovial fibroblasts in vitro, Ohashi N, et al.

Adiponectin may have an important role in development of endothelial dysfunction. It regulates enzymatic activity of the endothelial nitric oxide synthase (eNOS) and NO production through increasing mRNA stability, Ser1179 phosphorylation, and an association with the scaffolding heat-shock protein 90(Hsp90) molecule. In addition, it has been shown that adiponectin, by means of a phosphatidylinositol 3-kinase-dependent mechanism, stimulates, AMPK mediated phosphorylation of eNOS at Ser1179, increasing eNOS enzymatic activity. Lastly, in addition to the AMPK mechanism, adiponectin may promote endothelial cell function through expression of cyclooxygenase-2 (COX-2).

We aimed in this study to evaluate serum adiponectin level in rheumatoid arthritis patients with and without renal dysfunction and its relation to endothelial dysfunction and cardiovascular risk in these patients and effect of associated kidney damage on this risk.

It is promising to study these cardiometabolic factors and their correction in RA patients with considering the function of the kidneys.

Materials and Method

Patients

The present study was done with approval from Theodor Bilharz Research Institute and National Research Center.

52 patients ageing from 45 to 65 years with established diagnosis of RA according to the 2010 American College of Rheumatology and EULAR criteria for RA and renal dysfunction which detected by estimation of glomerular filtration rate (GFR)<90 mL/min/1.73 m2 and/or presence of positive proteinuria (not more than 3 months). All patients received stable therapy of RA more than 6 months. We exclude patients with ischemic heart disease related to other causes, diabetes mellitus, chronic kidney disease patients with estimated GFR<60 mL/min/1.73 m2 and/or positive proteinuria test for ≥ 3 months and patients with disease activity of RA DAS28 >3.2.

The RA activity index on the DAS28 scale was 2.5 [2.1; 2.9] points, the median BMI - 28.4 [25.7; 32.4] kg/m2, GFR - 92.5 [78; 100.5] mL/min/1.73 m2. We estimate hypertension in 29 (42%) RA patients with renal dysfunction, the median systolic blood pressure was 128.5 [125.5; 133.7] mm Hg, diastolic - 76.4 [72.5; 79.3] mm Hg.

All the patients receive Basic disease-modifying RA treatment e.g methotrexate with the average dose 15 [10; 15] mg per week, the average duration of treatment with methotrexate 62 [50; 84] months. 34 patients (65.5%) receive glucocorticoids with average daily dose of methylprednisolone 3.8 [2.5; 4.0] mg, the mean duration of glucocorticoid therapy 39 [29; 50] months. The hypertensive RA patients received antihypertensive treatment e.g ACE inhibitors, angiotensin II receptor antagonist, β-blockers, calcium antagonists, diuretics or combination of antihypertensive drugs. About 15 patients (28.9%) received Statins.

Study design

Main group consist of 29 (55.3%) patients with RA and renal dysfunction (median GFR 75.3 [70.3; 86.2] m/min/1.73 m2), compare group of 23 (44.7%) RA patients without renal dysfunction (median GFR 95.8 [88.6; 102.1] mL/min/1.73 m2).

Assessments

All patients were subjected to the following: history taking, full clinical examination. Height, weight, and waist and hip circumference were measured using standard approaches. We assessed disease activity for RA by the Disease Activity Score for 28 joints based on erythrocyte sedimentation rate (DAS28-ESR). C-reactive protein concentrations were determined using immunoturbidimetric methods. Standard laboratory blood tests of erythrocyte sedimentation rate, renal and liver function, hematological parameters, and glucose were performed. The GFR was estimated using the CKD-EPI formula. Cardiovascular risk was assessed by SCORE models adapted for patients without established diagnosis of RA according to the 2010 American College of Rheumatology and EULAR criteria for RA and renal dysfunction which detected by estimation of glomerular filtration rate (GFR)<90 mL/min/1.73 m2 and/or presence of positive proteinuria (not more than 3 months). All patients received stable therapy of RA more than 6 months. We exclude patients with ischemic heart disease related to other causes, diabetes mellitus, chronic kidney disease patients with estimated GFR<60 mL/min/1.73 m2 and/or positive proteinuria test for ≥ 3 months and patients with disease activity of RA DAS28 >3.2.
RA by introducing a 1.5 multiplication factor and total cholesterol/HDL cholesterol ratio according to EULAR evidence based recommendations for cardiovascular risk management in patients with RA and other forms of inflammatory arthritis. Adiponectin concentrations were measured with commercially available an enzyme-linked immuno-osorbent assay (ELISA) kit according to the manufacturer’s protocol (Ray Biotech, Inc cat, ELH adiponectin-001).

Determination of flow mediated vasodilation of brachial artery was performed based on Celermajer’s methodic. The diameter of the brachial artery was measured with 7.5 MHz transducer of Philips Evisor C to evaluate EDVD (End Diastolic Vaso-Dilatation).

Duplex scanning of extracranial carotid arteries was performed according to recommendations of the American Society of Echocardiography. Scanning was performed on Teodorbilharz research institute in the presence of pulsed color Doppler and Tissue Doppler, using linear sensors 5, 7.5 MHz and 3.5 MHz convex transducer.

**Statistical Analysis**

Data were collected and analyzed by computer program SPSS “version 17” (The Statistical Pack-age for the Social Science Program), Chicago, USA. Data were expressed as mean, SD, number and percentage. t-test was used to determine significance for numeric variables. Significance was considered according to the level of (p-value) as follows: p>0.05 = Non significant, p=0.05 = Significant, P<0.01 = Highly significant and p<0.001 = Very highly significant.

**Results**

Serum adiponectin correlates positively with duration of the disease, CRP, DAS28- ESR in both RA groups with and without renal dysfunction with higher significant correlation has been found in RA with renal dysfunction group.

The median cardiovascular risk level matched by mSCORE in RA patients with renal dysfunction was 4.4 [2.3; 5.2] % and in patients with normal renal function was 3.9 [2.2; 4.8] % (p>0.05). The majority 16 (53.5 %) of main group patients had moderate risk level {1-5} while the number of high {5} risk level patients was 4 (14%) and the number of low {1} risk level patients was 9 (32.6 %) but there was no significant differences in cardiovascular risk structure comparing with compare group (p>0.05). In 22 (76.2 %) RA females with renal dysfunction carotid atherosclerosis has been estimated as well as in 12 (52.6 %) compare group patients (p<0.05), higher prevalence of atherosclerotic plaques (AP) was significantly determined among main group patients with estimated carotid atherosclerosis (Figure 1). Regarding the number of traditional cardiovascular risk factors, the higher incidence of AP in RA patients with renal dysfunction also remained statistically significant. The majority of RA patients with renal dysfunction and carotid atherosclerosis had moderate cardiovascular risk level (Figure 2).

**Figure 1**: Estimated subclinical atherosclerosis in RA patients.

**Figure 2**: The structure of cardiovascular risk level in RA patients with renal dysfunction and estimated subclinical atherosclerosis.

The discrepancy of cardiovascular risk level and subclinical atherosclerosis manifestations may be associated with additional factors. Endothelial dysfunction was estimated in the majority of observed patients {40 patients (76.9 %)}. Regarding EDVD, it was significantly lower among the RA patients with renal dysfunction (median level 3.5 [2.0; 5.3] %) while in patients with normal renal function {5.9 [4.2; 10.5] %} (p<0.05). There was significant correlation between EDVD level and GFR (R=0.72, p<0.05) as well as
significant correlation between EDVD and SCORE level (R=-0.65, p<0.001), diastolic blood pressure (R=-0.58, p<0.05).

Median serum adiponectin level in RA patients was 16.3 [14.7; 17.9] mg/ml and significantly higher in RA patients with renal dysfunction (Figure 3) (p<0.05). Factors showed associated with increased adiponectin level, was as following GFR <90 ml/min/1.73 m2 (OR=2.11, p=0.003, 95% CI 1.56-2.12), endothelial dysfunction (OR=2.21, p=0.001, 95% CI 1.56-2.54) and glucocorticosteroid therapy (OR=1.54, p=0.001, 95% CI 1.02-1.87).

There is significant decrease of adiponectin in patients with endothelial dysfunction correction in compare to preserved endothelial dysfunction patients (15.3 % (p=0.01)) and GFR increasing on 18.2% (p=0.001) in those patients.

Discussion

Epidemiological studies in different groups demonstrate that a low serum level of adiponectin, is an independent risk factor for CVD.\textsuperscript{17}

A strong correlation between hypoadiponectinaemia and coronary heart disease has been documented in a number of studies. Two independent studies have consistently demonstrated that hypoadiponectinaemia is an independent risk factor for hypertension.\textsuperscript{18} Hyperadiponectinaemia is also an independent risk factor for diabetic cardiomyopathy.\textsuperscript{19}

Many studies first suggested that adiponectin is a protective molecule for myocardial infarction and coronary artery disease,\textsuperscript{20,21} while other larger group of studies have clearly indicated that low serum adiponectin concentrations do not predict future cardiovascular events. In a study carried out in more than 250,000 individuals, there is no association between adiponectin-increasing alleles and reduced risk of coronary heart disease.\textsuperscript{20}

Recently, it was reported that adiponectin levels seem to predict cardiovascular mortality in a sex-specific manner, with the paradoxical effect being observed in men but not women.\textsuperscript{19} This is not found in our study on RA patients whether males or females.

In this study there is association between high serum adiponectin concentration and increased cardiovascular risk and then mortality rate in RA patients especially with renal dysfunction. This indicates that under some chronic inflammatory conditions, adiponectin, rather than being an anti-inflammatory factor, exacerbates inflammation in several tissues and cell types so operating during low-grade chronic inflammation characterizing CVD. This may explain the adiponectin paradox on CVD risk and mortality that is found in patients with RA with or without renal dysfunction with unexpected association of high adiponectin level and increased CVD risk.

In our study, increased frequency of carotid atherosclerosis, including AP presence with instability signs was observed in RA patients especially those with renal dysfunction. However, the majority of these patients had established renal dysfunction and moderate cardiovascular risk level. High adiponectin level was found and in spite of its cardioprotective effect, it has paradoxical effect in these patients with endothelial dysfunction changes and increased cardiovascular risk and mortality. And this agree with what suggested by Otero, et al. that adiponectin role in RA is controversial.\textsuperscript{21} Also in this study, high significant correlation to kidney function was found.

As regarding, endothelial dysfunction, it was associated with increased adiponectin level and this indicates a complex relationship between muscle and adipose tissue exchange. Present study shows that the endothelial dysfunction correction in RA patients with renal dysfunction may cause benefit effects on range of cardio-metabolic factors.

These results support the need for RA specific cardiovascular risk stratification models with the consideration of renal function, potentially, the use of novel CVD risk biomarkers. The study results reinforce the need for more awareness in daily clinical practice of increased cardiovascular risk in RA patients with renal dysfunction.

In fact, several epidemiological data wonder about the anti-inflammatory and cardioprotective effects of adiponectin described in basic studies and disappointment cast doubts on adiponectin as a promising therapeutic target. Much has been done on adiponectin, but more has to be done.

Abstract

Introduction: One of the evolving defects in acute myeloid leukemia (AML) is the BCR/ABL fusion which is the trigger of chronic myeloid leukemia (CML). Differentiating Ph +ve AML from CML in blast crisis is an ongoing challenge. In our study, we tried to differentiate between both categories and determine the prevalence of this rare entity as well as its clinical and laboratory features.

Patients and Method: We enrolled in our study 175 patients from the National Cancer Institute, Egypt; Conventional Karyotyping and qualitative RT PCR for BCR/ABL fusion proteins were done for all the patients. Positive cases were confirmed by FISH.

Results: Five/175 patients were shown to have BCR/ABL translocation with an incidence of 2.8%. Four out of the five cases were having fusion protein p210 by RT PCR, while the fifth case was having neither p210 nor p190. Most criteria of differentiation were intermingling together.

Conclusion: Further studies should be done to confirm or exclude this provisional entity. Moreover, introduction of BCR/ABL analysis in the routine may be a useful tool for introducing TKIs in these patients, which may improve the survival.

Key words: BCR/ABL, Ph +ve AML, qualitative RT PCR.

Introduction

Acute myeloid leukemia (AML) is characterized by the expansion of a clone of myeloid blasts in the peripheral blood and the bone marrow\textsuperscript{1} reducing the normal blood cells\textsuperscript{2}. AML involves single or multiple myeloid lineages\textsuperscript{3} due to the accumulation of many genetic defects in hematopoietic progenitor cells\textsuperscript{4}.

The Philadelphia chromosome (ph) is the cytogenetic hallmark of chronic myeloid leukemia (CML) and it corresponds to the BCR/ABL rearrangement. Also, it is present in high-risk acute lymphoblastic leukemia (ALL)\textsuperscript{5}. BCR/ABL proteins lead to an unbalanced activated cell cycle even without growth factors\textsuperscript{6} leading to oncogenic effects\textsuperscript{7}.

During the previous years, many data in the literature favors the presence of Ph +ve, AML, which is now included as a new provisional entity in the 2016 revised WHO classification of hematopoietic malignancies\textsuperscript{8}.

BCR-ABL1 has been described in AML together with other recurrent genetic abnormalities\textsuperscript{8,9,10}. While according to the WHO, Ph +ve AML is a de novo AML in patients with no history of CML and don’t meet the criteria of neither mixed-phenotype acute leukaemia nor other AML subtypes\textsuperscript{3}. Also, late acquisition of BCR-ABL1 fusion on top of pre-existing AML has also been reported and should not be diagnosed as AML with BCR-ABL1\textsuperscript{11}.

Some authors stated that AML with BCR-ABL1 accounts for 0.5-3.0% of all AML cases\textsuperscript{5,12}. Most cases demonstrated the p210 fusion, while p190 transcripts were encountered in a minority\textsuperscript{3}. However, a case with p230 fusion was reported\textsuperscript{13}.

Since AML with BCR-ABL1 appeared to be an aggressive disease and have a poor response to the
traditional AML therapy or to tyrosine kinase inhibitor therapy alone\textsuperscript{3,14}, it is better to be treated with tyrosine kinase inhibitor therapy followed by allogeneic haematopoietic cell transplantation\textsuperscript{15}.

We aimed to determine the prevalence of the BCR-ABL fusion gene in AML cases with determination of the clinical and laboratory criteria of these cases.

**Subjects and Method**

In our study, 175 de novo AML patients were enrolled, with no previous history of any haematological disorder. They presented to the outpatient clinics in the National Cancer Institute between March 2016 and January 2018. All the patients were subjected to clinical and routine laboratory work up for the suspected AML patients, and the diagnosis of AML was based on WHO criteria analysis.

**RNA extraction and cDNA formation**

Total RNA was extracted from K-EDTA preserved BM cells using QIAamp RNA extraction blood Mini kit (QIAGEN® Austin, Texas, USA catalogue no.52304). Then complementary DNA (cDNA) was prepared from RNA by High Capacity cDNA Reverse Transcription Kit (Applied Biosystems, Thermo Fisher Scientific, USA; catalogue no. 4368814). Finally, cDNA purity and concentration was evaluated using spectrophotometer nano-drop (Quawell, Q-500, Scribner, USA) and used in qualititative RT PCR. All the procedures were done according to the manufacturer’s instructions.

**Qualitative detection of BCR/ABL fusion transcripts (p210 & p190):**

**Reagents:**

1-One PCR™ HotStar mix (Genedirex; Cat. No. MB206-0100):
2- Primers for RT PCR analysis of t(9;22)(q34;q11) with the BCR-ABL p210 and p190 fusion genes [16] (Table 1).

Stock primer solution was prepared using TE buffer, then a final working primer solution with final concentration of 10 pmol/µl.

PCR reaction was performed under laminar flow cabinet using a mixture of forward primer, reverse primer, master mix, cDNA and distilled water. The tube was centrifuged briefly, then placed in the Biometra thermal cycler for 35 cycles according to the manufacturer protocol.

The amplified products were detected by agarose gel electrophoresis with subsequent examination and photographing in UV epi-illuminator as shown in figure (1).

![Figure (1): Ethidium bromide-stained agarose gel electrophoresis for 16 AML cases; +ve:Positive control, L:ladder, lane(9):showing one BCR-ABL + AML with p210 b3–a2 transcript, lanes(1-8, 10-16):BCR-ABL negative AML cases.](image-url)
Interpretation of the results:

Interpretation was done. For p210, M-bcr breakpoints resulted in different sizes of PCR products were visualized at 417, 342, 243, or 168 bp for the fusion transcripts b3–a2, b2–a2, b3–a3 and b2–a3 respectively. For p190, the sizes of PCR products were expected at 521 or 347 bp, which corresponds to e1-a2 and e1-a3, respectively [16].

Statistical Methods

Survival analysis was done using Kaplan-Meier method. Comparison between two survival curves was done using log rank test.

Results

Patients were 93 males (53.1%) and 82 females (46.9%) with a male to female ratio of 1.13:1. Five/175 AML cases (2.8%) were found to have BCR/ABL fusion gene. All the cases were confirmed by Karyotyping and FISH analysis as shown in figure(2). However by conventional PCR and gel electrophoresis, only 4 cases were having p210 fusion gene while the 5th case was having neither p210 nor p190 fusion genes.

The demographic, clinical characteristics and laboratory data are shown in table(2).

BCR/ABL survival analysis

Regarding the OS, there was no statistically significant influence of BCR/ABL fusion gene on the OS of the AML patients with p value = 0.699 (Table 3). The DFS of the BCR/ABL positive AML patients wasn’t evaluated due to small sample size.

Figure (2): Examples of BCR/ABL translocation in the different cases;

**Discussion**

During the past years, there was an increasing number of data favoring the existence of Ph +ve AML. Many researchers reported its incidence from 0.5 to 3%.

Differentiation between Ph +ve AML and acute blastic crisis on top of CML is an ongoing challenge; however, no single clinical or hematologic feature distinguishes Ph +ve AML from CML blast crisis.

In our study, 5/175 AML patients were having Philadelphia chromosome in the karyotype and BCR/ABL fusion by FISH carrying an incidence of 2.8%; Four out of the five cases were having fusion protein p210 by conventional RT PCR, while the fifth case was having neither p210 nor p190. We attributed this result to the occurrence of a rare form of BCR/ABL translocation rather than p210 or 190.

Moreover, similar to the previous studies, all our patients had an acute course with no history of previous CML or antecedent hematologic disorder and none of our patients had dwarf megakaryocytes which are one of the hallmarks of CML.

All the 5 patients were having the FAB subtype AML M2, which is the most prevalent subtype among Ph +ve AML cases, and none of our patients was having recurrent cytogenetic abnormality, which goes with the WHO definition.

Patients with de novo Ph-positive AML are less likely to have additional chromosomal abnormalities compared to patients with CML with blast crisis (approximately 20% vs 80% respectively). However one study has reported more frequent additional cytogenetic abnormalities in the Ph +ve AML cases (55% to 57%). Similar to the literature, only 1 patient in our study (20%) had an additional cytogenetic abnormality (deletion 19p) which is also not characteristic to CML and favored the diagnosis of Ph +ve AML.

Two of our patients were having an extra Philadelphia chromosome which is one of the common additional cytogenetic abnormalities in CML, while it also occurred in about 2/9 and 2/16 of Ph +ve AML in previous studies. And this may be due to the less number of Ph +ve AML cases in our study, compared to the previous studies.

All the 5 cases are exhibiting wild forms of NPM1, which is reported to be mutant in 22% of Ph +ve AML rather than CML. However this difference may be due to the small sample size.

Commonly, Ph +ve AML patients also tend not to have splenomegaly or have only mild splenomegaly at presentation, lower incidence of basophilia and normal M:E ratio compared to patients with CML. However, these criteria were not typical for our patients, where 3 out of the 5 patients had splenomegaly. One case was having 11 basophils in the BM, 1 was having no basophils and the resting 3 cases ranged from 2 to 4 basophils.

Only the case which received a combination of chemotherapy with TKIs was still alive till the end of the study. The median survival time of the 5 positive cases was 2.9 months, setting the disease as a high risk AML when treated with either chemotherapy or TKIs alone.

The different discriminative criteria are shown in table (4). To summarize, the common criteria in all the cases were the absence of H/O of CML or any antecedent hematological disorder, like all the previous studies collectively, as well as the absence of dwarf megakaryocytes. However the other criteria are
intermingling together with no sharp cutoff. Further studies should be done to confirm or exclude this provisional entity.

**Conclusion**

Ph+ve AML is still a rare provisional category with no sharp cut off with the CML in blast crisis. Further studies should be done to confirm or exclude this entity and setting a treatment protocol to improve the prognosis.

**Funding**

This work is submitted in partial fulfillment of the requirement for the Medical Doctorate degree in the National Cancer institute, Cairo University, Egypt, and was funded from the same University.

**Ethical Clearance:** This study was approved by the ethical committee, review board of NCI, Cairo University in accordance with Helsinki guidelines. Written informed consent was obtained from all adult patients and from guardians of pediatric patients.

Early Outcome of Tricuspid Valve Repair Using Prosthetic Ring Annuloplasty versus Suture Annuloplasty

Mahmoud M. El-Zayadi¹, Mohamed Abul-Dahab Mahmoud², Abdullah Osama, Ashraf Helal³

Cardiothoracic Surgery Department, Faculty of Medicine, Cairo University, Egypt

Abstract

The purpose of this study is to compare the early outcome of tricuspid valve repair using prosthetic ring annuloplasty versus suture annuloplasty. Methods: In the period between March 2016 and September 2017, 40 patients with severe functional tricuspid regurgitation (TR) secondary to rheumatic mitral with or without aortic valve pathology divided into two equal groups underwent open heart surgery at Kasr Al-Aini Hospitals, Cardiothoracic surgery department. Group (1) had tricuspid valve repair using suture annuloplasty, while Group (2) had tricuspid valve repair using prosthetic ring annuloplasty. All patients were evaluated thoroughly preoperative, intra-operative, and post-operative. Particular attention was paid to clinical and echocardiographic findings of presence of tricuspid regurgitation (TR), its nature and degree, postoperative intensive care unit (ICU) events, ICU stay, hospital stay and follow up of the degree of TR post-operatively. Results: Evaluation showed that there is no significant difference between results of suture annuloplasty and prosthetic ring annuloplasty early postoperative, while late postoperative studies had proven significantly better outcomes with prosthetic ring annuloplasty than with suture annuloplasty techniques concerning low rate of recurrent TR. Conclusion: we concluded that using prosthetic ring for tricuspid valve repair was better than suture annuloplasty techniques as it was associated with less frequent rates of late postoperative recurrent TR.

Key words: Tricuspid regurgitation, Tricuspid valve repair, prosthetic ring, suture annuloplasty.

Introduction

The most common cause of Tricuspid regurgitation (TR) in adults is functional Tricuspid, as leaflets and chords are morphologically normal, but with right ventricular enlargement and dilatation with flattening of the tricuspid annulus. Distorted relation between leaflets, chords, and papillary muscles leads to leaflet tethering which prevents proper leaflet coaptation and increases valve regurgitation.¹

TR is commonly found in many patients undergoing left-sided heart valve surgery. Recent studies showed that TR is important to determine and surgically correct as significant TR usually does not improve after left-sided heart valve surgery and may also progress.²

Another important issue is choosing an appropriate technique for tricuspid valve repair. Many studies showed better long-term results with prosthetic ring repair³, while other studies showed better results with suture annuloplasty techniques⁴.

Patients and Method

Study Patients

This is a prospective, randomized, comparative clinical study done at cardiothoracic surgery department, Cairo University hospitals, in a period between March 2016 and September 2017. The study was conducted on 40 patients who underwent tricuspid valve surgery for repair of severe functional TR secondary to rheumatic mitral with or without aortic valve pathology. In all patients, left sided lesions were corrected during the same surgical procedure before tricuspid valve repair. In all patients, tricuspid valve repair was performed using annuloplasty techniques. Patients with organic tricuspid valve affection whatever the etiology were excluded.

Patients were allocated in one of two groups: group (A): 20 patients underwent tricuspid valve repair using suture annuloplasty, while in group (B): 20 patients underwent tricuspid valve repair using prosthetic ring annuloplasty (Edwards MC3 ring).

The grade of TR was evaluated by using transthoracic echocardiography (TTE) at resting conditions preoperatively. Baseline characteristics of the population are presented in Table 1. Each patient signed an informed consent form.

Clinical study end points

The end points of the study were to evaluate and compare suture annuloplasty versus prosthetic ring annuloplasty in repair of severe functional TR.

Study procedures

Echocardiography was performed at baseline, postoperatively in hospital, then in outpatient clinic 6 months after surgery for all patients in both groups. The severity of TR was assessed by means of TTE, M mode, two dimension and Doppler echocardiography.

Surgical procedures:

Suture annuloplasty was performed by standard operative techniques using either DeVega annuloplasty, modified DeVega annuloplasty and segmental annuloplasty.

Prosthetic ring annuloplasty was performed using Edwards MC3 ring.

Statistical Analysis

Data were collected, coded, translated to English to facilitate data manipulation and double entered into Microsoft Access and data analysis was performed using SPSS software version 18 under windows 7.

Simple descriptive analysis in the form of numbers and percentages for qualitative data, and arithmetic means as central tendency measurement, standard deviations as measure of dispersion for quantitative parametric data, and inferential statistic test:

For quantitative parametric data :

In-depended student t-Test used to compare measures of two independent groups of quantitative data

Paired t-test in comparing two dependent quantitative data.

For qualitative data

Chi square test to compare two of more than two qualitative groups.

Mc-Nemartest for paired dependant qualitative data.

The level P ≤ 0.05 was considered the cut-off value for significance.

Results

The preoperative demographics, clinical and echocardiographic characteristics are shown in (Table 1).

Means ± standard deviation or number (percentage) as shown. NYHA class= New York Heart Association functional class of dyspnea, MV= Mitral valve, AV= Aortic valve, TR= Tricuspid regurgitation, PASP= Pulmonary artery systolic pressure, RV= Right ventricle, LA= Left atrium, LVEDD= Left ventricle End diastolic diameter, ESD= End systolic diameter, EF= Ejection fraction. N.B: Pulmonary hypertension= Preoperative PASP (> 40 mm Hg).

Operative Data:

No differences were noted between two groups concerning intraoperative data with the exception of cardiopulmonary bypass (CPB) time and aortic cross clamp time (P <0.05) with high mean among 2nd group as depicted in table (2).

Postoperative Data:

Table (2) shows mean values for total period of mechanical ventilation, total ICU stay and hospital stay between both study groups. All differences were insignificant.

Table (2) also depicts the post-operative complications among patients in the two studied groups. All differences were insignificant, but we can notice that there was a case of postoperative bleeding that needed re-exploration in the 1st group and another 2 cases complicated with postoperative heart block and needed a permanent pacemaker occurred in the 2nd group.

Early Mortality and Outcome

There was no evidence of in-hospital (<30 days) mortality between study groups.

**Follow up (6 months duration):**

Clinical results

Significant reduction in preoperative symptoms of right-side heart failure was noticed in all patients. NYHA class was improved (from 3.3 to 1.25) and (from 3.4 to 2.2) in 1st and 2nd groups, respectively.

N.B: Mean postoperative values measured from in-hospital period till 6 months after discharge.

**Echocardiographic results:**

Postoperative follow up revealed good function of the mitral and aortic valves. After surgical intervention, left atrial and left ventricular dimensions were decreased in all patients, as well as PASP, which was decreased significantly from baseline (p < 0.05). Right ventricular dimension decreased significantly without difference between both groups.

Figure (1) shows the severity of TR after tricuspid valve repair. All annuloplasty types were efficient at reducing TR. Mean TR grade differed significantly at last follow-up between both groups (p < 0.01). Also, TR degree became worse in 1st group.

Figure (1): Severity of tricuspid regurgitation (TR) after tricuspid valve repair: (A) at discharge; (B) at follow-up.

Discussion

The ideal management of tricuspid valve disease is still controversial. Most of the patients have normal valve leaflets and a coaptation defect is related to annular dilatation. Surgical repair was directed mainly towards annular or commissural level, so there is a debate on repairing tricuspid valve using either suture or prosthetic ring annuloplasty techniques.

Among the suture annuloplasty techniques, De Vega annuloplasty is the most commonly used technique as it preserves the anatomy and flexibility of the annulus while being also easy, fast and more cost effective.

Some series have showed good short-term and long-term outcomes of De Vega annuloplasty, while other authors have denied these results due to high prevalence of recurrent postoperative TR at follow-up, especially when there is pulmonary hypertension and severe tricuspid annular dilatation.

Annuloplasty with a prosthetic ring was considered a solution to recurrent TR of suture annuloplasty techniques.

Significant correlation between degree of elevation of pulmonary artery pressure and the severity of tricuspid regurgitation was found. These results were similar to the results obtained by Mutlak et al.

Intraoperative exploration of the tricuspid valve revealed that leaflets are thin and normal and subvalvular apparatus is normal and redundant, but the annulus is dilated in all patients (100%) proving functional etiology as stated by Brest and Navia JL et al.

The use of prosthetic ring for tricuspid valve repair resulted in longer durations of CPB time and significantly longer cross clamp time. This is similar to the results obtained by Xinsheng Huang et al.

There is statistically significant difference as regards duration of mechanical ventilation with low mean among 2nd group, otherwise there is no statistical significance between study groups in the duration of ICU and hospital stay. This reflects the efficacy of both techniques in proper management of severe TR in early post-operative period.

In our study, comparison between suture annuloplasty group and prosthetic ring annuloplasty group in the follow-up period showed that improvement in left sided manifestations was highly significant for functional class of dyspnea with no statistical significance between values in both groups (p>0.05) reflecting adequate left sided lesions correction. These results were similar to the results obtained by Xinsheng Huang et al.

Also the improvement in right sided manifestations was highly significant with no statistically significant difference between values in both groups (p>0.05) reflecting adequate right sided lesions correction. These results were also similar to the results obtained by Xinsheng Huang et al.

On the other hand, PASP decreased significantly in both groups after 6 months. Xinsheng Huang et al. also reported a significant reduction in PASP from baseline in both groups (p < 0.05) during follow up period.

Color Doppler flow mapping is useful in evaluating the adequacy of repair. It accurately predicts the presence and severity of any residual TR early and late postoperative.

In our study, recurrence of TR was detected by echocardiography in 3 of the suture annuloplasty group of patients during the 6 months follow-up period. This may be due to occurrence of suture cut-through the tricuspid annulus (string- sign) during cardiac contraction. The previously-mentioned explanation for the early-term failure of suture annuloplasty repair was also endorsed by different surgeons.

Prosthetic ring repairs are better than other mentioned techniques, since, theoretically, the artificial ring takes tension away from the suture line and prevents recurrent annular dilatation. As residual TR after surgical repair can lead to biventricular failure, death or reoperation, the choice of repair should be founded mainly on the recurrence rate of the procedure.

Our study revealed that tricuspid valve repair using suture annuloplasty had been associated with
encouraging clinical results for treating functional TR, but postoperative follow up evaluation had suggested lack of uniform success. Recurrence rates with De Vega annuloplasty appear to be higher than those with prosthetic ring repair. Conclusion

After assessing all our results, it is evident that prosthetic ring annuloplasty is associated with good results compared with suture annuloplasty techniques as it protects from late recurrence of TR after surgery.

PI-RADS V2 as a Prostate Cancer Detectability Tool is it Dependable for Usage in Diagnosis?

Hisham Adel Abdel Fatah Mostafa1, Sameh Abdel Aziz Zaki Hana1, Mohamed Salah El Din Abdel Azeem2, Sherif Fathy Abdel Rahman1, Ahmed Abdel Samie Mahmoud1

1Radio Diagnosis Department, Faculty of Medicine, Cairo University, Cairo, Egypt, 2Uro-Surgery Department, Faculty of Medicine, Cairo University, Cairo, Egypt

Abstract

Background: Prostate Imaging Reporting and Data System (PI-RADS) is a scoring system that aims to enable consistent interpretation, communication, and reporting of prostate multiparametric MRI (mpMRI) findings.

Aim: To evaluate and investigate the upgrade of the multi-parametric MRI prostate besides the role of PI-RADS as a reporting and grading system in prostatic diseases.

Methodology: A clinical research trial conducted on 52 male study subjects having prostatic symptoms (from February 2015 till October 2016), the research was conducted within the radiology department of the Kasr AL-Ainy hospitals, and Egyptian national cancer institute. Cases recruited were referred from the Outpatient clinics of the urology department.

Results: All cases 100% of pathologically proven carcinoma were suspected to be in the peripheral zone by MRI, with T2 scoring PI-RADS 3 were 8 cases (24.2%), PI-RADS 4 were 12 cases (36.4%) and PI-RADS 5 were 13 cases (39.4%). Only 3 cases had mild hemorrhage after TRUS guided biopsy with no major symptomatic adverse effects noted.

Conclusions: Multi-parametric MRI prostate is cornerstone advanced tool for diagnosis and gives better results in the diagnosis of prostatic diseases. PI-RADS is an efficient way to help in the diagnosis that will result resulting in better management and aids in guiding TRUS biopsy for better visualization of lesions pre-biopsy leading to more precise biopsy and accurate diagnosis.

Keywords: Prostate Cancer, PI-RADS V2, Multi-parametric MRI prostate

Introduction

Technological advances in MRI imaging procedures lead to the evolution of multiparametric MRI (mpMRI), that integrates anatomic T2W with functional and physiologic evaluation, involving diffusion weighted imaging (DWI) and its derivative apparent diffusion coefficient (ADC) maps, dynamic contrast enhanced (DCE) MRI, and sometimes other techniques e.g in-vivo MR proton spectroscopy. Technological1,2,3

MpMRI includes morphological (T2-weighted Imaging, or T2WI) and functional imaging (Diffusion Weighted Imaging (DWI), Dynamic Contrast and Enhanced (DCE). While the performance of the individual sequences is being investigated, and the acquisition techniques are being refined, integration of mpMRI into the clinical practice has been challenging due to the lack of consistent approaches for assessing mpMRI and reporting of the clinical findings. 4, 5, 6
Prostate Imaging Reporting and Data System (PI-RADS) is a scoring system that aims to enable consistent interpretation, communication, and reporting of prostate multiparametric MRI (mpMRI) findings.\(^7\)\(^8\)

**Aim of the work.**

To evaluate and investigate the upgrade of the multiparametric MRI prostate besides the role of PIRADS as a reporting and grading system in prostatic diseases.

**Methodology**

A clinical prospective research study conducted on 52 male study subjects having prostatic symptoms (from February 2015 till October 2016), the research was conducted within the radiology department of the Kasr AL-Ainy hospitals, and Egyptian national cancer institute. Cases recruited were referred from the Outpatient clinics of the urology department.

Inclusive research criteria involved; Male patients having abnormal prostatic symptoms or raised value of PSA >4-6ng/ml. Exclusive research Criteria involved the following cases subjected to prostatic adenomectomy (open adenomectomy or TURP), impaired renal functions, presence of anal complications or rectal mass, refusal of examination, bleeding tendency.

All research study subjects recruited have undergone the following procedures:

Full relevant clinical examination, multiparametric MRI assessment, Cases having MR findings of suspicious prostatic carcinoma or high PSA >4-6ng/ml (according to their age) had further conventional B-mode sonographic examination and trans rectal biopsy.

**Equipment used:**

Multiparametric MRI prostate have been performed using high field strength 1.5 and 3 Tesla on Signa system (Philips Intera) using dedicated pelvic phased array coil. TRUS and biopsy was conducted under guidance of a digital sonographic scanner (EUB-7500; Hitachi medical, Tokyo, Japan). By placing a high frequency (7.5 MHz) endorectal end-fire probe in close proximity to the prostate.

**Techniques:**

**MR imaging protocol**

Fast <30-min protocol without an endorectal coil (ERC). Images on entire prostate as well as include T2WI, DWI and DCE-MRI. sequences are done at 1.5 T using a good 8- to 16-channel pelvic phased array (PPA), T2WI axial+ sagittal: 4mm at 1.5 T, 3mm at 3 T; in plane resolution: 0.5×0.5 mm to 0.7×0.7 mm at both 1.5 T and 3 T, DWI axial: 5mm cuts at 1.5 T, 4mm cuts at 3 T; in-plane resolution: 1.5×1.5mm to 2.0×2.0 mm at 1.5 T & 1.0×1.0mm to 1.5×1.5mm at 3 T. The ADC map should be calculated. At least 3 b-values should be acquired in three orthogonal directions and adapted to quality of SNR: 0, 100 and 800–1000s/mm2. For calculation of ADC, the highest b-value that should be used was 1000 s/mm2,DCE-MRI axial: 4mm at 1.5 T and 3 T; in plane resolution: 1.0×1.0mm at 1.5 T and 0.7×0.7mm at 3 T. concerning Quantitative or semi-quantitative DCE-MRI analysis is not essential to be performed. Maximum temporal resolution should be 15 s following single dose of contrast agent with an injection rate of 3mL/s. For DCE-MRI, imaging acquisition was continued for 5 min to detect washout. Unenhanced T1WI images from this sequence was used for detection of post-biopsy hematomas.

**Conventional TRUS**

In the beginning prostatic lesions were assessed using conventional B-mode sonographic examination. Optimal evaluation of the prostate gland by TRUS requires images in multiple planes, involving transverse, sagittal, and oblique, special attention was paid to the symmetry and echogenicity of the PZ. Cancer was only suspected when the PZ architecture was observed to be distorted.

**Histopathologic Diagnoses:**

Lesions were biopsied by US guided interventional procedures by true cut needle biopsy (via 22-gauge spinal needle). Imaging findings were correlated to sextant prostate biopsies and targeted biopsies on suspicious areas and 10-12 systemic core biopsy in equivocal cases. Pathological analysis of prostatic lesions samples was conducted within the pathology department of Kasr AL-Ainy and at the Egyptian National Cancer Institute by group of well-trained expert histopathologists.

**Statistical Analysis**

Research Data were coded and entered by usage of the statistical package SPSS (Statistical Package for the Social Sciences) version 23. Obtained research data have been summarized using frequency (count) and relative
frequency (percentage) for categorical research data. For comparing categorical research data, Chi square test was implemented. Exact test was used instead when the expected frequency is less than 5. P-values less than 0.05 were considered as statistically significant.

Results

Current research study had a cohort of 52 patients.

After TRUS biopsy, Pathological correlation showed 33 cases to have a prostatic carcinoma (figure 1), 17 patients with benign prostatic hyperplasia (figure 2) and 2 cases had prostatitis (figure 3).

As regards benign prostatic hyperplasia cases, central and transitional zone T2 highest PIRADS were PIRADS 3 in 3 cases (17.6 %) while peripheral zone highest PIRADS were PIRADS 4 in 2 cases (11.8% ) as represented in table (3), 2 cases of prostatitis (100%) were included in our study their results showing peripheral zone lesions with T2 PIRADS grading III.

All cases 100% of pathologically proven carcinoma were suspected to be in the peripheral zone by MRI, with T2 scoring PIRADS 3 were 8 cases (24.2%), PIRADS 4 were 12 cases (36.4%) and PIRADS 5 were 13 cases (39.4%). Only 3 cases had mild hemorrhage after TRUS guided biopsy with no major symptomatic adverse effects noted.

Fig (1) 75 years old patient presented with urinary hesitance and difficult micturition and increased PSA level. (a) Axial T2W reveals right ill-defined hypointense lesion PIRADS 4 (blue arrow), evidence of bone metastatic lesion “red arrow” (b) dynamic images reveal early homogeneous enhancement of the lesion. (c& d) DWI and ADC mapping showing a restricted pattern of diffusion PIRADS grade V. TRUS guided biopsy was done and pathology showed: Prostatic carcinoma.
Figure (2): Sixty-two years old patient presented with history of prostatic manifestations as difficult and frequency in micturation. (a) Axial T2WI showing rather homogeneous peripheral zone with no definite lesions, enlarged central zone with well marginated areas giving PIRADS 1 for peripheral zone and PIRADS 2 for central zone. (b) Post contrast enhancement reveals diffuse homogenous enhancement of the central and peripheral zones. (c & d): Diffusion and ADC mapping reveal normal signal with no areas of restricted diffusion PIRADS 1. TRUS: No definite sizable focal lesion enlarged central zone with well-defined margins. Biopsy revealed BPH with no neoplastic features.

Figure (3) Fifty-one years old patient presented with burning micturition. (a& b): T2WI showing right peripheral zone well-defined iso to low signal lesion PIRADS 3 (blue arrows) while its curve shows plateau curve (type II). (c & d): Diffusion and ADC mapping reveal suspected focus of low ADC signal with normal surrounding signal of the right peripheral zone PIRADS 3 (blue arrows). TRUS: A well-defined right iso-to hypoechoic focal lesion, enlarged central zone with cystic foci. Biopsy proved prostatitis.

Discussion

Prostate cancer is the 2nd most common cancer worldwide for males, and the 5th most common cancer overall. 9,10

Multi-parametric magnetic resonance (MR) imaging uses anatomic and functional imaging techniques for proper evaluation of the prostate.11,12

MR imaging is nowadays playing a role in the clinical pathways of detection, local staging, active surveillance, and posttreatment follow-up. 13,14

In our study we were aiming to discuss the role of PIRADS system as a diagnostic tool for proper
interpretation with better results and outcomes as well as better localization of prostatic lesions and determining their nature.

Our study included 52 cases from them 33 patients pathologically proven to have prostatic carcinoma, 17 patients with benign prostatic hyperplasia and 2 cases with prostatitis.

2 cases of prostatitis was included in our study their results showing peripheral zone lesions with PIRADS grading III (clinically significant disease is equivocal) with pathology showed prostatitis and the follow up MRI for one of them showed resolution of the lesion.

The individual T2W PIRADS analysis for carcinoma cases showed specificity 24.2% for diagnosis of equivocal carcinoma (grade III) and 36.4% for grade IV (clinically significant cancer is likely to be present) and 39.4% for grade V (clinically significant cancer is highly likely to be present).

Higher specificity results on combining T2W and diffusion PIRADS analysis showing that 54.5% for diagnosis of grade IV (clinically significant cancer is likely to be present) and 39.39 % for grade V (clinically significant cancer is highly likely to be present).

Overall PIRADS analysis for carcinoma cases showed specificity 54.5% for diagnosis of grade IV (clinically significant cancer is likely to be present) and 39.39 % for grade V.

The current research study results revealed and displayed that there was the similarities in findings between overall PIRADS and combination of T2W and diffusion, as overall PIRADS depending on diffusion sequence mainly only when diffusion results grade III we use dynamic with a positive dynamic add to higher staging grades and that occurred in our 2 cases of prostatitis was included in our study their results showing peripheral zone lesions with PIRADS grading III (clinically significant disease is equivocal) with pathology showed prostatitis and the follow up MRI showed resolution of the lesion.

PIRADS T2W sequences alone showed higher sensitivity but lower specificity but still it is the golden sequence for anatomical view and description for peripheral zone lesions and it has very important role in cases with benign prostatic hyperplasia.

Furthermore, prior research studies similar to the current study in approach and methodology have shown that overall staging of prostate cancer using T2-weighted magnetic resonance (MR) imaging at 1.5 T had statistical specificity values that ranged from 67% to 87%.1,3,6

In harmony to the current research study a prior research group of investigators have implemented T2W, DW, DCE, and MRS imaging protocols, have revealed and displayed among their findings that the positive predictive values (PPVs) for multiparametric MRI’s detectability of prostate cancer in the overall prostate, PZ, and CG to be 98%, 98%, and 100%, consecutively.4,7,9

Furthermore, it was previously shown that integration of T2WI, DWI, and DCE imaging was statistically significantly better regarding PZ tumor detection than either T2WI+DWI or T2WI alone.2,10

Prior research studies evaluating and assessing the addition of DWI to T2WI for the accuracy of prostate cancer detection, determined that DWI+T2WI was significantly more sensitive throughout the whole prostate compared to T2WI alone and was significantly more accurate in the PZ.11,13

Conclusions

Multi-parametric MRI prostate is cornerstone advanced tool for diagnosis and gives better results in the diagnosis of prostatic diseases. PIRADS is an efficient way to help in the diagnosis that will result resulting in better management and aids in guiding TRUS biopsy for better visualization of lesions pre-biopsy leading to more precise biopsy and accurate diagnosis. Guidelines with recommendations on prostate MR imaging should be further implemented in clinical routine.

Antiatherogenic Effect of L-Arginine in Streptozotocin-Induced Diabetic Rats

Omnia Aly, Ehsan Badawy and Hanan Hassan Zaki

Department of Medical Biochemistry- National Research Centre, Cairo Egypt.

Abstract

L-Arginine is one of the essential amino acids elaborated in numerous areas of human physiology which produce nitric oxide (NO). Current study was designed to examine the antiatherogenic and anti-diabetic activities of L-arginine in experimental diabetic rats’ model. Fifty rats were divided into; Control group, L-Arginine group, Diabetic group, Treated group and Prophylactic group. Fasting blood samples were collected from all groups for determination of fasting blood glucose, insulin, insulin resistance, atherogenic index (AI), cardiac risk ratio (CRR), atherogenic coefficient(AC), intercellular adhesion molecule-1 (I-CAM-1), tumor necrosis factor alpha (TNF-α), and nitric oxide (NO). The result showed that oral administration of L-arginine induced significant decrease in the plasma level of I-CAM-1, TNF-α, AC, AI, CRR, glucose, and insulin resistance while induced significant increase in NO, and insulin levels in the treated group . In conclusion, L-arginine may be a novel nutrient, which improves the endothelial function and protects against the development of atherosclerosis in diabetic rats.

Key words: Diabetes, TNF-α, I-CAM-1, L-arginine, Atherogenic Index.

Introduction

Endothelial dysfunction plays a critical role in atherosclerosis and cardiovascular complications in diabetic patients.

The occurrence of both decreased high-density lipoprotein cholesterol (HDL-C) and increased serum triglyceride (TG) levels were referred to as Atherogenic dyslipidemia which was an important risk factor for the development of coronary artery diseases. A new indicator of atherogeneity called atherogenic index of plasma (AIP) which increased significantly with atherogenic risk.

Inflammation and oxidative stress were responsible for tissue damage in diabetic patients. There were high levels of pro-inflammatory cytokines such as interleukin-1β (IL-1β), 5-lipoxygenase (5-LOX) and (TNF-α) in diabetic patients with insulin resistance triggered by free radicals as a result of hyperglycemia. TNFα has a specific role in the development of vascular dysfunction which can be considered as another risk factor for CVD.

The endothelial I-CAM-1 is an important intercellular adhesion molecules that are involved in atherogenesis, whose expression leads to migration and attachment of leukocytes into the vessel wall. This is an early lesion of atherogenesis. TNF-α, several inflammatory mediators, and oxidized LDL induce release of ICAM-1 from endothelial cells.

Reduction of atherosclerosis and platelet aggregation can be achieved by L-Arginine supplementation which can also inhibit the adhesion of monocyte to endothelial cells. As these are important steps in atherogenesis. The beneficial effects of L-Arginine can be achieved by increasing nitric oxide availability in the wall of the blood vessels.

Materials and Method

Drugs and reagents

L-arginine, Streptozotocin and all other using chemicals were purchased from Sigma-Aldrich (St. Louis, MO, USA)

Animals

Fifty male albino rats (weighing 180–200 g body weight) were individually housed and maintained in a controlled temperature room (22 ±2°C) with free access to water and standard diet.
Experimental Design:

Fifty rats were divided into five groups (10 rats each) Group I (Control group): healthy rats. Group II (L-arginine group): healthy rats received (10 mM L-arginine/Kg b.w./day orally). Group III (Diabetic group): diabetic rats. Group IV :( Treated group): diabetic rats received (10 mM L-arginine /Kg b.w./day orally). Group V (Prophylactic group): rats received L-arginine before (two months) and after (two months) induction of diabetes (10 mM L-arginine /Kg b.w./day orally) during the experimental period (8 weeks).

Induction of Diabetes:

Diabetes was induced by multiple intraperitoneal injections of freshly prepared streptozotocin (40 mg/kg of bodyweight) dissolved in 0.1 mol/l sodium citrate buffer (pH 4.5) for 5 consecutive days. The animals were allowed drinking 5% glucose solution overnight to prevent initial streptozotocin-induced hypoglycemic mortality. Forty eight hours after last streptozotocin dose, fasting blood glucose levels was monitored and animals with glucose levels > 200 mg/dl were considered diabetic and assigned for different treatment regimens.

Collection of Samples:

After the experimental period, animals were kept fasting for 8 hours before blood sampling, blood was withdrawn from the retro-orbital venous plexus of the eye using capillary tubes and collected in a tubes contain sodium fluoride for blood glucose estimation, b- Heparinized tubes for other biochemical parameters and c- plain tubes to obtain serum for lipids profile test.

Blood was centrifuged at 3000 rpm for 10 minutes using cooling centrifuge. Plasma was separated and immediately frozen.

The following parameters were estimated:

- Plasma glucose was determined using enzymatic colorimetric method Centronic, Germany.
- Insulin level, I-CAM-1 and TNF-α were estimated by Enzyme-linked immunosorbent Assay (ELISA) using BioSoure INS-EASIA Kit
- Insulin resistance was calculated from the equation:
  \[ \text{Insulin resistance} = \frac{\text{fasting glucose (mg dl}^{-1}) \times \text{fasting insulin (mIU ml}^{-1})}{405} \]

Statistical Analysis

All data were expressed as mean ± SE. Distribution of the data were verified to be normal using Tests of Normality – (SPSS package) (version 18). Statistical significance will be tested by one way analysis of variance (ANOVA) followed by Bonferroni post hoc analysis. P< 0.05 was considered to be statistically significant.

Results

Table (1) showed remarkable increase in glucose level and insulin resistance with remarkable decrease in insulin level in diabetic, prophylactic, diabetic treated groups as compared with control group; these results improved after treatment with L-Arginine.

Also results recorded; there were significant decrease in glucose level and insulin resistance with significant increase in insulin level in L-Arginine, prophylactic and diabetic treated groups as compared with diabetic group.

Table (2) recorded significant increase in I-CAM and TNF-α level in diabetic, prophylactic and diabetic treated groups as compared with control group. These results improved after the treatment with L-Arginine. Regarding NO level there was significant decrease in diabetic and diabetic treated groups as compared with
control group.

L-Arginine group showed significant decrease in I-CAM and TNF-α level with significant increase in NO level compared to diabetic group.

**Discussion**

Morbidity and mortality are mainly determined by cardiovascular disease (CVD) in diabetic patients, whose risk is 2 to 4 times higher than in non-diabetic 1.

Supplementation of L-arginine has an effective treatment that help in improving the insulin sensitivity and endothelial function which was related to major cardiovascular risk factors including hypertension, hypercholesterolemia, obesity and diabetes through the NO/c-GMP pathway 19.

In this study, fasting blood glucose was increased in diabetic group compared to control, while this value was obviously decreased by L-arginine supplementation in both treated and prophylactic groups compared to diabetic group (Table 1). Destruction of the B- cells by STZ was the cause of failure to produce insulin and excess accumulation of glucose in blood instead of its use and storage. The deterioration in insulin values in this study has also been reported in our previous work 20.

L-arginine administration caused an increase in secretion of insulin. Stimulation of NO generation in vascular smooth muscles and skeletal muscles is caused by the insulin signaling cascade mediating the insulin action in responsive tissues. NO stimulates the transport of glucose in skeletal muscles with increase in GLUT4 levels at its surface, leading to improvement in insulin resistance which is in agreement with our study 21.

The decrease in antioxidant capacity which was caused by hyperglycemia and increase in pro-oxidative and pro-inflammatory cytokines secretion contribute to diabetic complications. Increased levels of IL-1, IL-6, TNF-α, and other inflammatory cytokines were found in different insulin-resistant and diabetic states 22.

The study showed that ICAM-1 concentration was considerably elevated in diabetics compared to controls and considerably decreased in treated and prophylactic groups compared to diabetic group. (Table 2). Lehle et al. 22 reported that diabetes cause induction of TNF-α which lead to cytokines over expression, IL-1, monocyte chemoattractant protein-1 (MCP-1), IL-6 and IL-8. ICAM-1 receptors were stated following induction by these cytokines and then expression of ICAM-1. Also, ICAM-1 expression on endothelial cells is increased under high-glucose conditions. It was also possible that increased advanced glycation end products in diabetic states was responsible for increasing the circulating adhesion molecules. Poston et al. 23 demonstrated noticeable expression of ICAM-1 in human atherosclerotic arteries, and it was also possible that atherosclerotic lesions in diabetic patients with macroangiopathy contribute to the increased circulating ICAM-1 concentrations in these patients.

This study showed that TNF-α level was significantly high in diabetic group compared with control group, but these levels were improved after treatment with L-arginine (Table 2). This was due to L-arginine inhibits TNF-α, neutrophil infiltration, reactive oxygen species formation, release of elastase, and biosynthesis of eicosanoids [through COX-1 and 5-LOX inhibition in vitro and receptor blockage coupled in vivo mobilization of Ca2+]; which all contribute to initiation of the inflammatory process 5.
Study showed decrease significantly of NO concentration in diabetic group compared to control group. These results were compatible with finding of those of Suresh and Undurti\(^24\) who stated that diabetes mellitus was associated with increase of blood glucose, oxidative stress and decreased production of nitric oxide from endothelial cells, and this hyperglycemia was intensified by aldose reductase increased activity leading to depletion of the required NADPH for the nitric oxide generation from L-arginine by nitric oxide synthase.

Supplementation of L-arginine caused significant increase of NO in treated and prophylactic group compared to diabetic group. The NO formation from L-Arg played a major role in the cardiovascular functions regulation.

Through this study, it was found that the diabetic group showed significant decreased in HDL-C and also significant increase in LDL-C, total cholesterol and triglyceride compared to control group. These results were compatible with the previous studies which suggested that lipoprotein abnormalities were higher in diabetics than in non-diabetics \(^20\). It was suggested that high blood glucose levels lead to increase LDL-C and the LDL receptors in the liver became Glycosylated, leading to impairment of the ability of the liver to remove cholesterol from the blood. also, it leads to lipoprotein lipase inhibition and hyperlipidemia aggravation.

It was found in this study that the group received L-arginine (Prophylactic and treated groups) showed remarkable increase in HDL-C and decrease in LDL-C, total cholesterol and triglyceride compared to diabetic group. These results were compatible with Gad \(^25\) who stated that L-arginine not only participates as insulin secretagogue, but also, its antilipolytic action of polyamines formed from L-arginine, which caused enhancement of glucose oxidation and inhibition of lipolysis by endogenous cyclic AMP levels suppression in a way similar to insulin in isolated rat fat cells. Accordingly, atherogenic index, atherogenic coefficient and cardiac risk ratio showed in (Table 3) were significantly decreased in both treated and prophylactic groups compared to diabetic group.

**Conclusion**

Oral administration of L-arginine might be a novel nutrient which has a protected effect when took as a prophylactic and also had the ability to reduce endothelial dysfunction associated with diabetes. So this study aimed to evaluate the effect of the atherogenic index on vascular complications in diabetes.

Antegrade Intramedullary Nailing Versus Plating for Treatment of Humeral Shaft Fractures

Wesam Abo Sena1, Ahmed Mostafa Elkhalafy2, Mohamed Samir Rashed Shaheen1, Mina Nabil Grace2
1 Orthopedic Surgery Department, Faculty of Medicine, Cairo University, Cairo. Egypt,
2 El Helal Hospital, Cairo, Egypt

Abstract

Background: Fractures of the humeral shaft are commonly encountered by orthopaedic surgeons, accounting for approximately 3% of all fractures.

Objective: The present study aims to analyze and compare both the techniques in terms of functional and radiological outcome.

Method: The present prospective study conducted at Al helal hospital between December 2014 to December 2016, compared two groups of patients (n=20, n=20, total n=40) with either DCP or IMN. The results were compared both radiologically and clinically. The functional outcome was assessed using the constant score.

Results: Our results failed to establish convincingly that either technique is superior to other.

Conclusions: Nailing and plating have equal functional outcomes in cases with shaft humerus fracture.

Key Words: Trauma, fracture humerus, intramedullary nail.

Introduction

Fractures of the humeral shaft are relatively common injuries. They represent approximately 3% of all fractures.1 There is a bimodal distribution of humeral shaft fractures, with a peak in young male patients and a larger peak in older females usually by simple falls.2 Several fracture patterns have been identified for humeral shaft fractures.3

The conservative methods include U-shaped slab, hanging plaster cast, body bandage, prefabricated functional braces, and simple sling.4 The indications for surgical treatment of humeral diaphyseal fractures are failure of closed reduction, open fractures, segmental fractures, bilateral fractures, floating elbow injuries, fracture nonunion, fractures associated with vascular injuries or progressive neurological injury, and fractures in patients with multiple injuries.5

Several operative methods are available, including open reduction and plate fixation, external fixation, intramedullary nailing with Rush rods or Ender nails, and locked intramedullary nailing.6 Open reduction has several disadvantages7

Locked intramedullary nails usually can be inserted using closed techniques, avoiding the extensive soft tissue dissection required for plating. Interlocking nails give rotational stability, decrease the need for postoperative bracing and allow early mobilization of the extremity.8 When performing distal interlocking of an intramedullary humeral nail, there is risk of iatrogenic injury to the neurovascular structures.9

The anatomy and the function of the humerus are quite different from the long bones of the lower extremity.10

Aim of the Work:

The aim of the work was to compare the results...
of internal fixation of humeral shaft fractures by either using interlocking nail or dynamic compression plate.

**Patients and Method**

The current study is prospective comparative study included forty patients were operated up on at Al-Helal Hospital, suffering from humeral shaft fracture between December 2014 till December 2016.

Twenty cases of them were fixed by DC plates (group 1) and the other twenty by IM nails (group 2). They were operated under supervision of more than one consultant. All cases were followed for 12 months. They were all evaluated both clinically and radiologically. The clinical results were assessed according to The Constant-Murley shoulder scoring system. Radiological evaluation included assessment of union, malunion, failure of fixation and implant failure.

**Surgical technique**

**Intramedullary nailing**

General anaesthesia combined with interscalene block was used in majority of the patients. In supine position, a bolster was kept in between the scapula. Affected limb was scrubbed, draped and prepared. 3 cm incision was taken from the anterolateral edge of acromian extending distally. Once the deltoid fibers were split and retracted, the supraspinatus tendon was incised along the length of its tendon. Entry was made with the help of awl just lateral to the articular cartilage in the line of the medullary canal. Guide wire was passed and reduction of the fracture was achieved. After initial reaming of the canal, the expert humerus nail (Depuy Synthes®, Switzerland) was mounted on the zig and inserted over the guide wire. Proximal locking was done with the help of zig while the distal locking was executed by free hand technique. The position of the nail was checked in C arm in both the orthogonal views at all the major steps. Meticulous closure of the rotator cuff and distal part of humerus was done.

**Plating**

General anaesthesia combined with interscalene block was used in majority of the cases. All the patients were operated in lateral position. Affected limb was scrubbed, draped and prepared. 8-10 cm incision, centered at the fracture site was taken. Interval between long and lateral head of triceps followed by isolation of radial nerve and subperiosteal elevation of the medial head of triceps was performed with utmost care. A 3.5 mm dynamic compression plate (Depuy Synthes®, Switzerland) was applied in compression mode after the preliminary reduction of fracture was achieved. Position of the plate was assessed in both the orthogonal planes. The wound was closed over layers. Immediate postoperative x rays were taken to confirm the position of the implant (Figures 1-7).
Results

The prospective study included 40 patients were assessed after two weeks, six weeks, twelve weeks and twenty-four weeks. Results were assessed according to Constant’s scoring system. The range of movement was assessed according to degree of restriction of flexion and extension in comparison to normal elbow, and of a single direction of shoulder motion.

Regarding the demographic and basic clinical data, it was found that there was no significant difference between the two studied groups regarding demographic and basic clinical data as shown in table (1).

According to Constant-Murley scoring system, the results obtained were excellent in 29 patients (72.5%) 16 patient fixed with plate (80.0%) and 13 patient fixed with nail (65%), good in 7 patients (17.5%) 3 fixed with plate (15%) and 4 with nail (20%), and poor in 4 patients (10%)one fixed with plate (5%) and 3 with nails (15%). The excellent and good results were considered satisfactory while fair and poor results were considered unsatisfactory as shown in table (2).

| Table (1): Demographic and basic clinical characteristic of the two studied groups. |
|---------------------------------|-----------------|-----------------|------|
| Age (years)                     | Plate (N=20)    | Nail (N=20)     | p    |
|                                 | 37.53±10.92     | 35.84±10.77     | 0.441|
| Gender                          |                 |                 |      |
| Male                            | 15 (75.0%)      | 12 (60.0%)      | 0.388|
| Female                          | 5 (25.0%)       | 8 (40.0%)       |      |
| Side                            |                 |                 |      |
| Right                           | 9 (45.0%)       | 12 (60.0%)      | 0.410|
| Left                            | 11 (55.0%)      | 8 (40.0%)       |      |

The inter and post operative complications show that there was a significant increase in blood loss in plate group more than nail group, also the radiation time was significantly higher in nail group more than plate group, regarding the incidence of post operative complication it was found that there was no significant difference between the two studied groups as shown in table (3).

**Discussion**

The average age in group I was 37.53±10.92 year, and in Group II was 35.84±10.77 The shortest average time to union occurred in the age group 23-30 years (7.8 weeks), while the longest average time to union (10.5 weeks) occurred in elderly patients (above 50 years). This results was agreement with study carried out in 2007 by *Verbruggen and his colleagues*, included 40 patients with a mean age of 75 years showed union rate of an average of 16 weeks. The average time of union in both sexes was almost similar to each other’s; males have an average of 8.6 weeks while females had an average of 9.4 weeks.

Most current operative methods for stabilization of humeral shaft fractures have acceptable rates of union. *(12) Dabezies et al.,* all reported union in 97% of humeral shaft fractures treated with AO plating techniques. In these three series, 14% to 35% of fractures received bone grafting as part of the plating procedure. *(12,13) Dabezies et al.,* all reported union in 97% of humeral shaft fractures treated with AO plating techniques.

Heineman in 2010 found no difference in the rate of union between plate fixation and intramedullary nailing. Because they lack rotational control, flexible intramedullary nails more frequently are associated with non-union. *(14) Durbin et al.* reported union in 92% of 30 humeral fractures treated with Hackethal nailing.

In 2009 another series of 71 patients treated with interlocking nail in both antegrade (45 cases) and retrograde (26 cases) manners, there were no non-union with ante grade and 4 non-union with retrograde. *(16) Mamood et al.* found 85% of plating patients & 50% of nailing patients showed evidence of union on or before 16 weeks. One case of nonunion plating (5%) was treated by bone grafting as a secondary procedure. One case of nonunion interlocking (5.5%) was treated with closed exchange nailing with reaming.

In 2017 *Mamood et al.* found 85% of plating patients & 50% of nailing patients showed evidence of union on or before 16 weeks. One case of nonunion plating (5%) was treated by bone grafting as a secondary procedure. One case of nonunion interlocking (5.5%) was treated with closed exchange nailing with reaming.

In this series the rate of union compared favourably with these results as we had four cases (10.0%) of non union one case in Group I and 3 cases in Group II, the other 36 patients (90.0%) progressed to union in an average time of 8.8 weeks.

In 1987, *Hall et al.* observed that spiral and comminuted fractures gave better results than transverse fractures of the humeral shaft.

Middle third fractures were reported by *Martinez et al.* to be difficult to heal, possibly because of injury to the nutrient vessels at this level. The same was noted...
by Chao et al., in 2005. In this study, the middle third fractures tend to unite (average 9.5 weeks) but this tendency was not statistically significant.¹⁹,²⁰

Rodriguez-Merchán²¹ reported one (5%) superficial infection in 20 humeral fractures treated with plating. Hereported infection in 2.9% of 34 plated humeral fractures. Hall and Pankovich reported no infections in 86 humeral fractures treated with closed Ender nailing.¹⁸

A single deep infection reported by Henley et al.²² in a series of 33 humeral fractures treated with closed Hackethal nailing occurred in a fracture previously treated with external fixation. But Robinson et al. reported a 6.7% incidence of infection in 30 humeral fractures stabilized by the same methods. In this series there were 2 cases of superficial infection encountered in the 40 cases in Group I treated by debridement and antibiotic.²³

In this study we have two patients with radial nerve palsy postoperatively in Group I, one of them showed complete recovery within 3 months, the other did not show any improvement and planned for tendon transfer on the other side no patient in Group II with radial nerve injury.

The management of radial nerve palsy associated with humeral shaft fracture is a topic of debate. Although it is known that the majority of these injuries are neuropraxia that will recover spontaneously, the indication and need for operative exploration has been disputed, with authors offering conflicting opinions.²⁴

In 2013 series Pal et al., reported Radial nerve palsy was present in six patients after injury (10% incidence). Of the six patients who had undergone open reduction internal fixation with plating with associated nerve injury, three had a full recovery of function and one had partial recovery of motor function and two didn’t recover. There were no cases of post-operative radial nerve palsy after stack nailing while two patients who had a neuropraxia after plating had a full recovery on conservative treatment.²⁵

The lost degrees of elbow extension in group 1 patients may be explained by fibrosis that occur through triceps splitting affect extensor mechanism. This affect the full action of the triceps muscle. Jens et al. concluded that plate fixation offered an anatomic reduction of the fracture and predictable healing results. He included in his study 46 patients treated with open reduction and internal fixation.²⁶

The most frequent criticism of antegrade humeral nailing has been its potentially deleterious effect on shoulder function. In a series of humeral fractures stabilized predominantly by Rush rods, Stern et al. reported the development of adhesive capsulitis in 56% of cases treated with antegrade nailing.²⁷

The insertion point violated the rotator cuff in most of these patients, and nails frequently migrated proximally. Shoulder function returned to near normal after hardware removal.

Brumback et al. attributed loss of extremity function to factors other than the fracture or surgical treatment (neurological injury, soft tissue injury, heterotopic ossification) in 16 of 58 (28%) humeral fractures in patients with multiple injuries treated with flexible intramedullary nails.¹⁴

Conclusions

This prospective study demonstrated no statistically significant differences in healing outcomes assessed between humeral diaphyseal fractures treated with IM nails and those treated with plates. The two treatment groups were comparable with respect to demographics, fracture location and type, indications for surgery, and time to treatment. Healing occurred in a high percentage of patients within four months in both groups.

Although not quantifiable, it was our impression that antegrade nails were advantageous in comminuted AO Type C fractures. Despite the best attempts at minimizing and repairing rotator cuff trauma during antegrade humeral shaft nailing, the etiology of shoulder pain and dysfunction remains unexplained.

Expression of MicroRNAs 31, 155 and 29C and Their Relation to Pathogenesis and Severity of Alopecia Areata

El-Zawahry BM1, Amin IM1, Shaker OG2, Zaky IS1, Ibrahim NF1

1Dermatology Department, Faculty of Medicine, Cairo University, Egypt,
2Biochemistry Department, Faculty of Medicine, Cairo University, Egypt

Abstract

Alopecia areata (AA) is a common autoimmune disorder that targets anagen hair follicles. The most widely accepted hypothesis in its pathogenesis is that it is a T-cell–mediated autoimmune condition in genetically predisposed individuals. MicroRNAs (miRNAs) are implicated in disease etiology and treatment. Interestingly, miRNAs 31, 155 and 29c have shown an important role in alopecia areata. Since miRNA can be used as serum biomarker in other autoimmune diseases. This study aimed to assess and compare serum levels of miRNAs 31, 155 and 29c in 50 AA patients with their levels in 50 healthy subjects & correlate their levels to severity of AA. Serum levels of miRNAs 31, 155 and 29c were estimated by qRT-PCR technique and miRNAs 31 and 29c were found to be significantly higher in AA patients compared to controls. MicroRNA 155 however, showed no significant difference between serum levels of AA patients compared to controls. These findings suggest the important role of miRNAs 31, 29c and 155 in the pathogenesis of AA.

Key words: Alopecia areata (AA). miRNA 31. miRNA 155 . miRNA 29c.

Introduction

AA is the most prevalent autoimmune disorder and the second most prevalent hair loss disorder after androgenetic alopecia 1. The estimated prevalence of AA is approximately 1 in 1000 people2,3.

The exact pathogenesis of AA is still not completely clarified, but it is believed that it is a T-cell mediated autoimmune process which is trigged by endogenous or exogenous stimuli and maintained by the interaction of several molecules. In genetically predisposed individuals, under the effect of stress hormones, the HF enters a cycle of autoimmune growth inhibition 4.

The major pathomechanisms in AA include the anagen HF immune privilege loss, peribulbar inflammation, disturbed cycling, anagen arrest then peribulbar fibrosis. A lot of factors play a role in these mechanisms as cytokines, innate, adaptive immunity, proapoptotic mediators and profibrotic molecules under control of genetic and epigenetic mechanisms which leads us to the master role of miRNAs 5.

MiRNA is a small non-coding RNA molecule containing about 20-22 nucleotides and is found in humans, plants, animals and some viruses 6. It functions in RNA silencing and post-transcriptional regulation of gene expression 5.

MiRNA 31, 155 and 29c can be involved in peribulbar inflammation, fibrosis and arrested anagen phase 7, 8. MiRNA 31 regulates the production of mediators of inflammation and/or fibrosis 7, 9.

MiRNA 29c has a role in breakage of HF immune privilege as miRNA29c down-regulates TGF-β which keeps immune privilege intact 10. It contributes to apoptosis of target HF matrix cells expressing autoantigens 10, 11.

MiRNA-155 is a typical multifunctional miRNA. MiRNA-155 is involved in numerous biological processes including inflammation and immunity 12. Thus miRNAs 155, 31 and 29c can be potential therapeutic targets in treatment of AA in the future research 13.
Materials and Method

In this case-control study 50 patients were recruited from the outpatient clinic of the Dermatology Department, Cairo University Hospitals. The patient’s group included 35 males (70%) and 15 females (30%), whose ages ranged from 4 to 47 years (mean 25.86± SD 12.32 years). Any type of AA was included. The control group included 35 males (70%) and 15 females (30%), with ages ranging from 16 to 50 years (mean 28.85± SD 9.23 years). Both groups were sex matched (p = 0.147) and age matched age (p = 0.477).

i. Clinical evaluation

Skin lesions were evaluated with regard to onset, course, duration, types of alopecia areata and relation to stress. The extent and the severity of the disease were assessed using SALT score.

ii. Blood sampling and technique

Five ml venous blood samples were withdrawn from all patients and control subjects using BD vacutainer system. The mononuclear cells were separated by centrifugation. The cells collected were stored at -80 °C until the time of analysis.

Determination of miRNA was achieved across three consecutive steps: 1. Total RNA purification, including miRNA. 2. Quantitation of purified RNA, including miRNA. 3. miRNA reverse transcription into complementary DNA (cDNA). 4. Amplification and qRT-PCR analysis of the targeted miRNAs (miRNA-155, miRNA-31, miRNA-29 and SNORD 68 as an internal control using SYBR Green detection.

P value < 0.05 is significant

Results

The miRNA 31 and 29c expressions were higher in patient’s sera compared to controls, which was statistically significant (p = < 0.001). The miRNA 155 expression was higher in patient’s sera compared to controls, but the difference was not statistically significant (table 2).

Figure 1: Types of alopecia areata cases

The miRNA 31 and 29c expressions were higher in patient’s sera compared to controls, which was statistically significant (p = < 0.001). The miRNA 155 expression was higher in patient’s sera compared to controls, but the difference was not statistically significant (table 2).
Figure 2: Comparison between serum miRNA 31 in patients and controls

Figure 3: Comparison between serum miRNA 29c in patients and controls

No statistically significant correlations were detected between serum expression of miRNA 155, miRNA 31 nor miRNA 29c and other variables including AA types and SALT score; neither to each other.

Discussion

In AA patients, serum expression of miRNA31 in this study was significantly higher in patients compared to controls. MiR-31 negatively targets Serine/threonine kinase 40 (STK40) in keratinocytes which inhibits the proinflammatory NF-kB signaling pathway. It also regulates the production of proinflammatory and profibrotic mediators as TGF-β, and leucocyte chemotaxis contributing to peribulbar inflammation early in AA and peribulbar fibrosis later. It is known to inhibit peripheral regulatory T-cell generation so breaking the immune privilege. The inhibitory effects of miR-31 on anagen development were realized, as it inhibits Fgf and Wnt but stimulates Bmp pathway. Fgf and Wnt pathways promote the HF anagen stimulatory signals to the HF stem cells, while Bmp signaling operates as an anagen inhibitor antagonizing the activity of the Fgf and Wnt pathways. It also controls hair shaft formation via inhibiting hair matrix keratinocyte differentiation. In addition, it inhibits the expression of the keratin 17 which maintains keratinocyte and anagen integrity. Taken together, the role of miR-31 in clinical conditions with arrested anagen phase such as AA is proven.

In current study; miRNA 29c was found upregulated in patients’ sera but Wang et al found it downregulated in AA mice tissues. They explained their results by the fact that miRNA29c has been shown to suppress BAK1, that mediates apoptosis via granzyme B.

In current study, miRNA29c was found to be significantly increased in serum of AA patients when compared to controls. It may be explained by its proinflammatory role found in diabetic nephropathy as it up-regulates IL6/TNFα. It has a role in breakage of HF immune privilege as miRNA29c down-regulates TGF-β which keeps immune privilege intact. Its proapoptotic role is indicated by its ability to suppress p85α and CDC42 genes that normally suppress p53 expression so relieving p53 suppression causing apoptosis.

It can also cause cell cycle arrest in G1 phase by targeting CDK6. It was found that miR-29c directly bound with the 3’- UTR of VEGFA led to suppressed VEGF expression. VEGF was found to be significantly reduced in HF in the skin of AA patients compared with normal individuals. This reduction of VEGF production by hair follicles may lead to a loss
of vascular support to affected skin. With subsequent inflammatory changes resulting from inadequate tissue vascularization, this could lead to atrophy of HF. This hypothesis is supported by the finding that loss of capillaries is found early in alopecia areata and revascularization precedes hair regrowth.

Finally, a reduced HPA axis response was found to be associated with the increased expression of miR29c following chronic stress exposure, so miRNA29c can decrease POMC disturbing the immune privilege participating in AA pathogenesis.

In current study, miRNA 155 expression was higher in patient’s sera compared to controls, but the difference was not statistically significant. MiRNA-155 is upregulated by inflammatory mediators including TNF-α during innate immune response and was found to be important in Th 17 cells differentiation and function by directly inhibiting SOCS1. Accordingly, IL-17A production was found to be induced by miRNA 155. Moreover, miRNA155 is required for optimum DCs production of cytokines that promotes Th17 cell formation thus contributing to the chronic inflammation in AA. It targets CTLA-4, a major inhibitory molecule of T-cell responses leading to T cell proliferation.

Wang et al. detected upregulation of miRNA 155 in AA mice skin tissue samples. In the current work, miRNA-155 showed serum upregulation in AA patients, which was unexpectedly insignificant. The fact that most of our patients were of recent onset and therefore they are in the phase of acute inflammation, may explain the immature upregulation of miRNA155 which may possibly mature and be significant later in the course of the disease. It activates signal transducer and activator of transcription 3 (STAT3) and factors involved in TGF-β and IL-6 signaling contributing to chronic peribulbar inflammation and fibrosis. It has a tight relation to chronic inflammation evidenced by its relation to Th17 cells and chronic atopic dermatitis.

MiRNA 155 also contributes to immune privilege breakage as it negatively targets IL-10 and TGF-β 1, which are major immunosuppressant factors against autoreactive T cells. Its association with variable autoimmune diseases as myasthenia gravis and rheumatoid arthritis suggests its role in AA as both may be associated with AA. In this work patient selection excluded associated other autoimmune diseases by history. This may explain the insignificant upregulation present in this study.

MiRNA155 activates Stat pathway which leads to infiltration of autoreactive T cells attacking HFs. Other proposed mechanisms include, miR-155 as a critical posttranscriptional PD-L1 negative regulator in response to inflammation, so preventing its immunosuppressive action leading to persistent chronic inflammation. It can also help in peribulbar fibrosis late in the disease in a similar way to its mechanism in systemic sclerosis; miR-155 expression requires the NLRP3 inflammasome processing of IL-1 leading to fibrosis. Thus, the inflammasome is the initiator causing IL-1 transcription and autocrine signaling that drives the expression of miR-155 via an IL-1 signaling mechanism. MiR-155 synergizes with the inflammasome to induce a positive feed-forward signal that further promotes IL-1 release and autocrine signaling leading to continual collagen expression and fibrosis. MiRNA155 is expressed in Epstein-Barr virus (EBV)-infected cells and CMV infection also resulted in an upregulation of miR155, both viruses are considered major environmental factors in AA pathogenesis.

To the best of our knowledge, this study is the first to detect the serum expression levels of miRNA155,31 and 29c in human AA patients; Our findings paves the way for studying the possibility of being used as prognostic markers and therapeutic targets for AA.

Limitations

The low variety of onset (chronic 64%) and extent (92% of extent ≤ 10%) of AA patients included in this study so the exact relationship between the three miRNAs and AA types and extent cannot be established.

Conclusion

The current study highlights the contribution of miRNA155, miRNA31 and miRNA29c in the pathogenesis of AA. Their elevated serum expression in patients’ sera in comparison to controls; identifies their important role in the development of AA.

Abstract

Objectives: Evaluation of clinical picture and results of occipitocervical and atlanto-axial fusion with craniocervical instabilities

Patients and Method: The investigation included 22 patients, 14 males (63.6%) and 8 females (36.4%). Ages ranged (10 to 70) years. Instability resulted from fracture of the odontoid process in 8 cases (36.4%), transverse atlantal ligament injury with C1 C2 sub laxation in 6 cases (27.3%), osodontodium in 4 cases (18.2%), Morquio’s syndrome in 2 cases (9%), C2 Hangman’s fracture type III one case (4.5%), and transverse atlantal ligament injury associated with sub axial sublaxation in one case (4.5%). Trauma was the most common cause of instability (73%). Single hollow titanium anterior odontoid screw was done in 4 cases (18.2%), posterior atlanto-axial fixation in 12 patients (54.5%), three of them (25%) needed trans oral odontoidectomy prior to fixation, fixation was performed from C1 to C4 in one patient (4.5%), and occipitocervical fixation in 5 patients (22.7%). Postoperative Philadelphia neck collar was applied for 8-12 weeks.

Results: Postoperative clinical evaluation revealed good outcome of neurological ASIA grading. 10 patients improved (45.5%), while 11 patients (50%) remained at the same ASIA score as pre-operative, and only one patient (4.5%) deteriorated from ASIA score D to A. Pain and neck disability scores reduced postoperatively compared to preoperative. Fusion was achieved in 18 cases (81.8%) at last follow-up. Instrumentation failure occurred in only 2 cases (9%). Three mortality cases due to respiratory problems (2 cases died in the first week after surgery and the third case died one month after the surgery).

Keywords: Craniocervical instability, Occipitocervical fusion, Odontoid screw, Trauma.

Introduction

The craniocervical junction (CCJ) has unique anatomical and functional properties. It represents the interface between the cranium and the upper cervical spines. Ligaments and muscles have an important role in maintaining the stability ¹, ².

Craniocervical instability may be caused by different mechanisms such as, traumatic, inflammatory (rheumatoid arthritis), neoplastic, and congenital disorders (Morquio and Down syndromes) ³, ⁴.

Relatively wide cross-sectional area of the spinal canal at the CCJ, spinal cord injury is less common than expected. CCJ instability may present by disabling pain, cranial nerve palsy, sensory disorders, weakness, or even sudden death ².

The craniocervical junction encloses vital neurological and vascular structures. So special consideration is necessary for surgery at the CCJ ³.

Occipitocervical fixation has evolution due to advances in operative techniques. Surgical approaches of stabilization are classified as either anterior or
posterior approaches. Anterior approaches as transoral C1 and C2 fixation using T shaped plate, anterior odontoid screw (AOS) for type II odontoid fracture, and trans oral odontoidectomy for irreducible odontoid fractures. In contrast, several posterior approaches could be largely classified as either atlanto-axial fixation or occipito-cervical fixations. For challenging anatomy, a 3-dimensional computer navigation system may be used for trajectory planning intraoperative.

The aim of this study is to evaluate different techniques in the management of craniocervical instability and to compare the results with other results reported in the literature.

**Patients and Method**

This prospective study was conducted at the departments of Neurosurgery, Cairo University and Beni-suef University hospitals to allow 6-12 months follow-up for the last case operated upon. The study included 22 patients who suffered from craniocervical instability indicated for craniocervical or atlanto–axial fixation.

There were 14 males (63.6%), and 8 females (36.4%) and their ages ranged from 10 to 70 years, with mean age of 36.1 years ± S.D 16.57.

The causes of instability were fracture of the odontoid process in 8 cases (36.4%), transverse atlantal ligament injury with atlanto-axial sub laxation in 6 cases (27.3%), Osodontoidum in 4 cases (18.2%), Morquio’s syndrome in 2 cases (9%), Hangman’s fracture in one case (4.5%), and transverse atlantal ligament injury associated with sub axial sub laxation in one case (4.5%). Trauma was the most common cause of injury in our study 16 cases (73%).

As regards the clinical presentation, all patients had presented with posterior cervical pain with variable degrees of radiation to the occipital region. Pre-operative motor power according to ASIA motor score, one patient had ASIA grade A (4.5%), 2 patients were classified as ASIA grade B (9%), 6 patients had ASIA grade C (27%), 8 patients had ASIA grade D (36%), and 5 patients had ASIA grade E (22.5%) as illustrated in fig (1).

All cases had preoperative craniocervical X-ray, CT, and MRI examinations.

In our study, anterior odontoid screw was used in 4 cases (single hallow titanium screw) (18.2%), posterior atlanto-axial fixation with facet fusion in 12 patients (54.5%) three of them needed trans oral odontoidectomy prior to fixation, fixation was performed from C1 to C4 in one patient (4.5%), and occipitocervical fixation in 5 patients (22.7%), (occipit +C3 C4 C5 in 4 cases and occipit + C3 C4 C5 C6 in one case) as illustrated intable (2).

ASIA score grading system was used post-operative to assess neurological outcome. Fusion was assessed by cervical plain X-ray films and CT scan. All patients wore rigid neck collar postoperative until fusion was achieved.

Results

All surgeries were conducted smoothly without intraoperative complications or vascular injury. The mean duration of the procedure was 260 min (range 100– 420 min) and the average estimated blood loss was 225ml (range 50– 400 ml).

Regarding postoperative clinical evaluation according to ASIA grading, 10 patients had improved (45.5%) (four patients improved from ASIA score D to E, three patients from C to D, one patient from B to D, one patient from B to C, and one patient from A to C), while 11 patients remained at the same ASIA score as pre-operative(50%) (5 patients were ASIA score E, 3 patients were C, and 3 patients were D), and only one patient deteriorated from ASIA score D to A (4.5%) as illustrated in fig (2). Paresthesia in the area innervated by the greater occipital nerve was observed in only 4 patients. While in 3 patients improved through 40 weeks, only one patient paresthesiapersisted even 20 weeks later.

Fig (2): Showing post-operative patients’ distribution according to ASIA motor score

Postoperative X rays and CT detected proper reduction and alignment with evidence of bone fusion in 18 cases (81.8%). The rest 4 cases (18.2%), one case with atlanto-axial fixation suffered from progressive neck pain with limitation of neck mobility X rays and CT were done that detected fracture of right C2 screw with evidence of instability and cord compression that needed a second surgery, and the other 3 cases died from respiratory problems, 2 cases in the first week after surgery (the two cases of Morquio’s syndrome that were managed by occipitocervical fixation (occipit +C3 C4 C5), and the third case died after one month from surgery (the patient had odontoid fracture and managed by transoralodontoidectomy prior to posterior C1+C2 fixation, and was complicated by system failure and deep wound infection) as illustrated in fig (3).

Discussion

Occipito-cervical fixation is a difficult process in spinal surgery. Different techniques for occipitocervical fixation reported in previous studies using different internal fixation instruments.

Surgical approaches for stabilizing the craniovertebral junction (CVJ) are classified as either anterior or posterior approaches. Between anterior approaches anterior odontoid screw fixation is the most common. Posterior was classified as atlanto-axial or occipito-cervical (O-C) fixation.

Our study was carried out on 22 patients who suffered from craniocervical instability, and underwent occipitocervical fixation, where in 63.6% and 36.4% in males and females, respectively. Ages average were from ten to seventy years.

In this study trauma was the most common mechanism of injury in 16 patients (73%), similar to Songet al. whose found trauma was a common mechanism of injury. Instability resulted from trauma in 14 cases (44%), followed by rheumatoid arthritis in 8 cases (25%). Also in Goelet al. study trauma was the
cause of instability in 6 cases (75%).

Instability resulted from fracture of the odontoid process in 8 cases (36.4%), transverse atlantal ligament injury with C1 C2 subluxation in 6 cases (27.3%), os odontoideum in 4 cases (18.2%), Morquio’s syndrome in 2 cases (9%), C2 Hangman’s fracture type III in one case (4.5%), and transverse atlantal ligament injury with sub axial sub luxation in one case (4.5%). In Panigrahi et al.\textsuperscript{10} reported 91 fractures involving craniovertebral junction. Where 59% of patients had odontoid fractures, 24% had Hangman’s fractures, 10% had miscellaneous fractures of C2, 5.5% had isolated C1 fractures, and 1.1% presented with occipitoatlantal dislocation.

In our study neck pain was a presenting symptom in all patients. Neurological deficits were found as a common clinical presentation in (75%) with neurological deficit at variable degrees according to ASIA score, and this like the previously published studies as Hsu et al.\textsuperscript{5} and Lee et al.\textsuperscript{11}.

In this study, anterior odontoid screw was utilized in 4 cases (18.2%) with odontoid fractures. All cases showed proper reduction and alignment with evidence of bone fusion. This was consistent with Bhattarai et al.\textsuperscript{12}, included fifteen patients with odontoid fractures, who underwent AOS placement.

Posterior atlantoaxial fixation using screw-rod system was done in 12 cases (54.5%), C1 lateral mass screws and C2 trans pedicular screws in 10 cases, only 2 cases underwent C2 trans laminar screws. 10 cases of them (83%) showed proper reduction and alignment with evidence of bone fusion, while the other 2 cases (17%) had instrumentation failure (one case had right C2 screw fracture with evidence of instability and cord compression, the other case had deep wound infection with loose system) that needed another surgery and died one month after surgery due to respiratory problems. One case in our study (4.5%) had Hangman’s fracture, which was operated by C1 C2 C3 C4 fixation (C1 C3 C4 lateral mass and C2 one right side trans pedicular screw, left screw couldn’t be inserted due to comminuted fracture of left pedicle) proper reduction and alignment with evidence of bone fusion was achieved in the follow up. This was consistent with Stulik et al.\textsuperscript{13} and Goel et al.\textsuperscript{9} studies, all patients underwent atlanto-axial fixation using screw–rod system and all patients showed proper reduction and alignment with evidence of bone fusion.

In our study occipitocervical fixation was done in 5 patients (22.7%), (occipit + C3 C4 C5 in 4 cases and occipit + C3 C4 C5 C6 in one case). Three cases of them (60%) showed proper reduction and alignment with evidence of bone fusion, the other 2 cases with Morquio’s syndrome died post-operative during the first week due to respiratory problems. In Song et al.\textsuperscript{8} study, the fusion was achieved in 27 patients (84%) at last follow-up.

In our study all surgeries were conducted smoothly without intraoperative complications or vascular injury. These findings correspond to the results of Goel et al.\textsuperscript{9} study, that all surgeries were conducted smoothly without intraoperative complications or vascular injury, while other studies reported intra operative vertebral artery injury as in Stulik et al.\textsuperscript{13} study, which reported that in 2 cases during placement of C2 screw, without any clinical consequences after that.

In this study neck pain had improved in 95% and clinical evaluation revealed 10 patients (45.5%) had neurological improvement, while 11 patients (50%) remained at the same ASIA score as pre-operative, and only one patient (4.5%) deteriorated from ASIA score D to A. Consistent to observation of Song et al.\textsuperscript{8} that neck pain improved in all patients. Among 23 patients with cervical myelopathy, (78.3%) had improvement of the Japanese Orthopedic Association (JOA) scores at last follow-up, and the nine neurologically intact patients remained the same after surgery. In Goel et al.\textsuperscript{9} study all patients had clinical neurological improvement following surgery.

Conclusion

Anterior odontoid screw fixation using single hollow titanium screw is a safe and effective method for stabilizing an odontoid fracture while maintaining axial rotation, but its indications are relatively limited. Rod-screw system is a safe and effective method for the treatment of cranio cervical and atlanto-axial instability, provided that good orientation with the complicated anatomy of the cranio cervical junction.

Assessment of Bacterial Pigments as Textile Colorants

Yusra Y. Agha¹, Shababa A. Bahjat², Manar F. Thanoon³

University of Mosul/College of Science/Department of Biology/ Mosul/ Iraq

Abstract

The textile industry is considered the second most polluting industry in the world. Synthetic non-biodegradable petroleum-based dyes and toxic mordants play a major part in this pollution. Almost 20% of global water pollution has been associated with the textile dyeing practices. These controversies with the current environmental regulations, lead to a great demand for natural colors in food, pharmaceuticals, cosmetics, textiles and in the printing dye industry.

Recently, microbial pigments have been shown to be a promising alternative not only to synthetic dyes, but also to other biopigments derived from vegetables or animals as they are viewed as natural, non-toxic, have no seasonal production issues, offer excellent productivity, economical and most important they are ecofriendly.

An environmental screening of 77 samples was carried out for pigment production. Pigmented bacteria represented 55 (68%) of total samples with the highest percentage of pigmented bacteria found in air samples and the lowest percentage from water samples. Five potential pigmented isolates were chosen for pigment extraction and used for dyeing three types of fabrics - nylon, wool, and polyester. Furthermore, stability of dyes following treatment with acid, alkaline and detergents was studied to investigate the retention of dyes. Bacterial pigments in some unmordanted fabrics were retained 100% in cases of acid treatments while a small amount of discoloration was observed when subjected to alkali, or cold water and detergent. Apart from colorant, *Serratia marcescens* pigments demonstrated antibacterial activity against gram positive bacteria.

The current study demonstrated that coloring ability of the natural dyes can be compared to that of the synthetic dyes. Furthermore, these biochromes are also able to produce various shades similar to those of the synthetic dyes and express variable resistance to treatment with acid, alkaline and detergents.

Keywords: (Environmental, *Serratia*, Dyeing, Textiles).

Introduction

It has been a long time since microorganisms have been utilized to produce several different molecules such as antibiotics, enzymes, vitamins, texturizing agents . . . etc. but bacterial pigments are one of the most amusing and delightful research subjects in life sciences to elucidate their contribution in many industries. In nature, colorful and pigment producing microorganisms (bacteria, yeasts and fungi) are quite common. They create different pigments like carotenoids, prodigiosins, melanins, flavins, quinones, monascins, violacein and indigo [1].

Numerous artificial and synthetic colorants have been extensively utilized in foodstuff, dyestuff, cosmetic and pharmaceutical manufacturing processes. However, they are responsible for a variety of life-threatening effects on biotic and abiotic factors. To resolve the adverse effects there is universal interest in developing pigment production from natural sources. Natural pigments can be derived from two main sources, plants and microorganisms in addition to ores and insects [2, 3] . Microbial pigments have proved to be the most convenient owing to their stability, availability of cultivation techniques, easy and rapid growth in low cost culture media, without being dependent on

Corresponding Author:
Shababa A. Bahjat
Lecturer. Email: shabababahjat@gmail.com.
Phone no: +9647518462866
weather, demonstrate different color shades and they are biodegradable in nature [4].

In addition to colorants, bacterial pigments contain numerous biological properties including antioxidant, anticancer activity and antileishmanial and other therapeutic applications [5-7]. Additionally, natural dyes offer properties that greatly interest the textile industry, namely, antibacterial properties. Fabrics can harbor bacteria that reduce unfavorable odors. It has been indicated that many pigment extracts have antimicrobial properties [8] that are non-toxic, which makes them an interesting candidate as natural dyes applicable in the textile industry.

Pigments of different colors help shield the cells of microorganisms from the harmful effect of light rays of visible and near ultraviolet range. These pigments play a significant role as protective agents in preventing oxidative damage. They also prevent different types of cancer and assist in improving the immune response. [9].

As textile colorants are not as restricted by as many safety criteria as food colorants, a larger number of bacterial pigments can be applied in textiles and other non-edible products than in food. As such, biotechnology could play a major role in mass production of dyes. Microbial pigment production is now one of the growing areas of study to show its potential and versatility in a wide range of industrial applications.

The present research was undertaken in an attempt to use simple methodology for both isolation of potential pigmented bacteria as well as their application as natural ecofriendly colorants for dyeing purposes in textiles manufacturing. The intention is to bring microbial pigments beyond the research stage towards commercial production of natural colorants for the dyes market. Research on bacterial pigments should be intensified to find suitable, economical and a cost-effective growth medium to increase its applicability for industrial production. Furthermore, finding new microbial pigments with both mass production and antimicrobial properties is rewarding.

**Materials and Method**

**Pigmented bacterial strains:**

A total of 77 environmental (air, soil, and water) samples were collected in this study and screened for biopigment production.

**Soil samples:**

Soil samples (1 gm) were dissolved in 10 ml of sterile normal saline to make soil suspensions which were left at room temperature for 24 hrs, following which serial dilutions were plated on nutrient agar media, and subjected to incubation at 37° C. Soil samples were collected from various locations in public parks in Turkey, Mosul hotel gardens, etc. Plates were observed after 24-48 hrs. for pigment producing colonies visualized; orange, red, yellow, and pink. Pigments were more profound after 2-3 days at room temperature. These colonies were cultured on the same medium until pure cultures were attained.

**Water samples:** Direct plating of serial dilutions was made on nutrient agar medium, subjected to incubation at 37° C for 24-72 hrs. and observed for pigmented colonies.

**Air samples:** Nutrient agar plates were exposed to air for 15 min. and then incubated at 37° C for 24-72 hrs.

**Pigment extraction:** Nutrient agar was used for screening and storage of pigmented bacteria at 4° C. On the other hand, 10 pigmented isolates were cultivated on duplicate nutrient agar plates to obtain heavy growth. The extraction method of [10] was used with slight modification. Briefly, 5 ml 95% methanol was added to each plate to scrape and harvest the cells. Harvested cells from both petri dishes were centrifuged (3500 rpm, 20 min) The pigment was extracted from cell pellets with 99.5% (v/v) acetone in the ratio of 1: 5 (supernatant) at 60 °C for 20 min or until the pellet was colorless . The supernatant was subjected to filtration with a Millipore Filter (0.45 µm) to be used as a dye.

**Effectiveness as dyeing agent :**

Dyeing with bacterial pigments was done using three types of fabrics (unmordanted). White pieces (1 cm²) of fabrics (wool, nylon, polyester) were placed in sterile petri dishes. Methanol pigment extracts (2 ml) were spotted on the fabrics and subjected to incubation for 48 hrs. at room temperature, each piece of fabric was dried and divided into three smaller sections. These sections were then treated with acid, alkali, cold water plus detergent for 1 hr. [11]. Acid solution (pH 5) was adjusted using 0.1M HCl and an alkaline solution with pH 8 was adjusted with 0.1M NaOH. Soap solution was prepared by adding liquid soap to distilled water (1:1).
Results and Discussion

The textile industry is a fast-growing industry like many others in the world. Textile industries consume massive amounts of synthetic dyes and as a result the difficulty to treat textile seriously threatens the environment. Therefore, natural pigments have been a major focus of the industry which urgently needs a safe replacement. Of the many potential natural sources of colorants, microorganisms appear to hold great promise. Being easy to cultivate and extract, the genetically diverse microbe are a beneficial choice.

Various environmental habitats were screened to obtain new sources, and several pigments that produce bacterial strains were found indicating their massive presence. Results of the current study showed that a wide spectrum of pigments was demonstrated ranging from white, to different shades of yellow, orange, pink to red (Figure 1). Considerable pigment production by the isolates was observed after about 24 hours of incubation. Pigment production increased to a maximum after three days at room temperature, which correlates with the results of [11].

Also, pigmented bacteria represented approximately 68% of total samples, with the highest percentage of pigmented bacteria found in air samples and the lowest percentage from water samples.

These pigments are secondary metabolites synthesized by many bacterial species and have been shown to protect airborne bacteria from the effects of solar/UV radiation [12].

Twelve pigmented isolates were chosen for further extraction and textile dyeing. The predominant colors were shades of yellow to orange, blue, green, creamy, and red. Pigment diversity is caused by variances in their chemical structure compositions as well as the existence of certain chromatophores. Carotenoids have been found to be the most extensively disseminated pigments. This kind of pigment also has a significant role in bacteria, for instance, in photosynthetic processes, by inhibiting photo-damage, and providing resistance to oxidative impairment as a result of the production of activated forms of oxygen.

Effectiveness as dyeing agent:

The dyeing ability of five vibrant bacterial pigments was evaluated on nylon, polyester and woolen fabrics. Crude methanolic extracts demonstrated different shades of colors showing applicability as textile dyes as shown in (Figure 2.).

![Figure (2): Methanolic pigment extracts used for textile dyeing. a) Before millipore filtration, b) After filtration.](image)

Results clearly demonstrate that the pigment produced by five potential isolates named 1a, 1b, Serr, rea and Br, can be effectively used to dye three types of fabrics studied. The three types of fabrics showed equal affinity for bacterial pigments used (Figure 3).

![Figure (3): Bacterial pigments used in textile dyeing.](image)

The isolate serr exhibited a significant amount of red pigment production in the agar medium as well as in the liquid medium following 24 hrs. of incubation compared to other isolates. The selected strain was found to be *Serratia marcescens* based on the morphological and biochemical characteristics using the API 20-E. Thus, the strain serr was considered as one of the promising strains for pigment production in the current, polyester and woolen fibers were vibrantly stained after dyeing.
with red Serratia pigment.

It was noted that when fabrics such as nylon, wool, and polyester were treated with acid, alkali, cold water and detergent for 1 hr. some fabrics retained the dye, while others were destained (Figure 4 and Table 1). It was also found that when fabrics such as nylon, wool and polyester were treated with acid, alkali, and detergent and hot water and detergent for 1 h, the serratia red pigment was totally retained as a result of acid treatment.

These findings correlate with a study by [13], which indicated that red pigments produced by Serratia impart a red color to different types of textiles. The dye was found to be stable following wash performance tests.

Results of the present study demonstrated that soil, air and water bacterial isolates can lead to the production of pigments with anti-bacterial activity as shown in (Figure 5), which agrees with the findings of many researchers [14, 15].

**Figure (5): Antibacterial activity of Serratia marcescens pigment against a gram-positive bacteria.**

**Conclusion**

The rose red pigment obtained from *Serratia marcescens* can be utilized as a natural colorant to dye nylon, wool and polyester fabrics with a pink color. In addition to dyeing ability, natural bacterial pigments demonstrated an antimicrobial activity which makes them a potential candidate as an alternative to the various chemically synthesized dyes. However, studies to improve the fastness properties performance should be carried out.

Bedside Evaluation of Fluid Responsiveness in Shock State using Electrical Cardiometry

Miriam Magdy Aziz¹, Iman Khaled Eyada¹, Mohamed Abdallah Abd El Megeid¹, Ahmed OM¹
Pediatrics Department, Faculty of medicine, Cairo University, Cairo. Egypt

Abstract

Background: The initial hemodynamic management for pediatric shocked patients is giving aggressive fluid resuscitation, however fluid overload increases mortality and morbidity, so assessment and monitoring of fluid status have greatest benefit for critical patients to keep hemodynamic stability. Electrical cardiometry is an accurate, easy, and safe method for hemodynamic measurement, and can be used to monitor fluid responsiveness in critically ill patients.

Objectives: To examine stroke volume variation (SVV), evaluated through electrical cardiometry as a predictor of fluid responsiveness in management of shock.

Patients & Method: This was a cohort study done by observation of 60 shocked pediatric patients who received fluid therapy in the Intensive care units at Cairo University Pediatric Hospitals from July till December 2018.

Results: On comparing between patients who were volume non-responders versus volume responders, SVV was highly significant as it was higher in non-responders (P<0.000), also it was higher in patients who died than those who were discharged (p =0.002), it can be used as predictor of mortality with sensitivity of 80%, specificity of 75%, it also can be used as predictor of volume responsiveness with sensitivity of 85%, specificity of 92%.

Conclusion: Monitoring SVV, using electrical cardiometry could guide fluid therapy in critically ill pediatric cases, with beneficial impacts on morbidities and mortalities.

Key words: Fluid Responsiveness-shock-Electrical Cardiometry-stroke volume variation.

Introduction

Volume expansion, first-line treatment of acute circulatory failure, could be a therapeutic dilemma. Rivers et al. noted that, massive fluid management during first 6 h of resuscitation with severe sepsis and septic shock has been associated with improved outcome. Fluid overload has detrimental consequences¹; it prolongs mechanical ventilation and increases mortality of critically ill patients specifically those with sepsis, acute respiratory distress syndrome, intra-abdominal hypertension and acute kidney injury. Potential benefit of volume expansion must be balanced against risk of aggravating lung and tissue oedema².

It is crucial to evaluate whether volume loading will improve a patient’s malperfusion before a fluid bolus. Fluid responsiveness has variable definitions, the common being an increase in stroke volume by 10-15% after 500 mL of crystalloid infusion over 10 to 15 min³.

Electrical cardiometry (EC) is a monitor which measures electrical current produced through electrodes and changes of thoracic electrical bioimpedance, and is related to thoracic aortic flow and red blood cells (RBCs) alignment. When aortic flow stops, RBCs in the aorta are randomly orientated impeding the conduction. Once
the left ventricle contracts, the ejection flow compels the RBCs to parallel with the flow, which results in high conductivity and reduction of bioimpedance. The magnitude and frequency of pulsatile impedance changes are used to calculate hemodynamic parameters.

EC is FDA approved and validated for use in neonates, children and adults. A metaanalysis in 2016, including 20 studies and 624 patients comparing the CO measurement accuracy by using electrical cardiometry with other noninvasive technologies in pediatrics, showed that electrical cardiometry provided the most correct measurements.

Patients and Method

This was a prospective cohort study carried out over a period of six months at PICU of Cairo University pediatric Hospital from July till December 2018.

60 shocked patients fitting criteria according to Goldstein et al., 2005: unexplained metabolic acidosis: base deficit >5.0 mEq/L, prolonged capillary refill: >5 sec, core to peripheral temperature gap >3°C, tachycardia, tachypnea, hypotension, decreased mental status, weak peripheral pulse were included.

Patients were excluded if they had history of heart disease (valvular, myopathy, ischemic), cardiothoracic operation, dysrhythmias, or renal diseases. They were excluded due to underlying confounders such as volume overload, disturbed intracardic anatomy or significant arrhythmia that might interfere with ICON data and interpretation.

Patients’ hospital course was followed to determine the outcome.

Statistical Analysis

Data was subjected to computer assisted statistical analysis using statistical package for social science “SPSS” VERSION 23. Nominal data was expressed as frequency

Pediatric Risk of Mortality score was calculated for patient in his/her first 24 hours of PICU admission.

Electric cardiometry device (ICON):

Stroke volume variation (SVV), cardiac index (CI), stroke volume (SV), Systemic vascular resistance index (SVRI), index of contractility (ICON), thoracic fluid index (TFI) were measured immediately before and after administration of shock therapy (20cc/kg) within 2 mins from administration (up to 60 cc/kg) by electric cardiometry device ICON®. Four sensors were applied-first: approximately 5 cm above the left base of the neck, second on the left base of neck, third on the lower left thorax at the level of the xiphoid and the fourth one on the lower left thorax approximately 5 cm below the 3rd electrode at the level of anterior axillary line in older children, while in infant and young children 4 sensors were applied –first :approximately at forehead ,second on the left base of neck , third on the lower left thorax at the level of the xiphoid, fourth on lateral aspect of thigh 2 cm below symphysis pubis. EC monitor was connected to the sensor cable and the patients’ data were fed (name, age, sex, weight, height, blood pressure, CVP). The ICON monitor incorporates an algorithm which transforms the ohmic equivalent of mean aortic blood flow acceleration into an equivalent of mean aortic blood flow velocity.

We defined fluid reponders by normalization of (MAP, capillary refill time, heart rate, respiratory rate, central venous pressure) and their data was compared with data obtained using electrical cardiometery.

Improvement of the SVV and other data derived from ICON was determined by comparing patient data with normal reference range data already preset in ICON device.

We collected the following data from participants:

Demographic characteristics: Age, Sex, Weight, Height

Clinical findings: Vital signs: heart rate, respiratory rate and blood pressure) using PALS Guidelines, 2015, capillary refill time, central venous pressure, urine output in last 24 hours, if patient was mechanically ventilated or not, If patient received inotropes or not, Vasoactive-Inotropic Score was calculated patients who received inotropes, Peripheral pulsation felt or not, Conscious level (modified pediatric Glasgow Coma Scale)

Laboratory findings: Complete blood count, Kidney function test, Liver function test, CRP, Coagulation profile, Arterial blood gases
and percentage and was compared using Chi square test. Numerical data was expressed as mean +/- standard deviation and was compared using T test. Non parametric data was expressed as median “inter quartile range “and was compared using Mann Whitney u test. Associations between numerical variables was studied using Pearson’s correlation. P-values less than 0.05 was considered significant. Charts and graphs were prepared using Microsoft Excel 2010 TM.

Results

Patients’ median age was 18 (5.5 - 48) months; majority were females (53.3%). The median weight was 10.5 (6 – 16.5) kg. The median height was 72.5 (62.5-97.5).

Different age groups were included; 22 patients (36.6%) were less than 1 year old, 21 patients (35%) from 1-3 years old, and 17 patients (28.4%) were >3 years old.

45 (75 %) patients were invasively ventilated and 40 (66.7%) patients received inotropic support. Mean PRISM score was 10.40 ±4.44 SD (2-18) and median (IQR) VIS was 15 (0-40).

47 patients (78.3%) responded to fluid therapy while 13 patients (21.7%) did not.

Mean SVV significantly decreased while comparing between pre and post shock therapy. CI increased significantly post shock therapy. SV also showed improvement post shock therapy (p = 0.012). TFC, ICON and SVRI were non-significant (p = 0.665, P =0.289 and P =0.391 respectively)

ICON parameters after shock therapy, and on comparing between patients who were discharged and those who died the mean SVV, SVRI interpretation were highly significant among patients who were discharged and patients who died (p =0.009, P =0.000 receptively). Similarly ICON interpretation was significant (p = 0.041). SVV was higher among patients who died. ICON was higher among patients who were discharge. SVRI interpretation showed that it was higher in patients who improved.

The ROC curve shows that the best cut off point of SVV as predictor of mortality was >15 % with sensitivity of 80%, specificity of 75% and AUC of 70.5%. positive predictive value 61.5, negative predictive value 88.2

The ROC curve shows that the best cut off point of SVV as predictor of volume responsiveness was ≤19 % with sensitivity of 85%, specificity of 92% and AUC of 90%.

The ROC curve shows that the best cut off point of SVV as predictor of volume responsiveness in group age less than 1 year was ≤16 % with sensitivity of 61%, specificity of 100% and AUC of 80% while in group age 1-3 years was ≤19 % with sensitivity of 93%, specificity of 100% and AUC of 94%.
Discussion

Ueyama and Kiyonaka\(^1\), evaluated fluid responsiveness in critically ill patients and found that only 40–50% of the patients responded. That is far away from our study in which 78.3% responded to fluid therapy.

In our study; SVV showed significant improvement after fluid therapy and this is similar to Yi et al., 2017\(^1\) in his meta-analysis which approved diagnostic rate of SVV in expecting fluid responsiveness in children. A meta-analysis Zhang et al., in 2011 found SVV an accurate predictor of fluid responsiveness in adults. However, predictive value in Yi et al., 2017 was not as encouraging as reported in adult patients. It could be clarified through the physiological variations among children and adult cases, such as heart rate, chest wall compliance and vascular elasticity influencing SVV differently.

Thus SVV is a trustworthy predictor of fluid responsiveness in adult cases. However, the meta-analysis aimed to examine the ability of SVV to predict the response to volume expansion in pediatric patients. 6 investigations with a combined total of 224 cases, where data of meta-analysis reported a pooled sensitiveness of 68%, specificity of 65% \(^1\). Our data approved the diagnostic value of SVV in predicting volume responsiveness in children with sensitiveness of 85%, specificity of 92% and AUC of 90%.

The results clarified that CI statistically significantly increased after fluid therapy measured by electrical cardiometry before and after fluid administration within 2 minutes. Observational study done in 2018 in which transthoracic echocardiography was recorded immediately before, 5 minutes after, and 60 minutes after fluid bolus therapy showed that fluid bolus therapy resulted in a transient increase in CI in children with sepsis and acute circulatory failure. Fluid responsiveness was not sustained in the majority of cases \(^1\).

Van de Water et al.\(^1\), found TFC is a reliable measurement of chest fluid status and of changes in that fluid. This is against to our study as we found that there was no significant difference in TFC before and after fluid therapy.

Vergnaud et al.\(^1\), reported SVV dependably predicted fluid responsiveness only in children aged more than 3 years, while area under receiver operator characteristic curve (AUROC) is 50% in younger children.

Our results showed SVV was reliable to predict fluid responsiveness in all age groups included the study; ROC curve showed that the SVV can be used as predictor of volume responsiveness in group age 1-3 years with sensitivity of 61%, specificity of 100% and AUROC was 80% as well as >3 years with sensitivity of 93%, specificity of 100% and AUC of 94%.

Conclusion

SVV can be used as predictor of mortality with sensitivity of 80%, specificity of 75%. SV, CI and ICON can be used to guide fluid therapy in critically ill pediatric patients

Abstract

Purpose: Assessing DW MR imaging and ADC value in pediatric head and neck lesions and ability of determination benign from malignant masses.

Methods: Study was undertaken on 56 patients as 39:17, male: female, respectively where they had head or neck mass. Patients exposed to routine MRI to characterize lesions. Diffusion weighted imaging sequence was added to routine MR and evaluation of DWIs.

Results: We found that ± ADC of malignant, benign lesions as $0.64 \times 10^{-3}$, $1.58 \times 10^{-3}$, and $2.10 \times 10^{-3}$ mm$^2$/sec. ADC of $1.25 \times 10^{-3}$ mm$^2$/sec threshold value was used to differentiating among tumors which were represented 100% and 94.1% for sensitivity and specificity, respectively.

Conclusion: Beneficial roles for DW imaging to discriminate between malignant and benign head and neck tumors.

Keywords: Diffusion MR imaging, pediatric head and neck masses.

Introduction

Pediatric head and neck masses are common. Malignant tumors represent approximately 5% of masses. Preoperative diagnosis of malignant tumors is paramount for management which reflect on prognosis. Therefore, preoperative imaging is critical. Imaging also is helpful in guided fine-needle aspiration (FNA) or needle biopsy and to assess treatment response\textsuperscript{1}.

Now DW imaging is helpful to characterize tumors as well as differentiate tumor from non-tumor tissue. DWI is considered as a sensitive biomarker to monitor therapeutic response in neck malignancy\textsuperscript{2}.

Addition of DWI into routine MRI protocol will not add significant extra-time or burden for the patients as it is a completely non-invasive, fast sequence, highly sensitive, well-tolerated technique without contrast material administration\textsuperscript{3}. Aim of present investigation was assess potential roles and feasibility of diffusion-weighted MR imaging with calculated ADC value further get accurately characterize and differentiate benign form malignant pediatric head and neck masses.

Methods

Study Population:

This study included 56 (39 male and 17 female) patients, between March 2016 and October 2017, presented with head or neck masses. The mean age was 9.02 years (age range, 1–16 years). All patients were subjected to routine contrast-enhanced MRI to characterize these masses with anatomical and morphological details on local extensions and infiltrations. DW MRI was added to evaluate its role in characterization of the masses. Finally, diagnosis was confirmed by biopsy and histopathological assessment.

Technique:

Routine CE-MRI

The routine CEMRI technique was utilized supine position with standard circularly polarized head coil using MRI 1.5 Tesla (Phillips, Achieva XR, Netherlands). The following sequences were used; axial T1WI (450/12ms) TR/TE spin echo; axial T2WI (4540/96ms) TR/TE spin echo; axial STIR (9000/116/2500ms) TR/TE/TI; sagittal T1WI (430/10ms) TR/TE spin echo; coronal T2WI (4520/11ms) TR/TE spin echo, 5mm section thickness and 256x256 matrix size after intravenous administration of Gadolinium-DTPA (0.3 mg/kg), contrast-enhanced T1WI in axial, sagittal and coronal planes were obtained.

MR Diffusion Imaging

Axial DW was done through use single-shot T2-weighted echo planar spin-echo sequence (1600/107) diffusion gradient encoding in x, y, z orthogonal directions; b (0, 500 and 1000 sec/); view(24 - 24 cm); matrix (128-128); thickness, (7.5 mm); gap(0 mm); and final (1) signal acquired. At b, x, y, and z single-direction DW images and a baseline image (b _ zero sec/mm2) acquired 10 sections give 50 images at b in thirteen sec. (ten images of combined [{x _ y _ z}]/3) DW imaging, ten baseline image, and ten of x-, y-, and z-direction DW. DW get two hundred photo. DW data transferred to workstation for determined signal of each tumor.

ADC recorded at least 1cm regions of interest (ROI) of tumor on ADC. The ROI is placed on enhancing solid components as much as possible. We excluded cystic, necrotic, and hemorrhagic tumor areas.

Statistical Analysis

Results and entered were using SPSS program (24). Comparisons among quantitative variables done using non-parametric Kruskal-Wallis and Mann-Whitney 4.

ROC constructed with area under curve analysis to determined better cutoff of ADC to defined the malignancy.

Results

The masses were classified into benign solid (13 cases, 23.2%), cystic lesions (4 cases, 7.1%) and malignant tumors (39 cases, 69.6%) based on histopathological results. Table. 1 demonstrates the pathological entities detected by pathology analysis.

After accurate interpretation of the conventional MRI studies of these 56 cases, the primary diagnosis was, 17 cases were diagnosed as benign lesions (solid and cystic, Fig. 1), while 39 cases were diagnosed as malignant lesions (Fig. 2 and 3), relying on their morphological criteria, anatomical location and enhancement pattern. The analysis of diffusion weighted imaging based on signal intensity on b1000 images revealed 39 masses (69.6%) with high signal intensity and dark signal on ADC maps, reflective of restricted diffusivity. These cases were matching with the pathological diagnosed malignant tumors with sensitivity 100%. The remaining 17 cases (30.4%) were found to have facilitated diffusion.

Our results showed that, ±ADC of benign solid masses were 1.58±0.37 x 10^-3 mm²/sec while 2.1±0.18 x 10^-3 mm²/sec was found to present the cystic lesions. The mean ADC value of malignant masses was found to be 0.64±0.21 x 10^-3 mm²/sec. Statistical difference was noted among solid benign and malignant tumors (p<.0001). Fig. 4 shows Malignant tumors have lower ADC (mm²/sec) than benign solid masses or cystic lesions.

Fig. 1: 12-year-old male with facial masses/deformity. Coronal T2 weighted image and coronal CT bone window “a and b” images show extensive expansion of facial bones with heterogeneous predominately high T2 signal and ground glass appearance on CT images. Diffusion-weighted imaging “c and d” show intermediate signal in DWI and ADC map with ADC value of $1.55 \times 10^{-3}$ mm$^2$/s. The pathology revealed Fibrous dysplasia.

Fig. 2:11-year-old male with mass at the right masticator space. Axial T2 weighted and coronal T1 after IV gadolinium administration images show a heterogeneously enhancing infiltrating soft tissue mass (arrows) within the right masticator space. The mass is associated with perineural invasion along V2 course (circle). The diffusion weighted images demonstrate restricted diffusivity of the mass with ADC value $0.82 \times 10^{-3}$ mm$^2$/s. Pathology revealed Rhabdomyosarcoma.

Fig. 3: 2-year-old male with multiple lesions at the right sphenoid & left retro-maxillary/nasopharyngeal and left mandibular regions. Coronal T2 and T1 after IV gadolinium administration with fat saturation images at variable levels show multiple heterogeneously enhancing soft tissue masses (arrows) at the right sphenoid bone, left para-pharyngeal and left mandibular regions. These masses have restricted diffusivity on diffusion weighted imaging with ADC value $0.69 \times 10^{-3}$ mm$^2$/s. Pathology shows Langerhans cell Histiocytosis (LCH).

Fig. 4: Box and whisker plot of pediatric neck masses.

Discussion

Pediatric head and neck masses represent a challenge as they compass a wide spectrum of differential diagnoses. The optimal treatment depend on pathologic nature of these masses. Surgical approaches for malignant tumors certainly differ from those assigned for benign masses. Preoperative imaging with predicting benign from malignant tumors is paramount.
in management planning.\(^1\)

DWI could detect early pathological changes within tissues on the cellular level based on the random motion of water molecules. Increase in water content, change in composition or increase cellularity and decrease extra-cellular spaces significantly reflect on diffusivity of water molecules within different tissue.\(^5\)-\(^6\).

ADC of malignant pediatric neck tumors had lower value than of benign solid and cystic lesions. Which could assumed to histopathological variability between benign and malignant tumors. The malignant tumors have histopathologic characteristics such as hypercellularity with enlarged nuclei, hyperchromatism and loss of polarity. Consequently, the extracellular matrix and space diminish resulting in lower ADC values. Table. 2 demonstrates prior studies of DWI in the head and neck region.\(^7\)-\(^11\).

On our study the ADC (malignant cases) was 0.64 x 10\(^{-3}\), solid tumors 1.58 x 10\(^{-3}\), benign cystic lesions, 2.10 x 10\(^{-3}\) mm\(^2\)/s. ADC of 1.25 x 10\(^{-3}\) mm\(^2\)/s as threshold and benign lesions 100% and 94.1%, sensitivity and specificity, respectively.

These results are in the same track with Sakamoto et al.\(^12\) that found ADC of malignant cases is 1.13 ± 0.43 x 10\(^{-3}\) mm\(^2\)/sec, mean ADC of benign solid tumors, (1.56 ± 0.51) x 10\(^{-3}\) mm\(^2\)/s, which for benign cystic lesions, (2.05 ± 0.62) x 10\(^{-3}\) mm\(^2\)/s. ADC for 1.2 x 10\(^{-3}\) mm\(^2\)/s as threshold for distinguish among malignant and benign lesions.

The malignant cases were found that they have ADC value lower for the benign lesions, the mean ADC 0.64 x 10\(^{-3}\) mm\(^2\)/s.

On our study we found that, there is significant among the malignant lesions (\(P<0.001\)).

ADC difference in malignant tumors which could related to its cellularity, which agree of Abdel Razek et al.\(^11\) and Humphries et al.\(^13\).

There is significant P value of the ADC between the benign solid lesions and malignant lesions as well as between the benign cystic lesions and malignant lesions (\(P<0.001\)), while there is no significant P value between the benign cystic and solid lesions.

Future requirements to improve applications of diffusion MR imaging:

More standardization of DWI such motion-probing gradient directions, b values, and TR/TEs is very important. Updating current software tools to perform more complex quantitative is also needed.

Other limitations in this study included heterogeneity of the study cohort with widely variable pathological diagnoses. Additionally, the number of benign tumors was very small compared to malignant tumors.

**Conclusion**

Pediatric head and neck masses are one of the most important medical issues. Early detection help better therapeutic planning.

This study concluded that DW MRI is accurate, non-invasive and non-enhanced technique that could help proper characterization of masses with potential differentiation malignant from benign masses.

Prevalence of Obesity among Primary School Children Living in Egypt

Ali Mohammed El Shafie¹, Mohammed Bahbah¹, Zein Abdel latiff Omar¹, Wael Abbas Bahbah¹, Eman Salah Eladawy¹
¹Pediatric Department, Faculty of Medicine, Meniuofia University, Meniuofia, Egypt

Abstract

Obesity is a disease that dangerously affects health. BMI is the most preferable method to define. Childhood obesity is one of the major public health problems not only in low and middle income countries but also in high income. Obesity problem was in a rising curve in the last decade. School age is important period to early discover and effective intervention. Participants and methods: A cross sectional survey managed in 2018 including 31270 children in school age period in Egypt. Data was collected through a simple questionnaire and Measure weight, height and BMI. Assessment was in relation to BMI for age Z score. 200 obese children were selected randomly from the obese on basis of parental consent for investigations.

Results: 31270 students (6-11years) were studied. 15.02% overweight and 10.55% obese. Prevalence among boys (14.2%) more than girls 6.7%. higher in urban (15.5%) compared to rural (6.8%).higher among high socioeconomic standard (14.1%). Higher between (8-9 years) (15.9%) than other age groups. Cholesterol level was high in 20% of the selected cases while LDL was high in10% while Triglyceride was high in 25% of cases unlike HDL was low in only 15%. Conclusion: Overweight and obesity was 15.02% and 10.55% respectively. Higher among boys, urban and high socioeconomic. Cholesterol, LDL and TG were lower in 20%, 10% and 20% respectively and in HDL was lower in 15%.

Key words: Obesity, Prevalence, School Children.

Introduction

It is well recognized that childhood obesity is a significant public health issue, with adverse physical and psychological effects that persist beyond childhood into the adult years. After decades of rapid increase, it appears that childhood obesity prevalence in developed countries is starting to plateau. Reviews of international evidence have shown that the prevalence of obesity in children and adolescents is stabilizing in countries including Australia, Japan, France and US. However, evidence also suggests that such progress may not have been shared among children across all socioeconomic groups ¹.

Obesity is a multifactorial condition characterized by abnormal or excessive body fat accumulation. The etiology of obesity includes genetic, metabolic and environmental factors. Obesity appears mainly when the intake of calories is higher than the calories consumed. During last two decades, obesity has emerged as a leading public health problem; it is more prevalent in developed countries, affecting adult and children alike ².

Obesity is associated with physical problems, such as hypertension, coronary arteriosclerosis, elevated cholesterol, type 2 diabetes, joint problems and certain types of cancers. Psychologically, it is associated with decreasing self-image, anxiety and depression ³.

The age at which excess weight gain occurs has important implications for child health and development. The range of normal BMI changes during childhood growth, with values generally lowest during age 4-6 years followed by an increase and subsequent steady rise into the adolescence. Early adiposity rebound is
associated with greater adiposity in mid-childhood, which, in turn, has been associated with accelerated growth, advanced bone age, earlier pubertal transition and adult obesity. In older children, both overweight and obesity contribute to an increased risk of metabolic syndrome, type 2 diabetes, hypertension, dyslipidemia and obstructive sleep apnea. Thus, early recognition of obesity is an important step towards preventing long term adverse health consequences.

The global burden of disease studies in 1990, 2000, and 2013 showed that metabolic risk factors are the most important determinants of emerging non-communicable diseases all over the world. Obesity has now become a common health problem and its prevalence continues to increase in both developed and developing countries. The increasing incidence of childhood obesity and its attributed socioeconomic and public health burden is a real threat for developing countries. Recent studies reveal the increasing rates of obesity and their attributed ranges of adverse health outcomes in children and adolescents. Most obese children and adolescents already are at high risk for metabolic complications, and for a wide range of morbidities and mortality so lipid profile to these children help in decreasing this risk.

Metabolic syndrome is considered not only an adult condition but a pediatric as well. The main components of MS are: central obesity, hypertension and abnormal carbohydrate and lipid metabolism. When we identify the factors that constitute MS in the early stages of growth, there is an advantage of early initiation of treatment, reducing the risk of developing a classic MS.

The 2015 Egypt Health Issues Survey confirms that non-communicable diseases are on the rise and remain among the leading causes of death in Egypt. School age is a very special period where children develop and acquire knowledge and behavior in relation to health protection and promotion, so early determine obesity problem in this period will provide the easily bypass it.

In Egypt most of related articles that focused on overweight and obesity are focused mainly on children below 5 years but typically developed children at primary school age have not investigated the overweight and obesity and their relation to lipid profile. Therefore, due to the insufficient data and given the lack of studies in this field in Egypt due to un awareness of the Egyptian families about the problems of obesity and even some of the families didn’t know that obesity is a disease.

So the goal of this study was to determine prevalence of obesity in primary school age children in Egypt.

**Method**

Among all primary schools from seven Egyptian governorates were selected by randomly, 4 governorates from delta region and 3 of them from Upper Egypt. A cross sectional study was conducted between Aprils till November 2018 in children among age groups (6 to 11) years.

An approval from Menoufia Faculty of Medicine ethical committee was taken before beginning of the study.

A written consent form was signed by the manager of each school and authorities in the education ministry.

A written consent was signed by parents of the students after describing to them about the important of the study and that there was no any invasive maneuver to their children.

Selection of cases: the study was included 31270 students will be diagnosed according to Z score charts. The survey was conduct a questionnaire to the student includes the identification: (name, age, sex, and residence). Assessment of socioeconomic standard of family with questions about the father’s and mother’s education and occupation and family income according to modified.

Only 200 children were investigated to lipid profile after a written consent from their parents and briefly counseling them about obesity and high lipid profile relation also the diseases that precipitated secondary to this problem.

Anthropometric measurements were taken in situ. (Height, weight and BMI) we determined obesity according to Z- score for BMI.

The chosen child with criteria of both sex, age between 6 to 11 years, live in Egypt and apparently healthy. And the excluded child: age above 11 years or below 6 years, with skeletal deformity or long term steroid therapy.

The data were analyzed by SPSS (statistical package for social science) version 17.0 on IBM computer. We used two types of statistical analysis: Descriptive statistics e.g. percentage, mean and standard deviation.
and analytic statistics e.g. Chi-square test. P-value of < 0.05 was considered statistically significant.

**Results**

This table shows that the percentage of the age groups and sex, 6-7 y (30.28%) was higher and 10 y < (10.08%) , according to sex there were 51.62% male, female 48.38%, according to age the mean was 7.95 ± 1.52. (Table 1)

Chi-Square $\chi^2$ 755.40

P-value 0.00**
**Discussion**

Obesity has become a global problem that is not only limited to adults but also unfortunately, child and adolescent obesity has become a major public health problem.

The screening determined that 10.55% were obese according to WHO Z-Score for BMI curves for both sex.

Our study was similar to the prevalence of obesity among primary school children aged 8-10 years in Dar es Salam city, Tanzania was 9.5%.

The prevalence of obesity and over weight in our study were lower than Hispanics (18.2% boys, 15.2% girls).

Also it is lower than El shafie et al. Childhood obesity has more than tripled in the past 30 years. The prevalence of obesity among children aged 6-11 years increased from 6.5% in 1980 to 19.6% in 2008.

Our study revealed that prevalence of obesity among male children (14.2%) was higher than in female children (6.7%).

Unlike M. Alqarni shows existing trends of gender-specific and overall obesity prevalence in KSA. According to the statistics, rate of obesity is continuously increasing, Saudi women have a higher obesity rate than men; and the overall rate is projected to reach 59.5% by 2022.

We found prevalence of overweight and obesity in urban areas (21.5% and 15.5%) respectively higher than living in rural areas (10.1% and 6.8%).

This is in similarity with El- Shafie et al. this could be the dietary variation between rural and urban areas.

There was statistically significant difference obesity is higher in high socioeconomic than low and average.

An international systematic review published in 2010 examined obesity prevalence trends and reported leveling off of the obesity epidemic in recent years. leveling of obesity prevalence less apparent for more disadvantaged socioeconomic groups. However, impact of socioeconomic on obesity prevalence provided mixed results.

Our study is in agreement with the results of Janevic et al., who reported low socioeconomic status had a more detrimental effect on linear growth than on body weight.

**Conclusion and Recommendation**

The main purpose is to evaluate the prevalence of obesity among primary school age between 6 to 11 years and it was 10.55% and we determined the relation of obesity with socioeconomic standard than increase with high socioeconomic, also it more in boys and more common in urban. Finally we need more care from media and ministry of health to encourage the harm of obesity and the diseases occur secondary to Uncontrolled obesity and need special programs for obese child and a fitness programs aiming to reduce not only their weight but also decrease MS risk.

**Authors contributions**

AE devised the idea for the beginning of the research program. All authors helped in collecting the data of the manuscript and the result analysis. AE and ZO supervised the research. AE, ZO and WB greatly contributed to the manuscript revision. ZO and ESE wrote the article. All authors read and approved the final manuscript.

Abstract

Background: Nausea and vomiting are the most common side effects associated with the usage of chemotherapy among breast cancer women. Aim of this study was to investigate the effectiveness of acupressure on chemotherapy-induced nausea and vomiting among breast cancer women. Research design: Quasi-experimental design was used to achieve the aim of the current study. Setting: The current study was conducted in outpatient oncology clinics at Zagazig University Hospitals. Subjects: Breast cancer women were divided into two groups (acupressure and control). They are on routine care and regular treatment. Tools: Interview questionnaire consists of four parts were used for data collection: Demographic characteristics and medical history, risk factors for nausea and vomiting, awareness regarding complementary therapy and the Index of Nausea, Vomiting and Retching (INVR). Results: The results showed that the mean scores of total occurrence, experience, distress for nausea, vomiting, retching in acupressure group were statistically significant decreased compared to control group throughout follow up days (p<0.05). Conclusion: Acupressure technique is positively affect nausea, vomiting and retching among breast cancer patients. Recommendation: Acupressure as technique should be carried out as supportive nursing intervention to relieve chemotherapy induced nausea and vomiting in breast cancer patients.

Keywords: Acupressure, chemotherapy-nausea-vomiting breast cancer, pharmacological techniques

Introduction

Breast cancer is the deadliest cancer amongst females in developing countries, causing about half a million total deaths each year¹. In Egypt, according to Egyptian National sponsored programs for cancer registry; breast cancer incidence increased from 18.9% to reach 38.8% in 2014².

Chemotherapy is a significant constituent of therapy for many cancers, and new anti-cancer medicines appear one of the greatest areas of pharmaceutical development³. Nausea and vomiting are the greatest be afraid side effects of cytotoxic chemotherapy and it can have a causing harm influence on the health-concerning quality of life, compromise treatment outcomes and increase healthcare resource utilization⁴.

There has been growing interest in the use of complementary and alternative medicine alongside curative and palliative treatments, use have been associated with reduced therapy related toxicity, improvement in disease related symptoms and in quality of life⁵. Acupressure is the usage of pressure or localized massage to particular sites on the body, the Nei-Guan point (P6) is known for relieving nausea and vomiting⁶.

Furthermore, research results revealed that the mean nausea, vomiting, and retching scores for patients was utilized at the P6 acupressure point were statistically considerably lower than the patients in the control

group in breast cancer. Nurses should play key roles in helping patients to assess and manage chemotherapy-induced nausea and vomiting.

**Materials and Method**

**Design**

Quasi-experimental design was used to achieve the aim of this study.

**Setting**

The study was conducted in outpatient oncology clinics at Zagazig University Hospitals.

**Sample**

A purposive sample consisted of 56 breast cancer women undergoing chemotherapy on routine care. They were divided into two groups (study and control) using random allocation.

**Inclusion criteria**

1. Women aged 30-60 years
2. Stage of breast cancer I-III
3. Female who were starting their second or third cycle of chemotherapy
4. Receiving chemotherapeutic protocols such as Adramycin-Cyclophosphamid (AC), 5-fluouracil-Adramycin-cyclophosphamid (FAC) and 5-fluouracil-Epirubcin-cyclophosphamid (FEC)
5. Had nausea/vomiting with their previous cycle
6. Controlled diabetes and hypertension
7. Free from lymph edema in arms and bowel obstruction

**Tools for data collection**

An interview questionnaire sheet composed of four parts:

- **Part I**: Demographic characteristics and medical history
- **Part II**: Risk factors for nausea and vomiting
- **Part III**: Awareness regarding complementary therapy
- **Part IV**: Index of Nausea, Vomiting, and Retching

This index was developed by Rhodes and McDaniel [9]. Depending on a 5-point Likert-type questionnaire that consisted of eight questions. These were scored from 0 to 4 respectively, with inverse scoring for negative notifications therefore that a higher score indicates more severity of symptoms. This index assesses experience, occurrence, distress of nausea, vomiting, and retching. The scores of occurrence, distress, and experience as well as the total Rhodes score were added and expressed in means and standard deviations. The day “1” are considered as the acute symptoms while the days 2 to 7 are considered delayed symptoms.

**Pilot Study**

A pilot study was achieved on a sample of 6 women with breast cancer under treatment of chemotherapy. The person who takes part in the pilot study were excluded from the sample.

**Ethical Consideration:**

Official letters were issued from the Faculty of Nursing, Zagazig University to the Directors of the outpatient clinics. Moreover, confirmed for participation was taken verbally from each woman.

**Field work:**

The researcher started the collection of data (assessment phase) through interview with each woman individually. The researcher explained simple information regarding acupressure (definition, benefits, frequency, duration) and how to locate the P6 (Neiguan), i.e., place three middle fingers proximal to the upper wrist crease, the most distal finger will still just on the wrist crease. The p6 is located between the two central tendons by the index finger.

Patients were required to wear a wristband on both wrists continuously for seven days. The average time to complete the interview questionnaire ranged from 40-60 minutes. The effectiveness of the intervention was done through phone call using the same tool (post
intervention. They were asked to fill out the index at the same time each night through seven days. Data were collected through 11 months, starting from the beginning of September 2017 to the end of July 2018.

**Results**

Study results showed that studied groups (acupressure and control) their mean age was 46.5±9.5 and 46.6±8.5 respectively. Regarding marriage, 85.7% of acupressure group and 92.9% of control group were married.

Table (1) points to regarding occurrence of vomiting and retching were statistical significant decreased in acupressure group compared to control group post intervention through out follow up days (p<0.05). As regards the occurrence of nausea was statistical significant decreased in acupressure group compared to control group post intervention on first five days. Regarding total occurrence of nausea, vomiting and retching were statistically significant decreased in acupressure group compared to control group through out follow up days.

(*) Statistically significant at p<0.05
Table (2) reveals that nausea and retching distress were statistically significant decreased in acupressure group compared to control group post intervention throughout follow up days (p < 0.05). Concerning vomiting distress was statistical significant decreased in acupressure group compared to control group post intervention throughout follow up days except for sixth and seven days. Regarding total distress of nausea, vomiting and retching were statistically significant decreased in acupressure group compared to control group throughout follow up days.

Table (3) demonstrates that nausea and retching experiences were statistical significant decreased in acupressure group compared to control group post intervention throughout follow up days (p <0.05). In relation to vomiting experience was statistical significant decreased in acupressure group compared to control group post intervention on first five days. Regarding total Rhodes scores of nausea, vomiting and retching were statistically significant decreased in acupressure group compared to control group throughout follow up days

### Discussion

The current study results revealed that vomiting and retching occurrence were significantly decreased in the acupressure group compared to the control group throughout follow up days. These results might be due to compliance of breast cancer patients with wearing of the wrist bands. Similarly, in Egypt, \(^{10}\), found that there were low mean score for acupressure group rather than control group in acute and delayed vomiting, retching occurrence.

Furthermore, the current study results found that nausea occurrence was significantly decreased in acupressure group compared to control group throughout first five days. The rational of this phenomenon might be due to pressure on p6 relax stomach muscle and relieve stomach disturbance including nausea. In UK, this result was in agreement with [11], done a randomized controlled trial. They found that nausea occurred significantly less frequently in the acupressure group compared to the control across the five assessment days.

Regarding symptoms distress, the current study results showed that nausea and retching distress were significantly decreased in acupressure group compared to control group throughout follow up days. This reflected feelings of breast cancer women with support and interest which lead to improving psychological status. In turkey, this finding is on the same line with 7. Who found that the average scores for patients in the experimental group in terms of the distress may be caused by nausea and retching were decreased than with patients in the control group.

In addition to study results found that vomiting distress was significantly decreased in acupressure group compared to control group throughout follow up days. This finding was supported by12 who carried out a study in Egypt and found that the mean score of vomiting distress in study group using acupressure were decreased compared to control group.

Considering symptoms experience, the current study results revealed that nausea and retching experiences were significantly decreased in acupressure group compared to control group throughout follow up days. The explanation of these results might be reflect the feasibility of acupressure technique. Similarly, [13] in Mani pal found that nausea experience was significantly lower in the acupressure group than the control group.

On the same way, in UK,14 found that nausea levels in the proportion of patients using wristbands were lower than those in the proportion of patients using antiemetics-only group.

Moreover, study results revealed that vomiting experience was significantly decreased in acupressure group compared to control group throughout first five days. The rational of this result might be due to non pharmacological with pharmacological treatment double positive effect on decreasing chemotherapy induced nausea and vomiting. The previous finding was supported by study carried out by 15 in Coimbatore, found that significant values between acupressure and control group regarding level of vomiting using standardized rhodes index of nausea and vomiting across the five assessment days.

Regarding total occurrence, experience and distress of nausea, vomiting and retching. The current study revealed that the mean scores of total rhodes for nausea, vomiting, and retching experiences were significantly decreased compared to control group. These findings might be attributed to the acupressure P6 wrist band when applied to point P6 is effective, safe, convenient, cost effective, and provides an easy, self-administrated, that can be used to reduce chemotherapy induced nausea and vomiting. in congruent, researches conducted in Turkey by 7, in Egypt by 10, and in Uk by 11 where it was determined that the mean scores of total rhodes for nausea, vomiting, and retching for patients to whom acupressure was applied at the P6 was statistically significantly decreased than the scores of patients in the control group.

On the contrary, study carried out by 16 at Istanbul University Institute of oncology found that nausea, vomiting and retching experiences of the patients before utilizing a placebo and a real acupressure were identical and similar alterations had been showed 5 days after the therapy. It has been determined that there was no variation among the groups statistically. This might be attributed to different sample size, diagnosis and type of protocol of treatment.

Conclusion

The mean scores of total occurrence, experience, distress for nausea, vomiting, retching in acupressure group were statistically significant decreased compared to control group.

Recommendations

1- Acupressure as non-pharmacological method should be achieved as supportive nursing intervention to alleviate chemotherapy-induced nausea and vomiting in breast cancer patients.

2- Further studies should be achieved on a large scale with a randomized control design.

Correlation Between Trapezius Trigger Points and Head/Neck Posture In Subjects With Frozen Shoulder

Anagha Deshmukh1, Khushboo Bathia2, Smita Kanase3, Amrutkuvar Jadhav4

1Intern, Faculty of Physiotherapy, 2Assistant Professor, Department of Sports Physiotherapy, 3Assistant Professor, Department of Musculoskeletal Sciences, 4Associate Professor, Department of Orthopaedic Manual Therapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Objective: To find out correlation between head/neck posture and trigger points in upper trapezius muscle in frozen shoulder subjects.

Method: A total of 48 subjects (28 females and 20 males) between the age group 40-60 years with stage 2 of frozen shoulder were selected for the assessment of head/neck posture and trigger points in upper trapezius. Outcome assessment for head/neck posture included cranial vertical angle (CVA), cranial rotation angle (CRA); upper trapezius trigger points were explored through palpation. Both the readings were compared and analysed by Pearson correlation test using SPSS (version 20).

Result: Poor correlation between CVA and upper trapezius trigger points-(r=0.1647) whereas correlation between CRA and trigger points in upper trapezius-(r=-0.0972) in subjects with frozen shoulder which was statistically insignificant.

Conclusion: There is weak influence of head/neck posture and trigger points in upper trapezius. i.e. there is no greater/smaller deviational change in the forward head posture (FHP) in association with trigger points in upper trapezius in frozen shoulder subjects.

Keywords: Cranial vertical angle, cranial rotation angle, head/neck posture, trigger points.

Introduction

Frozen shoulder is a common shoulder joint condition characterized as painful, limited active as well as passive joint range of motion (ROM) of the shoulder. It is found in 2-5% of the general population and 10-15% of the diabetic population. Occurrence of Frozen shoulder is most commonly seen in females than in males, affecting the age group between 40-60 years.

The exact aetiology of Frozen Shoulder is unknown. However, it is an inflammatory contracture of the glenohumeral joint capsule resulting in pain, stiffness at shoulder joint. Capsular adhesions limit glenohumeral movements, dominating compensatory abnormal scapular movements like excess elevation, increased upward rotation of scapula during arm elevation. Weakness of glenohumeral external rotator muscles concerning with upper trapezius (UT) muscle overload result in pain, forming Myofascial trigger points (MTrPs) in UT. According to the line of muscle action and axis of scapular motion, the UT elevates and rotates scapulae and lower trapezius maintains horizontal and vertical equilibrium of scapulae. Thus, scapular motion is altered by imbalanced force production of upper and lower trapeziusthereby activating UT with increased superior translation of scapulae.

Abnormal motions of the scapula are in line with muscle imbalances inducing weakness of one muscle group and tightness of other leading to musculotendinous, ligamentous changes gradually resulting in symptomatic
pain, stiffness. Thus, altered muscle tension in and around the neck and shoulder muscles changes the neck posture. Forward head posture (FHP) results in postural abnormalities of the neck wherein the head/neck rest anteriorly to vertical line of body’s centre of gravity (COG). In FHP, weight of the head supported by neck is increased, flexion/extension of which exerts pressure on the surrounding muscles, joints of cervical vertebra.

Correct alignment of the vertebra of the cervical spine is related to muscle contraction. UT can alter the motion of cervical spine. FHP alters the scapular kinematics, kinetics by increasing the load on posterior cervical structures. Corresponding to UT overload, imbalanced scapular upward rotators have an impact on UT pain, MTrPs. FHP can induce problems related to muscle proprioception, like mechanoreceptors, spindle sensitivity alteration of neck muscles, loss of kinaesthetic acuity of neck movements. UT, serratus anterior being the primary stabilizers of scapula regulate force to control scapular motions. Activation of stabilizing muscles is altered due to abnormal orientation of the scapula. Increased activity of upper and lower trapezius is seen in FHP. Altered scapular alignment and FHP may contribute to shoulder pain, affecting UT with MTrPs and pain. MTrPs limit ROM exhibiting specific referred pain patterns on palpation also are associated with pain production, altered motor function. Among the postural muscles, UT is mostly affected with MTrPs.

Various method, tools are available to assess MTrPs including Pressure Pain threshold (PPT) with Algometer, instrument assisted soft tissue techniques, soft tissue Palpation. Looking at cost effectiveness and clinical feasibility; identification of MTrPs on palpation is a reliable method. With flat palpation, taut band is located, on compression of hyperirritable spot for a few seconds MTrPs are explored.

Assessment of FHP can be done with: Cervical Range of Motion Instrument (CROM), Photogrammetric method, Radiographs. One of the easily accessible method is Photogrammetric method: CVA [ICC-(intrarater)0.984, (interrater)0.983] measured on photographs captured in lateral view. The lesservalue of CVA,CRA greater is FHP. Availability of easily accessible method, tools is necessary for evaluation of FHP which can be done using various system softwares like Body style Analyzer, MB Ruler [intrarater (ICC>0.972); Test-retest(ICC=0.774)], Kinovea [ICC-(intrarater) 0.95 to 0.98;(interrater) 0.98 to 0.99] etc.

Previous studies show higher UT electromyographic activity during six different testing positions in Frozen shoulder contributing altered scapular movement, muscle imbalances limiting glenohumeral movements. This study aims at determining head/neck posture, presence/absence of trigger points in UT among frozen shoulder subjects, so as to aid them in attaining proper cervical spine posture, inactivating trigger points thereby achieving correct muscle balance.

Materials and Method

Study design-cross-sectional study, sample size-48 subjects, Study Place-KIMS Hospital Karad, Study duration-3months, Sampling method-consecutive sampling.

Inclusion Criteria: 1) Unilateral Frozen Shoulder, 2) stage 2 Frozen shoulder, 3) Male, female subjects, 4) Age group between 40-60 years of age

Exclusion Criteria: 1) Patients injected with corticosteroids, 2) fractures, dislocations of the shoulder, 3) undergone surgery of shoulder in past 3 years, 4) blockade/infiltration for last six months, 5) cervical pathologies like spondylolisthesis, facet osteoarthritis, disc herniation, stenosis.

Outcome measures: The outcomes were assessed by measuring CVA, CRA using photographic method. Adhesive markers were placed at Tragus of the ear, Canthus of eye, C7 spinous process. Self-balance posture was achieved by having the subject perform maximum cervical flexion/extension and gradually reducing it to place the head in comfortable position. The subjects were photographed in lateral view using SONY GX30 (digital camera). The distance between the camera and measurer was set 1.5m. CVA was measured by drawing a horizontal line passing through C7 parallel to the ground and a line passing through C7 and tragus of the ear. CRA was measured by line connecting C7 with tragus of the ear and line connecting tragus of the ear with lateral canthus of eye. Angles were measured on the digital photographs using Kinovea computer program.
UT Trigger points were explored through palpation. Having the subject in supine lying on the couch, examiner standing superiorly to the subject taut band was located with flat palpation using thumb. Palpation was perpendicular to muscle fibre orientation from medial third of superior nuchal lines, external occipital protuberance to lateral border of clavicle. Also, trigger points were palpated at spinous process C5-C6 approximately halfway between spinous process and acromion, hyperirritable spot was located using pincer grasp. The entire free margin of UT was lifted off underlying supraspinatus and apex of the lung after which muscle was rolled between the thumb and fingers to locate hyperirritable spot along length of the muscle. On compression of hyperirritable spot for 10 seconds presence/absence of trigger points was noted.7

Materials used—Camera (Sony Lens G30X), Laptop, Inch Tape, Adhesive Markers, Watch.

Ethical clearance was obtained from Institutional Ethical Committee KIMSDU. Demographic data was collected, explaining procedure to subjects. Each one was assessed for trigger points through palpation in supine lying and head/neck posture-CVA, CRA were assessed. Data was recorded, analysed in accordance to distribution of age, gender, diabetes, affected side, pain during assessment, association between CVA-trigger points and CRA-trigger points.

Association was determined using Pearson correlation coefficient (r). Correlations were considered weak when r<0.3, moderate 0.3<r<0.7 and strong when r>0.7. The statistical analysis was conducted at 95% confidence level wherein, p<0.05 was considered statistically insignificant.

Discussion

Among the 48 subjects, UT trigger points were present in 6 subjects and absent in 42 subjects. The mean degrees of CVA was (mean±SD) 45°±6.067 and CRA was 158°±7.296.

Antony Paul suggests that frozen shoulder commonly affects females, accordingly your sample includes 28 females and 20 males. Frozen shoulder commonly affects individuals in fourth to sixth decade of life, as in, our sample includes 10 frozen shoulder subjects between the age group 41-50 years and 38 frozen shoulder subjects between the age group 51-60 years (55.75±5.302).

Study includes 17 individuals with diabetes and 31 individuals without diabetes. Conversely, literature suggests that individuals with diabetes are more commonly affected with frozen shoulder. As this study was conducted in a limited geographical area, results could not be generalized with a smaller sample size.

This study shows 36 subjects had no pain during assessment and 12 subjects experienced pain during the assessment. Our study shows 42 subjects with no trigger points and 6 subjects with presence of trigger points. Whereas, Ferracini GN suggests presence of active and latent trigger points in various neck and shoulder muscles like Suboccipital, sternocleidomastoid, temporal, UT in subjects with migraine. In our study we found less number of subjects with UT trigger points as they were undergoing treatment limiting the generalizability of findings.

Altered patterns of muscle action, muscle imbalances leads to altered movement patterns of the head and shoulder muscles in individuals who use computers, smartphones for a prolonged duration. A study conducted on Predictors of UT pain and MTrPs in food service workers reviewed that, various factors like strength, posture, mobility and psychological factors are linked with UT pain and MTrPs in food service workers. In our study only 6 subjects were found to have trigger points in UT, as subjects were not differentiated according to the occupation, strength, mobility were not considered.

This study showed mean CVA as (45±6.067). A Study conducted on FHP angle in healthier older females suggested no significant correlation between FHP angle in relation to old age. The study showed mean CVA as (46.41±5.32). The mean value of CVA in our study is smaller as we had included both male, female samples in the study with varying duration of stage 2 frozen shoulder.

In this study CRA mean was 158.41±7.296, whereas a study conducted on three-dimensional analysis of motion reported average ROM in cervical spine across all age groups-total rotation (Mean 144°SD-23°) with wide variation in all age groups. However, discrepancies between studies suggest that above study was conducted among all age groups whereas, in current study we included frozen shoulder pathology between the age group 40-60 years and subjects were not having a specific angle range that can be identified as FHP.

In our study, mean CVA, CRA values are 45±6.067 and 158±7.296 respectively. Astudy conducted on the Effects of cervical Mobilization Combined with Thoracic Mobilization on FHP of neck pain patients suggested improvements in CVA, CRA on giving combination of cervical mobilization and thoracic mobilization. The mean values of CVA were 46.6±3.3 and 48.9±3.1 before and after respectively whereas, the mean values of CRA were 155.3±3.1 and 152.6±3.1 before and after respectively. In our study, mean values
of CVA, CRA are found to have wide range of difference as the study was cross-sectional, postural changes were considered secondary to frozen shoulder and subjects were undergoing treatment i.e. not freshly diagnosed with frozen shoulder.

Present study shows weak correlation between head/neck posture and UT trigger points. Correlation between CVA and trigger points was \( r = 0.1647 \); CRA and trigger points was \( r = -0.097 \) which was statistically insignificant. We found certain restraints in determining the association between UT trigger points with CVA and CRA as the subjects were not found to have a certain range of angle of FHP and due to lack of clinically accessible tools for exploring trigger points.

The limitation of this study was that other factors like psychological status, lumbar spine curvature, alignment of lower limb and postural measures like head tilt angle, head position angle, forward shoulder angle were not considered. Lack of gold standard assessment tool for identification of trigger points was another limitation of the study. Furthermore research is required to identify the correlation between head/neck posture and trapezius trigger points considering other variables like strength, mobility, neck pain, lower limb alignment, psychological status, occupation of subjects in order to prevent postural abnormalities, functional disabilities, improve cervical spine alignment and stability.

**Conclusion**

On the basis of results of our study, we conclude that correlation between CVA and UT trigger points was weak \((0.1647)\) whereas no correlation was found between CRA and UT trigger points \((-0.0072)\).

Dominant Factors of Central Obesity in Hypertensive Patients

Anila Istitis Atin\textsuperscript{1}, Ratu Ayu Dewi Sartika\textsuperscript{1}

\textsuperscript{1}Department of Nutrition Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

Background: Central obesity, which has increased in hypertensive patients over the past ten years, is a risk factor for long term complications such as type 2 diabetes, cancer and cardiovascular diseases. These diseases have health consequences ranging from increasing risk of early death to severe chronic conditions reducing the quality of life. When a person becomes overweight or obese at a young age, the incidence and severity of long-term complications due to obesity also increases significantly.

Objectives: This cross-sectional research study identifies the difference between sleep quality and other factors of central obesity in hypertensive patients. The study sample included hypertensive patients studied at the Puskesmas Tegal Gundil.

Material and Method: We recruited 92 hypertensive patients from Puskesmas Tegal Gundil, North Bogor District. Data were collected in 2017. The Global Physical Activity Questionnaire was used to assess physical and sedentary activity. Sleep quality and duration were assessed using Pittsburgh Sleep Quality Index. Energy, carbohydrate, protein, fat and dietary fiber intake are analyzed with the semi-quantitative food frequency questionnaire and Nutrisurvey software.

Result: The frequency of central obesity in our sample was 82.6\%, and there were significant relationships between central obesity and sleep quality, energy and carbohydrate intake.

Conclusion: A dietary approach to stop hypertension for Indonesians (DASHI) should be socialized for hypertensive patients.

Keywords: Central obesity, dietary intake, hypertensive patients, sleep quality.

Introduction

Obesity cases around the world have nearly tripled since 1975.\textsuperscript{1} When a person becomes overweight or obese at a young age, the incidence and severity of long-term complications due to obesity also increases significantly. The most common complications of obesity include type 2 diabetes mellitus, cancer, and cardiovascular diseases, including hypertension and stroke.\textsuperscript{2} Obesity is also closely related to metabolic syndrome, a collection of risk factors for dangerous heart attacks. According to the International Diabetes Federation (IDF) these risk factors include diabetes, increased fasting glucose, central obesity, high cholesterol and high blood pressure.\textsuperscript{3} These diseases have health consequences ranging from increasing risk of early death to severe chronic conditions reducing the quality of life.\textsuperscript{4}

Lack of physical activity is associated with obesity because imbalanced food intake and energy expenditure will result in accumulation of body fat.\textsuperscript{5} The main causes of being overweight and obesity is an energy imbalance between calories consumed and calories expended.\textsuperscript{1} Sedentary activities, such as watching television, contribute to an increased prevalence of obesity. Research in the UK with adult respondents demonstrated that longer durations of watching television are related to increased incidences of central obesity. Respondents who watch television \textgreater;6 h per day had a significant relationship tended to
be more obese compared to respondents who watched television for <2 h per day.  

The quality and duration of sleep are also associated with the incidence of obesity. Poor sleep patterns, including sleep deprivation and poor sleep quality, have an impact on hormone regulation processes, which can increase the risk of obesity. Theorell-Haglow’s study of Swedish women aged 20 years or more found that women with a sleep duration >10 h per day had a greater waist circumference than women who slept <8. The study also found that sleep-deprived respondents had greater waist circumferences than those who had enough sleep. Respondents with long or short sleep duration generally lacked physical activity, were smokers, were sick or were undergoing treatment and experienced psychological stress.

Central obesity is also associated with hypertension. Owalabi et al. found that central obesity was significantly related to the incidence of hypertension. In this study, 490 of 998 respondents (49%) were hypertensive patients. Of these, 74.1% of the hypertensive patients had central obesity. Our study aims to determine differences in sleep quality, sleep duration, physical activity, sedentary activity, energy intake, carbohydrate, protein, fat and central obesity fibre in hypertensive patients at the Tegal Gundil Public Health Center (Puskesmas) North Bogor District in 2017.

Method

This is cross-sectional, quantitative research. Physical activity assessed is at work, travel to and from places and sedentary activities. Sedentary activities in this study include sitting or reclining at work, at home, getting to and from places, time spent sitting at a desk, sitting with friends, travelling in a car, bus, or train, reading, playing cards, or watching television. Study of dietary intake included the intake of energy, carbohydrates, protein, fat and dietary fiber.

The study was conducted in the working area of Puskesmas Tegal Gundil, North Bogor District, Bogor City in May, July and September 2017. The study sample included hypertensive patients studied at the Puskesmas Tegal Gundil. The inclusion criteria of this study were: hypertensive patients aged 30–65 years registered as participants in the Program Penanggulangan Penyakit Kronis (Prolanis) or Chronic Disease Program and Pos Pelayanan Terpadu (Posbindu) or an integrated health service programme.

The instruments used in this study include the following. A plastic measuring tape with 0.1 cm accuracy, used to measure waist circumference (categorized as central obesity is ≥ 90 cm in men and ≥ 80 cm in women). A physical activity questionnaire taken from the Global Physical Activity Questionnaire, version 2, which assessed overall physical activity and sedentary activity or leisure activities. The sleep quality questionnaire was taken from the Pittsburgh Sleep Quality Index (PSQI) and was used to assess sleep quality with seven components; subjective sleep quality, sleep latency, sleep duration, sleep efficiency, sleep disturbances, use of sleeping pills and daytime dysfunction. A semi-quantitative food frequency questionnaire was used to determine the dietary intake of respondents during the prior month and calculated using Nutrisurvey 2007 software. Data analysis included univariate and bivariate analyses performed using statistical analysis applications. Bivariate analysis was performed using independent samples T-test and Mann–Whitney U.

Results

We studied 92 total hypertensive patients. Most hypertensive patients were classified as centrally obese (Table 1).

Hypertensive patient characteristics, including age, waist circumference, physical activity and sedentary activity, as well as sleep quality and duration and dietary intake (energy, carbohydrates, protein, fat and fibre intake), are presented in Table 2. The univariate analysis results indicate that the average age of respondents was 51.6 ± 8.4 years. The mean waist circumference was 91.23 ± 12.68 cm. Based on waist circumference measurements, 82.6% of respondents had central obesity (Table 2). Physical activity is calculated in MET-mins/week with a mean of 2583.7 ± 3325.12 MET-min/week. Meanwhile, mean sedentary activity was 350.92 ± 219.84 min/day. Sleep quality score has a mean of 5.86 ± 2.58.

The average sleep duration of the respondents was 6.48 ± 1.32 h. The average energy intake was 1573 ± 596 kcal. The average carbohydrate intake was 210.5 ± 77.8 grams. The mean protein and fat intake were 56.8 ± 29.8 grams and 57.0 ± 32.4 grams, respectively. The respondents’ fibre intake was 10.7 ± 5.5 grams.

The carbohydrate intake, energy intake and sleep quality have significant differences with central obesity.
The mean physical activity score in the group with central obesity was smaller compared to the non-central obesity group. The mean sleep quality score was greater in the central obesity group. Energy and carbohydrate intake is found to be greater in non-central obesity groups.

**Discussion**

The results showed that 82.6% of our hypertensive patients had central obesity, which is is alarmingly higher than the national obesity rate of 26.6%. Also, more women had central obesity (82.7%) than men (81.8%). This study is in line with a central obesity study in diabetics conducted in the Jatinegara Health Center, East Jakarta, which found a greater proportion of central obesity in diabetic women (82.7%) than men (72.7%).

In the current study, the group with central obesity had a lower physical activity score than the other group. There is a stigma of obese individuals who tend to be lazy, but excessive adiposity can limit joint and muscle movement and cause pain. This condition makes it more difficult for obese individuals to move. In addition, a disruption of dopamine signalling that controls body movement contributes to physical inactivity in obese individuals. The disruption of dopamine signalling can be caused by continuous exposure to an obesogenic diet (high-fat food) which interferes with dopamine synthesis.

The sedentary activity of the central obesity group was lower than the non-central obesity group. This finding is in contrast with previous research which has found a significant relationship between central obesity and sedentary activity since a higher waist circumference was associated with greater sedentary activity.

The PSQI questionnaire assesses sleep quality based on several components, such as sleep efficiency, sleep latency and sleep disturbances. In the sleep disturbance component, there are questions about possible sleep problems, such as not being able to fall asleep in 30 min, feeling too hot, feeling too cold, having a bad dream and unable to breathe comfortably. Respondents who experienced this sleep disorder had higher PSQI scores. In our study, 57.6% of respondents awoke at midnight ≥ 3 times/week. In addition, 9.8% of respondents had difficulty breathing comfortably 1–2 times/week and 4.3% experienced breathing difficulty ≥ 3 times/week. Sleep disorders such as obstructive sleep apnoea (which is the narrowing of the upper airway due to obstruction by the throat muscles that relax) are associated with hypertension and obesity.

The mean sleep duration in the central obesity group was not significantly lower than the non-central obesity group. In another study, sleep duration was not different in central obesity because short sleep duration decreased with age.

Various other studies propose that the main cause of central obesity is an energy imbalance. If the energy intake is more than the energy expenditure, energy will be stored in the form of triglycerides, which are mainly found in adipose tissue. In our study, energy and carbohydrate intake were significantly different between obese and non-obese groups, but the results were contradictory; the non-obese group had higher energy carbohydrate intake. The higher average energy and carbohydrate intake found in the non-central obesity group is consistent with Nuraini’s study. All respondents were Prolanis participants, so it was likely that they had been exposed to the dietary approach to stop hypertension for Indonesians (DASH); thus it is likely that the diet caused the central obesity group to have lower energy and carbohydrate intake.

Protein quality has an inverse relationship with abdominal fat. The quality of protein is defined as the ratio of essential amino acids to the protein consumed in grams. Approximately 10 grams of essential amino acids in one meal can stimulate maximum protein synthesis. If consumption of essential amino acids is below that level, there are no other anabolic responses. Protein consumed by respondents in this study most likely did not reach the recommended protein quality (essential amino acids in protein consumed <10 grams for each meal), so protein intake did not contribute to the occurrence of central obesity. A higher protein intake was found in the non-central obesity group. A study of fat intake and obesity shows that fat intake in the range of 18–40% of total energy has a small impact on body fat. In our study, protein and fat intake was found to be higher in the non-central obesity group, in line with energy and carbohydrate intake.

The mean fiber intake was not significantly different between groups; this finding is consistent with previous research which found that fiber intake was not related to obesity. This is because the average fiber intake is relatively low (14.7 grams/day) and contributes a small amount to daily calorie intake. In our study, greater fiber intake is in line with high energy and carbohydrate intake, and not from consumption of high-fiber foods.

**Conclusion**

The proportion of central obesity in our hypertensive patients was 82.6%. We found significant relationships between sleep quality, energy intake and carbohydrate intake with incidence of central obesity in hypertensive patients. Puskesmas can market and socialise the DASHI diet to hypertensive patients during consultation at the Puskesmas nutrition corner or during Prolanis activities. Also, Puskesmas can advocate for a healthy lifestyle for patients, such as engaging in routine physical activity 2–3 times a week and monitoring body weight and waist circumference. If the patients are able to live a healthy lifestyle, their health status will increase so that they will have good sleep quality.

Abstract

One factor in the occurrence of measles in children was measles immunization drop out during infancy. The purpose of this study was to determine the risk factors for measles immunization drop out in children aged 9-17 months. This study uses a cross-sectional design. Sample in this study was 126 mothers who had children aged 9-17 months. Study variables were measured using a questionnaire with the interview method. Logistic regression was used to look at the risk factors for measles immunization drop out and the odds ratio of these risk factors. Factors that influence the incidence of measles immunization drop out were the poor family economic status of AOR 7.0 (95% CI 2.55-18.65, p = 0.0001), lack of maternal knowledge AOR 3.61 (95% CI 1, 43-9.08, p = 0.006) and lack of family support AOR 6.54 (95% CI; 2.39-17.89, p = 0.006). Factors that did not influence the incidence of measles immunization drop out were the age of mothers <30 years old, mothers with elementary education, status of working mothers, perceptions of the role of health officers, perceptions of services at posyandu and distance to health facilities. Health officer is expected to provide information on the importance of measles immunization to mothers of children <5 years and include families at the time of counseling so that families know and support measles immunization, and provide information to the public through the media.

Keywords: Drop out, Immunization, Measles, First Dose.

Introduction

Measles is one of the infectious diseases that can cause an outbreak and increase every year. The measles rate incidence in 2015 was 3.2/100,000 people with the death of 1 case. In 2016 there was an increase of 5/100,000 population with 5 cases of death and 2017 increased by 5.6/100,000 population with death increasing to 14 cases.¹,²

Measles immunization drop out is calculated based on DPTHB1 immunization coverage with criteria set by the Indonesian government nationally not to exceed 5%.¹,³ Data on measles immunization drop out in Indonesia still experience fluctuations every year. In 2014 there was a drop out rate of 2.9%, in 2015 at 2.9%, in 2016 at 2.4% and in 2017 it increased by 2.6%.¹,² Measles immunizations drop out can cause the risk of unusual event. Unusual events that occurred in West Kalimantan Province in the last 3 years were 24 times with a 1.3% Case Fatality Rate.⁴ Unusual events that took place in Mempawah District accounted for 40% of all unusual events that occurred in West Kalimantan Province.⁵ The measles immunization drop out rate in Mempawah District still has not reached the nationally set target of <5%. In 2017 amounted to 5.46% and in 2016 amounted to 5.94%.⁶

The occurrence of measles immunization drop out is influenced by 2 main factors, namely behavioral factors, and factors beyond behavior. Behavior is the biggest factor in the measles immunization drop out. Behavior is influenced by 3 factors, namely predisposing factors including maternal characteristics (age, education level, employment status, economic status), maternal
perceptions of the role of immunization officers and the level of knowledge of mothers, enabling factors, namely the quality of services at the posyandu, access to health services and transportation towards health care, reinforcing factor is family support. Based on the background, it is necessary to analyze the risk factors for the first dose measles immunization drop out in Mempawah District.

Method

This study uses a cross-sectional design. The study data is sourced from a preliminary survey conducted in the Sungai Pinyuh Public Health Center (PHC) in Mempawah District, July-August 2018. Respondents in this study were mothers who had children aged 9-17 months.

The sample was 126 mothers obtained in the Sungai Pinyuh PHC in Mempawah District area. Sampling uses simple random sampling method with inclusion criteria for mothers who have children aged 9-17 months who were registered at the Puskesmas and reside in the Sungai Pinyuh PHC area in Mempawah District, have immunization records (KMS/village immunization books/other notes) and mothers are willing to be respondents and exclusion criteria for mothers who have children not immunized with medical indications or mothers refuse to participate.

Dependent variable in this study is measles immunization drop out. While the independent variables are maternal age, maternal education, family economic status, maternal employment status, maternal perceptions of the role of immunization officers, maternal knowledge, maternal perceptions of family support, maternal perceptions of services at posyandu, and distance to health facilities.

Data was collected using a questionnaire that had been tested for validity. Data processing and analysis was done by chi square and logistic regression. The analysis was conducted to see the frequency distribution of each variable, identify the factors associated with first dose measles immunization drop out and investigate the main independent predictors. The significance of all tests is set at p-value 0.05.

Result

The results showed that the average age of respondents was 29.16 ± 6.12. Based on the age variable category most of the respondents were <30 years old (54%). Most respondents have elementary education (55%), most respondents do not work (housewives) (82.3%).

Based on the statistical results obtained p value 0.032 with OR of 1.71 (95% CI; 0.97-3.02), so that it can be said that maternal education is a risk factor for the incidence of first dose measles immunization drop out. Based on the statistical results obtained p= <0.0001 with an OR of 2.03 (95% CI; 1.47-2.80), so that it can be said that the economic status of poor families is a risk factor for first dose measles immunization drop out. Based on the statistical results obtained p= <0.0001 with an OR of 2.53 (95% CI; 1.54-4.15), so that it can be said that the level of less maternal knowledge is a risk factor for first dose measles immunization drop out. Based on the statistical results obtained p= <0.0001 with OR of 2.28 (95% CI; 1.65-3.16), so that it can be said that family support is less a risk factor for first dose measles immunization drop out. Based on the statistical results obtained p=0.0229 with OR of 1.53 (95% CI; 1.10-2.13), so that it can be said that the perception of the role of immunization officers who are not good is a risk factor for first dose measles immunization drop out.

The results of logistic regression analysis showed that there were 3 factors that influenced the first dose measles immunization drop out, namely the economic status of the family with AOR 7.0 (95% CI 2.55-18.65, p=<0.0001) so that mothers with poor family economic status have a risk of measles immunization drop out 7 times greater than non-poor family economic status. Mother with less knowledge had an effect on measles immunization drop out with AOR 3.61 (95% CI 1.43-9.08, p=0.0060) so that mothers with less knowledge of the risk of measles immunization drop out by 3.61 times more large compared to well-knowledge mothers. Lack of Family support had an effect on measles immunization drop out with AOR of 6.54 (95% CI 2.39-17.89, p=<0.0001) so that mothers with less family support have risk of measles immunization drop out 6.54 times greater compared with good family support.

Discussion

Poor family economic status in this study obtained an OR of 2.03 (95% CI: 1.47-2.80, p=<0.0001), so it can be said that poor family economic status is a risk factor for first dose measles immunization drop out. Family economic status influences the completeness of measles immunization\textsuperscript{14}. Income has a large effect on immunization\textsuperscript{10}. Socio-economic conditions are the cause of the high drop out of immunization in children aged 11-23 months\textsuperscript{15,16}.

Mothers with less knowledge in this study were more at risk for measles immunization drop out with OR 2.53 (95% CI: 1.54-4.15, p = <0.0001), so that it can be said that mothers with less knowledge were a risk factor of first dose measles immunization drop out. Knowledge is the dominant factor in shaping one’s actions\textsuperscript{8,17}. Mothers who have high knowledge have more opportunities to give immunizations compared to mothers who have low knowledge\textsuperscript{12,18}. Mothers who have good knowledge about immunization have the opportunity to complete their child’s immunization (AOR = 2.4, 95% CI: 1.6-3.8)\textsuperscript{11,19}.

Less family support is a risk factor for first dose measles immunization drop out with OR 2.28 (95% CI: 1.65-3.16, p = 0.0001), it can be said that less family support able to cause first dose measure immunization drop out. Family support is one of the factors needed by a mother to provide immunizations, family support in question comes from a husband, father, mother, brother who is in one house.

Perceptions of the role of immunization officers who were not good in this study were obtained with OR 1.53 (95% CI: 1.10-2.13, p = 0.0229), it can be said that the not good perception of the role of immunization officers causing the first dose measles immunization drop out. The role of immunization officers influences the increase in measles immunization\textsuperscript{15,19,20}.

The mother’s age <30 years in this study obtained OR of 0.88 (95% CI: 0.62-1.24, p = 0.470) which was protective. Unlike the previous research, the age of the mother is a risk factor for measles immunization drop out\textsuperscript{21,22}. Age of a mother> 30 years is more likely to immunize her child\textsuperscript{11,13,14,23}.

Mothers who have elementary education were more at risk of having a first dose measles immunization drop out with a value and OR 1.71 (95% CI; 0.97-3.02, p = 0.032). In line with several studies which stated that there was an educational effect on measles of 1.25 times (95% CI: 0.511-3.22)\textsuperscript{16,22}. Children who have highly educated mothers were 2,306 times more likely to get measles immunization compared to uneducated mothers\textsuperscript{13,21,23}. Mothers who can read and write have the opportunity to complete their child’s immunization\textsuperscript{18}.

In this study the maternal employment status was not significantly associated with a first dose measles immunization drop out with p = 0.290. In contrast to several studies which state that the work of mothers influences the status of completeness of child immunization\textsuperscript{22}.

Conclusions

The risk factors that affect the first dose measles immunization drop out were the poor family economic status, lack of mother’s knowledge and lack of family support. Risk factors that do not affect first dose measles immunization drop out were maternal age, maternal occupation, maternal education level, perception of the role of immunization officers, services at posyandu and distance of health facilities.

PHC officers are expected to provide information about the importance of measles immunization to mothers of children <5 years and include families during counseling so that families know and support measles immunization, utilize posyandu cadres in counseling families, provide information to the public through the media.

Abstract

The low utilization of antenatal care routinely has an impact on the increasing difficulty of detecting potential risk of pregnancy complications resulting in maternal deaths. Knowledge constraints are the cause of the low utilization of antenatal services. Through the Antenatal Education (AE) class, it is hoped that mother’s knowledge and attitudes can be improved. AE class is not effective because of low participation of mothers. The purpose of study was to analyze the relationship need factors for ANC and their participation in AE class. It was a quantitative survey with cross-sectional design. Sample was 140 pregnant women that selected using purposive sampling based on characteristics of PHC.

The study showed no relationship between history of illness and pregnancy, perception of pregnancy, level of pregnancy complaints and perceived level of danger pregnancy for maternal participation in AE class. In a composite analysis it is proven that the need factors of pregnant women for antenatal care is related to the mothers participation in AE class. Mother’s perception of pregnancy is a key factor to increasing the taste and value of her needs. Increasing the sense of need can be done through improvement of women’s access and roles in the family and community about maternal health services. Continuous efforts need to be made as encouragement as well as support for AE class through structured and integrated socialization to every pregnant woman.

Keywords: Need factors, Antenatal Education, Antenatal Care, PHC, Semarang.

Introduction

Routine antenatal care is an effective strategy to detecting high risk of pregnancy.¹ If the risk factors are known early, the prevention and management efforts could more adequate. As in other developing countries, the continuity of antenatal care by mothers cannot be guaranteed. The use of ANC is also not optimal. Some influencing factors include limited access to health facilities, resources, demographic factors, socio-economic conditions, and health related factors, especially aspects of availability, accessibility and quality of service.² The level of knowledge and attitudes of mothers to care for her pregnancy affects the low utilization of ANC.³–⁵ Supply side factors have an important influence on ANC attendance, the design of ANC and particularly how to deal with the needs and concerns of mothers.¹ Non-compliance with standard ANC examinations has an impact on the higher risk factors for failure to detect complications which ultimately lead to the increased risk of maternal death.

The lower knowledge and attitudes of mothers have an impact on lower understanding and awareness of utilizing antenatal care according to WHO standards.⁶–⁸
Knowledge is a predictor of both attendance at ANC, in addition to socio-economic, parity and age. Education and antenatal care (ANC) is significantly related. It was suggesting that the higher level of education, the likelihood of receiving ANC during pregnancy is higher too, because educated women tend more aware about the importance of ANC during pregnancy. Limited knowledge is an obstacle in increasing utilization of health services, especially in developing countries, including Indonesia.

Antenatal education (AE) class is solution to overcome the constraints of knowledge related to pregnancy and complications risks. The impact orientation to increase maternal compliance in routine antenatal care visits, at least 4 times during the pregnancy period. AE class also has a community empowerment principles because it involves the role and participation of mothers. The success of AE class is determined by how much mothers as participants attend regularly and involved actively in various activities.

Organizing a antenatal education in several countries has proven success meeting the expectations of participants. Most participants in Sweden considered the AE class increase feelings of safety as parents and labor preparation. Antenatal education in Laos improve an average of 10% of knowledge and understanding of basic care for newborns. Study of Nolan et al shows that the existence of antenatal classes is very helpful in increasing self-confidence to become parents, establishing friendships and creating new social networks. Women in Iran have a higher level of happiness and satisfaction in their overall quality of life and health, especially in the postpartum period.

Adopting Andersen’s health service utilization model in behavioral changes, the need factor is one of the important factors that influence service utilization, including antenatal care. In some cases, women do not feel the need to seek professional care while pregnant. Mothers are reluctant to check their pregnancies because of perception that pregnant is a natural process. Mother often feels her pregnancy status is healthy, does not feel painful complaints and feels unsure about the competence and abilities of midwives.

**Method**

This is a quantitative survey with cross-sectional design. Research location in Semarang City, Indonesia, the city of second largest maternal mortality in Central Java Province, with 28,758 pregnant women in 2017. The number of AE class held was 271 classes. The proportion of mothers participating in AE Class is very small compared to its population which less of 10%.

Population is all pregnant women in Semarang City. Sample was selected using purposive sampling based on characteristics of PHC, which represented the area, distance variations to the city center and had the most, the least and without cases of maternal deaths in the last three years. PHC of Gayamsari, Purwoyoso and Rowosari were chosen. Total sample 140 mothers with determined accidentally and proportional.

Primary data was collected through interviews with structured questionnaires that have been tested for validity and reliability. Descriptive analysis and statistics using Chi-Square to test the relationship of needs factors and participation of AE class.

**Findings:** Based on study, the average age of mothers was 28 years old (SD 4.7), and 67.1% were in the best age range for pregnancy, ie 21-30 years old and parity ≤ 2 children are 93.6%. Most mothers have secondary education level (77.9%) and are housewives (73.6%). There are 93.4% of mothers having health insurance, especially government health insurance or BPJS (92.4%). Regarding monthly income, most of them have met the Semarang minimum wage standard of Rp. 2,300,000 per month. If differentiated between groups of AE class and Non AE class, the characteristics relatively similar.

Mothers with high socioeconomic status tend to not following AE class because easily access to health facilities. Another reason be caused of limited time and busy work. Similar to study of Liu et al (2014) that mothers with low socio-economic status are likely take less advantage of antenatal care and better wealth status was associated with increased maternal health services utilization. Study of Kisuule et al (2013) shows that busy working mothers make them late in the first antenatal care visit. Job busyness has an impact on the low attention and intensity of utilization of health services needed, including in AE class.

The results showed only 54.3% of mothers participated in AE class. Generally the participation in AE class is not routine because most of them only take 1-2 activities (standard 4 times per period). The most fun activity is pregnancy exercise. The majority reasoned because they did not know, were busy with domestic
work, the schedule did not fit the working hours, the perception that the pregnancy status was healthy and safe, and no one was delivering them. Socio economic and demographic factors increase maternal participation in utilizing various maternal care programs.1–5

All respondents have a history of illness and pregnancy which can affect their pregnancy status. The most cases suffered history of infectious diseases at about 40.7%, followed by hypertension and a history of congenital defects. As many as 26.4% of mothers had a history of anemia and 15% of mothers had a previous history of labor. Based on its category, there were 52.5% of mothers had a history of disease and history of pregnancy with a heavy category.

In its perception of pregnancy, 62.1% admitted that her current pregnancy status was not good. Mothers with severe complaints about pregnancy also had a greater percentage (61.4%). Although have many complaints, 59.3% of mothers considered their pregnancy be harmless. This is very interesting and becomes a contradiction because even though diagnosed it appears that most mothers have problematic pregnancies, but they tend to perceive the pregnancy to be harmless and safe. The perception aspect is the key to maternal management practices by mothers. Furthermore, based on the composite of need factors variable, it is known that 61.4% of mothers have a high level of need, especially in advanced pregnancy examinations, because statistically mothers have a high risk factor for the occurrence of the danger of pregnancy or complications. Descriptively, about 60% of mothers feel that their pregnancy is dangerous. Mothers who consider their pregnancies harmless and safe tend to not following AE class even though they have severe history of illness and pregnancy. The perception of dangerous level of pregnancy is related to maternal participation in AE class. Similar to Al-Ateeq et al.’s study that maternal perceptions and beliefs influence antenatal visits in Saudi Arabia.14

Most pregnant women, especially in Semarang and generally in Indonesia have values and beliefs that pregnancy is natural event because it is a God blessings. Therefore mothers do not be afraid of facing pregnancy or childbirth. Some people have values that routine ANC is not be needed, because as long as the mother is healthy, her pregnancy is also healthy and safe. However, it is also acknowledged that the fear of childbirth is still felt by some pregnant women so they try seeking antenatal care in hoping that their pregnancy is detected and monitored routinely. According to them, a healthy and safe pregnancy must also be pursued entirely by every pregnant woman.

Compliance with ANC and advice from health professionals can provide security and protection during labor. As many as 50% mothers stated that participation in AE class does not guarantee the safety of their pregnancies. When pregnant women assume there are no definite guarantees regarding the health status and safety of the pregnancy process, they tend to ignore it. It is recognized that women are more likely to use feelings in dealing with every problem. It could be caused by culture, values, habits or parenting patterns that affect a person’s personality.

* Significancy at p-value ≤ 0.05
Table 1 showed that more pregnant women of AE class who had a history of dangerous diseases and pregnancies (53.4%), whereas mothers who participated in AE class have a secure history of illness and pregnancy (62.7%). The p value=0.056 which only slightly exceeded of the threshold value for the hypothesis was rejected or accepted. There is no relationship between history of illness and pregnancy with the participation of AE class. Participants of AE class who perceive their pregnancies in good condition have a higher percentage (62.3%), while those who do not participate in AE class perceive pregnancy to be less good (50.6%). There is no correlation between perceptions of pregnancy and AE class participation (p=0.192). Mothers who experienced many complaints turned out to be mothers of AE class. No correlation between pregnancy complaints and participation of AE class with p value=0.446. Through composite analysis for looking at the factor level of maternal needs for antenatal care, it appears that more mothers from the Non AE class group have high level of need for antenatal care. In contrast, in class AE group, mothers actually had a low level of need (66.7% compared to 46.5%). Statistical tests prove significant relationship between the level of antenatal care needs and participation in AE class with p value = 0.031.

Maternal perception has a major contribution to participation of AE class. Perception directs the practice of pregnant women, where women who consider their pregnancy be safe and harmless tend to attend AE class despite having complaints during pregnancy. Conversely, mothers who consider their pregnancies are not good choose not to joint the AE class. This result is contrary to the previous descriptive analysis which illustrates the tendency of mothers who attend AE class have history of illness and pregnancy in bad status. Even though they know and have a history of illness and pregnancy, but when mother considers her pregnancy to be “no problem”, she tends to participate the AE class. Even though the mother does not have a history of severe illness and pregnancy, but when considering her condition as “problematic”, the mother will not participate in the AE class activities.

The context of understanding social cultural values contributes to practices and activities related to maternal health services. Culture and value are still upheld, which gives rise to unethical, disrespectful feelings and reluctance of mothers to honestly and openly share all her pregnancy problems with others, even though the person is a health worker or even a fellow pregnant woman herself. There is a perception and belief that pregnancy is a natural process. It is natural if mothers have experience and feel certain complaints. They tend to stay at home without seeking treatment because of the assumption that complaints will disappear when gestational age increases.

**Conclusion**

Needs are psychological aspects that move individuals in various activities. Perception of the level of need is influenced by the power of supporting and motivation. Mother’s perception of pregnancy is a key factor to increasing the taste and value of her needs. Although by diagnostic, pregnant women have a history of severe illness and high complaints of pregnancy, but when mothers perceive as “not a problem”, they tend to ignore routine ANC examinations. Increasing the sense of need can be done through improvement of women’s access and roles in the family and community about maternal health services. How the strategy to encourage mothers raise awareness about the importance of ANC services are essential. Continuous efforts need to be made as encouragement as well as support for AE class through structured and integrated socialization to every pregnant woman.

Factors Affecting Nurse Performance in Medical Ward

Desy Puspa Sari1, Bayu Saputra2, Muhammad Saleh2, Qomariyatus Sholihah3, Ibrahim Daud4

1Resbaharti Clinic, Tanah Bumbu, South Borneo, Indonesia; 2Dr. H. Andi Abdurrahman Noor General Hospital, Tanah Bumbu, South Borneo, Indonesia; 3Faculty of Engineering, Brawijaya University, Malang City, East Java, Indonesia; 4Graduate Programs, Indonesian School of Economics, Banjarmasin, South Borneo, Indonesia.

Abstract
Nurses are the world’s fastest-growing professions. The number of registered nurses increases every year. Nurse performance becomes the determinant of a hospital’s accountability. Factors affecting performance were divided based on their perspectives: individual differences, situational, and regulation. This research was analytic descriptive study with cross-sectional approach. The study was conducted in dr. H. Andi Abdurrahman Noor General Hospital, Indonesia from September to October 2017. The sample consisted of 24 nurses in the medical ward. An open-ended structured questionnaire was used as an instrument of data collection. Design the questionnaire based on observations of the literature that has been presented. Data were analyzed using a cumulative percentage system and presented in tables. Some respondents were dissatisfied with his personal appearance. This was influenced by eleven factors, with the most important factors were overwork, lack of facilities, and inability to control stress. From a situational perspective, some factors affecting nurse performance were workload (83.3%), facilities (66.7%), cooperation (29.1%), and work environment (12.5%). Supervision (45.8), salaries (37.5%), service fee (45.8%), and rewards (12.5%) were grouped according to the regulation perspective. While the ability (54.1%), skills (12.5%), and motivation (8.3%) had an individual impact.

Keywords: Factor, hospital management, nurse, performance.

Introduction
Nurses are the world’s fastest-growing professions. The number of registered nurses increases every year. In 2003, there were 2,449,000s and became 2,888,000s in 2014 (18 percent increase).1 In Indonesia, nurses are the largest health professions (compared to general practitioners, specialists, midwives, pharmacists and dentists) with 296,876 members (49%) in 2016. The national nurses ratio is 113.40 per 100,000 population in the same year, which is far from the target of 180 per 100,000 population in 2009.2 In these circumstances, the nurses-who is the first line in health care-is required to always do the best. So the assumption that the nurses are an important factor in determining the accountability of the hospital is not wrong.

Nurse performance in patient care is influenced by various factors. Study by Adatara et al (2016) found that optimal nursing performance was influenced by ability, mutualism, motivation, professionalism, clear assignment and target, availability of equipment, and functional feedback systems.3 While based on Yaghoubi et al study (2013) was found that the nurse performance correlated significantly with work environment, legality of work, continuous work evaluation, incentives, assistance from management to achieve work goals, clarity of main tasks and functions, and individual capability.4

Previous study was conducted by Kamati et al (2014) at a national referral hospital in Namibia. The study was conducted on 48 nurses from a 284 total population, using a questionnaire. The results showed that there was negative correlation between the nurses performance with short working mad, bad feedback,
low remuneration, poor work environment, and poor training. Limitations in this study were the absence of control that elements and the results were done in one hospital due to lack of resources.5

The large number of factors that affect nursing performance as employees makes Sonnentag and Frese divide them into three parts according to their perspectives: individual differences, situational, and regulation.6

### Individual Differences Perspective:
Many studies illustrate how individual differences perspectives affect their performance. To get a well-performing nurse, the hospital must select individuals based on their abilities, work experience, and motivation and personality.3,5,6

### Situational Perspective:
This perspective refers to environmental factors that could support the improvement of nurse performance. The most basic question in this perspective: “In what situations could the individual perform the best performance?” Some factors in this perspective are job characteristics, capabilities/circumstances that allow for stress control, and forced situations.4,5,6

### Regulation Perspective:
This perspective focuses on performance processes and concepts as a result of work. The most important question in this perspective: “How is performance generated?” And “What happens when a person works?” This regulation could be either financial or non-financial (feedback, social reward) interventions.3,4,5,6

Despite the numerous studies conducted, in its development, nurse performance remains an important point in hospital marketing. Therefore, strengthening the theory about the factors that affect nurse performance should continue to be done, as an effort to improve service to patients and build a good hospital image.

### Materials and Method
This research was analytical descriptive study with cross-sectional approach. The place this study was dr. H. Andi Abdurrahman Noor General Hospital, located in Tanah Bumbu District, South Borneo Province, Indonesia. Data is collected between September and October 2017. The population of this study was all nurses who numbered 165 people. Form total population, there were 24 samples of nurses who served in medical ward.

An open-ended structured questionnaire was used as an instrument of data collection. Design the questionnaire based on observations of the literature that has been presented. Open-ended questions allow respondents to be spontaneous in conveying and focusing opinions in their own words. Respondents were asked questions about the factors that according to their perspectives had the highest effect on nurse performance in the first order, to the last sequence they thought had the least influence.

Data were analyzed using a cumulative percentage system. Demographic characteristics, performance satisfaction levels, and factors that impact the nurses performance were analyzed with descriptive statistics and presented in tables.

### Results
Respondents consisted of 54.2% of female, with 16 respondents aged between 21-30 years, one respondent aged between 41-50 years, and the rest in middle age. More than half of the respondents had a diploma in nursing. More than 70% of respondents are non-permanent employees/contracts with varying work experiences, dominantly respondents worked less than four years as a nurse in this hospital.

Based on personal assessment of respondents, 66.7% were satisfied with his personal appearance. Most respondents felt that they had made the best effort to serve patients even though the equipment available at the hospital was not yet complete. While the rest felt not able to perform maximum service to patients (see Table 1).

### Table 1: Level of satisfaction with personal performance

</tbody>
</table>

Factors affecting nurse performance were ranked from the most-mentioned to the least. The most frequently mentioned factor in this case was the excessive workload (83.3% of the total respondents). This was influenced by the ratio between the nurses and the bed in medical ward (only about 1:12) and the documentation on the medical record which time-consuming for the nurses. Lack of facilities became the second largest factor (66.7%). The facilities include medical and non-medical equipment, such as diagnostic equipment, emergency equipment
and personal protective equipment. The inability to control stress in the workplace is the third largest factor (54.2%). This stress was mainly due to pressure from supervisors and leaders (see Table 2).

### Discussions

One that affects the workload of the nurses was the ratio between the patient and the nurses. According to the California Nurse Association (CNA), the number of patients supervised by the nurses varies according to the work unit, but does not exceed six patients. While, at the hospital where the research was conducted, the fact was still far from the ideal situation, where the average ratio was only 1:12. Document overload also results in excessive workload of nurses. When viewed from the Hospital Accreditation Standard of Indonesia 2012, there were still many overlapping forms on the medical record so that the time to complete the document becomes longer. This will impact on shorter nursing services and lead to limited nurse-patient interactions. In 2015, Muhammadi et al studied the factors that affectingnurse performance who work in intensive care unit (ICU). There were many things that cause poor of the nurse performance, including difficulty sitting down to work on documentation, unfriendly workplaces, poor workplace settings and inventory space, poor equipment conditions, drug delays, unpredictable situations, and poor cooperation.

Inadequate facilities were the second most mentioned factor. This was in accordance with study conducted by Adatara et al (2016) who found that the availability of equipment affects the poor performance of 28% of respondents. While stress and ability to control it is the third largest factor affecting the nurses performance. Simanjorang et al (2015) found a significant relationship between job stress and the nurses performance. It was also found in this study, in which the ability to control stress has been mentioned by more than half the number of respondents.

Other studies had also shown that organizational factors, interpersonal cooperation, nurses cooperation with other professions, and relationships with leaders or supervision had an impact on the nurses performance. Good relationships and regular supervisory supervision with various parties in the workplace will improve nurses ability and motivation to perform their duties better. Despite other influencing factors such as motivation, salary in accordance with regional minimum wages, and non-financial rewards. This was in accordance with James et al (2015) study, in which financial and non-financial rewards had a positive impact on the performance of health workers. Non-financial rewards can be promoted or candidates for specialized training.

The work environment was also an important factor, although it was ranked ninth from eleven factors that affectingnurse performance. While, the least-mentioned factor was the employment status. There was no evidence-base showing the relationship between employment status and nurse performance, but it was assumed that the status of government employees has higher income than contract workers, with the same workload. This clearly impacts financially for the nurses.

### Conclusion

From this research, there were eleven factors that influence nurse performance. If grouped according to Sonnentag and Frese theories, then the situational perspective had a great impact on nurse performance, followed by individual differences and regulation perspectives. Factors of the situational perspective in this study were the workload (83.3%), facilities (66.7%), cooperation (29.1%), and work environment (12.5%). Supervision (45.8), salaries (37.5%), service fee (45.8%), and rewards (12.5%) were grouped according to the regulation perspective. While the ability (54.1%), skills (12.5%), and motivation (8.3%) have an individual
impact. It was important to know by the hospital management, because if they improve the nurses’ performance means simultaneously they also improve the image of the hospital in a community perspective.

Conflict of Interest: The authors declare that they have no conflict interest.

Abstract

Objective: The aim of this study is to compare the effects of phonophoresis of nanoparticle Phyllanthus amarus phonophoresis gel (PP) and ultrasound therapy (US) in patients with osteoarthritis of knee (OA).

Method: OA knee patients (n=40) who had symptomatic knee pain were randomly allocated into 2 groups. There are US group (ultrasound group) and PP group (Phyllanthus amarus gel phonopheresis group)(20 in each group) were treated with an ultrasound program by using continuous mode, 1.0 W/cm², 10 minutes per session, once daily and 10 sessions. The nanoparticle Phyllanthus amarus gel was used in the PP group, while the US group was use the nondrug coupling gel. Pain and function assessment were measured by the visual analog scale (VAS) and the Western Ontario and McMaster Universities O-osteoarthritis Index (WOMAC), respectively. Moreover, the range of motion was used to measure by goniometers. Three primary outcomes were investigated before and after treatment 10 sessions.

Results: The VAS and total WOMAC scores were significantly increased post-treatment in both groups (P < 0.001). The PP group showed more significant improve VAS and total WOMAC scores than the US group (P<.001). However, ROM was not significant in both groups to compare to baseline.

Conclusion: The nanoparticle Phyllanthus amarus phonophoresis gel was significantly reduced pain and improve knee functioning. It is suggested as a new, effective method for treatment OA knee for relieving pain and improving function.

Keywords: Knee osteoarthritis; Phyllanthus amarus; phonophoresis; ultrasound therapy; visual analog scale.

Introduction

Osteoarthritis knee (OA knee) is a degenerative joint disease with the pathological bone characteristics changing that decrease hyaline articular joint and increase synovial inflammation. The chronic joint pain condition of the musculoskeletal system and a highly prevalent chronic condition among most common elderly more than 50 years and older and prevalence increases with age in women more than men. The main symptom of OA is the pain that lead to the quadriceps muscle weakness and limited joint movement and weight-bearing activities including standing, walking, up and down stair and muscle atrophy, causing decreased physical function in older adults with knee OA. The OA knee patient with symptomatic pain is treated in primary care including the several modalities approach, exercise therapy, pharmacological and surgical interventions for severe of OA knee. It is treated analgesic and non-steroidal anti-inflammatory drugs.
Phyllanthus amarus is Thai herbs which have pharmacological effects for anti-inflammation and antioxidant could be reduced pain\textsuperscript{4,5} by transforming electric to be acoustic wavelength. It is mostly used in musculoskeletal disease including OA knee for increasing nerve conduction velocity and firing rate, decreasing soft tissue inflammation, enhancing scar tissue remodeling, increasing soft tissue healing and increasing tissue extensibility (Baker and et al., 2001)\textsuperscript{6}. The aim of treatments was decrease pain symptoms and increase function. Application of US with the drug for permeating skin is called “Phonophoresis”.\textsuperscript{7} NSAIDs cream such as ibuprofen with US at 1 MHz frequency and 1 Watt/cm\textsuperscript{2} of power for 5-10 minutes per session at 10 times\textsuperscript{8}, is most common use in this technique to reduce significantly pain in OA knee and many pathologies such as shoulder pain, myofascial pain and OA knee\textsuperscript{9}. The Phyllanthus amarus is Thai herbs which have pharmacological effects for anti-inflammation and antioxidant could be reduced pain\textsuperscript{10}. Thus, the aim of our study was to evaluate the effectiveness of the nanoparticle Phyllanthus amarus phonophoresis gel treatment was developed and conducted for study to compare effects of the nanoparticle Phyllanthus amarus phonophoresis gel for changing pain and functional assessments including WOMAC score and range of motion (ROM) in OA knee patients with conventional US gel.

**Method**

**Participants:** The study’s protocol was approved by the institutional review board of the Faculty of Associated Medical Sciences, Chiang Mai University. All participants were written informed consent. Forty patients were diagnosed OA knee follow as the American College of Rheumatology (ACR) Classification Criteria.\textsuperscript{11} The sample size required for each group was 15 [and add 15% for drop out] (power =0.9 and significant level =0.05) which is calculated from a previous study\textsuperscript{12}. The inclusion criteria were the subjects had chronic knee pain, age ≥ 50 years, morning stiffness <30 min, and crepitus on the motion. The exclusion criteria were the history of taken anti-inflammatory or analgesic drugs and injection of steroid within 3 months.

**Treatment procedures**

**Phonophoresis of Phyllanthus amarus:** The Phyllanthus amarus gel was mixed with a standard coupling agent which was prepared by pharmacologist. Patients were received US with continuous mode, 1.0 W/cm\textsuperscript{2} power at once daily for 10 sessions. The participants were random the group using a computer program and examined by the physician with double-blind to group assignment.

**Outcome measures:** The clinical outcomes were monitored at baseline, 10 sessions after treatment.

1. **Visual Analogue Scale (VAS):** The severity of knee pain was assessed using the Visual Analog Scale (VAS) before and after treatment US at 10 sessions. The scale of VAS is the numeric scale at 0 to 100. 0 show no pain/limitation and 100 show very severe pain/limitation\textsuperscript{13}.

2. **WOMAC score:** The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) score was widely used assessed symptoms and disability questionnaire in patient with osteoarthritis\textsuperscript{14,15}. It consisted with knee pain, stiffness, and functional limitation. Subjects were assessed before treatment (pretreatment) and 10 sessions after the start (post-treatment)\textsuperscript{13}.

3. **Measurement of Knee ROM\textsuperscript{16}:** The range of motion was evaluated by plastic goniometer\textsuperscript{17}. The lying supine is the starting position for measuring the range of motion at both active and passive knee flexion and extension. Initial fully extended knee was considered zero position and maximal flexion of knee was recorded. The axis was at lateral epicondyle and the movable arm was at lateral face of the fibula.

**Statistical analysis:** The values are expressed as mean ± SD. The pre-treatment and the post-treatment data were compared within the groups using the nonparametric (Wilcoxon) tests. Statistical analysis was carried out by repeated measure ANOVA and was followed by Turkey’s post hoc test. The level of
Results

Sample Description: Total, 40 patients (70% female, n=14) with knee osteoarthritis were included in this study. The mean of age in US and PP were 64.30 ± 9.71 and 65.20 ± 8.34 years, respectively. There was no significant difference in sex, BMI and duration of knee pain in both groups. Descriptive analyses are presented in Table 1.

Note: BMI = body mass index; SD = standard deviation.

The effect of Phyllanthus amarus phonophoresis on the visual analog scale (VAS): Visual Analog Scoring of knee pain during the pre and post-treatment sessions is depicted in Fig. 1. Data indicate that the knee pain levels for after treatment in both groups (mean ± SD) significantly decreased (p < 0.001) compared to pre-treatment. Moreover, PP reduced significantly VAS score from 71 ± 8.74 to 15 ± 7.53 compare to US group (p < 0.001). These data suggest that PP group significantly reduced knee pain.

Discussion

This study assessed the effectiveness of Phyllanthus amarus phonophoresis for patients with knee OA. Pre and post-treatment, patients were assessed pain of knee by using VAS (numeric rate scale at 0-100-mm) and functional performance by using WOMAC questionnaire index. Studies have shown that treating the US and Phyllanthus amarus were the effective treatment for knee OA for reducing significantly VAS compared to baseline. In our study was assessed how Phyllanthus amarus phonophoresis of non-pharmacological treatments affect pain and WOMAC index scores\(^{(12)(18)(19)}\). Luksurapan et al.\(^{(20)}\) found that phonophoresis of piroxicam was using the stroking technique, continuous mode, 1.0 W/cm\(^2\), 10 minutes per session, and 5 times per week for 2 weeks. The VAS and total WOMAC scores were significantly increased in post-treatment in phonophoresis of piroxicam groups (P<0.001) according to the study of Boonhong et al.\(^{(21)}\) showed phonophoresis of piroxicam improvement in both VAS and total WOMAC scores post-treatment. Other research reported that therapeutic of phonophoresis using dexamethasone sodium phosphate in ultrasound waves of 1 MHz frequency, for 5 minutes, 10 sessions treatment period for patients with knee osteoarthritis could increase the total WOMAC scores and knee range of motion also improved significantly\(^{(22)(23)}\). Our results had shown that using ultrasound gel also could be improved pain and total WOMAC scores. However, our study showed that there has been no improved both flexion and extension
ROM of the knee. In this study, we proposed that the nanoparticle phonophoresis is enhanced by ultrasound and the benefits to treat with Phyllanthus amarus phonophoresis gel. Ultrasound is one of the deep heating modality which is used in physical therapy. The ultrasound has the property for healing procession, increase blood flow and connective tissue extensibility. Moreover, this study showed that US group had effective significantly in decreasing pain and increasing WOMAC compared to baseline according to Yeğin et al., 2017\(^{12}\). Phyllanthus amarus has a known antioxidant and anti-inflammation effect in vivo and in vitro study.\(^{10,24,25}\) The antioxidant effect of the phenolic compound has chondroprotective activities with anti-collagenase activity\(^{26}\). Phyllanthus amarus phonophoresis could be decreased pain and improve function. However, it could not increase ROM of the knee. Thus future research should study with other treatment for improving ROM of the knee including manual physical therapy approaches\(^{27}\), theraband exercise program\(^{28}\) and manipulation on range of motion\(^{29}\).

Conclusion

Phyllanthus amarus gel was used for relieving pain and improving function OA knee. The results of our study may ongoing research for the treatment knee OApaitents, and further Phyllanthus amarus phonophoresis is suggested as a new, effective method for treatment symptomatic knee OA.

Abstract

Context: Addressing the rising oral disease burden globally necessitates the need for oral health promotion with consideration of factors at grass root level.

Aims: The present study was undertaken to assess the influence of social determinants on the oral health of children aged 12 and 15 years in Bangalore.

Settings and Design: A cross-sectional study was conducted among 432 School children aged 12 and 15 years.

Method and Materials: Children were administered the questionnaire on social determinants of health and were instructed to get it filled by their parents. Oral health examination was conducted using DMFT index.

Statistical Analysis: Descriptive and Inferential statistics like Bivariate analysis determined the association of social determinants and health Outcomes.

Results: The bivariate analysis revealed that Family Strength, Mother’s education and Father’s occupation was significantly associated with the Oral Disease prevalence among children as perceived by parents. On clinical examination the mean DMFT score of children was 1.17±1.689 and was significantly associated with the monthly family income (p=0.031).

Conclusions: Social determinants influence the various aspects of oral health care in children. This necessitates the need for inter-sectoral measures to be implemented taking into account the social determinants at upstream and downstream levels initiating effective oral health promotion.

Keywords: “Oral health”, “Social determinants of Health”, “Bangalore”, “School Children”.

Introduction

Health is central to human life and well-being. A healthy individual enjoys a better quality of life, reflecting in their functional efficiency. However, from primeval times, the component of health refers to just general well-being. The compartmentalization of general and oral health has led to negligence of oral health on a hefty scale, especially in children.

General health and oral health are interlinked. The risk factors and causative agents of oral diseases are
often proved to be involved in general health disorders too. However, the slender acquaintance of these oral and general health disorders among health professionals has resulted in health promotion measures being narrow and secluded, separating the mouth from the rest of the body\(^\text{[1]}\). Thus health promotion approaches are often duplicated costing additional resources and burden to the health care delivery system\(^\text{[2]}\).

Amongst the various risk factors of general and oral health diseases in children, social determinants of health play an imperative role. Sustainable improvements in the overall health of children with equal reduction in health and oral health inequalities can be achieved by addressing these factors of social determinants which lie at the core of disease causation\(^\text{[3]}\).

Various review studies globally have addressed the issue of social determinants of health and oral health individually\(^\text{[3–6]}\). However, meagre studies have highlighted the effect of social determinants on general and oral health of children. Thus the present study aims at describing the effect of social determinants of health on various oral and general health factors in children.

**Materials and Method**

A cross-sectional study was conducted in 2015-16 in Bangalore on a sample of 432, 12 and 15 year old school children. Ethical clearance was obtained from the Institutional Review Board.

**Selection and Description of Participants:** Children studying in government schools aged 12 and 15 years and their parents were the target population. A multi-stage simple random sampling was followed. Utilising lottery method, Bangalore Urban South was selected from Bangalore District. Further among the 5 Zones in Bangalore Urban South, South zone 1 was selected. 6 schools in this zone were selected using table of random numbers.

Children present on the day of data collection and providing informed consent of the parents were included in the study. The sample size was estimated using the formula \( N = \frac{Z^2 \times PQ XD}{\Delta^2} \) where \( Z = 1.96 \) for 95% confidence level, \( P = \) Proportion of social determinants determining children’s health (0.4)\(^\text{[7]}\), \( Q = 1-P, \Delta = 0.05 \) (5% margin of error).

**Data Collection Process:** The study was conducted by abiding to ICMRs ethical guidelines for Biomedical Research on human participants. On obtaining permission from the school authorities, the children were administered the consent forms and the Questionnaire on Social Determinants of health. The Children were instructed to get it filled by their parents. The following day questionnaires were collected and oral health examination of the children was conducted by 3 calibrated examiners to assess for dental cariesDecayed Missing Filled Teeth (DMFT) Index wherein DMFT score of 0 was considered as absence of caries and DMFT score >1 was considered as presence of caries.

**Data Collection tool:** A self-administered questionnaire was developed in Kannada language which was validated for face and content validity. It was tested on a group of 30, 12-15 year old school children. The questionnaire consisted of 24 questions distributed over 3 domains namely: Personal/Biological Determinants (2), Social Determinants (10), Oral Health and Access to Health Services (12).

**Statistical Analysis:** Data was entered in Microsoft Excel and analysed using SPSS Version 16. The frequency of various determinants were expressed in terms of number and percentage. Bivariate analysis was performed to determine the association of various social determinants on the health and oral health related aspects of the participants.

**Findings:** The response rate was 92.13% (398/432). Non response was addressed using per-protocol analysis by including responses of participants completing the entire study process.

**Social Determinants of Oral Health:** The study consisted of children aged 12 years [155 (38.9%)] and 15 years [243 (61.1%)]. Majority of them were females [232 (58.3%)], Hindus [326 (81.9%)] and belonged to family size of 1-5 [281 (70.6)]. Majority of their parents were unskilled workers with lesser than middle school education and income of less than Rs. 12,000 and 227 (57%) participants owned a Below Poverty Line (BPL) card.

Among the participants 291 (73.1%) had not enrolled for any form of health insurance. Bivariate analysis revealed that mother’s education and BPL card holders were significantly associated with the acquisition of health insurance \((p<0.05)\) [Table 1].

201 (50.5%) participants revealed that in the past one year their child faced oral problems amongst which
dental caries [164 (41.2%)] was the most common oral disease [Table 2]. Bivariate analysis revealed that Family size, mother’s education and Father’s occupation were significantly associated with the occurrence of oral problems [Table 3].

Around 147 (36.9%) participants had taken their child to a dentist in the past one year, majorly for the treatment of dental caries [115 (28.9%)]. However, 251 (63.1%) parents had not taken their child to a dentist in the last 1 year. The cost associated with the dental treatment [157 (39.4%)] was the most common reason for not visiting the dentist [Table 2]. Bivariate analysis revealed that strength of the family was significantly associated with the dental visit behavior (p<0.05). 106 (72.1%) participants commonly sought dental care from a Government hospital with a dental Unit.

78 (80.4%) participants had spent less than Rs.5000 for dental treatment in the past 1 year. The facility of reimbursement for the dental treatment availed was utilized by 22 (5.5%) participants which was mostly from the place of work [11 (50.0%)]. 24.9% and 23.4% parents felt that oral problems influenced the academic performance of children and caused lose of time respectively.

**Oral Health Status of Children:** 208 (52.3%) children had a DMFT score = 0 and 190 (47.2%) had a DMFT score > 1. The mean DMFT score among children was 1.17+1.689. Bivariate Analysis revealed that family income was significantly associated with the caries status of children (p=0.031) [Table 4].

Discussion and Conclusion

The unicentric approach of the existing Oral Health promotion strategies fails to address the root cause of the problems treating only the disease at sight, thus bearing minimum effect on the incidence rates.

Oral diseases affect around 90% of children, hampering their quality of life\textsuperscript{[8]}. The present study was conducted on 12 and 15 year old government schoolchildren since it is the age recommended by the World Health Organization for Global monitoring of caries\textsuperscript{[9]}. Parents’ perceptions of their child’s oral health revealed that 50.5% children faced oral problems in the past, with dental caries being the most common problem (41.2%) which was significantly associated with family size, mothers’ education and father’s occupation. A similar study by Amin M S et al found that 44% of the parents rated their child’s oral health as good but 56% had dental decay\textsuperscript{[10]}. An unskilled laborer works on daily wages and hence may not be able to afford quality and appropriate dental care causing poor oral health status among children.

In the present study, a poor dental attendance (36.9%) was reported by the parents owing to the high cost of Dental treatment. 28.9% attendance was for treatment of dental caries. Contrary to our study a study by Lourenco et al showed that 53.3% of the parents reported to have taken their child to a dentist, majorly for routine dental check up\textsuperscript{[11]}. In addition a review by Gambhir et al reported that dental ignorance, lack of time and self-medication were the reasons for poor dental attendance\textsuperscript{[12]}.
The Mean DMFT Score was 1.12+1.689 which was significantly associated with the family income. A similar study by Paula JS et al found that the mean DMFT score among children aged 12 years was 1.09+1.70\cite{13}. A study by Martins MT found family income to be strongly associated with caries\cite{15}. Individuals with lower family income deter oral care needs due to the high cost of treatment and fear of post treatment complications.

The study has a good internal validity and the findings can be extrapolated to children aged 12 and 15 years old. In addition, the study has been conducted in accordance with the Strobes checklist guidelines.

This is a cross-sectional study, hence the influence of social desirability bias, recall bias cannot be ruled out. Social determinants of health have several distal and proximal factors amongst which only a few were considered in the present study. Inculcation of more factors like environmental influence, community factors and health behaviors with comparison between rural and urban child population should be taken up to get a more comprehensive evidence.

The present study proves as an evidence base for policy makers, stakeholders and community members to realize the importance of social determinants in oral health promotion, thus helpful in the successful planning and implementation of programs. The correlation of social determinants of health and oral health established in the present study necessitates a multi-factorial approach of disease treatment incorporating the social determinants of health which will provide an insight into the proximal and distal variables of risk factors leading to successful oral health promotion.

Abstract

Background: Indonesia has experienced an increased number of children with autism spectrum disorder (ASD). One of the challenges that Indonesia currently faces is how to reduce the perinatal and risk factors related with the incidence of autism. This study aimed to identify the perinatal and risk factors contributing to ASD.

Method: This research was a case control study involving 52 children with ASD in the case group and 201 normal children in the control group in Banyumas district, Province of Central Java, Indonesia. Data collection used independently completed questionnaires, concerning perinatal factors such as maternal age at birthing, gestational age, labor method, fetus presentation in labor, and history of complications during labor.

Results: Stepwise logistic regression analysis indicated a higher risk of preterm gestational age among children in the ASD group with $p=0.019$ and OR:5.883. Abnormal delivery method such as caesarean delivery or vacuum extraction also had association with the ASD group ($p=0.001$; OR=0.303). Abnormal fetus presentation during labor increased the risk of ASD ($p=0.004$; OR:6.908). Mother with complication during labor such as difficult labor, preeclampsia, and fetal distress correlated with ASD ($p=0.021$; OR:2.101). Multivariate analysis also showed complications during labor became a risk factor for ASD (OR: 2.142 (1.904-4.196). There was no correlation between maternal age below 20 years ($p=0.332$; OR=1.871) or 31-40 years ($p=0.115$; OR=2.868) with ASD.

Conclusion: Labor method, fetus presentation, and complication during labor were significantly related with ASD.

Keywords: Perinatal, labor, fetus, ASD, risk factors.

Introduction

Autism Spectrum Disorder (ASD) is a type of neurodevelopmental disorder. ASD presents with a range of severity and impairments in social, communication skill, and behaviors. Based on epidemiological data, it is estimated that the global prevalence of ASD is more than 7.6 million persons with various disabilities and has become 0.3% of the global burden of disease. In many developing countries such as Indonesia, ASD receives little attention and this lack results in fewer available studies about ASD. Consequently, Indonesia also has no current data about the exact national or provincial prevalence of ASD.

The cause of ASD is still unknown. A recent study showed that genetics account for only 35-40% of the contributing factors. The remaining 60-65% are likely...
due to a multi-factorial combination, involving prenatal, perinatal, and postnatal environmental factors. In a previous study, perinatal factors such as acute fetal distress, prematurity, exceeding the term, and difficult labor were found to be the most affecting factors in ASD. Considering the potential risk about perinatal factors, we used a case control study to investigate the association between perinatal factors and ASD.

Method

Research design: This case control study was conducted in a community in Banyumas District, Province Central Java, Indonesia. It was conducted over a period of four months from October 2017 to January 2018.

Population and samples: The sample included 253 children in Banyumas District, Province of Central Java, Indonesia. The sample population was divided into case group and control group. The case group was composed of 52 autistic children previously identified by psychologists in the Banyumas Autism Care Project (BACP) event. The control group was composed of 201 normal children. Inclusion criteria were children with age between 3-18 years old and willing to be a respondent with parental approval. Whereas, exclusion criteria were children with known neurogenetic conditions such as Down Syndrome, Mental Retardation, and Neurofibromatosis.

Sample size: Using sex differences between ASD within boys and girls as a risk factor and aiming to detect an odds ratio (OR) of at least 2 with a power of 80% using a 5% level of significance, the recommended sample size was calculated to be 58 cases and 58 controls.

Sample type and selection: Consecutive cases were selected over 4 months, during which time every weekend was allocated to visit the school of special needs children. We invited parents who have children with ASD and independently confirmed their approval by completing the informed consent form to permit their children to become participants for this study. The location for sampling was in the Research Center of the Faculty of Medicine, Universitas Jenderal Soedirman, Banyumas District, Central Java Province, Indonesia. Controls were selected from normal children who came with their parents and also were visited by the research team at local schools, until the required sample size was reached.

Instruments: This study used a demographic tool with questions about perinatal history. It consisted of five questions about Maternal Age at Birthing, Gestational Age, Labor Method, Fetus Presentation in Labor, and Complications during labor.

Data collection: Data were collected from parents of children ages 2-18 years old who were currently diagnosed using DSM 4 and DSM 5 by professional practitioners and then grouped in the case group (children with ASD) and the control group (children in normal state) during a four month study period using an independently completed questionnaire consisting of demographic factors and risk factors for ASD.

Statistical Analysis: Analysis were first done to describe the data and then to describe the trends resulting from each item. Bivariate analysis used Chi-square to explore relationships between variables. This study also used logistic regression for multivariate analysis to determine the most affecting factors in ASD.

Results

Two hundred and three respondents participated in this study. Maternal Age at Birthing, Gestational Age, Labor Method, Fetus Presentation in Labor, and Complications during labor together with the frequencies and presentation, P values and OR are shown in Table 1.

</table>
Table 1 shows the distribution of perinatal factors and relationship with ASD. Gestational age, labor method, fetus presentation in labor, and complications during labor were significantly correlated with ASD ($p<0.05$). Mother with preterm gestational age <37 weeks (OR: 5.883), fetus presentation (OR: 6.098), and complications during labor (OR: 2.101) had significantly increased risk for children with ASD. Meanwhile, abnormal labor method had a significant association with ASD, but it had a low relative risk (OR: 0.303). On the other hand, maternal age at birthing was not related significantly with ASD ($p>0.05$).

Table 2 shows the final result of multivariate analysis with logistic regression. Gestational age was excluded from the multivariate final result because it had a $p$-value more than 0.05. These result show fetus presentation in labor and complication during labor were the most affecting perinatal factors of ASD with OR: 4.487 and OR: 2.142.

### Discussion

For the Indonesian population sample, the most common perinatal risk factors related with incidence of ASD were preterm gestational age, abnormal labor method, abnormal fetus presentation in labor, and complications during labor with ASD. There were no significant relationship between maternal age at birthing and ASD. This result was the same with a recent study that showed an association between prematurity with ASD in Denmark\(^5\). Another study found there was a strong relationship between delivery circumstances such as labor method and fetus presentation with ASD in China\(^6\). A meta-analysis study also showed that history of complications such as difficult labor, preeclampsia, fetal distress, and other delivery problems significantly related with ASD\(^7\). Similar to this study, recent research found there was no relationship between maternal age at birthing with ASD\(^8\).

Infants with premature gestation get a high exposure to stressors during a critical period and it may affect the brain development. One study reported there were cerebellar lesions in preterm infants at risk of developing...

Preterm infants also had the largest gray matter cluster that included the left angular gyri and the heteromodal association region involved in complex language functions. This brain structure is known to be affected in ASD.

Abnormal labor method also had a relationship with ASD. Studies have shown a strong relationship between abnormal delivery method with ASD. Labor method such as vacuum extraction pose a potential harm such as brain injury. This brain injury could be a predisposing factor in ASD. Abnormal delivery method is also known have a potential risk as a brain injury agent and could contribute to abnormality in neurodevelopment in ASD. Infants with caesarian birthing history have been shown to have a lower APGAR’s score, which shows fetal distress syndrome could affect the infant’s neurodevelopment.

The next finding also showed that abnormal fetus presentation during labor increased the risk of ASD. Fetus presentation such as breech presentation is also known to be one of the risk factors for ASD. A fetus with breech presentation will experience a difficult labor and may need an abnormal delivery method such as caesarian that are risk factors of ASD. Previous study also had found that abnormal fetus presentation was related with ASD. One meta-analysis study had a similar result showing a strong relationship between fetus presentation with ASD. Breech presentation is also known as one of the risk factor in ASD. Breech presentation will conduct a difficult labor and need an abnormal labor method like caesarian. Other presentations such as placenta previa position also are known to cause delayed brain development and are potential risks for ASD.

History of complications during labor also could become a potential risk factor for ASD. Complications such as difficult labor, preeclampsia, and fetal distress can make infants susceptible to experience stress. Research in Australia found that complications during labor increased the risk of ASD. Another retrospective-cohort study in USA also found a potential risk of ASD related to the history of complications of intrapartum conditions. Circumstances during complications made infant more susceptible to get stress. These stressful complications potentially can cause infants to aspirate fluids into the respiratory system. Then, this impaired respiratory status of the neonate infant could be altered causing the brain to only get a little oxygen. In a lower oxygen conditions, the brain could be damaged causing a neurodevelopment disorder such as ASD.

Study Limitations: Perinatal factors could be significant risk predictors of ASD. However, this study had some limitation because further detailed explanation could not be given about the factors which potentially became a risk for ASD. Some factors need to be explained and examined more completely such as labor method, fetus presentation during labor, and history of complications during labor. It is considered important for further study to provide more detailed data to clearly determine the mechanisms and the effect of perinatal factors on ASD.

Conclusion

The perinatal risk factors for ASD included gestational age, labor method, fetus presentation in labor, and complications during labor.

This study highlights the importance of improving access to quality health services, with special care given to young mothers. Efforts in the future need to additionally focus on implementing preconception education and counseling programs to ensure more widespread pregnancy and delivery planning, which will help in improving maternal health and reducing the potential risks for autism spectrum disorder.

Conflict of Interest: The authors declare that they have no conflicts of interest.

Compare Transferrin Binding Protein (Tbp A) Gene Virulence of Pasteurella Multocida Type B of Buffalo and Vaccine Septicemiaepizootica

Desty Renata¹, Didik Handijatno², Wiwiek Tyasningsih²

¹Master student of Disease Science and Veterinary Public Health, ²Lecture Laboratory of Bacteriology and Micology Department Microbiology, Faculty of Veterinary Medicine, Airlangga University, Jl. Mulyorejo, Kampus C Unair, Surabaya, Indonesia

Abstract

Septicemia Epizootica (SE), is a fatal acute septicemia disease by Pasteurella multocida. B:2,5 and E:2,5 in cattle and buffalo. TbpA has a number of important role for bacterial cells, such as nutrient uptake, transport of molecules in and out of cells and interactions with the environment and host. P. multocida iron acquisition related gene, tbpA, has been considered as an important epidemiological marker. The purpose of this study was to compare the Transferrin Binding Protein A (TbpA) gene from P. multocida type B of buffalo and it with vaccine strain. Characterization of TbpA of P. multocida and vaccine strain was done using PCR then sequencing. Sample used in this study were P. multocida local isolate from NTT and vaccine strain (Katha). Isolation and identification were performed using bacteriological culture and biochemically characterization. Results from PCR showed positive a tbpA gene on P. multocida local isolate and vaccine strainis. The comparison of the results of sequencing between the tbpa gene isolates P.multocida and vaccines showed deletion.

Keywords: SeptisemiaEpizootica; Pasteurellamultocida type B; Transferrin Binding Protein A (TbpA) gene; PCR, buffalo.

Introduction

Septicaemia Epizootica (SE), is a fatal acute septicemia disease by Pasteurellamultocida serotype B:2,5and E:2,5 in cattle and buffalo. In Southeast Asian countries including Indonesia, Philippines, Thailand, Malaysia, Middle East and South Africa disease Septicemia Epizootica is an important bacterial disease. [16] In Indonesia the disease was first reported in 1884, in the area of Balaraja Tangerang. [7] SE disease is reported in several regions in Indonesia such as Bengkulu, North Sumatra, Riau, Jambi and East Nusa Tenggara. [19] Pasteurella multocida is a gram-negative bacterium, coccobacillus (short stems) of 0.4-0.8 μm long and 0.3μm in diameter and bipolar, non-motile bacteria, producing toxins, some of which are found as commensal flora in the upper respiratory tract in domestic animals or wild. [15] The pathogenesis of septicemiaepizootica disease is the interaction between host factor and virulence factor of bacteria (pfha, tbpa, toxa), such as lipopolysaccharide (LPS), capsule, outer membrane protein (omp). [17] P. multocida can cause pneumonia in cattle and sheep and in cattle and buffalo. [4] and stress factors such as weather changes, nutrient changes, fatigue etc. can cause fulminant infections. and so attacked in animals that immunospressed cause primary and secondary infections. TbpA has a number of important roles for bacterial cells, such as nutrient uptake, transport of molecules in and out of cells and interactions with the environment and host. [14] The receptors and transferrin and lactoferrin mechanisms involve iron-binding proteins expressed on the surface of bacterial cells, and then directly interact with iron-binding glycoproteins. The problem of SE disease in Indonesia is still commonly endemic, although vaccination has been done once a year using the SE vaccine made from the Katha strain. Identification of the virulence factors is helpful in the determination of the mechanisms of pathogenesis and development of control measures such as the establishment of an efficient vaccine. [11] The purpose of this study was to compare the Transferrin Binding Protein A (TbpA) of P.multocida local isolate from NTT and with vaccine strain.
Materials and Method

Samples: Sample of P. multocida isolate originated from NTT (Nusa Tenggara Timur) were obtained from Balai Besar Veteriner Denpasar, Bali. Sample was cultured on Blood Agar medium by streak and then incubated for 24-48 hours at 37° C in incubator. Previously, this isolate had been tested for its capsular type. Haemorrhagic Septicaemia vaccine (P. multocida Katha strain) from Pusat Veterinaria Farma (Pusvetma) Surabaya was used as a vaccine strain sample.

Re-identification of Pasteurellamultocida:
Inoculation on MacConkey Agar medium was performed to determine the growth properties of Pasteurella multocida. Which is P. multocida do not grow on Mac Conkey media. Furthermore, the examination using biochemical test, namely: TSIA test, SIM test, SCA test, Urease test, and Sugar test. [9]

DNA Extraction: Total genomic DNA of P. multocida was extracted with QIAamp® DNA Mini kit according to standard protocol.[21] Briefly, bacteria that have been cultured on Nutrient Agar (NA) at 37°C overnight, were inserted into tube. After addition of bacteria/vaccine incubated at 60 °C for 30 minutes. The 200μL AL buffer is added to the tube, then vortex. The mixture of the ingredients in the tube is transferred to the spin colomn, then adds 200 μL of 96% ethanol. After that, centrifuged at 8,000 rpm for 1 minute and washed using AW1 500μL. After that, centrifuged again for 3 minutes at 13,000 rpm and the bottom of the spin colomn removed. After that, it was centrifuged again for 1 minute at 13,000 rpm and transferred to an empty sterile tube. After that added 50μL AE Buffer and incubated for 1 minute at room temperature. Then centrifuged for 1 minute at 8,000 rpm.

Detection of TbpA gene by PCR assay:
Amplification of the TbpA gene was performed using both TbpA-F and TbpA-R primer in 20μl PCR mixture. Primer TbpA-F forward F: 5'-GACAGAAATATAGCTCGGGGAG-3’ and TbpA-R reverse R: 5'-TAA CGT GTA CGG AAA AGC CC-3’ with gene target 603bp.[8] The thermal cycling conditions are: 1 cycle at 95°C for 5 minutes; 40 cycles at 94°C for 30 sec, 50°C for 1 minute, and 72°C for 1.5 min; 1 cycle at 72°C for 10 minutes. This PCR profile is repeated three more times to ensure specific PCR products. And then analyzing the pcr product with electrophoresis in gel agarose 1%.

Sequencing: From the precipitation results, the Hi Formahide 25 μl of HI-DI suppressant was added and then heated at 25 C for 2 minutes, then incubated in ice for 3 minutes. After that it is transferred into the microtube to be inserted into the sequencing machine. The sequencing machine used is ABI PRISM 310 GENETIC ANALYSIS-Applied Biosystem 1 capillary with a length of 5-47 cm x 50 μm which can produce a sequence length of up to 700 nucleotides. Running is done overnight. [2]

Results and Discussion

Re-culture and Re-identification of Pasteurellamultocida: The result from recultured of P.multocida on Blood Agar incubated 37 ° C for 24-48 hours .Colonies of clear shiny bacterial bacteria, does not hemolyzed red blood cell and does not growing on Mac Conkey Agar medium can be said suspect P. Multocida. The suspect colonies of P. multocida were then confirmed by biochemical test, the TSIA was obtained in alkaline slat and butt, yielding no gas and H₂S. In the Indol test the pink ring appeared on the surface after Kovach’s reagent was added. In Urease Test this bacteria does not produce urease enzymes so it can not change the color of Urease media. In the Simon Citrate Agar Test this bacteria can not use citrates as carbohydrates so as not to change the color of the media Simon Citrate Agar. And in the sugar test this bacteria show sukrosa(+), glukosa(+), and manitol(+) which means fermenting sugars to form acids and laktosa(-), Maltosa (-) It means negative germ does not ferment sugar.

Detection of tbpA gene by PCR assayand Sequencing: The TbpAgene and from vaccine successfully amplified (Figure 1).And the result of comparison the sequencing between the tbpgene isolates P.multocida and vaccines showed deletion (Figure 2). In Indonesia, SepticemiaEpizootica disease is still commonly endemic, although vaccination has been done once a year using vaccines made from Katha strains.[13] Determination of pathogenesis mechanisms and the development of control measures such as efficient vaccine formation can be assisted by the identification of virulence factors.[11]

Bacteria Pasteurellamultocida serotype B: 2.5, as the cause of Septicemia Epizootica in buffalo and cattle. In the presence of transferin binding proteins, an outer membrane protein weighing 82-kDa that specifically binds to cow transferrin. And in Pasteurellamultocida
serotype B bacteria: 3.4 the same as katha strain vaccine does not express transferin binding protein. These results might indicate a role for transferrin binding in the pathogenesis of Septicaemia Epizootica in cattle and buffalo.

On the basis of presence in this study of tbpA genes in genomes, distinct categories of Pasteurella multocida isolates can be identified in this study; P. multocida isolates that have tbpA in genomes, these bacteria have potential for disease induction. Furthermore, PCR for virulence genes detection showed important role of tbpA in diseased buffaloes. Significant association tbpA virulence factors in P. multocida strains isolated from diseased buffaloes showed their association with the disease status.

The high prevalence of the acquisition of tbpA iron acquired genes in pasteurellamultocida isolates as well as roles associated with pneumonia and septicaemiaepizootica, providing additional bacterial advantages to increase pathogenicity in Septicemia Epizootica.[22]

Significant association results of virulence factor of tbpA gene in pasteurellamultocida isolated from sick livestock indicate disease status. According the TbpA protein is responsible for the extraction of iron from transferrin and also the outer membrane protein Ton B with a large surface to bind and force the separation of iron from the transfer.[19] In poultry strains was the opposite of cattle strains. if the poultry strain can not capture iron from any transferrin molecule, but on the strain of P. multocida cow that utilizes iron from cow transferrin,[15] which might be the explanation for the low frequency of tbpA gene in the chicken isolates.[7]

PCR detection of tbpA gene of P. multocida and Vaccine

PCR detection of tbpA gene of P. multocida and Vaccine

Figure 1. Results of PCR of TbpA gene of P. multocida and Vaccine strain

Figure 2. Results of Sequencing Isolate P. multocida and Vaccine strain.
Conclusion

In this study, the TbpA gene from local isolate P. multocida serotype B and vaccine showed positive. That is, the virulence factor plays an important role in SE disease associated with pneumonia, seen from the role of tbpA as a nutrient uptake transporter that helps regulate bacteria express protein proteins such as OMP to infect susceptible animals so more investigation of virulence and environmental and host associated with bacterial virulence factor. And the result of comparison the sequencing between the tbpA gene isolates P. multocida and vaccines showed deletion. However, this may suggest that virulence and environmental factors, including other genes, may have an important role in the induction of the disease.

Competing Interests: The authors declare that they have no competing interests.

Source of Funding: The authors would like to thank the my parents, Virgianto and Ratna Susilowati.

Ethical Approval: The research does not need ethical approval. However, samples were collected as per standard collection method without any harm and stress to the animals.

Relationship Between Big Five Personality Traits to Compliance of Site Operational Procedure (SOP) of Grinding Machine in Maintenance Contractor PT. X

Dewangga Lazuardi¹, Y. Denny Ardyanto W.², Tjipto Suwandi²

¹Student in Magister of Occupational Health and Safety, Faculty of Public Health, Airlangga University, Campus C Mulyorejo, ²Lecturer in Departement of Occupational Health and Safety, Faculty of Public Health, Airlangga University, Campus C Mulyorejo, Surabaya-Indonesia

Abstract

Site Operational Procedure (SOP) is implementation work procedures that are more focused on the work are a at PT.X. Initial review mentions that grinding workers do not apply the SOP correctly on their work steps. The behavior of workers was unsafe which could lead to accidents.

The behavior was a manifestation of the worker personality. Different worker personalities will produce different behaviors. The purpose of this study was to analyze the relationship of big five personality traits to compliance of SOP for grinding machine.

This research was observational with a cross sectional design. Respondent research was 54 grinder. Big five personality traits were independent variables. The dependent variable was compliance of SOP for grinding.

The results showed that 50 % of 54 respondents did not complied the SOP and analysis of multiple logistic regression showed about independent variabel that significantly effected to SOP complied was neuroticism traits \( (p = 0.006) \). An assessment of the traits of workers personalities, both openness, conscientiousness, extraversion, agreeableness, and neuroticism, shows a high category for each assessment of traits. The assessment shows that only neuroticism traits were related to SOP compliance with unidirectional values, it cause by workers whom easily worried and anxious tend to careless and self-destructive actions.

It is recommended to paying attention for the dominant personality background of workers while recruitment, especially the mechanical field. Personality can be used as an assessing predictor in compliance behavior with work procedures.

Keywords: SOP, personality, Big five, Grinding, Neuroticism.

Introduction

Compliedness of systematic work procedures is an important factor in the occupational health and safety management system. A job requires a clue as a guideline for workers to reduce the risk of accidents. Workers are required to obey work procedures to establish safe work behavior. Geller’s¹ theory explains that if someone follow and adhere to safe working procedures consistently, then indirectly will make workers safe behavior.

Compliedness of following work procedures will used to be an assessment of the behavior for workers in obeying the rules. Workers who did not complying work procedures properly did unsafely behavior at work. This would provided a great opportunity in causing the incidence of workplace accidents. Data on accident trends in Indonesia recorded around 9,891 cases of workplace accidents.
accidents, 2,218 of them fatal accidents to death, and 65 cases caused by violations of work procedures.\textsuperscript{2,3,4} Violations that often occurs such as work steps is not according to procedures, jokes while working, improper working position, works too close to a rotating machine, uses a machine that exceeds the standard limit.\textsuperscript{5,6} 

Companies are required to implement and supervise the implementation of Site Operational Procedure (SOP) in the workplace, so that workers avoid the risk of danger. SOP is a way of determining an activity or a work process.\textsuperscript{7,8} So that it can be seen that the implementation of SOP is something that cannot be considered trivial, because it is related to the chance of harm if it is not done properly.

Compliance with SOP is a form of behavior that can be influenced by individual internal factors, one of which is personality. The problem that often occurs in failure to comply with SOPs is that workers do not want to know the behavior that causes accidents.\textsuperscript{9} Behavior as a manifestation of personality will determine whether the individual can behave according to the rules or not. The personality of each worker is different, so the behavior that appears will also be different.

Assessment of big five personality is now often used as a predictor in assessing work behavior. The big five personality consists of five traits; openness, conscientiousness, extraversion, agreeableness, and neuroticism. Each of these traits, psychologically provide an overview of the employee’s personality and its relationship with behavior in compliance with workplace safety SOPs.\textsuperscript{10,11,12} For example, workers who have high openness traits in their personality will not necessarily behave well, compared to workers who have low agreeableness traits. Same thing with other big five personality traits.

In this study, researchers focused on SOPs with a special scale in grinding to see big five personality traits that affect their compliance.

**Materials and Method**

The design of this research is cross sectional with observational research. The respondent were included 54 people with inclusion criteria, physically healthy, had never been experienced an accident before and were willing to take part in this study. The independent variables of this study were big five personalities (openness, conscientiousness, extraversion, agreeableness, and neuroticism). The dependent variable was compliance with the SOP for grinding machine.

The data collection technique was filled out a valid questionnaire about the big five personality and compliance of SOP of grinding machine. Then, observated respondents regarding complianced of SOP. The analytical method used include descriptive analysis and quantitatively with Logistic Regression analysis.

**Finding:**

**a. Big Five Personality**

</table>

Based on the first trait, it showed that 32 respondents (59.3%) response to The Big Five Personality on the agreeableness traits indicator was the highest, while the neuroticism traits indicator gave a balanced response, 27 respondents (50%).

**b. Compliance of SOP of Grinding Machine:**

Half respondent (27 respondents) was found to be compliant with the SOP as many as respondents who did not comply with the SOP. Based on this, it can be seen that there were still workers who behaved non-compliance with SOP of grinding machine.

The results of respondents showed that most of each personality traits with a high category showed not compliant behaviour to the SOP. The percentage of openness traits was high at 63.3%, high conscientiousness personality at 65.5%, high extraversion personality at 66.7%, and high agreeableness personality at 62.5% which showed non-compliance with SOP. The traits of neuroticism was not given a percentage value that is dominant both in the high neuroticism category and in non-adherence or low and obedient neuroticism, because the value was balanced at 66.7%.

Based on the result showed that one of five traits has correlation to compliance of SOP grinding machine, it was neuroticism trait. The Prevalence Ratio (PR) was 2.00, showed that respondent who experienced of low neuroticism personality would have a chanced 2.00 more to compliance the SOP grinding machines then respondents who experienced high neuroticism.

Discussion

a. Big Five Personality: The results showed that the value of each personality traits was in the high category. The openness personality traits were the widest personality domain of the Big Five Personality because of the individual’s curiosity towards new things, including science, imagination, and creativity. Individuals with a high openness personality are described as curious, adventurous, and brave.13,14

An individual with high conscientiousness characterized as an individual planner for work, careful, thorough, and has strong goals. Individuals who have high conscientiousness will have greater achievement in organization and professional than individuals with low conscientiousness.15,16

Extraversion personality could be described by social relationships individually. Extraversion is a personality type that assesses social skills, communication and interaction, so this personality was very useful for disseminated information to coworkers.17,18 High individuals in extraversion tend to involve others in conversation, seek attention, and compete with coworkers.

This result explained that respondents who showed higher agreeableness were more than other traits. Personality agreeableness basically can be used as a predictor in assessing compliance, because the main characteristics of individuals who have high agreeableness were trustworthy, obey, honesty, courtesy, and they tend to be cooperative.19,20

The neuroticism traits were closely related to emotional stability. Individuals with high neuroticism personality were easily anxious, irritable, nervous, depressed, and not confident.21,22 Conversely, individuals with low neuroticism would found it easier to feel satisfied, happy and other positive emotions in their personality.12

b. Compliance of SOP of Grinding Machine: The level of the respondents compliance showed the same results whether they were obedient or not obedient. Many stages of work procedures were often not carried out by workers. Workers explained that they know and understand about SOPs of their regular jobs, but sometimes the demands of work targets and work habits that made them feel these
actions are not dangerous. Violation of the procedure would pose a potential hazard for workers, such as sparks, electrocution, scratches on grinding and noise.\textsuperscript{23}

We also find that there were many workers who behave complied with SOP of grinding machine. Workers who complied their work procedures on the basis of the willingness and awareness of workers obey and implement the OHS regulations that have been made by the company. Geller\textsuperscript{1} explained that compliance is a safety behavior that specific to the object of the work environment. Compliance with work procedures has an important role in creating work safety.

c. Analysis of Big Five Personality to Compliance of SOP: The test results showed that of the five big five personality traits, only neuroticism traits had a significant relationship with compliance of SOP of grinding machine. The results of the test value could be interpreted that workers who have low neuroticism traits have the opportunity to behave according to SOP 2 times greater than workers whose high neuroticism traits.

Workers of grinding showed that those who had a high value of neuroticism had properties such as being easily anxious and easily worried. They feel the feeling of being threatened by the danger of their work. That were what made them often work based on their habits that they consider safed and ignore the safety procedures that have been made by the company. In addition, workers who have feelings of worry and are easily anxious tend to act carelessly and endanger themselves.

The opposite results for workers who has low neuroticism personality values, they have more positive emotions and feel confident about every job they do. Those who have high emotional stability like this tend to be easier to think in overcoming problems in their jobs. Workers would showed cooperative behavior towards each job given and tended to be easy to understand the rules made by the company, and tended to behave obediently.

Pervin and Cervone’s\textsuperscript{12} explain that neuroticism is also called emotional instability. High neuroticism individuals tend to be nervous, sensitive, tense and easily anxious in this case they will easily feel worried and insecure. This traits have a strong influence on cognitive failure of individuals.\textsuperscript{24} The cognitive failures in question include disturbances, errors, and omissions would have minor consequences or cause accidents. This nature will have a bad impact on individual behavior in their work. Individuals with high levels of neuroticism are closely related to violations of rules or procedures.\textsuperscript{25,26}

Neuroticism have an influence on unsafe behaviors that cause workplace accidents, so as predictors in the model SOP adherence to the safety of workers.\textsuperscript{10,27} This is because neuroticism individuals who have concerns about a negative event tend not to be optimal at work and very easily disturbed, which increases the risk of their behavior. In addition, when a person has high neuroticism, he may consider feedback as a type of threat will produces anxiety and stimulation too intense. Thus, they often behave negligently, such as careless mistakes, fail to follow work norms or rules, or produce errors in their work.\textsuperscript{28,29}

**Conclusion**

Employees personality contributed to determining employee compliance with the SOP for grinding machine. Assessment of personality traits showed only neuroticism traits associated with SOP compliance. This was because workers who were easily worried and anxious tended to carry out careless and self-destructive actions, so they often violated work rules or procedures. While workers who has low neuroticism having positive emotions and were more confident, so they would behaved more in compliance with the SOP.

The Influence of Emotional and Spiritual Intelligence on Smoking Cessation Intention in College Student

Dewi Masithah¹, Oedojo Soedirham², Rika S. Triyoga²

¹Post Graduated Student of Department of Health Promotion and Behavior Science, 
²Staff of Department of Health Promotion and Behavior Science, Public Health Faculty, Airlangga University

Abstract

The number of smokers in Indonesia is the highest in the Southeast Asia region. 53.3% of male smokers over 15 years old was smokers. The results of Basic Health Research 2013 stated that every year tobacco users was increase. To stop smoking, a smoker needs strong intentions. The study was conducted at State University in Madura Island with male smoker student respondents with a sample size of 300 students. The sampling technique used the proportionate stratified random sampling method. The result showed that emotional and spiritual intelligence significantly influence on smoking cessation intention

Keywords: Intention, Smoking cessation, Emotional Intelligence, Spiritual Intelligence, Theory of planned behavior.

Introduction

Smoking is one of the behaviors that can trigger various types of diseases. Research conducted in the United States in 2014 showed that cigarettes are a major cause of chronic bronchopulmonary disease. Every year more than 7 million people worldwide died because of tobacco use and 80% of deaths occur in middle and low income countries.¹,²

Globally, 942 million men and 175 million women aged 15 or more are smokers.³ The results of The Indonesia Basic Health Research (IBHR) 2007 showed that the prevalence of tobacco users was 34.2%. In 2010, the prevalence of tobacco users was 34.7%, and increase to 36.3% in 2013. This showed that tobacco users was increased every years.⁴ Quitting smoking causes unpleasant physical and psychological symptoms. Physical symptoms such as felt include chest tightness, heart palpitations, and sweating. Psychological symptoms that occur include feeling sad, restless, angry, insomnia, difficult to concentrate, and irritable.⁵

To stop smoking, smokers need strong intention. Intention is a motivating factor that influences behavior. Intention indicates how hard someone is willing to try and how much effort someone makes to do a behavior. Intention is influenced by attitude toward behavior, subjective norm, and perceived behavior control. Attitude toward behavior is a function of trust about the consequences of behavior and an assessment of that behavior. Subjective norms are related to one’s normative beliefs about behavior. Perceived behavior control describes a person’s feelings, whether the person is capable or not able to perform the behavior. Attitude toward behavior, subjective norm, and perceived behavior control was influenced by background factors. One of this background factors is emotional and spiritual intelligence.⁶

Today there are many studies that connect emotional and spiritual intelligence with healthy living behaviors. The concept of emotional intelligence (EI) was originally introduced by Salovey and Mayer in 1990. Emotional intelligence is the ability to feel emotions, express emotions, regulate emotions, and use emotions to increase emotional and intellectual growth.⁷ Spiritual intelligence (SI) is the ability to handle and solve problems of meaning and value. Intelligence that makes one can judge actions or ways of life that are more meaningful than others.⁸ The purposed of this study was analyses the influence of emotional and spiritual

⁹ DOI Number: 10.37506/v10/i12/2019/ijphrd/192098
intelligence on smoking cessation intent in college student.

**Materials and Method**

This research is an observational analytic study with a cross sectional design with a quantitative approach. The sample in this study was male students. The male sex was chosen because from the initial survey there were no female smokers. The sampling technique was using the proportionate stratified random sampling method with a sample size of 300 respondent.

The independent variables in this study are emotional intelligence and spiritual intelligence. Emotional intelligence was measured by using modified Assessing Emotional Scale (AES) consisting of 20 questions and score range of 20-80. Spiritual intelligence is measured using a modification of The Spiritual Intelligence Self-Report Inventory (SISRI) which consists of 16 questions with a score range of 16-64. The intervening variable in this research is the attitude toward smoking cessation behavior, subjective norm, and perceived behavior control. Attitude toward smoking cessation behavior and subjective norms is measured by a questionnaire, each of which consists of 6 items with a score range 6-24. Perceived behavior control was measured by a questionnaire consisting of 8 item questions with a score range of 8-32. The influence between variables was analyzed by multiple linear regression analysis.

**Findings:** Respondents in this study were college students aged 18-24 years with mean 20.60 years and standard deviation (SD) 1,314. The age of most research respondents was 20 years with a total of 29.33%.

**Table 1. The influence of emotional and spiritual intelligence on attitude toward smoking cessation behavior**

</tbody>
</table>

Table 1 show the independent variables that influence attitude toward smoking cessation behavior was spiritual intelligence (SI) with $p < \alpha (0.024 < 0.05)$. The emotional intelligence (EI) variable does not significantly influence attitude toward smoking cessation behavior. Both EI and SI have a positive effect on the attitude toward smoking cessation behavior.

Emotional intelligence (EI) includes the ability to understand, regulate emotions, assess emotions of yourself and others and use emotions to support better thinking skills. A person with high EI has a better ability to regulate emotions. With better emotional regulation, the person does not feel stress and pressure when dealing with peers who force him to smoke.

Spiritual intelligence (SI) is one’s ability to think existentially critical, make personal meaning, have transcendental awareness, and expand conscious states. A person with high spiritual intelligence, the ability to make personal meaning and critical existential thinking is also high. Amirian & Pour (2015) states that someone with high spiritual intelligence, his health status is better than someone with lower spiritual intelligence. This indicates that spiritual intelligence provides support to deal with daily pressures and makes someone more adaptable to competition.

Smoking was a behavior that many student college did. Based on the initial survey, 71% of male college students were smokers. Quitting smoking is difficult if the environment around smokers is not supportive. Family is one of the factors that can influence someone to stop smoking. Family pressure and discomfort when having to smoke in front of family members is a reason given by smokers.

Since ancient times spirituality has become an integral part of human life. Spirituality is something that is related to the religiosity of a society. Spirituality is something that is related to the religiosity of a society. The practice of spirituality in a society can be based on the religion embraced in that society. Differences in ways of thinking and ways of looking at the community towards smoking cessation behavior can influence the norms that exist in these communities. Norms that exist in society can influence individual subjective norms.

Behavior control is the extent to which an individual controls desire to quit smoking and the individual feels that quitting smoking is easy. This study showed that behavioral control of smoking cessation behavior is low if the respondents gathered with friends. Trinidad et al (2004) state that emotional intelligence is related to the variable risk factors for smoking. Emotional intelligence has a protective association with psychosocial risk factors for smoking. Individuals who have high emotional intelligence feel the greater negative social consequences associated with smoking. This causes the individual to be more able to refuse the offer of smoking and has a low intention to smoke. Individuals with higher emotional intelligence are better able to accept the feeling that if they don’t smoke they will have fewer friends or feelings that they are not desirable to be part of the group.  

Spiritual intelligence is a mechanism that enhances people’s lives through the creation of more effective and deeper interpersonal and internal communication. Spirituality in a person allows individuals to give meaning to difficulties, tensions, and losses that cannot be predicted in everyday life. Spirituality can also make an individual look optimistic. If spirituality can make a person optimistic, someone with high spiritual intelligence should be optimistic about how he feels about quitting smoking. Smoking cessation behavior requires an optimistic view of smokers who intend to quit smoking. This optimistic mind encourages smokers to continue to quit smoking despite experiencing various difficulties.

Table 4 showed attitude variables toward smoking cessation, subjective norms, and perceived behavior control have a significant influence on the intention to quit smoking. These three variables have a positive influence on the intention to quit smoking. This means that the more positive the attitude toward smoking cessation the greater the intention to quit smoking that person has. The higher the subjective norm, the greater the intention to quit smoking that person has. The higher the perceived behavior control the higher the intention to quit smoking that person has. The lower the perceived behavior control the less the intention to stop smoking is owned by that person.

Asare (2015) showed that attitude is a variable that significantly influences intention. The same finding (Sulpat, 2018) showed that the attitude toward smoking cessation is an attitude towards smoking cessation behavior whether or not smoking cessation behavior is beneficial. A person’s attitude is influenced by various backgrounds. This background can come from individual factors, social factors, and information. Individual factors include personality, emotions, and intelligence. Social factors include age, gender, education, and religion. Information factors include experience, knowledge, and media exposure. Attitudes have aspects of thought (cognition), feeling (affection), and action predisposition (conation) but there is no assumption that one component easily overtakes the other components. This tripartite model only stipulates that there will be pressure for three components to be consistently evaluative of each other.

Subjective norms can be a social pressure on individuals to carry out a behavior. The existence of social pressure to stop smoking, for example, a campaign to stop smoking, or the opinion of important or influential figures about smoking cessation behavior is something strong to change behavior. Perceived behavior control describe a person’s feelings of being able or unable to perform the behavior. Perceived behavioral control refers to the individual’s trust in his ability to perform the behavior in question. Along with subjective norm and attitudes toward smoking cessation behavior, perceived behavior control are other important predictors of intention. Martinez & Lawell (2016) stated that low perceived behavior control can be caused by lack of skills or the existence of environmental barriers to individuals.
A person who believes that he cannot do behavior, even if he has a positive attitude or strong subjective norm to stop smoking, will have a reduced effect or weakening the formation of intention. An individual can have positive subjective attitudes and norms towards this behavior, but the perception of behavioral control acts as a precondition in forming intentions. Behavioral control perceptions also tend to vary as a function of various factors, such as previous individual experience, representative experience, persuasion, and physiological conditions. In the context of lifestyle or behavior, for example, perceptions of behavioral control can be influenced by previous individual failures. Perceived behavior control can adjust the ‘volume’ of intentions and the norm-intention relationship that is felt by blunting it between those with lower perceptions of behavioral control, and strengthening it among those whose perceptions of behavior control are higher. This proposition is also consistent with the conceptualization of perceptions of behavioral control as a motivating element in behavior formation and behavior change.22

Conclusion

Emotional and spiritual intelligence influenced the intention of smoking cessation. Emotional intelligence influenced the intention to stop smoking through perceived behavior control. Spiritual intelligence influenced the intention of smoking cessation through attitude toward smoking cessation. Both emotional intelligence and spiritual intelligence did not influence intentions of smoking cessation through subjective norms.

Ammonia Gas Release: Study of the Causes and Negative Impact Potential towards Workers and Communities around Fertilizer Company XYZ, Indonesia

Diana Mutia Pratiwi1, Roekmijati Widaningroem Soemantojo2,3, SuyudWarnoUtomo2,4

1Post-graduated Student, School of Environmental Science Indonesia University, Central Jakarta, 2Lecturer, School of Environmental Science Indonesia University, Central Jakarta, 3Lecturer, Chemical Engineering Department Indonesia University, Depok, 4Lecturer, Public Health Department Indonesia University, Depok, Indonesia

Abstract

Exposure to ammonia gas due to specific factor towards the environment, particularly to workers and the community has a potential negative impact, especially in the form of health problems. This study was to analyze the factor that causes ammonia gas release in the environment and the negative effects of especially workers and communities that lived around the plant. Narrative analysis by comparing the key informant interview, field observation, questionnaire with likelihood scale, severity scale, and also t-test sample was used as the method in this research. Based on the study, it was found that 71.11% ammonia gas release because of certain conditions while 28.90% because of the process part. Certain conditions that often caused ammonia gas release are located in ammonia storage tanks, cooling water reservoirs, and pumps and valves, with certain conditions such as clogging, negligence, maintenance, and start-ups. The impacts of ammonia occur on humans through inhalation and directly cause irritation, and respiratory problems that differ in each depends on the exposure duration and concentration level.

Keywords: Ammonia Gas, Ammonia Release, Ammonia Health Impact, Chemical Hazard, Fertilizer Plant.

Introduction

The more complex processes and technology in an industry, the higher the possibility to involve a material that can cause accidents that threaten human life and the surrounding environment(1). Ammonia gas exposure occurs in workers in industries engaged in synthesis, formulation, transportation, along with the use of these substances (2). Ammonia gas can be dangerous when contacted in tissues in living bodies that have moisture or contain water (3). When contact with humans, ammonia gas reacts with water in the surface layer of the eyes, skin, and respiratory tract to form caustic ammonium hydroxide compounds (4), causing a sensation such as burning or irritation in the area (5).

The release of ammonia gas in the air can cause serious health problems for humans and ecosystems, even in small concentrations ranging from tens of ppm (6).

This article presents a case in a fertilizer company XYZ, Indonesia. PT. XYZ is a company engaged in the manufacture of Ammonia and Urea Fertilizers located near the Musi River, approximately 7 km from the center of Palembang City, South Sumatera. The plant has 4 plants with a total production capacity of 1,149,000 tons per year of ammonia and 2,280,000 tons per year of urea. During the manufacturing process, ammonia gas is often released in the air in factory processes caused by instrument/human factors.

On September 14th, 2001, there had been a disruption due to plant activity which was prone to noise that reached 78 dB (A) and was contaminated ammonia gas which reaches 12 ppm near the surrounding community that lived in 700m radius from the plant. This is supported by the study of Navianti(7), it was analyzed that ammonia exposure was around 73.8% for exposure to high concentrations (2330 µg/m³), and 43.9% for exposure to low concentration ammonia gas (174.5 µg/m³). This value is quite high considering the quality standard for ammonia in ambient air according to PP. RI No.41 of 1999 is 1360 µg/m³/24 hours. On March 5th, 2014, tourists and residents who wished to visit Kemaro Island Palembang in the framework of the Cap Go Meh celebration were exposed to mild eye
irritation and discomfort in breathing when crossing the area around XYZ factory due to ammonia gas exposure. This disturbance has been happened for decades up until now. The purpose of this study is to analyze the most factor that often causes ammonia gas to be released in the environment, and the negative effects of ammonia gas release on the environment, especially workers and communities around the plant.

**Methodology**

The research was carried out in two places, namely inside the factory environment and the environment surrounding the factory. In the factory environment, the research location is limited to two criteria, which are the unit in the XYZ factory that produces or uses ammonia in the process, and was operated from 2001 until now, namely X-IB and X-III. In the environment surrounding the factory, the study was carried out in 1 Ilir Sub-District, Ilir Timur II Subdistrict with a distance between 500-1000 m from the factory.

Purposive sampling was carried out to get information about the ammonia gas release and the potential negative impact of free ammonia gas on workers, with the criteria in the form of Ammonia and Urea plants workers over 20 years old with more than 1-year working experience. The questionnaires distributed in the amount of 90 pieces, with the distribution of 22 pieces for workers of X-IB ammonia plant, 23 for workers of X-IB urea plant, 23 for workers at ammonia X-III plant, and 22 for workers at urea X-III. For community samples, the selection of sample locations was determined using random cluster sampling. The sampling locations were RT 19 RW 04, RT 16 RW 04, RT 12 RW 04, and RT 10 RW 04. Furthermore, the selection of samples was narrowed down by the addition of criteria in the form of people living with a distance between 500-1000 m from the PT. PUSRI factory with an age range of 25-40 years for more than 5 years. The questionnaires were distributed by 140 pieces, with the distribution of each RT numbering 35 questionnaires. The results analyzed for differences using the t-test as presented in Table 1. If the significance value obtained is <0.05, then there are differences between the two data variables tested. Conversely, if the significance value obtained is >0.05 then there is no difference between the two data variables tested.

**Result and Discussion**

Based on field observations, it was found that ammonia gas released due to certain conditions, namely:

1. Mechanical Problems at the pump, mainly due to corrosion or the equipment lifetime that cause a leakage
2. Negligence on the distribution and shipping process of Ammonia
3. Clogging in Process Equipment that causes a burden to another section, resulting in an inefficiency in urea conversion that caused excess unconverted ammonia released from the stack.
4. Turn around and plant maintenance that requires to drain the excess material out the equipment.

This is supported by Kidam & Hurme (7) study which states that out of 364 total industrial work accidents, the main contributing factors were equipment problems in the piping system (25%), reactors and storage tanks (14%), and process vessels (10%). Gyenes & Wood (8) has a similar opinion, where the main factor causing industrial workplace accidents is equipment problems which are 30% caused by aging equipment. The aging condition in question is a decrease in conditions and changes in equipment that are used over time (9). Every equipment in the factory has a lifetime or usage period before experiencing depreciation, which usually ranges from 10 years and above (10). In addition to equipment problems, a lack of knowledge of written work procedures, personal protective equipment, education, and work experience, work environment conditions and
work safety management are also supporting factors for potential accidents in industrial workers. 

However, this event has the potential to release ammonia in higher concentrations than other problems and has the potential to harm workers to the community. This statement is also supported in Pratiwi et al. that ammonia release tends to be recorded as accidental cases, where victims experience moderate injuries that require rapid medical treatment. The impact of similar exposure describes that the victim has difficulty breathing, severe irritation of the eyes, nose, and throat, and minor burns. The impact of brief exposure is different for each depending on the individual’s ability to adapt. This is also shown in Pratiwi et al. where the impact of the ammonia occurs in 5 minutes with a concentration of 20-25 ppm.

This study is different from Sekizawa & Tsubone and Federuk et al., namely disorders in individuals who have not adapted to occur in 10-15 minutes with a concentration of 20-30 ppm. Lessengger study states that exposure to ammonia concentrations reaching 32-35 ppm for 5 minutes will have an impact on dryness in the nasal cavity. Thus, it can be inferred that the difference in the description of the symptoms that was felt was different for each individual. This is also in line with the t-test analysis with variable symptoms of disturbances in ammonia and urea plant workers presented in Table 2.

Table 2. T-Test Results on the Disorders symptoms experienced by Ammonia and Urea Plant Workers in XYZ Factory

<table>

</tbody>
</table>

Based on the results of the t-test in Table 8, the sig value (2-tailed) is obtained 0.002 <0.005. So based on its decision making, it was concluded that there was a significant difference between the health problems experienced by ammonia plant workers and the urea plant. To strengthen the t-test results, the following are the percentage of symptoms experienced by workers which presented in Table 3.

</tbody>
</table>

Based on Table 3, there are differences in the symptoms experienced by respondents when exposed to free ammonia. The largest percentage is 31.11% (14 of 45 respondents) experienced irritation to the eyes with painful and dry eye characteristics, 17.78% (8 out of 45 respondents) experienced irritation to the nasal with the characteristics of feeling around the cavity when breathing, and 15.56% (7 out of 45 respondents)
experienced throat dryness with characteristics of a burning sensation and dryness in the throat. Unlike the ammonia plant workers, the largest percentage of the disturbances experienced by urea plant workers is dry throat by 24.44% (11 out of 45 respondents). About 20% (9 out of 45 respondents) experienced irritation to the nasal, while 17.78% (8 out of 45 respondents) experienced dry eye, nasal, and throat irritation in the same sequence of eye irritation and nasal cavity, then the throat felt burn when trying to breathe. Communities also showed different responses. Based on the results of the questionnaire given to 140 people from 4 different RTs, 85.7% of respondents stated that the first thing felt when exposed to ammonia gas was breathing discomfort, followed by eye irritation (92.9%), difficulty breathing in third place (22.9%). Dry nose and throat irritation ranks fourth (4.29% and 5.71%), and feeling nauseous is fifth (3.57%). Thus, it can be inferred that the impacts of ammonia occur through inhalation, directly cause irritation and respiratory problems (17). Ammonia gas will be absorbed directly by the eyes, nose, skin, and respiratory tract to the lungs. However, reactions to the skin and lungs do not occur suddenly, unless exposed to very high concentrations. However, most symptoms of the disorder are experienced only in the short term. The possibility of a long-term impact based on the respondents’ responses was shown in Table 4.

</tbody>
</table>

Based on Table 4, only 47.83% of the total respondents stated that there were health complaints due to periodic exposure to ammonia. From the 37 workers who experienced health issues, the disorder experienced by ammonia workers was the differences in skin color (9.09%) and sinusitis (45.45%), while the disorder experienced by urea workers was the differences in skin color (17.86%), 32.14% experience sinusitis and 50% experience changes in breathing patterns. The difference in skin color in question is chemical burns due to high concentrations of ammonia exposure. Sinusitis, in this case, is under the description in the Brautbar study, namely irritation of the mucus membrane in the nasal region due to exposure to ammonia and changes in breathing patterns according to the Sundbland et al. study are symptoms such as wheeze and asthma. Workers exposed to these gases and suffer the health issues need a recovery time of at least 1-4 days a week. The same thing was found in the respondents of the community. Of the 140 total respondents, 73 people (52.14%) complained of symptoms of the disease such as nausea, dizziness, and shortness of breath, while 67 (47.85%) people have no complaints. Based on the percentage of complaints, 94.52% (69 out of 73) respondents stated temporarily, and 5.88% (4 out of 73) respondents stated permanently. The complaints of permanent disruption by community respondents are lung and asthma. However, this cannot be ascertained because of the possibility of other factors (such as the community’s lifestyle or hereditary disease records).

Conclusion

Ammonia gas release that potentially causes a negative impact was due to a certain condition in the factory, mainly located in ammonia storage tanks, cooling water reservoirs, pumps, and valves. The certain condition occurs due to leakage, clogging, maintenance, and negligence. This event has the potential to release ammonia in higher concentrations than other problems and has the potential to hurt workers to the community. The impacts of ammonia occur on humans through inhalation, directly cause irritation and respiratory problems, which differs on each person. Ammonia gas will be absorbed directly by the eyes, nose, skin, and respiratory tract to the lungs. However, reactions to the skin and lungs do not occur suddenly, unless exposed to very high concentrations. Ammonia exposure strongly impacts on short-term diseases such as skin discoloration, sinusitis, wheeze and asthma symptoms that last 1-4 weeks, while long-term disease that caused
by ammonia still debatable due to a possibility of other factors such as lifestyle and genetic disease records.

Correlation between Types of Parenting with the Development of Children Aged 1-5 Years

Diana Septaria Abidin1, Irwanto2

1Magister Program of Public Health, Faculty of Public Health, 2Department of Child Health, Faculty of Medicine, Airlangga University, Surabaya, Indonesia

Abstract

Important period in child development is at the age of 1-5 years old. Parenting is one of the factors that cause development of child aged 1-5 years old. The objective of this study is to find the correlation between types of parenting parents with the development of children aged 1-5 years old. This research method is cross-sectional design. Data were collected during June-September 2015. Respondents in this study were parents and children 1-5 years old who met the inclusion and exclusion criteria. We used systematic random sampling technique until total sample of 345 parents and children achieved. Independent variables studies was types of parenting and dependent variable was development of children aged 1-5 years old. Data types of parenting was collected by questionnaire and development of children aged 1-5 years old was measured by Pre-Development Screening Questionnaire (KPSP). Analysis was using Chi Square. The authoritarian parenting 11.6%, 14.5% democratic parenting, 12.7% passive parenting and mixed parenting 62%. 73% of the KPSP with a “correct” development, “doubt” (13.6%), and “possible disorder” (13.3%). There is a significant correlation between types of parenting and development children aged 1-5 years old (p = 0.000) with contingency coefficient value 0.661. Risk factors for the disorder development are 69.7% for the variable parenting variables, maternal education, maternal occupation and nutritional status of children. Types of parenting had correlation with development children aged 1-5 years old.

Keywords: Parenting, development, children.

Introduction

Important period in child development is at the age of 1-5 years. At this aged, basic growth will influence and determine the child’s next development, but many children under 5 years old in developing countries are exposed to various risks, including poverty, malnutrition, poor health and a home environment that does not support stimulation, so this it adversely impact on their cognitive, motoric and social emotional development.(1)

The style of parenting is one of the factors in child development. Children under 5 years old, their development and growth depends on the care they receive. Lack of parenting at the beginning of life has a negative effect on growth and development of child.(2)

There is little data for child development status, but according to estimates more than 200 million children under 5 years old in developing countries do not develop to their maximum potential.(1) Data from the East Java Provincial Health Office shows an increase in hospital referrals from children with developmental deviations, around 23.96% in 2012 to 32.06% in 2013. While specifically in Surabaya around 15.83% of children under 5 years old experiencing developmental irregularities referred to the hospital.(3)

The results of the primaries study conducted on September 13, 2014 in Surabaya showed that from 30 parents and children aged 1-5 years, 65% of parents with mixed parenting had children with developmental categories according to their stages. Authoritarian parents, they have a parenting style by setting rules and guidance that their children are expected to follow. Meanwhile, democratic parenting encourages children to become independent, but still places limits and control over their actions. Democratic parents show support in responding to constructive child behavior. They also respond to adult, independent behavior and according to the age of their children, so that when children fail to meet the expectations of their parents, they are more forgiving than punishing.(4)
According to the research there are influences between parents’ attitudes, perceptions, and psychosocial on child development, poor attitudes and perceptions of parents with or without risk factors have a negative impact on child development.\(^5\)

This research was conducted because of the importance of knowing all aspects of child development and how parenting is applied by parents, therefore researchers want to know the relationship between parenting parents with the development of children aged 1-5 years old.

**Materials and Method**

The research with a cross-sectional method. Sample in this study were parents who had children aged 1-5 years old and children aged 1-5 years old who came to the Maternal and Child Health Center Surabaya in June-September 2015 that met the inclusion criteria. The inclusion criteria for parents in this study were parents who understood Indonesian, were willing to fill out questionnaires and allow their children to be examined for development by signing a letter of agreement to become a respondent. Inclusion criteria for the sample of children in this study were children in a healthy condition, did not have congenital abnormalities or disabilities.

Sampling method with systematic random sampling technique. In this study independent variables are parenting parents in children aged 1-5 years old, the dependent variable is the development that occurs in children aged 1-5 years old. Instruments in the form of parenting questionnaires that have been tested for validity and reliability to assess the type of parenting and Developmental Pre Screening Questionnaire (KPSP) from the Ministry of Health of the Republic of Indonesia to assess the development of children aged 1-5 years.

Statistical analysis using a computer program, SPSS version 21. Analytical analysis used nonparametric statistical tests, namely chi square to find out whether there is a relationship between types of parenting parents and child development. Multivariate analysis used in this study was a multivariate logistic regression analysis. This analysis is used for dependent variables with a measurement scale of categorical variable. In logistic regression the quality of the formula is obtained from the ability of discrimination and calibration. Calibration with the Hosmer and Lameshow method. In addition, the value of Nagelkerke R Square is also seen to see how much the proportions of independent variables can predict the occurrence of the dependent variable.

This research has been approved by the Health Research Ethics Commission (KEPK) from the Medical Faculty of Airlangga University Surabaya by letter No.083/EC/KEPK/FKUA/2015.

**Finding:** The number of samples obtained by systematic random sampling method were 345 respondents of parents and children aged 1-5 years.

* Significant Chi Square
The results of the analysis test using chi square are significant with the value of the contingency coefficient 0.661. Whereas, the results of the analysis test using logistic regression obtained p value <0.05 for the categories of parenting variables, maternal education, maternal occupation and nutritional status of children. Hosmer and Lameshow values 0.440. From the results of Nagelkerke R square obtained a value of 0.697, parenting variables, maternal education, maternal occupation and nutritional status of children having a risk effect on the incidence of below normal growth of 69.7% and 30.3% due to other factors.

**Discussion**

In the study of 345 parents respondents obtained the results of authoritarian parenting 11.6%, democratic parenting 14.5%, passive parenting 11.9% and mixed parenting 62%. In developmental tasks, 45% of children with authoritarian parenting cannot perform developmental tasks according to age. In mixed parenting, 73% of children can carry out developmental tasks according to age. In democratic parenting, 16% of children cannot perform developmental tasks according to age, while in passive parenting, 39% of children cannot perform developmental tasks according to age.

The five main factors that contribute to children’s growth and development are nutrition, parental behavior, parenting, social and cultural and environmental. The patterns of parenting is an important factor in the child development process. Family is the first social environment for children so that it gives the biggest influence on children’s development. Families, especially fathers and mothers provide the basis for the formation of behavior, character, morals and children’s education. The experience of interaction in the family will determine the pattern and behavior of children towards others people in the community.\(^{(2,4,6)}\)

Authoritarian parents place strict limits and controls on children. Authoritarian parents also enforce rigid rules, but do not explain to children reason for enforcing rigid rules, and authoritarian parents often show anger to children. Excessive and dominant parental control over children can cause children to behave aggressively and often sue others or behave otherwise, which is to be passive individuals who tend to avoid socializing.\(^{(7,8)}\)

The results of the study indicate that poor child care, with or without psychosocial factors, negatively influences early child development from the age of 6 months. Other studies also mention that it is very important to consider parenting styles for caring for children, because this can reduce parental anxiety in the care process.\(^{(5,9)}\)

Parenting has a significant relationship to the development of children aged 1-5 years old. The results of the analysis of parenting and child development analysis using chi square test showed that the results of p = 0.000 (p <0.05) then Ho was rejected and H1 was accepted. Contingency coefficient value is equal to 0.613 which means the strength of the relationship between variables of parenting and child development variables is strong. This result is consistent with other studies, namely the flexible balance between democratic and authoritarian parenting (mixed upbringing), is the most desirable parenting style for a child’s developmental needs.\(^{(10)}\)

Other research findings indicate that the relationship between parent and child is a special subsystem from the family, which is the most important determinant of children’s mental development, children’s emotional and socialization processes. The main characteristics of the parent and child relationship system are love that determines credibility of a child, communication with children, the desire to protect and provide security to children, and acceptance and unconditional attention, and holistic attitude.\(^{(11)}\)

Many factors influence the development of children in addition to parenting parents. Parents, especially mothers who have multiple roles, are often faced with conflicts between work interests and their presence in the family. High job demands and time consuming often hamper meeting the need for family togetherness, caring for and caring for children.\(^{(12)}\)

In this study the results of the analysis test using logistic regression test showed the results of p <0.05 for the category of parenting variables, maternal education, maternal occupation and nutritional status of children. The results of logistic regression analysis obtained the value of Hosmer and Lameshow with a significance value of 0.440, which means p > 0.05, so it can be concluded that Ho is accepted which means the model of estimation results is significant fit (model worthy of use). In addition, from the results obtained Nagelkerke R square value of 0.697, which means that the variables of parenting variables, maternal education, maternal occupation and nutritional status of the children are able to explain the effect of risk on development under normal conditions of 69.7% and 30.3% caused by other factors.
In addition to parenting, socioeconomic status can affect the growth and development of children. Children with families who have high socioeconomic conditions generally meet the needs fairly well compared to low socioeconomic children.\(^{(12)}\) Mothers who do not work, have more time to spend with their children. Mother can train and educate children, so that language development and children’s academic achievements are better if compared to working mothers.\(^{(13)}\)

Mothers who work still involved in meeting the needs of children and fulfill their role as mothers will provide comfort and emotional security to children. Relationships between children and mothers who are safe will have feelings of joy and cheerfulness. Such satisfying feelings allow the child to face a life that is free from the mother because she understands and accepts that the mother must sacrifice other things and not as a substitute for the mother. The child understands that the mother will be there if the child needs it and consumes time with her after the mother comes home from work. In such relationships, children understand that children are their mother’s priority and no one can change that.\(^{(14)}\)

Children’s nutritional status can affect development and growth. The first 1000 days of life from conception to the end of the second year of life are important periods of carrying out interventions to ensure healthy nutrition and development of children. In addition to interventions on the nutritional status of children, it is also important that children have a supportive and friendly environment to form strong bonds with their caregivers as a basis for optimal child development.\(^{(15)}\)

**Conclusion**

From this cross sectional study, we can conclude that the risk factors for children not being able to carry out developmental tasks according to their age are parenting. In addition to parenting, risk factors for maternal education, maternal occupation and nutritional status of children also influence children’s development. Therefore, the choice of parenting patterns, maternal education, mother’s work and children’s nutritional status are very important to be considered to optimize the development of children aged 1-5 years old.

A Comparison of Leisure Activities in Patients before and After a Stroke

Deok-Gi Hong\textsuperscript{1}, Doo-Han YOO\textsuperscript{2}

\textsuperscript{1}Assistant Professor, Dept. of Occupational Therapy, Wonkwang University, Institution of Health Improvement, Republic of Korea, \textsuperscript{2}Assistant Professor, Dept. of Occupational Therapy, Konyang University, Republic of Korea

Abstract

This study analyzes the characteristics of leisure activities of stroke patients according to gender, and comparatively assesses their activity levels before and after the onset of the disease. Leisure activity-related data were collected from 125 stroke patients using the Korean-Activity Card Sort and analyzed according to gender. An independent t-test and paired t-test were conducted to compare the retained level of leisure activity (RLA) after stroke according to the patients’ general characteristics. Most of the leisure activities men and women continued with after stroke were passive ones that did not require exercise or rely on cognitive abilities. The RLA after stroke in both men and women demonstrated a statistically significant difference as their roles changed in accordance with age. Healthcare practitioners should analyze the leisure activities of stroke patients and provide interventions to help them retain the current level of leisure activity or engage in new leisure activities.

Keywords: Activities, Activity Card Sort, Leisure, Health care, Stroke.

Introduction

Interest in therapeutic interventions to encourage stroke patients’ participation in local communities is on the rise\textsuperscript{1}. Leisure-based interventions are important as they have positive effects on personal life and strengthen the motivations for rehabilitation\textsuperscript{2}. Although the social interest in leisure activities continues to grow, the level of leisure activity participation in stroke patients is still low. Studies suggest that stroke patients spend most of their time engaging in passive activities such as watching TV in restricted areas, not participating much in social activities such as sports\textsuperscript{3}.

Existing studies have reported that participation in leisure activities in local communities has positive effects on improving the quality of life and life satisfaction of stroke patients. In addition, participation in leisure activities contributes to improving physical and psychological health management. It offers positive motivation for life and revitalizes the rehabilitation process of patients\textsuperscript{4,5}. Therapeutic intervention using leisure in the rehabilitation of stroke patients is a useful approach in promoting motivation\textsuperscript{3}. It is an essential factor associated with quality of life, which should be considered fundamental to the treatment process\textsuperscript{6}.

In previous studies, various factors influence leisure participation. Particularly, there are differences in leisure activities according to gender, education level and income\textsuperscript{7,8}. Considering these factors, identifying changes in leisure activities after stroke is essential for intervention planning\textsuperscript{9}. The present study attempted to investigate the evidence for leisure intervention. To this end, we conducted a comparative analysis of the characteristics of leisure activity before and after stroke according to gender.

Subjects and Method

A total of 125 stroke patients being treated at a rehabilitation center participated in our study. The selection criteria were: those who were diagnosed with stroke, who recorded 26 points or higher in the Mini-Mental State Examination-Korean (MMSE-K), and...
who were able to communicate smoothly\textsuperscript{10}. Table 1 shows the general characteristics of study participants. All participants were given an explanation of the study procedure and signed a written consent form for participation. We obtained approval from the institutional review board prior to the implementation of the research.

The Korean-Activity Card Sort (K-ACS) was used to assess the level of leisure activity of study participants. K-ACS and general characteristics information were collected face to face by the researchers. The K-ACS is a variant of the American ACS, modified according to Korean culture\textsuperscript{11}. The 67 activity cards consisted of 33 instrumental activities, 18 leisure activities, and 16 social activities. The K-ACS is classified into recovery and community-living versions. The scores for the five categories are ‘Never done = 0 score’, ‘Do now = 1 score’, ‘Given up = 0 score’, ‘Restart = 0.5 score’, and ‘New activity = 1 score’. Participants classify 18 leisure cards into one category. The level of leisure activity, including current, previous, and retained, was evaluated using the 18 leisure activity cards. The score calculation formula is as follows. 1) Level of current activity = ‘Do now’ + ‘Restart’ + ‘New activity’, 2) Level of previous activity = ‘Do now’ + ‘Given up’ + ‘Restart’, 3) Retained level of activity (%) = Level of current activity/Level of previous activity 100. Cronbach’s \(\alpha\) of the leisure activities area of the K-ACS was .93.

Data collected in our study were analyzed using SPSS 18.0. The general characteristics of study participants were analyzed using descriptive statistics. Changes in the level of leisure activity in subjects before and after stroke according to gender were analyzed using the paired t-test. The independent t-test and paired t-test were used to compare the retained level of leisure activity (RLA) after stroke based on gender and general characteristics. The statistical significance level \(\alpha\) was set at 0.05.

**Results**

Male participants showed a statistically significant post-stroke reduction in 15 leisure items except for watching TV, resting, and sitting and speculating. After stroke, all participants mostly spent time on passive leisure activities such as watching TV, resting, and sitting and speculating (Table 2).

Table 3 compares the RLA after stroke based on gender and general characteristics. A statistically significant difference was observed in the post-stroke comparison based on gender, general characteristics, and age. The female stroke patient group aged 65 years or older showed the highest RLA. In the comparison within each gender group, the female patient group aged 65 years or older showed more significant differences than the group aged between 55 and 64. Within the male group, significant differences were observed according to education level. The uneducated group showed a higher RLA than the educated group.

* p<0.05, ** p<0.01 compared between male and female, † p<0.05, ‡ p<0.01 compared within male and female, Retained level of leisure activity (RLA) = level of current activity/level of previous activity 100%

Discussion

Leisure activities refer to the enjoyment of free time without feeling a sense of duty. Leisure activities are a crucial factor in encouraging stroke patients to participate in the local community upon their return. Therefore, it is essential for stroke patients to maintain the occupational balance through exploration of and participation in leisure activities. However, the physical and psychological difficulties caused by stroke limit their exploration and participation. This eventually causes occupational imbalance and delays their return to the local community.

After stroke, both men and women engaged in leisure activities such as watching TV, resting, and sitting and speculating. However, while men continued with leisure activities such as listening to music and the radio, women showed reduced levels of engagement in these activities. Most of the leisure activities men and women engaged in after stroke were those that did not require exercise or rely on cognitive abilities. These
results correspond to the findings of existing studies that stroke patients have difficulties in participating in leisure activities relying on physical and cognitive skills.9, 14

The comparison between the genders demonstrated that women had a significantly lower RLA after stroke compared to men in the 55-64-year-old group. In the 65-years-or-older group, women showed a significantly higher RLA after stroke than men. The low RLA after stroke in women aged between 55 and 64 is probably because, being responsible for managing their households, it was not easy for them to participate in leisure activities. The elevated level in the older group is probably the result of a higher bandwidth for leisure activity given that a woman’s role in the family changes at around 65 years.15

In men, educated subjects higher RLA than those who were not educated. Before stroke, those without educational backgrounds were mainly engaged in occupations requiring physical activity such as agriculture, whereas the educated subjects were engaged in jobs requiring less physical exertion. Qualitative study on leisure activities in stroke patients have reported that patients made efforts to continue leisure activities similar to their past occupational activities.16 The 18 leisure activities included in the K-ACS focus on relatively basic physical skills. It is likely that the RLA after stroke was low in educated participants because the leisure activities were loosely associated with their pre-stroke activities.17

Conclusion
Disabilities caused by stroke interrupt patients’ engagement in leisure activities. It is recommended that healthcare specialists compare patients’ leisure activity history before stroke with the status after stroke and help them maintain the current level or engage in new activities to improve quality of life and maintain occupational balance. The limitation of this study is that it does not address various factors affecting leisure participation. In addition, K-ACS has 18 leisure activities, and other leisure activities are not included in the study data. Future research is expected to be conducted in consideration of these limitations.

Improving the Village Health Volunteers’ Knowledge, Malaria Diagnostic Skill and Home Visits through the Observed Training

(Study in Municipality of Tidore Islands North Maluku Province Indonesia)

Dwi Soesilo¹, Catharina U. Wahyuni²

¹Student Doctoral Program, ²Professor of Epidemiology, Department of Epidemiology, Faculty of Public Health, Airlangga University, Surabaya, Indonesia

Abstract

Municipality of Tidore Islands in North Maluku province, Indonesia, where this study conducted was a malaria endemic area. The malaria Annual Parasite Incidence in this area was 10.8 per 1000 inhabitants in 2010, 8.3 per 1000 inhabitants in 2011, 7.5 per 1000 inhabitants in 2012, 6.11 per 1000 inhabitants in 2013 and 2.10 per 1000 inhabitants in 2014, 2.10 per 1000 inhabitants in 2015. Geographically, this area is consisting of a number of separated islands. This reality reflects the complexity of delivering access, especially health care access to all those separated remote areas.

The aim of this study was to increase village health volunteers’ knowledge of malaria and diagnostic skill and home visit through observed training and to analyze the correlation between the knowledge of the village health volunteers toward the diagnostic skill.

This research was a Quasi-experimental research based in the community by observing the effects or developments of the results of training interventions called “The One Group Pretest-Posttest Design”. A linear regression analysis also conducted to analyze the correlation of observed health volunteer training toward the knowledge and the correlation between knowledge and the diagnostic skill.

Result: There has been an increase in village health volunteers’ knowledge after the observed training conducted which included knowledge about malaria in general and the provision of skills to diagnose malaria with sensitivity of 73.4% and specificity of 54.2%. Village health volunteers’ knowledge was significantly having correlation toward diagnostic skill (p=0.047) and 90.5% patients that visited completely by village health volunteers taking antimalarial drugs regularly.

Keywords: Malaria, village health volunteer, knowledge, diagnosis skill, home visit, observed training.

Introduction

Malaria remains one of the major public health problems worldwide. Based on the result of Basic Health Research, the Malaria’s Annual Parasite Incidences in Indonesia shown a decreasing incident from 2.47 per 1000 inhabitants in 2008 to 1.38 per 1000 inhabitants (¹). Data from Indonesia Health Profile informed that the Malaria’s Annual Parasite Incidents in Indonesia decrease from 1.8 per 1000 inhabitants in 2009 to 0.84 per 1000 inhabitants in 2016 (²)

North Maluku was the 5th highest Malaria’s Annual Parasite Incidence in Indonesia i.e. 2.44 per 1000 inhabitants in 2016 (¹)(²)(³). The Annual Parasite Incidents from 2013 to 2016 was 4.51 per 1000 inhabitants, 3.32 per 1000 inhabitants and 2.77 per 1000 inhabitants, respectively (²).

Beside the high incidents of malaria cases, drugs resistance also became an important issue in malaria control all over the world including in Indonesia. The fact that people can get anti-malarial drugs from various places makes inaccurate and inadequate treatment and it has an implication for the increasing of resistance of anti-malarial drugs. In 1996 there have been cases of chloroquine Plasmodium falciparum resistance with different degrees in various regions as well as Sulfadoxin–Primetamine in vivo and in vitro. An alarming development is the discovery of Plasmodium Vivax which is resistant to chloroquine between Papua regions, Nias, Maluku and Flores Islands.

Municipality of Tidore Islands in North Maluku province, Indonesia, where this study conducted was a malaria endemic area. The total population of this municipality was 110,102 inhabitants and 29,253 households in 2015. The malaria Annual Parasite Incidence 10.8 per 1000 inhabitants in 2010, 8.3 per 1000 inhabitants in 2011, 7.5 per 1000 inhabitants in 2012, 6.11 per 1000 inhabitants in 2013 and 2.10 per 1000 inhabitants in 2014, 2.10 per 1000 inhabitants in 2015. Geographically, this area is consisting of a number of separated islands. This reality reflects the complexity of delivering access, especially health care access to all those separated remote areas. The health facilities available in this municipality were one public hospital and tensub district public health centre. Limited human resources were also another problem.

Because of this, community empowerment became a crucial initiative to help the health officers in delivering health services access especially for malaria control in this island. Health volunteer trainings have been conducted, but unfortunately there was no information about the result of this training that had been observed.

Hence, the aim of this study was to increase village health volunteers’ knowledge of malaria and diagnostic skill and home visit through observed training and to analyze the correlation between the malaria knowledge of the village health volunteers toward the diagnostic skill.

**Method**

This research was a Quasi-experimental research based in the community by observing the effects or developments of the results of training interventions. Observation of the result variable was done before and after the treatment called “The One Group Pretest-Posttest Design”.

Data obtained through interview with 44 village health volunteers using a structured questionnaire before and after the observed training. An observation employed to evaluate the home visit after the observed training. The collected data was tabulated according to the variables and information needed.

A linear regression analysis also conducted to analyze the correlation of observed health volunteer training toward the knowledge and the correlation between knowledge and the diagnostic skill of village health volunteers.

**Result**

**Village Health Volunteers’ Knowledge:** Result of statistical analysis using paired t test with Confidence Interval 95% and α 0.05 was significance 0.000, meaning that there was a significant correlation between the observed training and the knowledge as shown in table 1.

</tbody>
</table>

Knowledge that had been given in the observed training included of the knowledge about the cause of malaria, the symptom of malaria, the transmission of malaria, the vector of malaria, the complication of severe malaria, the prevention activities for malaria control, the eradication of malaria and the drugs and also the treatment of malaria patients.
Village Health Volunteers’ Diagnostic Skill:
There was no test for village health diagnostic skill before the observed training. The result of village health volunteers diagnostic skill tested after the observed training was confirmed with the laboratory test result to determine the accuracy. Diagnostic skill result after the training and laboratory test confirmation presented in cross tabulation as shown in table 2.

Table 2: Crosstabulation between the Village Health Volunteer Diagnostic Skill Test Result and the Laboratory Test result

</tbody>
</table>

The sensitivity of the crosstabulation was 73.4%, which can be interpreted as 73.4% cases that was diagnosed malaria positive by the village health volunteer confirmed positive by the laboratory test result. The specificity of the crosstabulation was 54.8%, which can be interpreted as 54.8% cases that was diagnostic malaria negative by the village health volunteers also was confirmed negative by the laboratory test result.

Therefore the false (+) for village health volunteer diagnostic skill was 45.2% and the false (+) was 26.6% with the positive prediction 54.8% and negative prediction was 73.4%.

Home Visit by Village Health Volunteers (Observed in the field after the training conducted):
The home visit activities conducted by the village health volunteers had observed after the training completed for 94 patients in one cycle anti-malarial drug treatment. There was also no pre-test for a home visit by the village health volunteers, so no statistical correlation analyses had been conducted.

Table 3: Home Visit by the Village Health Volunteer after the Observed Training

<table>

*correlation is significant at the 0.05 level (2-tailed)
Result from statistic test using Pearson correlation shown that the knowledge of village health volunteers about malaria had a significant correlation toward the diagnostic’s skill with Confidence Interval 95% (p = 0.047).

**Discussion**

Early diagnosis and prompt effective treatment of uncomplicated malaria is critical to prevent severe disease, death and malaria transmission (7). Therefore, to help the health professional in order to deliver the services, especially in the remote area with geographical difficulties, the role of the village health volunteers became very crucial. In order to provide the knowledge and skill needed to perform the task. It is very important to provide trainings to improve the knowledge and skill of the village health volunteers with a measurable evaluation and observation.

The result of this research showed there was a significant correlation with knowledge level before and after the training conducted. It means the observed training has a significant correlation with the knowledge level of malaria gained by the village health volunteers.

It is important to increase the village health volunteers’ knowledge about malaria because the knowledge has a significant correlation toward the village health volunteers’ diagnostic skill. Therefore the increase of the knowledge will be improved the diagnostic skill of the village health volunteers. Early diagnosis will lead to early treatment that can prevent a complication and severe malaria and also prevent the transmission of the malaria.

The observed training conducted did not show any improvement on home visit by the village health volunteers. The observation trough a cycle of drug treatment for 94 patients with antimalarial shown that 44.7% or 42 visits completely by village health volunteers and 55.3% or 52 patients did not completely visit by the village health volunteers.

So that it is important to create other interventions in order to increase the activity of home visit by the village health volunteers because from crosstabulation that have done the 90.5% of patients with the complete home visit regularly taking antimalarial drugs as shown in table 5.

No data showed which kind of intervention will be effective globally. However, a combine intervention always reported has a better result compare with just one intervention. Hence, for better result it is important to seek for what kind of intervention that will give a better performance in order to increase the home visit by the village health volunteers.

**Conclusion**

Based on this research, there has been an increase in village health volunteer knowledge after observed training which was included knowledge about malaria in general and the provision of skills to diagnose malaria with sensitivity of 73.4% and specificity of 54.2%. It was sufficient as a step for early detection of malaria.
sufferers, especially in areas with difficult reach and limited laboratory facilities, further improvement will be achieved along with the skills and experience gained later.

Village health volunteers’ knowledge was significantly having correlation toward diagnostic skill. In order to increase the sensitivity and specificity of the malaria diagnostic skill by the village health volunteer equipped them with Malaria Rapid Diagnostic Test (RDTs) can be done as have been done in several endemic malaria countries such as in Zambia\(^8\), Tanzania\(^7\), Laos\(^9\) and other countries especially the country that have difficulties in delivering health services access to the community due to geographical condition.

The visit by village health volunteers may not have correlation with the success of malaria treatment. However, 90.5% patients that visited completely by village health volunteers taking antimalarial drugs regularly.

**Conflict of Interest:** There is no conflict of interest for both authors.

**Source of Funding:** This research was funded by the authors themselves. No other financial support received.

**Ethical Clearance:** All procedures performed in studies involving human participants had gotten ethical approval from the Health Research Ethics Committee, Faculty of Public Health Airlangga University

**Informed Consent:** Informed consent was obtained from all individual participants included in the study.

Physical Activity Changes Impact the Nutritional Status of the Elderly: A Longitudinal Study

Eka Rosiyati¹, Ratu Ayu Dewi Sartika¹

¹Department of Nutrition, Faculty of Public Health, Universitas Indonesia

Abstract

This study to determine the impact of physical activity on the nutritional status of elderly people. This longitudinal study used 2007 pre-elderly aged 55-59 years (808 subjects) and followed for 7 years until 2014. Data physical activity were assessed to evaluate changes in nutritional status as body mass index (BMI). The factors associated with nutritional status are reported in this study. For 7 years, no physical activity changes were reported (60,8%). Physical activity changes were only reported by a few subjects (16,1%), and improved from no physical activity to periods of < 30 min or ≥ 30 min. BMI increased as physical activity decreased, in terms of both types and duration. Regular physical activity is an important factor to enhance the quality of life for elderly people.

Keywords: Nutritional status, body mass index, physical activity, elderly, pre-elderly.

Introduction

The composition of elderly population is increasing rapidly in both developed and developing countries because of increased life expectancy. Data from Ministry of Health Indonesia reported that since 2015 Asia and Indonesia have an era characterized by an aging population because > 7% aged 60 years and older. The elderly population experience decreased physical endurance and are more susceptible to diseases, the elderly morbidity rate of 28.2% in 2015.

Nutritional status is an indicators used to measure the health status of people. The nutritional status of the adult population (> 18 years old) can be determined by body mass index (BMI). The BMI is divided into categories of thin (< 18), normal (≥18–< 24.9), overweight (≥25–< 27.0) and obese (≥27.0) (10). Ferra et al stated that low or high BMI is associated with several general conditions and diseases in elderly and it indicates that nutrition is an important part in medical evaluation in elderly patients. Study from Hwang et al found that BMI is a predictor for mortality in the elderly, with obesity (BMI > 25) as the significant independent predictor for all causes of mortality, whereas being overweight (BMI > 23) elevates the risks of mortality caused by cancer, cardiovascular disease, and diabetes.

Physical activity determines a person’s health. Excess energy due to a low level of physical activity can increase the risks of being overweight and the risk of obesity. Regular physical activity of moderate intensity has significant health benefit and may decrease the risks of cardiovascular disease, diabetes, breast cancer, and depression. Physical activity performed regularly tends to fix body composition by the reduction of abdominal fat and overall improvement toward weight control.

The WHO has published globally recommended physical activities for the health of adults aged 18–64 years, which include free-time physical activities, transportation (i.e. walking or cycling), occupation (jobs), household chores, games, and sports or planned exercise, in the contexts of daily life, family, and community activities. The present study, we aimed to analyze physical activity as a risk factor for pre-elderly and elderly obesity using BMI values published in the Indonesia Family Life Survey (IFLS) from 2007 and 2014 data.
Materials and Method

Study Design: This study was a longitudinal study. This design was deemed the best way to analyze body mass index and other factors that were measured repeatedly over a certain period time, between individuals and between times. The data were collected from secondary data by the Indonesian Family Life Survey (IFLS), which was a public domain from IFLS4 (2007) and IFLS5 (2014) data. This research was done in 13 selected provinces from Indonesian Life Households Survey. Altogether these provinces represented approximately 83% of Indonesia.

Subjects in this study was comprised of the elderly (55-59 years old) in 2007 then followed for 7 years until they were 62-66 years old in 2014. The number of individuals for was 808 subjects. The independent variable for this study was physical activity and dependent variable was nutritional status (BMI). Subjects were divided into three groups in terms of physical activity: 1) those not performing regular physical activity (mild, moderate or heavy), 2) those performing physical activity for periods of < 30 min, and 3) those performing regular physical activity for periods ≥ 30 min. Additional variables were observed including age sex, marital status, tribe, education level, occupation status, income, insurance ownership, smoking habits, accident records, fall records, nutritional status, and eating habits.

Univariate and bivariate analysis were performed. Univariate analysis was performed as the frequency distribution of the mean and standard deviation sociodemographic data. Bivariate analysis was performed to know relationship between independent variable and dependent variable.

Findings: The sociodemographic features are shows that 200 people (24.8%) were 55 years old, the greatest number of elderly subjects. The sex of elderly subjects was evenly distributed with 50.4% male and 49.6% female. Most subjects were married (71.2%), were Javanese (68.9%), were not elementary graduates (50.5%), were employed (68.8%), had income at percentile 1 (31.8%), did not posses insurance (54.8%), were non-smokers (57.9%), did not not have accident records (87.5%), had never fallen (89.5%), had normal nutritional status (58.4%), practiced physical activities for ≥ 30 min (70.8%), frequently consumed carbohydrate in a week (68.3%), frequently consumed protein (54.8%), and frequently consumed vegetables (59.7%) and fruits (61.3%).

Table 1 shows that the mean elderly BMI was 22.64, The mean carbohydrate consumption score, protein, fat/oil, vegetable and fruit respectively was 2.99, 1.94, 2.22, 3.75, 1.16.

Table 2 indicates that the mean BMI decrease as physical activity increases in duration. This could be seen through the mean BMI, which decreased from 23.5 kg/m² to 22.7 kg/m² when the physical activity increased to ≥ 30 min. In contrast, the mean BMI increased from 22.7 kg/m² to 23.0 kg/m² when the physical activity decreased to durations of < 30 min or didn’t perform physical activity.

</table>
Table 3 reveals a significant relationship between the mean elderly BMI (p < 0.05) and sex, education level, occupation status, income, and smoking habits. The mean BMI in females (23.4 kg/m²) was higher than that in males (21.8 kg/m²). Higher levels of education correlated with higher mean BMI values in the elderly. The highest mean BMI was found in the elderly group that graduated from senior high school (23.8 kg/m²) whereas the lowest was observed in the elderly group that had not graduated from elementary school (22.2 kg/m²). The unemployed elderly exhibited a higher mean BMI (23.2 kg/m²) value than observed in those who were employed (22.4 kg/m²). The non-smoker elderly group had a higher mean BMI (23.4 kg/m²) than the smokers (21.6 kg/m²).

**Discussion**

The nutritional status of elderly subjects in the present study was determined using BMI as an indicator and we found that mean BMI of females was observed to be greater (23.4%) than that of males (21.8%). This result agrees with the observations of the NCD Risk Factor Collaboration 11 which reported the 2014 the prevalence of obesity in females greater than males. BMI influences by change in body composition of the elderly and related to the aging process, which increases BMI by 1.5–2.5 kg/m². Decreasing height is another characteristic of the aging process, resulting from spinal thinning or osteoporosis. The decrease in height starts after the age of 30 years, with continued decrease approximately 1 cm per decade until the age of 70 years, and 0.5 cm per year afterwards 2.

The mean BMI of the elderly in this study is associated with education level which is higher education correlating with a higher mean BMI. It was observed that the primary school-graduated and secondary school-graduated elderly group had an mean BMI that differed significantly compared with the elderly group who had not graduated from elementary school. This result is consistent with that reported in the study by Zhoua et al., (17) which showed that greater BMI is found among those with elementary level of education or above compared with those less educated. A higher level education is associated with a better socioeconomic condition as supported by an adequate income.

The smoker elderly have a lower BMI (21.6 kg/m²) than the smoker elderly (23.4 kg/m²). This supports the results published by Jitnatrin et al., 9 showing that the BMI of smoker males was lower (21.6 kg/m²) than that of non-smoker males (22.2 kg/m²) with similar results observed for the mean BMI of smoker females (22.1 kg/m²) which was lower than that of non-smoker females (22.9 kg/m²). This may be due to the elevation of metabolic rate and/or reduced appetite caused by nicotine in smokers.

Most of the elderly (68.8%) in the present study were employed, and the mean BMI of the employed elderly was lower (22.4 kg/m²) than that of the unemployed elderly (23.2 kg/m²). A statistically significant relationship was observed between the BMI values of subjects with employed versus unemployed status (p < 0.05). This is likely due to greater physical activity performed by employed people than unemployed people.

Data on physical activities in the elderly group show that the majority (70.8%) spent ≥ 30 min performing physical activities. Most of the elderly subjects (491 people) did not exhibit changes in the type of physical activity although a small proportion (17 people) increased their physical activity from zero time spent to ≥ 30 minutes. The mean BMI increases as both type and duration of physical activity decrease, and vice versa. The mean BMI can reduced when physical activity is performed after not doing so.

Age and levels of sports and recreational physical activity are associated with fat-free mass change 7. The fat-free mass contributes 19% in people who experience
weight gain when decreasing physical activity. The fat-free mass represents 33% of the weight lost in people who experience a decrease in weight. The fat-free mass in the male elderly drops with age (0.2% per decade), whereas the fat mass is gained equally gains in both sex (7.5% per decade). Nelson et al.\textsuperscript{13} stated that the recommended physical activity for the elderly is to enlarge the volume of aerobic physical activity, helping to prevent unhealthy weight. Additional physical activities also help prevent weight gain in the elderly. The recommended goal includes aerobic physical activity performed 30–60 min per day moderate activity.

Barrigan et al.,\textsuperscript{3} showed that the elderly aged 60–69 years generally only have 6–10 min for physical activity with moderate intensity or more per day. Duray & Genc\textsuperscript{4} showed that due to decreased aerobic capacity in elderly people, walking and balance changes may cause a decrease in functional capacity. The WHO\textsuperscript{17} recommends that physical activity should be performed at least 150 min a week for moderate-intensity physical activity, 75 min a week for high-intensity physical activity, or an equal combination of the two activities.

In the present study, most of the elderly possessed normal nutritional status and practiced constant activities, except for increasing or decreasing physical activity due to specific physical limitations. Aging itself can be defined as the progressive deterioration or loss of functional capacity that occurs in an organism after a period of reproductive maturity. Specific functional capacities change with age and the physiological capacities of organs show aging at different rates. Between individuals, more difference is noted in older people than younger people\textsuperscript{1}.

According to Sun et al.,\textsuperscript{16} regular physical activity can lead to a significant health improvement at all ages, and can prolong the active years of independent living as well as enhance the quality of life for the elderly. The decrease in physical activity is due to indications of constant work and dietary changes. Physical activity in the elderly is needed to inform public health strategies for improved quality of life for the elderly. Sahin et al.\textsuperscript{14} have determined that elderly people may become more dependent on additional assistance at advanced ages for some instrumental activities.

**Conclusion**

However, our findings suggest that increased physical activity influences the nutritional status of elderly people, by reducing BMI. These results will help to improve the quality of life and strongly indicate the importance of a regular physical activity program.

Abstract

Result study in Sumur Batu Village in 2017 discovered that open defecation (OD) contributes to E.coli contamination in water flow at RW 04 Sumur Batu Village. The amount of people that has septic tank is expected having contribution to the contamination. From 10 water samples taken, show that the level of contaminant is exceeding the standard thus risking health. The increases of activity such as public bathing, washing and toilet facilities on the upstream and downstream and also feces final disposal on watershed/river basin, raise the risk of contamination of water flow in Sumur Batu Village.

In general, the program that will be conducted is the effort to organize, to maintain the environment, to analyze needs, and to increase the knowledge. With this activity, community is expected having concern to their health and environment. The aim of this community service is increasing people’s knowledge about the effect of open defecation, healthy latrine and the benefits of its use, related diseases, and then the behavior change and decreases in the incidence of the diseases.

From the results of activities before and after the intervention it was known that knowledge and attitudes increased from 37,5% to 54,3% and 53,1% to 78,6%, but not with behavior (from 53,1% to 37,1%).

Keywords: Open Defecation, Clean and Healthy Lifestyle, Sanitation.

Introduction

Indonesia health profile in 2014 shows that West Java Province is in top 5 province with the highest Community-Based Total Sanitation with the number 30,47% and in 2017 is increasing to 70,81% and the lowest open defecation free (ODF) is Bogor District (24,5%). Bogor district as one of the lowest percentage of ODF placed ODF as a priority program in the long-term development plan (RPJP).

The result of Laboratory tests conducted on 10 water source points in Sumur Batu Village (both tap water from groundwater and the flow of water around resident’s houses) showed that all water samples in the environment had E.coli contamination levels that aren’t in accordance with the standards regulation of the Minister of Health of Republic of Indonesia number 416 year 1990 about Requirements and Water Quality Supervision, and 41,6% of respondents stated that they still do OD along the river flow in Sumur Batu Village. This shows that the 70% ODF target in Sumur Batu Village has not yet been achieved which is indicated to have an impact on water pollution in the area. This can be attributed to the low level of public knowledge about ODF program and the risk of OD.

Anthropogenic activity and the results of E. coli content testing in the water flow in Sumur Batu Village showed a significant correlation, where fecal activity occurred in the tested stream. High E. coli contamination is found in not piping water or open water flow. In the upstream part of the waters showed
numbers of 122 coliform colony/ml samples and 64 coliform colony/ml samples. This amount increases with the length of the flow. 41.6% respondents claimed that they still did OD in the river flow, while 58.4% of them already had latrines and didn’t do OD. However, only 38.6% respondents had septic tanks as stools and 61.4% of other respondents still use rivers/stream as the final place for disposal of feces. 

62.4% of respondents in Sumur Batu Village who use tap water as their main water source are likely to have consumed contaminated water. The contamination is probably caused by the condition of the well that doesn’t meet the standards. Based on observation result, the wells are close to the open water flow that residents use for their activities. If the condition of the well doesn’t meet the standards or a leak occurs, it’s very possible for contaminated water to contaminate well water. The community’s highest complaint is itchy (67.3%). The low level of learning about sanitation from an early age can be one of the factors that contribute to the low of public awareness of the risk of OD. Sanitation learning and knowledge about OD that is still low, doesn’t have a significant effect on the feelings of most people when faced with OD behavior. This is indicated by the high of being disturbed and uncomfortable feeling when someone is doing OD around them. Most people also consider water that has been contaminated with feces from OD to be unclean and feel disgusted if they use it. External factors are thought to have impact on the application of community values to everyday life. Although people feel uncomfortable, the abundant availability of water in open streams makes them prefer doing OD. Since the high number of public inconveniences towards OD, the community has a high commitment in terms of the construction of communal latrines with qualified facilities to prevent OD activities (94.1%). Community commitment in such way and the core problems found can make community-based total sanitation as the right problem solving approach to achieve the ODF target in Sumur Batu Village. 

The availability of water, especially in dry season, can be used as a confounding factor on the decision of people doing OD. The value or trust of residents towards water contaminated with feces and the commitment of citizens in overcoming ODF is quite good. The purpose of this community service program is to increase public knowledge about adverse effects of OD, increase community knowledge about healthy latrines, improve community understanding of the benefits of using health latrines and septic tanks, change community behavior that is still defecated, and ultimately reduce the incidence of environmental-based diseases in Sumur Batu Village.

**Method**

Started with increasing knowledge in the community in the hope that increased knowledge will change community behavior, so that the community will be motivated to participate and concern about the community development and continued with the analysis of community needs. Program needs are identified starting from what is known, desired, done in the community, and what the target group feels about the behavior so that the program designed for the community is based on the answers or those questions.

Behavior change is influenced by 3 main factors, which are skills, availability of access/facilities, and social support. Other intervention efforts carried out based on priority issues are:

1. Community is not aware of health problems that will occur if doing OD.

**Activity plan (intervention):** Provide education to the community regarding the impact of open defecation and community-based total sanitation.

**Method and approach:**

a. Provide education through method of counseling to the community regarding the effects of OD and community-based total sanitation, which include:

- 5 pillars of community-based total sanitation
- Explanation the reasons for community still doing OD
- Diseases that can occur due to OD behavior from mild to severe
- Reasons to stop OD
- Flow of disease transmission through defecation
- Benefits of stop doing OD
- Introducing of various types of latrines

b. Conduct Q & A forum on environmental health, especially related to stopping OD.

2. Elderly who are used to defecating carelessly have
a psychological feeling that they will not be able to defecate if they don’t defecate on the river or at the garden.

**Activity plan (intervention):** Provide education to the community especially elderly who are still doing OD.

**Method and approach:**

- Provide good education through counseling method and personal approach to the community, especially the elderly regarding the dangers of health problems that may arise from OD.

- Provide confidence and motivation that the use of the toilet will give more comfort and safe to defecate.

3. Community is less aware of how to keep clean.

**Activity plan (intervention):** Provide education to the community on the importance of hand washing, provision of drinking water, and disposal household waste.

**Method and approach:**

- Teaching a good handwashing (6 hand washing steps) with soap and explaining the importance of health with the goal of being motivated to keep the people clean after being defecated as an effort to improve health and clean lifestyle.

- Explain the importance of clean water, clean water requirements, and types of clean water that can be sought.

- Teach how to manage household waste disposal either in the form of waste or water

4. People are having difficulties in obtaining clean water sources.

**Activity plan (intervention):** Create a discussion among citizens and provide option of solutions.

**Method and approach:** Providing advise to RW, RT administrators, and community leaders to conduct hygiene programs, prepare peer educators, in collaboration with village representatives, village head, and local health centers.

Furthermore, the evaluation phase is conducted to measure the success rate of the program. At this stage, the survey was conducted in the form of observation/observation of the checklist on the behavior of the community in the use of latrines and clean waterways and the spread of questionnaires about defecation to measure the level of knowledge and behavior of intervened residents. The data obtained from the baseline and endline surveys will be analyzed to determine the achievement of a predetermined success indicator, using the appropriate statistical method.

**Results and Discussion**

29.2% respondents didn’t have a toilet as a means of sewage, so that the activities were done on the river (15.6%), gutters (4.2%), public toilet (7.3%), and neighbor’s toilet (2.1%). From 70.8% respondents who had a latrine, it was known that 46.9% of them had no latrine to septic tank, but to the river (40.7%) and gutters (5.2%). In addition, 36.5% of the respondents didn’t have sewerage system but flowed to the river and the yard, 14.6% of respondents didn’t have clean water at their home and 43.8% claimed to have difficulty getting daily clean water.

Respondents with good knowledge on defecation before the intervention are about 37.5%, and increase after intervention (54.3%) and respondents with good attitude on defecation before intervention are about 53.1% and increase after intervention 78.6%. Thus behavior variable on defecation is decreasing from 53.1% to 37.1% after intervention (table 1).

Source: Primary Data (2018)

Basically, good knowledge will increase awareness, encourage attitude change and at led to behavior change.
Knowledge will change the behavior, change paradigm, and motivate people to adopt given information so community will be empowered to increase the health level so that community willing to participate and pay attention. Effort to create behavior change is a big problem because it’s related to social, culture (habit), education, and limited community’s economy, access, knowledge and community characteristics that lies within the community. Behavioral change can be attempted through skills, availability of access/facilities and social support. This will be done by doing promotive and preventive efforts and also accompanied by an appropriate approach to empower the community and forming self-help groups that are motivated actively participate.\(^{(8)}\)

This socialization program is expected the knowledge on sanitation and hygiene and at the end increasing the health level. Table 2 shows that the probability of the diseases to occur related to OD that are diarrhea (9,4%), symptom of diarrhea (25,0%, 10,4% and 22.9%) and also skin diseases (27,1%).

Effects of Integrating PBL and Simulation in Senior Nursing Students in Korea

Eunjoo Ji¹, Eun-Kyung Lee²

¹Assistant professor, Dept. of Nursing, Catholic Kwandong University; ²Assistant professor, College of Nursing, Daegu Catholic University

Abstract
The purpose of this study was to identify the effects of integrating PBL and simulation in senior nursing students. The present study was conducted with a quasi-experimental, single group, pretest-posttest design. Forty-seven senior students enrolled in an integrating nursing course in the fall semester of 2016 in South Korea. Life skills, knowledge, and confidence of basic nursing performance were administered before and after the use of integrating PBL and simulation. The data were analyzed using the paired t-test. The level of life skills (p=.001), knowledge (p<.001), confidence of basic nursing performance (p<.001) was significantly increased after taking course. This finding suggests that integrating PBL and simulation is an effective learning and teaching method in senior nursing student.

Keywords: Problem solving, Communication skill, Self-directed learning, Problem based learning, Simulation.

Introduction
The worldwide scarcity in the number of nurses is becoming a concern in the field of medicine. Although this phenomenon is also occurring in Korea, the shortage of nurses in Korea is different from that of other countries. According to the data released by the organization for economic cooperation and development (OECD) in 2018, the number of nurses per 1,000 individuals in Korea is 19.69, which is 1.5 times higher than the average of 13.60 in OECD countries. However, the number of nurses working at clinics is 6.8, which is lower than the average of 8.88 in OECD countries. This indicates that the shortage of nurses in Korea can be attributed to the shortage of nurses working in clinics rather than the shortage of nurse license holders. To understand the domestic nurse shortage, it is necessary to determine the status of job turnover. According to the study results of the Hospital Nurses Association, the turnover rate of general nurses was 13.9%; however, the turnover rate of new nurses was 29%, which is more than twice of that of the general nurse. This suggests that efforts are required to reduce the turnover rate of nurses.

New nurses fear that their inexperience in nursing can cause harm to a patient. The study of turnover experience of new nurses shows that differences between school education and real work environment and decreased self-confidence owing to inadequate job handling experience were the causes of job turnover, in addition to difficulties in their relationships with colleagues or patients, their own health problems, and skepticism about life. This indicates that it is possible to reduce the fear in new nurses regarding their skills and thereby reduce the turnover rate by performing competent nursing work. Therefore, it is suggested that efforts are needed to reduce the turnover rate of the nursing staff.

Nursing students can become familiar with nursing skills by observing and practicing them. However experiences of clinical skills training are concentrated on fundamentals of nursing practicum and are the least in clinical practice from the report. To achieve the goals of clinical practice education, self-initiative of the students is essential. Nursing students worry and fear that their inexperienced nursing skills will harm the patient. It is becoming a factor that makes college students...
Because confidence in performing basic nursing practices improves the satisfaction of clinical practice in nursing college students and the performance of new nurses, there is a need for intervention to improve confidence of basic nursing performance.

As it has been previously described, it is difficult to learn basic nursing directly in clinical practice. To overcome these clinical practice problems, it has been recently reported that the education method combining problem-based learning (PBL) and simulation has been used in nursing education and it has improved learning attitude, problem solving process, clinical performance, and nursing competence. The preceptor who is in charge of new nurses and the nursing managers in hospitals emphasize the necessity of basic nursing and problem-solving skills for patient nursing as core competencies of new nurses. In addition, it has been shown that simulation education before graduation is continued after graduating as a new nurse, who helped in improving clinical performance and critical thinking skills, and has also affected job turnover rate. Therefore, this study aimed to investigate the effects of integrating PBL and simulation (IPS) education on the confidence of nursing students with respect to basic nursing performance, communication skills, problem-solving skills, and self-directed learning skills and to propose an education method for nursing education as expected from the clinics.

**Method**

**Design:** This study is quasi-experimental, single-group and pre-test-post-test in design.

**Participants:** Participants were selected using convenience sampling from a population of undergraduate senior students enrolled in a mandatory integrating nursing course in the fall semesters of 2016 at a nursing college in Gangneung, Korea. There were 76.6% female and their average age was 24.13±1.75 years.

**Measures:** Life skill questionnaire for Korean college students and adults was used for communication skills (49 items), problem-solving skills (45 items), and self-directed learning skills (45 items). Each item is scored on a 5-point Likert-type scale, from 1 (very uncommon) to 5 (very frequent), with higher scores indicating a higher level of life skills. Cronbach’s alpha was .80~.93 for the sub-scales. In this study, Cronbach’s alpha was .92~.94. Knowledge were measured a self-administered questionnaire designed to assess senior nursing students’ knowledge about course topics. It was developed by researcher. It consists of chest pain (8 items), dyspnea (9 items), and fracture (5 items) patients care. Each item is scored on a 5-point Likert-type scale (not true=1, very true=5), with higher scores indicating a higher level of knowledge. In this study, α coefficient ranged .93 ~ .95. Confidence of basic nursing performance were measured a self-administered questionnaire with questions. It was developed by researcher. It consists of confidence of nursing performance on medication (IV, oral medication, 2 items), oxygen therapy (1 item), EKG & SPO₂ monitoring (1 item), intubation assist (1 item), crutch walking support (1 item). Each item is scored on a 5-point Likert-type scale (very low=1, very high=5), with higher scores indicating a higher level of confidence on basic nursing performance. In the current study, α coefficient ranged from .79 to .83.

**Procedure:** The IPS education was employed in the nursing course. The study duration was from October to December, 2016. This course was a two credit course (total 30 hours). This course was designed based on the framework of PBL combined with simulation and aimed to improve core nursing competency in the cardiovascular, respiratory and musculoskeletal nursing. The nursing students were assigned to 8 groups with 6 students each.

1. **Pre-test:** The preliminary survey was conducted immediately after the curriculum orientation. Pre-survey questionnaires comprise general characteristics, life skill questionnaire, knowledge, and confidence of basic nursing performance.

2. **Integrating PBL and simulation:** The program was run with a total of three sessions. Each session was organized based on various subjects. The PBL scenarios were evaluated by three experienced clinical nurses who served as subject matter experts. The three sessions were organized by considering patients with chest pain, those with dyspnea, and those with fracture as subjects. Each session comprised two scenarios related to the subject (total 6 scenarios). The first scenario was used for PBL and the second was used for the simulation scenario. The specific process is as follows.

   It took 4 h for each PBL scenario. Based on symptoms of PBL scenario, subject cases were analyzed from various perspectives and necessary data were collected to identify nursing problems and to determine
solutions for nursing problems. Simulation scenarios reduce the scope of nursing problems by focusing on diseases. Myocardial infarction in the first session, chronic obstructive pulmonary disease in the second session, and nursing problems in tibia fracture in the third session were organized as subjects to be addressed. Through the scenarios for each PBL and simulation, nursing students were given the opportunity to perform initial assessment, core assessment, and nursing intervention, to design problem-solving plans, and to choose and apply the necessary nursing skills directly to standardized patients.

In the nursing intervention for myocardial infarction and chronic obstructive pulmonary disease patients, nursing performance of ECG and SPO2 monitoring, oxygen therapy, administration of oral medication, IV side shooting and endotracheal intubation assist is included. Nursing intervention of tibia fracture patients includes crutch walking support and administration of oral medication.

For simulation education, trained personnel were recruited to perform the role of patient and guardian, and orientation on the role of patient and guardian was performed. Skills that could not be performed on the patient, IV side shooting and endotracheal intubation assist, were performed on IV simulator and intubation trainer. The 5-h simulation session was followed by a three step simulation process comprising briefing, simulation, and debriefing. The topics that must be learned for the simulation exercise, scenario outline, and learning objectives were included in the briefing. The simulations were run for 15 min per scenario. The group who did not perform the simulation practice was directed to perform hands on simulation, evaluate simulation practice of the other group, and group discussion for the simulation practice under the guidance of the teaching assistant. The group who finished the simulation practice was directed to write a reflection journal. Once all groups were finished with the simulation practice, there was an hour long debriefing period for the entire team. The course was directly managed by the researcher who has many years of experience in PBL and simulation education.

3. Post test: The post test was conducted immediately after completing integrating PBL and simulation.

Data analysis: The collected data was analysed using SPSS Statistics 21 version. In addition to using descriptive statistics, the paired t-test was used to compare the mean scores and the changes in the scores of variables at a significance level of .05.

Ethical Consideration: All participants were enrolled in a mandatory integrating nursing care course. However, participants who completed the questionnaire survey also filled out informed consent form agreeing to participate in the study. Students were briefed on the study purpose and process, as well their right to withdraw participation at any time without any adverse effect on their course grade.

Findings: Problem-solving skills (t=4.77, p<.001) and self-directed learning skills (t=2.53, p=.015) were statistically significant; however, communication ability was not statistically significant (t=1.76, p=.085). Knowledge was statistically significant in all three items (t=12.03, p<.001). In the confidence of basic nursing performance, the total score was increased with a statistical significance (t=3.92, p<.001), but among the sub-domains, oxygen therapy care was not significant (t=0.66, p=.511) (Table 2).

Discussion

In this study, IPS improves the problem-solving skills and self-directed learning skills. PBL education is an education method where learners organize their knowledge through the process of acquiring and utilizing the knowledge required for self-directed problem solving. It is a self-directed learning education as the learners strive to find the best solution for the problem in the process. Therefore, it appears that the process of finding the nursing problems together by group members and finding the solutions for the problems, has affected to improve the subjects’ problem-solving and self-directed learning skills. It may also be that providing additional opportunities to solve modified situations by applying PBL and simulation scenarios differently has helped to improve problem-solving skills. In addition, to successfully integrate PBL and simulation education in a nursing college, it is necessary to have a professor who serves as a learning guide and facilitator. It may have helped in improving problem-solving and self-directed learning skills that the researcher who has experience of PBL education and simulation education using various scenarios for many years has performed education.

We showed that IPS education has an effect on knowledge and confidence of basic nursing performance in this study. The confidence of the basic nursing performance might have improved because the basic nursing skills were directly performed through simulation. Considering the fact that the confidence of basic nursing performance improves job performance of new nurses and improved job performance lowers job turnover, it might help reduce the turnover of new nurses by applying the IPS education to the nursing college students who are about to graduate.

The researchers expected the communication skills of the nurses to be improved because they were communicating during the simulation process with the standardized patients; however, there was no difference in the communication ability of the subjects before and after the experiment. Programs for improving communication skills include helping students find problems in listening, empathizing, and communicating by themselves. In this study, however, we provided a virtual hospital situation and only the opportunity to talk with standardized patients and it might be the cause that we obtained the result. From a different perspective, we can think of the reasons underlying the insufficient basic nursing skills of the students. As mentioned earlier, because the basic nursing performance of nursing college students is focused in the fundamental nursing practice curriculum and there is little opportunity to practice the basic nursing skills in the clinical practice, the nursing skills is in a premature state although they are senior students before graduation. Therefore, IPS might not have improved communication skills because students concentrate on basic nursing skills that they need to develop rather than communication with standardized patients in the situation where students need to analyze and apply necessary nursing skills selectively. We propose a future study in which a program that allows the students to practice the basic nursing skills required in the scenarios is first executed, followed by the program analyzing its effect on the communication skills of nursing students.

Conclusion

This study confirms the effects of integrating PBL and simulation. However, this study has limitations; the subjects were nursing students of the same college; hence, it is difficult to generalize the results of the research; and we cannot exclude the possibility that the test effect and the effect of maturity could have intervened in the experimental design of pretest and posttest with the single group. We propose a study that includes intervention for improvement of communication skills and a study using a control group.

Descriptive Quality of Sleep to Clients with Hypertension

Evi Risa Mariana¹, Zainab¹, Mia Amalia¹

¹Department of Nursing, Health Politechnic of Banjarmasin, Banjarbaru, Kalimantan Selatan, Indonesia

Abstract

Sleep quality in hypertension patients is generally disrupted due to several factors that can impact on poor sleep quality and will affect the increase in blood pressure. The objective of the study was to assess the sleep quality of clients with hypertension. Sample collection conducted here was the accidental sampling technique based on 35 respondents suffering from hypertension. The data were collected using PSQI questionnaire and tension metre (sphygmomanometer). The results showed that there were classified into 3 degrees I, II, and III respondents having poor sleep quality. This may occur because of the higher degree of hypertension classification. It is likely to experience poor sleep quality based on some components of sleep quality such as subjectivity, sleep quality, sleep latency, sleep duration and sleep disturbance; thus, resulting in disruption of activity on the next day. It was suggested that the clients should pay an attention on the quality of sleep including in the work place.

Keywords: Sleep Quality, Hypertension, client.

Introduction

Hypertension is one of the important factors as the trigger of non-communicable diseases such as heart disease and stroke which is currently the number one cause of death in the world.¹ Hypertension has killed 9.4 million people worldwide each year. The World Health Organization estimates that the number of hypertensive patients will continue to increase as the population grows. In the next 2025, about 1.5 billion people in the world were affected by hypertension.²

The comparison of people suffering from hypertension is quite high, i.e. 51 people from 100 people suffering from hypertension.³ Based on the data of Basic Health Research 2013, some non-communicable disease cause death in South Borneo, one of them hypertension reaches 30.8%. Based on the hypertension patients per city in South Borneo in 2015, Banjarmasin is the highest hypertension patients with 18,730 patients, followed by Tanah laut 14.121 people, Banjar Regency 7,738 people, Kotabaru 6,680 people, Banjarbaru 5,629 people, Tapin 3,085 people, Barito Kuala 2,985 people and the rest ranged from 2,500 to over a thousand people.⁴

In general, people with hypertension suffered sleep disorders due to some physical conditions and environmental conditions experience so that the impact on poor sleep quality and will affect the increase in blood pressure decreases while normal (10-20% is still considered normal). This occurs because of a decrease in sympathetic activity during sleep. If sleep disorders, then there is no decrease in blood pressure during in blood pressure during sleep so that will increase the risk of hypertension. Every 5% of normal decline should occur and not be experienced by some one who suffers hypertension, and then the possibility of 20% will increase blood pressure.⁵ Sleep deprivation was a risk factor for hypertension in adults. Shorter sleep results can cause metabolic and endocrine disorders that can cause cardiovascular disorders.⁶

Based on a preliminary study that researchers conducted at the South community health center Banjarbaru some clients who suffer from hypertension complain often feel sleepy at 9-11 a.m, at night some people who suffer from hypertension have difficulty sleeping because of headache and some clients say should take drugs that give side effects drowsiness to make falling asleep. Based on the described problems, it was interested in conducting research on sleep quality on clients with hypertension in the work area of community health center Banjarbaru Selatan, Kalimantan, Indonesia.

Method

Types of Research: This research method is descriptive research that aims to assess the quality of
sleep on clients with hypertension in the work area of community health center Banjarbaru Selatan.

**Population & Sampling:** The population in this study was all hypertension clients in the work area of community health center Banjarbaru Selatan new cases and amounted to 4,498 people. Sample in this research is part of hypertension patient in working area of community health center Banjarbaru Selatan. Sampling technique in this research is by using accidental sampling technique.

**Data Collection:** In this study primary data about sleep quality on clients with hypertension obtained from questionnaires in the form of structured questions asked to the respondent and blood pressure measurement using tensi meter (*sphygmomanometer*).

**Ingredients:** The instrument of data collection used in this research is questionnaire PSQI (Buysse, et al, 1989) and tensimeter (*sphygmomanometer*).

**Data Analysis:** Data analysis used in this research use descriptive data analysis by using frequency distribution formula and presented by frequency distribution table, then drawn conclusion. From the characteristics of the respondent was made tabulation of frequency distribution of tabulation (cross tabulation).

**Results**

**Characteristics of Respondent**

**Table 1: Frequency distribution characteristics of responden by sex**

<table>
<thead>
<tr>

</tbody>
</table>

Based on table 5 of 35 respondents studied showed that respondents who have poor sleep quality with classification of grade I hypertension as many as 11 people (31.4%), respondents who have bad sleep quality with classification of grade II hypertension as much as 10 people (100%), of respondents who have bad sleep quality
quality with classification of grade III hypertension as many as 8 people (100%) and no respondents who have good sleep quality with classification hypertension grade II or grade III.

**Discussion**

**Hypertension Classification:** Based on table 3 it is found that from 35 respondents, respondents mostly have classification of hypertension degree I as much as 17 people (48.6%), this can be caused by age and gender factors where respondents came more than half of female respondents as many as 19 people (54.3%), and most aged between 45-59 years as many as 17 people (48.6%). So in this study, women aged 45–59 years tend to be affected by hypertension, which at that age will experience menopause women who cause estrogen hormones begin to disappear, the hormone estrogen is able to protect blood vessels.

In the pre menopause women begin to lose little by little the hor, one esterogen that can protect blood vessels from damage. This process continues as the amount of estrogen hormone decreases with age, which generally occurs in women aged 45–55 years. Prevalence of hypertension in women found is higher than men. Kumar explains that someone who is at risk of suffering from hypertension is over 45 years of age and high blood pressure around the age of 40 years, although it can occur in young age. Hypertensive progressiveness begins with pre-hypertension in patients aged 20–29 years (with increased cardic output), then becomes premature hypertension in patients aged 30–39 years (where peripheral resistance increases) hypertension at the age of 40–49 yers and eventually become hypertensive with complications at the age of 50+ years. The most suffering from hypertension was 41–65 years old (63.80%), followed by 25–40 years (25.50%), >65 years (8.50%), and <25 years (2.10%). Generally, blood pressure increases in age. Usually it was caused by decreased organ function.

Respondents suffering from pre-hypertension are female (5.88%), while those suffering from grade I hypertension (30.39%), and who suffer from grade II hypertension of female (19.63%).

**Quality of Sleep to Clients with Hypertension:** Based on the results of research conducted by researchers found that the majority of respondents ie as many as 29 people (82.9%) of the 35 respondents who studied had poor sleep quality based on some components of sleep quality. People suffering from hypertension will have a risk of getting poor quality sleep quality. Poor sleep quality in this study tends to occur in the subjectivity of the quality of sleep, sleep latency, sleep duration, sleep disturbance and disruption of activity in the day. In this study, more than 50% have poor sleep quality based on sleep disorders such as frequent to the bathroom, difficulty breathing, dizziness, pain and difficulty sleeping, which can wake her sleep. In America, 10% of the population in the United States experience hypertension associated with sleep sleep disorders.

Patients about 33% suffered from hypertension almost all experience sleep disorders. According Ingram et al., people with hypertension generally experience pain, other than that the patients is also easily tired, feel uncomfortable difficult breathing and difficulty sleeping that can disturb sleep in people with hypertension. 68% of the most common symptoms of hypertensive patients are nocturia. About 91% of people with hypertension have difficulty breathing during sleep. A total of 15 people (42.9%) of respondents who studied had poor sleep quality based on sleep duration. Most respondents studied said sleeping <6hours a day. Tarwoto and Wartonah explained that the duration of sleep for age <45 years is 7-9 hours/day, sleep duration for age 40-60 years ie ± 7 hours/day and sleep duration for age >60 years ie ± 6 hours/day.

Most respondents experienced difficulty sleeping, respondents need ± 60 minutes to be able to fall asleep. This is in accordance with research conducted by Mansoor which explains that people with hypertension usually take a longer time to start falling asleep. Normal people usually fall asleep within 20 minutes.

According to Buysse sleep quality is a complex phenomenon involving various domains, among others, assessment of subjective sleep quality, sleep latency, sleep duration or duration of sleep, efficiency of sleeping habits, sleep disturbances and disruption of daytime activities, so if wrong one of the seven domains are disturbed it will result in decreased quality of sleep. In this study the respondents had poor sleep quality based on subjective response about sleep quality as much as 22 people (62.9%), respondents had poor sleep quality based on sleep latency as many as 17 people (48.6%),
respondents had very high sleep quality both based on the efficiency of sleeping habits as much as 16 people (45.7%), and respondents have very good sleep quality based on the use of drugs as many as 32 people (91.4%).

In this study respondents had poor sleep quality based on the disruption of daytime activities as many as 18 people (51.43%), this is in accordance with research conducted by Potter & Perry\(^\text{13}\) showed that dizziness in people with hypertension can wake the patient does not get enough sleep, which will affect the activity in the next day, people suffering from hypertension will have the risk of getting poor sleep quality.

Autonomic cardiovascular control changes across sleep stages. Thus, blood pressure, heart rate and peripheral vascular resistance progressively decrease in non-rapid eye movement sleep. Any deterioration in sleep quality or quantity may be associated with in increase in nocturnal blood pressure which could participate in the development or poor control of hypertension. In the present report, sleep problems/disorders, which impact either the quality or quantity of sleep, are reviewed for their interaction with blood pressure regulation and their potential association with prevalent or incident hypertension. Obstructive sleep apnea syndrome, sleep duration/deprivation, insomnia, restless legs syndrome and narcolepsy are successively reviewed.

**Sleep Quality in Clients with Hypertension Classification:** Based on the results of research conducted by researchers showed that respondents classification tend to have poor sleep quality based on some components of sleep quality, it can be caused by age factor where the increasing of age hence decreasing of sleep quality which can influence health such as hypertension, on the contrary the higher the grade of hypertension have complaints such as dizziness, difficulty sleeping and have a short duration of sleep, which will affect sleep quality on clients with hypertension. Poor sleep quality is associated with increased risk of hypertension, and thus increases the risk of cardiovascular disease.\(^6\)

Remmes\(^23\) explains that sleep disorders can cause or worsen medical and psychiatric disorders such as hypertension, vascular disease, heart or brain, obesity and depression. In another study conducted by Calhoun and Harding\(^24\) explained that if poor sleep quality can increase blood pressure in a person. Poor sleep quality can lead to hormone regulation of blood pressure balance or aldosterone hormone does not work optimally, so less sleep time can make the nervous system become hyperactive which then affects the whole body including the heart and blood vessels.

Adults who had sleep disturbances, short sleep, and poor sleep quality were 1.84 times more likely to have hypertension than adults who did not have sleep disorders, short sleep, and poor sleep quality.\(^15\) On the other hand, if there is a lack of sleep will increase blood pressure and activate the sympathetic nervous system that in the long term it will trigger hypertension.\(^25\)

**Conclusion**

Based on the conclusions obtained from the results of research entitled sleep quality overview in Clients with Hypertension in the Work Area of community health center Banjarbaru Selatan are:

1. The results showed that most respondents have classification of grade I hypertension with 17 people (48.6%).
2. The results showed most of the respondents had poor sleep quality of 29 people (82.9%)
3. The results showed that the tendency in classification of grade I, II and III hypertension has poor sleep quality.

Patients’ Attendants Community Empowerment as Clean and Healthy Behaviors’ Volunteers in Hospital Setting

F. Sri Susilaningsih¹, Titis Kurniawan²

¹Fundamental of Nursing Department–Faculty of Nursing Universitas Padjadjaran, ²Medical–Surgical Nursing Department–Faculty of Nursing Universitas Padjadjaran

Abstract

Background: Clean and Healthy Behaviors (CHB) is one of important program in enhancing hospital’s therapeutic-environment. It invites active contributions from hospital’s acquaintances including patients’ attendants (PAs). Though, PAs play significant roles in patients’ care, most of hospital managements in Indonesia are seen less seriously concern about them. To succeed CHB program, it is essential to identify PA’s attitude, behaviors, perceived barriers in implementing CHB and PA’s characteristics that potentially support them become hospital’s CHB volunteer.

Method: This descriptive study involved 136 PAs who recruited conveniently from a district hospital in West Java Indonesia. All respondents asked to fulfill questionnaires including demographic data, attitude (10 items), behaviors questionnaire (10 items), and interviewed for their understanding on CHB program and their perceived barriers in performing CHB in hospital setting. The questionnaires were developed by researchers and tested for the validity and reliability (CVI: .75-1; CVR: +.5-1; Chronbach alpha .827 (attitude questionnaire) and .630 (behaviors questionnaire).

Results: The data showed that slightly-above half of PAs (50.7%) had favorable attitude toward CHB but reported low compliance in performing CHB (54.41%). Favorable and compliance PAs were mostly identified in those who were males, patients’ spouse or relatives, in-continuously accompanied patients, higher education, understood about CHB and report as PA to hospital. Additionally, most of compliance PAs identified had favorable attitude (70.79%; p < .05). This signifies the previous finding suggested that positive attitude is required for positive behaviors.

Conclusion: Generally, most of PA’s attitude and behaviors related CHB required improvement and PAs who were males, higher educational level, patients’ spouse/relatives, in-continuously accompanying patients and knew about CHB were potentially empowered to be hospital’s CHB volunteers.

Keywords: Clean & healthy behaviors, hospital, patients’ attendants, volunteer.

Introduction

Hospital as healthcare provider is a vital component in achieving communities’ highest health status. As a center of healthcare services, hospital is expected able to provide comprehensive services including preventive, curative as well as rehabilitative. In the other words, hospital ideally become an institution provides optimum therapeutic environment for individual, group or communities in gaining the highest health status.

In the other hand, however hospital also has been shown to be a reservoir for infectious agents including bacteria, viruses and fungi¹. Patients, staff, and neighbors of the health-care setting face unacceptable risks of infection if environmental hygiene is inadequate. Hospital environmental contamination may contribute to diseases transmission when hospital’s staffs contaminate their hands or gloves by touching contaminated surfaces, or when patients or visitors directly contact with contaminated surfaces. Thus, hospital might even become the epicenter of certain diseases’ outbreaks.

In order to improve hospital hygiene, previous studies proved that infection control program that include
enhanced cleaning effectively reduced the hospital acquired infection\textsuperscript{2,3}. Housekeeping and cleaning staff are important element in gaining effective hospital hygiene. It also proved that instituting direct observation, supervision, and education of staff as they clean, showed reductions of important hospital pathogens\textsuperscript{4,5,6,7}.

However then, there is a concern that these interventions might lose impact over time, since cleaning is physically demanding, poorly paid, and subject to inadequate staffing\textsuperscript{8,9}. Furthermore, there tends to be rapid turnover among janitorial and housekeeping staff, and this may be related to sickness levels as well as payment dissatisfaction, status, and conditions\textsuperscript{8}. It signifies that in achieving optimum hospital hygiene required other hospital’s acquaintances involvement rather than relied on hospital cleaning staffs.

In Indonesian context, there is one of important national program developed to improve hospital hygiene, “Perilaku Hidup Bersih dan Sehat (PHBS)” [clean and healthy behaviors (CHB)]. This program encourage hospital’s staffs, patients, and visitors to know, will, and enable their self in applying CHB in the healthcare service center setting and actively involved in gaining the healthy work place. The CHB in healthcare services center consist of hand hygiene, using clean water, using proper toilet, no smoking, no littering, no spitting, preventing diseases transmission, as well as eradicating mosquito larvae. Unfortunately, the national survey reported that CHB adherence in the healthcare services setting in each province still less than 50\%\textsuperscript{10}.

In Indonesia, almost each patient is companied by at least one patient’s attendant (PA) that play significant roles in fulfilling patients’ private needs and decision making that in some conditions hospital staffs face limitation in dealing with. In the other hand however PAs also increase the hospital’s resources burden (water, electricity, and facilities), infection risk, patient safety, as well as challenges in succeeding CHB program implementation.

As a behavior, there are some contributing factors related to CHB adherence. Previous studies conducted among students and public society reported that CHB adherence was closely related to individual’s knowledge, attitude, and facilities availability\textsuperscript{11,12} as well as gender and educational level\textsuperscript{13}. Whereas, study conducted among patients’ attendants (PAs) found that most of PAs reported the lack information, lack of social support, and lack of hand rub facilities accessibility\textsuperscript{14}.

Since PAs in Indonesian context is a general phenomenon, potential problem and the problem solving strategy should be identified. Thus it is important to conduct a study that aimed to identify PA’s perspective, attitude, and behaviors related to CHB, as well as their characteristics that potentially support them to be hospital’s CHB volunteers.

**Material and Method**

This descriptive study involved 136 patients’ attendants(PAs) that conveniently recruited from 5 inpatient units of adistrict general hospital in West Java Indonesia. Informed consent was applied prior to data collection. Data were collected using questionnaires and interview. Demographic questionnaire consisted of age, gender, educational level, type of PAs, PAs–patients’ relationship, and permission status. The attitude of CHB questionnaire consisted of 10 items with four scales from most agree to disagree, while CHB questionnaire consisted of 10 yes or no questions. The questionnaires were developed by authors based on CHB related literatures and tested for its’ validity and reliability before used. Questionnaires content validity test were conducted by four university experts that asked for evaluating the questionnaires’ content validity index (CVI) and content validity ratio (CVR). The experts scoring resulted in CVI: .75-1 and CVR: .5-1. The Chronbach alpha values were 0.827 and 0.630 for attitude and behaviors questionnaire respectively. The collected data were analyzed descriptively (frequency, mean, and percentage) as well as inferentially using Chi-square.

Table 1: Characteristic of respondents (n = 136)
Most of respondents were female (73%), reported not being informed about CHB (61.8%), and did not report to the hospital as PAs (86%). Additionally, more than half of respondents are patients’ son/daughter (58.8%), alternately stayed at hospital (58.8%) and hold the 9 years education (53.6%).

The table described that favorable attitude toward CHB was mostly found in male respondents (69.23%), patients’ spouse (80%), university educational level (80%), companying patients regularly in particular shift (83.33%), reported being informed regarding CHB in hospital (59.61%) and reported as PAs to the hospital (89.47%). Regarding the compliance, high compliance CHB was mostly identified among respondents who were male (69.23%), education level higher than elementary school (50–54.90%), patients’ relative (58.06%), not-continuously stay with patients (76.38%), reported being informed regarding CHB (51.92%) and reported to the hospital as PAs (63.16%).

</table>
It is found that slightly higher percentage of favorable respondents (50.7%) and low CHB (54.41%). There was also a significant relationship between attitude and CHB practice ($p = .00$), high CHB respondents mostly found among favorable attitude (70.79%) and oppositely low CHB respondents noticeably seen in the unfavorable ones (66.22%).

**Interview Finding:** Some issues identified through interview namely unexposed information regarding CHB in hospital setting, and never read the hospital poster introducing CHB. Mostly respondents suggested that they had been suggested to perform hand wash and do not litter. During companying patients in the hospital, most of PAs reported that they eat, drank, slept, did not perform hand hygiene, as well as used the similar toilet with the patients. PAs reasoned that there were no PA’s facilities for eat, drunk, and slept, while the available public toilets were dirty.

**Discussion**

Though the findings of this study indicate that either attitude or behaviors of PAs need an improvement, it provide new information that in the hospital setting, individual behaviors also consistently related to individual’s attitude. This strengthen previous study findings that conducted in non-hospital setting.11,13

There were some aspects might contribute to the results of this study, such as CHB program conducted by the hospital, and PAs characteristics involved. This Hospital Management conducting CHB program by involving all hospital staffs particularly healthcare providers (physicians, nurses, pharmacists, and nutritionists) to deliver the CHB message to their patients and PAs. Additionally, CHB posters are placed in some accessible places in hospital to improve hospitals attendants’ exposure to the CHB program. However, this study indicates that these strategies might not run as expected since more than half of PAs (61.8%) did not know about CHB, not access CHB posters and some who knows CHB expressed that CHB as hand hygiene and do not litter only.

Additional analysis found that patient’s bed utilization as the lowest item’s score in the attitude questionnaire. Whereas, using patients’ toilet, eat and drink as well as sleep in the patients’ room identified as the lowest items’ score in CHB questionnaire. These findings also clarified by interview findings suggested that PAs mostly utilize similar toilet with patients, eat, drink, as well as slept in the patient room. Respondent reported that the inconvenience public toilets, no garbage box, as well as lack of awareness and responsibilities on CHB as the main reasons for those actions. These conditions strengthen previous finding suggested that low adherence of CHB (particularly hand hygiene) was closely related to facilities availability and accessibility, support, and lack of information14.

These current PAs behaviors potentially increase the severity of hospital’s role in diseases transmission that harms the hospital attendants including patients, PA and staffs. Hospitalized patients and their diseases are highly potent to contaminate hospital environment and facilities. If the PAs utilize same room, toilet, and other hospital facilities, they are vulnerable for developing some infection diseases. In the other hand, PAs also potent to contaminate the hospital facilities and environment that further threaten patients as well as hospital staffs healthiness. These findings should be carefully concerned otherwise further impacts become unavoidable.

This study found that PAs who reported that they understood CHB program tend to hold favorable attitude and high CHB than those who did not. Understandings on the reasons why an action must be performed broaden individuals’ motivation and opportunities in performing expected behaviors. This study also found that favorable attitude and high CHB were more frequently identified among PAs who are male, patients’ spouse or relatives, intermediate to high educational level, alternately or shift based attendant, report that they informed and know about CHB, and report to the hospital as PA. It was different with previous finding suggested that females were more likely to perform better CHB13. In terms of educational level, higher level will improve possibility in exposing formal situation that CHB related topics, policy, culture, as well as habituation become part of the educational processes. Thus, more educated PAs will potentially be more favorable and perform CHB better than those who less educated ones.

Moreover, the favorable and better CHB mostly identified among respondents who not continuously attending patients. Though, the continuous attendants would have wider possibility being exposed with the information related program, policy and staffs responsible for the program, they also tend to have bigger burdens that threaten their personals’ needs fulfillment. These conditions may lessen their motivation in doing expected behaviors.
Since PAs number are similar or even bigger than hospitalized patients’ number, it is potent for them to be additional human resources for hospital in maintain and supervise the implementation of CHB in the hospital setting. In the social context, PAs have equivalent level “as PAs” they may potent to be more effectively deliver the CHB program message to the other PAs.

**Conclusion**

In general, although PA’s attitude and their CHB practice need to be improved, both are significantly correlated. Additionally, PAs with characteristics; male, spouse or patient’s relative, had higher educational level, in-continuous attending patients, reported knowing CHB, and reported to hospital as PAs are the PAs who are potential become hospital CHB volunteers.

Besides intensifying the efforts in exposing PAs to the CHB program and improve the facilities availability, it also important for hospital to develop PAs volunteers empowerment program as part of succeeding CHB program in hospital setting.

**Ethical Clearance.** This study is part of a Universitas Padjadjaran’s research and social service project in 2017 that fully funded by the university. It gained ethical clearance from the Dr. Hasan Sadikin General Hospital – a provincial tertiary teaching hospital located in Bandung West Java, Indonesia– document No: LB. 04.01/A05/EC/273/IX/2017.

A Study on Influence on Foreign Direct Investment with Special Reference to India’s Automobile Industry

R.V. Pazhani¹, Nabaz Nawzad Abdullah²

¹Assistant Professor, Department of Business Administration, ²Head of Business Administration Department, College of Administration & Economics, Lebanon French University

Abstract

The inflows of foreign direct investment (FDI) to Automobile Industry have been at an increasing rate as India has witnessed a major economic liberalization over the last few years in terms of various industries. The automobile sector in India is growing by 18 percent per year. The basic advantages provided by India in the automobile sector include, advanced technology, cost-effectiveness, and efficient manpower. Besides, India has a well-developed and competent Auto Ancillary Industry along with automobile testing and R & D Centers. The automobile sector in India ranks third in manufacturing three wheelers and second in manufacturing of two wheelers. The major investing countries are Mauritius (mainly routed from developed countries), USA, Japan, UK, Germany, the Netherlands, and South Korea. India needs to concern regarding the foreign direct investment (FDI) front. Future prospect of Indian Automotive Sector is looking bright. Indigenous automobile companies are replacing foreign multinationals paniesintermsofconsu mer satisfaction. Since 2002, automotive sector has chodeliverintheyearstocome. DirectInvestmentInflowsinIndia-OpportunitiesandBenefits, ImportantAspectsofFDIinAutomobileIndustry, RecentFDITrendsinIndia, Themajorforeignplayerswhohaveasignificantroleinthe development of Indian automobile industry, werediscussed and the passenger car segment growth, Production, Sales and Investment were analyzed. Here these archers using three statistical tools for analyzing the study, ARIMA, Linear & Compound Model for analysis purpose to measure future reproduction using timeseriesanalysis.

Keywords: FDI, Automobile Industry, Technology, Passenger Car Segments, etc.,

Introduction

Driving the most luxurious car has been made possible by the stiff competition in the automobile industry in India, with overseas players gathering the same momentum as the domestic participants. Hyundai Motor India Ltd is a wholly owned subsidiary of the Hyundai Motor Company headquartered in South Korea. It is the second largest automobile manufacturer with 17% market share as of 2017 and 5.5 billion USD turn-over in India, Hyundai Motors alone exported 240,000 cars made in India. Nissan Motors plans to export 250,000 vehicles manufactured in its India plant by 2019. It is the 5th largest automobile manufacturing company in India after Maruti Suzuki, Hyundai, Tata Motors and Mahindra. After 21 years of operations in India, General Motors announced that it will stop selling cars in India by the end of 2017, as a part of its global restructuring actions. Indian economy seems to bear a down trend in its major economic factors such as poor unemployment, low capital formulation, poor standard of living, undergrowth in GDP, increased Trade deficit, low infrastructural developments etc., In view of the economic crisis and the shortage of capital, the Government of India realized the importance of foreign capital for the development of the country. The developing countries started opening their economy, out of the compulsion, to achieve faster rate of economic growth and development. Even a communist country like China adopted liberalization policy as a strategy for accelerated economic growth during 1979. India also joined the race by 1991. FDI inflows to automobile sector have started pouring in since 2000. This study makes use of the published data from different sources, which in research referred to as the secondary data. The FDI inflow into automobile industry is increasing in position due to huge demand in this sector.
Passenger Vehicle: 15.96%  
Source: Society of Indian Automobile Manufacturers (SIAM)  
Commercial Vehicle: 3.95%  
Three wheelers: 3.60%  
Two wheelers: 76.49%  

Figure 1: Segmentation of Market Share of Automobile Industry in India

Top Automobile Companies in India

Tata Motors: Tata Motors is the largest automobile manufacturing companies in India. Established way back in 1945 Tata Motors is a multinational automobile company with its headquarters in Mumbai. Previously known as Telco TATA Engineering and Locomotive Company Tata Motors belongs to Tata Group. This company manufactures compact medium sized utility vehicles. Over the last few decades it has stood as the undisputed leader in the commercial vehicles segment.

Hindustan Motors Limited: Hindustan Motors Limited was founded in the year 1942 by B.M Birla. It is an operative subsidy of the Birla Technical Services group. This company held the title of the biggest manufacturer of cars in India before MarutiUdyog. Hindustan Motors was the pioneer in manufacturing automobiles in India. Some of the important cars and multi utility vehicles manufactured by Hindustan Motors Limited include; Mitsubishi Lancer, Trekker, Contessa, Ambassador, Porter, Pushpak and the Mitsubishi.

Ashok Leyland: Ashok Leyland is a leading commercial vehicle manufacturer in India. It was established in 1948. The company over the years has become synonymous with the production of trucks, passenger buses and emergency military vehicles. It happens to be the second largest commercial vehicle producer in India holding a market share of almost 30 percent.

Maruti Suzuki India Limited: Maruti Suzuki India Limited was established in 1981. A part of this company is owned by Suzuki Motor Corporation of Japan. It is the country’s largest passenger car manufacturing company. Credited for having brought in the automobile revolution in the country Maruti Suzuki India Limited was known as MarutiUdyog Limited till 2007.

Hyundai Motor India Limited: Hyundai Motor India Limited (HMIL) is owned entirely by Hyundai Motors of South Korea. Established on May 6 1996 this company in a short span of time has taken the Indian automobile industry by storm. Some of the popular cars manufactured by this company are; Santro, Getz Prime, Hyundai i10, Hyundai i20 Accent and the Verna and Sonata.

SWOT Analysis for Indian Automobile Industry

Strengths
- Domestic Market is large
- Government provides monetary assistance for manufacturing units
- Low Labor cost

Weaknesses
- Infrastructural setbacks
- Low productivity
- Too many taxes levied by government increase the cost of production

Opportunities
- Reduction in Excise duty
- Rural demand is rising
- Income level is at a constant increase

Threats
- Increasing rates of interest
- Too much competition
- Rising cost of raw materials

Automobile Technology in India: Automobile Technology or automotive technology refers to the technologies that are incorporated in automobiles or vehicles. With the continuous advancement of technologies new inventions in the field of automobile technology is only paving the way for more and more technologically superior and sophisticated vehicles. Automobile technology is one of the most essential parts of the automobile industry today.

Changes in Automobile Engines Technology: However the most important changes that has taken
place in the automobile industry in India pertains to the development of the engine. In the cars using petrol the carburetor engine has been replaced by the Multi Point Fuel Injection (MPFI) engine.

**Suspension technology:** The suspension system of a vehicle consists of springs, shock absorbers and linkages these together connect the vehicle to its wheels. However the main function of the suspension system remains to minimize jerks and to provide a smooth journey to its occupants. Apart from the above mentioned technologies steering technologies and safety technologies have also helped the automotive industry to reach great heights. Some of the most essential tips required for the owner and also the driver to follow seriously for the well-being of the vehicle and for a proper automobile maintenance in India are as under:

1. to focus the lights of the automobile properly
2. to check the air pressure of all the tires regularly
3. to change the water required for the engine

Apart from these general tips on the automobile maintenance in India for safe drive and the driver should also follow some preventative automobile maintenance policies like to check the air-filter every month, to be cautious while handling the battery, to check the brake fluid monthly, to get the oil filter replaced with every oil change, and many others.

**Foreign Direct Investment (FDI):** A foreign direct investment (FDI) is an investment in the form of a controlling ownership in a business in one country by an entity based in another country. It is thus distinguished from a foreign portfolio investment by a notion of direct control.

**FDI Policy of Government of India:** Government of India has taken various effective steps to simplify the Foreign Direct investment policy. The Foreign Direct Investment Policy (FDI Policy) of the Government of India prescribes the foreign investment cap in specified industrial sectors. Srivastava (2003) But in the recent times many activities have been transferred to unrestricted sectors in which 100% Foreign Direct investment is permitted. Broadly, the industrial sectors are categorized as:

1. Restricted
2. Prohibited
3. Unrestricted Sectors (Up to 100% foreign ownership)

All the sectors other than those mentioned below subject to terms and conditions in the FDI policy come under unrestricted sectors.

**Objectives of the Study:** The FDI in Automobile Industry has experienced huge growth within the past few years. The increase in the demand for cars and the vehicles is powered by the increased levels of disposable income in India. The automobile industry in India is growing by 18 percent per year. The automobile sector in India opened up to foreign direct investments in the year 1991. 100% Foreign Direct Investment (FDI) is allowed in the automobile industry in India. The production level of the auto mobile sector has increased from 2 million in 1991 to 259.7 million in 2016 after the participation of global players in the sector.

1. The main objective of this study is to analyze the FDI inflows in India's Automobile Industries.
2. To examine the trends and composition of FDI flow in Automobile Industry.
3. To Examine the source of FDI on Economic Growth

We present a methodology that holds special interest on FDI in flows in Automobile and other studies have found a special effect on passenger car segment growth rate and also explains automobile sector growth, production, sales, export and import rates, passenger car growth rate, and other factors related to FDI and Automobile Industry.

**Methodology:** In our study we focused on FDI flows, which has become a very important source of capital to developing countries. This section of the study presents the empirical results of the impact of FDI flows in India’s economic growth in automobiles sector after post liberalization era, especially with passenger car segment. The result will be based on regression analysis (ARIMA, Co-efficient, linear & Compound Model). The period of study is from 1992 to 2015 collection of FDI flows to India.

**FDI for Automobile Industry:** Automobile industry comprises FDI approvals granted for automobile sector, passenger car, Auto ancillaries etc. During the period from January 2000 to December 2009, cumulative FDI inflows received from FIPB/SIA, acquisition of existing shares & RBI’s automatic routes only. The amount of FDI inflows project specific in respect of all countries & Sector are not centrally maintained prior to January 2000. The liberalization of the portfolio investment
led to a surge inflow of capital for investment in the primary and secondary market for Indian equity and corporate bond market. In 2009, the automobile industry is expected to see a growth rate of around 9%, with the disclaimer that the auto industry in India has been hit badly by the ongoing global financial crisis.

** Correlation is significant at the 0.01 level (2-tailed), Linear Model: \( Y = a + bt \), \( Y =-42998+8586.16 \), Compound Model: \( Y = a (bt) \)

A **linear equation** is an algebraic equation in which each term is either a constant or the product of a constant and (the first power of) a single variable. A linear equation can involve more than two variables.

The general linear equation in \( n \) variables is:

\[ a_1x_1 + a_2x_2 + \cdots + a_nx_n = b. \]

In this form, \( a_1, a_2, \ldots, a_n \) are the coefficients, \( x_1, x_2, \ldots, x_n \) are the variables, and \( b \) is the constant. When dealing with three or fewer variables, it is common to replace \( x_1 \) with just \( x \), \( x_2 \) with \( y \), and \( x_3 \) with \( z \), as appropriate.

**FDI Growth Rate for Automobile Industry:**

The favorable Indian market conditions are acting as a catalyst for luxury and premium carmakers, which are receiving impetus from new launches. (Czech National Bank, 2016) The top-end carmakers have posted double-digit growth for the quarter ended June 30, 2013, with firms like Honda at 45 per cent and Audi recording 28.8 per cent, besides others. The production of passenger vehicles in India was recorded at 3.23 million in 2012-13 and is expected to grow at a compound annual growth rate (CAGR) of 13 per cent during 2012-2021, as per data published by Automotive Component Manufacturers Association of India (ACMA). Profit after Tax growth is only after 1993-94 228.6% decreased to 16.1% at 1996-97 and gradually increased to 139.4 % (2002-03) and reduced to-31.4 % due to US crises at 2008-09. Sales also 0.2% (2001-02) increased to 25%. (2009-10). Total income growth rate of the automobile industry is increased from 3.4 (2008-09) to 24.2% (2009-10) (Safiuddin, 2010)

**Passenger Car and Multi Utility Vehicles:**

India is emerging as an export hub for sports utility vehicles (SUVs). Global automobile majors are looking to leverage India’s cost-competitive manufacturing practices and are assessing opportunities to export SUVs
to Europe, South Africa and Southeast Asia too. India is also one of the key markets for hybrid and electric medium-heavy-duty trucks and buses.

Passenger car sales stood at 1.89 million units in 2012-13. Additionally, share of luxury cars to the total passenger car market of India is expected to increase to four per cent by 2020. The total number of passenger cars in India is likely to touch around 8 million units by 2020. (Britton, 1980)

Table 2: Growth Rate of Passenger Car and Multi Utility Vehicle (%)

<table>
<thead>
<tr>

</tbody>
</table>

Profit after Tax on Passenger Car and MUV is 103.9(1994-95) decreased to-44.5% (1998-99) and increased to 52.3 % (2009-10). Sales also increased from 7.1% (2002-03) to 15.6% (2004-05) and decreased to 3.4 % (2009-10) and are expected to remain stable in 2011-12 4.5 to 5 %.

Passenger Car Growth Rate: Excise duty hike, high interest rates and fuel prices hit passenger car sales in April 2012. Sales in this segment grew a mere 3.4% in the month, data from industry body Society of Indian Manufacturers Association (Siam) showed. After record high sales in March, domestic passenger car sales grew to 1, 68,351 units in April 2011-12, from 2, 29,866 units a month earlier. Growth in the popular entry-level car segment crawled by a mere 0.7%, indicating the common man is finding it tough to drive in their dream car10.

Conclusion

The Indian automotive industry is the second fastest growing in the world. About 8 million vehicles are produced annually in this country. During 1991-2015, India has emerged as the third largest market in the Asia Pacific Region. With various car manufacturing companies setting up their units in different parts of the country, the production of the cars will increase at a very fast rate.

Abstract

Haemorrhagic Septicaemia (HS), in Indonesia known as Ngorok disease is a fatal acute septicemia disease in cattle and buffalo caused by Pasteurella multocida. Outer membrane Protein H (OmpH) is one of the major proteins in P. multocida envelope has been purified and characterized as porin immunodominant. The aim of this study is to find out the homology of nucleotide sequence of 37 kDa OmpH gene of P. multocida of local isolate from NTT with vaccine strain (Katha) and 5 referen isolates and predict the epitope of 37 kDa OmpH gene. Detection of 37 kDa OmpH gene was done using PCR. Homology analysis of nucleotide and amino acid sequences was performed on the BLAST program at NCBI. Epitope prediction of 37 kDa OmpH genes P. multocida from NTT and vaccine strains was performed using the online programme B Cell Epitope Prediction Tools. The results showed that 37 kDa OmpH gene of P. multocida from NTT has 99% homology to vaccine strain (Katha) and isolates from China, Iran, India, Mesir, and 89% homology to isolate from USA and 37 kDa OmpH gene of P. multocida local isolate from NTT were likely to be immunogen candidates based on B cell epitope that had 11 epitopes. These findings indicate that P. multocida local isolate from NTT has a chance as immunogen candidate, which can be developed as a vaccine candidate and diagnostic kit for HS.

Keywords: Haemorrhagic septicaemia; P. multocidatype B; outer membrane protein H(omp H) gene; PCR; sequence; epitope.

Introduction

Hemorrhagic Septicemia caused by Pasteurella multocida is a fatal acute septicemia disease in cattle and buffalo. In perspective of economic, it becomes the most important bacterial disease in Southeast Asia including Indonesia, Philippines, Thailand, Malaysia, Middle East and South Africa[1].

In Indonesia, HS outbreak still occurs although vaccination has been done once a year using vaccine made from Katha strain. The most recent case is the sudden death of 24 livestock in Kupang district, NTT in December 2016. The results of laboratory tests at the Balai Besar Veteriner Denpasar, confirmed the death of these livestock due to HS[2].

P. multocida strains belong to sero group B and E are the one who cause HS. The complex interactions between host factors and bacterial virulence factors, such as lipopolysaccharide (LPS), capsule, protein outer membrane (omp), and putative hemolysin has an effect on the pathogenesis of the disease[3].

Outer membrane Protein H (OmpH) is one of the main proteins in P. multocida envelopes that has been
purified and marked as immunodominant porin. This porin is highly immunogenic, showing epitopes on the surface of bacteria \[4\]. Study by Tan et al.\[5\] using mice polyclonal antiserum in immunoblotting studies showed that omp with a molecular weight of 37 kDa was reactive to all local isolates and ATCC strains. In the same study, recombinant 37 kDa OmpH can protect mice and be able to stimulate high antibody titers.

The new vaccination approach based on the rational design of B cell and T cells epitopes (epitope-based vaccines) promises a great induction of immune responses, and can handle more effective pathogens with genetic variation\[6\]. Identification of epitopes suitable for diagnostic use or prophylactic intervention is an important prerequisite for epitope-based vaccines and diagnostics.

The purpose of this study is to find out the homology of nucleotide sequence of 37 kDa OmpH gene of \(P.\) multocida of local isolate from NTT with vaccine strain (Katha strain) and 5 referen isolates and predict epitope of 37 kDa OmpH gene.

**Material and Method**

**Sample:** \(P.\) multocida isolate from NTT (Nusa Tenggara Timur) were obtained from Balai Besar Veteriner Denpasar, Bali. Previously, this isolate had been tested for its capsular type. Haemorrhagic Septicaemia vaccine from Pusat Veterinaria Farma (Pusvetma) Surabaya was used as a vaccine strain (Katha) sample. Reference isolates from GenBank were used as a comparison with accession numbers, namely: HM582886.1 (China), CP017961.1 (Iran), FN908433.1 (India), KY436382.1 (Egypt), CP015562.1 (USA).

**Reculture and Identification of \(P.\) multocida:** \(P.\) multocida isolate was re-cultured in Blood Agar media and incubated for 24-28 hours at 37\(^\circ\) C. After that, the morphology was seen using Gram examination and its growth on MacConkey Agar (MCA). Furthermore, the examination using biochemical test, namely: TSIA test, SIM test, SCA test, Urease test, and Sugar test\[7\].

**DNA Extraction:** Total genomic DNA was extracted with QIAamp® DNA Mini kit according to standard protocol Qiagen\[8\]. Briefly, bacteria that have been cultured on Nutrient Agar (NA) at 37\(^\circ\)C overnight, were inserted into tube. After addition of bacteria/vaccine incubated at 60 \(^\circ\)C for 30 minutes. The 200\(\mu\)L AL buffer is added to the tube, then vortex. The mixture of the ingredients in the tube is transferred to the spin colomn, then adds 200 \(\mu\)L of 96% ethanol. After that, centrifuged at 8,000 rpm for 1 minute and washed using AW1 500\(\mu\)L. Then centrifuged back at 8,000rpm for 1 minute and washed again using AW2 as much as 500\(\mu\)L. After that centrifuged at 13,000 rpm for 3 minutes and the bottom of the spin colomn removed. After that, it was centrifuged again for 1 minute at 13,000 rpm and transferred to an empty sterile tube. After that added 50\(\mu\)L AE Buffer and incubated at room temperature for 1 minute. Then centrifuged at 8,000 rpm for 1 minute.

**PCR assay:** Amplification of the ompH gene was performed using both ompH-F and ompH-R primer in 20\(\mu\)l PCR mixture. The primers used was developed from the primers used by Tan et al.\[5\]. Primer ompH-F forward 5’-CAGCAACACGTTTACAATCAAGACGGTAC-3’ and ompH-R reverse 3’-GAAGTGTACGCGTAAA CC-5’ with gene target 946 bp. The thermal cycling conditions are: 1 cycle at 95\(^\circ\)C for 5 minutes; 40 cycles at 94\(^\circ\)C for 30 s; 50\(^\circ\)C for 1 minute, and 72\(^\circ\)C for 1.5 min; 1 cycle at 72\(^\circ\)C for 10 minutes. This PCR profile is repeated three more times to ensure specific PCR products. The PCR product was analyzed by electrophoresis in 1% agarose gel.

**Sequencing:** Purification of the PCR product was carried out with QIA quick spin column from Qiagen. Addition of Big Dye Terminator 1.1 cycle version as much as 1.6 \(\mu\)l and 5x sequencing buffer as much as 6.4 \(\mu\)l, then added H\(_2\)O ad libitum. Then the mixture was put into the PCR machine with a pre denaturation program of 96\(^\circ\)C for 3 minutes. 25 cycles for denaturation 96\(^\circ\)C for 10 seconds, annealing 50\(^\circ\)C for 5 seconds, extension temperature 60\(^\circ\)C for 4 minutes. Final extension 4\(^\circ\)C. After that, 3M NaOAC 2 \(\mu\)l (\(\pm\) 1/10 x vol) and 95% ethanol 50 \(\mu\)l (\(\pm\) 2 x Vol) were added then vortexed and incubated in ice for 10 minutes. Then centrifuged 14,000 rpm for 20 minutes at 4\(^\circ\)C. Then the ethanol solution is slowly taken, after that pellet is added 200\(\mu\)l 70%-80% ethanol, then centrifuged 14,000 rpm for 5 minutes at 4\(^\circ\)C. Then a 70% ethanol solution is slowly taken, then the resulting pellets are dried in the vaccum pump for 10 minutes, and stored at-20\(^\circ\)C\[9\].

**Homology Analysis and Epitope Prediction:** Sequencing results were processed using Bioedit program. Homology analysis was carried out using the BLAST program atNCBI (National Center for Biotechnology Information). Homology analysis of sequence of 37 kDa OmpH of NTT local isolate
compared with vaccine and nucleotide sequence data of 5 isolates from other countries accessed from GenBank. The nucleotide sequences of the 37 kDa OmpH were then translated into amino acid sequences using the online DNA to Protein Translation program. Epitope prediction was carried out through the B Cell Epitope Prediction Tools online program.

**Nucleotide Sequence Accession Number:** The DNA sequence of the 37 kDa OmpH gene of *P. multocida* isolate from NTT and vaccine were submitted to GenBank and assigned the accession number MK183754 and MK205393.

**Result and Discussion**

Reculture and Re-identification of *Pasteurella multocida*: Recultured Blood Agar showed the colonies were transparent, grayish, shiny, and were found to be non-haemolytic. No growth was observed on Mac Conkey Agar medium. The colonies were then confirmed by biochemical test, while it fermented glucose, fructose, mannitol and sucrose, but did not fermented maltose and lactose, the TSIA was obtained in alkaline slat and butt, yielding no gas and H₂S. The colonies were positive for indole test and no reaction was seen with Simon Citrate Agar and Urease medium.

The ompH gene was successfully amplified using OmpH-F and OmpH-R primers. The PCR product was obtained with the same bandsize of 946 bp of both samples (Fig. 1).

Study by Kanaiyalal [10] on the OmpH gene *P. multocida* HS case obtained 1kb PCR products. Whereas Tan et al. [5] whose primers was used in this study 37 kDa OmpH gene was obtained 980 bp.

The sequencing results of *P. multocida* isolate from NTT was 894 bp while for *P. multocida* from vaccine was 893 bp. In the analysis of nucleotides sequence of the 37 kDa OmpH gene *P. multocida*, the total length of the nucleotides that are parallel to the gap and insertion is 909 nucleotides. Table 1 shows the results of homology analysis.

The results showed that 37 kDa OmpH gene *P. multocida* from NTT isolate was relatively more similar to isolates from the continents of Asia and the Middle East. Nucleotide sequences of 37 kDa OmpH *P. multocida* isolates NTT and vaccines showed high homological levels of *P. multocida* OmpH from other countries.

The results of the protein sequences of the 37 kDa OmpH *P. multocida* NTT isolates were 298 amino acids while the vaccines were 297 bp amino acids. Kanaiyalal [10] obtained 296 amino acids of OmpH protein sequence in cattle and buffaloes. Multiple sequence alignment from amino acid sequences showed that 37 kDa Omp HP *P. multocida* from several countries shows high homology with little variation in amino acid composition in several parts. Luo et al. [11] aligned the OmpH sequence of 15 *P. multocida* serotypes and found that this protein was very conserved (72-100% identity), which supports the findings of this study.

Results of analysis of amino acid sequence OmpH *P. multocida* P-52 by Singh et al. [12] obtained the greatest variation limited to two discrete regions that are associated with the hydrophilic domain, i.e. amino acids to 82-102 and 223-240. According to Selleyei et al. [13] these two discrete regions encode large external loops that might interact with the host’s immune system. This variable area can work as a strain-specific epitope that takes an important role in serotype-specific immune responses [12].

Epitope prediction was done using Kolaskar and Tongaonkar Antigenicity scale. The results of the prediction of B cell epitope on 37 kDa OmpH were found 11 epitopes in NTT isolate and vaccine, with 9 identical epitopes, namely: GLSALAYAEL, DVHVKRLYAGF, DVGVSDDYTYFLG, GAYVFS, GFVVAGL, SQKYVTVA, ALEVGLN, KVYTDL, and SIILGAGYKLHKQVETF (Table 2 and Table 3).

The ability of epitope to induce an immune response is determined by the log score, the greater the log score, the better the ability of epitope to induce immunity. The linear epitope prediction results showed that 37 kDa *P.
multocida OmpH local isolates NTT and vaccine strains were immunogenous and had almost the same ability to induce humoral responses, with the best ability, namely epitope with the largest log score of 1,266.

Epitope identification and analysis can show that proteins are responsible for triggering the body’s immune response, and proteins with high immunogenic properties can be used for the development of peptide-based vaccines from Indonesian local isolates. In the diversity of epitopes in pathogens, it is important to note that not all epitopes, even those that appear dominant, are equally capable of producing antibody production. Particularly for linear epitope B cells there are several reasons, including, the accuracy of epitope prediction results is only 75% and most B cell epitopes (approximately 90%) are conformational, some studies have found that linear B epitope cells produce antibodies that do not cross reacting with original antigens and linear B epitope cells does not always give rise to memory cells so that to know the ability of the epitope to protect exactly need continuous research [14][15].

Conclusion

From this study it can be concluded that *P. multocida* local isolate from NTT has a high homology in nucleotide sequence and gene of 37 kDa OmpH *P. multocida* local isolate from NTT can be potential as immunogenic candidates that can be used as vaccine candidates and diagnostic kits.

Abstract

Grouper cultivation is still constrained by the availability of seeds due to diseases caused by bacteria. Vibriosis is a disease caused by bacterial infections of the Vibrio genus such as *Vibrio alginolyticus* and *Vibrio parahaemolyticus* which are the most common in hatcheries. Whole Cell Vaccine (WCV) contains endotoxin components as antigens to stimulate antibody formation, including lipopolysaccharide from the cell wall of gram-negative bacteria. There is a problem of oral vaccination which can damage when it enters the low pH digestive system. Therefore, it is necessary to conduct a research to find out the ability of the Whole cell vaccine (WCV) of *Vibrio alginoliticus* bacteria by microencapsulation method of alginate gel as an oral alginate particle vaccine *Vibrio alginoliticus* to increase the survival of the grouper seeds of *Epinephelus sp*. This study used four types of treatment, namely control (-) without vaccine, control (+) using alginate only, dosage treatment 0.025 mg/5gr BB fish/day and 0.05 mg/5gr BB fish/day. The results of the Whole Cell Vaccine using alginate gel microcapsules process can increase the life range of cantang grouper seeds by 80% at 0.05 mg/5gr BB fish/day and 73% at 0.025 mg/5gr BB fish/day.

**Keywords:** *Vibrio alginolyticus*, Whole Cell Vaccine, Alginate, Grouper, Vibriosis.

Introduction

Vibriosis has been found in grouper cultivation\(^1\). More than 70% of grouper diseases were caused by this. There has been a report regarding to the prevention of vibrio disease using vaccines given by injection. However, the ineffective treatment on how to give the vaccines as the prevention becomes an obstacle. Furthermore, the use of vaccines orally, especially vibrio disease, has not been widely reported.

Vibriosis is caused by bacterial infection from the Vibrio genus such as *Vibrio alginolyticus* and *Vibrio parahaemolyticus*\(^2\). According to Suprapto\(^3\), the use of Whole Cell vaccines and Extracellular products can provide high life range on shrimp. However, the use of WCV on cantang grouper seeds still needs to be investigated for its effectiveness.

Taslihan\(^4\) et al. (2000) stated that *V. alginolyticus* in rat grouper caused several symptoms such as red mouth, red spots, ulcers in the mouth, swelling of the abdominal cavity (due to swelling of internal organs and accumulation of residual metabolic fluid), and breaking of the fins.

Sumaryam\(^2\) stated that for seed-sized fish, the most appropriate vaccination is orally. Unfortunately, the problem may exist during the oral vaccination obstacle which is the dissolution of antigens in the water before they can enter the fish body and damage the antigen when passing through the digestive tract because of the low pH, so the vaccine must be given a layer that can protect the antigens while in the water and prevent the damage while passing the digestive system.

Microencapsulation is widely used in pharmaceuticals and other fields to cover a taste or a smell, extend the range of the drug release, improve the drug molecular stability, improve the bioavailability and as a multi-particle dosage form to produce controlled drug delivery systems and target\(^5\).
Sodium alginate is used for microencapsulation of drugs without using organic solvents, thus it minimizes the toxic effects due to the use of organic solvents in the manufacture of microcapsules\(^6\).

To find out the success of the anti-genes which enters the intestinal cells, it is necessary to prove microscopically. One such verification technique is to use the Scanning Electron Microscope (SEM) method.

**Method**

**Isolation and Culture of Vibrio alginolyticus**

**Bacteria:** *Vibrio alginolyticus* bacteria were obtained from Pathology Laboratories collection at the Center for Marine Aquaculture Research and Fisheries Extension, Gondol, Singaraja. *Vibrio alginolyticus* bacteria are grown on TCBS media.

Bacterial isolates were cultured in petri dishes with TCBS media. To make 400 ml culture media, 35 g of TCBS is needed to be mixed into 400 ml of distilled water. The Erlenmeyer is covered with aluminum foil and put in an autoclave at 100\(^\circ\)C, for 10 minutes to sterilize the medium from another pathogen. TCBS is poured into a petri dish, and then stored at room temperature for 24 hours. Isolate *Vibrio alginolyticus* was put into the media, then incubated for 24-48 hours in an incubator at 30\(^\circ\)C.

**Whole Cell Vaccine (WCV) Vibrio alginolyticus**

**Bacteria:** Petri which contains bacteria added 2 ml PBS and washed 3 times for 10 minutes. The bacteria obtained were turned off with 3% formalin for 72 hours. Each WCV was washed 3 times for 10 minutes by centrifugation. Bacterial density was made as much as 50 mg/ml, then stored in-4\(^\circ\)C until it was used.

**WCV Microcapsules Vibrio alginolyticus**

**Bacteria:** The mixture of 300 ml distilled water with 6 grams of sodium alginate was used to make a solution. The WCV suspension with alginate is dropped into CaCl\(_2\) solution. The comparison of WCV and alginate used is 1: 6 v/v\(^7\). Next, the microcapsules formed in CaCl\(_2\) solution were washed using distilled water by centrifugation at 4000 rpm for 10 minutes. Then, the supernatant was washed again at the same speed and time.

The washing process was done three times until the microcapsules were free from CaCl\(_2\) solution. After the washing process, microcapsules were dried by aeration at room temperature for about 3-7 days. Dry microcapsules were then crushed and filtered using a 400 mesh filter, and stored in a sterile bottle.

**Vaccination and Tests for Grouper Seeds:**

Vaccination is carried out by mixing the microcapsule vaccines on feed with (A) 0.025 and (B) 0.05 mg/5gr BB fish/day. This dose refers to the research of Fandina\(^8\). The control (-) treatment was not given a vaccine, while the control (+) was only given alginate. Then, vaccination was given to grouper seeds in the hatchery pool of 15 birds/m3 which are 1-2 months old and 5-7 cm for 7 days and then tested by soaking in water mixed with 10\(^8\) CFU/ml *Vibrio alginolyticus* suspension\(^9\). The soaking process was done for about 3 hours, furthermore the feed was given 5% of fish biomass per day. Feeding phase was done twice a day, and was observed during the maintenance for seven days for monitoring the water quality, finding the mortality rate and calculating the survival rate of seeds by using this formula\(^10\):

\[
SR = \frac{N_t}{N_0} \times 100\%
\]

**Note:** SR = Grouper seed survival rate, N\(_0\) = The initial number of grouper seeds, N\(_t\) = The final number of grouper seeds

**Scanning Electron Microscope (SEM) in Grouper Intestines:** SEM was done to detect the results of vaccines which were found in the intestine, based on proposed method by Ghosh\(^11\). 1 cm intestine was taken after 60 minutes feeding which the vaccine was already mixed in the feed. Then, it was soaked with glutaraldehyde solution. The processes of intestinal segment as follows; The intestine was inscribed longitudinally to expose the mucosal surface, then it was cut into small pieces and applied to thin thermocol sheets with the upper mucosal surface. After that, the segment was soaked with 2.5% glutaraldehyde in a buffer solution for 30 minutes, the intestine was repeatedly washed with heparin salt [2 g heparin (10,000-15000 iu)] and added 20 ml of 0.67% NaCl solution for 5 to 7 minutes to remove the mucus. After rinsing in a phosphate buffer (pH 7.2), the tissue was immersed in glutaraldehyde for 18 hours at 4\(^\circ\)C.

Then it was dehydrated in graded ethanol as follows: 50% (30 minutes), 70% (45 minutes), 90% (1 hour) and absolut Ethanol (1 hour). Next, the tissue was immersed in pure amyl acetate for 24 hours. Critical Point Drying (CPD) was carried out by nitrogen liquid in a vacuum. Then the tissue is coated with gold on the IBCoater ion and placed under a scanning electron microscope for subsequent observation and photography.
Observation after Testing: Observations were conducted after testing the immersion of $10^8$ CFU/ml bacteria, which was observing the clinical symptoms due to bacterial infection and the life range of fish for seven days and continued with Scanning Electron Microscopy (SEM) in the grouper intestine.

Results and Discussion: The color of the colonies from *Vibrio alginolyticus* bacteria was yellow, swarm-shaped, with sleekly edges, and convex elevation. This bacteria is fermentative on sugar (glucose, sucrose and mannitol), and produced the oxidase enzyme and catalase. The characteristics of these isolates showed that the species were based on the Bergey Manual of Determinative Bacteriology Identification Guidelines\(^\text{[12]}\) called *Vibrio alginolyticus*. The final result of microcapsules vaccine with alginate gel was powder. The egg white was used to mix the vaccine and the feed. The mixture form of both vaccine and the feed was shown in Figure 1.

There was an enhancement of the body’s ability to stimulate an antibody production on the fish seed which was which was feed the WCV vaccine, as a result that the life range of the experiment was higher than the control treatment. This research was in accordance with the results of the study reported by several researchers namely Kamiso\(^\text{[13]}\), Hernayanti\(^\text{[14]}\), Astuti\(^\text{[15]}\), and Nindarwi\(^\text{[16]}\).

Observation of external symptoms was conducted by observing clinical symptoms in external organs and the behavior of grouper seeds to ensure that the of fish seeds mortality was caused by bacterial attacks. The observation result on the clinical symptoms and grouper seeds behavior after the test showed that there was a decline appetite, passive movement, and hemorrhage in the fins. This result was in accordance with a research conducted by Nindarwi\(^\text{[16]}\) which showed that clinical symptoms and fish seeds behavior, that infected by the *Vibrio alginolyticus* batteries, decreased their appetite, unbalanced circling movements, hemorrhagic in the mouth area, and lateral lines at the pina (pectoral, dorsal, and anal).

The intestine of grouper seeds is taken after one hour of feeding which mixed with the vaccine, this time allocation is chosen because the feed has been digested at that time. Based on Kusumawati\(^\text{[17]}\), the speed of the grouper gastric is empty in 2.9%/hour. The results of the SEM test on the treatment of 0.05 mg/5gr BB fish/day
and 0.025 mg/5gr BB fish/day showed that there was an antigen which was caught by the fish intestine cells as shown in Figure 3. In the control treatment (-) and control (+) there are no antigens in the cells in the fish seed intestines.

![image of SEM of grouper seeds intestine in control (-) (a), control (+) (b), a dose of 0.025 mg/5gr BB fish/day (c), and dose of 0.05 mg/5gr BB fish/day (d).]

The alginate gel microcapsules can protect the Whole Cell Vaccine in the digestive system so that the vaccine can be received by intestinal cells. Suprapto[9] said that the alginate gel can subside in acidic conditions, and eroded in alkaline conditions so that it can protect the antigens when exposed to acids in the fish stomach, then it released the antigens in the fish digestion system which has alkaline conditions.

The antigens bounded by macrophages which found in the intestine, will be encoded by a protein and can be recognized by specific immune receptors to produce antibodies. It based on the theory by Jewetz[18], which said that there are many active macrophages in the intestine and these macrophages have a role as antigen presenting cells (APC).

The calculation result of the grouper seeds’ survival rate percentage after being tested with Vibrio alginolyticus showed that the vaccinated seeds’ Survival Rate (%) increased compared to the control.

Facilitating and Inhibiting Factor in Clinical Nursing Education: Concept Paper

Herdina Mariyanti¹,², Kee Jiar Yeo²

¹Nursing Faculty, Universitas Airlangga, Surabaya, Indonesia, ²School of Education, Faculty of Social Science and Humanities, Universiti Teknologi Malaysia

Abstract

Clinical nursing education is one of a component in nursing education that conducts in a clinical setting involving real situation, teaching and learning process in the clinical setting.

Objective: The purpose of this article is to discuss about facilitating and inhibiting factor in clinical nursing education. Nursing student expects that through clinical nursing education, their skill and knowledge will improve and finally they will get their competencies. In this article emphasized that many factors that facilitating and inhibit nursing student learning experience during their clinical nursing education. Theory-practice gap is one of inhibiting factors in clinical nursing education. One of facilitating factors in clinical nursing education is supportive clinical learning environment.

Keywords: Inhibiting factor, barrier, facilitating factor, clinical learning, clinical nursing education.

Introduction

The fundamental aim in nursing education is to produce competent and professional nurses who able to apply theoretical knowledge and skill in the health care (1). Clinical Nursing education is one of a component in nursing education that conduct in a clinical setting involving real situation, teaching and learning process in the clinical setting. On clinical nursing education also helping the nursing student achieve their competencies (attitude, skill, and knowledge) in real clinical settings according to nursing education institutional standard (the professional standard) (2). Kpodo, (2) stated that the clinical setting involves hospital setting, clinical, or other settings.

Clinical education provides an opportunity for a nursing student to imply theory and skill that they got from classroom setting in of real environment (clinical setting) (3). Many factors affect nursing student learning experience during the clinical education process (3).

Objective: There are two objectives of this article. First objective is to discuss about facilitating factors in clinical nursing education. The second objective of this article is to discuss about inhibiting factor in clinical nursing education.

Clinical Nursing Education

Clinical education is healthcare education which conducted in a clinical setting, or in the community under supervision registered practitioner (4). Chabeli & Muller 2004; Eta et al. 2011; Nxumalo 2011 in Kpodo (2) stated that clinical nursing education is one of a component in nursing education that conducts in a clinical setting involving real situation, teaching and learning process in a clinical setting. Student understanding that in clinical education, they would be implying the theory that they get from the classroom setting (5). Kpodo, (2) stated that the clinical setting involves hospital setting, clinical, or other settings.

Goal of clinical nursing education for the nursing student is to develop graduate of nursing student competency, who prepared to become professional clinician beginners (6). Clinical nursing education also enable student to develop their clinical skill, give opportunity to student in applying theory to practice and applying problem-solving skill; student also have opportunity to improve their interpersonal skill, and become socialized about professional norms in clinical setting, become socialized about nursing profession professional norms and ethics, and become socialized about social-political healthcare milieu (6).
Allari and Farag (5) found that nursing student expectation about the impact from their clinical learning were improving clinical skill and to achieve competencies. Nursing student expects that through clinical education, they would improve their clinical skill and achieve their competencies(5). Ma et al (7) found that the role of clinical learning is improved professional responsibility ethics student caring ability. There are facilitating factors and inhibiting factors which has an impact for student in their clinical nursing education.

**Facilitating factor in clinical nursing education:**
Elçigil & Sari (8) found that facilitating factor in clinical nursing education are clinical environment, teamwork, mentor, and patient. The meaning of clinical environment are physical condition and new educational environment. The student stated that clinical setting with good condition have good impact on their clinical learning (8). The student also stated that during their clinical education, student always exposed to the new clinical environment. With new and different clinical environment, student have the opportunity to perform the different practice and intervention that can prepare a student when they work after their graduation (8). The second factor that facilitating factor in clinical education are teamwork. The meaning of teamwork is acceptance and communication(8). The student stated that the relationship between student and nurses staff, and nurses staff attitude are important thing that affect student learning on clinical setting. When nursing student involved as a health care team, then the student will more spirited to attending clinical setting and make student feel motivated. For communication part, effective communication from nurses staff will motivate student to get more knowledge and it will help students to become part of the health care team (8).

A third factor that facilitating student in clinical education is a mentor. Good attitude from a mentor will motivate student to learn more. Positive feedback and friendly attitude during giving feedback from a mentor can motivate student (8). A fourth factor that facilitating student learning in clinical practice is ability to teach and nursing competence of mentor (8). The student stated that when mentor perform knowledge and demonstrated new skill, also helping student in performing a new skill, then it will make student feel motivated (8). A fifth factor that facilitating student learning in a clinical setting is patient attitude. The student stated that when patient allow nursing students to take care of them, it can improve student motivation to learning more (8).

Lofmark, (9) found that facilitating factor that contributing in clinical education in nursing is a student allowed to take their own initiative and responsibility during their clinical practice. During their clinical practice, nursing student allowed to report about the patient condition to nurses staff, nursing student allowed to work as a nurse under supervision from clinical supervisor. Lofmark, (9) also stated that a factor that facilitating factor that contributing in clinical practice are student allowed to be independent during their clinical practice. Independent also provide opportunity for nursing student to take decisions related to their clinical practice. Another factor that facilitating clinical practice for nursing student is practicing task and receiving feedback from clinical educator. A Student who practicing different task and receiving feedback from clinical nursing educator, will improve their confidence, and student can learn from mistake that they made during practice clinical task (9).

Shokria Adly Labeeb, RN, Chitra Vellolikalam Rajith, RN, Manal Ahmed Ibrahim, RN, & Nabil Ahmed Kamal, (10) found that there are 5 facilitating factors that contributing in clinical learning. There are clinical practice, clinical supervision, clinical instructor, supportive clinical learning environment, client factor and laboratory practice (10). The student also explains that similarities between the laboratory practice and clinical practice make them more confidence to conduct nursing procedure (10).

Shokria Adly Labeeb, RN, et al., (10) stated that other facilitating factor in nursing student clinical learning is clinical supervision. A student expressed that they very happy when they get continuous supervision from their clinical instructor (10). Continuous supervision is an important part in guiding, teaching, and evaluating clinical skill that performed by student in clinical areas (10).

Another facilitating factor in clinical learning for nursing student is a clinical instructor (10). The student stated that effective communication with the clinical instructor facilitating clinical learning (10). The student also stated that a good attitude and positive behavior from clinical instructor will make student maintain communication with the clinical instructor (10). The student also stated that immediate feedback from clinical instructor will help students to identify their deficiency and their achievement about clinical skill that they performed (10).
Other facilitating factor in clinical learning are supportive clinical learning environment (team related factor) \(^{(10)}\). The student stated that medical team, including doctors, nurses, and other health professional team influence their clinical learning \(^{(10)}\). Good collaboration between student, nurses, doctor, others health team member will enhance their learning \(^{(10)}\). The student also stated that communication between student will help their clinical learning by sharing knowledge and clinical nursing skill \(^{(10)}\). Other facilitating factor in clinical learning for nursing student is client related factor \(^{(10)}\). The student stated that they happy when they able to provide complete care for patients and their family \(^{(10)}\). The student also stated that patient acknowledgement for their care that provide to the patient will make student felt happy \(^{(10)}\).

Another aspect that facilitating for student good learning are student-mentor relationship \(^{(11)}\). Aspect related to student-mentor relationship are mutual respect and trust, an open and inviting communication \(^{(11)}\). Relationship between student-mentor should be constructive, respectful, supportive dialogue and mutual openness \(^{(11)}\).

**Inhibiting factors in clinical nursing education:** Jahanpour et al.\(^{(12)}\) found that barrier in clinical learning were inappropriate communication. Nursing student found inappropriate communication from nurse staff in a clinical setting. Nursing student also reports that nurses staff always blamed nursing student if something bad happened in their ward. Second, Ineffective role model. Nursing student report that although nurses educator and nurses staff were technically skilful, but they did not perform the procedure without upholding standard.

Third, theory-practice gap. Nursing student revealed that there were theory-practice gap in clinical setting. Nursing student revealed that they face up problem such as confusion about how to do a procedure (nursing action procedure) based on theoretical knowledge that they get from classroom or based on the habit of ward in reality situation \(^{(12)}\).

Newton et al.\(^{(13)}\) and Jennifer and Ockerby \(^{(14)}\) found that lack of affordance is barrier for nursing student learning in their clinical education. They found that the meaning lack of affordance is when nurses staff was indifferent to nursing student when nursing student come to the clinical setting and did not give opportunity nursing student to learn in a clinical setting. Other research, as conducted by Killam and Heerschap \(^{(15)}\) founded some barrier in nursing student clinical education. The barrier is large of group \(^{(15)}\). The student felt that large group in their clinical education would contribute to the decrease of feedback. Clinical educator didn’t have enough time to give the feedback one by one in a large group \(^{(15)}\). Another barrier is lack of practice time. They didn’t have the opportunity to learn with appropriate time \(^{(15)}\). Truong \(^{(16)}\) found that barrier in clinical learning for nursing student was limitation in facilities. Also, student report that too many students in clinical wards would be decreasing their opportunity to learn and practice through their experience \(^{(16)}\). In this study also found that patients and their family reject to care by students \(^{(16)}\). Another barrier was that the lack of confidence that felt by students. \(^{(16)}\) They felt less confidence when they provide nursing care for patients, that led them lose the opportunity to learn in their clinical learning \(^{(16)}\).
student also described that theory-practice gap being their barrier during their clinical learning.

Awe and Omolola (17) found in their research that communication as barrier for international nursing student. Student revealed that they got difficult to find appropriate medical terms that they used in clinical settings, for international nursing student only focus translating words during their clinical learning. They also misunderstood about what the patient and nurses staff said, which affect their nursing care that given to the patient (17). Sharif and Masoumi (18) found that barrier that faced up by nursing student during their clinical learning were theory-practice gap. During their clinical education, they got difficult to integrate between what they got from classroom setting into real practice in a clinical setting. The student also felt that what they do in their clinical education is not the real professional work. The student said that what they had learnt during four years in a classroom setting, were different with they had done in their clinical education (18). They think that what they had done during their clinical education can be done by other people without professional education (18).

Lofmark (9) found that student-supervisor relationship deficiency is one of barrier in clinical learning. The student stated that some supervisor in their clinical practice did not rely on about their attendance in the clinical setting. The student spent their time without supervision. Some student also stated that they hadn’t received any feedback from supervisor on their clinical practice. Second, lack of nursing practice guidelines. The student stated that during their clinical practice student experienced difficulties finding guidelines about nursing practice. Third, lack of time. Student stated that they had lack of opportunity to learn, to participate in ward activity. Student only allowed to observe in the care of patients. Fourth, some student stated that sometime student facing unsuccessful in their clinical learning. For example, the student fails on intravenous peripheral insertion, or they unable to answer some question from a patient (9). This experience leads to feelings of inferiority for students. The student also stated that they felt the knowledge insufficiency in their clinical practice. They said that theory that they got from classroom setting was insufficient (9).

**Conclusion**

Clinical nursing education is one of a component in nursing education that conduct in a clinical setting involving real situation, teaching and learning process in the clinical setting. Goal of clinical nursing education for the nursing student is to develop graduate of nursing student competency, who prepared to become professional clinician beginners. Many factors that facilitating and inhibit nursing student learning experience during their clinical nursing education.

Confirmatory Factor Analyze on Education Characters of Teenagers Based on the Character System Theory in Sexual Prevention of Premarital in Jember District

Iis Rahmawati¹, Dewi Suminar Retno², Oedojo Soedirham³, Pinky Saptandari W.⁴

¹Student Doctor Degree in Health Sciences Faculty of Public Health, ²Lecturer in Psychology, ³Lecturer in Anthropology, ⁴Lecturer in School of Public Health, Airlangga University, Indonesia

Abstract
Currently the problem of teenage characters in Indonesia became the spotlight of the public. The problem that arises in the community is premarital sexual behavior. Cases regarding sexual behavior in adolescents from time to time are increasingly alarming. While in the community there is a shift in moral values that are getting farther away so that the problem has become commonplace. Whereas this behavior is something that must be avoided by each individual so that it requires adolescent character education in premarital sexual prevention. The research sample was 229 students in six high schools in Jember Regency. The study used a multistage random sampling technique. Variable characteristics of adolescents include indicators of moral knowledge, moral feelings, and moral actions. Data analysis uses confirmatory factor analyze (CFA) with data estimation parameters using software (analysis of moment structures (AMOS version 21). P-value parameters of adolescent characters to moral knowledge (0.000), p-value parameters of adolescent character to moral feelings (0.000), p-value parameters of adolescent characters to moral actions (0.000). Model fit value in the comparative fit index (CFI) (1.000). Moral knowledge, moral feelings, and moral actions are stated as significant as a measure of the construct of adolescent character. The value of the CFI fit index produced is 1.000, indicating that the model is fit. Means that the character of adolescents can be formed through moral knowledge, moral feelings, and moral actions.

Keywords: Education, adolescent, knowledge, feelings, actions.

Introduction
Indonesia as a developing country has a demographic character with the largest percentage of the population aged young (15-24 years) among other ages. The number of teenagers aged 10-24 years has reached 64 million (27.6%) of the total population of Indonesia. A large number of adolescents is a great potential for the advancement of the nation, but if it is not properly cultivated or left alone it develops in a negative direction and becomes a burden on the state (1).

Adolescence occurs physically and psychologically and often faces various health risks. Physical changes in adolescence are characterized by the emergence of a variety of primary and secondary sexual signs and psychological changes including changes in emotions to be sensitive and behaviors wanting to try new things. Although adolescents have matured in sexual organs emotions and personality are still unstable because they are still looking for identity so that they are vulnerable to various temptations and social environments. So that teenagers are very easily affected by the environment, including various negative influences such as doing various deviant and self-destructive actions and others, namely premarital sexual behavior.

According to 2012 National Population and Family Planning Agency data, out of wedlock pregnancies due to premarital sexual behavior as much as 48.1% occur in adolescents aged 15-19 years and abortion rates reach 2.5 million, namely 800 thousand abortions carried out by teenagers. Sexuality is a complicated problem for adolescents because adolescence is a time when a person is faced with various challenges and problems that come from themselves and the environment. These challenges and problems have an impact on adolescent behavior, especially sexual activity. Cases of sexual behavior in adolescents from time to time are increasingly alarming.
While in society there is a shift in moral values that are getting farther away. So that the problem has become commonplace. Whereas this behavior must be avoided by every individual.

According to study that character education is an effort to shape the human personality through the process of knowing the good, loving the good and acting the good, namely the education process that involves three domains: moral knowledge (moral knowing), moral feeling (moral feeling or moral loving) and moral action (moral acting or moral doing). So that noble deeds can be formed into habits of mind, heart, and hands without involving these three domains character education will not work effectively (2).

According to study that the three domains are character systems. As a character system, these three domains cannot be separated but are interconnected, interact with each other, and influence each other. These three domains were then elaborated by Lickona into various character components. Moral knowledge(moral knowing)consisting of 1) moral consciousness; 2) knowledge of moral values; 3) understanding other points of view; 4) moral reasoning; 5) decision making and 6) self-knowledge. Feelings of moral (moral feeling)consisting of 1) the conscience; 2) self-esteem; 3) empathy; 4) love goodness; 5) self-control; and 6) humble. Moral action (moral action) consists of 1) competence; 2) desire; and 3) habits (3).

The family has two functions. The first function is related to sexual problems. The second function is child care. In addition to physical maintenance, this function also includes the formation of character and behavior of children to be able to live in a wider circle, how children are formed through relationships with both parents. Parents are the main and first person in providing character education at home as an effort to prevent the premarital sexual behavior (4).

### Materials and Method

This research was conducted from January to June 2018 in Jember Regency, Indonesia. This study includes a cross-sectional approach using students in several high schools. The inclusion criteria included: 1) Jember High School 5, Kartika 4 Jember Middle School, Pancasila Ambulu Middle School, Balung State High School, Kasyan Puger Islamic Middle School and Kencong 1 Middle School; 2) students in 6 high schools aged 16-17 years; 3) students in 6 active high schools; 4) students in 6 high schools with male and female sex.

The techniques used are multistage random sampling because the population is limited according to the criteria of a cluster particular(high school). The sample includes students (n = 229) in SMA 5 Jember, SMA Kartika 4 Jember, SMK Pancasila Ambulu, SMA Balung, Islamic High School Kasyan Puger and SMA 1 Kencong. The research instrument used a Likert scale questionnaire to determine education teenage character about moral knowledge, moral feelings, and moral actions. Data collection techniques include filling out the teen character questionnaire format, moral knowledge, moral feelings, and moral actions. Data analysis using confirmatory factor analysis(CFA) with parameter data estimates using analysis of moment structures (AMOS version 21) (15). The CFA test aims to find out how well the measurement indicators measure a latent concept (construct) and to determine the model’s fit value in the comparative fit index (CFI).

### Results

Adolescent character factors (X3) are measured through 3 indicator aspects namely moral knowledge (X3.1), moral feelings (X3.2), and moral actions (X3.3). Descriptive analysis results can be seen in table 1.

#### Table 1. Frequency Distribution of Adolescent Character Factors as Premarital Sexual Prevention Efforts

Table 3 shows that the CFI fit index value is 1.000 and CFI value > 0.90 indicates that the model is fit.

**Discussion**

Characters Teens To Knowledge Moral:

Knowledge moral (moral knowing) as the first aspect has six elements, namely the moral conscience (moral awareness), knowledge of moral values (knowing moral values), the determination of the angle of view (perspective taking), the logic of moral (moral reasoning), courage to take an attitude (decision making), and self-knowledge. The six elements are components that must be taught to children to fill their cognitive domain (2).

Parents are often negligent in providing moral knowledge, this is evident from the results of the study (table 1) which describes the indicators of adolescent character factors that most respondents rarely get moral knowledge from parents related to premarital sexual behavior as many as 125 respondents (54.6%). The most dominant statement that is rarely done by parents about moral awareness, namely “having sexual relations before marriage can damage morals, including belonging to immoral acts”.

According to study that the notion of the character contains values such as 1) religion, religious education is expected to foster attitudes of children who are able to stay away from things that are prohibited and carry out religious orders; 2) decency includes values that relate to others such as courtesy, cooperation, tolerance, mutual respect, mutual respect, respect for others, not premarital sex; 3) personality has values related to self-development such as courage, shame, honesty, independence (5).

Moral awareness includes three things, namely: 1) the feeling of compulsion or the obligation to do moral actions; 2) moral awareness can be rational and objective in the form of actions that are generally accepted by society, as objective and universally applicable; 3) moral awareness can take the form of freedom (6).
According to study that moral development is best understood when considering a combination of social and cognitive factors, especially those involving self-control. When developing self-moral (moral self), individuals adopt standards regarding right and wrong that serve as guidelines and prohibitions in behavior. In the process of self-regulation, one can monitor the behaviors and conditions that accompany them, assess between behavior and moral standards, and regulate actions based on consideration of consequences for themselves (7).

**Youth Character to Moral Feelings:** Indicators of moral feeling are strengthening aspects of teenage emotions to become human beings with character. Strengthening is related to the forms of attitudes that must be felt by adolescents, namely awareness of identity, confidence (self-esteem), sensitivity to the pain of others (empathy), love of the truth (loving the good), (self-control self-control) and humility (humility). After these two aspects have been realized, moral acting as an outcome easily appears in adolescents (3).

The results of the research on indicators of moral feelings (table 1) show that most respondents rarely get moral feelings from parents related to premarital sexual behavior as many as 142 respondents (62.0%) about indicators of good love “my parents conveyed not to have sexual relations before married because it can harm yourself and family”. Adolescence is a transition period between childhood and adulthood that often faces various sexual health risks. Encouragement or sexual desire is assumed to have existed in adolescents because during adolescence the reproductive tool begins to function and requires a container to accommodate the aspirations of teenagers related to the transition experienced (6).

According to study that the dimensions of adolescent attitudes toward premarital sexual behavior have four dimensions, namely: 1) the biological dimension is a dimension related to the functioning of reproductive organs including how to maintain or care for reproductive health, optimally functioning knowledge about the dangers of sex free; 2) the psychological dimension associated with one’s feelings; 3) the moral dimension includes the assumption of individuals towards free sex, for example, the assumption that free sex is a normal relationship, not normal, normal, unnatural, permissible, not permissible, or good, not good according to each individual; 4) the social dimension is the dimension that sees how sexuality emerges in relationships between people, how one adjusts to the demands of the role of the social environment, and how the socialization of the role and function of sexuality in human life (8).

**Youth Character To Moral Actions:** Indicators of moral action. The results of the study (table 1) show that most respondents rarely get moral actions from their parents related to premarital sexual behavior as many as 108 respondents (27.2%) regarding the desire that is “my parents invited to discuss how the impact of having a relationship before marriage and the challenges that it will be faced if it is not ready mentally and financially in a family”.

Teenagers act more using emotions and are still lacking in rationality thinking. In these conditions, parents often experience difficulties. Research results that family support that is expected by adolescents during their puberty period is to be considered, the desire for parents to act as friends, to give love, to understand, to inform and to fulfill their needs (9).

According to study that sexual behavior is behavior driven by a sexual desire that is carried out alone, by the opposite sex or same-sex without any marriage ties according to religion (10). While premarital sexual behavior is a sexual behavior that is carried out without going through an official marriage process according to the law and religion and belief (5). The research showed that 29.3% had sexual intercourse, the first age did an average of 16 years and about 38% used condoms during sexual activity (11). The research shows that 41.5% of unmarried adolescents have had premarital sexual intercourse, <10% have high-risk sex (12). There is a significant relationship between attitudes towards premarital sexual behavior because attitude is something that can give a certain tendency to individuals to react in the form of certain behaviors (13). Premarital sexual behavior is related to one’s morality. The moral is a teaching about good and bad deeds or behavior, morals, and obligations (14).

According to study that moral tendencies consist of: 1) awareness of the ability to recognize standards ethics and morals and commitment in doing something good; 2) self-control, namely the ability to control impulses and gratification immediately and replace by doing something good and right; 3) humble namely knowing one’s own limitations and self-rationalization abilities; 4) moral habits, namely the ability to develop good behavior patterns so that they become habits; 5)
willingness, namely the commitment to do something good and right even in difficult situations(3).

Fit Model Value: Table 2 shows that the CFI fit index value is 1.000. The CFI value>0.90 indicates that the model is fit. Means that the character of adolescents can be formed through moral knowledge, moral feelings, and moral actions.

Conclusions

The results of research on adolescent character variables, that is, most parents rarely give importance to moral knowledge, moral feelings, and moral actions to adolescents in premarital sexual prevention. This has an impact on the character of adolescents, so they risk doing irregularities such as premarital sexual behavior.

Is it True that the Child is King?: Qualitative Study of Factors Related to Nutritional Status of Children in West Lombok, Indonesia

Ina Kusrini¹, Mara Ipa², Agung Dwi Laksono³

¹Unit of Health Research and Development Magelang, Ministry of Health, Center Java, ²Unit of Health Research and Development Pangandaran, Ministry of Health, West Java, ³Research and Development Center of Humanities and Health Management, Ministry of Health, Jakarta, Indonesia

Abstract

Nutritional status in infants and toddlers is a very important indicator to indicate whether the development of health of a region is successful or not. The purpose of the study was to explore factors related to the nutritional status of troubled children in West Lombok Regency, Indonesia. The study was conducted with a qualitative design. Data was taken through interviews and observations on toddler suspected of having nutritional status problems. Data were analyzed by content analysis and thematic analysis method. The results of the interview were showed that the value of children for people living in the West Lombok, “the children is a king”. Although the results of observations were showed a different situation. Poverty makes parents of toddlers have no choice, and ultimately choose to work abroad. Toddlers whose parents work abroad must be entrusted to their relatives or grandmothers. Such conditions make the pattern of parenting, including the pattern of feeding, not optimal. This condition was exacerbated by poverty that surrounds them and the presence of infectious diseases that infect the toddlers. It can be concluded that the value of children is not related to the nutritional status of children. The main factors that were assessed to be related to the nutritional status of children in the West Lombok District were poverty. While other factors are related to family factors, infectious diseases, feeding pattern, and parenting patterns.

Keywords: Toddler nutrition status, qualitative studies, the value of child, poverty, local food.

Introduction

Child growth is an index of nutritional status that shows general well-being in the community¹. Growth failure in children can result in increased morbidity so it can also predict mortality rates². The incidence of growth failure at the age of the toddler has an impact on the growth of the next age. A boy who experiences failure to grow, in adulthood will become a stunted man with all its consequences, work productivity is less so disturbing in achieving family economic status, while a girl who experiences growth failure will become a stunted woman who when will be at risk for having a low birth weight baby³.

A concept of nutrition and child development developed by UNICEF identified causes directly or indirectly towards growth. Nutritional intake and health status are factors that directly influence a child’s growth. Food availability in the household, parenting patterns and environmental health are factors that influence the nutritional status of children indirectly through their influence on nutritional intake and children’s health status. While socio-economic conditions are a big factor covering the factors of food availability, parenting patterns and health of the family environment. So that these socio-economic factors have a strong influence on the nutritional status of children even though indirectly⁴.

West Nusa Tenggara Province (NTB) is one of 20 provinces with a high prevalence of growth failure in toddler in Indonesia. West Lombok Regency which is
one of the Regencies in NTB with the prevalence of growth failure in toddler has increased based on the results of Riskesdas. The prevalence of under-fives with less weight was 27.59% (2007) to 28.47% (2013); the prevalence of stunting toddlers shows 41.74% (2007) to 46.89% (2013) and the prevalence of underweight toddlers from 17.62% (2007) to 26.89% (2013)\(^5\). As one of the regencies in NTB, West Lombok is a health problem area, in the poor category. According to data on socio-economic status data (PSE) in 2011, West Lombok had a PSE figure of 19.7%. While the level of public education, which is characterized by indicators of the average length of school, only 5-6 years, shows that the level of education of the people in West Lombok is still relatively low, with the largest percentage of population>10 years old having elementary school education and below\(^7\). Based on the description of the background, the purpose of this study was to explore factors related to the nutritional status of problematic children in West Lombok.

### Materials and Method

The study was conducted using a qualitative design through semi-structured interview method and observations on individual informants in West Lombok Regency, Indonesia. We collected data on three regions with different topographic characteristics, namely the mountains (Duduk Atas Village), the coast (Melase Village), and the plains (Limbungan Utara villages). Data collection was conducted in February-May 2015. The informants interviewed consisted of nutrition program holders, health workers, community leaders, religious leaders, parents and child caregivers of toddlers with the nutritional disorder. There were 41 people interviewed, consisting of 18 men and 23 women. Observations were made according to the field context in the environmental situation, feeding patterns, and parenting patterns.

Recording of nutritional problems and possible causes was carried out as a life history case study in toddlers who have nutritional status problems. There were 3 nutritional status problems of children under five who were the target of the study, namely underweight, wasting and stunting. Criteria for malnutrition was using standard guidelines from WHO\(^8\).

A qualitative design was very useful when the aim was to explore the value or reason behind a phenomenon\(^9\). Qualitative interviews were very suitable to examine the opinions and personal experiences of informants\(^10\). In this study, the result data of interview and observations were analyzed using content analysis and thematic analysis method\(^11\). Finally, data were presented as information in narrative and matrix form.

### Findings

#### Potential Causes of Problems in Toddler Nutrition Status:
The various topographical conditions of the West Lombok have different consequences. Although there are a number of problems that are considered to be generally applicable, for example, poverty and infectious diseases, there are some things that are typical according to regional characteristics. Specific problems are mainly in mountainous areas related to accessibility and availability of local food.

#### Table 1. Potential Causes of Problematic Nutritional Status in Toddlers in West Lombok District in 2015

<table>
<thead>

| The mountains (Duduk Atas Village) | Jul                | 1. Parents divorce, then stay with grandma. When grandmothers work, toddlers are left by neighbors.  
2. Inadequate breastfeeding complementary foods, often only consume rice mixed with warm water and salt.  
3. Limited external access.  
4. Socio-economic is low. |
|                             | Firm               | 1. Inadequate breastfeeding complementary foods, often only consume rice mixed with warm water and salt.  
2. Toddlers often get sick.  
3. Limited external access.  
4. Socio-economic is low. |
|                             | Nov                | 1. Inadequate breastfeeding complementary foods, often only consume rice mixed with warm water and salt.  
2. The eating habits of the family of instant noodles.  
3. Limited external access.  
4. Socio-economic is low. |
Based on Table 1, several factors related to the nutritional status of children are a family environment, infectious diseases, feeding patterns, parenting patterns, and poverty. Poverty is found predominantly in families of informant toddlers with nutritional problems.

The most common factor in the case of a toddler’s nutritional status in West Lombok is poverty. This factor is considered to have a direct influence on the nutritional status of children. Poverty which includes the family of toddlers greatly affects the ability of the family in an effort to provide quality food as an intake of nutritional resources for toddlers.  

Given the conditions in the target area, the environmental factors in which the family lives are considered to be a factor that influences the nutritional status of the child. Environmental conditions are very influential on the availability of food that can be accessed by the community. The environment is also considered influential in the way and efforts of the community in meeting their nutritional needs.

Another factor that was assessed as influencing the nutritional status of children in West Lombok Regency was the presence of infectious diseases, parenting patterns as well as the knowledge of toddler caregivers. The findings of these causal factors are in accordance with the conclusions of several other studies on nutritional status in toddlers. Good knowledge from mothers or caregivers of toddlers will also influence the pattern of parenting as well as patterns of feeding to toddlers.

“The child is a king”: The Value of Children that Questioned Again

For people who live in the West Lombok Regency, “the child is a king”, children are everything. So, they revealed when interviewed about the value of children for parents and family. However, based on the results of observations showing different situations. Often poverty makes parents of toddlers not have a choice. Poverty makes many parents of toddlers who are forced to choose to work outside the area. Being a labor force abroad is the choice that is finally taken by parents of toddlers. Although according to the family left behind, the results did not also bring economic goodness to the family.

“IT’s hard to find work here, there are many men who go abroad, there are a lot of people in Malaysia, so do in Saudi... “
(Pi, hamlet head, 54 years old)

“If they come home with a lot of debt, they have principles, they are already working exhausted, so to eat by themselves, no one thinks about being saved for the house.”
(Is, 15 years old)

In fact, toddlers who live in villages without biological parents are not kings. Toddlers whose parents become laborers abroad must be entrusted to their relatives or grandmothers. Observations on toddlers with nutritional disorders find the condition of children who are thin and short. Directly proportional to the pattern of parenting toddlers, eating patterns of toddlers entrusted is
also far from the value of “king”. The poverty condition that also applies to families entrusted makes toddler food intake also seems to be modest.

“There were fifteen months given milk, I forgot... when I was given rice... sometimes 10 months, now nothing wants... Al*-al* (instant drink) want, eat rice, eat alone... just rice sometimes given salt,sometimes just rice...”

(Sa, grandmother, 45 years old)

Although claiming that the child is king, the treatment of children shows different conditions. The pattern of care that applies in the target area in West Lombok Regency is the impact of the situation and poverty that includes the people in the region. Economic pressure makes parents have the heart to leave their children. In this situation the value of children is no longer economically valuable as is the value of children in Indonesia and other developing countries in general but it is more like the value of children in developed countries, which considers children to be a burden. For them, the value of children is more an obligation.

Given the situation in the target area in West Lombok Regency, the nutrition program administrators need to identify local food items with high nutritional value. This is an input of learning for the people of West Lombok in general, and mothers of toddlers in particular. Learning about processing local food ingredients to improve the nutritional status of children. The use of local food needs to be recommended to improve the nutritional status of children who are more sustainable.

**Conclusion**

Based on the results of research and discussion it can be concluded that the value of children is not related to the nutritional status of children. The main factor considered most related to the nutritional status of children in West Lombok District is poverty. While other factors that are also considered to be related are a family environment, infectious diseases, feeding pattern, and parenting patterns.

**Conflict of Interest:** None.

The Independence and the Quality of Life of Workers with Disabilities Caused by an Occupational Accident in Gresik and Sidoarjo, Indonesia

Indriati Paskarini¹, Tri Martiana², Tjipto Suwandì³

¹Student in Doctoral Program of Public Health, ²Lecturer in Department of Occupational Health and Safety, ³Lecturer in Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, Campus C Mulyorejo, Surabaya-Indonesia

Abstract

Introduction: An occupational accident causes a disability in workers. The disability condition will make the workers experience substantial limitations from every side of their life both in a social context and economic context, the dependence to their family, inability to live independently. The disability can also cause the workers to lose their job. The bad financial condition and the dependence give a negative impact on the quality of life of the workers with disabilities. The aim of this research was to analyze the influence of independence toward the quality of life.

Method: This research used a cross-sectional method. The population of this research was the workers with disabilities caused by an occupational accident in Sidoarjo Regency and Gresik Regency. The number of samples in this research was 182 participants. The sampling technique was done by using simple random sampling technique. The variables that were analyzed were the characteristic of the individual, the independence, and the quality of life. The measurement instrument for independence was done using Lawton-Browdy instrumental activities of daily living scale; the measuring instrument for the quality of life was done using WHOQol100 questionnaire (a standardized questionnaire). The data analysis was done using linear regression test with a significance level (α) of 0.05.

Results: Nearly 78% of participants had independence in the ‘moderate’ category with an average score of 81.51. The 78% of participants also had the quality of life in the ‘moderate’ category. Based on the regression test, it was obtained a result that the independence had a significant impact on the quality of life of workers with disabilities caused by occupational accident (p < 0.05).

Conclusion: The independence has a significant impact on the quality of life of workers with disabilities caused by an occupational accident. The better the worker’s independence is, the better the quality of life of the worker with a disability caused by an occupational accident is.

Keywords: Independence, Quality of Life, Worker with disability, Occupational Accident.

Introduction

The occupational accident rate increased sharply in the last five years. According to ILO, around 270 millions of work-related accident and 2 millions of fatality happen in the world every year. The number of occupational accident cases in East Java was 20,488 cases. The impacts of the occupational accident are as follows: functional disability, partial disability, total disability, and fatality. Based on the data of BPJS for employment in 2016, the 150 workers suffered from the functional disability and 135 workers suffered from the partial disability.

The workers with disabilities would experience...
substantial limitations from every side of their life in the social and economic context. The socio-economic risk suffered by the workers with disabilities is losing a job. The condition judged to be relative to the standard of an individual or group that the workers with disabilities had previously caused a big possibility for them to lose their job. If they get a new job, they will be paid below the standard. Such financial condition will give a bad impact on the quality of life of the workers with disabilities.

The quality of life is a life condition in the context of the system, value, and culture where they live based on the individual perception and related to the goal, expectation, standard, and the interest of each individual's life. According to David Felce and Jonathan Perry in Brown, the quality of life covers five domains i.e. physical well-being, material well-being, social well-being, emotional well-being, and productivity well-being. There are many factors affecting the quality of life; they are the physical, spiritual, and health condition, level of independence, the relationship with the social environment and the like. The decline in the quality of life is a consequence of the accident that results in disability condition.

An independence is an ability of someone for decision-making toward their life and the capacity to execute their tasks with full of responsibilities without relying on other people's help. The condition of workers with disabilities gives an impact on their independence level to do their basic daily activities such as bathing, eating, going to the toilet, preparing meals, shopping, and transferring/walking. The people with disabilities will feel uncomfortable if there is a person helping them to bathe, even in their own house. Sometimes, they will feel uncomfortable if they should wait for other people's helps to do their daily activities.

The research that has been conducted is generally about the influence of independence toward the quality of life of people with disabilities due to disease. However, the number of researches that select workers with disabilities as the research subject is less. The aim of this research was to analyze the influence of independence toward the quality of life of workers with disabilities caused by an occupational accident.

Method

This research was a descriptive research with a cross-sectional design. This research was conducted in Gresik and Sidoarjo. It was conducted from March to April 2018.

The population of this research was the workers with disabilities (diffabilities) due to an occupational accident in Gresik and Sidoarjo. The number of samples used in this research was 182 workers. It was determined using simple random sampling technique.

The data that had been collected was in form of primary and secondary data. The primary data of this research was obtained from an interview with the workers with disabilities caused by an occupational accident in Gresik and Sidoarjo. Meanwhile, the secondary data was collected from the document of the BPJS for employment (Social Security Administration Body for Employment) in Gresik and Sidoarjo. Then, the data that had been collected were analyzed descriptively and it was presented in form of narration that illustrated the variables that had been investigated.

The independent variable of this research was independence while the dependent variable was the quality of life. The measuring instrument used in this research was the standard measuring instrument composed by WHO that had been tested on the validity and the reliability. The measuring instrument for independence was Lawton-Browdy instrumental activities of daily living scale. Meanwhile, the measuring instrument of the quality of life used WHOQol-100 questionnaire (a standardized questionnaire). The data analysis was used for analyzing the regression between two variables using linear regression test.

Results

The result of this research was the sociodemographic characteristics, the independence level, the level of quality of life, and the influence of independence toward the quality of life.

Socio-demographic characteristics: The data of sociodemographic characteristics of the participants can be seen in table 1 below.
The research finding showed that 73.6% of the participants were men. Most of the participants (31.3%) aged around 40 years to 49 years and 84.6% of the participants were married. Most of the participants (86.3%) were still working after suffering from the disability. Nearly 75.8% of the participants suffered from a functional disability and the 61.5% of the participants suffered from disability in their fingers especially in their right fingers.

The Independence of the Participants: From the research finding, it was obtained that the maximum score for independence was 100 and the minimum score was 45.83. The independence covered the independence in self-care tasks (eating, bathing, dressing, and toileting) and independence in using the instruments (calling, washing, shopping, and using transportation), and vocational independence/managing finances. Almost all participants had independence in self-care tasks. They could do the self-care tasks without other people’s help. The average score of independence in self-care tasks was 99.9. The average score of instrument independence was 84.5. Meanwhile, the average score of vocational independence was 78.5. The independence was categorized into three categories i.e. low, moderate, and high. The 78% of the participants were categorized in ‘moderate’ category with an average score of 81.51. The complete data can be seen in table 2.

The Quality of Life of the Participants: From the research finding, it was obtained the maximum score for the quality of life of 100 and the minimum score was 25. The quality of life comprised six domains i.e. physical domain, psychological domain, the domain of the level of independence and productivity, the social relations domain, the environmental domain, and spiritual domain. The average score of physical domain was 53.26; the average score of psychological domain was 53.43; the average score of the domain of the level of independence and productivity was 52.71; the average score of the social relation domain was 68.78; the average score of the environmental domain was 57.5; and the average score of spiritual domain was 66.2. The quality of life was categorized into three categories namely low, moderate, and high. Nearly 78% of the participants were categorized in ‘moderate’ category with the average score of 58.64. The complete data can be seen in table 3 below.

The Influence of Independence toward the Quality of Life of the Participants: The workers with disabilities had low independence and 72.9% of them had a low quality of life. The result from cross tabs can be seen in table 4.
Table 4. The Crosstabs of Independence toward Quality of Life

Based on the linear regression test, it was shown that the independence of workers with disabilities caused by occupational accident had a significant impact on the quality of life. The result of the test can be seen in table 5.

The score for the influence of independence toward quality of life was \( p < 0.05 \). It means that the lower the independence level of workers with disabilities is, the lower the level of quality of life is.

**Discussion**

An independence is the ability of someone in decision-making and the capacity to execute the tasks for their life with full of responsibility without relying on other people. In a psychological dictionary, independence comes from a word “independent” that can be defined as a condition where someone does not rely on other people in making decisions and he or she has self-confidence character\(^{13} \). The independence of someone in living and working is strongly related to disability\(^{2} \). Disability gives an impact on job, social life, and the ability to be independent\(^{14} \). Most of the participants suffered from disability in their right fingers/hand. Their disability condition enabled them to be independent (the independence in self-care tasks). Some of them were less independent in instrumental independence (using instruments) and in vocational independence (managing financial matters). Most of the participants had independence in the ‘moderate’ category.

The disability condition did not only give an impact on the physical condition but also on the psychological condition. Someone will feel ‘little’, have no potency, and have no ability to live independently\(^{3} \), emotional, feel meaningless, feel useless, experience frustration, and depression\(^{6} \). The disability condition would result in the participation restriction in workers with disabilities in the world of work, and it would indicate an increase in financial burden. It caused the dependence to their family. The dependence on family (being dependent) gave a direct impact on the quality of life.

This research finding revealed that there was a significant impact on the quality of life of the workers with disabilities caused by an occupational accident. This showed that the higher the level of independence of the workers with disabilities was, the higher the quality of life they had and vice versa. Therefore, an attempt to form the independence in workers with disabilities caused by occupational accident was needed.

The quality of life of workers with disabilities caused by an occupational accident that was decreased at the beginning could be increased if they had a good support from their family and the company. The supports were to make them rise to the occasion, to increase their self-confidence for having a social relation, working, developing their potency, and forming their independence\(^{15} \). The workers who had suffered from disability caused by occupational accident would get
compensation/disability compensation from Indonesian Social Security Administration Body for Employment. The amount of compensation/disability compensation depends on the percentage of disability they suffer. The compensation/disability compensation received by the workers with disabilities caused by an occupational accident is very important. The compensation becomes the main requirement to live independently.  

To improve the socio-economic status in workers with disabilities, the strategy for eliminating the physical and social obstacles and promoting health and welfare/well-being/quality of life is needed. It can be inferred that the level of independence of someone gives an impact on the quality of life of the person. Delcourt, et.al stated that the domain of independence was the most influential domain in the quality of life in stroke survivor.

**Conclusion**

The independence of workers with disabilities caused by occupational accident has a significant impact on the quality of life. The lower the level of independence of workers with disabilities is, the higher the quality of life they have.

**Conflict of Interest:** Nil

**Source of Funding:** Nil

**Ethical Clearance:** Received from the Ethics Committee of Faculty of Public Health, Airlangga University, Indonesia.

**Recommendation**

a. Creating an accessibility to eliminate the physical and social obstacles (being dependent) for the workers with disabilities caused by an occupational accident.

b. Strengthen the regulation and the promotion for the workers with disabilities to be able to maintain their quality of life.

Effect of Sleep Duration on Physical Activity among Hypertensive Patients in Bogor, Indonesia

Inggriani Priscilia¹, Ratu Ayu Dewi Sartika¹

¹Department of Nutrition Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

Objectives: Physical inactivity has become a global health concern that is associated with consequences such as premature death. In particular, lack of physical activity may impair blood-pressure control, potentially causing complications in hypertensive patients. The general objective of the present study was to elucidate the effect of sleep duration on physical activity of hypertensive patients of the Puskesmas Tegal Gundil in Bogor City, Indonesia.

Method: This study using a cross-sectional analysis with 97 hypertensive who were treated at the Puskesmas Tegal Gundil in 2017. Physical activity was determined using the Global Physical Activity questionnaire, and items about sleep duration, sleep quality, and stress, from the Pittsburgh Sleep Quality Assessment, and Perceived Stress Scale questionnaires. Results: The results from this study showed that 32% of the respondents had less of physical activity.

Conclusion: Physical activity was found to be unrelated to sleep duration; in contrast, higher age was associated with less physical activity in patients with hypertension.

Keywords: Age, Hypertension, Physical Activity, Lifestyle Induced Illness, Sleep

Introduction

The global prevalence of hypertension has been increasing in recent years, making its control and prevention a matter of growing importance.¹ Physical activity is recommended as a lifestyle modification to prevent and control hypertension. Epidemiological and experimental studies have shown that there is a relationship between physical activity and blood-pressure reduction in patients with hypertension.² ³ Understanding of a lack of activity can be done by way of someone not doing physical activity for at least 30 minutes per week.⁴ The report by World Health Organization has claimed that physical inactivity is responsible for 1% of Disability Adjusted Life Years (DALYs) that are lost globally.⁵

Physical inactivity has become a major global health problem, and it is associated with premature death.⁵ In Nigerian study showed that 31.4% of adults with hypertension engaged in low levels of physical activity.⁶ In North Tomohon, Indonesia, 36.6% of the population with hypertension showed only mild levels of physical activity.⁷

Patients with hypertension who do not engage in physical activity may develop poor blood-pressure control, which may lead to additional complications. Several factors cause hypertensive patients to reduce their routine physical activity, such as reduced duration of sleep⁸, Age⁹, gender¹⁰, occupation¹¹, body mass index.¹², stress¹³, and sleep quality.¹⁴

Limited duration of sleep is an important factor underlying the lack of physical activity in hypertensive patients because can causing of sleep problems, such as obstructive sleep apnea that occur in hypertensive patients.¹⁵,¹⁶

Sleep deprivation may lead to increase in sleepiness and reduction in physical activity during the day.⁸

Physical inactivity in hypertensive patients can cause several complications. This study aimed to determine whether there is a relationship between sleep duration and physical activity in hypertensive patients.

**Material and Method**

This study was performed on cross-sectional data obtained from a group of hypertension respondents. This research was performed in May until July 2017. Physical activity was chosen as the dependent variable, whereas sleep duration and other potential risk factors including age, gender, occupation, body mass index, stress, and sleep quality were chosen as independent variables. A purposive sampling approach in the study, by which 97 respondents who met the following inclusion criteria were selected: hypertensive patients aged 30–65 years registered as participants in the Program Penanggulangan Penyakit Kronis (Prolanis) or Chronic Disease Program and Pos Pelayanan Terpadu (Posbindu) or an integrated health service programme.

The instruments used in this study: BMI was calculated based on measurements of the patient’s weight and height (categorized as overweight BMI score ≥25 kg/m² or normal BMI score <25 kg/m²). Level of physical activity was measured using the WHO Global Physical Activity Questionnaire (categorized as “less active” <600 MET/min or “active” ≥600 MET/min). Sleep duration and sleep quality were measured using Pittsburgh Sleep Quality Index: sleep duration categorized as “unfulfilled” (<7 h) or “fulfilled” (≥7 h) and sleep quality categorized as “bad” (score, ≥5) or “good” (score, <5). Stress were measured by the Perceived Stress Scale (Categorized as “stress” ratio score ≥13 or “no stress” ratio stress <13). Age categorized as “late-age adult” (45–64 years) or “middle-age adult” (25–44 years). Gender categorized as “female” or “male”. Occupation categorized as “employed” or “unemployed.”

**Findings:** The characteristics of respondents in this study are shown in Table 1. Based on the results of bivariate analysis (Table 2), the incidence of “late adulthood” hypertension has a risk of 3.77 times for physical activity “less active” (value p < 0.05).

**Discussion**

The results showed that 32% of our hypertensive patients had less active. Regular physical activity may reduce the risk of coronary heart disease and stroke, diabetes, hypertension, colon cancer, and depression. In addition, it may reduce the occurrence of complications in patients with hypertension. Physical activity with WHO recommend that individuals are regarded as physically active when their physical activity is at least 600 MET/week.

In this study was found that someone who is less active is found in people who have sufficient sleep by 34.8%. Petterson et al.\textsuperscript{18,19} has said that who found that individuals with a long duration of sleep tend to be lacking in physical activity. This may have something to do with the fact that some people have irregular sleep patterns that can affect their daily sleep.

In this study was found that “less active” levels of physical activity were found more often in “late-aged” hypertensive patients (37.3%). This was supported by a significant relationship between age and physical activity that Late-aged hypertensive patients has a 3.77 times higher chance of having a “less active” physical activity levels. This observation is in line with the outcome of a study by Gómez-Cabello et al.\textsuperscript{20} has said that physical activity decreases substantially with age.

Physical function refers to the strength of muscles that reaches its peak at ages between 25 and 35 years, slightly decreases between 40-49 years, and significantly declines at ages of 50 years and above. Ageing will complicate physical activity due to a declined physical condition and the emergence of illnesses also associated with a decrease in physical capacity as experienced subjectively by individuals, which also tends to decrease physical activity levels.\textsuperscript{21} Sarkisian et al.\textsuperscript{22} has said that there was a relationship was found between age and physical activity because individuals heighten their life expectancy when engaging in regular physical activity.

In this study, no significant difference was found between genders on physical activity. This is consistent with results reported by Finkelstein et al.\textsuperscript{23} and Touvier et al.\textsuperscript{24} have said that there was no relationship between gender and physical activity. Although this was found in the present study, a larger proportion of women were found to engage in mild physical activity (32.9%) than men (25%). This confirms the outcome of the study by Azevedo et al.\textsuperscript{25} has said that women showed lower physical activity than men, that age 20 years and older.

Furthermore, we found that 33.3% of respondents who were unemployed had a “less active” level of physical activity. The reason for this may be that...
individuals who do not work or have retired do no longer engage in physical activities related to work, such as commuting. This is in contrast to observations by both Shaw and Spokane\textsuperscript{26} and Finkelstein et al\textsuperscript{23} have said that there exists a relationship between work and physical activity. Individuals who do not work are more likely to spend time at home performing sedentary activities such as watching television, sitting, lying, playing cards, and reading.

In the results of bivariate analysis using chi-square tests showed no significant relationship between body mass index and physical activity level. In our study, a “less active” physical activity level was found in 35.1\% of individuals belonging to the normal nutritional status group. This confirms the findings of Ingledew and Sullivan\textsuperscript{27} and Jensen and Steele\textsuperscript{28} have said that individuals who consider themselves to be overweight tend to perform physical activities regularly to lose weight compared to individuals who do not.

In this study show that the proportion of respondents with “less active” physical activity levels who were not stressed was 32.1\%. This is not in line with previous studies, indicating that stress can interfere with a person’s capacity to engage in physical activity because of stress-related impact on brain functioning, which may negatively affect the overall physical condition. Short or long sleep duration may have multiple endocrine-related effects, including increases in blood levels of stress hormones such as catecholamines and cortisol. Increased levels of stress hormones may interfere with the brain’s efforts to cope with stressful situations and render individuals less motivated to engage in physical activity.

Although no significant relationships were found between the quality of sleep and physical activity. Less active were found in 33.3\% of respondents with poor sleep quality. This confirms the results from studies by Lee et al\textsuperscript{4} and Chang and Chen\textsuperscript{29} have said that individuals who experience poor sleep quality show decreases in regular physical activity. A possible reason for this finding is that poor sleep quality may cause decreases in limiting physical activity during the day, cumulative effects on energy levels like eating to much food or uncontrolled to eat food, and perturbing emotional regulation.\textsuperscript{30} The discomfort experienced by individuals as a consequence of poor-quality sleep may also cause persons to lose their ability to maintain healthy behavior.\textsuperscript{31}

## Conclusion

The observed prevalence of “less active” levels of physical activity in hypertensive patients at Puskesmas Tegal Gundil was observed to be 32%. Hypertensive patients aged between 45 and 64 years showed a lower level of physical activity. This suggests the usefulness of the Puskesmas especially Prolanis and Posbindu to stimulate exercise by 30-minutesessions with gymnastic exercises two to three times per week.

Abstract

Children are what every family is longing for. All families expect their children to grow up optimally and healthily for both their mental and physical so that they will be able to perform their daily life excellently and become the reliable human resource for the nation. As the nation’s asset, children need to get a proper attention since in the womb until reaching adult age. The objective of this study was to analyze the correlation between parenting (especially eat-fostering behavior) and the children’s nutritional status in Cikarawang Village, Bogor. This was a cross sectional study. The subject of this study was children with the age that ranges between 12-59 months. The data regarding the subject’s characteristic and socio-cultural characteristic were obtained from an interview with the toddler’s mom. Anthropometry data including body weight and body height were obtained by directly measuring the subjects. The data regarding eat-fostering behavior were obtained from interview using questionnaire. The proportion of children with malnutrition and good nutrition was 40% and 50%. There was no correlation between eat-fostering behavior and mother’s education, with p>0.05.

Keywords: Nutritional status, eat-fostering behavior, mother’s education.

Introduction

The advancement of a country is highly related to its human resource quality, while human resource quality of a country is reflected from the country’s health level. The health level describes individual, group, or society’s health condition which is reflected from Life Expectancy Index, mortality, morbidity, and nutritional status of children under five. Children are precious subject for a family. All families expect their children to grow up optimally and healthily for both their physical and mental so that they will be a qualified human resource for the country. As the nation’s asset, children need to receive attention since in the womb until they reach adult age.(¹)

The factors that affect children’s nutritional status are categorized as direct factors and indirect factors. Direct factors include food adequacy and children’s health. Meanwhile, indirect factors include family’s food security, nursing of mother and child, and environment’s sanitation. Generally, a child’s major need is food. Food highly affect children’s growth. Food adequacy is needed for the children to grow up in accordance to their genetic ability. Children’s basic needs to help them grow are categorized into three things, they are asah, asih, asuh (teach, love, care for).(²) Physical growth is often used as a measurement of children’s nutritional status for both individual and population. Parent’s role is an important focus in the effort of nurturing children’s nutritional status.(³)

Based on the data of Riskesdas 2013, the prevalence of underweight, stunting, and wasting in West Java and Bogor regency was considered high. The prevalence of underweight in West Java was 15.7% which consists of 4.4% malnutrition and 11.3% undernutrition, while stunting was 35.3% and wasting was 10.9%. The prevalence number of underweight in Bogor Regency was 14.3% which consists of 1.6% malnutrition and 12.7% undernutrition. From the mentioned data, it can be concluded that the prevalence of undernutrition in Bogor Regency was higher than in West Java. Besides that, the prevalence of stunting in Bogor Regency was 28.3% and wasting was 5%. According to the Riskesdas
in West Java and Bogor Regency, the prevalence of undernutrition and stunting was higher for 12-59 months children than for 0-11 months children.\(^{(4)}\)

Parenting (fostering behavior) is an attitude and behavior of the parents in their interaction with their children. These attitudes and behaviors are able to be observed from parents’ way to discipline their children, to foster their children’s emotion, and to control them. To educate basically means a real effort of the parents to evolve the total potential of their children. The children’s future is highly affected by their experiences, including their parents’ way to foster them.\(^{(5)}\)

The children in rural area tend to have poorer nutritional status compared to the children who live in the urban area. A research regarding eat-fostering behavior for children under five found that 57.1\% children under five in rural and urban area suffered undernutrition. However, according to the other research regarding Positive Deviance of the children’s nutritional status, the children from low-income family that possess a good eat-fostering behavior actually had an ability to optimize their nutritional status.\(^{(6,7)}\)

The role of a mother is considered very important to the growth of the children. According to the previous studies, there were several conclusion regarding this notion. First, there were correlations between mother’s eat-fostering behavior and the children’s nutritional status. Second, eat-fostering behavior held an important role on the children’s growth disorder. Third, parenting affected children’s growth through food adequacy and health condition.\(^{(8)}\) Therefore, this study aims to analyze the correlation between mother’s eat fostering behavior and the children’s nutritional status in Cikarawang Village, Bogor.

**Methodology**

The design of this study was cross sectional study. The subject of the study was children under five (12-59 months). This study was conducted from January 2018 to April 2018. Data processing, analysis, and interpretation were conducted in the Department of Community Nutrition, Faculty of Human Ecology, Bogor Agricultural University. The sampling technique that was used in this study was purposive sampling in accordance to these criteria: a complete family, having a child under five, and willing to be involved in the study as a respondent. The sample number was determined using a particular formula.\(^{(9)}\) The data that were used in this study was primary data. These primary data that were collected consist of the children’s body weight, the children’s body height, the mother’s eat-fostering behavior, the mother’s knowledge regarding nutrition. Anthropometry data which include body weight and body height were obtained from a direct measurement. The data regarding the mother’s eat-fostering behavior were obtained from interview using questionnaires. This research study had passed ethical review number 130/IT3.KEPMSM-IPB/SK/2018.

<tr>
<td>Total</td>
<td>40</td>
<td>100</td>
</tr>
</tbody>
</table>

Based on Table 1, the percentage of children having ‘good nutrition’ status based on surpassed half the total number and reached 60\%. This result indicated that the nutritional status of children under five in Cikarawang Village was considered good. Body weight is one of the parameters that describe the current or past body mass. The status of ‘good nutrition’ is able to be achieved if someone’s body receives enough essential nutrition substance.\(^{(9)}\) However, the percentage of children with undernutrition in Cikarawang Village was higher than in West Java and Bogor Regency which were 11.3\% and 12.7\%.\(^{(4)}\) This means that the problem of undernutrition is still an important concern for Cikarawang Village, Bogor Regency. The result of this study was consistent with the study that was done by Rona in 2016. The mentioned research study resulted 36\% children with undernutrition. If the data of this study and Rona’s study are merged, the percentage of undernutrition status will be higher.\(^{(10)}\) The study stated a possible correlation between children’s nutritional status and their mother’s education level. When the study was conducted, 62.5\% of children’s mother possessed a low education level. The stages of formal education in Indonesia based on Indonesian Republic Government Act No 66 the year of 2010 are divided into elementary education, middle stage education (middle school and high school) and higher education (college education including diploma, bachelor, master, and doctorate). The result of this
study revealed that most respondents (mother’s child) possess an elementary school certificate only. Their percentage was 28.5%. However, the research study of Fardhiasih stated that there was no correlation between nutritional status and mother’s education level since the information technology is getting advanced nowadays. The advancement of information technology makes it easy for mothers to access information from various media including information regarding nutrition and parenting.\(^{(11)}\)

The next factor that affects children’s nutritional status in this research study was income of the family. All family’s income of the respondents was earned by the fathers. All of the mothers (100%) were housewives. Most of the fathers worked as non-agricultural laborer, the percentage was 57.5 %. However, the research study of Fardhiasih stated that there was no correlation between family’s income and children’s nutritional status since under-standard income families were still considered able to afford normal food that contains nutrition which is needed by the body.\(^{(11)}\) Meanwhile, the other research study stated that there was a correlation between family income and children’s nutritional status.\(^{(12-13)}\) This means, low-income led to the low ability to afford food which contains adequate nutrition. The low quantity of food consumption also led to the risk of infection diseases and eventually caused a low level of nutrition in the body.\(^{(14)}\)

<table>

<tr>
<td>------------------------</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Less good</td>
</tr>
<tr>
<td>Good</td>
</tr>
<tr>
<td>Total</td>
</tr>
</tbody>
</table>

Based on Table 2, eat-fostering behavior that was considered good was performed by mothers that did not go to school (32.5%). According to the statistic test, there was no meaningful correlation between eat-fostering behavior and mother’s education with p-value p>0.05. Eat-fostering behavior is the practice of fostering which is applied by a mother to her children regarding children’s dietary and eating behavior in order to give adequate nutrition for the children.\(^{(15)}\) Eat-fostering behavior in Cikarawang Village was considered less good (55%), however, the mothers possess a considerably good knowledge (55%) regarding children’s dietary and nutrition because of the technology advancement that helps them in accessing useful informations. Besides that, the help of kaderposyandu—people that are trained to help families in raising their children according to the government’s program—which diligently shares their knowledge to the mothers regarding children’s dietary and nutrition. Based on the literature, the higher the education level of someone, the easier they understand given information. The easier they understand the information, the easier they implement the concept into their practice. Therefore, a mother’s education level will eventually affect the mother’s behavior and attitude in facing the matter of children’s dietary and nutrition.\(^{(16)}\)

The study that was done by Erny in 2012 stated that statistically there was a significant difference in parent’s education level between normal children and children with stunting p>0.05. Parent’s education level highly affect their parenting behavior since the higher education led to a better understanding on the importance of parents’ role for their children’s growth. The parents which possess a higher education level are expected to have a good knowledge regarding children’s dietary and nutrition, and they will eventually understand the proper way to process foods and to manage the children’s behavior so that the children receive adequate nutrition. The knowledge of nutrition means the ability of mothers to arrange the daily dish, and to process various foods that are needed by their children.

**Conclusion and Recommendation**

Based on the research study that was conducted in Cikarawang Village, Bogor Regency, there was still undernutrition case which took 40% of the total respondents. There was no overnutrition case that was found in the village. Eat-fostering behavior of the parents. Eat-fostering behavior in the Cikarawang Village, Bogor Regency was considered less good (55%), however, the mothers have a considerably good knowledge 55%. There was no correlation between the mother’s education level and eat-fostering behavior (p>0.05). Most of the mothers did not go to school for their formal education, however, they have adequate information regarding children’s dietary and nutrition with the help of technological advancement. A further research study regarding this topic is encouraged to be conducted. For instance, the support of fathers and
psychosocial parenting on the growth monitoring of the children under two, and the research regarding pre-post positive deviance especially the issues of status through the increase of women’s knowledge and women’s empowerment for the optimal growth of children under two by conducting several training events.

The Correlation IUDs Use Duration and Types of IUDs with Blood Curprum (Cu) Levels in Women with IUD Contraception: A Cross-Sectional Study

Didik Agung¹, Abdul Rohim Tualeka¹, Denny Ardyanto¹
¹Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, Kampus C, Surabaya

Abstract
An increase in population, especially in developing countries can have a negative impact if it is not balanced with the welfare of the population. Therefore, Indonesia provides a policy to use contraceptive devices for the population. One contraception used is an IUDs. The concept of the IUD itself has reportedly had a negative impact, especially increasing colonization by Candida spp. due to the content of Curprum (Cu) from the IUD. The purpose of this study was to analyze the relationship between duration of use and type of IUD at blood Cu levels in female workers using an IUD contraception. This research has never been done in Indonesia. The results showed that the majority of respondents used the Copper T type IUD, having an age range between 36-49 years with an average duration of IUD usage of 7.1-7.5 years with a mean value of Cu levels that exceeded the normal cuprum values allowed in the body. The IUD type variable has a moderate correlation between the levels of cuprum in the blood of workers (p = 0.435). The old variable using the IUD has a strong correlation with the cuprum levels in the blood of the respondents (p = 0.74). Conclusion: The type of IUD and the duration of use of the IUD have a relationship with levels of Cu in the blood. Women who use an IUD are expected to consume foods that have a high content of antioxidants to reduce levels of Cu in the blood.

Keywords: Copper T, Curprum (CU), IUD, Lippesloop.

Introduction
In ten years, Indonesia’s population increased rapidly by 32.5 million from 205.1 million in 2000 to 237.6 million in 2010¹-². In balancing population growth very quickly, the government has always tried to suppress population growth through the Family Planning Program (KB) to play an active role in creating the welfare of the Indonesian population².

An IUD (Intra-Uterine Device) is a small object of flexible plastic, most of which have copper coils (Copper, Curprum, Cu), but some are not metallic, some have hormones³. The actual mechanism of this IUD tool is unknown. One theory says that the device can increase the fallopian tube peristalsis which makes the fertilized ovum enter the uterus in a condition that is not sufficiently developed so that it cannot properly implant.⁴

Side effects from the use of injectable hormonal birth control method are erratic bleeding, the occurrence of amenorrhea, increased body weight, headache, pregnancy may still occur by 0.7%, sporting, metrorrhagia, vaginal discharge and hematoma. Based on another research, a history of mothers using a combination of progesterone estrogen contraception has a risk of cervical cancer 17,875 times compared to women who do not use progesterone estrogen combination contraception⁵. The results of Sipra Bagchi’s research showed that
33% of users of IUDs with 33.7% Cu were abnormal in cervical cytology. Another results of research show colonization by Candida spp. and mycoplasmic infection was diagnosed significantly more frequently after one year of use of Cu-IUD than at the start. During the study period, women who used Cu-IUD complained significantly more often experienced vaginal discharge, pelvic pain, and increased menstrual flow.

This research has never existed before in Indonesia. Therefore, it is necessary to conduct a study on the correlation of the use of IUDs with Cu levels in the blood of female workers in the University of X’s Public Health Faculty as the main form of preventive prevention of effects on IUD use.

Materials and Method

The population subjects were all 10 Intra Uterine Device acceptors at the University X Faculty of Public Health. Samples are objects that are studied and are considered to represent the entire population. The sampling technique in this study is a total population of 10 people.

This study used an observational type with cross-sectional design. This research was conducted at the Faculty of Public Health, University of X. The research was conducted in December 2017 until April 2018. Prior to the study, respondents were given informed consent and guidance on the procedures for the study was conducted for 10 minutes before the study began. After the respondent gets an explanation of the research that will be conducted, respondents who agree to be involved in this research are expected to fill in the consent sheet to be the research respondent who was signed by the respondent. Next, the respondent is registered and takes the measurement queue number. This research has received ethical approval from the Ethics Committee of the Public Health Faculty of Airlangga University with ethics number 136-KEPK.

Subjects will be conducted the in-depth interview by using structured interviews with questions in the form of age, type of IUD, duration of IUD usage. The subjects will also be measured Cu levels in the blood by taking blood samples. Initially, blood veins were taken in one cubic vein of 2-3 cc using a syringe, then blood mixed with anti-coagulant so as not to thicken, after blood enters the tube until the desired volume, the needle is ready to be extracted and the blood sample is then examined using tool photometry.

Data analysis was performed using the Spearman correlation test and Pearson correlation test with SPSS Inc version 21. The classification of the correlation coefficient interpretation is as follows.

Source: Sugiyono (2010)

Result

Figure 1. Distribution of Mean, Standard Deviation, Minimum-Maximum Value at Age, Duration of Use and Cu Level based on Types of IUDs

Source: Primary Data, 2018
Most of the respondents (80%) used Copper T IUDs. Respondents who used Copper-T type IUDs were 38 years old on average, respondents who used the Lippesloop type IUD were 39 years on average. The average respondent who used a Copper T IUD had an IUD usage period of 7.1 years and 7.5 years for a Lippesloop type IUD. All Cuprum blood serum levels in the respondents are in the abnormal category (normal = 0.7-0.12 g/dl).

The correlation coefficient between age and Cu content of 0.178. This can be interpreted that age has a very weak correlation with the blood cuprum levels of workers. The average respondents using Copper T IUDs have a cuprum content of 3.54 g/dl. While the average respondent using the Lippesloop type IUD has a cuprum level of 2.952 g/dl. The type of IUD also has a moderate correlation with the blood serum levels of workers (p = 0.435). The average respondents who used an IUD for 1-4 years had a cuprum level of 3.693 g/dl. The average respondent who uses an IUD for 5-8 years has a cuprum level of 3.187 g/dl. The average respondent who uses an IUD for 9-12 years has a cuprum level of 3.116 g/dl. The duration of use of the IUD has a strong correlation with the blood serum levels of workers (p = 0.74).

**Discussion**

Most of the respondents (80%) used an IUD with the type of Copper T. Copper T type IUDs are made of polyethylene and in the vertical part are given fine copper wire windings. Lippes Loop is made of polyethylene, the shape is like a spiral or a continuous S letter. The results showed that the highest Cuprum levels in the respondent’s blood were found in respondents who used Copper T IUDs of 4.298 g/dl. The results of the examination showed that Cuprum levels in the blood were above normal. This shows that all types of IUDs, either Copper T or Lippesloop, have the same risk for exposure to Cuprum metal, even though the Lippesloop IUD does not contain copper. Metal toxicity in humans is influenced by several factors, namely the dose/metal content that enters, length of exposure, age, gender, eating habits of certain foods, physical conditions, the ability of body tissues to accumulate metals. The presence of Cuprum levels in respondents who use the
Lippesloop IUD is possible from eating certain foods containing cuprum.

The average age of respondents using IUD copper T is 38.12 years, with the youngest age 29 years while the oldest age is 49 years. The average age of respondents using the Lippesloop IUD was 39.5 years with the youngest age 36 years and the oldest age 43 years. Based on the table data shows that cuprum exposure can occur in all age groups. At a younger age, it is more risky because it is seen from the results of the study showing that the increasing age of the respondent, the percentage of the cuprum in the blood above normal, the smaller This can be caused by increasing age the resistance of certain organs is reduced to the effects of cuprum. The older a person is, the higher the concentration of the cuprum accumulates in the body tissues, because increasing age means that the cuprum toxicokinetics decreases.

The average length of use of copper T IUD is 7.1 years with the largest usage time is 12 years and the smallest is 1 year. The average use of the Lippesloop IUD is 7.5 years with the largest duration of use which is 11 years and the smallest is 4 years. Metal toxicity in humans is influenced by several factors, namely the dose/metal content that enters, length of exposure, age, gender, eating habits of certain foods, physical conditions, the ability of body tissues to accumulate metals\textsuperscript{10}. Copper plays an important role in the homeostatic mechanism in the human body, but excessive exposure can cause harmful effects on health. Copper exposure to the body can cause damage to fat, DNA and protein\textsuperscript{11}. Levels of Cuprum of blood for all workers exceed the standard levels of cuprum allowed. The duration of IUD use has a strong correlation with the blood levels of the cuprum in the respondent's negative direction. Therefore, it is recommended for respondents, especially with the average IUD usage of 7.1-7.5 years to increase consumption of foods containing high glutathione and low levels of copper (antioxidants), for example asparagus, broccoli, tomatoes, grapes, peas, especially in initial installation of Copper T type IUDs that can reduce the risk of negative effects on the IUD.

Feasibility Study Development of Hemodialysis Services in Sidoarjo Hospital

Jaufan Fata Almadani

Faculty of Public Health, Universitas Airlangga

Abstract

Hemodialysis services must be owned by hospitals to handle cases of patients with increasing kidney disease. This study aims to conduct a feasibility study on the development of hemodialysis services in Sidoarjo hospital. This study assesses the feasibility of developing hemodialysis services based on aspects of needs, feasibility of development and financing. We took demographic data and internal data from hospital management and Hemodialysis Installation. The study found that from the aspect of need, hemodialysis services are needed in Sidoarjo hospital, and from the feasibility aspects of development based on the needs of building land, facilities, human resources and equipment, Sidoarjo hospital can fulfill these needs. But from the aspect of financing, considering the highest number of patients are Board of Health Insurance, so the income for Sidoarjo hospital is very small and very difficult to achieve profits.

Keywords: Hemodialysis Services, Needs, Feasibility, Financing.

Introduction

Kidney disease is a degenerative disease and has various types such as Glomerulonephritis, Kidney Amyloidosis, Diabetic Kidney Disease, Renal Vascularity, Urinary Tract Stones, Tubulointerstitial Diseases, Urinary Tract Infection, Chronic Kidney Disease, Acute Kidney Failure and many more. Kidney failure is grouped into two broad categories: (1) acute kidney failure, where the whole or almost the entire work of the kidney is suddenly interrupted but eventually can improve again as usual, and (2) chronic kidney failure, also known as CKD (Chronic Kidney Disease), where the kidney progressively loses its nephron function one by one gradually until all of its kidney function decreases/is damaged.

Handling of kidney disease can be done in various ways, starting from controlling blood pressure, diet regulation, pharmacological therapy, fluid and electrolyte restriction, to kidney replacement therapy (Renal Replacement Therapy) which can be in the form of hemodialysis, peritoneal dialysis or kidney transplantation. Patients with stage 5/ESRD (End Stage Renal Disease)/terminal stage kidney disease/terminal renal failure (GGT) require kidney replacement therapy (Renal Replacement Therapy), one of which is hemodialysis (HD), where the number of patients currently in need Hemodialysis is increasingly increasing in number and of course requires a lot of medical expenses.

Based on data from the World Health, it is said that worldwide the number of people receiving renal replacement therapy is estimated at more than 1.4 million, with an incidence of about 8% per year. Indonesia is one of the countries with high rates of kidney failure, according to the Indonesian Nephrology Association (PERNEFRI) in the Report of the Indonesian Renal Registry, in 2012 there were 16,040 patients with kidney failure. Reported in 2012 only 9,161 patients were active in hemodialysis activities. In Jakarta alone, there were 1,192 hemodialysis patients with various diagnoses of major diseases.

Hospital is a health service institution for the community with its own characteristics that are influenced by the development of health science, technological advances, and the socio-economic life of the people who are still able to improve services that are more quality and affordable by the community in order to realize high health. Sidoarjo hospital is a type B education hospital which is a hospital owned by the Sidoarjo government. Increasing competition in the service sector at this time, makes Sidoarjo hospital must be able to maintain its
existence in this era of competition, without neglecting the quality and safety of patients in the hospital.8,9

One of the areas in the hospital that is a priority in the effort to improve the quality of service in the hospital is hemodialysis services that have increased the number of patients in recent years10. The number of kidney failure patients each year has increased by about 15%. Cases of kidney failure in patients who seek treatment and require the most hemodialysis due to diabetes cases are around 33%, and increase from year to year. The availability of hemodialysis machines in Sidoarjo hospital as many as 19 machines was felt to be still lacking, so that a number of hemodialysis machines had been added up to now reaching 23 hemodialysis machines. However, the availability of hemodialysis machines is still insufficient11.

In Sidoarjo, there are 4 hospitals that have hemodialysis services, namely Sidoarjo hospital with 23 units, Mitra Waru hospital with 4 units, Delta Surya hospital with 4 units, Siti Khodijah hospital with 4 units and Siti Hajar Sidoarjo hospital with 10 units. According to data at Siti Hajar Sidoarjo hospital, every month there are 3-5 additional cases for dialysis. While in Sidoarjo Hospital, there are still many patients who cannot be served for hemodialysis, one of them because of the limited number of HD units. More than 400 patients with Chronic Kidney Disease undergo hemodialysis at the Sidoarjo hospital at present. Because of the excessive number of patients with Chronic Kidney Disease, they are forced to queue to get hemodialysis services. Because, the number of hemodialysis machines in Sidoarjo Hospital is very limited to only 23 machines. Therefore, hemodialysis services at the hospital are divided into three shifts. In the morning shift, service starts at 6:30 a.m. to 11:00 p.m. The afternoon shift starts at 12:00 until 16:00 and the afternoon shift starts at 17:00 to 20:00. Within a day, the average number of dialysis patients reaches 69-70 people. Seeing these conditions, Sidoarjo hospital was moved to plan the construction of buildings for hemodialysis, with the addition of hemodialysis units reaching 50 units in 2018 and 100 units in 201912,13.

In accordance with the need to develop a Hemodialysis unit with the planning of adding a hemodialysis machine in Sidoarjo hospital, a comprehensive analysis of all matters related to the feasibility study or Feasibility Study is needed. This study aims to conduct a feasibility study on the development of hemodialysis services at Sidoarjo hospital.

Method

Starting from general data collection including geographic data, demographic data and morbidity data in Sidoarjo, the team also began taking internal hospital data and the productivity of hemodialysis services. From the general data and internal data, then an analysis is conducted to find out the need for the development of hemodialysis services at Sidoarjo hospital through forecasting calculations. Forecasting calculations are carried out based on the normative needs of hemodialysis. The team also collected special data on hemodialysis installations covering data on land, buildings, infrastructure, human resources and equipment. Furthermore, the special data is carried out a feasibility analysis by comparing the hemodialysis service standards with real conditions. The team also conducted an analysis of internal factors, especially regarding the quality of hemodialysis installation services at the Sidoarjo hospital at present. From the analysis data, the team can analyze the feasibility of developing hemodialysis services at Sidoarjo hospital.

Result and Discussion

Hemodialysis Service Needs in Hospital: Based on the geographic data description that Sidoarjo hospital is in the center of Sidoarjo area. Sidoarjo hospital is a place of reference for hospitals and health centers in the surrounding area. Among other things is the Krian, Mojokerto, Pasuruan, Bangil area. As well as based on demographic data from Sidoarjo population which is associated with an estimated prevalence of chronic kidney failure of 0.2%, the increasing number of patients who need hemodialysis will also increase. Besides that, the higher the awareness of the population towards health and the high number of patients who use facilities of national health insurance, there are data on the increasing number of hemodialysis patients with facilities of Board of Health Insurance.

Data in 2014 showed that end stage Renal Disease (ESRD) was in 4th place out of the top 10 diseases in Sidoarjo District Hospital. In the following year, 2015 and 2016 stated that End Stage Renal Disease (ESRD) disease had increased so that it was ranked 3rd in the 10 most diagnosed inpatients in Sidoarjo Hospital. This shows the higher cases of kidney failure treated in Sidoarjo hospital. With the description of the increasing number of kidney failure patients in Sidoarjo Hospital comparable to the increasing number of patients who require hemodialysis services.
Data on mortality of kidney failure patients in Sidoarjo hospital from 2014 to 2016 has decreased. This shows the success of the national health insurance program so that people can perform hemodialysis services regularly to maintain their health. This is in accordance with the description of the increasing number of active patients who need hemodialysis services\(^1\).

Based on the analysis of hemodialysis service needs according to geography, demography, socio-economic, mortality and morbidity in Sidoarjo, Sidoarjo hospital is feasible to develop hemodialysis services.

Based on forecasting calculations, it was found that up to 2027 it is estimated that the number of regular hemodialysis patients is 574 patients with a normative assumption so it is predicted that hemodialysis in 2027 with the highest estimate of 59,727 actions. Thus, a machine and bed are needed with the highest estimate of 103 in 2027. This includes the need for infectious patients as much as 3 machines.

Based on the hours of hemodialysis services at Sidoarjo hospital currently divided into 3 sessions a day, the need for hemodialysis services is very high. In accordance with the organizational consensus to ensure maximum or adequate results, the duration of hemodialysis is 5 hours. For the final results that are in line with expectations, a number of hemodialysis machines are needed. By using aspects of internal needs, it can be concluded that Sidoarjo hospital is feasible to develop hemodialysis services for 103 machines and bed.

Feasibility of Hemodialysis Service Needs at Sidoarjo Hospital: Based on the analysis of the feasibility of building land, it can be concluded that in general the building land for current services with a capacity of 23 machines and TT is still considered to be less in accordance with the standards. To meet national standards, Sidoarjo hospital needs to add land and buildings. In accordance with the management plan of Sidoarjo hospital, it has prepared a land area of 1700 m\(^2\), it can be stated that the Sidoarjo hospital is feasible to carry out development to meet the current normative needs, even the land area is feasible to develop up to 103 HD, bed, and machines.

Based on the analysis of infrastructure feasibility, it can be concluded that in general the infrastructure for hemodialysis services currently with a capacity of 23 machines and bed still has some that do not meet the standards. To fulfill the national standards, Sidoarjo hospital needs to add additional infrastructure, including integrated management information system, communication system for external telephone. In addition, it is also necessary to improve the quality of hemodialysis services through assessment of quality indicators. There are several quality indicators in hemodialysis installation, but there are still some indicators that have not reached the standard. Sidoarjo hospital management is committed to improving service quality in the development of hemodialysis services, in this case Sidoarjo hospital can develop hemodialysis services up to 103 machines\(^1\).

Based on the analysis of the feasibility of human resources, it can be concluded that in general for hemodialysis services at present with a capacity of 23 machines and bed is in accordance with national standards. Thus if the human resource needs have met the requirements according to current normative needs, Sidoarjo hospital is worthy of developing hemodialysis services for up to 103 machines.

Based on the analysis of equipment and medicine feasibility, it can be concluded that in general for hemodialysis services at present with a capacity of 23 machines and bed is in accordance with national standards. There is still a need to add some emergency equipment and emergency medicine. Thus if the equipment and drug needs have met the requirements according to the current normative needs, the Sidoarjo hospital is feasible to develop hemodialysis services for up to 103 machines.

Based on some of the above analysis it can be said that Sidoarjo hospital is currently in accordance with national standards. And it can be concluded that Sidoarjo hospital is feasible to develop hemodialysis services for 103 machines and bed.

Feasibility of Financial Capabilities or Financing: The financing needed for the development of hemodialysis services as investment costs for building land, infrastructure, human resources and equipment amounting to IDR 38,838,158,520. The pure costs derived from the Board of District Public Services will be very difficult with the income value calculated based on INA CBG’s rates, because the majority of hemodialysis patients are patients of Board of Health Insurance.

The financing needed for the development of hemodialysis services as investment costs for building
land, infrastructure, human resources and equipment amounting to Rp. 38,838,158,520. The pure costs derived from the Board of District Public Services will be very difficult with the income value calculated based on INA CBG’s rates, because the majority of hemodialysis patients are patients of Board of Health Insurance.

To achieve financial feasibility, several alternative scenarios are needed to finance hemodialysis services. The amount of investment costs, and the amount of direct and indirect costs in the operation of hemodialysis services are very heavy when compared with the estimated income. Several scenarios for alternative development feasibility calculations are carried out. Starting from calculating building land to calculating direct and indirect costs, such as the cost of distributing medical services, purchasing equipment, and so on. Intensive discussion is needed to obtain efficiency solutions in order to achieve financing feasibility16.

The calculation scenario in this alternative financing scenario 4, seeks to reduce HD services to 10% of HD tariffs, and reduce consumable costs by 10%. From the calculation, there is an NPV of (-) Rp. 16,132,666,320. From these results it can be concluded that the assessment of the development of hemodialysis installation of Sidoarjo Regional Hospital from the financial aspect with an alternative scenario of Financing 4 is still not feasible.

The results of the calculation of alternative financing scenarios can be used to be one of the considerations and evaluations, are current HD rates too low?, or Unit costs, investment costs, and a disproportionate rate of medical services? So that later it is expected that the results of better calculations can generate benefits for the hemodialysis installation of Sidoarjo hospital.

**Conclusion**

The feasibility level can be concluded based on the feasibility analysis and assessment process. Based on the description of the feasibility analysis above illustrates that in terms of the need for hemodialysis services there is clearly a need for, and in terms of the feasibility of development in terms of the needs of building land, facilities, human resources and equipment, it can be concluded that Sidoarjo hospital can meet these needs. But in terms of financing, given the highest number of patients is Board of Health Insurance, so that the income for Sidoarjo hospital is very small and it is very difficult to achieve profits.

Prescription Pattern of Antibiotics for Upper Respiratory Tract Infection in Shah Alam, Malaysia

Kavitha Ashok Kumar¹, Mohammad Rafiq Bin BaderuKhisam², Ashok Kumar Jeppu³

¹Head Of the Unit, Otorhinolaryngology, International Medical School, ²BMS, International Medical School, ³Associate professor and Head of the Unit, Biochemistry, International Medical School, Management and Science University Shah Alam, Malaysia

Abstract

Background: Upper respiratory infection (URTI) is a contagious infection of the upper respiratory tract which includes the nose, pharynx and larynx. Most of these infections are viral in origin yet treated often with antibiotics. Overuse of antibiotics is a worldwide problem. The aim of this study is to evaluate the prescribing pattern of antibiotics in management of URTI among doctors in Shah Alam and to determine the antibiotics most often prescribed for URTI.

Material & Method: A cross sectional study was conducted at two private hospitals and seven clinics in Shah Alam. A total number of 128 doctors participated in this study. The data was collected through well-structured questionnaires. Analysis of data was done by using descriptive statistics.

Result: This study showed few prescriptions for antibiotics in treatment of URTI as most of doctors (89%) did not recommend it. Although the number of cases of URTI diagnosed weekly was high, yet most of them were non-bacterial and did not require any drugs. However, most of the doctors interviewed had not attended clinical antibiotic training though they were well aware of the latest Malaysian Antibiotics Guidelines. Amoxycillin was the most prescribed antibiotic in certain cases of URTI which needed antibiotic prescription.

Conclusion: Most of URTI cases do not require antibiotics for treatment. The prescription pattern of antibiotics in Upper Respiratory Tract Infection showed no difference between the doctors involved in hospitals and clinics.

Keywords: Antibiotics, Upper respiratory tract infection, doctors.

Introduction

Upper Respiratory Tract Infection (URTI) is a contagious infection of our upper respiratory tract which includes the nose, pharynx, larynx, and bronchi. It may manifest as common cold, pharyngitis, laryngitis, epiglottitis, laryngotracheobronchitis (Croup), otitis media and sinusitis. Most of these cases are caused by viruses like rhinovirus, adenovirus, parainfluenza virus, herpes simplex virus, respiratory syncytial virus, Epstein-Barr (EB) virus, influenza virus, Coxackie A virus, coronavirus and cytomegalovirus. Only 10% of these cases are caused by bacteria and warrant antibiotics. The common bacteria causing URTI are Beta-hemolytic streptococci, Pneumococci, Staphylococci, H. influenza, Corynebacterium diphtheria, and Chlamydia trachomatis. Overuse of antibiotics is a worldwide problem. Hence, WHO has used antibiotic prescription for URTI as an indicator for assessing the optimum or overuse of antibiotics. According to WHO report on prescription pattern of antibiotics in developing countries, over the period of 1982-2006, had shown increase in the rate of antibiotic prescription by 71%⁴ and 57%⁵. Antibiotic use in URTI was 85-90% in developing countries like China, India, Thailand and South Africa⁶. This can cause adverse effects, increase healthcare cost and may result in increased resistance to antibiotics. This study was conducted with the aim to evaluate the current trend in prescribing of antibiotics for URTI in Shah Alam, Malaysia.
Material and Method

This is a cross sectional study, conducted on 128 doctors working in two private hospitals and seven clinics in Shah Alamevaluating the prescription pattern concerned with the use of antibiotics in the management of URTI. The convenient sampling technique was used. Medical officers in general medicine, otorhinolaryngology, pediatrics and emergency departments were included in this study. Houseman officer and other hospital staff who are not involved in drug prescription were excluded. Permission was taken from the heads of department of all the hospitals and clinics to conduct the study. Ethical clearance was obtained from the institutional ethical board.

Study tool: A questionnaire was developed after extensive literature search. It was pilot tested on a small group of 10 doctors and revised for ambiguity. The questionnaire included questions on their educational status, experience, status of their training on their antibiotic use, the frequency of treating patients with URTI and attitude towards prescribing antibiotics. A written informed consent was attached to each survey form that was answered by the respondents. A random selection of prescriptions from URTI patients treated in these healthcare institutions were collected to verify the actual prescribing behaviors and compared with the answered questionnaire.

Statistical Analysis: All the data collected was statistically analyzed by using SPSS version.

Result and Analysis

In this study, a total of 128 doctors participated from 2 hospitals and 7 clinics in and around Shah Alam, Malaysia. 62.5% had >5 years of experience in clinical practice while 37.5% had 3-5 years of experience. Most of them (82%) had no special training on use of antibiotics. 114 of the 128 doctors were aware of the latest Malaysian antibiotic guidelines (Table 1).

URTI was encountered frequently by our study population. The number of cases of URTI treated by the doctors per day is shown in Figure 1. Fifty-five doctors claimed to see more than 10 cases of URTI per day, while 59 said they saw about >5-10 cases per day. Eight doctors dealt with 1-5 cases while twenty-three treated less than 1 patient of URTI per day.

![Figure 1: No. of URTI cases seen by the study population per day.](image)
**Recommendation for antibiotic use:** In our study, only 14 out of 128 doctors (11%) recommended antibiotics for URTI treatment while the vast majority 114(89%) did not prescribe it. The diagnosis for which antibiotics prescribed were acute tonsillitis, acute sinusitis and otitis media. Among the antibiotics prescribed, the most common drug was of penicillin group (amoxicillin), followed by cephalosporin and macrolides (Figure 2).

![Figure 2: Antibiotics prescribed by the study group.](image)

**Alternative treatment method used in the treatment of URTI:** The doctors in our study group used alternative options to provide symptomatic relief to patients with URTI. Seventeen recommended high dose of vitamin C, forty-three prescribed antihistamines, twenty-five suggested hydration therapy, fifteen traditional remedies while twenty-five recommended rest and allowing self-recovery (Figure 3).

![Figure 3: Alternative treatment method used to treat URTI by study population.](image)
Discussion

In this study, a total of 128 doctors participated. Most of them were expert in the treatment of URTI with 80 having 5 years or more experience, while 48 had about 3-5 years of clinical experience. Due to their vast experience, they were aware of the latest Malaysian National Antibiotics Guidelines (NAG). However, majority of them had never attended any workshop/training on antibiotic use. It is a challenge for clinicians to identify between viral and bacterial infection. Most of the drugs given are aimed to minimize the symptoms and promote effective recovery. In our study, most of the doctors (89%) did not recommend antibiotics for URTI cases with only 11% preferring to use antibiotics in treatment of URTI. An earlier study in primary care settings in Malaysia by Teng et al reported use of antibiotics in 33.8% of URTI cases. In a similar study in India, Kotwani and Holla way reported use of antibiotic in 45% and 57% of uncomplicated URTI cases in public and private hospitals respectively. Similar data was presented in a systematic review from China where 83.7% of patients with URTI were prescribed antibiotics. An alarming 18.4% were prescribed 2 antibiotics while 1.1% got 3 antibiotics. The authors however mentioned about the downward trend in antibiotic prescription in recent years. Mohitosh et.al in Bangladesh too reported URTI to be a common cause for antibiotic prescription. Even in a developed country like France a study on antibiotic use in paediatric age group between 2008-2012 reported an unacceptable higher use of antibiotics.

We have observed a decrease in the prescriptions for antibiotics in our study. This may be attributed to the study being conducted in an urban area with availability of specialist care and the doctors being aware of the antibiotic guidelines. The reasons cited by the respondents for not prescribing antibiotics were to prevent antibiotic resistance among patients, to prevent side effects especially to infants and young children, the type of causative microorganism and the level of severity of the case. Instead of antibiotics, some of the doctors in our study preferred to use alternative method to treat URTI and provide symptomatic relief. Prescription of anti-histamines was the commonest among them. Others included giving high doses of Vitamin C to help boost the immune system, hydration treatment or fluid replacement, anti-inflammatory drugs or suggesting rest as they believed in self-recovery. Similar observation was made by Reshmi et al who also reported the use of symptomatic treatment for patients with URTI.

In our study, there were 14 cases of URTIs where antibiotics were used. In some cases of tonsillitis, laryngitis and sinusitis antibiotic coverage was needed to prevent complications in immunocompromised individuals or when virulent organism was suspected.

The most prescribed drug was of Penicillin group (amoxicillin), followed by cephalosporin and macrolides. Similar prescription pattern has been described by Teng et al. The choice of antibiotics given maybe due to the commonest causative organisms being gram-positive type of bacteria such as Streptococcus. In Bangladesh, Mohitosh reported cephalosporins to be the commonest antibiotic prescribed. In a similar study in Kerala by Reshmi et al, azithromycin was the commonest antibiotic prescribe.

This is in contrast to the observations of Shamsuddin et al who in 2013 reported inappropriate use of antibiotics in 18% for URTI.

Conclusion

This study reveals that most doctors in Shah Alam are familiar with Malaysian Antibiotic Guidelines, which is reflected in fewer prescriptions for antibiotics in the treatment of URTI cases. When dealing with URTI, alternative symptomatic treatment like vitamin C, antihistamines, good hydration were advocated by our study group. However, a similar study in future on a larger population including both urban and rural healthcare settings as well as both private and public hospitals would be able to substantiate the changing trend in the prescription pattern of antibiotics among doctors for URTI in Malaysia.

Limitation of the study: This study was conducted on a small population of doctors. All the doctors were working in urban, private health care settings. Hence the findings of this study do not reflect on the rural and public healthcare settings.

Effect of Adding Different Levels of Green Tea Powder Camellia Sinensis to Diet on Some Physiological Traits in Broiler

Khawla A. Salman¹, Sunbul J. Hamodi², Luma K. Al-Bandr³

Department of animal production, Collage of Agriculture engineering science, University of Baghdad, Iraq

Abstract

This study was conducted at the Poultry Researches Station/Department of Animal Resource/Directorate of Agricultural Researches/Ministry of Agriculture, during the period from 15/5/2018 to 21/7/2018 to study the effect of adding green tea powder in broiler diet on some physiological traits.

In this study 300 (Ross 308) broilers at age of one day has been used, these birds has randomly distributed to 5 dietary treatments, each treatment has three replicated (20 birds/replicates) T1 control treatment without adding green tea powder while T2 was used (0.5 %) of green tea powder, T3 used (1%) green tea powder, wherever T4 used (1.5%) of green tea powder and T5 used (2%) green tea powder. The birds had been fed with one diet during the experiment period and the diets content were calculated as (16), the results of this study showed:

There was a high significant difference (P<0.01) in plasma total protein for adding treatment and reached the best average in T5 treatment and a minimum average in T1 treatment, observed a highly decreased (P<0.01) in plasma albumin levels for T4 treatment compared with other treatments, and there is a highly increased (P<0.01) in plasma globulin levels in T5 and T4 treatment compared with T1, T2 and T3 treatments, there was a highly decreased (P<0.01) in cholesterol levels in T5 compared it with control and other treatments, in the same time the results showed a high significant decreased (P<0.01) in high density lipoprotein (HDL) for T5, T4 and T1 treatments compared to T3 and T2 treatments, and there was a high significant decreased (P<0.01) in low density lipoprotein (LDL) in T2, T3, T4 and T5 compared to control, there was a highly decreased (P<0.01) in very low lipoprotein (VLDL) levels in T5 compared with other treatments. For the triglyceride the results showed a high significant decreased (P<0.01) in blood plasma for T2, T3, T4 and T5 treatments compared with control treatment.

This study recorded a highly decreased (P<0.01) in ALT level for T5 compared to T4, T3, T2 and T1, in the other hand there was a highly significance (P<0.01) in same trait for T3, T4 and T5 compared with T2, wherever the results showed a highly decreased (P<0.01) in AST level in T5 and T4 treatment compared with T1, T2 and T3 treatments.

Keywords: Green tea powder, Camellia sinensis, physiological trait, broiler.

Introduction

Due to the development presents in poultry and the infection of poultry with infectious diseases lead to decrease in reproductive performance and this leads to increase in veterinary costs and therefore high production costs so the researchers interested in herbals for the purpose of improving the productive and physiological performance of animals, including domestic poultry, and their use as an alternative to preservatives for the production of healthy and functional foods (1), for avoiding the negative effects of the use of medicinal drugs with the chemical origin of the birds, and to maintain consumer health and enhance the immunity of the body by stimulating the immune system (2).

Green tea has many purposes such as antitoxin, anticancer, antivirus, antibacterial and anti-obesity...
and others purpose which belong that green tea contains catechins compound (GTCs) \(^3\), and contains phytochemicals, such as polyphenols and caffeine. Polyphenols found in green tea include epigallocatechin gallate (EGCG), epicatechin gallate, epicatechins and flavonols \(^4\), these flavonoids contains a substance called catechins, the major catechins present in green tea are epicatechins (EC), epigallocatechins gallate (EGCG), epicatecholamines (EC) and epicatechins gallate (ECG)\(^5\), which have antioxidant, anticarcinogen, anti-inflammatory, and anti-radiation biochemical effects in vitro \(^6\). Other components include three kinds of flavonoids, known as kaempferol, quercetin, and myricetin \(^7\).

Green tea is a rich of minerals elements which are essential for health like zinc, Iron, silver, manganese, magnesium, sodium, potassium, titanium, copper, bromium, aluminum, nickel and phosphorus \(^8, 9, 10\), these metal ions promote the antioxidant property of green tea \(^11\).

Green tea is reported to contain 4000 bioactive compounds, The active constituents in green tea are powerful antioxidants call polyphenols, and this polyphenols belong to flavonoids family \(^12\), and it’s consider as basic phenolic compounds in green tea responsible for antioxidant activities that are form in the process of metabolism \(^13, 5\).

The aim of this study was to investigate the effect of adding different levels of green tea powder to broiler and its effect on the physiological performance and the.

Materials and Method

**Birds and Dietary treatment:** This study was carried out at the poultry research/office of the agricultural research/ministry of agriculture for 15/5/2018 to 21/6/2018 on 300 (Ross 308) broilers at one day age and randomly distributed to five dietary treatments with three replicated (20 birds/replicates), T1 control treatment without adding green tea powder, while T2 used 0.5 % green tea powder, T3 used 1% green tea powder, T4 used 1.5% green tea powder and T5 used 2% green tea powder. All the treatments gave ad libitum diet and water in all the experiment period, the diet contents chosen as \(^14\) which showed in (table 1).

Statistical Analysis: Completely randomized design (CRD) was used to study the effect of different treatment in all traits, and multiple range tests was used to compare the significant differences between means. Data were analyzed by using statistical analysis system.

Results and Discussion

 Noticed from table (2) a high significant different ($P<0.01$) in total protein in T5 compared with other treatments, and a high significant decreased ($P<0.01$) in T4 compared to T1, T2 and T3, and a high significant decreased ($P<0.01$) in T4 compared to T1, T2 and T3 treatments.

 Also observed from table (2) a highly decreased ($P<0.01$) in plasma albumin levels in T4 compared with T1, T2, T3 and T5 treatments, while there was a highly increased ($P<0.01$) in globulin levels in T5 and T4 compared with T1, T2 and T3 treatments.

The means with different letters within the same column are significantly between them, ($P < 0.01$) **

 Table (3) showed a highly decreased ($P<0.01$) in cholesterol levels in serum in T5 compared with T1 and other treatments, in the same time the results showed a high significant decreased ($P<0.01$) in high density lipoprotein (HDL) for T5, T4 and T1 treatments compared to T3 and T2 treatments, a high significant decreased ($P<0.01$) in low density lipoprotein (LDL) in T2, T3, T4 and T5 treatments compared to T1 treatment, while there is a highly decreased ($P<0.01$) in very low lipoprotein (VLDL) levels for T5 treatment compared with other treatments, results obtained from table (3) a high significant decreased ($P<0.01$) in triglyceride in T5 compared with other treatments, may be due to supplementing of green tea in diet may prevent an excessive accumulation of lipids in the liver and other tissues as a result of green tea content from caffeine and catechin which may have an inhibitor effect on intestinal absorption of lipids, and may be due to the caffeine and catechin content of green tea may have an inhibitor effect on intestinal absorption of lipids (24), and this may be due to the contain of green tea on the compounds epigallocatechins gallate (EGCG) that works to reduce from differentiation and proliferation of lipid cells and the manufacture of fat and the birth of new fat cells and fat block and thus reduce body weight and reduce the oxidation of fat and the level of triclipers in plasma blood and free fatty acids and cholesterol source, as well as the factor effect on cholesterol it’s same effect on triglyceride (25).

 The reasons for moral improvement can be explained in the lipid of plasma in the green tea supplementation coefficients so green tea is currently used in the fight against obesity as it is used in lowering fat level and preventing excess weight (26).

Abstract

Objective: To evaluate the bronchorelaxation effect of methanol extract of Coptosapelta flavescens Korth. root (MECFR) on cholinergic, histamine receptors and beta2-adrenoceptors, in vitro.

Method: The research design was experimental in which a 4-mm long guinea pig’s bronchus was kept in an isolated organ bath containing Kreb’s-Henseleit solution at 37°C, pH 7.4 and flooded with carbogen gas. The study was divided into 3 groups: in Group 1 and 2, the bronchial rings were incubated in 3 concentrations of MECFR, and then contracted with cumulative doses of methacholine and histamine, respectively; in Group 3, the bronchial ring was incubated in 3 concentrations of propranolol, contracted with a single dose of methacholine, and then the MECFR was administered in cumulative doses.

Results: In both Group 1 and Group 2, the dose-response curves of all 3 doses of MECFR shifted to the right with lower E_max (P<0.05) as compared to the negative control. In Group 3, the dose-response curves showed MECFR has bronchorelaxation effect on bronchial rings both in the presence of propranolol and without, with similar E_max (P>0.05).

Conclusion: MECFR exhibits bronchorelaxation effects by acting as non-competitive antagonist at the cholinergic and histamine1 receptors, and also by acting as beta2-adrenoceptor agonist.

Keywords: Beta2-adrenoceptor, cholinergic receptor, Coptosapelta flavescens Korth root, histamine receptor.

Introduction

Coptosapelta flavescens Korthis a liana plant of the Rubiaceae family. In East Kalimantan, the root is used traditionally as a potion to cure cough and shortness of breath.1 It’s pharmacological activities such as bronchorelaxation is yet to be scientifically proven.

The autonomic nerves mediate both contraction and relaxation of airway smooth muscles. The parasympathetic cholinergic nerves dominate the airway and mediate contraction, whereas the adrenergic-sympathetic nerves mediate relaxation. Acetylcholine (ACh), the main neurotransmitter of the parasympathetic nervous system, activates M_3 cholinerger receptors responsible for the contraction. Unlike cholinergic stimulation, adrenergic stimulation relaxes the airways.2

Beside the autonomic nervous system, there are several types of cells, such as epithelial cells; inflammatory cells; and myocytes that can release various mediators such as histamine, endothelin and arachidonic acid metabolites, which can modulate airway contractions.3

Asthma treatment with bronchodilators aims to relax the
airway smooth muscles by antagonizing cholinergic and histamine receptors and stimulating beta₂-adrenoceptors.

This study evaluated the effect of the MECFR on cholinergic receptors, histamine receptors and beta₂-adrenoceptors and in inducing bronchorelaxation in vitro, using the guinea pig’s isolated bronchial rings. Isometric force transducers were used to measure the parasympathetic tone of the smooth muscle in the airway of guinea pigs.²

**Materials and Method**

**Materials:** Coptosapelta flavescens Korth roots (CFR) were collected from Paser Regency of East Kalimantan Province. Identification was done by the taxonomist of Forestry Faculty of Mulawarman University. Proanalytic methanol and the ingredients to make Kreb’s-Henseleit solution were purchased from Sigma-Aldrich distributor in Surabaya. Carbogen gas (95% O₂ gas and 5% CO₂ gas) was purchased from PT Murni Gas Rayain Samarinda.

Test animals were 3-4 mo old male guinea pigs weighing 300-400 g obtained from Pharmacology Laboratory, Faculty of Medicine of Mulawarman University Samarinda.

Tools for bronchorelaxation test were six-chamber isolated organ bath, octal bridge amplifier, Power Lab/16SP digital recorder, isometric transducer, pH meter, tweezers and surgical scissors.

**Preparation of MECFR:** Dried and ground simplicia of CFR (300 g) were macerated in 1.5 l of proanalytic methanol solution and shaken continuously for 3 days. All the collected filtrates were then evaporated using a 50°C vacuum rotavapor.

**Guinea pig’s bronchial preparation:** Guinea pigs (Cavia porcellus), were fasted for 12 h and subsequently anesthetized and sacrificed. Surgery was done by opening the abdomen and thorax. The lungs and trachea were then dissected and put in a Petri dish containing Kreb’s-Henseleit solution. The bronchial segments were then cut into a length of 4 mm and put into an organ bath filled with 10 ml Kreb’s-Henseleit solution. The bronchial ring was arranged following the procedure described by Albuquerque.⁴

**Bronchorelaxation activity test on cholinergic receptors:** Prior to treatment, bronchial rings were equilibrated in Kreb’s-Henseleit solution for 60 min, and every 15 min the solutions were replaced with a new Kreb’s-Henseleit solution. After equilibration, 200 μl each of MECFR solution dose 10%, 20% and 30% were added into the organ baths. After 10 min, they were then contracted with cumulative doses of methacholine. Atropine 2nM was used as positive control and 10% Dimethyl Sulfoxide (DMSO)-ethanol solvent was used as negative control (NC)

**Broncho relaxation activity test on histamine receptors:** After the bronchial rings in the Kreb’s-Henseleit solutions reached equilibration, 200 μl each of MECFR solution at 10%, 15% and 20% were administered to the bronchial ring for 10 min followed by cumulative doses of histamine to induce contraction. Chlorpheniramine Maleate (CTM) 1μM was used as positive control.

**Broncho relaxation activity test on beta₂ adrenoceptors:** After the bronchial ring in the Kreb’s-Henseleit solution reached equilibration. The bronchial rings were incubated with three doses of Propranolol 1,0.5μM, 1μM and 1.5 μM for 10 minutes. Afterwards, they were contracted with a single dose of Methacholine 10⁻³M. Finally, the MECFR solutions were added in cumulative doses. Aquabidest and 10% DMSO-ethanol solvent were used as NC.

**Calculation of percentage contraction/relaxation:** Percent of bronchial contractility was calculated using the following equation:

\[
\% \text{ contractility} = \frac{\text{Contraction or Relaxation response (g) – response of NC (g)}}{\text{Max precontraction response (g)}} \times 100
\]

The dose-response curve (DRC) was then plotted, which is a curve of log concentration vs percent of bronchial contractility for each treatment. After Eₘₐₓ was determined, EC₅₀ was obtained from the calculation of linear regression equations (20-80% Eₘₐₓ) of DRC. To determine the receptor potential against test material, pD₂ which is equal to -log EC₅₀ were calculated.

**Statistical Analysis:** Data were presented as mean ± s.e.m. Bronchial contraction or relaxation response was presented as DRC, Eₘₐₓ and pD₂ values of each treatment. All were analyzed with SigmaPlot 12.5. Significant differences were determined using one-way analysis of variance (ANOVA), followed by the Tukey test. P values of 0.05 or less were considered to be statistically significant.
Results

MECFR activity on cholinergic receptors: Figure 1 shows the contractile effects on bronchial rings contracted with methacholine after being incubated with MECFR of 10%, 20%, and 30% dose. They were represented as DRC labeled as methacholine (met)-MECFR10, met-MECFR20 and met-MECFR30 respectively. All three DRCs shifted to the right with lower E_{max} (P < 0.05) than DRC of NC (met-NC) (Table 1). This showed the effect of MECFR in inhibiting methacholine-induced contractions of bronchial ring, indicating that the extract antagonized cholinergic receptors in a non-competitive manner. In contrast, the DRC of Atropine sulfate labeled as met-As in Figure 1, shifted to the right with E_{max} (P > 0.05) that is not significantly different from met-NC (Table 1). Therefore, Atropine as positive control had a competitive antagonist effect on cholinergic receptors.

The potency of MECFR to inhibit bronchial ring contraction is indicated by the values of pD_{2} in Table 1 which show that the increase of MECFR dosages from 10, 20 to 30% resulting in a decrease in pD_{2} (p < 0.05) as compared to control. As the extract’s concentration became higher, there was less potential for agonist to induce bronchial smooth muscle contraction. These results showed that the inhibitory effect of MECFR was dose-dependent.

MECFR activity on histamine receptors: Figure 2 shows the contractile effects on the bronchial rings given cumulative doses of histamine after being incubated with MECFR at 10%, 15%, 20% dose and CTM. They were presented as DRCs labeled as His-MECFR10, His-MECFR15, His-MECFR20 and His-CTM respectively. All DRCs shifted to the right compared to the DRC of NC (His-NC). This suggested that all doses of MECFR and CTM had histamine receptor antagonist activity. E_{max} data on Table 2 shows that, CTM 1 μM has competitive antihistamine activity as the E_{max} is not significantly different (p>0.05) than E_{max} of His-NC, whereas MECFR10, MECFR15 and MECFR20 have noncompetitive antihistamine activity because their E_{max} are significantly different (p<0.05) than E_{max} of His-NC. As the extract’s concentration increased, the antihistamine activity became more noncompetitive. Table 2 also shows that as the extract’s concentration increases the pD_{2} value gets smaller, indicating that the potency of histamine receptors towards histamine became weaker as they were occupied by MECFR.

MECFR activity on beta_{2}-adrenoceptor: Figure 3 shows the relaxation effect on bronchial rings which were given cumulative doses of MECFR after being incubated with 0.5 μM, 1.0 μM, 1.5 μM propranolol and without propranolol, then contracted with a single dose of Methacholine 10^{-5}M. They were presented as DRCs labeled as Pro0.5MECFR, Pro1.0MECFR, Pro1.5MECFR and MECFR, respectively. The higher the MECFR concentration, the greater the increase in relaxation which is marked by the negative sign. When the relaxation response of bronchial rings incubated with and without propranolol are compared, pD_{2} in Table 3 shows that the affinity of propranolol-occupied beta_{2}-adrenergic receptor towards MECFR is smaller and significantly different (p < 0.05) than the receptor not occupied with propranolol. This shows that MECFR has activities that are less potent in beta_{2}-adrenergic receptor because it was inhibited by propranolol. Table 3 also shows that there is no significant difference (P > 0.05) between the E_{max} of propranolol-incubated and non-incubated bronchial rings. This shows that MECFR competes with propranolol to occupy beta_{2}-adrenergic receptor, and it can remove propranolol to such extent that the maximum response reached (E_{max}), was not significantly different than the E_{max} on beta_{2}-adrenergic receptors that was not occupied with propranolol. This result indicates that MECFR is a beta_{2}-adrenergic receptors agonist.

Discussion

This study showed the effect of MECFR as cholinergic M_{3} receptors non-competitive antagonist in the airway smooth muscles. The right-shifted DRCs showed that larger amount of methacholine were needed to produce the same contraction effect as they had been inhibited by the extract. This inhibition suppressed E_{max} as MECFR occupied M_{3} cholinergic receptors at different sites than the agonists, such that the methacholine was unable to increase its maximum contraction. The potency of agonist to contract the bronchial smooth muscles was weakened as the dose of MECFR that occupied cholinergic M_{3} receptor increased. This indicates the presence of chemical components in CFR which can act as cholinergic M_{3} receptor antagonist. The chemical blocks the released ACh ligands from interacting with the cholinergic M_{3} receptor, resulting in the relaxation of the airway smooth muscles. Other plant extracts that also act as cholinergic M_{3} receptors antagonist are the ethanol extract of Curanga fel-terrae leaves and water extract of Nigella sativa.
This study also showed the effect of MECFR as H₁ receptors non-competitive antagonist in the airway smooth muscle. The potency of histamine agonist to contract airway smooth muscle decreased as the dose of MECFR that occupied the histamine receptors increased. The effects of MECFR in this study resulted in the inhibition of H₁ receptors, causing histamine mediators released by mast cells unable to be bound to H₁ receptors, resulting in no contraction. Other plant extracts that can inhibit H₁ receptors are the ethanol extract of Nyctanthes arbor-tristis leaves ⁸ and the water extract of Bunium persicum. ⁹

This study also showed that MECFR has effects on beta₂-adrenoceptor as it could shift propranolol (competitive beta-blocker) aside; and indicated that there are active ingredient in MECFR that stimulates beta₂-adrenergic receptor. Beta₂-adrenergic receptor activation induces stimulation on adenylate cyclase through trimeric Gs protein with alpha subunit. Stimulation of adenylate cyclase catalyze the conversion of Adenosine Tri phosphate (ATP) to cyclic adenosine mono phosphate (cAMP), which leads to the relaxation of airway smooth muscle. ¹⁰ Other plants that were reported having bronchorelaxation effect through beta₂-adrenoceptor such as Nigella sativa water extract with Thymoquinone as its active ingredient, ¹¹ the methanol extract of Myxopyrumserratulum leaves. ¹²

The bronchodilatory activities of MECFR are influenced by its secondary metabolites contents, e.g. saponins, polyphenols, terpenoids, steroids, and anthraquinones, contained within it. ¹³ Terpenoids in the MECFR can have effects like thymoquinone, widely contained in the essential oil of *Nigella sativa*, which inhibits methacholine-induced contraction of airway smooth muscles and stimulates beta₂-adrenoceptor which leads to the relaxation of airway smooth muscles. ¹⁴ Polyphenol in MECFR could have similar effects as quercetin, which is found in abundance in fruits and vegetables, in relaxing bronchus by inhibiting ACh-and histamine-induced contraction and increasing cAMP through beta₂-adrenoceptor stimulation. ¹⁵

Analogous with secondary metabolites from other plants, the active ingredient contents in MECFR which are responsible for guinea pig bronchial ring relaxation therefore are polyphenol, terpenoid and steroid.

Figure 3: The DRC of bronchial rings given with cumulative doses of MECFR in the presence and absence of propranolol.

Conclusion

Coptosapelta flavescens Korth root extract relaxes guinea pig bronchial ring through non-competitive antagonism of cholinergic and histaminergic receptors, and agonism of beta2-adrenoceptor, therefore it could be exploited for therapeutic use in asthma and upper respiratory disease.

Insulin Resistance in Obese and Non Obese Pre-Pubertal Children: Cross Sectional Study in Indonesia

Leersia Yusi Ratnawati1, Bambang Wirjatmadi2, Merryana Adriani2, Soenarnatalina3

1Doctoral Student at Health Science, Airlangga University; Departement of Public Health Nutrition, Public Health Faculty, Jember University, 2Departement of Nutrition School of Public Health, Airlangga University, Surabaya, 3Departement of Bioastatistic and Population, Airlangga University, Surabaya, Indonesia

Abstract

High prevalence of childhood obesity increases risk of insulin resistance in pre-pubertal children. The purpose of this study is to identify the presence of insulin resistance in pre-pubertal obese children and compare with children who had normal nutritional status. Observational analytic study with a cross sectional design is used for this research. There are 60 elementary school students aged 6-9 years involved in this study, 30 obese students and 30 students with normal nutritional status based on BMI for Age. Fasting insulin, fasting blood glucose and HOMA IR index were carried out in Parahita Laboratory at Sidoarjo. Statistical analysis using independent t-test was used to determine differences in fasting blood glucose, fasting insulin and HOMA IR between two groups and linear regression to analyze the effect of obesity on insulin resistance with a significance value < 0.05. The results showed mean scores of BMI obese and non-obese group were 25.6 and 15.96 respectively, the mean value of BMI z score among obese group and non-obese was 3.7 and-0.6 respectively; the abdominal circumference value of obese and non obese group consist of 84.95 and 59.48 cm. Statistical analysis showed no significant difference in fasting blood glucose levels, but fasting insulin levels and HOMA IR between 2 groups differed significantly. Obesity (BMI and abdominal circumference) influenced incidence of insulin resistance. Furthermore, obese and non-obese groups have different sensitivity of insulin response but had the same blood glucose level; obese group had higher HOMAIR than non-obese group. So, there needs an intervention to reduce obesity at an early age to reduce the risk of insulin resistance in pre-pubertal age.

Keywords: Insulin Resistance, Obesity, Pubertal Pre.

Introduction

Insulin resistance is a state of impaired metabolic response insulin sensitivity in the target cell so that more insulin levels are needed than ‘normal’ to maintain a normoglycemic state1,2. Obesity is a low-level chronic inflammation caused by excess energy intake, as a major factor in decreasing insulin sensitivity, which makes obesity a major risk factor for insulin resistance3. Zeitler et al (2008) said that several large-scale and retrospective studies on a large scale showed a correlation between adiposity and insulin resistance and metabolic syndrome4.

Childhood is a critical period as the onset or continuation of the incidence of obesity5. Childhood obesity is associated with an increase in several complications of metabolic syndromes, such as insulin resistance, glucose intolerance and type 2 diabetes in the future6.

Obesity develops into insulin resistance through the cellular mechanism of insulin which is characterized by impaired insulin ability to inhibit glucose output from the liver and increase glucose absorption in adipose tissue and muscles7. Insulin cannot fulfill its role in stimulating GLUT 4 translocation from the cytosol to the plasma membrane which will facilitate the transport of glucose to the target cell8. Disruption of stimulation of GLUT 4 translocation is due to the inhibition of the IRS 1 phosphorylation process of tyrosine kinase that occurs at the post-receptor. Decreasing GLUT 4 causes an increase in stimulation of greater insulin production to maintain normal blood glucose (normoglycemic) conditions.
Puberty gives an important role in the development of diabetes mellitus which begins with a condition of insulin resistance. During puberty, there is an increased resistance to the work of insulin which causes hyperinsulinemia. Increased growth hormones (estrogen and progesterone) during puberty give a role in increasing insulin resistance. After puberty and entering adulthood, the basal stimulation of insulin response decreases.

Determination of pre-pubertal age as the target of the study also has purposeto identifying earlier potential risk of degenerative diseases in the future as indicated by the HOMA IRindex. Until now, there has been no normal threshold of the HOMAIR index for children (<18 years). However, as a reference we use the results of the review of Izabel et al (2016) on 7 selected articles, recommending cut-off for HOMA IR 2.5 for both boys and girls\(^9\). The purpose of this study is to identify the presence of insulin resistance in pre-pubertal obese children and to compare the control group, namely children who had normal nutritional status (non-obese).

**Materials and Method**

Sixty children (30 obese and 30 normal)were randomly recruited during March to October 2018. Subject recruitment was using simple random sampling with inclusion criteria: age 6-9 years, at pre pubertal stage and BMI screening. Obesity and normal nutritional status was defined according to WHO 2005 standard in children. Obese children were defined when BMI > + 3 standard deviationand normal children were defined when BMI +/-2 standard deviation for age and sex. Pubertal staging was defined according to Tanner and Whitehouse. (child growth foundation, 2017).Exclusion criteria included Tanner stage 1 or more. The research was done in 3 elementary school in Sidoarjo, East Java, Indonesia: Madrasah Ibtidaiyah Muslimat NU Pucang Sidoarjo, SDN Pucang 1 dan 2 Sidoarjo.

**Anthropometry assessment** using WHO Procedure standard. Weight assessment was using digital scale (GEA type eb 9350) to the nearest 0.01 kg, wearing light clothing and without shoes. Standing height was measured without shoes, to the nearest 0.1 cm, using Microtoice. (GEA). Abdominal circumferences were measured using a flexible tape to the nearest 0.1 cm. Abdominal was measured at the end of expiration midway between the lower rib margin and the iliac crest\(^{10}\) BMI was calculated using the formula kg/m\(^2\).All measurements were taken twice.

**Laboratory assessment.** After 8 hours overnight fast, all participants were gotten venous blood sample 5 cc in Parahita Laboratory Sidoarjo, East Java. Fasting blood sample was withdrawn for estimation of fasting plasma insulin and fasting blood glucose.

Fasting insulin assessment was using ECLIA (Electro Chemiluminiscence Immuno Assay) method (µU/mL). Fasting glucose was assessed by Hexokinase (mg/dL). Cut off level for diagnosing insulin resistance/impaired insulin sensitivity with HOMA-IR was >2.5.

\[
\text{HOMA IR} = \frac{\text{fasting insulin (mU/mL)} \times \text{fasting glucose (mmol/L)}}{22.5}
\]

All participants and their guardians or parents signed an informed consent for participation in the study. The study protocol was approved by the local ethics committee of Public Health Faculty, Airlangga University. This work has been carried out in accordance with the code of ethics of the WHO-CIOMS 2016 for experiments involving human.

**Statistical analysis.** The data were analyzed by SPSS statistical software. Independent test was performed for comparison between the mean valuesof the different groups for parametric data. Linier regression correlationwas used for correlation between different variables. For all tests a probability (p) less than 0.05 was considered significant.

**Results**

**Anthropometric Parameters:** Anthropometric parameters was a standard to determine an individual nutritional status. Anthropometric parameters that are often used to determine obesity is Body Mass Index (BMI).

<table>
<thead>
<tr>
<th>Parameter Antropometri</th>
<th>Obese</th>
<th>Non Obese</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Mean</td>
<td>SD</td>
</tr>
<tr>
<td>Body Mass Index (BMI)</td>
<td>26,05</td>
<td>3,2</td>
</tr>
<tr>
<td>Abdominal Circumference (cm)</td>
<td>63,73</td>
<td>7,6</td>
</tr>
</tbody>
</table>
The results of the average anthropometric measurements showed a considerable difference between obese and non-obese groups. The results of the average measurement of the obese group BMI values showed a very high BMI rate of 26.05 with minimum value 20.2 and a maximum reaching 31.8, while the non-obese group mean of BMI value was 16.03, with minimum value 12.8 and maximum 19.8. The results of measurements of the abdominal circumference also showed significant differences between the obese and non-obese groups. The average abdominal circumference of the obese group is 83.73 with a maximum value reaching 101 cm, while the non-obese group is 58.07 cm and the maximum value is only up to 70 cm.

The difference in anthropometric values between the 2 groups was strengthened by the results of the independent t-test which showed significant differences in the values of BMI and abdominal circumference. The difference in anthropometric values between obese children and non-obese children showed a considerable difference, i.e. 2.45 for the obese group and 1.06 for non-obese children. Even in the obese group, there were children with HOMA index values above 4 (the normal limit of the HOMA index for adults). The high value of the HOMA index in obese group compared to non-obese group was also supported by the results of independent t-test which showed a significant difference between obese and non-obese groups with a value of $p = 0.000$. Independent t-test results showed that there were differences in fasting insulin levels between obese and non-obese groups ($p = 0.000$), where fasting blood glucose levels between obese and non-obese groups were the same or no significant difference ($p = 0.484$). This means that between the obese and non-obese groups have different abilities in the insulin response at the same blood glucose level, with a higher HOMA index value in the obese group.

### Table 2: Fasting Glucose, Fasting Insulin and HOMA IR

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obese</th>
<th>Non Obese</th>

<tr>
<td>Fasting Insulin</td>
<td>13</td>
<td>6.29</td>
</tr>
<tr>
<td>HOMA IR</td>
<td>2.75</td>
<td>1.3</td>
</tr>
</tbody>
</table>

Descriptively the measurement results of the average HOMAIR index between obese children and non-obese showed a considerable difference, i.e. 2.45 for the obese group and 1.06 for non-obese children. Even in the obese group, there were children with HOMA index values above 4 (the normal limit of the HOMA index for adults). The high value of the HOMA index in obese group compared to non-obese group was also supported by the results of independent t-test which showed a significant difference between obese and non-obese groups with a value of $p = 0.000$. Independent t-test results showed that there were differences in fasting insulin levels between obese and non-obese groups ($p = 0.000$), where fasting blood glucose levels between obese and non-obese groups were the same or no significant difference ($p = 0.484$). This means that between the obese and non-obese groups have different abilities in the insulin response at the same blood glucose level, with a higher HOMA index value in the obese group.

### Discussion

**Anthropometric Parameters:** Obesity is an excessive body weight as a result of excessive fat accumulation with BMI for age thresholds > 2 Standard Deviations. The International Obesity Task Force (IOTF) recommends several method for determining obesity in children. The recommended measurement method is based on data from 6 developed and developing countries, such as: the United States, Britain, the Netherlands, Hongkong, Singapore, and Brazil. The IOTF recommends indigo z-score BB/TB to determine obesity in children. Other anthropometric measurements use waist/abdominal circumference, skinfold thickness, and percentage of body fat using a multi-frequency bioelectrical impedance analysis (BIA) technique underwater weighing (densitometry), and magnetic resonance imaging (MRI).

This study used 2 simple anthropometric parameters to measure and assess the obesity status of the subject.
The parameters used are BMI and waist circumference. Both of these parameters were chosen in addition to being simple in the implementation procedure and also not requiring expensive costs in the implementation. This procedure can be done by anyone who is trained before. Anthropometric assessment BMI and waist circumference showed that there were significant differences between obese and non-obese groups. Obese groups have higher ratio values of body weight and height compared to non-obese groups.

**Insulin Resistance:** Insulin resistance in early childhood is increasing along with the increasing prevalence of obesity in the world. Insulin resistance is a complication of obesity that is often found in children and adolescents who are obese\(^6\). Indonesia does not yet have a database of screening for insulin resistance incident. The incidence of insulin resistance was reported by several separate studies with different research subjects, ranging from risky adult groups to the child age. The results of this study specialize in certain age groups namely prepubertal age, where the risk factors for insulin resistance tend to be lower compared to the puberty age.

The evaluation of IR HOMA values as a parameter of insulin resistance shows that the average obese HOMA value of the group as a risk group shows 2.75 with the highest score of 5.4. There is no international standard for limiting IR HOMA values for pre-puberty children. Izabel et al (2016) mentioned in a review of 7 selected articles, recommending cut off for HOMA IR 2.5 for both boys and girls\(^9\). The average value of HOMA IR 2.75 shows that most obese children in the study had experienced insulin resistance. Prolonged insulin resistance will cause metabolic disorders that correlate with several metabolic syndromes which in the future (20 years) may develop into diabetes and cardiovascular disease\(^11\).

**Obesity and Insulin Resistance in Prepubertal Children:** Obesity develop insulin resistance, characterized by impaired insulin ability to inhibit liver glucose output and encourage glucose storage in fat and muscle\(^7\). Increased plasma fatty acids are commonly found in obese conditions. Fatty acids are secreted from adipocyte cells to provide energy to the body and tissues. Obesity correlated with insulin resistance can be explained by competition between the increased circulation of fatty acids and glucose in oxidative metabolism related to insulin sensitivity of cells. Fatty acids and potential metabolites such as acyl-CoAs, ceramides and diacylglycerol function as molecules that activate protein kinases such as protein kinase C (PKC), Jun kinase (JNK) and nuclear factor-κB (NFκB) and kinase-β (IKKβ) inhibitors. These kinases will interfere with insulin signals by increasing the resistance of serine phosphorylation from the IRS, the key mediator of insulin receptor signals.

Obesity represented by anthropometric parameter values of BMI, abdominal circumference has an important influence in the process of early detection of simple insulin resistance events characterized by high HOMA IR values. The results indicate that there is a significant effect BMI, abdominal circumference value on HOMA IR. (\(p = 0.000; p = 0.000\))

Childhood is a critical period in the development of obesity and its complications are divided into several periods, including prenatal and perinatal periods, and periods of obesity rebound during children (periods of 5-7 years and adult periods)\(^12\). The adiposity rebound period is the age between 5-7 years showing a critical period of development of adipose buildup. A time when adiposity rebound has significant implications for obesity in the future. Critical period as the onset or continuation of the incidence of obesity\(^5\). Childhood obesity is associated with an increase in several complications of metabolic syndromes, such as insulin resistance, glucose intolerance, and type 2 diabetes and other metabolic syndrome diseases such as increased cholesterol, blood pressure, coronary heart disease, cancer and osteoarthritis\(^6\)

**Conclusions**

Pre-pubertal age obesity increases the risk of insulin resistance. Obese and non-obese groups have different abilities in the insulin response at the same blood glucose level, with a higher HOMA IR in the obese group. So, there needs an intervention to reduce obesity at an early age to reduce the risk of insulin resistance in pre-pubertal age.

Abstract

Tuberculosis (TB) in the world continues to increase, Indonesia ranks 4th after India (2.0 million-2.5 million), China (0.9 million-1.1 million), South Africa (0.40 million-0.6 million) and Indonesia at 0.4 million-0.5 million cases, 155-222 cases/100,000 population/year (WHO, 2012). The prevalence of childhood TB in Indonesia in 2011 was reported to be 8.8% of the total TB cases and 2-16% at the provincial level (WHO, 2012). Child TB case data from Public Health Offices is 8.8% of 3,153 cases, the incidence of TB in South Kalimantan Province is 241 cases/year. Data on child TB in South Kalimantan Province from 2009-2011 found as many as 28 cases with AFB + age 0-14 years. In 2014 and 2015, the proportion of pediatric TB patients found in Banjarbaru City was 10.84% and 8.5% compared to all TB patients.

Housing Health is a matter that must be considered to reduce the risk of TB cases in children because it involves the characteristics of the conditions of the home environment that affect the degree of public health. This study was an intervention study with a cross sectional approach. The study population was children with TB who were recorded and reported to the TB program responsible/executor of the Banjarbaru City Health Office. The sample of this study were all children with TB in the Health care in the Banjarbaru City area in January-December 2018. The results showed that there was no significant correlation between the health of the home environment in the incidence of pulmonary TB in Banjarbaru City children (p-value = 0.883) and there was no significant relationship between houses to increase the health status of children with tuberculosis in Banjarbaru (p-value = 0.419).

Keywords: Tuberculosis children, Management of homes, homes, neighborhoods.

Introduction

Tuberculosis (TB) in the world continues to increase, especially countries that are grouped in 22 countries with large burden of TB (high burden countries) and most have wetland areas so that in 1993 WHO declared TB one of the world’s emergencies (global emergency) and as an emergency disease diseases. Indonesia ranks 4th after India (2.0 million-2.5 million), China (0.9 million-1.1 million), South Africa (0.40 million-0.6 million) and Indonesia at 0, 4 million-0.5 million cases, 155,222 cases/100,000 population/year¹.

The prevalence of TB in children aged less than 15 years from the UK and Wales national survey in 1983 was 452 cases, in the United States based on a survey of 11 years (1983-1993) 171 cases of child TB were obtained. Child TB is 15% of all TB cases, while in developed countries it is 5-7%. The prevalence of childhood TB in Indonesia in 2011 was reported to be 8.8% of the total TB cases and 2-16% at the provincial level¹.

Child TB case data from Ministry of Health is 8.8% of 3,153 cases, the incidence of TB in South Kalimantan Province is 241 cases/year. Data on child TB in South Kalimantan Province from 2009-2011 found as many as 28 cases with AFB + age 0-14 years. In 2014 and 2015, the proportion of pediatric TB patients found in Banjarbaru City was 10.84% and 8.5% compared to all TB patients².

Integrated efforts to overcome or break the chain of transmission of TB disease have been carried out but the results are still not maximal and this must consider
the risk factors for TB disease. Risk factors for TB in children closely related to the incidence/incidence of TB are population factors which include the source of transmission, patient contact history, socioeconomic level, level of exposure, bacillus virulence, low endurance related to genetics, nutritional conditions, physiological factors, age, nutrition, immunization, and environmental factors which include the state of the physical environment of the housing (temperature in the house, ventilation, lighting in the house, humidity of the house, density of occupants and the environment around the house) and work.

Housing health is a matter that must be considered to reduce the risk of TB cases in children because it involves the characteristics of residential conditions that affect the health status of the community. The healthy condition of the home also contributes to achieving public health goals which according to Winslow is prevention disease, prolongation of life, and improvement of mental and physical health and efficiency through improvements to the physical environment of housing (temperature in the house, ventilation, home lighting, house humidity, occupant density and type of house floor) with an integrated management system for residential management.

The results of the study to prevent TB transmission include giving BCG immunization to children according to the schedule, providing nutritious food to maintain children’s immunity, giving babies exclusive breastfeeding for a minimum of six months, maintaining cleanliness of the home environment by cleaning the house floor every day, clean the toilet and bathroom, keep air circulation in the house, try to open the windows and doors at home every day so that the room in the house is exposed to sunlight (TB bacteria will die when exposed to the sun), do Clean and Healthy behavior, try children do not come into direct contact with people affected by TB to minimize TB transmission.

Occupancy density is one of the risk factors for TB infection which is more commonly found in groups of subjects who have more than one source of transmission. If housing becomes more crowded, the transfer of infectious diseases through the air will be easier and faster, especially in one house there are family members who are affected by TB, children will be very vulnerable to direct exposure. The number of sources of transmission in one house will increase the risk of TB infection in children. The results of the study in the City of Brebes showed that there was a relationship between the condition of the home environment (occupancy density) and the incidence of TB with a value of p value = 0.000 and OR = 5,168.27 According to Rusnoto et al. (2005) that there was a significant relationship between humidity and pulmonary tuberculosis incidence (OR = 6.3; 95% CI = 2.651-14,971). The results of the Jelalu (2008) study showed that 73.7% of cases of pulmonary tuberculosis in adults in the District Kupang is influenced by 4 variables, one of which is the humidity of the house.

According to Rusnoto et al. (2005) that there is a significant relationship between the extent of ventilation and the incidence of pulmonary tuberculosis, the results of the odds ratio (OR) of 16.9 with 95% Confidence Interval (CI) 2,121-134,641, with a value of p = 0.001.

Dahlan’s (2001) study showed that home ventilation is the most contributing variable that regulates room temperature for the incidence of pulmonary tuberculosis, statistically showing a significant relationship p <0.05 with OR = 8.8 (p = 0.000).

According to Susiloawati (2012), the incidence of smear positive tuberculosis has a chance or greater risk for people living in a house with positive smear tuberculosis, a house with zinc roofs, extensive ventilation <10% of floor area compared to people who do not live in a house with positive smear tuberculosis, home no zinc roof, ventilation area ≥10% of floor area in the upland area was statistically significant.

According to Rusnoto et al. (2005) that there are a significant relationship between home lighting and the incidence of pulmonary tuberculosis with an odds ratio (OR) of 7.926 with 95% Confidence Interval (CI) (3,129–20,080). The housing condition is not sufficiently light and has a ground floor/cracked cement also has a large proportion of pulmonary tuberculosis.

This type of soil floor has a role in the process of pulmonary tuberculosis, through indoor humidity. Ground floor tends to cause moisture, in the summer the floor becomes dry so that it can cause dust which is harmful to its occupants. This is supported by the results of a study by Mahfudin (2006) that the condition of houses with soil floors has a significant relationship with the incidence of pulmonary tuberculosis with OR 2.2 (1,135; 4,269). This is also supported by the results of research by Ruslan et al. (2017), there is a relationship between BCG immunization with pulmonary tuberculosis.
immunization status and the incidence of pulmonary tuberculosis in Banjarbaru City (0,000), there is a relationship between house floor area and incidence of pulmonary TB in Banjarbaru City (0,006), there is a relationship between house occupant density and incidence of pulmonary TB in children in Banjarbaru City (0,0006)⁹.

Efforts to get a high TB control work result requires integration from planning to prioritizing financing¹⁰. One of the measurable control systems for infectious disease control is residential management. Residential management is an intervention model to provide an understanding of management of the formation of habitable healthy homes based on the Decree of the Minister of Health of the Republic of Indonesia NO. 829/Menkes/SK/VII/1999 which consists of requirements for building materials, components and arrangement, lighting, air quality, ventilation, transmitting diseases, water, means of food storage, waste and occupancy density of bedrooms¹¹.

Materials and Method

This study was an intervention study with a cross sectional approach. The study population was children with TB who were recorded and reported to the TB program responsible/executor of the Banjarbaru City Health Office.

The sample of this study was all children with TB in the Puskesmas in the Banjarbaru City area from January to December 2018.

Based on the table above, it can be seen that the number of family members <4 is 10 (33.3%) and the number of family members > 4 is 20 (66.7%). While the most work from TB research in Banjarbaru City is Employees/PNS with a total of 13 (43.3%). While the smallest spelling is farmers/fishermen with number 1 (3.3%). the length of time the child has the most TB is > 1 month with 5 people with a percentage (16.7%) and the length of time the child has TB at least > 3 weeks there is 1 person with a percentage (3.3%). respondents who experienced pulmonary TB were found in an environment that did not meet the housing environmental health requirements, namely 6 (20%) respondents. While respondents who did not experience pulmonary TB were found in an environment that fulfilled the housing environmental health requirements, namely 24 (80%) respondents. Based on the table above, it can be seen that of the 30 (100%) respondents who met the criteria for a healthy home of 23 (76.7%) respondents. While those who did not meet the criteria for a healthy home were 7 (23.3%) respondents.

Based on the table it can be seen there are 6 (20%) respondents who suffer from pulmonary TB. While there were 24 (80%) respondents who were known not to have pulmonary TB.

</table>

Based on the findings in the field, out of 24 (100%) respondents with good Environmental Health, there were 4 (16.7%) respondents who suffered from pulmonary pulmonary TB. This can occur because a good Home Health Environment does not guarantee that it is far from all aspects of the disease, especially pulmonary TB.

Chi Square test results with a confidence level of 95% to see a relationship between Home Environmental Health on the incidence of pulmonary TB in children in Banjarbaru City found that the p-value = 0.883. From the p-value value in the results of the statistical test, Ho’s decision was accepted (p > 0.05), which means that there was no significant relationship between Home Environmental Health and the incidence of pulmonary TB in children in Banjarbaru City.

Based on the table above, respondents who suffer from pulmonary TB are more prevalent in respondents who have houses that meet the requirements, namely as many as 4 (17.4%) respondents compared to those whose houses do not meet the requirements, namely as many as 2 (28.6%) respondents.

Chi Square test results with a confidence level of 95% to see the existence of residential relationships to an increase in health status of children with TB in Banjarbaru city showed that the p-value = 0.419. From the p-value values in the results of the statistical test, Ho’s decision was accepted (p > 0.05) which means that there was no significant relationship between houses to improve the health status of children with TB in the city of Banjarbaru. This research is in line with Asfiradyati’s research (2016) there is no relationship between the physical environment factors of the house which include natural lighting (p-value 0.102), house walls (p value 0.137), ventilation area (p value 0.805), and house floor (p value 0.700) with the incidence of pulmonary TB in infants/children12.

Discussion

Chi Square test results with a confidence level of 95% to see the existence of residential relationships to an increase in health status of children with TB in Banjarbaru city showed that the p-value = 0.419. From the p-value values in the results of the statistical test, Ho’s decision was accepted (p > 0.05) which means that there was no significant relationship between houses to improve the health status of children with TB in Banjarbaru City.

Conclusion

1. There is no significant relationship between Home Environmental Health on the incidence of pulmonary TB in children in Banjarbaru City (p-value = 0.883)
2. There was no significant relationship between houses to improve the health status of children with TB in Banjarbaru (p-value = 0.419)

Relationship of Environmental Factors, Sanitation Means and Sanitation Behavior with Fly Density Level (Review of Food Stalls in Banjarbaru City)

Lenie Marlinia1, Laily Khairiyati1, Nida Ulfah1, Nanda Suji Paramita2, Putri Muslimah2, Rezeky Norwinardi2, Tien Zubaidah3

1Environmental Health Department, 2Student of Public Health Program Medical Faculty of Lambung Mangkurat University, 3Health Polytechnic of the Ministry of Health of Banjarmasin

Abstract

Many food stalls lack the cleanliness of the surrounding environment so that it becomes a supporting factor for the development of disease vectors. Based on a preliminary study conducted in December 2017, it was seen a collection of flies on five food stalls around the city of Banjarbaru. The purpose of this study was to analyze the relationship between environmental factors, sanitation facilities, and sanitation behavior with the level of density of flies in food stalls in Banjarbaru City. This study was an observational analytic study with a cross sectional design. The results showed that the density of flies with high, medium and low categories were found in 3 stalls (6%), 18 stalls (36%) and 29 stalls (58%). There is no correlation between temperature, humidity, light intensity, clean water supply, waste management, and sanitation behavior with the level of fly density (p value> 0.05). There is a relationship between toilet facilities and sewerage with the level of fly density (p value <0.05).

Keywords: Flies density, environmental factors, sanitation facilities, sanitation behavior.

Introduction

A food stall or canteen is a simple business that usually sells traditional food or home-cooked food, which is relatively affordable for consumers. In general, food stalls provide a simple place to enjoy food sold. The requirements for sanitation of canteens/food stalls have been explained in the Decree of the Minister of Health of the Republic of Indonesia Number 109/Ministry of Health/SK/VII/2003 concerning the feasibility of sanitation hygiene in restaurants and restaurants. Hygiene requirements for canteen/stall sanitation must meet the stipulated conditions, one of which is basic sanitation facilities1.

The existence of food stalls in a settlement is a supporting requirement for city residents if they want to immediately enjoy a meal in a place or taken home in terms of practicality. However, many of them lack the cleanliness of the surrounding environment so that it becomes a supporting factor for vector development2. Therefore, food stalls require basic sanitation that must be kept clean in order to prevent the arrival of disease vectors, such as flies. Flies that perch on food have the potential to carry contaminants and reduce food quality3.

Flies are insects from the diphtheria order that have a pair of membrane-shaped blue wings. All body parts of a house fly can act as an infectious agent (body, feathers on hands and feet, feces and vomit)4. Dirty and smelly environmental conditions can be an excellent place for growth and breeding for house flies. The presence of flies in food can be a serious threat to human health. Flies become mechanical vectors of agents for viruses, bacteria, protozoa, and worm eggs from trash into human food5.

With varied educational backgrounds and insights, food sellers need to get the attention of various parties in order to maintain the safety of food sold from disease transmission. Based on a preliminary study conducted at several food stalls around the city of Banjarbaru in December 2017 there were visible flies in five food stalls. This is because the seller does not take precautions in the form of a serving lid to protect food from flies. Besides that, it was seen that there were still food debris scattered...
Fly populations increase depending on season and climate conditions, and the availability of suitable breeding sites. Environmental temperature, air humidity and rainfall are fly populations increase depending on season and climatic conditions, and the availability of suitable breeding sites. Environmental temperature, air humidity and rainfall are components of weather that affect the quality and quantity of flies in nature. The population of many house flies will cause disruption to humans and can be a vector that carries diseases to humans such as dysentery, diarrhea, typhoid, cholera and other digestive disorders. Weather components that affect the quality and quantity of flies in nature The population of many house flies will cause disruption to humans and can be a vector carrying diseases to humans such as Decentri, Diarrhea, Typhoid, Cholera and other digestive disorders.

Flies are more active in places that are protected from light than places that are directly exposed to sunlight. The density and spread of flies in an area is influenced by its reaction to light, temperature, humidity, texture and surface color that are favored for rest. The density of flies will be high if the temperature is between 20-25°C. The population decreases if the temperature is >45°C and <10°C. Flies are generally active in low air humidity. At temperatures above 20 °C the fly will be outside the house, in a place close to free air. When not eating, flies will rest on horizontal surfaces or on cables that stretch or vertical places and on the roof in the house especially at night.

Based on the above background, research is needed on the relationship between environmental factors (temperature, humidity, light intensity), sanitation facilities (provision of clean water, latrine availability, waste management and sewerage) and sanitation behavior with fly density at food stalls in around the city of Banjarbaru.

**Material and Method**

This type of research is an analytic observational study with a cross sectional study design. The population in this study were all food stalls managers around the city of Banjarbaru. The minimum sample used for correlational research is 50 samples.

</table>

Based on table 1 above, there are 29 food stalls (58%) that have a low category of fly density, there are 21 food stalls (42%) with medium fly density categories. The density level of flies has a moderate category standard if there are 3-5 tail/grill blocks and low if there are 0-2 tail/grill blocks. The most common fly is the type of house fly (Musca domestica). Other types of flies are large flies (Sarcophagacalcitrans) and green flies (Chrysomyamegacephala).

The table also shows that the temperature that does not support fly density is dominant in 46 food stalls (92%). The moisture factor that does not support the development of flies is in 29 stalls (58%).

Based on the table, most of the light intensity supports the density of flies in food stalls as many as 34 food stalls (68%). The provision of good clean water has mostly been applied by food stalls in the city of Banjarbaru with a total of 39 fruits (78%). Based on the table above, it is known that for latrine facilities, most have implemented 40 food stalls (80%) well.

A food stall that implements good and poor waste management is balanced with 25 food stalls each. In the table above, it can be seen that there are only 28 food stalls (56%) in the waste water drainage category.

Based on table 2 above shows that at a supportive temperature, the moderate density of fly flies is less than the temperature that does not support. Whereas in the low category density of flies more in temperature conditions that do not support compared to the temperature that supports. From the table above, it can be seen that the results of the chi square statistical test show a p-value of 1,000 which means there is no relationship between temperature and the density of flies. The results of Erza NA and Bambang W (2017) research also show that there is no significant relationship between temperature and fly density inside and outside the home.

Based on the table above shows that in the supporting humidity, the medium density level of flies is less than that which does not support moisture. Whereas in the low category fly density level more in conditions of humidity that do not support compared to the supporting humidity. From the table above, it can be seen that the results of the chi square statistical test show a p-value of 1,000, which means there is no correlation between humidity and the density of flies in food stalls in the city of Banjarbaru.

Table 2 above shows that in the light intensity that supports, the moderate density of fly flies is less than the light intensity that does not support. Whereas the low category of fly density is more in the condition of light intensity that does not support compared to the light intensity that supports it. The results of the chi square statistical test showed a p-value of 0.454 where there was no correlation between light intensity and the density of flies in food stalls in the city of Banjarbaru.

The table above shows that in the supply of clean water that is lacking, the level of density of flies in the medium category is less than the provision of good clean water. The results of the chi square statistical test showed a p-value of 0.193 where the value of p> 0.05 means that there is no relationship between the supply of
clean water and the density of flies in food stalls in the city of Banjarbaru.

The table above shows that in the waste management that is lacking, the level of density of flies with the medium category is more than that of good waste management. The results of the chi square statistical test showed a p-value of 0.05 where the value of p < 0.05 means that there is a relationship between waste management and the level of density of flies in food stalls in the city of Banjarbaru.

The table above shows that in the wastewater drainage that is lacking, the level of density of flies with the medium category is more than that of good waste management. The results of the chi square statistical test showed a p-value of 0.030 where the value of p < 0.05 means that there is a relationship between sewerage and the density of flies in food stalls in the city of Banjarbaru.

The table above shows that in poor sanitation behavior, the level of fly density in the medium category is more than that of good sanitation behavior. Whereas the low category of fly density is more in terms of good sanitation compared to poor sanitation behavior. The results of the chi square statistical test showed a p-value of 0.079 where the value of p > 0.05 means that there is no correlation between sanitation behavior and the level of density of flies in food stalls in the city of Banjarbaru.

Discussion

The flies around the settlements are Musca domestica house flies and Chrysomya megacephala green flies, and the Blirik fly Sarcophaga sp. These flies breed in habitats in piles of dirt, garbage that has decayed and is full of bacteria and other pathogenic organisms. High or abundant fly populations can interfere with human peace because they cause discomfort around and can transmit various types of digestive disorders due to various types of bacteria that are transmitted.

Fly populations increase depending on the season and climate conditions, and the availability of suitable breeding sites. Environmental temperature, air humidity and rainfall are components of weather that affect the quality and quantity of flies in nature. Fly larvae are very vulnerable to air humidity, deviating air temperatures and excessive rainfall.

Musca domestica and Chrysomya megacephala are cosmopolitan and synanthropic flies which means that these flies have a high dependency relationship with humans because the nutrients needed by flies are mostly in human food. Depending on the season and temperature: Adult flies live 2-4 weeks in summer and are longer in winter, which can reach 3 months, they are most active at 32.5°C and will die at 45°C.

The level of knowledge and how to behave adequately regarding the hygiene and sanitation of food stalls are other factors that may also influence the spread of flies around it. In addition, based on the facts in the field, another factor also is not applying the sorting of organic and non-organic waste in these places.

Ways to prevent flies from dirt containing germs can be sought by making construction of latrines that meet the requirements. Good waste management, such as collecting, transporting and disposing of waste, will be better sequentially because it can eliminate fly media. Garbage bins that meet the requirements, among others, are made of waterproof material, are not easily corroded, strong, closed and easy to clean so as not to become a nest of disease vectors. In addition, the waste is transported at least 1 x 24 hours.

To protect food, equipment and people in contact with flies can be done by: 1) food and eating utensils used must be anti-fly; 2) food stored in the larder; 3) food needs to be wrapped; 4) windows and open places wire screens; 5) other electric appliance fans can be installed to prevent incoming flies; and 6) attaching sticks to trap flies.

Conclusion

1. There is no relationship between temperature and density of flies in food stalls in Banjarbaru city with a p-value of 1,000.
2. There is no correlation between humidity and the density of flies in food stalls in Banjarbaru with a p-value of 1,000.
3. There is no correlation between light intensity and the density of flies in food stalls in Banjarbaru with a p-value of 0.454.
4. There is no relationship between the supply of clean water and the density of flies in food stalls in Banjarbaru city with a p-value of 0.193....
5. There is a relationship between waste management and the level of density of flies in food stalls in Banjarbaru city with a p-value of 0.05

6. There is a relationship between sewerage channels and the density of flies in food stalls in Banjarbaru city with a p-value of 0.030

7. There is no correlation between sanitation behavior and the density of flies in food stalls in Banjarbaru city with a p-value of 0.079.

Children’s unwanted pregnancy and early marriage is still quite high in Indonesia. Parents’ role have important factor on Children’s unwanted pregnancy and early marriage. The objective of this study were to determine parents’ role which affecting unwanted pregnancies and early marriage aged 13-18 years. A cross-sectional study was conducted on 60 families who had children 13-18 years who were married. A guided self-administered questionnaire, which included the characteristics respondents, parental permissiveness, reproductive function, education function, socioculture function, and religion function, were used. Approximately 61.7% permissive parents, 68.3% of family had supporting religious function, 25.0% less supporting the reproductive function, which were significantly ($p < 0.05$) associated with unwanted pregnancies. Permissive parents had 2.18 times greater unwanted pregnancy (PR = 2,18, 95% CI 1.21, 3.92, $p < 0.05$) compared to less permissive parents when adjusted for other variables. This study highlights a high unwanted pregnancies and early marriage that is associated with parental permissiveness, religious function, and reproductive function of families.

**Keywords:** Parental permissiveness; Reproductive function; Religious function; Unwanted pregnancies; Early marriage.

**Introduction**

Unwanted pregnancy and early marriage means premarital pregnancy in a woman aged 10–19 years\(^1\). Premarital unwanted pregnancies and early marriage in children (less than 18 years) are important public health issues in developing countries, including in Indonesia\(^2\). This is related to the impact caused by both mother and child. Baby born by a girl who married at the age of a child have more risk of death high, and possibly two times bigger to die before the age of 1 year compared to children born of a mother who is twenty annual. Babies born by the child’s bride also has higher probability for premature birth, with weight low birth body, and malnutrition\(^3\).

Child’s Unwanted pregnancies are the dominant factor in the occurrence of child marriage in Indonesia\(^4,5\). The number of child marriage in Indonesia is still relatively high in the East Asia and Pacific region. National Social and Economic Survey showed approximately 25% women marry under the age of 18\(^6\). Supported by the Indonesian Demographic and Health Survey (2012), 17% of women were married before the age of 18\(^7\).

Likewise in West Kalimantan Province, Indonesia, there is still a high age of child marriage due to unwanted pregnancies. In 2015 year, Age Specific Fertility Rate (ASFR) in West Kalimantan’s was the highest in Indonesia, as many as 104 per 1000 births\(^8\). One of the initiation factors the child’s age marriage is premarital sexual behavior that affects pregnancy\(^5,9,10\).

Sintang District is one of disadvantaged, frontier, and outermost regions which are still very limited in terms of access to information, facilities and infrastructure. There are still many public health problems in the area, including early marriage and unwanted pregnancy in children\(^11\). The results of the preliminary survey indicate that children who live in border areas tend to be more likely to do early marriage (unwanted pregnancy is the main factor). Evidenced by ASFR in Sintang District with the highest age of 15-19 years in West Kalimantan, 62 per 1000 births. The dominant cause is free sex\(^12\).

Multiple studies have examined the level of education, families’ role\(^13\), early sexual debut\(^14\), low self-esteem, low educational\(^15\). Research on pregnancy in adolescents has been done a lot, but research that addresses the focus on parenting parents, especially
parental permissiveness and the application of family functions is still limited, and the focus on children who live at border areas has not been widely studied.

Based on ecological factors among children’s environment, including parental relationships with their children was related by risky behavior. A positive family environment is an important place in good development for adolescents. Family is a protective and prevention factor of risky behavior.

It is needed a research to determine the influence factors of unwanted pregnancy in children, especially in border areas, so that it can be used as a basis for intervening as a preventive and protective unwanted pregnancy. The purpose of this study was to determine the relationship between parental permissiveness and the application of family functions with children’s unwanted pregnancies in the border area, Sintang District.

**Method**

**Subject:** This research was conducted on all families with children who experienced pregnancy in the Mensiku Health Center Work Area, which was obtained from a cohort of pregnant women from January 2016 to June 2017 as many as 60 families. This study was an observational study with a cross sectional approach. The sampling technique using total sampling.

**Instruments:** Data were collected through a structured interview questionnaire that was adopted and given to all participants. The questionnaire covered matters parental permissiveness, reproductive, socio-cultural, environmental, education, economy, religious, love, and protection function. Closed-ended questions were included with two answering options.

Parental permissiveness was measured to determine whether parents are permissive to dating behavior in children, and free dating behavior in children as long as they do not get pregnant.

The reproductive function measures whether giving sexual education or reproductive health to their children.

The function of religion measures whether running religious activities and participating in religious activities. The education function measures whether families encourage their children to continue to further education. The environmental function measures whether the environment around the case of an unwanted pregnancy is normal. The love function measures whether the family gives attention and affection to children. The Economic Function measures the family’s economic status based on the Regional Minimum Wage.

The socio-cultural function measures the socio-cultural conditions that are more permissive in unwanted pregnancies.

**Data analysis:** Data analysis used univariate and bivariate analysis, with X2 test (Chi Square) and 95% confidence level (α-0.05). In the cross sectional study, the value of Prevelen Ratio (PR) is used to determine the closeness of the relationship.

**Results and Discussion**

Approximately 93.3% of participants are aged 16-18 years, senior high school (48.3%), pregnancy delivery age was 29-41 weeks (98.3%), and unhealthy dating (96.7%).

*Statistically significant (<0.05)
This study showed that parental permissiveness of dating behavior was significantly associated with unwanted pregnancy ($p = 0.004; 95\%\ CI = 2.176$) (See table 1). Participants who had permisive parents were 2,176 times and less supporting of reproductive function were 1,696 times more likely to get unwanted pregnancy.

Less supporting of family function could increase the likelihood of unwanted children. Statistically, social, love, frequency, education, economy, and environment function didn’t have a significant relationship, but it showed a positive trend. It is a family that functions better than an unwanted school.

Pregnancy under 20 years has a negative impact on the condition of the fetus and maternal health (premature babies, bleeding, disabled babies, and even death). This finding shows all participants had unhealthy dating behavior. It indicates the sexual initiation earlier amongst border children. Earlier sexual initiation could be a trigger the premarital sexual intercourse$^{23,24,25,26}$. As a finding this study that approximately 60.0% of participants gets unwanted pregnancies. Low education in children’s pregnancy were worse the condition. It is because of the lack of information about pregnancy and health$^{27}$. Especially the children who live in the border area (including disadvantaged, underdeveloped and outermost), which lack access to information, and educational facilities. This is one of factor that contributes the increasing in Age Specific Fertility Rate in West Kalimantan particulary, and Indonesia generally.

Parental education level of participants was low. Its had affects the style of parenting to their children, including in carrying out family functions and providing sexuality. Education and parental marital status are one of the determinants that do not directly affect unwanted pregnancies in children$^{28}$. 

Parental permissiveness is significantly associated with unwanted pregnancies in children. The findings of this study indicate that most parents are permissive towards dating (81.7%), allowing a child’s relationship with a girlfriend/boyfriend (65.0%) and freeing the child’s relationship with a girlfriend/boyfriend provided they are not pregnant (58.3%). It will increase risky sexual behavior on children$^{29}$. Supported by the lack of knowledge about sexuality would increase the risky sexual behavior, that impacts on unwanted pregnancy. Children in the border area are very limited information, facilities and infrastructure (disadvantaged, underdeveloped, and outermost). This are supported by the permissiveness of parents to dating, which increases the chances children’s unwanted pregnancy. Research shows that children living in border areas are vulnerable to human trafficking (including child prostitution)$^{30}$.

In line with research conducted by Kincaid et al. (2012) states that the role of parents greatly influences adolescent sexual behavior. Parents who are more permissive to adolescent sexual behavior, then the tendency will increase the risk of adolescents involved in risky sexual behavior$^{31}$. Parents are one of the primary protective factors in the behavior of risky adolescents$^{29,32}$.

This study also shows that religious functions that support significance are related to unwanted pregnancies on children who live in border areas. The application of religious values in family life can prevent and protect children that are prohibited by religion, including premarital sexual behavior which impacts on unwanted pregnancies. This study focuses on religious life that is applied in families, which includes carrying out religious worship (76.7%), attending religious activities (96.7%), and families informing that having a relationship before marriage is a violation of religious and sinful norms.
(75, 5%). This research indicates that the application of religious functions in the family can prevent and protect children from unwanted pregnancies.

Reproductive function in the family has a significantly association with unwanted pregnancy on children who live in border area. The focus of this study is communication about reproductive health properly. Based on the results of this study, internal communication as a form of reproductive function can prevent and protect children from unwanted pregnancies. The focus of this study shows that most families do not discuss with children about sexually irregularities (71.7%), not provide pubertas information (56.7%). This is in line with previous research, sexuality communication conducted as a preventive factor for risky sexual behavior and unwanted pregnancy in children.

The results of the study found that there was no significant relationship between socio-cultural, environmental, economic, protection, and love functions with an unwanted pregnancy (p value > 0.05). Although not significantly related, indicates a positive relationship trend. This means that the social, cultural, environmental, economic, protection, and non-supportive functions have a greater chance of unwanted pregnancy than those who support. The family is the first and foremost educator for adolescents. Parents play an important role in socializing the norms that exist in society.

Effective and efficient intervention is needed in involving the role of the family in applying family functions, so it could be a primary prevention and protection of risky behavior of children, including unwanted pregnancy. This finding has implications for program development of culturally grounded prevention and intervention techniques based on family approach. The results suggest that programs that emphasize parental involvement in applying family function and regarding parental permissiveness might be most effective in preventing risky sexual behavior that affects unwanted pregnancy. The study’s limitation is the number size of this research still small. Future, the researcher should add the sample size.

Conclusions

This cross-sectional study could be considered to be a preliminary study identifying factors related unwanted pregnancies amongst border child aged 13-18 years. Parental permissiveness and family function among border children should be improved.

Conflict of Interest: The author declares that there is no conflict of interest.

Acknowledgements: We would like to thank all of the participants in the study for the time and help given throughout. Without their participation, this research would not have been possible.

Efficacy of Proprioceptive Neuromuscular Facilitation and Closed Kinetic Chain Exercises on Quadriceps and Plantar Flexors Among Geriatrics

Logeshwari Selvaraj¹, N. Nousheen Fathima², D. Hepzibah Rubella¹

¹Assistant Professor, ²BPT Final Year Student, School of Physiotherapy, Vels Institute of Science, Technology and Advanced Studies (VISTAS), OMR, Thalambur main road, Chennai

Abstract

Elderly population’s quality of life decline at a faster rate and hence there is an increase in mortality rates. Anti-aging process can be emphasised by scheduled exercise programs which enhances beneficiary adaptations in vascular physiology and neurovascular coupling. The mobility function is disturbed due to reduced muscle strength, inappropriate activation of motor units, insufficiency to maintain balance which leads to higher risk offall in the elderly people. Closed kinetic chain exercises control the musculoskeletal system against gravity at rest and in motion thereby protecting the postural stability. PNF has a positive effect on balance and functionality in older adults.

Materials and Method: A Quasi experimental study was done for 50 community dwelling elderly people from “Vishranthi Charitable Trust” with mean age of 73±4 years who were selected based on the inclusion criteria. Closed kinetic chain exercises for quadriceps and plantar flexors along with PNF technique such as anterior elevation and posterior depression were given and followed up for 3 weeks. The pretest and post test values were obtained using 6-min walk test, the knee extensor strength measurement and fall risk questionnaire.

Result: There was a significant difference in 6-min walk test, fall risk questionnaire p<0.05 in improving the strength of quadriceps and plantar flexors, and there was non-significant difference in the knee extensor strength.

Conclusion: Hence the study concludes that there is an impact on PNF and Closed kinetic chain exercise on quadriceps and plantar flexors to enhance balance among geriatrics.

Keywords: Geriatrics, closed kinetic chain exercise, PNF, quadriceps and plantar flexors.

Introduction

Anti-aging process can be emphasised by scheduled exercise programs which enhances beneficiary adaptations in vascular physiology and neurovascular coupling. In today’s era exercises have shown higher growth than accommodating to secondary lifestyle.

In most individuals just the euphoria of exercise has drastically delayed the aging process.

Elderly population’s quality of life decline at a faster rate and hence there is an increase in mortality rates. The main cause of aging is due to morphological, functional and biochemical changes in the body that makes the person more susceptible to deformities as it is a natural, progressive and dynamic process.(1) The essential element for the performance of purposeful activities such as postural maintenance during gait is postural balance which decreases with age.

Reduction in muscle strength and maintenance of muscle properties for daily activities leads to increase in dependency level and reduced self confidence. The
mobility function is disturbed due to reduced muscle strength, inappropriate activation of motor units, insufficiency to maintain balance leads to higher risk of fall in the elderly people. Balance is essential for controlled and co-ordinated movements. It plays a major role in the sensory input such as vision, vestibular system and proprioception.

The foot and ankle plays a major role in balance and postural control. As aging progresses, there is alteration in the gait pattern characterised by reduced speed, cadance and increased variability of step duration and length.

The function of muscle strength decreases about 25% after the age of 65 which results in decreased size of muscle fibres, the contraction and relaxation of the muscle is also decreased. In elderly the capacity to generate strength of the muscle is reduced and due to this there is decrease in physical and functional independence.

Closed kinetic chain exercises control the musculoskeletal system against gravity at rest and in motion and the postural stability is also protected. Joint stability is enhanced by reducing the shear strength and compressive forces adding to the joints. There is also an increase in the co-contraction of muscle and eccentric contraction. (3)

Proprioceptive neuromuscular facilitation has a positive effect on the balance and functionality of older adults. (1) It reduces fall risk in the population and is presented as an interesting exercise program which enhances balance on elderly including co-ordination and proprioceptive activities also. (4)

**Materials and Method**

A Quasi Experimental study was done for community dwelling elderly population from Vishranthi Charitable Trust. 50 participants were taken and the study was conducted for duration of 3 weeks. Patients included for the study were: Old aged people in between the age of 65-85 years; Both male and female are included; Mini Mental State Examination > 24; Fall Risk Questionnaire with the total of 4 and above were included. The exclusion criteria for the study was–Recent orthopaedic surgeries in the lower limb; Patients with neurological disturbance, cardiovascular disease, vestibular disorder, mentally unstable and non co-operative patients were excluded from the study.

**Procedure:** The participants were explained about the study and the procedure. The pretest was done based on the outcome measures such as Fall Risk Questionnaire; The knee extensor strength (THIGH GIRTH) was measured for the right and left leg; 6 min walk test was done and the time duration was noted. After the pretest the participants were made to do the concerned exercises.

**Closed Kinetic Chain Exercises**

<tr>
<td>Double leg squat (3 sets 12 reps)</td>
<td>Single leg squat (3 sets 12 reps)</td>
<td>Single leg squat with weight (3 sets 12 reps)</td>
</tr>
</tbody>
</table>

The patient was asked to raise both their heel and stand with their toes for 12 counts and 3 sets, then the patient was asked to squat using both their legs. This was done for a week. The next set of exercises was done on 2nd week such as single leg heel raise and single leg squat for 3 sets and 12 repetitions. The 3rd week exercise was progressed using 2 kg weight which is administered on the lower part leg above the ankle and the patient was asked to do single leg heel raise and single leg squat with the weight for 3 sets and 12 repetitions.

**Proprioceptive Neuromuscular Facilitation:** The treatment in the study consisted of the pelvis in anterior elevation and posterior depression. Anterior Elevation was done by asking the patient in left side half lying position with knee slightly flexed. The therapist was stood in a diagonal position behind facing the patient. One hand of the therapist was on the patients right ASIS and the left hand was reinforced over the right and the patient was commanded to pull their pelvis up and forward. The same method was administered for the right side also. Posterior Depression was done by asking the patient in left side half lying position. The therapist left hand was placed over the patients right ischial tuberosity and the right hand is reinforced over the other. The patient was commanded to” Sit back over my hands” till the patient completes the end range. This technique was done for 3 weeks for every session. The total duration of the exercise was 30 minutes. After the 3 week of exercise post test was done using the outcome measures such as fall risk questionnaire; The knee extensor strength.

Result

The study shows that there is a significant difference between the knee extensor strength and fall risk questionnaire and the 6 min walk test with p<0.05 in improving the strength of the quadriceps and plantar flexors. The study shows that there is no difference between the thigh girth measurement in both legs.

Discussion

The present study was aimed to find the effect of PNF and Closed kinetic chain exercise on quadriceps and plantar flexors among geriatric patients for 3 weeks, for subjects with high fall risk and balance problem due to weak quadriceps and plantar flexors. Lanza et al found that the older adults showed significant increase in time required to attain target velocity indorsiflexors. This age related delayed progression of contraction velocity might be due to number of changes in muscle morphology and function subordinating with age, including a selective loss of type II muscle fibres for which an impaired ability to generate high motor unit discharges at greater rate. Teasdale et al and colleagues reported that attention demanded during normal walking was higher in older adults than younger adults regardless of their phases during gait cycle. After the improvement of balance in the present study the subjects were able to cross any obstacle without any difficulty.

Closed kinetic chain exercises played a major role in improving the strength of the muscles along with functional performances in older adults thereby reducing the fall risk prevalence.

Limitations:

- Small size was small.
- Long term follow-up can been done.
- This study can be compared with other geriatric population with any pathophysiological conditions to know the efficacy of closed kinetic chain exercises.
- Efficacy of other muscle group can be evaluated to examine the hip, knee and ankle strategy.

The Development of an Integrative Holistic Program in Early Childhood Care and Education: A Policy in the Indonesian Context

M. Fadlillah
Departemen of Early Childhood Education, Universitas Muhammadiyah Ponorogo, Indonesia

Abstract
Policies on early childhood care and education in Indonesia continue to grow. One interesting policy to discuss is integrative holistic early childhood development. The HI-ECD program is considered effective in ensuring the fulfillment of early childhood development rights. HI-ECD in early childhood education unit includes education, health and nutrition services, care, and protection. The aim of HI-ECD is to fulfill the essential needs of early childhood, both physically and psychologically so that they can become healthy, intelligent, and noble persons, and ready to enter the next level of education. In addition, the long-term goal is to prepare and succeed the Indonesian gold target by 2045. This study was based on an analysis of government-issued HI-ECD documents as well as various relevant literature.

Keywords: Integrative holistic programs, education, health and nutrition, care, protection, early childhood.

Introduction
Early childhood is the next generation of the nation that will bring change in the future. They have very rapid growth and development, both physically and intellectually. It is estimated that when a child enters kindergarten, his brain weighs almost 90% of the brain of an adult. Various studies show that the first five years of children’s life are the most valuable period where the child’s brain and intellectual development occurs very rapidly. Bloom explained that 50% of children’s intellectual development occurs at the age of four and reaches 80% at the age of eight. Therefore, early age-from birth to eight years-is called the golden age. Care, education and practice of the environment greatly influence the next development of the child.

This priceless early age attracts the attention of various parties around the world, including Indonesia. Various policies and programs are offered to optimize the development of early childhood. Early childhood care and education (ECCE) has been studied by researchers in recent years. ECCE is not only for preparation to elementary school level, but also to fulfill and develop children’s needs holistically in terms of social, emotional, cognitive and physical needs. ECCE helps children obtain optimal language, math, and social-emotional skills. In addition, ECCE can be used as a means to reach and meet the needs of children who are less fortune. The ECCE program must continue to be developed and improved in order to provide the best service for early childhood. ECCE is one of the best investments a nation can make to prepare for better human resource development.

In Indonesia, ECCE is one of the strategic programs in preparing Indonesia’s golden targets in 2045. The Directorate General of Early Childhood, Non-formal and Informal Education (Dirjen PAUDNI) asserts that starting from 2012 each village must have at least one early childhood education (ECE). This shows the government’s seriousness in paying attention to ECCE. Although the role in ECCE is still far from what is expected. This is because most of the implementation of ECCE still relies on and is dominated by private parties. As a result, facilities and infrastructure supporting the ECCE are very limited, even the welfare of teachers is very alarming. This condition does not only occur in Indonesia but it is also experienced by other countries. Another problem is that only around 7.3 million children out of approximately 26.2 million children aged 0-6 years received ECCE services through various program.

As a form of government’s attention and support in ECCE, a policy on integrative holistic early childhood
development (HI-ECD) was issued. This policy is very much needed as a law shelter for an integrated holistic program for early childhood, as well as standardization in implementing the program at school and in the community. HI-ECD policy is set forth in the Presidential Regulation of the Republic of Indonesia (Perpres RI) Number 60 of 2013. This policy is intended to guarantee the fulfillment of the right to early childhood development. With this policy, the HI-ECD program must be implemented in ECE unit. Unfortunately, the policy of implementing HI-ECD in ECE unit has not been much analyzed. How is the development of the HI-ECD program in ECE unit? How is the technical implementation? and What are the obstacles to HI-ECD in ECE unit? This article aimed to examine and analyze HI-ECD policies in ECE unit.

Method

Type of research: Qualitative explorative method was used in this study. The researcher wanted to understand and review the policies and implementation of HI-ECD development programs in ECE unit. The exploration method was used to reveal new knowledge about HI-ECD policies issued by the government. Jacobsen explains that exploratory research questions aim to reveal new knowledge about a phenomenon that occurs. With this method, the researcher could find out how far HI-ECD was applied in ECE unit, including development concepts, implementation techniques, and constraints found in ECE unit.

Data Collection: In order to gain an understanding of the integrated holistic development program in ECCE, the researchers documented the data. The data that have been documented were then understood, reviewed, and analyzed using the hermeneutic approach. Hermeneutics is an approach to theory and practice of interpretation. That is, this approach is intended to interpret how people understand the construction and practice of a particular policy. Skjaeveland explains that a hermeneutic approach can be used to analyze certain documents and policies. In this study, hermeneutic approach was used to study ECCE policies. The documents that Perpres RI Number 60 of 2013 concerning HI-ECD; technical instructions for implementing HI-ECD in ECE unit; Minister of Education and Culture Regulation(Permendikbud) Number 137 of 2014 concerning National Standards for Early Childhood Education; and Permendikbud Number 146 of 2014 concerning ECD Curriculum 2013.

Results and Discussion

HI-ECD is a strategic policy of the Indonesian government in improving the quality of ECCE services. In addition, its purpose is to meet the essential needs of children so that they can achieve optimal growth and development. These essential needs include health and nutrition, educational stimuli, moral-emotional fostering and nurturing.

This step is a breakthrough for the government to prepare smart, healthy, and noble human resources as we know that the government has a golden target for Indonesia in 2045. Darman mentions that the target of golden Indonesia 2045 can only be achieved through quality education. With quality education, it will produce quality human resources. Mulyani reveals that there are four conditions to manifest golden Indonesia in 2045, one of which is to improve human quality. Indicators of the progress of a nation are highly determined based on the quality of its human resources. Perpres RI Number 60 of 2013 was issued by the government as a form of attention and encouragement so that children as the next generation of the nation can be well served and guaranteed their needs.

Model of HI-ECD Program in ECE Unit: HI-ECD program in ECE unit is an early childhood education plan that contains comprehensive and integrated services on all aspects of children development. The development essences are physical and non-physical which include health, nutrition, psycho-social, and mental fulfillment. HI-ECD is also meant as a form of early childhood development that is diverse and interrelated simultaneously, systematically, and integrated. HI-ECD program includes education, health and nutrition services, care, and protection. All services must be carried out in an integrated manner in ECE unit. That is, every ECE unit is required to organize HI-ECD program. HI-ECD model in ECE unit can be seen in Figure 1.

Figure 1: Model of HI-ECD program in ECE unit
Since the issuance of the Perpres RI Number 60 of 2013 concerning HI-ECD, legally the policy must be applied in various ECCE programs. In the ECE unit, the HI-ECD program is implemented and developed in an integrated manner with reference to the Permendikbud Number 137 of 2014 concerning national standards for early childhood education, Regulation of the Permendikbud Number 146 concerning 2013 ECE Curriculum, and technical guidelines for the implementation of HI-ECD in ECE unit.

Implementation of HI-ECD Program in ECE Unit: HI-ECD is applied in ECE unit through four forms of services, namely: education, health and nutrition, care and protection. All of these services must be obtained by each child simultaneously. ECE unit must be able to provide programs for services education, health and nutrition, care, and protection to ensure that all children live well. Programs and forms of HI-ECD activities in ECE unit can be seen in table 1.

HI-ECD in the form of educational services can be implemented by providing educational stimuli to stimulate various children’s developments, both physically and spiritually. Six spheres of child development that need to be optimized are religious and moral, physical-motoric, cognitive, linguistic, social-emotional, and artistic. With this education service, it is expected that children will be better prepared to enter further education.

HI-ECD in the form of health and nutrition services is carried out by giving children nutritious food and conducting regular health checks, as well as inviting children to behave in a healthy life. Mulyani said that 25% of Indonesian children experience malnutrition. Health and nutrition are essential factors for children’s growth and development, but the nutritional status of preschool-aged children in Indonesia is still worrying. Even though health and nutrition are one of determinants in preparing high-quality human resources. For this reason, health and nutrition services are inseparable programs in HI-ECD.

Parenting services in HI-ECD are collaborative activities between schools, teachers, and parents. This parenting program is intended to provide information on each child’s needs and development, both from parents to school and from the school to the parents. In addition, to maintain good relations between schools, teachers, parents, and children. As explained by Olson, DeFrais, Skogrand the role of educators in parenting is ideally done together, because parents and children have different roles.

HI-ECD in the form of protection services is carried out to provide a sense of security and comfort for children in participating in ECD activities. This protection covers two things, physical and psychological. Maslow in the theory of human needs hierarchy explains that there is a need for security or comfort that must be obtained by children in order to achieve further needs. Protection services also prevent children from bullying and discrimination from teachers and peers. If children feel safe and comfortable, they can learn to the fullest. Programs and forms of HI-ECD activities in ECE unit is described below:

HI-ECD program in the form of educational services includes: learning of religious and moral values, physical-motor learning, cognitive learning, language learning, social emotional learning, and art learning. The activity model of religious and moral values at the ECE Unit, among others: doing worship, being honest, maintaining personal hygiene and the environment, respecting other, and knowing religious holidays. Physical-motor learning for example: doing coordinated body movements, doing physical games, drawing, cutting, and sticking. Kognitif learning in the ECE unit includes: getting to know shapes and textures, know letters and numbers, knowing big and small sizes, and getting to know more and less number. Language learning can be either communicating verbally, arranging simple sentences, reading and listening to stories, and reading and writing your own name. Social emotional learning includes playing with peers, sharing with peers, and respecting the rights of others. Finally, the activity model of art learning for example: humming and singing, playing a musical instrument, drawing and painting objects, and making various works/crafts.

HI-ECD in the form of health and nutrition services can be either early detection of children’s development, having meals together, and clean living behavior. Early detection activities of child development include weighing the body, measuring height and head circumference, examining eyes, ears, and teeth, getting periodic immunization. Eating together can be done with getting nutritious food every morning, drinking milk every morning, and getting vitamins. As for, clean life behavior activities include getting used to wash hands and throwing garbage in its place.
HI-ECD in the form of parenting services can be either forming a group of parents and parenting seminar. The activity model of forming a group of parent for example: holding consultations and activities with parents, and involving parents in the school program. While parenting seminars are done by way conducting counseling and socialization of child development.

Finally, HI-ECD in the form of protection services can be done in a way safeguarding the school environment, for example making a guardrail and providing tools and materials to play based on the age of the children and free of chemicals. As for, the activity model of supervision of learning activities include being friendly to children and monitoring children while playing.

The form of HI-ECD programs and activities in each ECE unit can vary according to the ability. This is because in designing a HI-ECD program, it must be in accordance with the needs of the children. In addition, the facilities and quality of human resources also affect programs and forms of activities. According to Unicef, the barriers to HI-ECD that are often experienced are the problems of low cost, quality and motivation of teachers, ECE programs that have not led to integrative holistic, as well as the lack of community participation.\(^{(23)}\)

To realize a HI-ECD program that is of high quality and can reach all early childhood, collaboration from various parties is needed. Parents, schools, community leaders, and the government must be fully involved in the HI-ECD program. Parents have the role of implementing HI-ECD in the family through parenting activities. Schools can play a role in providing stimulation of education, guidance, supervision and carrying out cooperation with relevant parties to support HI-ECD. Community leaders can play a role by providing assistance, guidance, and work partners for ECE unit, and if possible they can provide facilitation, advocacy and counseling related to HI-ECD. The government can provide various assistance through related agencies, such as the education office, health services, and social services. These offices can be partners to meet the needs of ECE unit in implementing HI-ECD programs. Through strong collaboration from various parties in the HI-ECD program, the government has been able to run optimally.

### Conclusion

Integrative holistic early childhood development policy issued by the government through the Republic of Indonesia Presidential Regulation Number 60 of 2013 has made a major contribution to ECCE in Indonesia. The implementation of HI-ECD in ECE unit is realized through education, health and nutrition services, care, and protection. Through the HI-ECD program, the essential needs of children can be fulfilled so that children can grow and develop optimally, smart, healthy, cheerful, and noble.

The Analysis of Hospital Service to Patients Covered by National Social Insurance Program in Indonesia

M. Rosul Asmawi

Universitas Islam Syekh-Yusuf, Tangerang, Indonesia

Abstract

This study intends to reveal public service degree performed by hospitals in providing services with Social Insurance Administrator Healthcare Program (SIAHP) in Indonesia. This research was conducted at six hospitals in Indonesia. A series of in-depth interviews were conducted to explore all forms of individual or collective perception of hospital services include responsiveness, assurance, tangibles, accessibility, empathy, reliability, personal attention, convenience, measuring perception services and customer service expectations, improving services and lowering costs, valuing customers, and clarity. The interviews were conducted with ten key persons, consisted of patient (P), patient’s family (F), nurse (N), doctor (D), resident doctor (R) and employee (E). The result showed that health services for SIAHP patients was less satisfying particularly the level on registration services, polyclinic services, pharmacy services, payment services, laboratory services, and outpatient and inpatient services. The patient’s dissatisfaction occurred because of the time of service, the availability of prescribed medicines. Therefore, hospital management needs to pay special attention to the service process to ensure the patients obtain optimal service.

Keywords: Public service, health services, SIAHP patients, public hospital services, private hospital services.

Introduction

Indonesia has implemented new schemes on national health insurance. One of the scheme known as a Social Insurance Administrator Healthcare Program (SIAHP) which is intended for all Indonesian people with the aim to maintain good health. The SIAHP cooperates with health institutions such as public and private hospitals. Starting at 2014, Askes Indonesia Company changed its name to SIA. Since its foundation, the program has conducted various efforts to achieve better service level. It is hoped to provide patient satisfaction. This research was conducted considering SIAHP becomes an important part of public health development in Indonesia.

The focus of the study is related to SIAHP services which include registration, polyclinic, pharmacy, payment, laboratory, outpatient and inpatient services. Health institutions providing SIAHP services are the locus of this research. In theory, SIAHP is a public service as it involves the community. Public services provide services to the community possessing an interest in the organization in accordance with the established basic rules.

Public service fulfills society needs in state implementation. Public services must be continually improved to provide satisfaction to service users. Therefore, the apparatus always innovates to ensure service qualities that appropriate for usage, “quality is a special standard where availability, performance, reliability, maintainability, and characteristics can be measured” 1.

Public hospitals and private hospitals should understand the service dimensions that lead to customer satisfaction. Public services experiencing problems were caused by a bureaucratic culture which tends burden the community. Therefore, it is necessary to build a
bureaucratic culture where the bureaucrats as servants of the state providing services to the community. The changing culture is a long and expensive process, and requires a high commitment from all members of the organization to generate profit for themselves and the organization. Organizational culture can be formed by bureaucrats and all members of the organization should have a purpose. The purpose of establishing an organization culture is to ensure the survival or to gain a more competitive advantage.

The empirical condition revealed people are not satisfied with the services provided by these institutions due to several problems related to service quality and the inhibiting factors causing non-optimal public service. First, in terms of service implementation, is still constrained by the weak support of human resources (HR). Second, related to the public service quality, viewed from the perspective of customer satisfaction, the complaints or public dissatisfaction is associated with the provision of public services. Therefore, it is necessary to understand the concept of service quality itself, although the definition is rather difficult to understand. The concept of service as "The concept of service quality is somewhat elusive and resists easy definition, but essentially it emphasizes customer satisfaction as its primary objective". However, the concept of service quality basically emphasizes customer satisfaction as the ultimate goal. Furthermore, the concept of service quality should include: (1) measuring customer service expectations; (2) by improving services and lowering costs; and (3) provide customer appreciation.

The objective of this study was to reveal public service degree performed by hospitals in providing services with SIAHP in Indonesia.

Method

The study was conducted between January and April 2018 in three regencies in Indonesia, consist of Tangerang, Surakarta and Nganjuk. The approach used in this study is a qualitative approach with the aim to determine the health service level in hospitals in Indonesia. Samples were taken from some public hospitals in Tangerang Regency, a public hospital Tangerang City, a private hospital Awal Bros Tangerang City, private hospital Siloam Tangerang City, a public hospital in Surakarta Central Java and a public hospital Nganjuk East Java with the consideration of having homogeneity of the similar population. This qualitative approach used case study model to assess the health service quality in SIAHP patients, such as registration, polyclinic (doctor), pharmacy, payment, laboratory, outpatient, and inpatient service.

The focus of this research includes responsiveness, assurance, tangibles, accessibility, empathy, reliability, personal attention, convenience, measuring perception services and customer service expectations, improving services and lowering costs, valuing customers, and clarity (details of costs and procedures of administrative services).

Data obtained from the patient (P), patient’s family (F), nurse (N), doctor (D), resident doctor (R) and employee (E) through the interview, researcher observation field and documentation in the form of primary data with an interview and secondary data taken from research sites. This in-depth interview was also conducted with informants possessing adequate expertise. Although this study is limited by sample size, some important insights on satisfaction can be obtained from this study.

While data analysis is qualitative, where data is collected in the form of relevant findings, according to research focus, then presented in narrative form descriptively, factually and systematically. The following step is to draw conclusions in the form of data analysis with a logical explanation, where both data qualitatively and quantitatively (secondary data) presented with complementary.

Research Finding: This research examines health services conducted by public hospitals and private hospitals in Indonesia, especially in relation to patient care SIAHP as the findings as follows:

Responsiveness: Observations of the research indicate that community complaints have two forms, direct and indirect. Direct complaints are in the form of submitting a complaint to the organizer. Direct complain often occurs, but there’s a lack of response. Indirect complaints are letter posted in complaint box and/or via e-mail. This method does not necessarily obtain an answer, people who complain are never invited to talk together.

Some patients and patient family started that their complaints were never been solved satisfactorily. “I once delivered complain directly to the manager, however, there was no follow-up, I was only asked to
wait patiently without any clear deadlines or problem solving mechanisms. (P1)

“I had an experience for complaining, but the existing health workers were unable to provide a solution so I had to find other officers who were more suitable. I got not enough information to go to the right officer for the problem I was facing.” (F2)

On the other hand a nurse stated that they could not provide optimal services because of the patient’s queue level and limited personnel in the hospital. “There are very many patients we have to serve, they have different health problems, while the number of personnel owned by hospitals is very limited.”

This opinion was also supported by a doctor. “The hospital always provides the best service, but sometimes there are two problems that cannot be solved directly by the officer.” (D1)

Other patients expressed hope that the queue to get services could be accelerated. “I hope that the queue at registration, medical or pharmacy services can be accelerated, and every problem can be solved immediately” (P2)

The responsiveness is one dimension of service quality. Service quality is considered good when it gets a response from service providers. Observations by researchers in the field indicate that the response to health services is lacking due to the lack of service personnel and a large number of people who come for treatment.

Moreover, the responsiveness is the willingness to help customers and provide prompt service. This dimension is concerned with dealing with the customer’s requests, questions, and complaints promptly and attentively. A firm is known to be responsive when it communicates to its customers how long it would take to get answers or have their problems dealt with. To be successful, companies need to look at responsiveness from the viewpoint of the customer rather than the company’s perspective.

Assurance: The second dimension of service quality is assurance. This ensures patients obtain clear information on patients’ rights and obligations. Based on the study, the predetermined time frame was required to reduce confusion; It means that people know what to do and how to follow a predetermined path. However, based on interviews with informants and observations in the field, there were some persons remain confused, e.g. The availability of medicines prescribed by doctors in the pharmacies. Some patients feel this situation burden them. Pharmacies might run out of required medicines and resupply takes time. On the other hand, the patient requires it.

One of the patient’s family complained about the unavailability of medicines. “I often find in pharmacy having no generic medicines prescribed by doctors, so I had to look for these medicines to other pharmacies.” (P2)

This problem is according to pharmacy officers because the pharmacy might run out of required medicines and supply takes time. On the other hand, the patient requires it immediately.

Assurance is as the employees’ knowledge and courtesy and the service provider’s ability to inspire trust and confidence. Assurance may not be important in relative to other industries where the risk is higher and the outcome of using the service is uncertain. Thus, for the medical and healthcare industry, assurance is an important dimension that customers look at in assessing a hospital or a surgeon for an operation. The trust and confidence may be represented in the personnel who links the customer to the organization.

From the hospital’s point of view, assurance is a very important dimension observed by customers in assessing the hospital or doctors who work professionally. The trust and confidence of healthcare providers in these patients is a form of assurance.

Tangibles: Tangibles are used by firms to convey the image and signal quality. This was prevalent in all health care institutions. Patients usually arrive early, some minutes or even hours prior to service opening time, causing long queue. A similar case occurs in medical examination service.

Observations in some public hospitals and private hospitals revealed patients having to wait all day to get a medical examination.

Some patients complain about the length of the queue to get health services. “I usually arrive 30 minutes before the service starts, but it turns out that there are many other patients who are in line. Besides that, we also have to wait to get services from a doctor with a waiting time of between 30 and 90 minutes.” (P3)
The patient’s family also complained about the length of the queue in the pharmacy. “The queue does not only occur during registration but also when in the pharmacy, we have to wait long enough to get the medicine we need” (F3)

The patients register in the morning to obtain queue number, while the examination is conducted in the afternoon until the evening. Obviously, this old service management is related to the inadequate availability of infrastructure facilities, including medical personnel (nurses and doctors). In general, private hospital patient does not experience long queue all day long due to cash payment. Therefore, public hospital experience relatively long service and the private hospital can provide fast service.

Although the strategic importance of quality in the context of health care is widely accepted, significant differences exist between the various healthcare providers. A recent study in Egypt found, that the level of satisfaction of private hospital patients is higher than those of public hospital patients. Quality of care in the context of healthcare reveals a significant difference between different health care providers. The level of patient satisfaction in private hospitals is higher than general hospital patients. Customer service expectations, improved services and lower costs and customer’s appreciations are not generally experienced by the customers.

The essence of the problem lies in the reimbursement of the costs of the highly unbalanced SIAHP, while public hospitals and private hospitals are required to carry out the mandate of the law. Therefore, SIAHP services and government law implementation is important. This required the willingness of the management so customers may perceive as good service quality. The analysis of service quality enables hospital management to allocate the financial resources for improving performance in the areas that have more influence on the customers’ perception of service quality.

Reliability: Based on the empirical study exhibits that the average service officer can normally only work with a reasonable workload, so this reliable attitude is only encountered in those who have high empathy attitudes and full responsibility.

A patient complains about the alertness of the officer. “I see the officers busy but the service time are long enough, the officers also look less agile to handle their duties.” (P2)

The reliability is defined as the ability to perform the promised service dependably and accurately or delivering on its promises. This dimension is critical as all customers want to deal with firms that keep their promises and implicitly communicated to the firm’s customers.

However, in reality, the hospital to provide less satisfaction to the patient. This is a fact that is still widely found from hospital services in Indonesia. The lack of public services is related to development policies, especially regarding income and poverty, one of these approaches over the other, but rather to explore their implications for development policy. For the income-based approach, those implications have been explored at some length (for example, see World Bank, 1990).

Personal Attention: Usually, healthcare providers provide services according to generally accepted service standards. Therefore, this personal attention gives more deep attention such as empathy behavior. A large number of SIAHP patients who come to health services are in situations and conditions that do not allow extra attention, but this service can be quickly resolved.

Limited place and service personnel cause a long line of queue. These patients want to be served immediately, hence it is very difficult for the officer to pay special attention. However, management could increase service quality by increasing service counters; and health workers (service personnel and doctors).

A nurse stated that the large number of patients to be served caused very little attention to each patient. “We have to prioritize the completion of services to all patients, so that there was not enough time to provide personal attention.” (N2)

The bureaucratic habits and culture of the physician should also be changed. Doctors which usually starts their practice at late morning (after 09.00 am) could start earlier at 08:00 am as normal working time. Hence the patients do not have to wait for examination and make the waiting room crowded.

Conclusions

Research focuses exhibited the general picture that health services for SIAHP patients were fell at the level of less satisfying on registration services, polyclinic services, pharmacy services, payment services,
laboratory services, and outpatient and inpatient services. The patient’s dissatisfaction occurs because of the time of service, the availability of prescribed medicines. Therefore, hospital management needs to pay special attention to the service process to ensure the patients obtain optimal service.

The Effect of Sticky Autocidal Mosquito Trap (SAMT) on the Index of Transovarial Transmission of Dengue Viruses

Malik Saepudin¹, Soeharyo Hadisaputro², Sitti Rahmah Umniyati³

¹Department of Environmental Health of Ministry of Health Polytechnic Pontianak, West Kalimantan, ²Medicine and Health Sciences Study Program, Faculty of Medicine, Diponegoro University, Semarang, Central Java, ³Department of Parasitology, Faculty of Medicine, Public Health and Nursing, Gajah Mada University, Yogyakarta, Indonesia

Abstract

Dengue Hemorrhagic Fever (DHF) is a health problem in Indonesia. All areas in Indonesia have the risk of DHF transmission, as the geographical environment condition, temperature and optimal rainfall cause the incubation period of extrinsic disease agent shorter and the pattern of Dengue virus transmission increases. This research aims to prove the effect of Sticky Autocidal Mosquito Trap (SAMT) on the index of transovarial transmission of Dengue viruses in the endemic regions of DHF. This research used a quasi-experimental design, namely Interrupted time series with a nonequivalent no-treatment control group time series. The population and sample in this research were Aedes aegypti mosquitoes in two endemic regions of DHF, namely Sungai Jawi Dalam and Batulayang Villages. There was a decrease into 0% since the 2nd week post intervention until the end of the research (4th week post intervention) in intervention area. However, on the contrary, there was an increase found starting from the 1st week in control area by 200%, from 3% to 10%. It is concluded that SAMT have significant effect on the decrease in the Index of Transovarial Transmission of Dengue viruses in the endemic regions.

Keywords: Sticky Autocidal mosquito Trap, Transovarial Transmission Index, Dengue Virus.

Introduction

Dengue Hemorrhagic Fever (DHF) is still a health problem in Indonesia. All areas in Indonesia have the risk of DHF transmission, as the geographical environment condition, temperature and optimal rainfall cause the incubation period of extrinsic disease agent shorter and the pattern of Dengue virus transmission increases. Based on existing reports, DHF has become an endemic problem in 33 provinces and 436 districts or cities, 605 sub-districts and 1800 villages. In the 2012-2013 period, dengue incidence reached 41.25/100,000 population, with Case Fatality Rate 0.7%. An increase in dengue cases occurs every year, as in 2014, it was noted that the number of dengue cases was 549 cases with 68 deaths, and five districts/cities, including the city of Pontianak, was declared as Outbreak (KLB). West Kalimantan Province was 2nd ranked in the Kalimantan region, after East Kalimantan, with 5,762 cases of DHF. In addition, the transovarial transmission index in Pontianak reached 76.6% in 2012.

The biting behavior of mosquitoes has an effect on the ability of mosquitoes to transmit dengue virus both horizontally and vertically transmission. The Horizontal transmission is the transmission of dengue virus from one person to another through mosquito bites, while vertical transmission (transovarial) is the transmission of dengue virus from infected mosquitoes to its progenies, so that since the stage of eggs, larvae, pupae and newly hatched young adult mosquitoes, they have been infected by a virus. The viruses can be transmitted through their bite to reach 80%, which results in an increased risk of transmission. The dengue virus can grow and multiply without causing death in mosquitoes because there is no cytopathic effect that forms. Viruses can only live on the living cells of certain suitable organisms...
(host cells), so that when these cells die, the virus dies. The intended host cell is *Aedes aegypti* mosquito. Therefore, there is a need to eliminate the *Aedes aegypti* mosquito as the host of the Dengue Virus to reduce the incidence of DHF in endemic areas. This is in line with WHO recommendations that the best way to control *Aedes aegypti* mosquitoes is directed at their habitat in residential settlements.

Based on the habit and the complex cycle of *Aedes* sp., it requires innovative and complex control of the egg-larvae/larvae-pupae-mosquitoes, so that the purpose of controlling the vectors of the *Aedes* sp. mosquitoes is right on the target. Thus, the control of DHF is specifically done on the vectors to prevent the spread of the viruses to some extent so as not to potentially transmit the DHF disease. The commonly used measurement is the virus Transovarial Transmission Index (TTI). The development of Sticky Autocidal Mosquito Trap (SAMT) is designed complexly, which is a combination between Sticky and Autocidal design, so that it has two functions, one side to catch the adult mosquitoes by sticking them on the sticky ovitrap and the other side as an autocidal ovitrap. The combination serves as a trap for gravid female mosquitoes infected with Dengue virus and simultaneously kills the mosquito larvae which are transovarily infected with Dengue virus, so that it can prevent the transovarial transmission of the virus and prevent the incidence of DHF in the endemic areas.

**Materials and Method**

**Traps: SAMT:** The sticky autocidal mosquito trap (SAMT) consists of 4 basic components: 1) ovitrap lid; 2) adhesive tape as adult mosquito killer; 3) buoy and nylon filter at the bottom of the capture chamber to prevent adult mosquitoes from moving between the capture chamber and the infusion reservoir; 4) rice straw soaking water as infusion reservoir to attract adult female gravid mosquitoes to lay eggs. The cost of materials was calculated at US$ 3.5 per trap without labor, and we hope to reduce its cost once the trap can be mass-produced.

This research is a quasi-experimental research using the interrupted time series design with a nonequivalent no-treatment control group time series. The time series study is often conducted for the purpose of determining the effect of either intervention or treatment. The research unit was a group of houses/buildings located in the selected research location consisted of 100 houses. The selection of research unit/location was conducted by using purposive sampling based on the evaluation and monitoring guidelines of the endemic areas of DHF vector control program from Ministry of Health and larvae index measurement guidelines from World Health Organization (WHO), and based on 5 (five) criteria; first, one of the villages was highly-endemic for 4 consecutive years having DHF cases; second, characteristics of the location (settlement, vegetation, and topography) that are equal; third, there are fatal cases of DHF in the last 4 years; fourth, there are new cases within the last 3 months before the research conducted; fifth, having a distance of about >5 km between research locations (between the treatment and control location). Then, there were 2 (two) villages in two sub-districts selected as the research locations, they were Sungai Jawi Dalam Village in West Pontianak Sub-District as experimental group and Batu Layang Village in North Pontianak Sub-District as control group. In the experimental group, intervention was done with the installation of SAMT intervention, but in the control group without intervention. Population and sample of the subject could not be identified for their density exactly, but could be measured by using the traditional index size of Aedes in research location and followed bymonitoring questioner. The presence of dengue virus on head squash preparation was conducted based on immunocytocchemical streptavidin biotin peroxidase complex (ISBPC) assays as described by Umniyati to identify the transovarial transmission index. The transovarial transmission index measurement was done 8 times in 8 weeks which 4 times before and 4 times after intervention, both in the intervention and control areas.

**Results**

This research has been approved by the ethical commission of Health Research of Faculty of Medicine of Diponegoro University based on the certificate number: 243/EC/FK-RSDK/2016. It was involved *Ae. aegypti* mosquitoes from hatched larvae in the ovitrap in the intervention area and control area in Pontianak City, West Kalimantan, Indonesia to confirm the effect of SAMT on the reduction of the transovarial transmission of DENV.

**The Microscopic Images:** The mosquitoes used were 7 days old average *Ae.aegypti* mosquitoes, which only fed with 10% sugar water solution without bloodfed. Each preparation contained 12 head squash of mosquitoes. Specifically, the positive and negative control mosquitoes were taken from Parasitology.
Laboratory of Faculty of Medicine of Gadjah Mada University. According to the Standard of Procedure of immunocytochemical streptavidin biotin peroxidase complex (ISBPC) method which has been prepared and standardized by Umniyati, the DENV detection was started from material preparation, coloring and microscopic examination with 40x, 100x, 400x, and 1000x magnifications. Positive control mosquitoes were male *Ae. aegypti* intrathoracically injected with DENV-3 strain H-87, whereas negative control mosquitoes are male Anopheles mosquitoes, because the mosquito is not the vector of DENV. The result of immunocytochemical assay to detect dengue antigen on head squashes from intervention area and control area is presented in Figure 1.

**Figure 1:** The Micrograph photos of head squash preparation with a magnification of 100x10 which show no brownish color on the negative control (A) and show brownish color deposits throughout most fields having brain tissue in positive control (B). The DENV positive antigen in the form of brownish hexagonal granules spreaded in the brain tissue of mosquitoes from the intervention area (image C) and Control area (image D) based on immunocytochemical assay streptavidin biotin peroxidase complex assay using monoclonal antibody DSSE10 against DENV.
Figure 1 shows the brown color of the brain of *Ae. aegypti* mosquito originating from intervention area weaker than the mosquitoes originating from the control area. This study also indicates that the images of positive infection rates of (+++), (++), and (+) could be found in the specimen of the control area, while there was only positive infection rate of (+) found in the intervention area.

**Results of TTI:** Effect of SAMT on the reduction of the transovarial transmission of DENV in *Ae. aegypti* presented in Figure 2.

Based on Figure 2, the percentage of TTI in the SAMT intervention area was 30% lower than the control area of 40%. There was a decrease on the TTI since the 3rd week before intervention in the intervention area. The TTI at the 1st week before intervention and the 1st week post intervention was 3%, and there was a decrease into 0% since the 2nd week post intervention until the end of the research (4th week post intervention) in intervention area. However, on the contrary, there was an increase found starting from the 1st week in control area by 200%, from 3% to 10%.

**Discussion**

The overview of the research locations showed that the characteristics of the endemcity and geographical environment and population of both locations are relatively similar. The transovarial transmission index measurements were conducted 8 times in 8 weeks; 4 times before and 4 times after the intervention. The measurements were conducted to obtain the information of treatment effect by comparing the results before and after the intervention. The management of bias against the confounding variable in this research used the statistical analysis. The results of measurement and statistical analysis with Wilcoxon signed rank test and Mann Whitney U Test in the same direction showed that temperature, humidity, and adult mosquito density do not have significant difference with a p-value > α (0.05). Thus, the effect of the decrease in the transovarial transmission index was actually by SAMT intervention, not by environmental conditions, such as temperature and humidity, predators, and mosquito density in the research locations.

The results of this research indicated the percentage of TTI in the intervention area with SAMT modification of 30% is lower than in the control area of 40%. This condition is still lower than in the previous research conducted in Pontianak City as an endemic region with a transovarial transmission index of 76.6% in 2012. The intervention using the modified SAMT indicated a positive (+) infection rate which is lower than in Control group which has a positive (+++) infection rate. This is
in line with the number of mosquitoes and larvae trapped in SAMT, which they were more than those trapped in the standard Ovitrap. The trapped adult mosquitoes and larvae have an effect on the replication of virus on mosquito cells as Obligate Intracellular Parasite, that is the ability of the virus that can only live in the living cells of mosquitoes, so that when the living cells in which it lives die, it will also die\textsuperscript{11}. According to the results of research on virology, certain conditions cause the replication of virus in different organs during embryogenesis process or in the final stages of the life of a mosquito may be varied. There was statistically significant difference. Thus the intervention carried out within 4 weeks succeeded in reducing TTI, because the number of mosquitoes infected with the dengue virus was trapped in SAMT, so that the population of the infected \textit{Ae. aegypti} mosquitoes was reduced. as in previous research that dengue virus is a true cell parasite whose existence is very dependent on its host, if the host dies then the DENV also dies.

The results of previous studies that vertical transmission of dengue virus occurs in 7 generations, DENV is continuously transmitted transovarially to generation (F)-7 then survives in the next generation\textsuperscript{12}. However, the time of intervention with SAMT for four weeks (four egg cycles into larvae) showed its effectiveness in destroying the dengue virus in \textit{Ae. aegypti}. Dengue virus in the ovarian tissues of mosquitoes will die with \textit{Ae. aegypti} trapped in SAMT. Intervention activities were carried out in the case area, so epidemiological investigations were carried out and action was focused on fogging and larviciding Thus the SAMT intervention carried out after the application of fogging and sprinkling of abate powder was selectively very effective for destroying the remaining or newly infectious mosquitoes from other endemic areas.

The success of the SAMT intervention can also reduce the occurrence of the risk of transmission throughout the time of delay in the patient going to the hospital. Delays in going to a hospital or health service will be a moving source and effectively transmit the virus horizontally or vertically. According to Achmadi U.F, that patients generally come to the hospital after it lasts 4 to 5 days since a person has a virus in his blood circulation. During that time there has also been an escalation of horizontal transmission of the virus that resembles a series of measurements: one to two, two to four, and so on. This is also the reason for the delay in implementing fogging focus\textsuperscript{13}. This intervention with SAMT will be able to solve the problem of the DHF pandemic due to the increasing increase in mobility, thus expanding the occurrence of transovarial transmissions throughout the world, for example in Malaysia, Thailand and Singapore and in Indonesia. Transmission like this also occurs in some urban villages endemic to DHF in the city of Yogyakarta, in some districts endemic for dengue in Central Java and also in Sampit, East Kotawaringin Regency, Central Kalimantan. The possibility will continue to expand to other regions in Indonesia\textsuperscript{14}.

Therefore in the future this tool needs to be tested extensively, so as to provide a wider value of benefit, especially in monitoring and controlling DHF vectors in endemic areas simultaneously and thoroughly. Based on the above, that the use of SAMT modification is effective in reducing the transovarial transmission index in \textit{Ae. aegypti} mosquitoes, so that it can suppress as low as possible transmission to humans who are vulnerable to endemic areas\textsuperscript{15}.

**Conclusion**

It is concluded that SAMT have significant effect on the decrease in the Index of Transovarial Transmission of Dengue viruses in the endemic regions.

Contraceptive method use in Indonesia: Trends and Determinants between 2007, 2012 and 2017

Maria Gayatri1,2, Budi Utomo1

1Department of Biostatistics and Population, Faculty of Public Health, Universitas Indonesia, Jl. Lingkar Kampus Raya Universitas Indonesia, Depok, 2Indonesia National Population and Family Planning Board, Jl. Permata No. 1, Jakarta Timur

Abstract

Background: The contraceptive prevalence in Indonesia was still dominated by short-acting method. Recently, the use of traditional contraceptives in Indonesia show an upward trend which is high risk of unintended pregnancy and sexual transmitted disease. This study aims to examine the determinants of contraceptive use in Indonesia and find the differences in characteristics of users.

Material and Method: Data used were from the IDHS 2007, IDHS 2012 and IDHS 2017. Contraceptive method mix was used as dependent variables. Chi-square test and binary logistic regression were applied to find the significant factors.

Findings: The findings indicated that contraception in Indonesia was mostly used for fertility limiting. About 90% of contraceptive method mix in Indonesia are contributed by modern contraceptive method. Modern contraceptive method are frequently used by women who live in rural areas. Compared to modern contraceptive users, traditional users in Indonesia were more likely have good education and occupation and live in urban areas.

Conclusion: Women who used traditional method should be encouraged to switch into the more effective modern contraceptive method. Strategy to promote the use of Long-Acting Reversible and Permanent Method needs to be strengthened.

Keywords: Long-acting, short-acting, method-mix, modern contraception, traditional contraception.

Introduction

Family planning improve maternal health through reducing the number of pregnancies and reducing the probability of high-risk pregnancy. Family planning program ensures that all babies are wanted and planned. This program allowed couples to decide the number and timing of pregnancies. The family planning program in Indonesia has promoted modern contraceptive method especially for long-acting contraceptive method but the use of Long Acting and Permanent Method in Indonesia is still low. The contraceptive prevalence was still dominated by the use of injectables and oral contraceptives. The contraceptive prevalence rate increased from 50% in 1991 to 64% in 2017. Based on 2017 Indonesia Demographic and Health Survey (IDHS), the main reason among currently married women for using contraception was limiting pregnancy (40%) rather than spacing the next pregnancy (24%).

On the other hand, the use of traditional contraceptives in Indonesia show an upward trend in a decade from 5% in 2007 and 4% in 2012 to 6% in 2017. Traditional contraceptive method include periodic abstinence and withdrawal. These method are less effective compare to modern method if it is not used with self-discipline and proper knowledge. The main disadvantage of traditional method is high risk of unintended pregnancy and sexual transmitted disease. Users of periodic abstinence should discipline, have a
honorable timing management and good knowledge. In this method, women should identify the fecund period in their cycle. However, only 22% Indonesian women know accurately the fertile period.

This study examines the determinants of contraceptive use in Indonesia between 2007-2017 and determines the differences in characteristics between traditional and modern contraceptive users by exploring the changes in contraceptive method mix.

**Material and Method**

Data used were from the IDHS 2007, IDHS 2012 and IDHS 2017. All surveys were nationally representative samples that produced cross-sectional data on reproductive history among women in reproductive age between 15 and 49 years. Samples were limited to currently married women and they were using any contraceptives at the time of interview. Total samples in this study were 18,981 women from IDHS 2007; 20,640 women from IDHS 2012; and 22,623 women from IDHS 2017. Sample weights were used in the analyses.

Contraceptive method mix in this study was the percentage distribution of contraceptive users by the method. The dependent variable in this study was contraceptive used that redefines as 1 = using traditional contraceptive method and 2 = using modern contraceptive method. Descriptive analysis such as percentage was used in this study. Chi square test was carried out to analyze the difference between modern and traditional contraceptive use based on socio-demographic characteristics. Binary logistic regression was used to determine the difference in adjusted Odds Ratio. P less than 0.05 were considered significant.

**Findings:** Method of contraception include “modern” and “traditional”. Modern contraceptive method consist of female sterilization, male sterilization, IUD, implant, injectables, pills, condom and LAM, while traditional method consist of periodic abstinence, withdrawal and other traditional method.

Figure 1 presents the contraceptive method mix among currently married women for the last three surveys: 2007, 2012 and 2017. Modern contraceptive method dominated the method mix among three surveys. The data showed that the proportion of modern contraceptive method remained around 94 percent during 2007 and 2012, but it had down to 90 percent in 2017. On the other hand, traditional method had slightly improved from 6% during 2007 and 2012 to 10% in 2017.

In all survey years, injectable was the predominant method which about 50% used by women in Indonesia (see figure 1). Oral contraceptives were also popular in Indonesia which about one fifth of women using pills as their contraceptive method. The IUD’s share of use decreased slightly by 0.6% between 2007 and 2017. The proportion of contraceptive users relying on implants increased steadily form 4.5% in 2007 and 5.3% in 2012 to 7.4% in 2017. Moreover, the proportion of married women of reproductive age practicing female sterilization increased slightly from 5% in 2007 to 5.9% in 2017. However, the proportion of male sterilization was stagnant and still low at less than 0.5% in Indonesia between 2007 and 2017.

![Figure 1: Mixed contraception used 2007, 2012 and 2017](image-url)
Table 1 presented data on sample characteristics of married women who use any contraceptives. About 60.5% of currently married women who used contraceptives in 2007 were aged between 25 and 39 years. This percentage decreased to 57% in 2017. Contraceptive users were dominated by women who already have one or two children, which about 60% of these women used any contraceptive method. Contraceptive use among nulliparous was still limited. Less than 1% of nulliparous married women used contraceptive to delay their first pregnancy.

According data on fertility intention, the contraception in Indonesia were mostly used for fertility limiting rather than spacing purposes. The percentage of women who used contraception for limiting increased from 59.1% in 2007 to 63.3% in 2017. Based on the profile of contraceptive user (table 2), more than 60% of currently married women who use contraception lived in Java and Bali, while the rest lived in other islands in Indonesia.

Table 2 showed the percentage of social demographic characteristics and other factors related to current used of contraceptive method. Compared to modern contraceptive users, traditional users in Indonesia were more likely to be older women, have higher parity, have higher education, have better knowledge on ovulatory cycles, working as white-collar workers, and live in urban areas. Correct knowledge of the ovulatory cycles was one of the important factors for traditional method users to avoid pregnancy.

The results of binary logistic regression were also shown in table 2. All factors were significant in bivariate statistics. Model 1 presented some factors which were not significant influencing contraceptive used. Two factors were dropped out from model 1: parity and wealth condition. Model 2 (see the last column in table 2) showed the significant factors associated to contraceptive used which consist of women’s age, fertility intention, knowledge of ovulatory cycle, education, women’s occupation, place of residence and region.

**Discussion**

This study investigates determinants of contraceptive method used by currently married women in Indonesia. About 90% of contraceptive method mix are contributed by modern contraceptive method. Although the used of long-acting method is still low, but the trend from three IDHS shows a gradual increased. A study qualitative study about Long-acting and Permanent Method (LAPM) in two provinces in Indonesia shows the reasons to choose short-acting rather than long-acting method are lack of awareness of benefit and side effects
of LAPMs, the fear of surgical consequences, the myths about negative effects of LAPMs and religious beliefs.

The results indicated that women used modern or traditional methods for limiting rather than spacing births. Similar results have been found in the Philippines where modern contraceptive use was dominantly used to limit births. However, for traditional methods (periodic abstinence and withdrawal) are frequently being used for spacing since women are still open if they have another pregnancy and also women’s belief that using traditional contraceptives is better than not using any contraceptives.

Multivariate analysis shows that women who live in rural areas tend to use modern contraceptive methods compared with those in urban areas. The result also presents that women from Java and Bali islands are more likely to use modern contraceptives compared to those from other islands. It is probably related to the Village Midwife Program that established since 1989 to address the access gaps to reproductive health care for rural women. The Village Midwife Program in Indonesia is significantly associated with the increase of injectable contraceptive use.

Traditional methods are common methods used by women in good education and occupation and lived in urban areas in Indonesia. A study shows that women prefer traditional methods since it is not associated with any negative side effects and no risk of subfertility. Therefore, counseling should be focused on effectiveness and safety of modern contraception.

Indonesia is a country that has method mix skewed toward injectables and oral contraceptives as short-acting reversible contraceptive methods. Besides Indonesia, there are four countries with skewed method toward injectables as dominant method: Ethiopia, Haiti, Myanmar and Rwanda. Skewed method mix is defined as a single contraceptive method that used by 50% or more users in a given country. Injectable and oral contraceptives are predominance in Indonesia which about 70% of women use the method. Injectable and oral contraceptives are mostly used by women younger limiters, older limiters and some women who want to space their pregnancies.

There is a mismatch between fertility intention that about 60% of women want no more children but they still use short-acting method. Indonesian Government has promoted LAPM as it is mentioned in the Indonesia’s Medium-Term Development Plan (RPJMN) 2015-2019 to increase the used of LAPM form 18.3% in 2015 to 23.5% in 2019. Therefore, to achieve national goals related to long-acting method, it is important to ensure the availability and accessibility of LAPM, improve health provider’s knowledge in providing quality contraceptive services to the clients and improve the quality of contraceptive counseling.

The use of modern contraceptive method to delay pregnancy among nulliparous is still low. Delaying the first pregnancy for women aged less than 18 years are important since pregnancy poses higher risk of complication that can be serious and even fatal causes maternal and child mortality. The low use of modern contraceptive method by nulliparous women may also contribute by the fear of subsequent fertility after stopping the method. Based on systematic reviews of many studies, contraceptive method—other than female and male sterilization—do not affect the return of fertility after discontinuing reversible contraceptive method. Reversible contraceptive method are safe to delay the first pregnancy. Therefore, counselling should be strengthened among nulliparous women in order to convince couples that contraceptive method do not reduce long-term subsequent fertility.

Conclusions

Based on the analysis, the contraception in Indonesia was mostly used for fertility limiting rather than spacing purposes. About 90% of contraceptive method mix in Indonesia are contributed by modern contraceptive method. The contraceptive prevalence was still dominated by the use of injectables and oral contraceptives. However, the traditional method are increased steadily in the last decade. Traditional method are mostly used by women in good education and occupation and lived in urban areas. Women who used traditional method should be encouraged to switch their method into the more effective modern contraceptive method. Moreover, strategy to promote the use of Long-Acting Reversible and Permanent Method needs to be strengthened.

Abstract

Maternal mortality rate (MMR) is the death rate of woman during pregnancy, childbirth, and purpureal periods which is caused by various factors but not by accident or incidental. Banjar Regency always gets the third highest maternal mortality in South Kalimantan Province. MMR of Banjar Regency in 2015 was 11 cases, in 2016 was 11 cases, and in 2017 became 10 cases. This study aims to explain the relationship between risk factors and the incidence of maternal mortality of Banjar Regency in the 2015-2017 periods. This research is a type of quantitative research, with case control design with a ratio of 1:1 between case (maternal mortality) and control. It used total sampling technique for case group. The number of respondents in this study amounted to 36 people consisting of 18 respondents in the case group and 18 respondents in the control group. Based on the results of the research there is no significant relationship between age, parity, education, job status, family income, ANC, recidency, time to reach health facility, childbirth helper, and place of delivery with maternal mortality in Banjar Regency.

Keywords: Risk factors, maternal mortality, Banjar Regency.

Introduction

Maternal mortality is the death rate of woman during pregnancy, childbirth or in 42 days after the end of pregnancy but not by accident.¹ Maternal Mortality Rate (MMR) in Indonesia was still high, if compared to ASEAN countries.² Data from the Indonesian Demographic Health Survey in 2007 showed that MMR was 228 per 100,000 live births.³ MMR in South Kalimantan in 2012 was 123/100,000 live births.⁴ This could not reach the SDG target to reduce MMR below 70/100,000 live births.⁵

Three of the highest cases of maternal mortality in South Kalimantan in 2016 were Kotabaru District (13 cases), Banjar Regency (11 cases), and Tapin District (9 cases). While in 2017 were Kotabaru and Banjarmasin (8 cases), Banjar Regency (7 cases), and 6 in Hulu Sungai Tengah Regencies.⁶

Maternal and perinatal health are national problems that need to be priority.⁷ One of maternal death’s effect is child’s growth and development.⁸

Based on the background of the above problems, the researchers are interested in conducting research on “Risk Factors Analysis Related to Maternal Mortality in Banjar District on January 2015-September 2017 Periods”.

Materials and Method

This research used case control design using 1:1 ratio and using total sampling technique for case. The number of respondents were 18 case respondents and 18 control respondents. The instruments were maternal mortality document and KIA books. Bivariate analysis used chi square statistical test.
Table 1: Risk Factors of maternal mortality based on chi square test

</table>

There was no relationship between age and maternal mortality (p=0.228). This was caused by samples taken into 20-35 years old as 77.8%. That age was the optimal age for pregnancy and childbirth because the function of reproductive organs and hormonal balance has been stable. The results of this study was in line with the Jayanti Research (2016) which states that there was no relationship between maternal age and maternal mortality (p value = 0.174).9

Based on field findings in 12 mothers (66.7%) with 20-35 years old but experienced death, the cause of death were 5 people experienced bleeding (41.7%), 2 people experienced labor complications (16.7%), 1 person hyperthyroidism (8.3%), 1 person experiencing amniotic embolism (8.3%), and 1 person giving birth not helped by health workers (8.3%). Those facts could be the other influencing factors that caused maternal mortality.

Based on the field findings on 2 mothers with risk age (11.1%) did not experience death because they did ANC routinely. ANC could find out the health conditions of mothers and babies. According to Supriyono (2012)
one effective way to prevent complications in pregnancy was detecting a high risk as early as possible through regular check to health workers and obtaining adequate services.\textsuperscript{10}

There was no relationship between the amount of parity and maternal mortality (\(p = 0.314\)). This was due to the most number of parity from the sample taken was primigravida (55.6%), not multigravida. This showed the possibility of primigravida had the opportunity to pose a risk of maternal death, such as preeclampsia. The results of this study was in line with the research of Sabatini and Inayah (2013) which stated that there was no relationship between parity and maternal mortality (\(p = 0.561\)).\textsuperscript{11}

Based on field findings on 8 mothers with primigravida (44.4%) but experienced death due to bleeding experienced by 4 mothers (50%), hypertension was experienced by 2 mothers (25%), retention of placenta experienced by 1 mother (12.5%), and amniotic embolism was experienced by 1 mother (12.5%). This showed that more deaths occurred in this study due to complications of pregnancy and childbirth.

Based on the findings of the field in 6 mothers with multigravida (33.3%) did not experience death due to delivery assisted by health workers. Although there were mothers who have risk factors, but with a competent birth attendant would reduce the risk.

There was no relationship between education and maternal mortality (\(p = 0.314\)). The results of this study was in line with Aeni’s research which stated that there was no relationship between education and maternal mortality (\(p = 1,000\)).\textsuperscript{12} Although the results was not significantly, but table 1 shows that mothers with low education tend to be at risk of maternal death.

Based on field findings on 8 mothers with primigravida (44.4%) but experienced death due to bleeding experienced by 4 mothers (50%), hypertension was experienced by 2 mothers (25%), retention of placenta experienced by 1 mother (12.5%), and amniotic embolism was experienced by 1 mother (12.5%). This showed that more deaths occurred in this study due to complications of pregnancy and childbirth.

Based on field findings on 8 mothers with multigravida (33.3%) did not experience death due to delivery assisted by health workers. Although there were mothers who have risk factors, but with a competent birth attendant would reduce the risk.

There was no relationship between education and maternal mortality (\(p = 0.314\)). The results of this study was in line with Aeni’s research which stated that there was no relationship between education and maternal mortality (\(p = 1,000\)).\textsuperscript{12} Although the results was not significantly, but table 1 shows that mothers with low education tend to be at risk of maternal death.

Based on field findings on 8 mothers with primigravida (44.4%) but experienced death due to bleeding experienced by 4 mothers (50%), hypertension was experienced by 2 mothers (25%), retention of placenta experienced by 1 mother (12.5%), and amniotic embolism was experienced by 1 mother (12.5%). This showed that more deaths occurred in this study due to complications of pregnancy and childbirth.

Based on the findings of the field in 6 mothers with multigravida (33.3%) did not experience death due to delivery assisted by health workers. Although there were mothers who have risk factors, but with a competent birth attendant would reduce the risk.

There was no relationship between income and maternal mortality (\(p = 1,000\)). This was caused by mothers who experience death consisting of low-medium family income and high income as the same percentage (50% each). The results of this study was in line with Aeni’s (2013) study which states that there is no relationship between family income and maternal mortality (\(p = 0.350\)).\textsuperscript{12}

Based on the findings of the field in 6 mothers with high income but experienced death (33.3%) due to 3 mothers died because of bleeding (74%) and 1 mother with risky parity (25%). This shows that although working with a good socio-economy still caused death if they had complications during pregnancy and childbirth and with high parity. One parity and high parity (more than three) had a higher incidence of postpartum hemorrhage.\textsuperscript{14}

Based on the findings of the field in 11 mothers who did not work but did not experience death (22.3%) due to their income included in the high category, so that mothers could meet their daily needs during pregnancy and maintain their health.

There was no relationship between income and maternal mortality (\(p = 1,000\)). This was caused by mothers who experience death consisting of low-medium family income and high income as the same percentage (50% each). The results of this study was in line with Aeni’s (2013) study which states that there is no relationship between family income and maternal mortality (\(p = 0.350\)).\textsuperscript{12}

Based on the findings of the field in 6 mothers with high income but experienced death (33.3%) due to 3 mothers died in bleeding, 1 mother died in hyperthyroidism, and one mother died in risky parity. Various risks related to reproductive behavior, health status and how to maintain health could cause complications during pregnancy and childbirth.\textsuperscript{15}

Based on the findings of the field, 12 mothers with low income did not experience death (66.7%) because mothers were able to give birth in health facilities and assisted by health workers. In addition, low income families were provided with health insurance which the premi were paid by the government, so that they
could deliver in health facilities to minimize the risk of maternal death.

There was no relationship between ANC compliance with maternal mortality (p = 1,000). It happened because the sample dominated by mothers who performed complete ANC (94.4%) in case and control. The results of this study was in line with Aeni’s (2013) study which stated that there was no relationship between ANC compliance with maternal mortality (p value = 0.08).12

Based on the field findings of 17 complete ANC mothers who experienced death (94.4%) due to high risk age, pregnancy complications, labor complications, and parity that could cause maternal death. Age of 20-35 years was the best age for pregnancy and childbirth.16

Based on field findings, 1 mother with incomplete ANC but did not experience death because in terms of age and parity was not at risk to experience death.

There was no relationship between the characteristics of the place of residence with maternal mortality (p = 1,000). This was caused by mothers who lived in rural had the same percentage with woman who lived in urban (50%). The results of this study was in line with the research of Sabatini and Inayah (2013) which states that there was no relationship between the characteristics of the place of residence and maternal mortality (p value = 0.139).11

Based on the findings of the field in 7 mothers who lived in urban areas (38.9) but experienced death due to 3 mothers died in hypertension (42.8%), 1 mother died of bleeding (14.3%), 1 mother died in hyperthyroidism (14.3%), 1 mother died of amniotic embolism (14.3%), and risky/multigravida parity (14.3%). Even though the mother lived in urban where health facilities were available, but if they had complications would cause maternal death. The effect of diseases on pregnant would make worse the condition of the mother and more susceptible to complications.12

Based on field findings in 11 (81.1%) mothers who lived in rural did not experience death because mothers were still able to access health facilities. This was supported by the availability of facilities owned by health workers made mothers felt safe and reduced the risk of childbirth.17

There was no relationship between the distance of coverage to health facilities and maternal mortality (p = 0.691). This was due to the overall sample taken had a fast travel time to health facilities which was 55.6%. The results of this study was in line with Juharni’s (2013) study which stated that there was no relationship between delays in referral travel and maternal mortality (p value = 0.074).16

Based on the findings of the field in 3 mothers with travel time to health facilities <8 minutes (16.7%) but experienced death due to other factors, there were 2 mothers with multigravida (66.7%), and 1 mother with a late decision to be referred (33.3%). The delay would bring a significant contribution to maternal mortality. First delay was in recognizing the existence of emergency condition. The second delay was in reaching referral health facilities, due to geographical and transportation facilities The third delay was obtaining medical assistance in referral health service place.18

Based on field findings in 13 (72.2%) mothers with long travel time (> 8 minutes) did not experience death due to mothers giving birth in health facilities that could reduce the risk of maternal death.

There was no relationship between birth attendants and maternal mortality (p = 0.104). The results of this study was in line with Aeni’s research which stated that there was no relationship between birth attendants and maternal mortality (p value = 0.104).

Based on the findings of the field in 14 mothers who gave birth to health workers (77.8%) but experienced death due to other factors, namely risk age (4 mothers/28.6%), risk parity (4 mothers/(28.6%) and delay in reaching health facilities because of the long travel time (6 mothers/42.8%). Thus, the presence of risk factors in the form of total parity and long travel times could cause maternal death even though it has been helped by health workers.

There was no relationship between the place of delivery and maternal mortality (p = 1,000). Although not significantly meaningful, table 1 showed that mothers who gave birth in health facilities tend to minimize the risk of death. The results of this study was in line with Suriani’s research (2017) which stated that there was no relationship between the place of delivery and maternal mortality (p = 0.126).13

Based on the findings of the field in 14 mothers who gave birth at a health facility (77.8%) but suffered death. Even though in the selection of the place of delivery was
correct, the incidence of maternal death also occurred in health facilities because of delay of the mother in referring the mother to the health facility, and they were late to be helped.\textsuperscript{13}

Based on field findings on 5 mothers who did not give birth at a health facility (27.8\%) but did not experience death because they were helped by a midwife and with an adequate midwife kit.\textsuperscript{19}

**Conclusion**

The results of this study indicated that there were no relationship between age, parity, education, job status, family income, ANC, recidency, time to reach health facility, childbirth helper and place of delivery with maternal mortality, but the data showed that there were complications during pregnancy and childbirth as risk factors that caused maternal death.

The suggestions were ANC must be done as early as possible. The complete facilities and infrastructure are also needed.

Abstract

Aims: The aim of study is to assess the knowledge and awareness on forensic odontology among dentists in Bhimavaram town

Method and Material: A structured questionnaire comprising of 14 close ended questions (Sharma et al 2015) with slight modifications, validated through a pilot survey was distributed among 100 dentists residing at Bhimavaram town and were assessed. The questions were about importance of dental records and their maintenance, identification of child abuse or bite marks, importance of dental witness in the court of law for person identification and interest among dentists to learn about forensic odontology.

Results: This present study showed that 90.9% MDS participants and 77.7% BDS participants were maintaining their dental records in their dental practice, though 94.5% MDS and 75.5% BDS were aware about forensic dental witness, only 1.8% of MDS participants were called by court of law for forensic evidence. Only 7.2% of MDS participants were trained and confident in handling forensic related cases.

Conclusions: The results show that knowledge and awareness about forensic dentistry among BDS and MDS individuals are in primitive stage. However very few members of participants were trained in forensic dentistry which suggests that practice of same is to be progressed in Bhimavaram town.

Keywords: Forensic Odontology, Dentists, Awareness, Knowledge, Dental record.

Introduction

Forensic science refers to areas of endeavour that can be used in a judicial setting and accepted by the court and general scientific community to separate truth from untruth. Forensic is derived from the Latin word “forum”, which means “court of law”. Odontology refers to the study of teeth. Forensic odontology, therefore, has been defined by the Federation Dentaire International (FDI) as that branch of dentistry which, in the interest of justice, deals with the proper handling and examination of dental evidence, with the proper evaluation and preservation of dental findings.

Forensic dentistry involves the dispensation, reassess, evaluation and presentation of dental evidence with the rationale of contributing scientific and objective data in lawful processes. It is a challenging and captivating twig of forensic science that involves the application of dental sciences in the identification of
deceased individuals through the assessment of ante-and post-mortem records.[4] From AD 66 till date, dental identification has proved imperative in identifying deceased individuals, the first case being accepted by the law in the year 1849.[2] The term “forensic” has its origin in the Latin word “forensis” from “forum,” which means a place where legal matters are discussed.[5]

Interest in forensic dentistry was relatively dormant until the 1960s when renewed interest was sparked by the first formal instructional program in forensic dentistry given in the United States at the Armed Forces Institute of Pathology. [6] The first forensic dental identification in India was reported in a review conducted by Sansare and Dayal in 1995. According to this review, M. Raja Jayachandra Rathore of Canouj died on the battlefield in 1191. His body was identified by his false anterior teeth. This was probably the first case of identification using dentition from India.[7] Forensic odontology has become an integral part of forensic medicine over the past 100 years.[8] It may also be sub classified into forensic-odonto-toxicology, which deals with cases of poisoning, but this field is yet to gain popularity globally. [9]

A properly maintained patient record is a very important aspect of this patient care. In general, a “record” can be defined as information generated in the course of an organisation’s official transactions and one that is documented to act as a source of reference and a tool by which an organisation is governed.[10] A detailed and accurate dental record is essential as it serves the dentists own best interests in the event of a malpractice suit.[3] A complete record also enables communication with another practitioner who may be required to provide care to the patient in the absence of the primary clinician. They are essential for dental audit, which is a vital part of quality control. A dental audit critically analyses every aspect of dental care. Forensic dentists require knowledge encompassing a number of disciplines, since the dental records obtained can identify an individual or afford the information needed by the authorities to establish neglect, fraud or abuse. [3]

**Subjects and Method**

**Study design and population:** A cross sectional descriptive study was carried among 100 Dentists practicing in and around Bhimavaram town. Dentists possessing both BDS and MDS degree were included and consent was obtained. The study design and protocol was reviewed and approved by Institutional Ethical Review Board. The questionnaire survey validation was carried out and cron-bach’s alpha coefficient value of 0.84 was found.

**Methodology:** A structured questionnaire adapted from Sharma et al[14] with a little modification written in English which included 14 questions on the Knowledge Awareness and Practices about Forensic Dentistry (Odontology) was given to all the dentists willing to participate in the study, confidentially and anonymity of the participants was assured for same.

**Statistical analysis:** Descriptive statistics was done to summarize the responses to the questionnaire, with the results being presented as frequencies and percentages. Chi-square test was done to compare the 2 groups and the level of significance was set at $P \leq 0.05$.

The data were analyzed using Statistical Package for Social Sciences (SPSS) version 16.0 (SPSS Inc., Chicago, IL, USA).

**Results**

A total of 100 sample were taken, among these MDS were 55%, BDS were 45 % (table-1), (table-2)

**Do you maintain dental records in your clinics?:** Among the total subjects majority of MDS and BDS participants are maintaining their records in their regular practice. 35 (77.7%) members of the BDS and 50 (90.9%) members of MDS are maintaining their records in their regular practice. However the association between the groups are not significant ($P=0.104$)

**Do you know that you can present forensic dental evidence in the court as an expert witness?:** Among 55 individuals of MDS 52(94.5%) participants and 34(75.5%) members of the BDS among 45 individuals are aware with a significant difference ($P=0.052$) as they can present the dental evidence as an expert witness in court of law.

**Do you know the relevance of dental records in recognising the dead and accused criminals?:** Among 55 individuals of MDS 52(94.5%) participants and 34(75.5%) members of the BDS among 45 individuals are aware with a significant difference ($P=0.052$) as they can present the dental evidence as an expert witness in court of law.

**Do you have knowledge on bite mark patterns of teeth?:** About 18(40%) members of the BDS and
35(63.3%) individuals of MDS participants had an adequate knowledge about bite marks which are considered as most debated area in forensic significance and the association is significant (p=0.020).

**Have you been called by authority/court for forensic evidence related?:** Among all the BDS and MDS participants, Only 1 (1.8%) MDS participant was called by the court as forensic expert witness and the association was not significant (P=0.317).

**Do you think you have a crucial role in identifying deceased in the incidence of mass fatality?:** Among the total study group, 22 (48.8%) members of the BDS and 40 (72.7%) of MDS individuals were aware that they have a role in identifying deceased during a mass fatality and the association is with significant difference (P=0.02).

**Are you confident in handling forensic dentistry related cases?:** Among all the participants of the BDS and MDS, Only 2 (4.4%) members of the BDS and 5 (9%) members of MDS were confident enough to handle forensic dentistry related cases. However the association was not significant (P=0.252).

**Can you estimate dental age of an individual by examining the teeth?:** Among the study group, 31 (68.8%) of BDS and 53 (96.3%) of MDS individuals in the study had mentioned that they are able to estimate the dental age of an individual by examining the dental status of patient and the association is significant. (P=0.016)

**Do you think your present knowledge level/awareness about forensic dentistry is adequate?:** Among the study group only 4 (8.8%) of BDS and 9 (16.3%) of MDS individuals were with an adequate knowledge regarding forensic dentistry, although the values are not statistically significant (P=0.166).

**Can you identify indicatory of domestic violence and child abuse?:** Among all the participants 20 (44.4%) participants of BDS and 45 (81.4%) of MDS individuals mentioned that they are able to identify domestic violence, child abuse. However the association was significant (p=0.002).

**Have you handled any forensic dentistry related cases?:** Out of 55 MDS study group only 4 (7.2%) individuals handled forensic related dental cases, none of BDS individuals had experience in handling forensic related cases. (P=0.045).

**Have you been trained about forensic dentistry?:** Among all the participants, only 4 (7.2%) of MDS participants were trained in proper handling, examination and evaluation of dental evidence, which will be then presented in the interest of justice.

**Are you part of a forensic team in your city?:** Among all the participants, only 3 (5.4%) of MDS participants are in a forensic team in the study area, remaining 52 members of MDS and 45 members of BDS are not the part of forensic dentistry (p=0.083).

**Are you interested to attend any forensic odontology program in near future?:** Among study group 34 (74.5%) of BDS participants and 52 (94.5%) of MDS participants are interested in gaining knowledge about forensic deontology programmes for further evaluation. (p=0.052). (Graph-1, Graph-2)

**Discussion**

Keiser-Nelson defined forensic odontology as “that branch of forensic medicine which deals with proper handling, examination, presentation of dental evidence in court of law”.[1] Forensic odontology is an imperative branch that would lend a hand in solving cases of abuse and death.[1] According to board of Australian guidelines, forensic dentistry is considered as one of 13 recognisable dental specialities.[12] A forensic team should be comprised of crime scene investigator, forensic biologist, forensic pathologist, forensic toxicologist and forensic odontologist.

The practice of forensic odontology has gained significance in a number of urbanized countries across the globe but in developing countries like India, it is yet to gain full impetus. The law enforcement authorities in India usually look up the help of dental surgeons in government service rather than private dental practitioners who have degrees in forensic odontology from universities outside India and who are not in government service. Due to natural calamities like recent Titali in srikakulam or tsunami in 2004, the death toll in India was about more than 15,000[13] but it is a question left unrequited whether all victims were recognized. This could have been made possible if there were ample forensic odontologists for identification of the victims. The fruit for success of identification lies in accessibility and precision of record compilation and maintenance. So, greater familiarity and awareness of forensic odontology among the dental practitioners would be required in the emergent field of dentistry. This study was conducted
among the dental practitioners to assess their knowledge awareness about forensic odontology.

The present study was conducted among 100 dental practitioners (45 BDS, 55 MDS) of age group above 25 years. In the current study, the ratio of males and females is 3:1 with a range from 1 to 40 years. Among all individuals MDS participants had a better knowledge about forensic odontology and thereby playing a role in identifying victims in mass disasters. A similar study conducted by Sharma et al. [14] in 2015 also showed that more of MDS individuals had knowledge about forensic odontology when compared with BDS individuals.

90% MDS individuals and 77% of BDS individuals were maintaining their dental records in their regular practice. This is with the accordance of study conducted by Nagarajappa et al. [15] in Kanpur who proved that all the dental practitioners maintain dental records and can become valuable members of the dental identification process by developing and maintaining standards of record-keeping, which would be valuable in restoring their patient’s identity. Another study done in Rajasthan by Preethi [1] et al concluded that 93% of individuals included in the study were not maintaining dental records.

The results showed that maintenance of dental records is in its infant stage. Neither all the dentists maintain the dental records nor do they have knowledge and awareness on advantages of maintaining the same. The advantage of maintaining dental records of the patient is that, it serves as a future reference when needed to produce in court of law as forensic evidence but the irony is that is that if it is maintained, it is solely maintained for dental insurance claims and not for forensic purpose. Whether the records maintained by practitioners are complete and useful for forensic odontology would be a valid question?

The progression of forensic odontology in India has been relatively slow though there is a greater demand of forensic odontologists world-wide. The great deal of forensic work done by dentist is ‘Age estimation’ through human dentition. Though there are various method of age estimation, radiographic age estimation is the most prominent method. Age estimation plays an important role in the cases involved in the court of law. In the current study, 96% of MDS and 69% of BDS individuals were able to estimate the dental age of an individual by examining the dentition which is in accordance of study conducted by Sharma et al in which most of the participants are confident enough in identifying the age of the patient by examination the human dentition.

In current study group majority of individuals were able to recognize child abuse and domestic violence. They were able to distinguish the injury caused by bites through arch alignments and specific tooth morphology. Kenney and Clark have cited researches that suggest approximately 50% of injury in child abuse cases occur in the oral and perioral region. [16] Regarding the knowledge about forensic odontology among the participants majority of MDS participants were aware of the techniques, presentation, collection, identification and evaluation of dental evidence. Studies done by Khare et al and Harchandani et al concluded that there is lack of knowledge and awareness among the dentists in India about Forensic odontology. [17, 18] The present study had shown that many dentist are not having adequate knowledge in handling forensic dental cases as they were not trained about forensic dentistry and not a part in the forensic team in the city. The participants want to increase their knowledge about forensic dentistry through journals, workshops, CDE’s.

Conclusion

The current study conducted among 100 dental practitioners clearly reveals that the knowledge and practices of forensic dentistry are at an infant stage. No matter whatsoever, the importance of providing proper education and training in forensic odontology is the currently the need of the hour. Every dental practitioner has a responsibility to understand the importance of forensic implications associated with practice.

Abstract

This study aimed to determine the effect of Milk Urea Nitrogen (MUN) levels as an indicator of protein intake to estrogen levels and pregnancy status in dairy cows. Eighteen productive heifers from wagir district, Malang were collected out from criteria. Thus, they were groups based on MUN levels and reproductive status. Feeding is done in the same pattern. Blood drawing for estrogen level were analized by Enzyme Linked Immunosorbent Assay (ELISA). Milk extraction for analysis of urea levels using the Barthelot method. Pregnancy examinations were carried out three months after Insemination. Data analysis were processed using SPSS (Statistical Package for the Social Sciences) for Windows programs. The results showed that non-pregnant cow had MUN levels from 16-28 mg/dL and high estrogen levels at time of estrus were the same as estrogen levels in pregnant cow. It can be concluded that the same feed pattern different produces MUN levels, estrogen and pregnancy status, depending on the efficiency of nitrogen utilization in the body and physiological health of individual dairy cows.

Keywords: Friesian holstein, feed, estrogen, MUN, Pregnancy.

Introduction

High crude protein intake can increase milk production while increasing Blood Urea Nitrogen (BUN) and Urea Nitrogen (MUN) levels. Studies reported negative effects between Blood Urea Nitrogen (BUN) or Milk Urea Nitrogen (MUN) and fertility. Nutrition management plays an important role to achieve optimal production. Rumen Degradable Protein (RDP) will be partially absorbed by the rumen wall and some will enter the portal blood and carried to the liver in the form of ammonia and converted to urea. Thus, it will be carried by the blood to the kidneys which will come out in the form of urine and the mammary glands that come out in the form of MUN. The optimal MUN concentration for cow is 12-17 mg/dL. In some studies, MUN levels can affect fertility if the MUN concentration is above 18 mg/dL or above 19 mg/dL. The fertility decreases due to ammonia and changes in uterine pH during the luteal phase of the estrus cycle which is a critical period at the initial stage of embryo development that affects embryo quality.

Hormone estradiol plays a role in the estrus cycle, folliculogenesis and ovulation processes. Estradiol stimulated by LH is initially secreted by follicular cells. Excess urea may interfere with the neuromodulation of episodic GnRH/LH release in cows, especially during the early post-partum period.
The purpose of this study was to determine the effect of Milk Urea Nitrogen (MUN) levels on estrogen level in ovulation and determine pregnancy status in dairy cows by giving the same feed pattern.

**Materials and Method**

**Sample collection:** The study was conducted at the Wagir District, Gunung Kawi-Malang, East Java, Indonesia. Sampling was carried out on productive heifer based on recording data. The collected data were based on the criteria. Divided into three groups based on MUN levels and reproductive status. Blood drawing for estrogen level analysis was done at the time of estrus (H0), seven days after estrus (H+7), and twenty-two days after estrus (H+22). Milk extraction was carried out on the seventh day after estrus (H+7). A pregnancy checkup with rectal palpation.

**Estrogen Hormone Levels:** Estrogen hormone levels in the study using Enzyme Linked Immunosorbent Assay (ELISA).

**Milk Urea Nitrogen (MUN) Levels:** Milk urea levels in this study were examined by Barthelot.

**Pregnancy:** Pregnancy examinations were carried out 3 months after insemination using the rectal palpation.

**Data Analysis:** The data obtained were analyzed by independent t-test with SPSS (Statistical Package for the Social Sciences) for Windows programs.

**Result and Discussion**

**Selection and Grouping of Samples:** The data collection of female dairy cows was carried out at the farm in Preet, Sumbersuko Village, Wagir District, Gunung Kawi-Malang, Indonesia and was selected based on characteristics (Table 1), then 18 samples of dairy cows were obtained. After that, a grouping based on dairy cows which is a first-calf heifer, still productive, not pregnant, and has a normal estrus cycle. Feeding in dairy cows uses the same pattern, which is hay grass and KUD-made concentrates which produced significantly different levels of MUN (p <0.05) in each group (Table. 3). This is related to the use of nitrogen in each individual different cow for milk production and energy. Some studies report the presence of genetic variations in MUN concentrations (indirect indications of BUN) between cows and similar breeds, showing genetic differences in efficiency of nitrogen utilization[15,16,17]. Nourozi’s[18] said that the concentration of urea nitrogen will increase if high protein feed is given. Giving high crude protein has a negative effect on Blood Urea Nitrogen (BUN) and Nitrogen Urea Milk (MUN). BUN is directly proportional to MUN[19,20]. According to Gulinski[21], high levels of protein ration cannot always be optimally utilized by livestock, depending on the efficiency of N utilization for milk production, if not utilized, the concentration of urea nitrogen can increase. The urea nitrogen concentration in ruminants can be influenced by protein feeding and N utilization efficiency for milk production[22].

Ammonia is a result of protein metabolism, which will enter the liver and be converted in the form of urea. In the blood, the urea will be filtered by the glomerulus so that the filtrate will form, then the filtrate enters into Bowman’s capsule and finally flows in the tubes which are then excreted into urine[23]. Glomerulus Filtration Rate (GFR) is one way to measure the concentration of urea nitrogen in dairy cows[24]. If physiological problems occur in the kidneys, the BUN levels will be high. High levels of BUN indicate an inefficient use of N intake in the body for growth and milk production[21,22].

**Estrogen:** The results of the study of estrogen hormone levels at estrus (H0) were significantly different (p <0.05) in group II with group I and group III (Table. 4). Groups with high MUN levels in group III produced high MUN and estrogen at the time of estrus (H0). Urea increase in blood may affect GnRH secretion by changing the hypothalamic environment which can have a direct toxic effect on neurosecretory cells which are pulses of the GnRH generator so that they can change the environment of amino acid neurotransmitters in the preoptic area (POA) which can reduce the release of opioid peptides endogenous which interacts with GnRH neurons on the hypothalamic basal media[12]. So that there is an increase in estrogen levels at the time of estrus (H0) despite high MUN levels.

The hormone estrogen is associated with the growth and development of follicles in the follicular
phase, especially the formation of large follicles. In large follicles (dominant follicles) that undergo high estrogen-containing selection in follicular fluid, and immediately after the follicle selection process ends it contains mRNA for gonadotropin receptors and steroid hormones\textsuperscript{[25]}. If the concentration of urea or ammonia in high blood meal will reduce the LH bond to the ovarian receptors, causing a decrease in the level of ovulation and progesterone production\textsuperscript{[12]}. LH in granulosa cells functions as a stimulator and aromatase activity, and physiologically together with insulin is a regulator of estradiol production\textsuperscript{[24]}.

The results of the study were based on the identification of the estrogen hormone, showing all groups of cows ovulate (Table 2). The total protein intake given has no effect on milk production (Table 3), as opposed to Alstrup\textsuperscript{[26]} giving protein concentration in feed is directly proportional to the increase in milk production. The response of different milk production to the same quality and quantity of feed as in the results of the study can be caused by genetic factors\textsuperscript{[27]}.

**Pregnancy:** In the study MUN levels had an influence on pregnancy status, although all cows in the group ovulated (Table 2). Rectal palpation shows 6 pregnant from a total of 18 cows. This is related to the consumption of feed given, feed with a high content of RDP in dairy cows is closely related to an increase in the concentration of BUN or MUN and a decrease in pregnancy rates\textsuperscript{[1,20]}. In cattle with NEB and high RDP feeding proven to produce ammonia and urea which have a damaging effect on the development of oocytes and embryos\textsuperscript{[7]}. High urea levels have no effect on ovulation as the results of the study, but can affect changes in uterine pH, mineral imbalance in the uterus, affect ovarian function and hormonal imbalances in the estrus cycle, which can disrupt the development of gametes and embryos\textsuperscript{[2,28,29]}. According to Jourritsman\textsuperscript{[30]}, negative effect of protein supplementation associated with urea-N enhancement in the blood, which can affect the development of follicles and embryos in the ovary.

The effect of urea levels on fertility tends to occur during the division and blastocyst process in the embryo, whereas the increase in high blood urea is likely to occur before ovulation\textsuperscript{[28,29]}. In addition, high urea levels can increase prostaglandin F2α secretion and disrupt the secretion of progesterone in the uterus which causes suboptimal conditions for embryonic development.\textsuperscript{[12]}

**Conclusion**

Non-pregnant cow had MUN levels from 16-28 mg/dL and estrogen levels increase at time of estrus were the same as estrogen levels in pregnant cow. Low and high level of MUN affects to the estrogen levels and pregnancy rate. That depending on the efficiency of nitrogen utilization and the physiological health of individual dairy cows.

Abstract
The data of the carrier rate of ESBL producing bacteria in pregnant women in Indonesia is limited. ESBL-producing bacteria colonization among women during labor is one of the risks for spreading and infection to the neonate. This study aimed to compare the carrier rate of ESBL-producing bacteria in pregnant women in the community and hospitals. This study was an observational analytic study with cross-sectional approach. Samples were collected from rectal swab of pregnant women who visited during antenatal care at the Primary Health Center (PHC), and inpatient pregnant women that referred to Dr. Soetomo referral hospital, Surabaya. The samples were cultured on MacConkey Agar media supplemented with cefotaxime 1 mg/L, incubation 37oC overnight. The growth colonies that were suspected ESBL producer were further identified by biochemically and confirmed the ESBL using the DDST (Double Disk Synergy Test) method. Among 200 samples (101 from PHC and 99 from hospital), 79 ESBL producers were identified, 28 (40%) from PHC and 51 (68.9%) from hospital. The carrier rate of ESBL producing bacteria was significantly different between PHC and hospital (p=0.001; 95%CI = 1.54-4.98). The antibiotic consumed by pregnant women was higher in hospital rather than PHC (p=0.001). Conclusion: The carrier rate of ESBL producing bacteria among pregnant women in hospital was higher than PHC. Antibiotic used was identified as risk factor.

Keywords: ESBL, Enterobacteriaceae, Pregnant woman, Indonesia.

Introduction
Extended-spectrum beta-lactamase (ESBL) is a plasmid-mediated derivative enzyme and is produced by Enterobacteriaceae mainly E. coli, K. pneumoniae, and K. oxytoca, although it is also known to be found in Proteus sp., Salmonella sp., and other gram-negative bacteria¹. Initially, ESBL was known as HAI (Healthcare-associated infection), since the late 90s, ESBL producing enterobacteriaceae findings have been reported in the community regarding urinary tract infections (UTI)².

In 2001 and 2002 was first reporting of ESBL producing bacteria from fecal in Spain and Poland. However, studies conducted in Indonesia have not found any carrier of ESBL producer, as well as in the following year, the increase was still relatively small, at 10%. After 2008 the rapid increase emerged from reports in Thailand, which stated an increase of more than 60%².
**Escherichia coli** is a normal gastrointestinal flora that most often detected since ESBL findings in the community were reported\(^3\). Although *E. coli* is a commensal bacterium, different environments could change it be pathogenic\(^4\). Known as a cause of urinary tract infections (UTI), surgical wound infections, and neonatal meningitis, *E. coli* colonization has also been reported in pregnant and non-pregnant women. *E. coli* infection in pregnant women could have an effect on pregnancy outcomes including infection in newborns\(^5\).

The most common cause of early-onset sepsis in several studies is coagulase-negative *Staphylococcus* sp. While in other studies were group B *Streptococcus* sp. (GBS) and gram-negative bacteria such as *E. coli* and *Klebsiella* sp.\(^6\).

Every year was estimated around 23.4% of newborn deaths were caused by infection, of which half occurred in their first week of life\(^7\). This might occur because of the vertical transmission process, which occurred during labor bypassed through the vagina or the horizontal transmission process that could occur due to contact between the mother and the baby after birth\(^8\). The presence of these routes also allows the risk of introducing ESBL producing enterobacteriaceae from mother to baby.

This study aimed to compare the carrier rate of ESBL-producing bacteria in pregnant women in the community and hospitals.

### Materials and Method

This study was an observational analytic study with the cross-sectional approach. The subjects of the study consisted of 101 community respondents, namely pregnant women who went to the Jagir Primary Health Center for antenatal visited, with inclusion criteria having not been hospitalization for the past year, and 99 pregnant women were included until 7 days after labor who were hospitalized at Dr. Soetomo hospital, and Airlangga University hospital with inclusion criteria have been hospitalized for more than two days. Each respondent in this study had obtained information for consent and filled out an informed consent form as an agreement to take part in the study. The data from respondents were collected, after filling the questionnaire which included demographic data, antibiotic consumed and other data.

From each respondent, rectal swab was taken using Amies transport media and on the same day, were immediately cultured on MacConkey selective media supplemented with 1 mg/L cefotaxime. The growth isolates were identified biochemically (TSI, indole, motile, citrate, MR and VP test), then proceed with the ESBL confirmation test using the double disc synergy test (DDST) method, which cefotaxime 30 µg, ceftazidime 30 µg, ceftriaxone 30 µg, aztreonam 30 µg, and amoxicillin/clavulanic acid 30/10 µg antibiotic discs with 15 mm distances from edge to edge, was applied on Mueller Hinton agar media. The test results were considered positive when showed an increasing diameter of inhibition zone of disc that facing against clavulanic acid discs. The examination was carried out in the Laboratory of Clinical Microbiology, Dr Soetomo hospital Surabaya.

The data was analyzed by SPSS Statistical Software Version 20.

### Result

During the study, as many as 200 pregnant women were recruited, 101 from PHC and 99 from hospital. The demographic data in both PHC and hospital showed mostly aged from 21 until 35 years old. The education level were 12(11.9%) university graduate, 67(67.7%) high school, 19(19.2) primary high school, and 3(3%) primary school or lower in PHC, while in hospitalized patient were 10(10.1%) university graduate, 44(44.4%) high school, 27(27.3) primary high school, and 18(18.2%) primary school or lower. Table 1.

The total 200 fecal specimens were collected during the study, 101 from PHC and 99 from hospital. Among these, 79 ESBL producers were identified, 28 (40%) from PHC and 51 (68.9%) from hospital. Table 2. The ESBL producing bacteria, were dominated by *E. coli* 42 strains (53.2%), *K. pneumoniae* 12 (15.2%), *S. paratyphi* 5 (6.3%), *Shigella* spp. 2 (2.6%) and the others. The carrier rate of ESBL producer between pregnant women from PHC and hospital was significantly difference (p=0.001; 95%CI=1.54-4.98).

The antibiotic consumed by pregnant women during the study were 28 (40%) among pregnant women in PHC and 51 (68.9%) for hospitalized pregnant women who visiting PHC rather than pregnant women that were hospitalized during their labor (p=0.001; 95%CI=1.54-5.53). Table 3.

Discussion

ESBL-producing bacteria usually colonized the intestine without caused signs of infection. Their spread could occur either fecal-oral or through hand contact of health workers or contaminated objects. Infection that could be caused by ESBL-producing
Gram-negative bacteria includes even systemic or local infections. This study showed that the prevalence of ESBL producing bacterial gut flora in pregnant women in hospital was 51.52% that was highly significance against pregnant women from PHC 27.72% (p=0.001, 95%CI=1.54-4.98). The data suggest that the carrier rate of ESBL-producing bacteria among pregnant women in the Hospital was almost twice more than the PHC.

This data similar with the study of many countries in Africa showed that the overall pooled prevalence of colonization with ESBL producing enterobacteriaceae in pregnant women and post-partum women in Africa was 17% (10% – 23%)\(^{20}\). The study in Madagascar, in which the incidence of neonatal sepsis was high, among pregnant women in community showed also the similar prevalence of gut bacterial flora producing ESBL colonization, of 18.5\(^{21}\). It would be impact of the transmission of ESBL producing bacteria to the sepsis neonates. The other studies also showed the similar rate of ESBL producing gut flora enterobacteriaceae, such as Tanzania 15% (in 2013)\(^{22}\), India 15% (data 2007-2009)\(^{23}\) and Madagascar 10% (in 2009)\(^{24}\).

The prevalence of ESBL producing gut flora in hospital was significantly higher than community pregnant women. It was suggested due to the many factors, such as antibiotic selective pressure or transmission during hospital stay. The existence of a high ESBL carrier in a hospital compared to a community could be related to selective antibiotic\(^{11}\).

Woodmansey et al (2004) showed the influence of antibiotic selective pressure and transmission during hospital care for the increasing of ESBL colonization\(^{12}\). Results of fecal carriers investigations in normal deliveries and cesarean deliveries infants showed a significant association with ESBL producing enterobacteriaceae carrier risk\(^{12}\). Not only the history of care in a long-term care place that can spread ESBL-PE to acute care facilities, but also the spread of ESBL-PE in long-term care places obtained during treatment in acute care facilities\(^{13}\).

This study showed that antibiotic consumed by pregnant women in hospital is higher than in PHC. As the study of Kang et al (2012), the criteria of women, age, illness, severity of disease, co-morbid conditions, history of the use of cephalosporin antibiotics and penicillin derivatives, it was found that a history of antibiotic use was a factor that had a significant correlation\(^{14}\). Antibiotic used can disrupt the gut microbiota, in both of oral or injectional antibiotic treatment. It can suppress the gut flora and allowing he emergence and development of resistant bacteria, such as ESBL producing bacteria\(^{15}\).

In this study, *E. coli* and *K. pneumoniae* were the most prevalent ESBL producing bacterial gut flora. That was like the multicenter study result that conducted in Surabaya, Malang and Semarang, where *E. coli* and *K. pneumoniae* were known as the highest ESBL producing bacteria in Indonesia\(^{16}\). Especially ESBL-producing *E. coli* and *K. pneumoniae* have been known as a serious pathogen in both of hospital and in community since decades ago\(^1\).

Frequently, *K. pneumoniae* and *E. coli* are species that were often found to be the caused of UTI in the pregnancy and postpartum periods where 80% were resistant to the third and fourth generation of cephalosporins\(^{17}\). A study in patients with UTI showed that of 22 Carbenemase-producing gram-negative bacteria, four strains also produced ESBL\(^{18}\).

Until the late 1990s, the highest ESBL producing bacteria were *K. pneumoniae*, but the situation has changed since the early 2000s when isolates were more often obtained from the community. This was related to the dominance of *E. coli* as ESBL producer and CTX-M expression was more commonly found\(^3\). The CTX-M type was more easily spread because it used an enzyme encoded by the genes carried by the plasmid and/or other mobile genetic material, while the SHV, and TEM type spread through clonal bacteria\(^{19}\).

*Escherichia coli* is an intestinal commensal bacteria that most commonly found in the female reproductive tract. However, extra intestinal *E. coli* was the second most common caused of obstetric infections. Its presence could be causing different manifestations among pregnant women, including amniotic membranes infections, urinary tract infections or endometrial infections, sometimes even caused sepsis\(^4\).

All these data showed the important of exploring the ESBL producing bacteria harbouring among pregnant women. The high carrier rate of the ESBL producing bacterial among pregnant women, not only will impact for infection in the pregnant women itself, but also their baby.
Conclusions

This study showed that there was a significant difference between the carrier rate of ESBL-producing gut bacterial flora in pregnant women in the Primary Health Center (community) (27.72%) and hospitals (51.52%). The dominant bacterial was *Escherichia coli*. Antibiotic use was a risk factor for ESBL producers colonization.

Conflict of Interest

None declare.

Ethical Clearance

This study was approved by the Ethical Committee from the Dr. Soetomo Hospital and Airlangga University Hospital.

Abstract

Trypanosomiasis or surra is a disease caused by blood parasite of Trypanosoma evansi. Trypanosomiasis disease in Indonesia includes Strategic Diseases of Infectious Diseases (SDID). The purpose of this study is to detect Trypanosomiasis in horses in Bima, Indonesia. A total of 90 horse blood samples were used for the study. Sample examination using blood smears technique with Giemsa staining and Card Agglutination Test of Trypanosoma evansi (CATT). The result of examination of blood samples by microscope obtained 3 positive samples infected T. evansi and by CATT obtained 1 positive samples containing antibodies against T. evansi. It was concluded that trypanosomiasis in horses in Bima was 3.3%.

Keywords: Bima, Blood Smears, Card Agglutination Test of Trypanosoma evansi (CATT), Horse, Trypanosoma evansi.

Introduction

Bima is one of the cities in the province of West Nusa Tenggara, known as a tourist destination in Indonesia because it has natural beauty, customs, and the diversity of animals such as horses. The horse in Bima is used as a means of transportation, a source of meat, milk and a horse game. The existence of horses in the area can be threatened by disease and one such disease is Trypanosomiasis. Trypanosomiasis or Surra is a disease caused by \textit{Trypanosoma evansi} \textsuperscript{[1]}.

Trypanosomiasis in Indonesia is a disease that is categorized as Strategic Diseases of Infectious Diseases (SDID) list in Minister of Agriculture decree number 4026 / Kpts / OT.140 / 4/2013 on the establishment of strategic infectious animal diseases \textsuperscript{[2]}. Clinical features of infected horses \textit{T. evansi} is decreased body weight, low reproductive, growth delay, decreased work force, state of immunosuppression (decreased immune responsiveness) and death \textsuperscript{[3]}.

The first incident of this disease in Indonesia was known in 1897 which was identified by Panning C. A from horse blood located in Semarang, Central Java. Outbreak of Surra disease occurred in Tegal, Central Java in 1898 with prevalence of 7% and in 1900 - 1901 surra disease spread to Pasuruan, East Java and in 1920 - 1927 there were 25,000 head of livestock \textsuperscript{[4]}. Study results from Mastra \textsuperscript{[5]} stated that the prevalence of antibodies to Trypanosomiasis on Sumbawa island has an average of 15.3% with variations ranging from 11.2% - 20.8%. In 2010 Sumba region experienced outbreak of Surra disease. A total of 4268 animals infected with Trypanosomiasis consisting of 1608 horses, buffalo 2648 head, and 196 cows and 1760 dead tail consisting of 1159 horses, 600 buffalo, and 1 cow. Morbidity and mortality data were obtained from accumulated disease incidence over a 2-year period from 2010 to 2012 \textsuperscript{[4]}.
While in Kabaru Village, Rindi Sub-district, East Sumba District, from 100 horses taken blood samples, there were 8 horses that were positive for *Trypanosoma evansi* so it can be concluded that the prevalence of Typanosomiasis in the area is 8% [6]. Another incidence of Surra disease occurred in Banten in the year 2013 - 2014 recorded 14 buffalo in Pandeglang regency infected by Surra disease. This incident was supported by PCR analysis results against the bloodsucking flies vector (*haematophagous flies*), showing a positive outcome indicating the threat of outbreaks of Surra outbreaks, with an initial incidence in May 2013 [7].

The diagnosis of trypanosomiasis can be done by examining the presence of parasites as a gold standard diagnosis and antibody testing of *Trypanosoma* with Card Agglutination Test of *Trypanosoma evansi* (CATT), and can be confirmed by molecular examination (PCR). Research data can be used as a basis for control of trypanosomiasis in Bima, and and support government programs to treatment and prevent Surra disease.

**Method**

The samples used in this study were 90 samples of horse blood taken from horse raised in regency and city of Bima, collected in January 2018. Examination of samples by blood smear method and Card Agglutination Test of *Trypanosoma* (CATT). The research was conducted at the Parasitology Laboratory of Faculty of Veterinary Medicine, Airlangga University, Surabaya and Veterinary Research Center of Bogor. The tools used in this research are cotton, venoject, vacuum tube with EDTA, glass object, shaker / rotator, stick, plastic card and timer. The material used is alcohol 70%, Giemsa 10%, absolute methanol, Card Aglutination Test of *T. evansi* (CATT) production by Institute of Tropical Medicine Antwerp, positive control and negative control serum against *T. evansi*.

**Ethical approval**

Ethical approval was obtained from Animal Care and Use Committee (ACUC), Veterinary Medicine Faculty, Airlangga University. No: 1.KE.134.08.2018.

**Take blood of sample**

Blood collection can be done on cattle in standing position, sitting or lying down, in a state of calm. Blood is taken through the jugular vein by first cleansing the fur and giving antiseptic. The needle is inserted in the jugular vein, when the blood is seen starting out, then the needle is connected to the vacutainer tube [8].

**Preparation of blood with Giemsa staining**

Blood that has been taken directly dripped over glass and made blood smear. The dried blood was then fixed by using absolute methanol for ± 3 minutes, and stained with 10% Giemsa solution, 30 minutes. The preparations are then washed in running water, and allowed to dry at room temperature. The preparations are examined under a microscope with 1000x magnification using immerse oil.

**Card Aglutination Test of *Trypanova evansi* (CATT)**

The CATT test is in accordance with the Institute of Tropical Medicine Antwerp [9] procedure. The first stage, preparing CATT antigen. CATT buffers up to 2.5 ml are taken and transferred into vials containing CATT antigen, mixed well. The second stage prepares the reaction control. 0.5 ml CATT buffer is captured and transferred into 2 vials intended as positive and negative controls after which already equipped with drops on vials. Sample preparation to be tested with 1: 4 or 1: 8 dilution ratio. Agglutination reaction stage, 25 μl serum or plasma dripped on the test area of CATT, then add 1 drop of CATT antigen, and mixed with stirrer until evenly distributed, test on a flat bed orbital rotation for 5 minutes at 70 rpm. After 5 minutes, read the test results by comparing the existing standard as shown in Figure 1.

![Fig 1. Standard reading of CATT results](image)

**Results**

The test results using two different method namely blood pillow and CATT obtained different results. The results of examination using blood smear obtained 3
samples from 90 samples obtained *T. evansi* (Figure 2), while using Card Agglutination Test of *Trypanosoma evansi* (CATT) obtained 1 positive antibody 3 (+++), which can be seen in Figure 3.

**Figure 2. Trypanosoma evansi on the blood smear with Giemsa staining (Magnification 1000X)**

Serologically tested results using Card Agglutination Test of *Trypanosoma* (CATT) of 90 samples tested, obtained 1 positive sample (positive 3 / +++). CATT test results can be seen in Figure 3.

**Figure 3. Serological test results using CATT**

*Description: + positive control, - negative control, 1-5, 6-8 is the sample. Sample no. 7 by showing positive results +++.*

**Discussion**

Based on the results of research that has been done in Bima using horse blood samples with blood testing method and serological test in this case is Card Agglutination Test of *Trypanosoma evansi* (CATT) got different results in both method. In the test by using blood smear method of 90 samples tested there are 3 positive samples *Trypanosoma* sp and visible parasitic formation on examination of blood smear in accordance with Figure 2, whereas, on the test using CATT only 1 sample positive. Differences in test results can be seen from the working principles of each method. The working principle of the blood smear is to find the causative agent of the blood protozoan *Trypanosoma* sp. which is different from the CATT that detects antibodies. This is one of the reasons why there are differences between the two method. The use of CATT is excellent for detecting chronic infection because *Trypanosoma* sp. antibodies have been established and can be detected. In the case of acute infection, the use of CATT is not recommended because antibodies from the host have not been established and usually horses with trypanosomiasis disease are fast, acute and fatal [5].

The results of the study concluded 0.3% of horses in Bima suffer from Trypanosomiasis. This result is lower than the report on Trypanosomiasis in the surrounding area (Sumbawa island). Mastra [6] reported that seroprevalence of Surra disease in regency and city of Bima is 20.8% and 20.0% in cattle, buffaloes and horses. The spread of Trypanosomiasis disease in regency and city of Bima can not be separated from the vector role of blood-sucking flies *Tabanus* sp. which acts as a mechanical vector [10]. Another factor contributing to the Trypanosomiasis event in Bima is maintenance management. The maintenance of horses in Bima is done extensively, so the control of a disease event is also difficult to suppress and implement. In addition, the presence of vectors of bloodsucking flies that many in the field is an important factor of disease transmission [2]. The other factors of transmission are in Bima has tradition of horse race, that can make the transmission and spread of Trypanosomiasis disease is higher because use horses from others Bima area and outside Bima area. Need for preventive measures to support government programs in addressing the spread of this disease with maintenance management, vector control and control of livestock traffic.
Based on the results of the examination with CATT, it is recommended to use a blood smear as a gold standard examination to detect agents causing trypanosomiasis in horses.

Conflict of interest

The authors declare that there is no conflict of interests.

Abstract

After the life of the schizophrenia, post-Restrain is a person who has been free from restraining, but stress reaction on the client family schizophrenia post-Restrain has not been said to end the role in family factors. The aim of the study was to investigated stress reaction and family experiences in primary care post restrain schizophrenia and to explain the stress reaction and experience of families who have people with schizophrenia post-restrain. Material and Method: A total of 135 families who have people with schizophrenia post-restrain October to December 2018. This research Mix Method: Sequential Explanatory design, the research instrument used was The Kempe Family Stress Inventory with The sensitivity of the KFSI was calculated at 80%. The specificity was 89.4%, the positive predictive value was 52.5%. Negative predictive value was 96.8%. The results of the study illustrated that the total mean score of a stress reaction in families normal was 43.48 [S.D=5.6], Mild was 34.33 [S.D=4.7], Severe was 56.45 [S.D=4.45]. The psychological burden was expressed by families in the form of fear and worry, the results showed a reaction to high stress and family experience lacking in primary care of people with post-restrain mental disorders. Conclusions: Most of the stress on families who have schizophrenia post-restrain in East Java is still showed revealed that the overall family stress reaction parent beaten of deprived schizophrenia and A majority parent has substance abuse history and Multiple stress.

Keywords: Stress, Experience, Schizophrenia, Primary care, Post-Restrain.

Introduction

After the life of the schizophrenia, post-Restrain is a person who has been free from restraining, but stress reaction on the client family schizophrenia post-Restrain has not been said to end the role in family factors. The psychological burden was expressed by families in the form of fear and worry to treat Schizophrenia, family stress reaction parent beaten of deprived schizophrenia and substance abuse history and multiple stress¹. Primary care is the basic ability of humans to meet their needs to maintain life, health, in accordance with health conditions²,³. Families have several important reasons for the treatment of schizophrenia, as families are most associated with schizophrenia, families are considered to be most aware of the condition of family members who experience schizophrenia⁴,⁵. WHO [World Health Organization] said at least one in four people in the world have mental problems, it is estimated there are around 450 million people in the world who have mental health problems⁴,⁵. The results of the Basic Health Research stated that the prevalence of severe mental disorders in the Indonesian population was 0.17% and the prevalence of mental
disorders in East Java in severe mental disorders (psychosis/schizophrenia) was 0.22\% and mental-emotional disorders at 6.5\%\(^5\). The results of the basic health research in 2018 showed schizophrenia 7 per mile previously only 1.7 permil, Mean while, the East Java Provincial Health Office recorded at least 731 people suffering from mental disorders in 26 districts / cities\(^5\). From the preliminary study conducted on October 18, 2018, the family experience of questionnaires, family stress reaction parent beaten of deprived schizophrenia and substance abuse history and multiple stress reaction in biological and psychological matters such as expressed by families in the form of fear and worry to treat Schizophrenia.

**Materials and Method**

This study used Mix Method: Sequential Explanatory design. Research variables are stress reactions on family and family experiences. Target participant who treating post restrains schizophrenia in East Java Indonesia 2018. Total 135 families were selected using by simple random sampling technique who treating post restrain schizophrenia. Step 1 explorative questionnaire and step 2 explanation three biggest themes of finding the study in step 1. The research instrument used was The Kempe Family Stress Inventory with The sensitivity of the KFSI was calculated at 80\%. The specificity was 89.4\%. the positive predictive value was 52.5\%. Negative predictive value was 96.8\%\(^23\).

The sample size was calculated using power analysis. The sample size are 1) the power of a statistical test (1-β), 2) level of significance (α), and the population effect size (γ). Therefore, the sample size in this study has estimated the significance at 0.05, a power of 0.80, and the small effect size 0.25, requiring a sample size of 135 families for the study. The questionnaire of this study was developed by the researcher based on a literature review of The Kempe Family Stress Inventory with The sensitivity of the KFSI was calculated at 80\%. The specificity was 89.4\%. the positive predictive value was 52.5\%. Negative predictive value was 96.8\%. We used SPSS 21.0 to conduct statistical analyses of all data. Quantitative data were presented as, Mean, Standard deviation (SD) and We used to in depth interview of qualitative data.

Parent Beaten or Deprived

With regard to the theme of Parent Beaten or Deprived, as stated by the participants:

“Sometimes if the desire is not followed he is angry and threatens to hit” (P1)

“Other than that when schizophrenia asked about something, he threw objects near him....(P6) (P8)

“Ever hit a neighbor when asking for food and drink...” (P1)

Other Barrier related to Deprived

“ When schizophrenia went on a rampage or was angry I did restrain it back” (P3)

“I help provide food and drink and take a bath if needed”(P4)

Parent has Criminal or Mental Illness Record, or Substance Abuse History

“Schizophrenia has experienced divorce with his wife, it happened about 1 year ago....” (P7) (P9)
“Schizophrenia, when fired from their work, is often daydreaming and alone, and asking for money to be able to work again...” (P10)

Multiple Stresses or Crises

“Yes, when schizophrenia goes on a rampage, I ask my neighbors and other families for help in engaging in schizophrenia so as not to harm others, this makes me very stressful” (P11) (P5)

“Schizophrenia also sometimes, clothing, urinates and defecates in places so it makes me very disturbed and stressed, I am patient and resigned...” (P2)

Discussion

Families stress reaction in treating schizophrenia is felt like a psychological burden showed revealed that the overall family stress reaction parent beaten of deprived schizophrenia. The psychological burden was expressed by participants in the form of fear, worry and increase blood pressure6,8,9. The fear here is because coping mechanisms, for example, the client sometimes if the desire is not followed he is angry and threatens to hit will get angry and hurt others around him. Feelings of worry until the heart flutters also feel family if schizophrenia goes on, do not go back home and make mistakes outside6,9,10. The family believes that post-restrain schizophrenia is left by work by his family, schizophrenia post restrain will run around the house, angry, and harm other people so that the perceived family is not calm while taking care of post restrain schizophrenia. The family system approach to mental health is justified under conditions of self care, and therapeutic interventions for children must, therefore, also involve parents and siblings8,9,10,11. Knowledge of unique family attachment patterns is useful for adapting therapeutic treatments and preventive interventions for schizophrenia and families affected by the family burden. Family members assist in caring for clients. If the family works, then other family members who help take care of client needs such as eating and drinking. The family helps meet the needs of personal hygiene in schizophrenia. The family revealed that post-restrain schizophrenia has a desire to take a bath and did not want to take a bath. The relationship between the general tendency to avoid actions in problem situations and the tendency to seek social transfer to overcome stress12,15,17. Assertive behavior was also found to correlate with the tendency to be involved in substitution activities26. Greater willingness to display assertive behavior is observed in subjects who express a tendency to avoid thinking about problems and find active solutions in stressful situations11,18,19,20. Therefore, the family tries to meet the needs of post-restrain schizophrenia bath so that personal hygiene in schizophrenia can be well maintained and can prevent disease. The family stated that the fulfillment of bathing needs is illustrated by bath time, bathing method, bathing place, and problems when bathing are not met. The hospital or nurse must do family coping while facing various problems in treating the client’s mental disorder after post. This activity can be realized through the provision of counseling services and health care workers always control families and clients. Multiply family empowerment in managing the various burdens faced by families who care for post-mental disorders18,19,20. The need for primary care elimination in schizophrenia post-restrain helps fulfill the need for self-elimination care in schizophrenia post-restrain. Schizophrenia also sometimes urinates and defecates in places so it makes me very disturbed and stressed, I am patient and resigned. Family environment interaction affects both aggressions directed outward and symptoms of mood and anxiety disorders in a specific way20,21,22. The family explained that the method of schizophrenia post-restrain removal is varied, that is by covering the soil, being given a hole, given water to wash, toilet, and indoors.

Conclusion

Most of the stress on families who have schizophrenia post-restrain in East Java is still showed revealed that the overall family stress reaction parent beaten of deprived schizophrenia and A majority parent has substance Abuse History, parental reports of symptoms of PTSD (post-Traumatic syndrome) and depression have strong negative effects on girls’ outcomes, including stigma experienced, externalizing behavior, and school days rather than boys8,10,11,15,16,24. The perceptions of family caregivers in this area and about their free time, this can provide a broader perspective for mental health therapists, rehabilitation managers and policy makers to understand needs, overcome challenges and barriers from this family care group11,12,15. Researchers argue that meeting the needs of primary care for family baths helps meet the need to bathe post-restrain schizophrenia. The family revealed that post-restrain schizophrenia had a desire to take a bath and did not want to take a bath. The relationship between the general tendency to avoid actions in problem situations and the tendency to seek social transfer to overcome stress12,15,17. Assertive behavior was also found to correlate with the tendency to be involved in substitution activities26. Greater willingness to display assertive behavior is observed in subjects who express a tendency to avoid thinking about problems and find active solutions in stressful situations11,18,19,20. Therefore, the family tries to meet the needs of post-restrain schizophrenia bath so that personal hygiene in schizophrenia can be well maintained and can prevent disease. The family stated that the fulfillment of bathing needs is illustrated by bath time, bathing method, bathing place, and problems when bathing are not met. The hospital or nurse must do family coping while facing various problems in treating the client’s mental disorder after post. This activity can be realized through the provision of counseling services and health care workers always control families and clients. Multiply family empowerment in managing the various burdens faced by families who care for post-mental disorders18,19,20. The need for primary care elimination in schizophrenia post-restrain helps fulfill the need for self-elimination care in schizophrenia post-restrain. Schizophrenia also sometimes urinates and defecates in places so it makes me very disturbed and stressed, I am patient and resigned. Family environment interaction affects both aggressions directed outward and symptoms of mood and anxiety disorders in a specific way20,21,22. The family explained that the method of schizophrenia post-restrain removal is varied, that is by covering the soil, being given a hole, given water to wash, toilet, and indoors.
process elimination in post-restrain schizophrenia in East Java Indonesia.

Abstract

Breast milk is the best nutrient for infant especially for the newborn. Nutrition in breast milk has benefits for improving infant’s growth and development. The infant are expected to be the successor of the nation that has competitiveness and high productivity by getting the best nutrition in the breastmilk. This research aims to determine the relationship of breastfeeding with infant’s growth and development in Sudiang Raya District Makassar City. This research is an analytic with cross sectional study design. The population were all the infant aged 6-12 months in Sudiang Raya distric as many as 192 infants. Total sample were 78 infant. The results showed that the exclusive breast feeding was high (66,7%) compared to the non-exclusive breast feeding (33,3%). Based on data analysis found that there were a significant relationship between breastfeeding and infant’s growth based on BB/U index with ρ: 0,000, PB/U index with ρ: 0,001 and BB/PB index with ρ: 0,010. There were also a significant relationship between breastfeeding and infant’s development with ρ: 0,000. Giving breast milk to the infant can increase growth and development so that it can improve their health status.

Keywords: Breast milk, Infant, Growth, Development.

Introduction

Based on data from the 2013 basic health research for the city of Makassar, breastfeeding <1 hour was 63.6%, breast milk for the past 1-6 hours was 20.5%, who gave breast milk for the last 7-23 hours was 1.5%, breastfeeding for the last 24-47 hours was 7.7% and the last ≥48 hours was 6.8%²,⁵,⁹. Growing and developing are two things that have different meanings. Growth and development is a continuous process that occurs since conception and continues into adulthood. Therefore, in the process of reaching this age the child must go through various stages of growth and development¹⁵,¹⁶,¹⁸.

Data from the Ministry of Health of the Republic of Indonesia (2006) in Kholifah (2014), there are 16% of children under five in Indonesia who experience general developmental disorders. Whereas UNICEF (2011) data in Fauzia (2015), there are 27.5% or 3 million children under five who experience motor development disorders. This shows an increase in the number of toddlers who experience general developmental disorders which include gross motor development disorders, fine motor skills, hearing loss, intelligence and delayed speech.

Based on the description of the low rates of exclusive breastfeeding, the importance of the benefits of exclusive breastfeeding and the number of patients with growth disorders in Indonesia which continues to increase, the authors are interested in examining the
“relationship between breastfeeding and infant growth in the Sudiang Raya area of Makassar City”.

Material and Method

This study is an analytical study with a cross sectional study design. This research was conducted in the Sudiang Raya Urban Village in February-June 2017.

The population in this study were 192 infants aged 6-12 months. The sample was chosen by random sampling method and selected 78 babies. The instrument used was the Pre Development Screening Questionnaire, digital scales and fixation boards.

The type of data collected consists of two types, namely primary data and secondary data. Primary data is data obtained from respondents through observation and interview activities.

The primary data collected is as follows:

1. Respondent and family characteristics including name, age, date of birth, parent’s name, address of parents, work of parents, education of parents, tribes of parents and religion of parents obtained through interviews.

2. Providing breast milk to babies obtained through interviews directly with the mother of the baby.

3. Baby growth which includes data on body weight and body length of the baby. Body weight data was measured using weight scales and body length data was measured using a fixation board conducted directly by the researcher towards the respondent.

4. Development of infants is assessed based on the suitability of development based on the age of the baby at that time. Developmental screening uses the form of the Pre Development Screening Questionnaire conducted by researchers on parents, closest people or baby caregivers.

Meanwhile, secondary data obtained in the form of the number of babies, schedules and locations of posyandu were obtained through the Sudiang Raya Health Center in Makassar City.

Data on body weight and body length were processed using the WHO Antro application that displays the nutritional status of the sample.

Data from the sample development interviews were assessed manually based on scoring from the Pre Development Screening Questionnaire form. Data analysis using SPSS with the chi square test.

n¹ = 78

Based on age, it was found that infants who were sampled were generally aged between 6-8 months as many as 56 infants (71.9%). According to gender, it is known that babies are generally female, as many as 41 babies (52.6%) and exclusively breastfed as many as 52 babies (66.7%)

It is known that mothers of babies generally aged between 19-30 years are 58 people (74.3%). While the baby’s father is generally aged 19-30 years as many as 43 people (55.1%), the majority of parents’ education is graduating from high school. The mother of a baby with high school education graduated as many as 50 people (64.1%) and father of a baby with high school education as many as 52 people (66.7%). Mother’s work as a housewife is 70 people (89.7%), while the baby’s father works as a private employee as many as 29 people (37.2%).

The chi-square test results of the relationship between breastfeeding and infant growth based on index body weight according to age and body length according to age with a value of $\rho = 0.000$, body length according to age index with a value of $\rho = 0.001$ and index body weight according to body length with a value of $\rho = 0.010$. According to the results of the study, infants who were exclusively breastfed had normal nutritional status based on the body weight according to age index of 51 infants (98.1%) and those who were not exclusively breastfed 18 infants (69.2%) had good nutritional status. Based on body length according to age index, 50 infants (96.2%) had normal body length and were given exclusive breastfeeding and 17 babies (65.4%) had normal body length but were not given exclusive breastfeeding. Meanwhile, based on the body weight according to body length index all infants fed exclusively breastfed had normal nutritional status while 22 infants who were not given exclusive breastfeeding (84.6%) had normal nutritional status and 4 infants (15.4%) among them were thin.

</tbody>
</table>

The results of statistical analysis prove that there is a significant relationship between breastfeeding and infant development in the Sudiangan Raya area of Makassar City with a value of $\rho = 0.000$. Infants who were exclusively breastfed were 52 babies (66.7%), 49 infants (94.2%) of whom had development according to their age and 3 babies (5.8%) had inappropriate developments. Meanwhile, of the 26 babies (33.3%) who were not given exclusive breastfeeding as many as 17 babies (65.4%) had inappropriate development and 9 babies (34.6%) had the appropriate development.

Discussion

Mother’s milk (ASI) is the best food for newborns, breast milk should also be given as early as possible when the new baby is born. Breastmilk given to babies after birth until the fourth or seventh day contains colostrum which is a liquid that is rich in protein and functions to fight infection, thereby reducing morbidity and even mortality. The provision of ASI can also help the survival of babies, especially families from low socio-economic groups by helping to alleviate the family’s economic burden and improve the quality of life for babies from poorly maintained sanitation environments.

Based on the results of research conducted in the Sudiangan Raya area of Makassar City in infants aged 6-12 months, it was found that 52 infants (66.6%) received exclusive breastfeeding and 26 exclusive breastfeeding (33.4%). The provision of exclusive breastfeeding to infants is higher than that of infants who are not given exclusive breastfeeding according to previous studies. Previous research conducted in the working area of the health center in Tamalanrea, Makassar, also stated that more groups were given exclusive breastfeeding.
namely 29 respondents (56.9%) compared to non-exclusive breastfeeding groups, namely 22 respondents (43.1%)\textsuperscript{19,20,21}. Growth is a quantitative change in the form of an increase in the number, size, dimensions of cells, organs and individuals. Not only changes in physical size of the body but also the structure of organs and brain\textsuperscript{18,19}.

Based on the results of statistical analysis states that there is a significant relationship between breastfeeding and infant growth in the Sudiang Raya area of Makassar City based on the index body weight according to age, body length according to age and body weight according to body length. The chi-square test results of the relationship between breastfeeding and infant growth based on index body weight according to age with a value of $\rho = 0.000$, body weight according to age index with a value of $\rho = 0.001$ and index body weight according to body length with a value of $\rho = 0.010$.

This is in accordance with previous research where there was a significant relationship between exclusive breastfeeding and the growth of 6-month-old infants in the Working Area of Berseri Pangkalan Kerinci Health Center, Pelalawan Regency. Likewise with the research which states that exclusive breastfeeding affects the nutritional status of infants\textsuperscript{9,10,11,14}.

Giving intake other than breast milk for infants under 6 months of age can increase the risk of infectious diseases and trigger malnutrition. This is because the provision of intake other than breast milk cannot be properly digested by the intestines of the newly developing baby and the non-sterile manufacturing process can mediate the entry of infectious disease-causing bacteria\textsuperscript{4}.

Development is a change that occurs quantitatively and qualitatively, increasing the ability of the body’s function to be better and predictable which is an interpretation of maturation or maturity. Changes in development occur in gross motor function, fine motor, cognitive, language, emotional and behavioral development as a result of development that is influenced by the environment\textsuperscript{1,3,4}.

The results of statistical analysis prove that there is a significant relationship between breastfeeding and infant development in the Sudiang Raya area of Makassar City with a value of $\rho = 0.000$. Infants who were exclusively breastfed were 52 babies (66.7%), 49 infants (94.2%) of whom had development according to their age and 3 babies (5.8%) had inappropriate developments. Meanwhile, of the 26 babies (33.3%) who were not given exclusive breastfeeding as many as 17 babies (65.4%) had inappropriate development and 9 babies (34.6%) had the appropriate development.

The results of this study are in line with research conducted in July (2015) where there was a significant relationship between exclusive breastfeeding and exclusive breastfeeding on the development of children aged 3-12 months in which 25 infants (41.7%) who were exclusively breastfed had normal development.

Optimal child growth is influenced by three basic needs. The three basic needs are ASUH in the form of fulfilling children’s basic needs in the form of intake such as breastfeeding and monitoring growth, ASIH in the form of fulfilling children’s emotional needs such as love and treatment from people around their environment and ASAH obtained through the learning process\textsuperscript{20,21}.

### Conclusion

1. Based on the body length according to age index, 96.2% had normal body length exclusively breastfed and 65.4% had normal body length but were not given exclusive breastfeeding. Meanwhile, based on the body weight according to body length index all infants who were given exclusive breastfeeding had normal nutritional status (100%) while 84.6% of infants who were not given exclusive breastfeeding had a normal nutritional status and 15.4% were thin.

2. Infants aged 6-12 months who are given exclusive breastfeeding in the Sudiang Raya area of Makassar City have a development that is in accordance with their age of 62.8%. Meanwhile, infants who were not given exclusive breastfeeding had an inappropriate development of 65.4%.

3. Giving breast milk to infants aged 6-12 months in the Sudiang Raya area of Makassar City has a significant relationship to the growth of infants with $\rho: 0.000$ for index body weight according to age, $\rho: 0.001$ for display body according to age index and $\rho: 0.010$ for index body weight according to body length index.

4. Giving breast milk to infants aged 6-12 months in the Sudiang Raya area of Makassar City has a significant relationship to the development of infants with $\rho: 0.000$. 
Conflict-of-Interest Statement

There was no conflict of interest at the time this research was conducted.

Source of Funding

This study received independent funding and assistance through the Makassar health polytechnic Risbinakes fund of the Ministry of Health of the Republic of Indonesia.

Ethical Clearance

Before the research was conducted, researchers obtained ethical clearance from the ethics commission of health research at the Makassar Health Polytechnic.

Efficacy of Ice Ball Oral Care on Subjective-Objective Oral Health Status in Cancer Patients: A Pilot Study

Nayeon Shin¹, Jummi Park²

¹Nusing Department, CHA University, Bundang CHA Hospital, 13497.
²Nursing Department, Namseoul University, 31020, Korea.

Abstract

Background/Objectives: Oral mucositis and oral discomfort are common side effects in cancer patients undergoing chemotherapy. The purpose of this study is to examine the efficacy of ice ball oral care on subjective-objective oral health status induced by chemotherapy in adult cancer patients among Korean women.

Method/Statistical analysis: Participants were randomly assigned either to the experimental group (n=15) that received ice ball oral care during chemotherapy or the control group (n=15) that received normal saline oral care during chemotherapy.

Findings: There was a significant difference in oral mucositis, and oral discomfort between the two groups, and there were significant changes over time and the group by time interactions.

Improvements/Applications: The findings of the study demonstrated that ice ball oral care was more effective than the normal saline oral care in improving subjective-objective oral health status in adult cancer patients undergoing chemotherapy.

Keywords: Cryotherapy, Drug Therapy, Oral Mucositis, Nursing, Health.

Introduction

Chemotherapy is reportedly applied to 60-70% of cancer patients.¹ It may improve the patients’ survival rate, but, at the same time, might expose its toxicity to normal cells as well as cancer cells, and result in a vast level of destruction of cells and other side effects including oral mucositis.² Oral mucositis usually results from destruction of mucous membrane, which is attributable to decline of immunity and damage to oral epithelial cells from toxic treatments such as chemotherapy and radiation therapy.³

Chemotherapy is likely to result in stomatitis of Level 3 or higher (frequency of 47%)⁴. Oral discomfort including saliva change, burning sensation⁵, might often lead to decline of nutrition intake⁶ and whole body septicemia⁷, which would require decreased drug dosage or lengthened time of treatment⁸.

Thus, it is essential to provide nursing that would reduce risk factors of impeding oral comfort of cancer patients undergoing chemotherapy before therapy begins. Many factors affecting the strength and frequency of oral mucositis have been reported: types of chemotherapeutic agents and their dosage,² cancer types and patients’ haematologic status, oral health before therapy and oral nursing during chemotherapy⁹. The most important element for prevention of oral complications would be oral nursing.¹⁰ The change in one’s oral health would be an index that might indicate the result of treatment or oral health⁹, and would help suppress the occurrence of oral mucositis due to side effects of chemotherapy.
Oral mucositis which is objective oral health status might be a dangerous disease that can negatively influence therapy and even threaten a patient’s life. Thus, adult cancer patients should be given a proper and effective oral nursing to prevent oral mucositis, but, in reality, therapeutic intervention after the outbreak of the disease is the focus of clinic rather than prevention of the disease. Adult cancer patients tend to have enduring neutropenia due to chemotherapy, which often leads to infectious diseases such as oral mucositis. Therefore, every effort to prevent them from being infected by oral mucositis and effective oral nursing should be provided.

The guidelines for preventing oral mucositis and complications used home and abroad emphasize education of basic oral nursing, oral health matters and oral health management. Also, application of mouthwash liquids such as normal saline, chlorohexidine, and nystatin is recommended and oral cryotherapy is often suggested for patients under chemotherapy.

Oral cryotherapy can lead to vasocontriction and reduce blood flow to oral membrane, and, as a consequence, block the occurrence of reactive oxygen in cells due to anticancer medicine or radiation. Thus, it can an expected effect of reducing exposure to toxicity of anticancer agents. It has been reported that oral cryotherapy using ice cubes help maintain low intraoral temperature, reduce intraoral blood flow, alleviate inflammation, and exposure to toxicity of anticancer medicine.

Thus, we are in need of scientific and objective investigation that explores the prevention of oral mucositis and oral discomfort which is subjective oral health status resulting from chemotherapy. The results of such researches are expected to provide knowledge and information on basic nursing, and empirical evidence and data that can be practical applied in the clinic field.

Method
Design

The present research proceeded with a random control group pretest posttest design to identify how ice ball oral care affects mucositis and oral comfort of adult cancer patients undergoing chemotherapy.

Participants

The criteria for selection of subjects were as follows: (1) patients diagnosed of cancer hospitalized for chemotherapy, (2) those within the normal range in tests of white blood cell, neutrophilic leukocyte, hemoglobin, platelet count, albumin, creatine, alkaline phosphatase, and (3) those within the normal range of OAG (less than 8 points), without dysphagia, and melt ice balls and melt them in the mouth.

The predicted number for this pilot study was 30, half of which can be allocated for each of the two groups. A total of 30 patients were finally registered as the subjects. The participants were randomly classified into two subgroups: the experimental group of 15 and the control group of 15 patients. In an effort to reduce the risk of intervention contamination, the subjects were first allocated to the control group and after measurement of the control group, the experimental group were given intervention. To minimize the experimenter effect, then, the researcher performed the intervention of ice ball oral care, and an assistant conducted a pretest and a posttest.

Intervention

Experimental group

Following the guidelines of oral care nursing for cancer patients and the results of previous studies, nurses were asked to give the patients of both groups the following instructions, demonstrate them and check if they accurately follow it; to brush the teeth using the same toothbrush and toothpaste for 3 minutes 4 times every day, after every meal and before going to bed. Also, both groups were instructed not to use commercial mouthwash during the chemotherapy period, since it can stimulate oral membrane. During the intervention period, the experimental group were offered ice ball of 2.5cm in diameter in a bottle.

Control group

The control group, in contrast, did receive the same treatment of nursing except that they were not given ice balls oral care.

Measurements

Mucositis: The current research adopted Oral Assessment Guide (OAG) developed by Elier et al. OAG measures medical workers’ evaluation of patients’ changes in 8 areas by palpation and ocular inspection: voice, deglutition, lips, tongue, saliva, mucous membrane, gum and teeth. Each item was measured on a 3 point scale: 1 point for normal, 2 points for moderate
changes like swelling, redness, and changes in color and viscosity of saliva, and 3 points for serious changes including ulcer, bleeding and infection. The reliability of the instrument, in Elie et al.\textsuperscript{14} was .91 and the reliability in this study was obtained at .95.

**Oral discomfort:** This study adopted Beck’s\textsuperscript{15} Oral Perception Guide. This tool consists of 8 items measured on a 4 point scale: lips, tongue, gum, saliva, teeth, appetite, voice and discomfort when eating. The total score would range from 8 to 32 and a higher score means a greater level of oral discomfort. The reliability and validity of the scale was not reported in Beck’s\textsuperscript{15} research. Cronbach’s $\alpha$ in this study was .78.

**Data collection and analysis**

Data was collected for 3 months between April, 2017 and June, 2017. The participants were recruited by posting an advertisement for research subjects in the wards and the outpatient clinic department in Korea.

The collected data was analyzed by using the statistical program of SPSS WIN 24.0. Descriptive statistics, chi-square tests, and Fisher’s exact test were used to identify the homogeneity of participants’ characteristics and outcome baseline variables between the experimental and control groups. The test of homogeneity of oral discomfort was analyzed by Mann Whitney U test. The changes in their mucositis and oral discomfort were analyzed by paired t-test. The scores of mucositis of the two groups were the same at the pretest. Thus, the changes in their mucositis and oral discomfort after the chemotherapy were measured by using paired t-test.

**Ethical consideration**

To protect the rights of the participants, this study was conducted after receiving approval from the C University Institutional Review Board (IRB No. 01-009).

**Results**

**Demographic characteristics**

**Comparison of General and Clinical Characteristics and Study Variables between Experimental and Control Groups at Baseline**

The research subjects’ age and level of education were collected for their general characteristics. Their clinical characteristics included the name of the diagnosed disease, period of cancer diagnosis, cancer surgery, stage of cancer, and chemotherapy agent.

The data for these characteristics can be found in Table 1. Chi-square and fisher’s exact test identified homogeneity of the two groups, since no significant difference was found.

As for mucositis, the subjects of both groups had no oral problems with the score 8.0 of OAG, and thus the two groups do not show normal distribution, since the dependent variables of both groups are identical (Table 1).

| Table 1. General and Clinical Characteristics of Homogeneity Test between Experimental group and Control group (N=30) |
|---|---|---|---|---|---|
| Variables | Categories | Exp. (n=15) | Cont. (n=15) | $\chi^2$ | p | Range |

Test of interventions

Mucositis

There will be a significant difference between the experimental group and the control group in mucositis depending on the measurement. The result found that the two groups exhibited a statistically significant different after intervention. The mucositis of the experimental group gradually increased from 8.00 at the pretest, to 9.36 after the chemotherapy. The control group scored 8.00 at the pretest and 9.98 after chemotherapy (Table 2).

Oral discomfort

Paired t-test tested that there will be a significant difference between the experimental group and the control group in oral discomfort depending intervention. It was found that the two groups showed a statistically significant different. The oral discomfort of the experimental group gradually decreased from 11.06 at the pretest, to 10.08 after the chemotherapy. The control group scored 11.86 at the pretest and 12.98 after chemotherapy (Table 2).

Discussion

It was found that ice ball oral care had a significant impact on mucositis. Both groups exhibited worsened oral mucositis. Other than the pretest, the two groups exhibited statistically significant difference in the occurrence of oral mucositis depending on the time of measurement (Table 1).

This finding is different from that of a previous research\(^6\), in which 3 groups of cancer patients were set: a group using chlorohexidine as the hydrous fluid to prevent oral mucositis, another group with oral cryotherapy, and another group without cryotherapy. It was found in that research that the delay period for dietary intake for the three groups was 8.5 days, 12.13 days, and 13.55 days. Thus, it was hard to claim that oral cryotherapy is responsible for the change in oral mucositis, since no significant difference was found.

Previous researches reported in the literature that oral cryotherapy decreased the occurrence of serious oral mucositis in the group of blood cancer patients under stem cell transplantation and that Melphalan can be used as an effective nursing drug to prevent oral mucositis\(^16\). Toro et al.\(^17\), reported that 90 percent of the experimental group with oral cryotherapy did not have oral mucositis in contrast to mere 34% of the control group using physiological saline solution. Also, in the measurement of oral mucositis on the 9\(^{th}\) day after the start of chemotherapy, the experimental group under oral cryotherapy marked the average of 0.43 in WHO grading, whereas the control group who only had brushing and rinsing the teeth recorded 1.14, which

†Fisher’s exact test

Table 2. Homogeneity Test for Mucositis and Oral discomfort between Experimental group and Control group (N=30)
clearly shows that oral cryotherapy contributed to lower occurrence of oral mucositis\textsuperscript{16}.

It was also found that ice ball oral care exerted a significant effect on oral discomfort. Oral discomfort was the worst after chemotherapy in control group. This finding is basically consistent with the research report that 40 percent of the patients under chemotherapy expressed oral discomfort such as mouth dryness, change in one’s taste and appetite, and difficulty in indigestion and that oral discomfort increased with a greater number of chemotherapy sessions\textsuperscript{18}. This finding is in the same line of the reports that oral discomfort can be dependent on the process of oral mucositis\textsuperscript{9}, types of anticancer medicine\textsuperscript{7} and oral nursing method.\textsuperscript{19}

Considering the agreement that oral comfort gradually worsens as the number of chemotherapy sessions\textsuperscript{18} further researches should control exogenous variables like the period of anticancer drug and haematological change in the process of chemotherapy\textsuperscript{8}.

\textbf{Conclusion}

The current research found that oral cryotherapy exerted a significant effect on oral mucositis, and oral discomfort of adult cancer patients under chemotherapy among Korea women. Thus, it can be used as an effective treatment to help reduce oral mucositis and oral discomfort of those patients. However, it should be admitted that the present research has a limitation in that the research subjects were recruited from a single medical institution and the size of samples is relatively small. Further researches are expected to expand to a set of institutions and a bigger group of subjects to help come to a generalized conclusion.

Abstract

Dengue fever is one of the main problems of public health in the world and nationally. This research was carried out in Banjarbaru City, South Kalimantan Province. The study population was the population of Banjarbaru City with a sample of 100 respondents in 5 sub-districts, namely South Banjarbaru District, North Banjarbaru District, Cempaka District, Landasan Ulin District and Liang Anggang District. This research is an observational study with case control research design, while the type is explanatory to explain the causal relationship between variables. Based on the results of the study it can be seen that there are 3 variables that have a relationship and 15 variables that are not related to the incidence of DHF in Banjarbaru City. Related variables include the habit of removing or recycling used goods (p-value = 0.045), the habit of cleaning the yard (p-value = 0.024), fogging program (p-value = 0.034).

Keywords: Environmental management, Dengue fever.

Introduction

Dengue is one of the main problems of public health throughout the world. Dengue fever is still endemic in certain areas, especially in tropical countries such as the continents of Asia and Africa. This disease is also one of the biggest killers, 86% of deaths occur in groups with high risk factors such as infants, toddlers and pregnant women1.

According to the WHO report, every year new cases of dengue fever of around 250 million are found with nearly 880,000 deaths. The incidence of dengue fever throughout Indonesia tends to decrease, which is 4.10% (in 2005) to 1.38% (in 2013), but has not reached the specified target of 1.25%. In addition to the progress that has been achieved, there are still many obstacles that must be faced, among others, access to services in remote areas, considered neglected disease, epidemiological disparities, management weaknesses especially limited competent resources, inadequate funding, weak cross-sectoral collaboration and community independence in controlling fever bleed2.

Most endemic areas of dengue fever are areas with a middle to lower economic condition so that dengue fever more often affects residents with lower to lowest economic status. The same was stated by Breman et al. That the poor population had the greatest risk of 58% of cases of dengue fever in the 20% of the poorest population in the world plus they got the worst service and the economy worsened due to their illness3.

There are 424 districts in Indonesia endemic to dengue fever from 576 existing districts, an estimated 45% of Indonesia’s population is at risk of contracting dengue fever. In 2009 there were 1,143,024 clinical dengue fever, 200,000 were examined by confirmation. This number may be smaller than the actual situation because the locations that are endemic to dengue fever are remote villages with difficult transportation facilities.
and low access to health services⁴.

Based on data, if compared to last 2016, the trend of dengue cases decreased. Because, in January 2016, there were 1,890 cases of dengue fever in South Kalimantan, up to 14 people who died. Then, in February 2017 there were 1,358 cases with 5 fatalities. It was recorded that as of early April 2016, the number of cases of dengue attacks that occurred reached 3,359 cases, with the death toll increasing to 22 people.

The number of people with dengue attacks rose sharply by 1,350 cases compared to the previous month. Most areas of DHF attacks include Banjarbaru City, Banjar Regency, Tabalong, Tanah Bumbu, Hulu Sungai Selatan, and Hulu Sungai Tengah. In 2015, the number of dengue sufferers was 3,668 cases with 40 people killed. In addition to DHF, South Kalimantan is also an area prone to dengue fever. South Kalimantan Health Office records 155 villages and urban villages or about 10 percent of the number of villages / kelurahan are vulnerable or in the red category of dengue fever.

**Material and Method**

This study is an observational study with a case control research design, while the type is explanatory, namely to explain the causal relationship between variables through hypothesis testing and by using the survey method. The population in this study were the people of Banjarbaru City who were spread in 5 Subdistricts namely South Banjarbaru District, North Banjarbaru District, Cempaka District, Landasan Ulin District and Liang Anggang District. The 5 sub-districts in detail were divided into 20 urban villages with a total of 100 respondents.

Based on table 1, it can be concluded that the majority of respondents’ dwellings have occupancy and humidity densities that meet the requirements. 97% of respondents have occupancy density that meets the requirements. 60% of the research respondents have ideal occupancy humidity levels. 99% of respondents have breeding places and 96% have mosquito resting
Based on the findings only found 26% of respondents detected had larvae in their homes. Based on table 1, it is known that the majority of respondents have implemented the Mosquito Nest Eradication (PSN) program by 3M Plus. This can be seen from the positive habits of respondents, namely, the habit of draining landfill by 96%, the habit of closing landfill meetings by 60%, and the habit of removing or recycling used goods by 87%.

In this study, the habit of installing wire nets, the habit of hanging clothes, sleeping habits using mosquito nets, the habit of using mosquito repellent, habit of napping, and the habit of cleaning the yard are also habitual factors studied to find a connection with the incidence of dengue in the Banjarbaru City community.

Table 1 illustrates that there are negative habits of respondents that can lead to dengue cases, namely, the lack of respondents who put wire nets (22%) and sleep using mosquito nets (32%). In addition, the majority of respondents have other negative habits such as hanging clothes (58%), cleaning the home page <4 times a week (70%) and nap habits (81%).

Based on the table above, it can be seen that there are 3 variables that have a relationship with the incidence of dengue in the city of Banjarbaru. These variables include the habit of getting rid of or recycling...
used goods (p-value = 0.045), the habit of cleaning the yard (p-value = 0.024), fogging programs (p-value = 0.034). While other unrelated variables include occupant density (p-value = 0.197), humidity (p-value = 0.699), resting place (p-value = 1,000), larvae existence (p-value = 1,000), landfill drainage habits (p-value = 1,000), habit of closing TPA meetings (p-value = 0.433), installing wire netting (p-value = 1,000), habit of hanging clothes (p-value = 1,000), sleeping habits using mosquito nets (p-value = 0.423), habit of using mosquito repellent (p-value = 0.098), nap habit (p-value = 0.234), larvae presence (p-value = 1,000), mosquito larvae examination (p-value = 0.436), program abasiasi (p-value = 1,000), and epidemiological investigations (p-value = 1,000).

Discussion

In handling DHF, the role of the community to suppress this case is very decisive. Therefore the program of Eradicating Mosquito Nests (PSN) by 3M Plus needs to be carried out continuously throughout the year, especially in the rainy season. The PSN program, namely: 1) Drain, is to clean the place that is often used as a water reservoir such as a bathtub, water bucket, drinking water reservoir, refrigerator water reservoir etc. 2) Close, which is to close tightly places water storage such as drums, jugs, toren water, etc.; and 3) Reuse or recycle used goods that have the potential to become mosquito breeding sites for dengue transmission. Chi Square test results with a confidence level of 95% were used to see the relationship between the habit of recycling used goods and the incidence of dengue in Banjarbaru City, South Kalimantan, the results showed that the p-value = 0.045. which means that there is a significant relationship between the habit of recycling used goods and the incidence of dengue in Banjarbaru City, South Kalimantan.

The results of statistical tests show a p-value of 0.043 where the value of p <0.05 means that there is a relationship between the habit of cleaning used goods and the incidence of dengue in the city of Banjarbaru. The results of this study are in line with the results of Kurniawan’s research (2013) which states that there is a relationship between the habit of cleaning the yard and the incidence of DFH in Gonilan Village, Kartasura District, Sukoharjo Regency (p-value = 0.034).

The Ministry of Health of the Republic of Indonesia suppresses the spread of dengue disease by creating a P2DBD program (Dengue Hemorrhagic Fever Control) with the existence of Kepmenkes No. 581 of 1992 concerning the eradication of DFH (and Kepmenkes No. 92 of 1992 concerning Amendments to the Attachment to the Minister of Health Decree No. 581 of 1992), coupled with the Decree of the Director General of Disease Management (P2) & Environmental Health (PL) No. 914 of 1992 concerning P2DBD technical instructions.

Implementation of P2DBD program optimally is basically to reduce the number of dengue cases. Activities in the P2DBD program carried out to date include Epidemiological Investigations, Fogging Focus, Larvicides, Periodic larval examinations, Eradication of Mosquito Nests (PSN), and Health Extension.

The results of the statistical test showed a p-value = 0.034 where the value of p <0.05 means that there is a fogging program with the incidence of dengue in the city of Banjarbaru. The results of this study are in line with the results of Rahayu’s research (2013) which states that there is a relationship between fogging focus and the incidence of DFH in the target area of Sambungmacan I Puskesmas Sragen Jawa Tengah in 2013 (p-value = 0.000).

Conclusion

1. There is no relationship between occupancy density and the incidence of dengue in Banjarbaru City, South Kalimantan.
2. There is no moisture relationship with the incidence of DFH in Banjarbaru City, South Kalimantan.
3. There is no relationship between breeding sites and the incidence of dengue in Banjarbaru City, South Kalimantan.
4. There is no relationship between the resort and the incidence of dengue in Banjarbaru City, South Kalimantan.
5. There is no relationship between larva’s existence
6. There is no relationship between the habit of draining landfill and the incidence of dengue in Banjarbaru City, South Kalimantan.

7. There is no relationship between the habit of closing the landfill meeting with the incidence of dengue in Banjarbaru City, South Kalimantan.

8. There is a relationship between the habit of getting rid of or recycling used goods with the incidence of DHF in Banjarbaru City, South Kalimantan.

9. There is no relationship between installing wire mesh with the incidence of DHF in Banjarbaru City, South Kalimantan.

10. There is no relationship between the habit of hanging clothes and the incidence of dengue in Banjarbaru City, South Kalimantan.

11. There is no relationship between sleep habits using mosquito nets and the incidence of DHF in Banjarbaru City, South Kalimantan.

12. There is no relationship between the habit of using mosquito repellent and the incidence of dengue in Banjarbaru City, South Kalimantan.

13. There is no relationship between the habit of napping and the incidence of dengue in Banjarbaru City, South Kalimantan.

14. There is a relationship between the habit of cleaning the yard and the incidence of dengue in Banjarbaru City, South Kalimantan.

15. In the environmental management application program related to dengue prevention programs, there are variables related to the incidence of DHF in Banjarbaru City, South Kalimantan, namely fogging program variables while unrelated variables include larva examination programs, epidemiological investigations, and abatement.

Abstract

Diarrhea was ranked second as the leading cause of death in infants. Diarrhea in Indonesia is still an endemic disease and is a potential disease outbreak accompanied by death. Health profile data in 2016 showed that there were 6,897,463 estimated cases of diarrhea in health facilities, while those handled only around 2,544,084 (36.9%). The cases of diarrhea in South Kalimantan were 107,725, while those handled were only 9,986 (9.3%). Banjar Regency is the highest regency, both cases of diarrhea with a total estimated cases of 22,422, while those treated are 9650 (43%). The influence of the CLTS method which includes open defecation, CTPS (Hand Washing with Soap) behavior, drinking and food water management, waste management and household wastewater management with the incidence of diarrhea in infants in Banjar Regency. The design of this study is analytical, with a cross sectional approach. The population in this study were all mothers who had toddlers in Banjar Regency. The sample hereinafter referred to as the respondent in this study was determined using a purposive sampling technique with a minimum sample size of 100 people. Chi-square statistical test with 95% confidence level. The results of the study of all family members have behaved well with defecation in sanitary ware that is 100% and doing a good CTPS of 100%, there is no significant effect of the influence of drinking water and food with the incidence of diarrhea in infants in Banjar Regency, there is no significant effect between waste management and the incidence of diarrhea in infants in Banjar Regency, there is no significant effect between household wastewater management and the incidence of diarrhea in infants in Banjar Regency.

Keywords: Flies density, Environmental factors, Sanitation facilities, Sanitation behavior.

Introduction

Diarrhea was ranked second as the leading cause of death in infants. Every year around 2.5 billion cases of diarrhea occur in children under the age of five, and it is estimated that the number of cases will be relatively the same over the past two decades. Diarrhea is a disease that tends to cause death in sufferers and toddlers are the most vulnerable groups affected. The highest incidence of diarrhea cases occurs in the first two years of life and will decrease with increasing age¹.

Diarrhea in Indonesia is still an endemic disease and is a potential disease outbreak accompanied by death. Health profile data in 2016 showed that there were 6,897,463 estimated cases of diarrhea in health facilities, while those handled only around 2,544,084 (36.9%). The cases of diarrhea in South Kalimantan were 107,725, while those handled were only 9,986 (9.3%). Banjar Regency is the highest regency, both cases of diarrhea with a total estimated cases of 22,422, while those treated are 9650 (43%).
Material and Method

The design of this study is analytical, with a cross-sectional approach, which aims to determine the effect of the CLTS method which includes open defecation behavior, handwashing with soap behavior, management of drinking water and food, waste management and household wastewater management with the incidence of diarrhea in toddlers in Banjar Regency. Cross-sectional design is a study to study the dynamics of correlation between risk factors and effects, by approaching, observing or collecting data at one time.

The results of the study showed that all respondents had applied good defecation behavior. This means that all family members have defecated in sanitary latrines. The results showed that all respondents had applied good CLTS behavior. This means that all family members have behaved handwashing using soap and running water. Respondents whose method of managing drinking water and food are classified as good are 99 (99%) respondents. Meanwhile, respondents with poor management of drinking water and food were only 1 (1%) of respondents. Respondents whose waste management has been classified as good at 94 (94%) respondents. Meanwhile, respondents whose waste management is still classified as poor are only 6 (6%) respondents. This is due to the fact that in the area that is the location of the research itself, there is indeed a landfill, so that people are easy when they want to dispose of garbage, moreover there are officers who carry the garbage.

Respondents who experienced diarrhea were more prevalent in respondents who had good drinking water and food influences as many as 55 (55.6%) respondents compared to respondents who had poor water and food influences as many as 1 (100%) respondents. Whereas the respondents who did not suffer from diarrhea were more prevalent in the respondents who had the influence of drinking water and good food, as many as 44 (44.4%) respondents compared to those with poor drinking water and food, as many as 0 (0.0%) respondents.

Respondents who experienced diarrhea were found more in respondents who had good waste management, as many as 51 (54.3%) respondents compared to respondents who had poor waste management, that is 5 (83.3%) respondents. Whereas the respondents who did not suffer from diarrhea were more prevalent in respondents who had good waste management, that is as many as 43 (45.7%) respondents compared to those with less good waste management, namely 1 (16.7%) respondents.

Discussion

Open defecation behavior reflects a culture of ignorance of society that can be interpreted as an attitude of no matter what, not participating in thinking about
other people’s cases. In this case the community does not care about the adverse effects of open defecation on themselves and others. Family latrines that do not meet the requirements are the cause of environmental pollution including soil pollution, water pollution, food contamination, and fly reproduction. Feces that are disposed of in the open can be used by flies which play a role in the transmission of fecal diseases, flies like to place their eggs in open human feces, then flies alight on feces and human food2

Sanitation facilities, healthy hygiene behavior (PHBS) have a close relationship with the incidence of diarrhea. The behavior of washing hands before eating, before feeding the baby and also after defecating becomes a factor in breaking the chain of transmission of diarrheal diseases. The behavior of removing stool in the place (toilet) is also very influential in preventing the transmission of diarrheal diseases3

The results of previous studies indicate that the incidence of diarrhea occurs mostly in respondents who use the poor type of TPSS as many as 45 respondents (42.5%). But based on the results of the analysis, there was no correlation between the incidence of diarrhea and the type of TPSS used. This is because although the type of TPSS is bad, the respondents are usually more often to burn dirt / garbage that is piled up or throw it into the sea so that the environment is kept clean4.

Drink and food hygiene and sanitation efforts basically include people who handle food, food storage, food processing equipment, food storage and presentation. Foods that are not managed properly and properly by food handlers can cause negative impacts such as disease and poisoning due to chemicals, microorganisms, plants or animals, and can cause allergies. The cleanliness factor of handlers or food management commonly called personal hygiene is a procedure to maintain cleanliness in the management of safe and healthy food. The cleaning procedure is clean behavior to prevent contamination of the food being handled5.

**Conclusion**

1. There is the influence of defecation behavior with the incidence of diarrhea in infants in Banjar Regency.
2. There is the influence of Hand Washing with Soap behavior on the incidence of diarrhea in infants in Banjar Regency.
3. There is no influence of water, drinking and food management with the incidence of diarrhea in children under five in Banjar Regency.
4. There is no effect of waste management on the incidence of diarrhea in children under five in Banjar Regency.
5. There is no effect of household wastewater management with the incidence of diarrhea in children under five in Banjar Regency.

Abstract

Background: Awareness and knowledge about reproductive health among children in the elementary school in Indonesia was really low. Education about reproductive health is needed to increase the knowledge of reproductive health among elementary school students. This research is conducted to analyze the impact of Training-of Trainer model in elevating the knowledge of elementary school students as peer educators for reproductive health.

Method: This research used quasi-experimental method, with pretest and posttest one group only design. The samples of this research are 30 peer educators, which were selected purposively from 3 state elementary schools in the District of Brebes, Central Java, Indonesia. The intervention that had been given was a training about reproductive health for a whole day by a Facilitator Teacher and a Peer Educator from State Junior High School 2 Brebes. The assessments had been conducted before intervention and a month after intervention.

Result: According to the difference test using Wilcoxon Match paired Test, significant differences were found in the knowledge of the participants before and after Training-of Trainer model intervention (p=0.002) and there was an of 1.26 points in the knowledge.

Conclusion: Education about reproductive health by using training-of-trainers for a whole day could significantly elevate the knowledge of peer educators related to reproductive health within a month after the training had been conducted. The roles of peer educators are crucial because as peer facilitators, they are more trusted and it makes children more comfortable in performing discussion. Trained peer educators are expected to be reliable agents in changing reproductive health behavior of elementary school students.

Keywords: Knowledge, Training-of-trainers, Reproductive health, Elementary school students.

Introduction

Maternal mortality ratio (MMR) in Indonesia still high, which reaches 229 cases out of 100,000 live birth (133-379) during 2008.¹ MMR in Brebes is the highest in Central Java, which causes by, among others, adolescent pregnancy. Marriage record in Brebes in
2015 shows that 40% of total marriage number occur in 13 to 18 year old children, which 70% of it are caused by adolescent pregnancy. Adolescent pregnancy later causes the lack of information about reproductive health among younger generation, including children in the elementary school. This causes numerous marriage that happen after they are graduated, or even before their graduation.

The needs and the types or risk in reproductive health in adolescents and younger generation have different features with children and adults. The types of risk of reproductive health are including pregnancy, abortion, sexually transmitted diseases, sexual abuse, and limited access to information and healthcare service.\textsuperscript{2,3} particularly normal birth. Method: Ovid Medline, CINAHL, Cochrane and Web of Knowledge databases were searched to identify research articles published in English from 2000 to 2012, using specified search terms in a variety of combinations. All articles included in this structured review were assessed using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA These risks later cause several related factors, such as early marriage and solicitation to perform sexual intercourse, access to education and jobs, gender inequality, sexual abuse, media exposure, and lifestyle.

Awareness and knowledge related to reproductive health among elementary school was really low. Nowadays, the efforts in providing reproductive health to elementary school students is still considered as a taboo. Education through peer educators by using training-of-trainers model is expected to be one of strategic moves to increase the knowledge about reproductive health among elementary school students. The purpose of this research is to analyze the impact of Training-of Trainer model in increasing the knowledge among elementary school students as peer educators of reproductive health.

Method

This research used quasi-experimental method, with pretest and posttest of one group design to evaluate the impact of Training-of Trainer model in order to increase the knowledge, attitude, and practices about reproductive health among elementary school students by the peer educators. The population of this research was 30 elementary students within the District of Brebes, Central Java, Indonesia, during July to December 2017. This research was specifically conducted to three state elementary schools, with an approval from the local government. After purposive random sampling screening had been conducted, 30 peer educators from three elementary schools were selected as participants. Data analysis for this research was through difference test by using Wilcoxon Match Paired Test because the data could not be normally distributed.

Findings

The total amount of peer educators was 30 participants, which majority were females (66.7%), consisted of 11 year old students (56.7%) and 5th grade students (66.7%). The latest education of the fathers’ participants were mostly Bachelor degree (63.4%), however, some were junior high school graduates (3.3%). Meanwhile, the latest education of the mothers’ participants were mostly senior high school or vocational school (40.1%), however, some were elementary school, junior high school, and associate’s degree graduates (3.3%).

Fundamentally, adolescents started facing several health risks during puberty, one of those is reproductive health. In a circumstances when reproductive health was not being maintained well, it would certainly cause various problems, such as early pregnancy disturbance, abortion, sexually transmitted diseases like HIV/AIDS, and sexual violence. The condition of adolescents’ reproductive health was also affected by nutrition, physical health, psychological, economics, and gender inequality that makes it hard for young women to avoid the exposure of sexual intercourse or commercial sexual intercourse.\textsuperscript{4–6}

World Health Organization (WHO) released a guide about adolescent pregnancy prevention and the impact of poor reproductive health management among adolescents from LMICs, which focused on four main strategies in preventing adolescent pregnancy: (1) improving the access to contraception and its usage; (2) preventing marriage below 18 year old; (3) improving knowledge and understanding about the importance of adolescent pregnancy prevention; and (4) preventing non-consensual sexual intercourse and sexual abuse.\textsuperscript{7}

Result in Table 1 showed that there were knowledge improvements after intervention that were inferred from several knowledge unawareness related to reproductive health, such as: physical transformation in males during puberty, characteristics of physical transformation, procedure in handling female students during menstruation, nocturnal emission in males, definition of nocturnal emission as a normal and natural occurrence when semen was ejected out through male’s reproductive organ. It showed that students were paying attention and able to gain more knowledge and information.

</tbody>
</table>

The result of normality test, as appeared in Table 2, obtained abnormal distribution of pretest variable (p=0.001) and abnormal distribution of posttest variable (p=0.000), therefore, Wilcoxon Test was chosen for this research. From difference test by using Wilcoxon Test, significant knowledge difference between before and after intervention was revealed (p=0.002).

Due to fulfilling the information about reproductive health, reproductive health education is urgently needed. Several educational model like role play, booklet, and fun learning were effective and showed significant results in improving knowledge and awareness about reproductive health. A study from United Nation Fund for Population Activities emphasized that the knowledge in reproductive health, physical transformation in male and female, and physical protection could still be unfulfilled, especially because of the lack of knowledge, social stigma, law and policy that obstruct the access of unmarried adolescents to contraception and abortion, and judgmental attitude from healthcare service officers.

Andrade et al. in their research stated that reproductive health and sexual education program in school focused on the relation between adult and children by conducting training and encouraging teachers to improve the connection with students. Teachers were
trained to provide advices to adolescents and their parents about reproductive and sexual health.\textsuperscript{11} A study about reproductive health counselling in elementary school students by counsellors through booklet with simple language proved that it significantly elevated students’ awareness and motivation to protect their reproductive health.\textsuperscript{12}

Reviewing the program conducted before, the keys of success in raising the awareness about reproductive health was by building training network, and conducting training and education about reproductive health. However, it needed more effort to create a continuous implementation of reproductive health education, which was by improving the availability and access to qualified reproductive healthcare services across Indonesia.\textsuperscript{13}

\textbf{Conclusion}

The result of this research shows that elementary students in Brebes Regency are lack of knowledge about reproductive health. Education on reproductive health is urgently needed in order to improve knowledge about sexuality and decision making for the future goals among elementary school students. If elementary school students have more profound comprehension about reproductive health, sexuality, and gender, the younger generation will understand the risk of involve in unsafe sex and unfulfilled needs. Sharing the responsibility among males and females will also give a better chance.

Total score of knowledge difference among participants between before and after intervention through education about reproductive health by peer educator reveals significant difference with $p=0.002$ and average improvement of 1.26 point. It implies that reproductive health education through training-of-trainers model by peer educators significantly improves knowledge of elementary school students.

Effect of Feeding Moringa Oleifera Leaves Capsule’s on The Uric Acid in Pre-Elderly

Nurhayati¹, Clara Meliyanti Kusharto², Siti Madanijah², Efrizal³

¹,³Master Student, ²Department of Community Nutrition, Bogor Agricultural University, Indonesia.

Abstract

The objective of this study is to investigate the effect of moringa leaves powder which is packed in a capsule to the uric acid level of pre-elderly and elderly. The subjects of this study were 24 pre-elderlies and elderlies which were 47 years old and older. These subjects were divided into two groups, one was given 2g of moringa leaves powder and the other was given 3g of moringa leaves powder. The experiment was conducted for 14 days. The subjects’ blood sample was taken to measure their uric acid level. The result of this study indicated that moringa leaves capsule’s intervention decreased the uric acid level as demonstrated by the measurement in Day-7 and Day-14. Therefore, this research concluded that moringa capsule intervention for 14 days had an ability to decrease uric acid level.

Keywords: Moringa Leaves Capsule, Uric Acid Level.

Introduction

Hyperuricemia (high uric acid level in blood) is the major biochemical cause of gout which is linked with several chronic diseases, such as obesity, hypertension, coronary heart disease, diabetes, and kidney injury. Hyperuricemia is caused by the activity of xanthine oxidase enzyme. This enzyme holds an important role on the purine catabolism and takes two forms, they are xanthine oxidase (XO) and xanthine dehydrogenase (XDH). XDH enzyme is converted to be XO and catalyzes hypoxanthine oxidation to be xanthine and eventually become uric acid which caused gout disease.

Uric Acid (UA) is the last metabolite of endogenous and purine metabolism that will be released from the human body through urine, feces, and sweat. Inhibiting xanthine oxidoreductase (XO) significantly repairs endothelium dysfunction independently aside from uric acid decrease. Natural polyphenol compound that is contained by several plants is able to be used as xanthine oxidase inhibitors (XOIs) to inhibit the uric acid synthesis. Potential of various natural active ingredients on the XO regulation and uric acid serum concentration was already studied in the model of gout. One of the plants which contain polyphenol compound is Moringa Oleifera.

Moringaoleifera Lam. is a species of the Moringaceae family that is well known for its varied medicinal uses and high nutritional value. Moringa had been reported as a valuable source of both macro- and micronutrients. In addition, the leaves possess phytochemicals, including glucosinolates, flavonoids, and phenolic acids. Many studies have shown that moringa leaves have various bioactivities and health benefits, including antibiotic, antitrypanosomal, hypotensive, antispasmodic, antiulcer, hypocholesterolemic, and hypoglycemic activities. Several studies indicated that the intervention of moringa leaves extract was able to decrease the uric acid level of male Wistar rat. Scientific research regarding the effect of moringa leaves powder consumption to the uric acid level was numerously done, however, they were mostly conducted to the animal as their subject, and only a few of them that was conducted by involving human as their subject. Moringa leaves capsule has already been widely consumed and circulated in the market, however, the study regarding its effectiveness to the decrease of the uric acid level has not been done for pre-elderly and elderly.
Material and Method

Research design is Quasi-experiment. This research was conducted through two steps, they were introductory research (analysis of antioxidant, total phenol and total flavonoid contained in the moringa leaves powder), and moringa leaves powder intervention. The main ingredients in this study were moringa leaves powder which was obtained from the MoringaOleifera garden, the property of the Research and Development Center of MoringaOleifera that is located in Blora, Central Java. The analysis that was conducted to moringa leaves powder was conducted to observe the activity of antioxidant, total phenol, and flavonoid. Antioxidant analysis used DPPH spectrophotometry method. Total phenol analysis used Folin-Ciocalteuaucolorimetric method. Total phenol analysis procedure was in accordance to kemenkes (2011). Total flavonoid analysis was in accordance to BPOM (2004).

The second step of the research was the intervention of moringa leaves powder capsule. The subjects were divided into three groups, one as a control group while the other two were treatment groups. Control group was given allopurinol 100 mg twice a day (morning and afternoon)14. Meanwhile, the first treatment group was given 4 capsules (equal to 2 g leaves powder) twice a day (2 capsules in the morning and 2 capsules in the evening), and the second treatment group was given 6 capsules (equal to 3g leaves powder) twice a day (2 capsules in the morning and 2 capsule in the evening). In the first meeting with the subjects, their blood sample was taken to be measured as initial data along with the questionnaire. Intervention was conducted for 14 days. Questionnaire data consisted of subject’s identity, economic and social characteristic, body weight and height measurement, food consumption, medical record, knowledge and behavior. Blood was taken in the pre, mid and post-treatment. The equipment that was used to measure uric acid level was Easy Touch® II Blood Uric Acid Test Strips.

Subject selection was conducted purposively according to predetermined criteria (posbinducikarawangmember that is 47 years old or older and is currently suffering from hyperuricemia [blood’s uric acid level ≥ 6 mg/dL and ≥ 7 mg/dL for female and male respectively], and disposes to sign the informed consent). Subject number calculation was based on the certain formula, and it has resulted in 24 subjects which were divided into two groups (control and treatment group). Data processing and analysis were done using software Microsoft Excel 2013 and software SPSS 16. Respondents’ characteristic data were descriptively analyzed. The first analysis step was to test the normality of the data using the Kolmogorov Smirnov test. Spearman correlation test would be used if the data did not pass the normality test, and Pearson correlation test for the data that passed the normality test. Paired-test was used to observe uric acid level changes before and after intervention for both treatment groups, meanwhile, the comparison between control and treatment group used ANOVA test.

Results

The Composition of Antioxidant, Total Phenol, and Total Flavonoid of Moringa Leaves

Chemical compounds’ concentration in the moringa capsules is quite varied based on the location where the plant grows, whether it is sub-tropical or tropical area1. However, researchers agreed that moringa leaves are a good source of antioxidant. Moringais already deemed as a natural antioxidant2. The result of IC50 that was obtained from the observation of moringa leaves powder was 78.54 ppm. Meanwhile, phenol level that was detected was 0.47% and flavonoid was 0.39.

The Effect of Intervention to the Subjects’ Uric Acid Level

| Table 1 | Pre, mid and post-treatment uric acid level |
|-----------------|------------------|------------------|------------------|
| Subject’s Group | Control | Treatment | ANOVA |
| Pre-treatment D-0 | Average ± SD (mg/dL) | 9.32 ± 1.77 | 6.6 ± 1.16 | 5.77 ± 0.46 | 0.352 |
| Mid-treatment D-7 | Average ± SD (mg/dL) | 9.32 ± 1.77 | 7.02 ± 0.76 | 6.1 ± 0.22 | 0.044 |
| Post-treatment D-14 | Average ± SD (mg/dL) | 10.82 ± 2.18 | 8.32 ± 1.19 | 6.33 ± 1.04 | 0.000 |
| Δ uric acid from D-0 to D-7 | Average ± SD (mg/dL) | 2.72 ± 0.97 | 1.82 ± 1.87 | 2.63 ± 1.77 | 0.001 |
| p-value Paired test | 0.064 | 0.015 |
| Δ uric acid from D-7 to D-14 | Average ± SD (mg/dL) | 1.22 ± 0.84 | 0.82 ± 1.04 | 3.42 ± 1.96 | 0.016 |
| p-value Paired test | 0.109 | 0.008 |
| Δ uric acid from D-0 to D-14 | Average ± SD (mg/dL) | 3.93 ± 1.59 | 2.73 ± 2.39 | 3.50 ± 2.27 | 0.002 |
| p-value Paired test | 0.038 | 0.013 |
Based on the measurement from D-0 to D-7, the uric acid level of all the control group (+) and treatment group significantly decreased (p<0.05). The result of the paired test between D-7 and D-14 demonstrated that there was a significant uric acid level decrease for treatment group (p<0.05), meanwhile, control group’s uric acid level were quite stable significantly (p>0.05). Overall, the paired test for the measurement results from D-0 to D-14 demonstrated that all groups experienced an uric acid level decrease (p<0.05). The difference between the uric acid level at D-0 and D-14 (∆ uric acid level) for the control group (+) and 3g treatment group were the highest of all. They were 2.72 ± 0.97 mg/dL and 2.63 ± 1.77 mg/dL respectively. Meanwhile, 2 g treatment group’s ∆ uric acid level was 1.82 ± 1.87 mg/dL.

UA level decreased in all treatments (Table 1). This result showed that there was a possibility for allopurinol and moringa leaves powder capsule to suppress the increase of UA level so that the intervention of moringa leaves powder were possibly not significant. The result of the ANOVA test in the initial measurement (H-0) showed that there was no difference of UA level between groups (p>0.05). The result of ANOVA results in the D-7 and D-14 measurement showed that there was a significant decrease of UA level (p<0.05). Based on the Duncan test, the UA level between control (allopurinol) and treatment groups in the D-7 and D-14 were significantly different. This indicated that the intervention of moringa leaves powder capsule significantly decrease UA level (p<0.05). Overall, all the groups demonstrated UA level decrease, however, a consistent UA level decrease until it reached normal level was only demonstrated by the treatment group.

**Discussion**

Allopurinol is a medicine that is generally used to inhibit xanthine oxidase activity and decrease uric acid level serum. Allopurinol inhibits oxidase by using the concentration of xanthine oxidase (SOD), GSH-Px, adenosine deaminase (MDA), and NO. Xanthine oxidase catalyzes the conversion of hypoxanthine to be xanthine and eventually become UA. Oxygen reactive species that is excessively produced by UA production leads to the excessive production of MDA and NO that will eventually increase the activation of SOD and GSH-Px. SOD catalyzes superoxide anion in the dismutation reaction, and GSH-Px helps to decrease lipid hydroperoxide and hydrogen peroxide. The increase of Reactive Oxygen Species (ROS) production decreases double unsaturated lipid to form MDA and holds a function to be a biomarker of oxidative damage and the decrease of the antioxidant level. Besides that, XO is able to catalyze inorganic nitrite to be NO by increasing the activity of nitrite reductase.

Natural polyphenol compound that is contained by several plants is able to be used as xanthine oxidase inhibitors (XOIs) to inhibit uric acid synthesis. Polyphenol compound is able to inhibit the expression and release of several inflammation-pro-mediator and a proteolytic enzyme, the different transcriptional factor activity, and in-vitro ROS production. Study on the animal with rheumatoid arthritis, osteoarthritis and gout showed that there was a decrease in tissue damage and uric acid level. Antioxidant and flavonoid in several plants which are linked to the modulation that is oxidative stress are able to be an alternative medicine for hyperuricemia since it inhibits the activation of XO.

Phenol, flavonoid, and antioxidant which have a significant double effect on the prevention of free radical activity hold a potential to be XO inhibitor which decreases uric acid as the effect of hyperuricemia. In the experiment which used rats with hyperuricemia, antioxidant and flavonoid did not only push down the high level of UA and XO but also manage the level of factors regarding oxidative stress, especially in the liver. Moringa leaves powder capsule is able to be a strong candidate for curing hyperuricemia because of its role in inhibiting XO activity which (several of them) linked to its modulation from oxidative stress.

**Conclusion**

The intervention of moringa leaves powder capsule for 7 days potentially cures hyperuricemiaby suppressing uric acid level, meanwhile, the intervention of moringa leaves powder capsule for 14 days was significantly decrease uric acid level.

Abstract

The objective of this study is to investigate the effect of moringa leaves powder which is packed in a capsule to the uric acid level of pre-elderly and elderly. The subjects of this study were 24 pre-elderlies and elderlies which were 47 years old and older. These subjects were divided into two groups, one was given 2g of moringa leaves powder and the other was given 3g of moringa leaves powder. The experiment was conducted for 14 days. The subjects’ blood sample was taken to measure their uric acid level. The result of this study indicated that moringa leaves capsule’s intervention decreased the uric acid level as demonstrated by the measurement in Day-7 and Day-14. Therefore, this research concluded that moringa capsule intervention for 14 days had an ability to decrease uric acid level.

Keywords: Moringa capsule, Moringa tea, Uric acid.

Introduction

Uric acid is the last metabolite of endogenous and purine metabolism that will be released from the human body through urine, feces, and sweat. The high intensity of uric acid in the blood (hyperuricemia) might be indicated several diseases, such as rheumatic, arthritis, cardiovascular disease, neurological disease, insulin resistance, hypertension, and kidney disease. Hyperuricemia is affected by xanthine oxidase enzyme activity. This enzyme plays an important role in purine catabolism and it has two form, they are xanthine oxidase (XO) and xanthine dehydrogenase (XDH). XDH enzyme is converted to be XO and catalyzes hypoxanthine oxidation to be xanthine and eventually become uric acid which is a major trigger forgout disease. XO was significantly and independently repair endothelial dysfunction of uric acid decrease1.

Natural polyphenol compound that is contained by several plants is able to be used as xanthine oxidase inhibitors (XOIs) to inhibit the synthesis of uric acid2,3. One of the plants which containing polyphenol compounds is Moringa Oleifera. Moringaoleifera Lam. isaspeciesof the Moringaceae family that is well known for its varied medicinal uses and high nutritional value. Moringa Oleifera(kelor in Indonesian) is deemed to have an ability in curing various diseases due to its content, they are secondary metabolites such as tannin, saponin, alkaloid, flavonoid, phenol, and glycoside4,5. This study reported that there was a decrease in the wistar rats’ uric acid levels when moringa tea with quersetin 10 mg/kg was given to the rats for 14 day6,7. Scientific studies regarding moringa product consumption mostly use animals as their subject, and there were still limited numbers that observe human.

Material and Method

This study was used quasi-experimental design. This study was conducted in two steps. First, initial study (antioxidant analysis) and main study (moringa leaves product intervention). The main materials that was used in this study were moringa leaves powder and tea which were obtained from Moringaoleifera Garden (The property of PusatPenelitiandanPengembanganMoringaoleifera–Moringa Oleifera Research and Development Center in Blora, Central Java). The antioxidant analysis used DPPH and spectrophotometry. Subject’s inclusion criteria in this study were: 1) The member of PosbinduCikarawang which are 47 years old or older, 2)
hyperuricemia, 3) Physically independent, indicated by being able to walk 20 steps without any help, 4) Willing to participate and sign the informed consent. Subject’s exclusion criteria in this study were: 1) Currently participating in the other study, 2) Routinely consumes antioxidant supplement and/or phytopharmaca, 4) Routinely consumes drugs which decrease uric acid level. These subjects were divided into two groups. First, the group that was given 1 package of moringa tea (equal to 1.5g moringa tea). Second, the group that was given 2 moringa capsules (equal to ± 0.5g moringa leaves powder). Both products contain antioxidant activity (IC50-DPPH) for approximately 139.93 ppm every day for 14 days. Uric acid level measurement used Easy Touch® II Blood Uric Acid Test Strips as its tool. Data processing and analysis were done using Microsoft excel 2013 and SPSS 16 program. To identify the difference between uric acid level before treatment and after treatment, this study used paired-test. Meanwhile, to compare control groups in the study, ANOVA test was used.

Results

Antioxidant activity

Moringa leaves capsule contains chemical compounds which are quite various. Moringa leaves tend to have different content of chemical compounds which is depended on the origin area of the leaves (whether it is sub-tropical or tropical area)\(^1\). Moringa is deemed to be natural antioxidant\(^2\). This study’s result demonstrated that antioxidant IC50-DPPH on both forms of moringa product was 139.93 ppm.

*significant p<0.05; p1) Paired-samples T test; p2) Anova

During the period of treatment, blood sampling was undergone once in seven days. In the initial measurement (day-0), subject’s uric acid level was 10.32 mg/dL. Uric acid levels test result demonstrated that 18 subjects were categorized hyperuricemia. Based on the result of paired-test, during Day-0 to Day-7 treatment, all groups that were given moringa capsule, moringa tea, and the control group experienced a significant uric acid level decrease (p<0.05). Paired test result of Day-7 to Day-14 demonstrated that treatment groups for both moringa capsule and moringa tea experienced a significant uric acid level decrease (p<0.05), meanwhile, control group’s uric acid level remains stable (p>0.05). Paired-test result of Day-0 to Day-14 indicated that all groups (a group that was given moringa capsule, a group that was given moringa tea, and control group) experienced a significant uric acid level decrease (p<0.05). The uric acid level difference (table 10) between day-0 and day-7 measurement (∆ uric acid level) of the control group and moringa tea group was the highest, while moringa capsule group experienced slower decrease. Uric acid level decreased for all treatment groups. This result demonstrated that there was a possibility of allopurinol, moringa capsule, and moringa tea to be able to inhibit uric acid level increase. ANOVA test result in the initial measurement (day-0) indicated that there was
no significant uric acid level difference between groups (p>0.05). ANOVA test result between groups of Day-7 to Day-14 indicated a significant decrease (p<0.05). Based on the advanced test(Duncan test), uric acid level of the control group (allopurinol), morgina capsule and morgina tea of day-7 to day14 was significantly different. This result indicated that the consumption of morgina capsule and morgina tea (p< 0.05) significantly decrease uric acid level compared to the control group. Overall, all groups demonstrated uric acid level decrease, however, the consistent uric acid level decrease was only demonstrated by the group which was given morgina tea.

Discussions

Hyperuricemia is the major biochemical cause of gout which is linked with several chronic diseases, such as obesity, hypertension, coronary heart disease, diabetes, and kidney injury. Studies regarding hyperuricemia pathogenesis inhibitor effectiveness and medicinal treatment tend to be linked with several focuses, they are: a) Hyperuricemia pathogenesis depends on the enzyme in the purin metabolism and kidney transporter uric acid; b) xanthine oxidase, c) transport protein regarding uric acid metabolism in the kidney, several of them contribute to the uric acid reabsorption, such as URAT1, ABCG2 and GLUT9, several of them are protein secretion, such as OAT1 and UAT. Natural polyphenol compound contained by several kinds of plants is able to be used as xanthine oxidase inhibitors (XOIs) to inhibit uric acid synthesis. Polyphenol compound is able to inhibit expression and extrication of several inflammations and proteolytic enzyme, different transcriptional factor activity, and reactive oxygen species production by in vitro. Studies on the animal models’ rheumatoid arthritis, osteoarthritis, and uric acid demonstrated a decrease in tissue damage and uric acid level. Antioxidant and flavonoid in plants that are partially linked with oxidative stress modulation were able to be an alternative medicinal treatment for hyperuricemia disease since it inhibits the activation of xanthine oxidase.

Phenol, flavonoid, and antioxidant had a significant double effect on the antidote of free radicals and is potentially act as an inhibitor of xanthine oxidase to lessen the effect of hyperuricemia. In the experiment of wistar rats with hyperuricemia, antioxidant and flavonoid did not only press the high uric acid level and xanthine oxidase level but also managed the factor level which linked with oxidative stress, especially in the liver. Moringa capsule and morgina tea are able to be a candidate of medicinal treatment for hyperuricemia because it inhibits xanthine oxidase activation, which is partially linked with its modulation of oxidative stress. Allopurinolis a drug that is mainly used to decrease xanthine oxidase and uric acid level serum. Moringa capsule and morgina tea which is consumed every day for 14 days consecutively have a potential to inhibit XOD in the hyperuricemia medicinal treatment. As much as 1.5 g morgina powder capsule 3 g morgina tea contains the equal amount of antioxidant which is 139.93 ppm. This is supported by the study of in vivo and in vitro experiment on the wistar rats, indicated that morgina leaves decreased wistar rat’s uric acid serum, inhibited liver’s XOD and adjusted it with mRNA transcription in the transporter of kidney’s uric acid URAT1, GLUT9, OAT, UAT and ABCG2 to be normal in the transcription level. In the liver’s purin metabolism, xanthine and hypoxanthine is oxidized into uric acid by XOD. The experiment of morgina tea consumption for wistar rats, the effect was demonstrated by significantly inhibiting XOD activity. Liver’s enzyme activity (XOD and ADA) and kidney’s mRNA expression of genes (GLUT9 and URAT1) was analyzed to further identify the mechanism that leads to hypouricemic effect. Xanthine and hypoxanthine are oxidized to be uric acid by XOD which is happened in the liver. This fact indicated that morgina tea’s hypouricemic effect is based on the inhibition of XOD activity. The increase of ADA activity leads to the increase of xanthine and hypoxanthine in the body and causes cytotoxicity. Besides that, the decrease of activity which is able to increase anti-inflammation effect in the body. Tea is able to prevent ADA hepatic activity until the certain limit for the hyperuricemic rats. Two kinds of tea in the certain dose is not only able to decrease the forming of xanthine and hypoxanthine, inhibit ADA activity, and eventually decrease uric acid level in the body, but also help to increase body’s anti-inflammation ability.

Conclusion

The consumption of morgina capsule and morgina tea for seven days consecutively has a potential effect on the medicinal treatment of hyperuricemia by decreasing uric acid level. Meanwhile, the consumption of morgina capsule and morgina tea for fourteen days consecutively has a potential to significantly decrease uric acid level.

Abstract

Introduction: Child developmental disorder during the first 1000 days of life should be a serious concern because it will have an impact on children's development in the future. Distance birth, exclusive breastfeeding and parenting could affect the child's development during the first 1000 days of life.

Method: This research is an observational analytic research with a case control approach. The study was conducted in Klaten, Karanganyar and Sragen district in February-June 2017. Subject retrieval using multi-stage random sampling. The variables in this study are within the child, exclusive breastfeeding, parenting and toddler development. The research data obtained through interviews using a questionnaire and analyzed using chi-square analysis.

Results: Child spacing <2 years (Heading) (OR:1.71; p <0.001; CI (95%) = 1.07 to 2.74), exclusive breastfeeding (OR: 4.81; p <0.001; CI (95%) = 2.87 to 8.06) and parenting (OR: 6.36; p <0.001; CI (95%) = 3.79 to 10.69) significantly associated with children development in the First 1000 Days of Life.

Conclusion: Child spacing less than 2 years (heading) can interfere with the process of child development. Exclusive breastfeeding and good parenting can make the child development process be better according to the age.

Keywords: Child spacing, Exclusive breastfeeding, Parenting, Child development, First 1000 Days of Life.

Introduction

Period of the first 1000 days of life (HPK) beginning from the phase of pregnancy up to 2 year old child is a crucial period determinants of health and intelligence of the human resources in the future. Growth and very rapid development occurred during the first 1000 days of life. The health problems that occur in the period of 1000 HPK will not only affect the physical growth, but also on mental development and intelligence, which is visible from the physical size that is not normal and the quality of work that is not competitive which results in lower economic productivity.

Developments is a continuous process. Health Departments of Republic Indonesia certify the quality of child’s development requires serious attention.
says about 250 million children under five years are at risk of development that are not optimal. The incidence of developmental disorders that occurred in Indonesia as much as 18%. Disruption that often occurs in children such as delays in motoric, language, behavior, autism, and hyperactivity. The high incidence of developmental delay is caused by the lack of parents’ knowledge about the importance of the first 1000 days of life. Child development during 1000 HPK can be affected by several factors such as child spacing, exclusive breastfeeding and parenting.

Pregnancy spacing can affect fetus health. Too close pregnancy spacing can cause serious complications in pregnancy or childbirth. Birth spacing <2 years may increase the risk of low birth weight and fetal death when born. Baby with LBW will have an impact on children’s growth, productivity and intellectual in a future. Ma’ruf et al also explains that the birth spacing <2 years can cause premature birth which affects the development disorder.

Breastfeeding is one of the factors that can affect children health and development. Children aged 0-6 months are breastfed exclusively have better health, optimal growth and development also improve children intelligence. The research of Fitri et al, also states that children exclusively breastfed experienced age-appropriate developmental 5.474 times greater than children who are not exclusively breastfed.

Parenting is the attitude of parents to interact with their children. Parenting system by parents determine the development of children. Candrasari explains that the pattern of positive parenting can help the development of children be better. Based on the description above, it is necessary to do an analysis of birth spacing, exclusive breastfeeding and parenting with development at the first 1000 days of life.

**Materials and Method**

This study was an observational analytical with case-control approach. The subject was 390 mothers of toddlers ages 2 to 2.5 years that live in Klaten, Sragen and Karanganyar. This study was conducted in February 2018 to June 2018. This study was using cluster random sampling, where all members of a population has an equal opportunity to be a subject of research. The sampling techniques used are Multi Stage Random Sampling. Birth spacing, exclusive breastfeeding, parenting and child development data were obtained through interviews using questionnaire. Data analysis was done with the Appropriate measuring scale test bivariate analysis with variables and objective analysis of the chi-square test and alpha 0.05, the next Obtained results narration and clarified with the display of the graph and table.

Table 2 presents the bivariate analysis of the relationship between child spacing and the development, obtain chi-square value is calculated by Odds Ratio (OR) of 1.71 and p <0.001; CI (95%) = 1.07 to 2.74. Based on these results can be interpreted that the mothers of child spacing of ≥ 2 years children have the possibility of 1.71 times to have a child with appropriate development than the child spacing <2 years (Heading). This shows that there is a significant relationship between the child spacing and the development.

The bivariate analysis of the relationship between exclusive breastfeeding and development, obtained chi-square value is calculated by Odds Ratio (OR) of 4.81 and p <0.001; CI (95%) = 2.87 to 8.06. Based on these results can be interpreted that children exclusively breastfed had 4.81 times the possibility to have an appropriate development compared with exclusive breastfeeding. This shows that there is a significant relationship between exclusive breastfeeding and development.

The bivariate analysis of the relationship between parenting and development, obtained chi-square value is calculated by Odds Ratio (OR) of 6.36 and p <0.001; CI (95%) = 3.79 to 10.69. Based on these results can be interpreted that children with good parenting have the possibility of 6.36 times to have appropriate development than children with less parenting. This shows that there is a significant relationship between parenting and development.

Discussion

Distance relationship of children with toddlers developmental

National Family Planning Coordinating Board (BKKBN) states that a good pregnancy spacing is between 2 to 3 years. Hardinsyah and Supariasa states that pregnancy spacing of less than 2 years (Heading) can cause babies born with LBW that can eventually interfere with growth and development of children.9

The results showed that most respondents (60%) birth spacing> 2 years. Child spacing significantly associated with toddler (p = <0.001). With the existence of birth spacing, it lowers the risk of malnutrition because mothers are relatively healthy and have enough time to take care for the children, it is likely the child will live in an environment that is rich in stimulation can be optimally growth physically, mentally and psychologists.16

Additionally mothers of children with a child spacing less than 2 years (Heading) have the possibility for breastfeeding and giving attention to the children
who were born before, so that weak maternal conditions will impact on the health of the fetus in the uterus and can cause babies have developmental disorders.\textsuperscript{17,18}

**Exclusive breastfeeding relationship with the toddlers developmental**

Exclusive breastfeeding is breastfeeding without additional other fluids either formula, water, juice, or other supplementary foods until the age of 6 months old baby. Before reaching the age of 6 months, baby’s digestive system is not able to function perfectly, so he has not been able to digest food other than breast milk.\textsuperscript{17}

The results showed that most respondents (77.2\%) gives exclusive breastfeeding. Exclusive breastfeeding significantly associated with the development of toddler (p = <0.001). Children who are exclusively breastfed will be healthier, improve gross motor development to the children and children can avoid obesity.\textsuperscript{19} Data obtained from the Demographic and Health Survey in 2012, stated that the children growth disorder in Indonesia because it does not obey to exclusive breastfeeding in infancy.\textsuperscript{20}

This is according to research conducted by Ali &Dhaded that children who are given exclusively breastfed have better development than children who are not breastfed exclusively, especially in gross motor skills sectors.\textsuperscript{21}

**Correlation between parenting and toddler developmental**

Parenting is the interaction between children and parents in educating, guide and discipline as well as protecting the child reaches maturity with the norms that exist in society.\textsuperscript{22} Application of parents’ parenting is very important because a mother is the first environment and the early forming interpersonal relationships with children.\textsuperscript{23} Child development is influenced by internal and external factors.\textsuperscript{24} Parenting system and the child’s environment are one of the external factors that influence the development of toddler.\textsuperscript{25}

The results showed that most of respondents (61.0\%) have a good parenting. Parenting related to toddler development significantly (p = <=0.001). Good parenting will also impact on children’s development.\textsuperscript{24} Parenting is influenced by several factor such as; culture, education, socioeconomic status and age.\textsuperscript{14}

**Conclusion**

Birth spacing (Heading), exclusive breastfeeding and parenting shown to be associated with the development of children in the first 1000 days of life. Child spacing with less than 2 years is known to interfere the child development process. While exclusive breastfeeding and good parenting can support children’s development better. Education about exclusive breastfeeding and good parenting to the mother can be done as an attempt to improve child’s development in the period of first 1000 days of life.

Abstract

This study investigated user-furniture (chairs and tables) compatibility among computer users in Ibadan, Nigeria. Participants were 95 male and 105 female computer users. Participants’ anthropometric variables and their workstation furniture were measured using a broad blade anthropometer and a metallic tape respectively. Male participants had significantly higher (p < 0.05) popliteal height, knee height, buttock-popliteal length and eye height than the females. User-furniture mismatches in sitting elbow height/table top height (male: 100%, female: 100%), popliteal height/seat height (male: 68.75%, female: 86.54%), buttock-popliteal length/seat length (male: 53.13%, female: 50%) and knee height/table bottom height (male: 9.38%, female: 5.77%) relationships were observed among the participants. Popliteal height/seat height mismatch was significantly associated (p=0.002) with gender. Computer users’ workstation furniture may be designed with adjustable heights using different percentiles of users’ anthropometric dimensions to minimize the incidence of work-related musculoskeletal disorders among computer users.

Keywords: Mismatch, Workstation, Body dimension, Computer users, Ibadan, Nigeria.

Introduction

The modern day office and business worlds rely extensively on the usage of computers and this makes computer workstations common globally¹. A working environment that confines the user to awkward postures due to poorly designed furniture over a prolonged time may result in psychophysiological stress²,³. When workstations are not well designed, workers often use the furniture not in the manner for which it is designed or adapt the workstation potentially resulting in a mismatch. Ergonomic considerations are imperative to reduce health-related deleterious consequences such as work-related musculoskeletal disorders (WRMSDs)⁴.

A crucial stress-generating factor for workers is a mismatch between the demands placed on them and the control they have over the physical environment.
A mismatch between the anthropometric characteristics of computer users and the computer workstation design will likely result in WRMSDs especially those associated with poor posture. The occurrence of WRMSDs is linked with physical workplace factors that include prolonged static muscle load and poorly designed work stations. Variations in body size from one person to another is large. Consequently, the body dimensions should match with the furniture in a particular workstation. Any mismatch can lead to industrial hazards and low productivity. To have workstation furniture that fits the majority of the workforce, measurement of relevant population-based anthropometric dimensions is recommended for optimal dynamic sitting using validated guidelines. Ergonomics recommendations for design of workstations seem not strictly adhered to in low-to-middle income countries like Nigeria and studies on workstation-user compatibility among computer users also appear limited. Adedoyin et al. reported high prevalence of low back pain and other musculoskeletal disorders among a cohort of computer users in six Nigerian universities. Assessment of workstations and musculoskeletal pain among computer users in a similar Nigerian environment documented by Johnson et al. did not assess users’ anthropometrics. Therefore, this study was designed to explore the compatibility between furniture dimensions and anthropometric variables of computer users in Ibadan, Nigeria.

**Material and Method**

Two hundred desktop computer users (male = 95, female = 105) from private, public and commercial establishments in Ibadan, Nigeria participated in this cross-sectional survey. The study was conducted in compliance with Helsinki Declaration. Participants gave their informed consent once the procedure was explained to them. Permission was also obtained from the managers of all establishments involved.

**Procedure**

Participants were seated normally with clothes, while the anthropometric data (sitting elbow height, popliteal height, knee height, thigh depth, buttock-popliteal length and eye height) were measured using an anthropometer (locally designed and calibrated by the Instruments Department, University College Hospital, Ibadan, Nigeria) and following the procedures described by Bridger and Parcells et al.

The chairs and tables dimensions (seat height, seat length, seat width, backrest top height, backrest bottom height, table top height and table bottom height) were also measured as described by Chaffin et al. and Parcells et al. using a retractable metallic tape measure (Master Class Tools, South Africa). Measurements were taken over the participants’ normal clothing to the nearest centimeters using the procedure described by Lavender et al. Participants’ clothing were reasonably light considering the prevailing temperature in Nigeria.

**Data Analysis**

The data were analysed using SPSS 25.0 version software (SPSS Inc., Chicago, Illinois, USA). The mean and standard deviation of the anthropometric variables and the furniture dimensions were calculated. Independent t-test was used to compare male and female anthropometric variables and furniture dimensions.

User-furniture mismatches were determined as follows:

- **Sitting elbow height/table top mismatch** - table top higher than sitting elbow height.
- **Popliteal height/seat height mismatch** - seat height below 88% or above 95% of popliteal height.
- **Buttock-popliteal length/seat depth mismatch** – seat depth below 80% or above 95% of buttock-popliteal length.
- **Knee height/table bottom height mismatch** – table bottom height higher than knee height by more than 2 cm.

Frequency tables were used to summarise mismatches and compatibility. Chi-square test was used to test the association of user-furniture compatibility and mismatches with sex.

**Findings**

Anthropometric dimensions of male and female participants are compared in Table 1. Males had significantly higher popliteal height (p < 0.001), knee height (p < 0.001), buttock-popliteal length (p = 0.013) and eye height (p < 0.001) than their female counterparts.

*denotes significant difference at p < 0.05

Table 2 displays the comparison of the dimensions of the furniture used by male and female participants. The dimensions of the furniture used by male and female participants most of the measures were comparable. Women had significantly higher seat height (p < 0.001) and lower back rest bottom height (p < 0.001) than men while men’s backrest width are significantly wider (p = 0.033) than women’s.

Summaries of selected furniture dimensions (seat height, seat length, seat width, backrest top height, backrest bottom height, table top height, table bottom height) are highlighted and displayed in Table 3.

Table 4 shows that all participants had sitting elbow height/table top height mismatch (male: 100%, female: 100%). User-furniture mismatches were also observed in popliteal height/seat height (male: 68.75%, female: 86.54%), buttock-popliteal length/seat length (male: 53.13%, female: 50%) and knee height/table bottom height (male: 9.38%, female: 5.77%) relationships.

Discussion

The importance of adjustable workstations is highlighted by the sex related differences. This was an expected finding, as men are anatomically known to be different from women in terms of their height, thigh length and hip width. All computer users (100%) were working with tables that were too high for their sitting elbow height. It is therefore necessary for working arm to be raised to compensate for this and that the shoulder be raised or abducted stressing the deeper posterior neck musculature to provide stabilization for the neck. The mean table top height in this study was about 51.5 cm higher than participants’ sitting elbow height (75.04 vs 23.50 cm) which is contrary to the recommendation that they should be at the same level.

One hundred and fifty-six participants (78%) with 90 of them being females had a popliteal height/seat height mismatch. The majority of sitting surfaces were too high meaning that the underside of the thigh would become compressed causing discomfort. Previous research has shown that users usually compensate for this by moving their buttocks forward on the chair.

Approximately half (52%) had a mismatch in their buttock-popliteal length/seat depth relationship with the seats too deep resulting in the front edge of the seat pressing on the area just behind the knee cutting off blood circulation to the legs and feet. Users compensate for this by sliding forwards which then results in poor lumbar and upper backrest support with the likelihood of a slumped, kyphotic posture.

For knee height/table bottom height relationship, only a few workers (7.5%) had a mismatch with the thigh and knee lower than the corresponding table bottom height. As a result, there was enough room for the table clearance while the patella and the uppermost part of the thigh are accommodated conveniently without any stress.

Customarily, Nigerian workers in public and private offices work for 40 hours per week (8 hours daily for 5 days) while those in commercial establishments work for 54 hours per week (9 hours per day for 6 days). It is therefore logical to assume that spending these number of hours using mismatched workstation will predispose the workers to varying degrees of WRMSDs. Increased prevalence of WRMDs among computer users is linked to poor workstation design and incorrect working postures. Hence, the need for good workstation design. Ergonomic intervention is reportedly capable of achieving significant reduction in the prevalence of musculoskeletal symptoms and consequent increase in productivity. Bridger recommended that ergonomically designed workplaces must be flexible enough in order to avoid postural fixity, causing static loading of the musculoskeletal system. This implies that workers can carry out their tasks, most times, in more than one working posture in a well-designed workstation without undue stress. The postures an individual adopts at work should involve minimal energy expenditure, stress and strain and is expected to be conducive for maximum efficiency of the worker.

Conclusion/Recommendation

There was little compatibility between computer users’ body dimensions and their workstation highlighting the need for adjustable workstations. In view of unaffordability of this, it is recommended that workstations furniture be designed to allow adjustability and at low costs to fit the majority. If employers are to continue procuring traditionally designed furniture, employers are encouraged to at least buy as much variety in furniture sizes possibly using the 5th, 25th, 75th and 95th percentiles of the population’s anthropometrics. This could possibly accommodate the variety of users’ sizes. This would go a long way in minimizing/reducing the incidence of work-related musculoskeletal disorders.
and consequently increase productivity among computer users.

Future studies may improve on sample size and probably include more detail such as Rapid Office Strain Assessment which would provide more ergonomic information regarding computer use.

Abstract

Tuberculosis (TB) is a disease caused by bacteria called Mycobacterium tuberculosis. It usually spreads through the air & attacks low immune bodies. Recently, several techniques are applied to diagnosis the TB diseases. Unfortunately, diagnosing TB is still a major challenge. In recent years, a variety of techniques have been developed. In this paper, texture feature set is obtained using three different categories like statistical, structural and gray level dependent features. After that, the feature selection scheme is carried out and TB classification is done using GANN classifier. In GA-NN, genetic algorithm and neural network are combined to do the classification process. Once the abnormal TB is classified via GA-NN classifier, the TB region is identified via morphological operator. Experimental results demonstrate that the proposed method outperforms than the existing method.

Keywords: Tuberculosis, GA-NN, Kernel FCM.

Background

Less than half of all TB cases worldwide are ever diagnosed, and fewer than 60% of those diagnosed are cured and TB is projected to remain one of the world’s top 10 causes of adult mortality by the year 2020¹. Tuberculosis (TB) is the second leading cause of death from a contagious disease worldwide, after HIV. With about one-third of the world’s population containing latent TB, and an estimated nine million novel cases happening every year, TB is a main global health problem². TB is a contagious disease caused by the bacillus Mycobacterium tuberculosis, which naturally affects the lungs. It stretches through the air when people with vigorous TB cough, sneeze, or else expel infectious bacteria. TB is most common in sub-Saharan Africa and Southeast Asia, where extensive poverty and malnutrition decrease resistance to the disease. In addition, opportunistic infections in immune-compromised HIV/AIDS patients have worsened the problem³. The subsequent method are employed to analyse TB: thorax radiography⁴; biological culture⁵; ⁶; the Mantoux (tuberculin sensitivity/skin) test⁷; interferon-γ tests⁸; amplified nucleic acids-based tests⁹ (which allow lab-on-chip platforms⁹,¹⁰); and sputum smear microscopy¹¹⁰,¹¹. Of these tests the two most normally employed to make sure whether a subject is infectious are biological culture and sputum smear microscopy¹². To fragment the TB region, kinds of literature have been proposed in the latest years. In ¹³,¹⁴, the author offered a segmentation and classification method for TB bacteria identification. Besides, Feature extraction and selection are imperative steps in TB detection and classification. The best feature set should have efficient and discriminating characteristics; while mostly diminish the redundancy of features space to avoid the “curse of dimensionality” problem¹⁵. Frequent features comprise mean, variance, skewness, kurtosis, energy, and entropy¹⁶.

The test of TB bacteria all this time is prepared physically, so that is necessary a long time enough and coached laboratory staff. As a result of this research is a developed system which can identify TB bacteria by employed microscope imaging. Quite a lot of researchers in the world have prepared very much research about the examination of TB diagnosis by employing image processing technique¹⁷. Artificial Neural Network
(ANN) is one of the most employed medical data classification method to remove patterns in an intelligent and dependable way and has been very much employed to find models that explain data relationship\textsuperscript{18,19}. On the other hand, neural networks are recognized to generate highly precise results in practical applications. Moreover, Neural networks have been effectively used to medical data classification, diagnosis aides, biomedical study and drug development\textsuperscript{20}.

**Proposed TB Diagnosis System**

After HIV/AIDS Tuberculosis is the second top infectious killer. Tuberculosis, as well called TB, is a contagious disease caused by Mycobacterium tuberculosis. The fast advance in computer capabilities, image processing algorithms and artificial intelligence techniques had supported the research and improvement of computer-aided tuberculosis diagnosis system. The system plans to help medical technologist and develop the precision of clinical diagnosis. In this article, a TB diagnosis system is suggested mixture of Rough-Set Theory Based Feature Selection and CBGA-NN Classifier. The suggested method contains three significant phases, (1) Feature extraction, (2) feature selection (3) TB classification and (4) Region identification. The simple block diagram of proposed approach is presented in figure 1.

**Results and Discussion**

The proposed TB diagnosis process discussed in the previous section is implemented. The proposed technique for TB diagnosis is implemented in MATLAB. This section presents the results obtained from the experimentation and its detailed discussion about the results. The proposed approach of TB diagnosis is experimented with the CT images and the result is compared with accuracy, sensitivity and specificity curve. Simulation experiments were carried out with medical CT image dataset, which is publically available dataset. size of 512×512 Test images are used in the proposed method of TB diagnosis.

**Classification using KFCM classifier**

The fundamental plan of this section is to decrease the dimension of the features by means of kernel fuzzy c-means (KFCM ) clustering in order to improve the classification. KFCM minimized the following objective function
cluster centers and membership functions are obtained and specified by:

\[ c_j = \frac{\sum_{j=1}^{n} u_j K_H(x_i, c_j) x_i}{\sum_{j=1}^{n} u_j K_H(x_i, c_j)} \]

\[ u_{ij} = \frac{(1 - K_H(x_i, c_j))^{-1/m - 1}}{\sum_{k=1}^{c} (1 - K_H(x_i, c_j))^{-1/m - 1}} \]

Where,

\[ K_H(x_j, c_i) = K_1(x_j, c_i) + K_2(x_j, c_i) \]

\[ K_1(x_j, c_i) \rightarrow \text{Linear kernel} \]

\[ K_2(x_j, c_i) \rightarrow \text{Quadratic kernel} \]

\[ \phi_{\text{comb}} \rightarrow \text{defined as a combination of multiple kernels} \]

\[ N \rightarrow \text{the d-dimension center of the cluster} \]

\[ N \rightarrow \text{is the measured data,} \]

\[ m \rightarrow \text{is the any real number greater than 1,} \]

**Classification using GANN classifier**

Genetic algorithm begins with solution encoding process, which symbolizes set of weights (input and output layer). A solution is stated as a \( SL_k \) dimensions vector and each dimension (position) symbolized as a weight. A solution \( SL_k \) points out the weight allocation information (for neural network structure). \( k \) is from 1 to \( z \), which indicates the number of solutions in the population. A solution \( SL_k \) contains \( w[i] \) and \( w[j] \), which point out the information of input and output weight allocation. The length of the solution is similar as the number of weights allocated in the NN structure. The search ends when the maximum number of iterations is attained.

**Performance matrices:**

\[ \text{Sensitivity} = \frac{\text{Number of true positives}}{\text{Number of true positives} + \text{Number of false negatives}} \times 100 \]

\[ \text{Specificity} = \frac{\text{Number of true negatives}}{\text{Number of true negatives} + \text{Number of false positives}} \times 100 \]

**Conclusions**

In this paper, we developed a Tuberculosis (TB) diagnosis system combining GA-NN and KFCM.
Initially, texture feature set is obtained using three different categories like statistical, structural and gray level dependent features. Feature selection was applied to improve the classification performance. The classification was done by two important phases, like training and testing phase. Extensive experimental results have clearly demonstrated the proposed TB diagnosis system can achieve the state-of-the-art performances on standard TB dataset.

Abstract

Smoking behavior mostly occur in adolescence which is characterized by increased frequency and intensity of smoking. Smoking can cause various diseases and deaths. There are internal factors and external factors that influence smoking behavior. The study aims to determine the influence of adults, peers, advertisements, and curiosity motive and the psychological impact on adolescents in Tinggede Village, Sigi Regency. This study uses a mix method research type. The sample size and informants involved were 46 respondents and 6 informants. Quantitative research data were analyzed univariat using the chi-square test. The results showed there was a relationship between the influence of parents (\(\rho = 0.039\)), peers (\(\rho = 0.039\)) and curiosity motive (\(\rho = 0.018\)) with adolescent smoking behavior and there was no relationship between advertisement and adolescent smoking behavior (\(\rho = 0.238\)). As well as the perceived psychological impact of informants feeling more confident, feeling calm and feeling fine. The conclusion of this study is that there is a relationship between the influence of adults and peers, and motive of curiosity with adolescent smoking behavior and there is no relationship between advertisement and the smoking behavior and psychological impact on adolescents in Tinggede Village, Marawola District, Sigi Regency. It is recommended for adolescents to be able to be selective in facing the influence of adults, peers and positive or negative advertisements in everyday life.

Keywords: Smoking, Adolescent, Impact, Psychological.

Introduction

The increasing prevalence of smoking causes the problem of smoking to become increasingly serious. According to the WHO\textsuperscript{(1)}, the number of world smokers reached 1.35 billion people. About 1 billion men in the world are smokers, 35% of them are from developed countries and 50% from developing countries. On the average of 435,000 residents in the United States have died from diseases related to smoking habits each year (1 of 5 deaths).

Based on 2008 Global Youth Tobacco Survey (GYTS) data, 30.1% of the population of Southeast Asia are smokers. In Indonesia, 57,563,866 adult residents are smokers, making it the fifth highest cigarette consumer country in the world\textsuperscript{1}.

According to WHO\textsuperscript{1}, it can be concluded that Indonesia ranks third after China and India in the ten largest smokers in the world. The number of smokers
in Indonesia reaches 65 million. Meanwhile, China has 390 million smokers and India 144 million smokers. Tobacco kills more than 5 million people every year, and in 2020, it is projected to reach 10 million people.

The data from the Health Promotion Technical Implementation Unit of the Central Sulawesi Provincial Health Office, it is known that there are 172 (57.14%) households that smoke in Palu City from the 301 monitored households. In 2012, 63.34% of them smoked. Then, it increased in 2013 as many as 57.14% of them smoked\(^2\).

Smoking is a health problem because it can cause various diseases and even death. Smoking is a major factor in cardiovascular disease and hypertension. Cigarettes contain hundreds of chemical components that are toxic and oxidative. Smoking habits allow toxic substances in cigarettes to accumulate in the blood, one of which is nicotine\(^3\).

Based on the results of Basic Health Research in 2010, most smokers started smoking when they were children or adolescents. Adolescence is a period of transition from childhood to adulthood, and at this age, teenagers or adolescents do a lot of smoking behavior. Smoking behavior in adolescents continues in accordance with the stages of development that will increase which is marked by increasing frequency and intensity of smoking\(^4\). Smoking habits in adolescents are influenced by several factors such as adults, peers, personality, and information media that display cigarette advertisements\(^5\).

**Method**

The type of research used was quantitative research with a cross sectional study approach, conducted in September 2015. The research was conducted in Tingggede Village, Marawola District, Sigi Regency. The population of the study was 83 adolescents and there were 46 respondents taken as samples with Simple Random Sampling technique.

**Data Collection**

The research data used are primary data and secondary data. The primary data were obtained from the results of observations and interviews with adolescent smokers. The process of data collection is done by using a questionnaire to describe the variables studied. While the secondary data was obtained from the Office of the Village Head of Tingggede, Marawola District, Sigi Regency, in the form of data on the number of teenagers. The variables in this study consist of dependent variables and independent variables. The dependent variable is smoking behavior in adolescents. While the independent variables include the influence of adults, peers, the influence of advertisements, and the motives of curiosity. After data collection was done, the data was processed and analyzed. Then, the results of the analysis were presented in the form of a frequency distribution table that explains everything related to this research.

**Results**

**The Factor of Smoking Behavior**

Table 1 showed that smoking teenagers who imitate adult smokers are as many as 16 people or 34.8% while those who do not imitate adult smokers are as many as 30 people or 65.2%. Chi Square test results obtained a value of \(\rho < 0.05\) or \(X^2\) calculate value \((4,261) > X^2\) table \((3,841)\) so that Ho in this study was rejected, meaning that there is a relationship between the effect of imitating adults and adolescent smoking behavior. This table 1 showed that adolescents who smoke because they imitate their peers are as many as 16 people or 34.8%, while adolescents who do not imitate their peers are 30 people or 65.2%. Chi Square test results obtained a value of \(\rho < 0.05\) or \(X^2\) calculate value \((4,261) > X^2\) table \((3,841)\) so that Ho in this study was rejected, meaning that there is a relationship between the effect of imitating peers and adolescent smoking behavior.

Table 1 shows that there are 19 adolescents or 41.3% who smoke because of the effect of advertisements, while adolescents who smoke not because advertisements are as many as 58.7%. Chi Square test results obtained a value of \(\rho < 0.05\) or \(X^2\) calculate value \((1,391) > X^2\) table \((3,841)\) so that Ho in this study was accepted, meaning that there is no relationship between the effect of imitating advertising and adolescent smoking behavior. Table 1 shows that adolescents who smoke because of the motive of curiosity are as many as 15 people or 32.6%, while adolescents who smoke not because of the motive of curiosity are as many as 31 people or 67.4%. Chi Square test results obtained a value of \(\rho < 0.05\) or \(X^2\) calculate \((0,018) > X^2\) table \((3,841)\) so that Ho in this study was rejected, meaning that there is a relationship between the effect of curiosity and adolescent smoking behavior.

Discussion

The Relationship of the Effect of Imitating Adults and Adolescent Smoking Behavior

Adults are examples and models for teenagers, but for adults who do not concern the importance of health, they have indirectly taught unhealthy behavior or lifestyle. One reason that makes many adolescents smoke is their parents’ poor parenting style, for example, the behavior of parents who smoke and the behavior emulated by their children from generation to generation. The results of the analysis show that the value of ρ = 0.039 which means that there is a relationship between imitating adults and adolescent smoking behavior. This can happen because the permissive parenting of parents usually provides very loose supervision. It provides opportunities for children to do things without sufficient supervision. Parents tend not to reprimand or warn their children when they are in danger and very little guidance is given by them. If parents provide good parenting, it is possible for children to follow good behavior from their parents. However, if parents have bad habits or behaviors such as father or mother who also have smoking habits, children will follow the example of their parents' behavior. This study is in accordance with research, based on the results of the chi-square test, the value of ρ = 0.013 was obtained. It means that there is a relationship between the influence of peers and the smoking behavior of adolescents in Slongohimo Wonogiri 1 Public Middle School, because ρ < of α or 0.013 < 0.05. Peers can be interpreted as groups of people who have the same background, age, education and social status, and they can usually influence the behavior and beliefs of each member. In addition to the same age level, peers also have the same level of maturity.

The Relationships between the Influence of Imitating Advertisements and the Adolescent Smoking Behavior

Advertising is a medium to convey information to public about a product and it has a function to persuade public about cigarette products. The results of the analysis show that the value of ρ = 0.238 which means that there is a relationship between the action of imitating advertisements and smoking behavior of parents become exemplary figures as smokers. Their children will naturally have a greater chance to imitate and become smokers like them. Parents who smoke will influence their teenagers to smoke more than parents who don’t smoke. Adolescents whose both parents and older siblings smoke will be four times more likely to be smokers compared to them whose parents do not smoke.
adolescents. This is because cigarette advertising does not stop influencing teenagers to consume cigarettes. Teenagers cannot avoid the invasion of thousands of advertisements in electronic media and printed media. Mass or electronic media that often display a picture that smokers are the symbol of manliness, triggered teenagers to imitate or follow the behaviors which are performed by the models in the advertisement. This research is similar to Ariani’s research (14). Based on the results of the research’ data analysis using chi-square, the value of $\rho = 0.311$ was obtained. This means that there is no relationship between advertising and smoking behavior of Semarang State Senior School 4 students, because $\rho < \alpha$ or $0.311 < 0.05$. It also explains that risk factors for the emergence of smoking behavior in adolescents are influenced by several factors, one of which is environmental factors.

The Relationship between the Effect of Curiosity Motive and Adolescent Smoking Behavior

The curiosity motive is a strong desire that emerges from the adolescents to try a new thing that they have not known its positive and negative effects. The results of the analysis show that the value of $\rho = 0.018$ which means that there is a relationship between the motive of curiosity and the smoking behavior of teenagers. There are several psychological reasons that cause a person to smoke. It is for the sake of relaxation and to reduce anxiety or tension. In most smokers, the psychological bond with cigarettes is due to the need to deal with oneself easily and effectively. Cigarettes are needed as a balance tool. This is the reason that makes teens dare to try smoking. The desire to know and being predictive of the influence of drugs including smoking tend to be the reason for a smoker. Being curious is teenagers’ nature. They always want to know everything that they still do not know and its negative effects. This research is similar to Ariani’s research. Based on the results of data analysis using chi-square, the value of $\rho = 0.000$ was obtained. This means that there is a relationship between the motive to try smoking and smoking behavior in students of Tangerang City Junior High School 3, because $\rho < \alpha$ or $0.000 < 0.05$. The authors declare no potential conflict of interest in this research.

Conclusion

The conclusion of this study is that there is no significant relationship between the factors imitating the models in an advertisement and smoking behavior in adolescents. However, there are three factors that have a significant relationship to smoking behavior in adolescents in Tinggede Village, namely the factor of imitating adults, imitating peers and motive of curiosity. Adolescents are expected to be able to increase their knowledge and be able to filter the negative and positive influence of adults, peers and advertisements so that they can be selective and careful in choosing a social environment. There should be parents’ attention and control towards the behavior of their children who have started smoking from an early age.

Abstract

Background: The study aim was to knowing the impact of stress on the conversion of prediabetes to type 2 diabetes mellitus in adults.

Method: This study used a prospective cohort design. The data used are secondary data from the Cohort Study of Risk Factors for Non-Communicable Diseases in Bogor, Indonesia. Data collection in this study was carried out since 2011 until 2015 with a total population of 5890. Based on the exclusion and inclusion criteria, the total of study participants were 1059.

Results: During 5 years of follow-up, among prediabetic adults there were 169 subjects categorized as T2DM and 219 subjects categorized as stressed. Bivariate analysis shows that stress and age at baseline is a risk factor on the conversion of prediabetes to T2DM (p < 0.05). Final model on multivariate analysis, shows the hazard ratio of stress was 1.815 (95% CI: 1.307 - 2.520) with p < 0.05.

Conclusion: This findings, expected to be used as information and motivation in an effort to make prevention and control of T2DM. Especially in individuals with prediabetes who suffer from stress because it has an impact with conversion of prediabetes to T2DM.

Keywords: Type 2 diabetes mellitus, Prediabetes, Stress, Prospective study.

Introduction

Diabetes mellitus has become a global epidemic with 220 million worldwide prevalence in 2004 and it is estimated that by 2030 it will increase to 366 million and will be ranked 7th as the cause of death (¹). In adults, based on data from WHO states that 422 million people were diagnosed with type 2 diabetes mellitus in 2014. This number is increasing compared with year 1980, from 4.7% to 8.5% in the adult population (²). The initial stage of the emergence of type 2 diabetes mellitus is an increase in blood glucose levels in the body that exceeds the normal limit but still not enough to meet the criteria for type 2 diabetes mellitus or what is called prediabetes or known as intermediate hyperglycemia (⁴–⁷).

According to the CDC, individuals with prediabetes can increase their risk of developing type 2 diabetes mellitus, heart disease and stroke (⁸). Research from De-Vegh, et al (2011) states that within a period of 2-7 years, around 30-70% of people with prediabetes will develop type 2 diabetes mellitus (⁹). Prediabetes is a serious problem that must be treated immediately, because in addition to being able to increasing risk but on the other hand according to ADA can prevent and inhibit the occurrence of type 2 diabetes mellitus (¹⁰).

Risk factors of type 2 diabetes mellitus according to WHO, ADA, and Ministry of Health of Indonesia (³,⁷,¹⁰) consist of risk factors that cannot be modified and modifiable risk factors. As one of the modifiable risk factors, several studies have been carried out, and there is any association between stress and type 2
diabetes mellitus. In general, stress is vulnerable to adulthood. According to Pearlin and Skaff (1996) stressors that are often encountered in adulthood are problems in marriage, divorce, job changes, and problems that arise due to children. Based on these descriptions, we were interested in knowing the impact of stress on the conversion of prediabetes to type 2 diabetes mellitus in adults in Bogor, Indonesia.

Materials and Method

This study used a prospective cohort design. The data used are secondary data from the Cohort Study of Risk Factors for Non-Communicable Diseases in Bogor, Indonesia. Data is not publicly, the use of data for research must be with permission from the Health Research and Development, Ministry of Health of Indonesia. Data collection in this study was carried out since 2011 until 2015 with a total population of 5890 adults. The focus of this study is on adults, so that the inclusion criteria used are individuals aged 25-65 years and have complete blood glucose examination data. The exclusion criteria were diagnosed with type 2 diabetes mellitus before the study and had blood glucose levels that met the criteria for type 2 diabetes mellitus at the baseline.

At the baseline, there were 5209 adults with complete blood glucose measurements. Then, we excluded samples that had blood glucose levels that met the diagnostic criteria for type 2 diabetes mellitus (n = 433) and samples that had normal blood glucose level (n = 3717). The focus of this study is adults with prediabetes. Diagnostic criteria for prediabetes are if fasting glucose levels <126 mg / dL and 2 hours plasma glucose on OGTT are in the range 140-199 mg / dL are categorized as Impaired Glucose Tolerance (IGT) and or if fasting blood glucose levels are in the range ≥ 110 <126 mg / dL and 2 hours plasma glucose on OGTT are in the range 75 <140 mg / dL was categorized as Impaired Fasting Glucose (IFG). Based on the exclusion criteria, with only by taking individuals diagnosed with prediabetes, the total of study participants were 1059.

The study was conducted through interview method, laboratory measurements and examinations on individuals selected as samples. The instruments used in data collection in surveillance activities are questionnaires and the Step Approach Method from WHO. The dependent variable in this study was type 2 diabetes mellitus, while the independent variable was stress. The covariate variables in this study were age, sex, educational level, economic status, marital status, family history of diabetes mellitus, and physical activity. Measurements on stress and physical activity in this study used the SRQ (Self Reporting Questionnaire) and IPAQ (International Physical Activity Questionnaire). Blood glucose levels were only measured in observations in the 3rd and 5th year. Censored if loss to follow up and blood glucose measurements are not diagnosed with type 2 diabetes mellitus. Data analysis performed was Cox Proportional Hazards.

Results

Descriptive statistics

Table 1 shows that during 5 years of follow-up, there were censored subjects (n = 890) consist of loss to follow-up in 320 subjects and non T2DM in 570 subjects. Categorized as event (T2DM) in 169 subjects. Stress was the main independent variable in a total of 1059 subjects, there were 219 stressed subjects with 52 subjects categorized as T2DM or 23.7% of stressed subjects were T2DM. Sex as covariates showed that the majority of the subjects in the study were 781 women with T2DM patients at the end of the observation period were 136 subjects (17.4%) while in men from the total number, only 33 subjects (11.9 %) had T2DM. A total of 606 subjects were ≥ 45 years old and as many as 20% had T2DM at the end of the observation period, 29% loss to follow up, and 51% were categorized non-T2DM subjects.

There were 181 subjects with a family history of diabetes mellitus with 18.8% had T2DM and 49.7% subjects who were not categorized as T2DM. Whereas in 878 subjects who did not have a family history of diabetes mellitus, 15.4% had T2DM and 54.7% were not categorized as T2DM. In economic status, there were 923 subjects with low economic status and 16.1% had T2DM while in 136 subjects with middle/high economic status there were 14% had T2DM. Based on educational level, there were 634 subjects belonging to the low educational level and 16.1% had T2DM whereas in the high educational level there were 15.8% had T2DM. The subjects in this study were more married subjects with a total of 904 subjects, 15.6% had T2DM whereas in single subjects as many as 18.1% had T2DM. In the physical activity it was found that the majority of subjects had sufficient physical activity and as many as 15.5% had T2DM whereas in subjects who lacked of

Bivariate and multivariate analysis

Table 1 showed that 7 of the 8 independent variables have an influence on the conversion of prediabetes to T2DM. Stress variables, sex, age, physical activity, family history of DM, economic status, and marital status have HR values > 1 although only stress variables and age have p-value < 0.05. Stress in bivariate analysis has the value of HR 1.917 (1.382 - 2.659). In addition, age significantly affected the conversion of prediabetes to type 2 diabetes mellitus. Age had an HR value of 1.931 (1.382 – 2.697). In the multivariate analysis, it was found that sex and age is a confounder between stress and conversion of prediabetes to T2DM. The final model showed that stress has an impact on the conversion of prediabetes to type 2 diabetes mellitus with a value of HR 1.815 (1.307 - 2.520) with p-value < 0.05. It can be concluded that prediabetic individuals who suffer from stress have a 1.8 times greater risk of becoming T2DM compared to individuals who do not suffer from stress.

Discussion

The total subjects in this study were 5890 and 1059 subjects (18%) had criteria for prediabetes. From 1059 subjects as the study participants, during the 5-year follow-up 16% were diagnosed with T2DM. This result is higher than the prevalence of T2DM in Indonesia in 2018 (10.9%) (17). The main results in this study were the effect of stress on the conversion of prediabetes to T2DM. The incidence of T2DM in subjects who had stress was 23.7% with HR 1.815 (1.307 - 2.520) in multivariate analysis after controlling confounder. This result is relatively high and the hazards ratio indicate a strong association of stress on the conversion of prediabetes to T2DM. A narrow range of confidence intervals indicates there is no chance variation on the results of the analysis.

The results in line with the study from Arroyo, et al. in 2004 which produced an RR value of 1.22 for the association between depression and type 2 diabetes mellitus with a 4-year cohort study (18). In addition, there are other studies conducted by Everson, et al. in 2004 which produced RR values of 1.46 for associations between depression and type 2 diabetes mellitus with a 3-year cohort study (19). The study we conducted can strengthen the results of other studies regarding the effect of stress on the occurrence of T2DM, especially in Indonesia. Stress is the beginning of depression which is estimated to be number 2 on the main cause of burden of disease in Indonesia in 2020. There is a lot of evidence that diabetes and depression are related. Depressed
adults have a 37% increased risk of developing type 2 diabetes mellitus \(^{20}\). Stressors that are the beginning of the onset of stress in adults are usually economic problems, marriage, and problems that occur when having children \(^{16}\).

The covariates in this study are sex, age, physical activity, family history of DM, economic status, educational level, and marital status. Based on sex, women had an incidence of T2DM of 17.4% with HR 1.590 (1.082 - 2.334) which indicated that women were more at risk of becoming T2DM in line with previous studies \(^{2,21}\). The same thing applies to the age variable where subjects aged \(\geq 45\) years old had an incidence of T2DM of 20% with HR 2.007 (1.432 – 2.814) indicating that individuals of older age would be at risk of becoming T2DM accordance with the theory and previous studies \(^{22}\).

Sex and age is a confounder so it must include in the final model to get the pure effect of stress on the conversion of prediabetes to T2DM. Confounder is a bias in research that we can control its influence. In addition, researchers also cannot control the quality of data and do not know the conditions in the field when retrieving data so that the possibility of other biases that occur do not we known.

**Conclusion**

The incidence of T2DM in subjects who had stress was 23.7% with HR 1.815 (1.307 - 2.520) in multivariate analysis after controlling confounder. This result is relatively high and the hazards ratio indicate a strong association of stress on the conversion of prediabetes to T2DM. The final results of the study are expected to be used as information and motivation in effort to prevent and control type 2 diabetes mellitus, especially in individuals with stress and have been diagnosed with prediabetes.

**Limitations**

This study is a secondary data analysis, not all covariate variables were examined.

Study of Effect of zinc in the diarrhea of breast feeding babies, (aged between 6 months to 2 years) of North Karnataka population

Preeti Amarkhed¹, Sachin Hatti*,² Roopa Bellad³

¹Assistant Professor, Department of Paediatrics, KBNIMS, Gulbarga-585101.
²Senior Resident, Department of Paediatrics, KBNIMS, Gulbarga-585101.
³Professor, Department of Paediatrics, JNMC, Belgaum.

Abstract

Background: Malnutrition especially during the early few years of life predisposes to micronutrient deficiencies such as iron and zinc.¹ Children in developing countries are frequently affected by diarrhea, which causes excess fecal loss of zinc. In such settings, zinc supplementation has been shown to reduce the rates of diarrhea and enhance the physical growth.²

Aims and Objectives: To study the effect of zinc supplementation on the incidence of diarrhea among healthy breast fed babies of age group 6months to 2 years.

Materials and Method: The present study was a randomized controlled trial from May 2016 to September 2017 with both control and interventional group having 100 patients. A total of three follow ups (6, 9 and 12 months) were performed during the study period and the anthropometric measurements and data regarding morbidity with respect to number of episodes of diarrhea were recorded and results analyzed.

Results: A total of 200 babies were enrolled in the study. First and second follow up visits were done in 186 and 172 babies respectively. 168 babies completed all the three follow-up visits of which, 53.6% (90) and 46.3% (78) belonged to the interventional and control groups respectively. The overall incidence of acute diarrheal illness in the interventional group was less (42.2% Vs 62.8%) when compared with the control group and a statistically significant difference in the incidence between the two groups was observed at six to nine months only (p = 0.007).

Conclusion: Zinc supplementation significantly reduces the morbidity associated with diarrhea in breast fed babies.

Keywords: Diarrhea, Zinc, Infants, North Karnataka.

Introduction

The World Health Organization (WHO) estimates that malnutrition is associated with over 55% childhood deaths in developing countries including India.¹ According to National Family and Health Survey (NFHS) 3 data, 43% of malnutrition is found in infants between 6 to 11 months which could be due to inadequate breast feeding and inappropriate complementary food. Malnutrition especially during the early few years of life predisposes to micronutrient deficiencies such as iron and zinc.¹ Approximately 30% to 50% of children in developing countries have low serum and plasma levels of zinc, again putting them at high risk for malnutrition and associated illness.²

Corresponding Author:
Dr. Sachin Hatti
Senior Resident, Department of Paediatrics, KBNIMS, Gulbarga-585101
e-mail: ******
Cereal based weaning food is often recommended as the first complementary food is an important source of dietary iron but is very low in zinc. Therefore zinc supplementation may be important to meet the older infants zinc requirements particularly in less protected environments with the high infectious burden and limited dietary options. Children in developing countries are frequently affected by diarrhea, which causes excess fecal loss of zinc. In such settings, zinc supplementation has been shown to reduce the rates of diarrhea and enhance the physical growth.

**Methodology**

This study, randomized double blind placebo controlled trial was conducted during the period of April-2007 to August-2008 in the department of Pediatrics, KLES Dr. PrabhakarKore Hospital and Medical Research Centre, Belgaum. Exclusively breast fed (EBF) healthy term babies of five months of age with birth weight ≥ 2.5 kgs visiting the under five clinic of Pediatric Out Patient Department (OPD) were enrolled. The sample size was 200 (100 each group). The participants were randomized into the interventional and the control group using computer generated randomization list. Preterm and IUGR babies, babies with metabolic disorders, congenital malformations (Cleft lip palate, congenital heart disease), severe or protracted illness requiring hospitalization for more than one week in the past and top fed babies were excluded.

**Method of collection of data**

An informed consent of the participants fulfilling the above criteria was taken before enrolling in the study. The study was approved by the Ethical and Research Committee of J. N. M. C, Belgaum. The participants were enrolled in the study at five months of age. The period of enrollment was from April-2007 to Jan-2008. At enrollment, after assigning an identity digit number to the mother-infant pair, the data regarding the demographic profile and breast feeding practices were collected and entered in a pre-designed semi structured questionnaire. Mothers were counseled regarding the importance and benefits of EBF and about complementary feeding practices.

The study intervention was initiated at six months of age after recording the baseline anthropometry (weight, length and head circumference). The infants in the interventional group received zinc supplement (zinc gluconate) in the form of an oral syrup in the dose of 10 mg/day (2.5 ml once daily) and the control group received 2.5 ml/day of placebo. The placebo was sugar syrup prepared from a reputed pharmaceutical company which was similar to the zinc supplement with respect to appearance, color and taste. Mothers were instructed to administer the drug dose by the measuring cup every day morning one hour before feeding. To know the compliance of the drug, mothers were provided with a calendar to mark each day that the drug was administered. These calendars were reviewed during the monthly visits and the number of days that the drug doses were missed was recorded. Mothers were also asked to return the bottles each month so that any unused portion could be measured. The intervention was continued up to twelve months in both the groups. Mothers were also asked to record on the calendar provided, the date when a new complementary food was introduced and to keep a detailed every day diet record of the amounts (using standard household measures) of non breast-milk foods and fluids consumed.

A total of three follow ups (at six, nine and 12 months) were performed during the study period. The anthropometric measurements and data regarding morbidity with respect to number of episodes of diarrhea were recorded. Infants were also assessed for compliance of the drug in terms of any adverse effects, number of missed doses and the reason for the same was noted done. Any co-incidental administration of other supplements (multivitamins, iron, and calcium) by physicians was also noted during these visits. Throughout the study, mothers were asked to record on the calendar any symptoms of infant illness; using standardized guidelines for the description of symptoms. Mothers were asked to record on the calendar any symptoms of infant illness; using standardized guidelines for the description of symptoms and also diagnosis made by other physicians. Data of number of episodes of diarrhea was used for analysis in both the groups.

**Statistical Analysis**

The effect of zinc on the incidence diarrhea was studied. The incidence of diarrhea in the two groups was compared with Chi square test. ‘p’ value of less than 0.05 was considered statistically significant. Results are presented as means (± S.D.) unless otherwise indicated.
Definitions used in the study: Diarrhea: Passage of three or more loose or watery stools during a 24 hour period for at least two days where there is change in consistency of stools. An episode of diarrhea was defined as at least one day of diarrhea, with the final day of the episode being the last day meeting the diarrhea definition followed by at least 48 hours without diarrhea.5

Results
The present study was conducted from April-2007 to August-2008 during, total of 200 babies were enrolled in the study. First and second follow up visits were done in 186 and 172 babies respectively. 168 babies completed all the three follow-up visits of which, 53.6% (90) and 46.3% (78) belonged to the interventional and control groups respectively. The general demographic data was well matched between the groups. Of the 200 babies enrolled, 49.5% (99) were males and 50.5% (101) were females. In the interventional group, males and females were 50% each and 49% were males and 51.0% females in the control group. Mean birth weight of the babies was similar in both the groups (2.82 ± 0.26 Vs 2.83 ± 0.27). Among the total 168 babies who completed all the three follow up visits, at 12 months majority (93.3% Vs 91.0%) were completely immunized in both the interventional and control groups. At nine months (94.4% Vs 97.8%) continued breast feeding, were as only 83.3% were breast feeding at 12 months in both the groups. Duration of breast feeding was also well matched between the two groups. Therefore the baseline characteristics of the study population were similar and well matched between the two groups. In both the interventional and control groups supplement was consumed for complete 180 days (77.8% Vs 89.7%), and less than 180 days (22.2% Vs 10.3%) with no statistically significant difference between the groups. There was a high level of adherence to the supplementation protocol, with mean number of days being similar between the groups (178.51 ± 9.65 Vs 176.0 ±17.22).

The overall incidence of acute diarrheal illness in the interventional group was less (42.2% Vs 62.8%) when compared with the control group and a statistically significant difference in the incidence between the two groups was observed at six to nine months only (p = 0.007).

Discussion
Inadequate breast feeding and inappropriate complementary food are the important causes (up to 43%) of malnutrition in infants which predisposes to micronutrient deficiencies especially iron and zinc.1 Zinc deficiency is associated with growth retardation and increased rates of diarrhea and pneumonia in children. Current recommendations for zinc intake during infancy are based on the assumption that breastfed babies usually meet their zinc requirement during the first six months of life6 and zinc status is likely to become marginal beyond this age.7 The studies in developed countries have observed a variable effect of zinc supplementation on incidence of diarrhea and majority of these trials have been conducted in infants more than one year old or on formula feeds.8 Therefore, the present study was conducted to know the effect of zinc supplementation on incidence of diarrhea on healthy breast fed infants.

The socio demographic characteristics in our study were well matched between the two groups and is similar to another study.8 The mean birth weight of the babies was 2.8 kgs in the study, which is well within the standard birth weight for Indian babies.

Zinc deficiency, a prevalent condition of young children in developing countries, is associated with decreased immunocompetence5 and increased rates of serious infectious diseases5 also evident from the recent randomized controlled trials of zinc supplementation in

poor children in developing countries. These trials have demonstrated that zinc supplementation can substantially reduce the incidence of diarrhea. Most trials reported to date have varied with regard to the magnitude of the effect demonstrated and the presence of a differential effect by sex, age, nutritional status, or baseline plasma zinc concentration.  

A stronger reduction in morbidity after zinc supplementation has been observed at 9 to 12 months and above, possibly because of the higher incidence of diseases in older age groups, were exposure to antigens is usually higher and the protective effect of maternal antibodies is waning. Hence, our study was planned to know the effect of zinc supplementation on morbidity during this period of life. In our study the Interventional group had a lower incidence of diarrhea.

On the contrary, another study reported no effect of zinc supplementation on diarrheal infections. The possible reasons for this lack of effect were, the preventive effect of zinc on diarrheal disease was shown to be more pronounced in children aged more than 12 months than in younger ones and a high proportion of infants were still being breastfed, together with high accessibility to safe water and family factors such as the relatively high educational level of the mothers, might have added a protective effect. No effect of zinc supplementation on diarrhea was also observed in Indian children 6 to 11 months of age, in contrast to strong beneficial effects observed among older ones. The different prevalence’s of zinc deficiency caused by varying rates of prematurity, IUGR, exclusive breast feeding and early morbidity may explain the varying responses to zinc supplementation in very young infants.

### Summary and conclusion

A total of 200 babies were enrolled in the study. First and second follow up visits were done in 186 and 172 babies respectively. 168 babies completed all the three follow-up visits of which, 53.6% (90) and 46.3% (78) belonged to the interventional and control groups respectively. The overall incidence of acute diarrheal illness in the interventional group was less (42.2% Vs 62.8%) when compared with the control group and a statistically significant difference in the incidence between the two groups was observed at six to nine months only (p = 0.007) From the present study it is evident zinc supplementation did have a positive effect on reduction of diarrheal episodes in exclusively breast infants suggesting that most of the infants in developing countries like ours are zinc deficient and would certainly benefit from zinc supplementation especially during complementary feeding.

Abstract

Background: Malnutrition especially during the early few years of life predisposes to micronutrient deficiencies such as iron and zinc. Approximately 30% to 50% of children in developing countries are at high risk for malnutrition and associated illness and have low serum and plasma levels of zinc.

Aims of the Study: To study the effect of zinc supplementation on serum zinc levels among healthy breast fed babies aged between 6 months to 12 months.

Materials and Method: The present study was a randomized controlled trial from May 2016 to September 2017 with both control and interventional group having 100 patients. A total of three follow ups (6, 9 and 12 months) were performed during the study period and mean serum zinc levels were measured.

Results: A total of 200 babies were enrolled in the study. First and second follow up visits were done in 186 and 172 babies respectively. 168 babies completed all the three follow-up visits of which, 53.6% (90) and 46.3% (78) belonged to the interventional and control groups respectively. The mean serum Zn level of the interventional group was higher 198.9 ± 47.19 compared to the controls 133.90 ± 68.65 highly significant statistically with an effect size was 65.025 (CI 95%, 21.38 to 108.66, p = 0.005).

Conclusion: The mean serum zinc levels are significantly higher in children with who were given zinc supplement.

Keywords: Serum zinc, Breast feeding, Malnutrition, North Karnataka.

Introduction

Malnutrition especially during the early few years of life predisposes to micronutrient deficiencies such as iron and zinc. Approximately 30% to 50% of children in developing countries are at high risk for malnutrition and associated illness and have low serum and plasma levels of zinc. Zinc requirements of breast fed infants are generally met with exclusive breast feeding (EBF) until five to six months of age, due to the favorable bioavailability of the zinc in human milk. Hence, zinc status in exclusively breast fed infants is likely to become marginal beyond six months of age.

Cereal based weaning food is often recommended as the first complementary food is very low in zinc. Therefore zinc supplementation may be important to meet the older infants zinc requirements. Children in developing countries are frequently affected by diarrhea, which causes excess fecal loss of zinc. Nearly one third of child deaths could be prevented by a combination of exclusive breast feeding for six months, optimal complementary feeding practices and zinc and vitamin supplementation. Various studies have been conducted on zinc supplementation in preterm, low birth weight infants but there are very few studies in on
zinc supplementation in healthy term infants during the period of introduction of complementary feeding. Hence the present study was conducted to evaluate the effect of zinc supplementation on serum zinc levels in healthy term breast fed infants.

**Aim of the Study**

To study the effect of zinc supplementation on serum zinc levels among healthy breast fed babies aged between 6 months to 12 months.

**Methodology**

This study was conducted in the Department of Pediatrics, KBN teaching and general hospital, Gulbarga during the period of May-2016 to September-2017. It was a randomized double blind placebo controlled trial. Exclusively breast fed (EBF) healthy term babies of five months of age with birth weight ≥ 2.5 kgs visiting the underfive clinic of Pediatric Out Patient Department (OPD) were enrolled. Sample size was 200 (100 each group). The participants were randomized into the interventional and the control group using computer generated randomization list. Preterm babies and IUGR babies, babies with metabolic or neurodegenerative diseases, congenital malformations, severe or protracted illness requiring hospitalization, top fed babies were excluded.

**Method of collection of data**

The study was approved by the ethical committee. An informed consent was taken. The participants were enrolled in the study at five months of age. The period of enrollment was from May-2016 to Feb-2017. At enrollment, an identity digit number to the mother-infant pair was assigned.

The study intervention was initiated at six months of age. The infants in the interventional group received zinc supplement in the form of an oral syrup in the dose of 10 mg/day (2.5ml once daily) and the control group received 2.5 ml/day of placebo. The placebo was sugar syrup prepared from a reputed pharmaceutical company which was similar to the zinc supplement with respect to appearance, color and taste. Mothers were instructed to administer the drug dose by the measuring cup every day morning one hour before feeding. To know the compliance of the drug, mothers were provided with a calendar to mark each day that the drug was administered. These calendars were reviewed during the monthly visits and the number of days that the drug doses were missed was recorded. Mothers were also asked to return the bottles each month so that any unused portion could be measured. The intervention was continued up to twelve months in both the groups. A total of three follow ups (6, 9 and 12 months) were performed during the study period. During each follow up visits, mothers were reinforced to continue breast feeding and advised regarding complementary feeding. Infant also assessed for compliance of the drug in terms of any adverse effects, number of missed doses and the reason for the same was noted. Any co- incidental administration of other supplements (multivitamins, iron, and calcium) by physicians was also noted during these visits. Throughout the study, mothers were asked to record on the calendar any symptoms of infant illness; using standardized guidelines for the description of symptoms.

**Serum Zinc level estimation**

Non fasting venous blood was drawn with use of plastic syringes. Blood samples were taken only when infants were free of symptoms of any illness for more than 10 days before the procedure at 12 months of age. To minimize the influence of diurnal and post prandial variation on plasma zinc, all of the samples were collected in the morning (09:00 AM and 11:00 AM), approximately two hours after a feeding. Serum was separated and aliquots were stored in mineral free, plastic vials at -20°C centigrade until processed. The materials and procedures were checked to rule out possible zinc contamination before sampling started. Serum zinc concentrations were estimated.

**Statistical Analysis**

Serum zinc outcomes were converted to effect sizes, which were calculated as the difference between the means of the zinc and control groups divided by their pooled standard deviation (S.D.). Effect sizes of 0.2 are considered of small magnitude, effect sizes of 0.5 are considered moderately large, and those of 0.8 are considered large.68

‘p’ value of less than 0.05 was considered statistically significant. Results are presented as means (± S.D.) unless otherwise indicated.

**Results**

The present study was conducted from May 2016 to September 2017 during which a total of 200 babies were
enrolled in the study. First and second follow up visits were done in 186 and 172 babies respectively. 168 babies completed all the three follow-up visits of which, 53.6% (90) and 46.3% (78) belonged to the interventional and control groups respectively. The general demographic data was well matched between the groups.

Consumption of the supplement

In both the interventional and control groups supplement was consumed for complete 180 days (77.8% Vs 89.7%), and less than 180 days (22.2% Vs 10.3%) with no statistically significant difference between the groups. There was a high level of adherence to the supplementation protocol, with mean number of days being similar between the groups (178.51 ± 9.65 Vs 176.0 ± 17.22). Vomiting (regurgitation excluded), within 15 minutes of ingestion of the supplement was the commonest side effect observed in both groups but more in the Zinc group.

Other supplements

Majority (76.6% Vs 61.5%) in both the groups received no supplements other than the study intervention. Among those who received other supplements, multivitamins was the commonest in both the groups (12.64% Vs 21.79%), followed by iron (4.59% Vs 3.84%), and calcium (6.89% Vs 12.82%). No significant difference was observed between the groups with respect to consumption of other supplements.

Serum Zinc Levels in the Two Groups

The serum zinc estimation was done in a convenient, random sample of 30 of which 20 belonged to interventional and 10 to the control group. The mean serum Zn level of the interventional group was higher 198.9 ± 47.19 compared to the controls 133.90 ± 68.65 highly significant statistically with an effect size was 65.025 (CI 95%, 21.38 to 108.66, p = 0.005).

Discussion

Zinc supplementation and serum zinc levels

Serum zinc concentration was significantly higher at the end of the study in infants who received zinc supplementation, with a highly significant effect size of 65.025 were the compliance was also good, indicating that the zinc supplementation was successful in improving the zinc status of these infants. Similar observations were noted in other studies with varied effect sizes. The increase in mean plasma zinc concentrations were significantly more in the interventional group compared to placebo in another study (27.3 Vs 6.1 µg). However, in the present study the mean increase in serum zinc concentrations from enrollment could not be assessed because of lack of baseline serum zinc levels.

Serum zinc concentrations are generally maintained within the normal range with small or moderate reductions in zinc intake. Moreover, factors unrelated to the level of zinc nutrition, (recent meals, time of day, infection, tissue catabolism) can also affect serum zinc concentrations. Thus, the serum zinc concentration may not always be a reliable indicator of an individual’s true zinc status. Although the population’s mean serum zinc concentration has been proposed as a useful indicator of the zinc status of groups of individuals, little information is available on the ability of this indicator to predict the population’s functional responses to zinc supplementation.

Moreover, information is needed to assess the responsiveness of the mean serum zinc concentration to zinc supplementation to determine whether this measure could be used as an indicator of successful delivery and absorption of supplemental zinc in public health intervention programs. Given the current limitations of zinc status determination with plasma or other biologic samples, it would be helpful to have simple assessment method that could be used to decide which populations would benefit from interventions to improve zinc nutriture.

Summary and conclusion

A total of 200 babies were enrolled in the study. First and second follow up visits were done in 186 and 172 babies respectively. A total of 168 babies completed all the three follow-up visits of which, 53.6% (90) and 46.3% (78) belonged to the interventional and control groups respectively. The mean serum Zn level of the interventional group was higher 198.9 ± 47.19 compared to the controls 133.90 ± 68.65 highly significant statistically with an effect size was 65.025 (CI 95%, 21.38 to 108.66, p = 0.005). The mean serum zinc levels are significantly higher in children with who were given zinc supplement.

Abstract

Background: Malnutrition especially during the early few years of life predisposes to micronutrient deficiencies such as iron and zinc. Children in developing countries are frequently affected by ARI. In such settings, zinc supplementation has been shown to reduce the rates of pneumonia and enhance the physical growth.

Aims of the Study: To study the effect of zinc supplementation on the incidence of pneumonia among healthy breast fed babies aged between 6 months to 2years.

Materials and Method: The present study was a randomized controlled trial from april 2017 to august 2018 with both control and interventional group having 100 patients. The patient were followed up at six, nine and twelve months for anthroprometry and number of episodes of ARI and results analysed.

Results: A total of 200 babies were enrolled in the study. First and second follow up visits were done in 186 and 172 babies respectively. 168 babies completed all the three follow-up visits of which, 53.6% (90) and 46.3% (78) belonged to the interventional and control groups respectively, with significant reduction in the incidence of ARI in the zinc supplemented group.

Conclusion: Supplementation of zinc had a significant reduction in the incidence and prevalence of acute lower respiratory tract infections.

Keywords: Respiratory, Zinc, Breast feed, North Karnataka.

Introduction

Malnutrition is associated with over 55% childhood deaths in developing countries including India as estimated by World Health Organization (WHO). Malnutrition especially during the early few years of life predisposes to micronutrient deficiencies such as iron and zinc. Approximately 30% to 50% of children in developing countries have low serum and plasma levels of zinc, again putting them at high risk for malnutrition and associated illness.

Cereal based weaning food is often recommended as the first complementary food and it provides an important source of dietary iron but is very low in zinc. Therefore zinc supplementation may be important to meet the older infants zinc requirements particularly in less protected environments with the high infectious burden and limited dietary options. Children in developing countries are frequently affected by ARI(Acute respiratory infections). In such settings, zinc supplementation has
been shown to reduce the rates of pneumonia and enhance the physical growth.²

**Aim of the Study**

To study the effect of zinc supplementation on the incidence of pneumonia among healthy breast fed babies aged between 6 months to 2 years.

**Methodology**

This study was conducted in the Department of Pediatrics, KLES Dr.PrabhakarKore Hospital and Medical Research Centre, Belgaum during the period of April-2007 to August-2008. Study design was randomized double blind placebo controlled trial. Source of data: Exclusively breast fed (EBF) healthy term babies of five months of age with birth weight ≥ 2.5 kgs visiting the under five clinic of Pediatric Out Patient Department (OPD). Sample size was 200 (100 each group). The participants were randomized into the interventional and the control group using computer generated randomization list. Selection criteria: Inclusion criteria was all the healthy term babies appropriate for gestational age (AGA) with birth weight ≥ 2.5 kgs visiting the under five clinic of Pediatric OPD and babies of mothers who were willing to come for follow-up regularly. Preterm babies and IUGR babies, babies with metabolic or neurodegenerative diseases, congenital malformations (Cleft lip palate, congenital heart disease), severe or protracted illness requiring hospitalization for more than one week in the past, top fed babies were excluded.

**Method of Collection of Data**

An informed consent of the participants fulfilling the above criteria was taken before enrolling in the study. The study was approved by the Ethical and Research Committee of J. N. Medical College, Belgaum. The participants were enrolled in the study at five months of age. The period of enrollment was from April-2007 to Jan-2008. At enrollment, after assigning an identity digit number to the mother-infant pair, the data regarding the demographic profile and breast feeding practices were collected and entered in a pre-designed semi structured questionnaire. Mothers were counseled regarding the importance and benefits of EBF.

The study intervention was initiated at six months of age after recording the baseline anthropometry (weight, length and head circumference). The infants in the interventional group received zinc supplement (zinc gluconate) in the form of an oral syrup in the dose of 10 mg/day (2.5ml once daily) and the control group received 2.5 ml/day of placebo. The placebo was sugar syrup prepared from a reputed pharmaceutical company which was similar to the zinc supplement with respect to appearance, color and taste. Mothers were instructed to administer the drug dose by the measuring cup every day morning one hour before feeding. To know the compliance of the drug, mothers were provided with a calendar to mark each day that the drug was administered. These calendars were reviewed during the monthly visits and the number of days that the drug doses were missed was recorded. Mothers were also asked to return the bottles each month so that any unused portion could be measured. The intervention was continued up to twelve months in both the groups. Mothers were also asked to record on the calendar provided, the date when a new complementary food was introduced and to keep a detailed every day diet record of the amounts (using standard household measures) of non breast-milk foods and fluids consumed.

A total of three follow ups (at six, nine and 12 months) were performed during the study period. First visit was at six months, when the baseline anthropometry [weight for age, length for age, head circumference] was recorded and the intervention was started. During the second follow up at nine months, the data regarding morbidity with respect to number of episodes of ARI was recorded. Third follow up was at 12 months when, along with morbidity and anthropometry data was also collected.

During each follow up visits, mothers were reinforced to continue breast feeding and advised regarding complementary feeding. Infants were also assessed for compliance of the drug in terms of any adverse effects, number of missed doses and the reason for the same was noted. Any co-incidental administration of other supplements (multivitamins, iron, and calcium) by physicians was also noted during these visits. Throughout the study, mothers were asked to record on the calendar any symptoms of infant illness; using standardized guidelines for the description of symptoms.

**Outcome measures**

a) Anthropometric measurements:

**Weight:** The infant was weighed nude. Weight was recorded on weighing scale for infants with an accuracy
of ± 10 gms.

**Length:** The length was measured in terms of crown heel length, to the nearest of 0.1 cms. To measure the crown heel length, the infant was placed supine on an infantometer and mother was asked to keep the vertex snugly touching the fixed vertical plank. Legs were fully extended by pressing over the knees and feet kept vertical at 90°. The movable pedal plank was snugly applied against the soles and length was read from the scale.

**Head circumference:** The occipito-frontal head circumference was measured with a tape. Tape was encircled over the most prominent part of occiput and supra orbital areas and was measured to the nearest of 0.1 cms. The mean of two measurements were recorded as the observed values for all indexes.

**Morbidity data**

Mothers were asked to record on the calendar any symptoms of infant illness; using standardized guidelines for the description of symptoms and also diagnosis made by other physicians. Data were collected and grouped into two major categories: acute respiratory infection, and other illness. Data of number of episodes of ARI was used for analysis of morbidity in both the groups.

**Statistical Analysis**

The incidence of ARI in the two groups was compared with Chi square test. ‘p’ value of less than 0.05 was considered statistically significant. Results are presented as means (± S.D.) unless otherwise indicated.

**Definitions used in the study**

1. **Exclusive breast feeding:** An infant receives only breast milk and no other liquids or solid not even water, with the exception of drops or syrups consisting of vitamin, mineral supplements or medicine.

2. **Complementary feeding:** Defined as the transition from exclusive breast feeding to family food, which typically covers the period from 6 – 18 to 24 months of age and is a very vulnerable period.

3. **ARI:** Upper respiratory tract infection was defined as history of cough or difficulty in breathing with or without fever for more than one day not associated with rapid breathing and/or chest indrawing (or) a cough of more than one day with nasal discharge. Lower respiratory tract infection was defined as history of cough or difficult breathing with or without fever, lasting more than one day and accompanied by rapid breathing, chest indrawing, or both.

**Results**

The present study was conducted from April-2007 to August-2008 during which a total of 200 babies were enrolled in the study. First and second follow up visits were done in 186 and 172 babies respectively. 168 babies completed all the three follow-up visits of which, 53.6% (90) and 46.3% (78) belonged to the interventional and control groups respectively. The general demographic data was well matched between the groups.

**Discussion**

Inadequate breast feeding and inappropriate complementary food are the important causes (upto 43%) of malnutrition in infants which predisposes to micronutrient deficiencies especially iron and zinc. Zinc deficiency is associated with growth retardation and increased rates of diarrhea and pneumonia in children. Current recommendations for zinc intake during infancy
are based on the assumption that breastfed babies usually meet their zinc requirement (through breast milk and initial stores) during the first six months of life\textsuperscript{9} and zinc status is likely to become marginal beyond this age.\textsuperscript{10}

Therefore, the present study was conducted to know the effect of zinc supplementation on the incidences of ARI in healthy term exclusively breast infants with a standard recommended complementary feeding pattern.

The socio demographic characteristics (maternal age, literacy, and socioeconomic status) were similar in both the groups. The baseline parameters of the study population (gender distribution, birth weight, immunization status, duration of breast feeding) were well matched between the two groups and is similar to another study.\textsuperscript{11} The mean birth weight of the babies was 2.8 kgs in the study.

### Zinc and Morbidity

Zinc deficiency, a prevalent condition of young children in developing countries, is associated with decreased immunocompetence\textsuperscript{12} and increased rates of serious infectious diseases,\textsuperscript{12} also evident from the recent randomized controlled trials of zinc supplementation in poor children in developing countries. These trials have demonstrated that zinc supplementation can substantially reduce the incidence of acute lower respiratory infections. Most trials reported to date have varied with regard to the magnitude of the effect demonstrated and the presence of a differential effect by sex, age, nutritional status, or baseline plasma zinc concentration.\textsuperscript{12}

A stronger reduction in morbidity after zinc supplementation has been observed at 9 to 12 months and above, possibly because of the higher incidence of diseases in older age groups, were exposure to antigens is usually higher and the protective effect of maternal antibodies is waning.\textsuperscript{12} Hence, our study was planned to know the effect of zinc supplementation on morbidity during this period of life. In our study the Interventional group had a lower incidence of morbidity from ARI and diarrhea.

</table>

A study reported 40% lower risk of severe acute lower respiratory tract infection (ALRTI) in less well nourished infants with weekly supplementation of iron and zinc from 6 to 12 months of age, suggesting intermittent simultaneous supplementation with Iron and zinc would give promising results.\textsuperscript{13}

### Zinc and ARI

In our study there was a significant reduction in the incidence of ARI in the zinc supplemented group which is similar to observations of other studies.\textsuperscript{14} A number of studies in developing countries have demonstrated a substantial reduction in the prevalence of pneumonia in children supplemented with zinc.\textsuperscript{15} Zinc supplementation reduced the incidence but not duration of pneumonia or respiratory tract illnesses in children under five years of age as reported in a meta-analysis.\textsuperscript{16}

Supplementation of zinc with vitamin A had a significant reduction in the incidence and prevalence of acute lower respiratory tract infections. However, the incidence and prevalence was more in the group who received zinc alone.\textsuperscript{17} Contrary to this, two studies reported no increased incidence of respiratory morbidity with zinc given alone.\textsuperscript{12} Routine zinc supplementation in children aged six months to three years in an urban slum resulted in a lower incidence of pneumonia.\textsuperscript{12} Zinc when given together with antimicrobial therapy to young children with pneumonia was associated with a significant reduction in the duration of pneumonia when compared with controls, who received the same antibiotic but no zinc.\textsuperscript{18} Another study reported that zinc supplementation had no effect on the duration of hospitalisation or clinical signs associated with severe infections.\textsuperscript{19}

### Summary and Conclusion

A total of 168 babies completed all the three follow-up visits of which, 53.6% (90) and 46.3% (78) belonged to the interventional and control groups respectively.

A significant reduction of the number of episodes of ARI was noted in the interventional group at 9 and 12 months both with p value being < 0.001. Supplementation of zinc had a significant reduction in the incidence and prevalence of acute lower respiratory tract infections.

Independent Family Group Model Improving Health Status and Quality of Life of Elderly in the Community

Ni Made Riasmini¹, Junaiti Sahar², Yupi Supartini¹, Raden Siti Maryam¹

¹Nursing Major, Health Polytechic of Jakarta III, Jakarta Indonesia.
²Faculty of Nursing, Universitas Indonesia.

Abstract

Increasing number of elderly population impact in the problems faced, especially degenerative diseases, so that elderly are vulnerable groups. Family support as an importany source of support for improving the welfare of elderly. The development of an independent family group model is a family empowerment model which is an integration of self-help groups and support groups is expected to increase health status and quality of life in the community. A quasi-experimental study of non-equivalent pretest-posttest control group design was used in this research with 196 respondents from 5 (five) regions in Jakarta with random selection. Analysis of data used General Linier Model Repeated Measure (GLM-RM) test. The results showed the existence increased health status and quality of life of the elderly before and after the implementation of an independent family group model (at 3 and 6 months after intervention). The conclusion was independent family group model effectively improves the health status and quality of life the elderly in the community.

Keywords: Health status on elderly, Independent family group model, Quality of life on elderly.

Introduction

The elderly people are vulnerable groups in the community, at risk and more sensitive groups exposed to various risk factors, including economic, social, physical, biologic, genetic factors. The vulnerability condition of the elderly can affect the role of the family so that it becomes a burden for families, communities and the government.¹ In developing countries, the rapid demographic transition cause drastic changes in population structure with a rapidly increasing population in the world. The elderly population in Indonesia increase from 2010 equal to 7.5% becomes 8.49% in 2015. The prediction for 2035 is 15.77%. This is in line with the increase in life expectancy 70.1 years in 2010-2015 increased to 72.2 years in 2030-2035. The high life expectancy is one indicator of the success of achieving national development, especially in the health sector.²

The morbidity rate is one indicator used to measure the health status of the population. The lower as morbidity rate, the better their health status of the population. When viewed from 2005-2014, the health status of the elderly population has increased which is marked by a decrease in morbidity in the elderly.³ Even though morbidity is declining, but the elderly are still experiencing degenerative diseases. Health problems such as COPD, cancer, hypertension, heart failure, and arthritis that disease is a major cause of disability in the elderly so that it becomes a burden for families, communities and the government.⁴ Various problems occur in the elderly will have an impact on various aspects of social, economic and health. An increasing number of elderly people with disabilities or dysfunction or a lack support systems related to the development of the family, women work so that it will increase the elderly’s need for long term care and a decrease in quality of life.⁵ Therefore, it is necessary to prepare the elderly from an early age through a life cycle approach, so that quality elderly can be reached.

In Indonesia, government policies and programs that deal with the problems of the elderly from various departments already include social welfare and social
security, health care systems, family and community support, quality of life and special facilities and infrastructure for the elderly, but still not reaching the essence of empowerment efforts for the elderly which are integrated. Meanwhile, with increasing life expectancy, it is possible for older people to be in the family and community environment. Therefore, it is necessary to empower the elderly to improve the independence and quality of life of the elderly so as to reduce the burden on families and communities that have an impact on reducing long-term care costs.6

Improving the quality of life of the elderly is one indicator of success in overcoming various problems of the elderly. Quality of life is a state of well-being that includes the ability to carry out daily activities that reflect physical, psychological and social well-being and client satisfaction with the level of functioning and its ability to control disease and helplessness.7 Improving the quality of life of the elderly can be done through empowering the potential of the elderly in carrying out daily living activities by supporting independence in carrying out various activities that are capable of doing it.8 In addition to support from family and outside the family such as friends, neighbors, community members, as well as government, private and elderly observe groups in providing services in a comprehensive and holistic manner.9

The Indonesian government has developed an elderly empowerment program through the elderly groups at the district level, but has not reached the essence of empowerment of the elderly as a whole. Family empowerment programs through elderly family development as well as community-based approaches through Family Empowerment Posts (Posdaya) have also been developed to overcome various problems in handling the elderly, but there is no place for families that can be used as a gathering place to share experiences in caring for elderly and an effective strategy is not yet known to improve the quality of life of the elderly. Therefore, an independent family group model can be developed as one of the models of family empowerment.

Material and Method

The design used in this study is the quasi-experiment pre-post test with control group design. This design uses three times measurements, namely before the model intervention, at 3 months and 6 months after the model intervention. The population in this study is families who have elderly in the Jakarta region. While the sample in this study are families who have the elderly at home, with the following criteria: 1) adults to pre-elderly (20-59 years), 2) living with the elderly in one house, 3) As primary caregivers in the family. While the elderly with the criteria: 1) aged 60 years and over, 2) have physical or psychological problems but not bed rest, 3) do not experience visual and auditory disability. The sampling strategy uses a cluster multi stage method with a total sample of 196 caregivers (98 the intervention group and 98 the control group). Data analysis with statistical tests, namely the General Linier Model Repeated Measure (GLM-RM) and Canonical Test.

Independent Family Group Model

The model developed is an independent family group model which is a model of integration between support groups and self-help groups. The implementation stages of the model are: 1) Conduct training for health workers, elderly cadres and caregivers; 2) Form 10 independent family groups in 5 (five) Jakarta regions; 3) Conduct group activities through meetings that are held routinely which is 2 weeks in the first 3 months with assistance, then once a month for the next 3 months independently; 4) After 3 months of intervention, then the data collection was carried out (1st post-test). At 6 months after the intervention (2nd post-test).

Measurement Tools

The health status data collection tool uses the Short Form Health Survey/ SF-12SF-12 questionnaire consisting of 12 items using 1-5 likert scale. SF-12 is calculated with the value of physical component summary and mental component summary using scales 1-60. The quality of life of the elderly is measured using modifications from WHOQOL-BREF and WHOQOL-OLD(using a likert scale (0-4), consisting of 15 items including the autonomy domain, personal relationships, social relations, activities, physical and psychological adaptation.21 The instrument has been tested on 30 respondents with Alpha Cronbach above 0.7.

*General Linier Model Repeated Measures Test
The results showed that there was a difference in the health status of the elderly before and after the intervention of the independent family group model (3 months and 6 months after the intervention). The results of research which shows that the elderly health status scores were significantly different in the intervention group after 6 months of family carers’ training program intervention compared to the control group. The research on family care for the elderly through support groups illustrates that families benefit in caring for the elderly through counseling and support systems. Important factors that determine how families cope with stress in caring are their ability to obtain social support and social interaction through support groups. Support groups help families acquire caring skills, education about diseases and ways to deal with stress so that it can be applied in caring for elderly at home. Several studies have found that family support and social support can improve the physical and mental health of the elderly. The level of family support is significantly related to the health status of the elderly. Social support from the family is beneficial for the health and well-being of the elderly and can protect the elderly from dangerous situations and life events that are full of stress.

The results of interviews with caregivers after following the activities of independent family groups found that caregivers felt the benefits of increasing knowledge, insight, and experience in caring for the elderly so as to be able to care for the elderly properly, be able to be more patient, be wiser and be able to understand the needs of the elderly and able to care for the elderly if sick. This shows that the intervention of independent family groups can improve the ability of caregivers in caring for the elderly who experience health problems both physically and psychologically so as to have an impact on improving the health status of the elderly. This is consistent with the study that social support is significantly related to the physical and mental health of the elderly.

The model of an independent family group is effective in improving the ability of the family to be independent of the elderly and to improve the harmony of family relationships with the elderly which has an impact on improving the quality of life of the elderly. This is important for the elderly due to warmth, openness in the family can provide a feeling of security, acceptance and love and provide happiness in their lives so as to improve their quality of life. Supported by the results of research that elderly people who live in a family environment have a better quality of life than older people who do not live in a family environment. Families who care for the elderly also need a variety of support and health services that can maintain the quality of life of the elderly such as emotional support, social integration support, and reward support, assistance in decision making related to health services, financial needs, life planning for the elderly, assistance in carrying out physical tasks, support in accessing and negotiating with health and social services, assistance in managing the household. Similar with there is a relationship between the role of cadres with the growth and development of toddlers by KPSP. Its needed involve the active participation of the parents in the early detection of toddler growth and development.

Similar result the health training program related to the quality of life of the elderly is based on the ability to do Basic ADL and Instrumental ADL. Improving the quality of life of the elderly can be done through empowering the elderly’s potential in carrying out daily living activities by supporting independence in carrying out various activities that are capable of doing it, in addition to support from family and outside the family such as friends, neighbors, community members also support government, the private sector and the elderly observer group in providing services in a comprehensive and holistic manner.

There is a positive correlation between the quality of life of the elderly and social support from family, friends and meaningful people. Supportive family behavior is an important source of social support for elderly. This results of studies based on the canonical test that there is a strong relationship between the intervention of the independent family group model for the elderly. The social support provided through this model contributes to health improvement behavior in the family by strengthening the sources of support and it has an impact on improving the health status of the elderly and ultimately can improve the quality of life.

Conclusion

An independent family group model has been tested to be effective in improving the health status and quality of life of the elderly, so that it can be used as a model of family empowerment that can be applied in the community. Sustainability models require support groups that are able to provide assistance and move families to participate in group activities regularly. The
application of this model focuses on caregivers who care for the elderly at home. Through training and group meetings routinely able to increase the knowledge, attitudes and skills of caregivers in caring for the elderly.

Abstract

Background: Self-help group is one of the intervention groups with activities including exchanging ideas, overcoming problems, and mutual support among older people. Elderly people with hypertension are a vulnerable group and it is important to improve their health so they can maintain greater independence.

Objective: This study aims to determine differences in knowledge, attitude, and behavior in older people with hypertension by self-help group intervention.

Method: The research method used is non-equivalent pretest-posttest with the control group. Including intervention trainings and meetings for elderly hypertensive respondents. The samples were older people suffered from hypertension (45-59 and >60 y.o). Sampling method used random sampling resulted 44 respondents group as the intervention group and 42 respondents in the control group. Statistical test used independent t-test.

Results: There are differences in hypertension knowledge between the intervention group and the control group after the intervention of self-help group (0.66 ± 3.27; p value 0.001).

Conclusion: Self-help group’s intervention can serve as an important tool for health workers to implement education change that can empower elderly hypertension in the community.

Keywords: Education change, Older people with hypertension, Self-help group activity.

Introduction

Hypertension is a disease which suffers most of elders, marked with high blood pressure, yet generally the symptom is not noticeable, so it is often called the silent killer. It is estimated that 76% hypertension cases are not entirely diagnosed within the nation, so in this case, the person who already contracted with hypertension may not realized. According to WHO, the proportion of the people who are suffered from hypertension caused by ageing are 1 out of 10 people aged between 20-30 years old and 5 out of 10 people aged 50 years old or higher. Therefore, early detection is important, and it is important as well to always check their blood pressure and keep it within the normal level.

Health Profile in Indonesia in 2010 describes the increasing hypertension cases, in the form of essential hypertension, which requires hospitalization are 19,874 cases and 955 among them are died, while new cases in 2010 are approximately 80,615 which require outpatient treatment care. The prevalence of hypertension sufferer in Indonesia obtained through measurement of age within> 18 years old is 25.8% and the chance will increase on elderlies. Hypertension is the third leading cause of mortality (6.8%) for all ages after stroke.
(15.4%) and pulmonary tuberculosis (7.5%). Women between 45-54 years old are more likely (8.6%) to suffer hypertension than men which is 8%.6

The high incidence of hypertension requires more attention and all supports from all parties, especially the family as a closest support system to the client. Family support cooperated with participation from society can improve the elders’ ability in addressing their problem as well as to generate new intervention strategies for sustainability of health care system23. One intervention that can be done is through Self-Help Group (SHG). SHG is a group of people that help each other in which they provide support for each member of the group or mutually beneficial for each member. They share common problems, share feelings, and experiences about the disease and dependency problems.7

SHG is the group’s activities which empower its whole members to resolve their own problems. Through all participation within the group, each member will feel more open, more useful, and more empowered to make decision to reduce the burden on families, loneliness and guilt.8 SHG can reduce the symptoms of the disease, lower the crisis and hospitalization, improve social skills and extend social networks, and increase healthy behaviors and perception of good health.9

Some of the results of other relevant researches find significant differences in knowledge, attitudes and behavior of pre-elderly before and after intervention psychoeducation models.10 The frequency and strength of bond with friends or people who matter on their life are associated with lower somatic symptoms and blood pressure, in which social support and social networks have a profound effect on the lives of the older people to improve physical and psychological function.11 Through the intervention, it is expected that they are able to maintain their health on their own in order to reach healthy, active and productive old age.

Material and Method

This research used a quasi-experimental design with nonequivalent pretest-posttest on a control group. The random sampling was used in the intervention group in three Rusunawa which are subsidized apartments or vertical housing provided by the provincial government. The sample size for intervention group was 44 elderlies and for the control group was 42, so the total was 86 elderlies. The intervention group did pre-test and health education activities related to health development and treatment of hypertension on elderlies as well as things that must be considered by the older people.

The group activity was conducted once a week within a month. The first meeting of the self-help group activities included sharing experiences on hypertension treatment that had been done recently (written in workbook for elderlies). The second meeting, the activities were to share experiences on the proper treatment for hypertension between elderlies and facilitators, to discuss herbal therapies for hypertension and how to make a proper herbal medicine, and to practice the deep breath relaxation technique. The third meeting was to share experiences, to try the herbal therapies, and to practice acupressure to treat high blood pressure. The fourth meeting activities were to share the experiences of doing at least 2 acupressure techniques, deep breath relaxation, and then do the post-test. Meanwhile, the control group did the pre-test and measured the blood pressure, and then did post-test and re-measured their blood pressure.

Findings

Based on the characteristics of the elderlies, both the intervention and control groups are similar characteristics, for example, the majority of respondents are female, married, and have poor educational background (only attended elementary school). Both groups are nearly equal in hypertension medical record in which they have suffered for around 1-5 years, have taken prescribed antihypertensive medication, and performing routine blood pressure check. The intervention group never receives any health education or counseling about hypertension before. Both groups own mobile phones and can operate them well.

The characteristic of hypertension before intervention on both groups shows that the intervention group have moderate hypertension ranged from 160-179 mmHg for systolic and 100-109 mmHg for diastolic. Meanwhile, the control group have mild hypertension ranged from 140-159 mmHg for systolic and 90-99 mmHg for diastolic. Both groups’ hypertension statuses are improved or changed after intervention of self-help groups in which their blood pressure became normal ranged from 120-139 mmHg for systolic and 80-89 mmHg for diastolic based on 30 respondents’ test results.

The result of the equality test analysis shows that there is no difference on all variables between intervention and control groups (p value > 0.05). Thus all the variables between the two groups are equal.

<td>Control</td>
<td>42</td>
<td>1.19</td>
<td>5.29</td>
<td>-2.350 – 2.696</td>
<td></td>
</tr>
</tbody>
</table>

The analysis also shows that there is significant difference in mean value of elderlies’ knowledge on treating hypertension after intervention in the intervention group compared to the control group (Table 1). Formed SHG and its activities including to share experiences, health counseling, and coping skills of elderlies with hypertension can increase knowledge about hypertension. This is in accordance with that the provision of effective health education can influence on the improvement of knowledge of individuals or groups.\(^{15}\) This is in line with a research statement that sharing knowledge and coping skills can help the members of the group to choose a suitable strategy for them.\(^{16}\) The involvement of a person in the group is an empowerment process that provides an opportunity to work with others, to learn about decision-making skills, and problem solving as well as to manage the resources available in the community.\(^ {17}\)

This program can be conducted because the support from all parties, from the health center, the KPLDH (Ketuk Pintu Layani Dengan Hati) organization of Rusunawa in cooperation with ‘Kader Kesehatan’ to identify and collect the data related to the elderlies with hypertension and self-help group. This is suppoted with previous research that some activities can be done at the meeting of SHG such as the announcement of events, sharing feeling (may be positive or negative), the opening of the meeting by the facilitator, the disclosure feelings of group members, discussion, question and answer session, ended with the closing in which there is a reward and suggestions or criticism.\(^ {18}\) SHG uses workbook and guidelines which help each member to do self-health monitoring and management, reduction of the incidence of negligence, and improving social support.\(^ {19}\) The SHG can teach someone to understand others through sharing experiences, providing an opportunity to meet regularly, mutual support and exchange coping skills with each member.\(^ {20}\) Another research said there is a relationship between the role of cadres with the growth and development of toddlers by KPSP as pre-screening questionnaire.\(^ {27}\)

Activities in SHG have been agreed upon beforehand and implemented in a sustainable manner through the workbook. The workbook must be filled with positive and negative behaviors related to the efforts done to control blood pressure and to cope when problems or symptoms of hypertension appearing. It is expected that through the workbook, those activities can become a habit that is done continuously which creates healthy lifestyle. This is in accordance with a statement that if the behavior was integrated with health promotion in lifestyle, it can produce a positive health experience throughout life\(^ {21}\), and there was a significant increase in knowledge after the use of booklet media and modules on prevention of anemia in peer education in teenagers girls.\(^ {25}\)

Experiencing healthy life becomes one of the purposes of the implementation of the SHG as it is expected after attending SHG can enhance healthy behaviors and perceptions about the healthy state in which the client will accept the disease, will know proper treatment, will know better coping mechanisms and disease management, will improve the quality of life and sense to maintain health, will have higher self esteem, accept the problem without blaming, will be more creative, and can spend most of the time with their families. Noise as a part of environment variable could interfere with correct hearing and potential error in measurement of blood pressure.\(^ {22}\) According to research there were significant results which are noise, age, hereditary factors, physical activity to hypertension.\(^ {26}\)

**Conclusion**

Based on this research, both groups have hypertension record and have regularly check the blood pressure as well as having mobilephone as communication media,
and most of the control group members have received health education or counseling on hypertension compared to the intervention group. The staff of Puskesmas and Rusunawa are expected to enhance and sustain the activities conducted in ‘Posyandu Lansia’ or Hypertension Clinic through providing health education or counseling on hypertension treatment focusing on the skills or practices; blood pressure routine check for those who cannot come to ‘Posyandu Lansia’ or the Clinic; and take the benefit of Mobile Phone to form a Whatsapp (WA) group as a media to inform and remind each others to come when the activities are scheduled as well as to knowledge and positive or negative experiences.

Abstract

Background: Motivation of health workers is necessary to generate the organizational commitment towards the patients and the hospital. Therefore the knowledge about what motivates and satisfies them is very essential.

Objective: The primary objective of the study was to explore the relationship between Work Motivation and Job Satisfaction among Nurses in the Clinical Settings

Method: The study is conducted through online survey, target being nurses of Government or a private run hospitals. Sample size was 100.

Results: The study shows majority of the study population belonged to age group between 25-30 years (55%). Gender-wise distribution showed 48% males and 52% females. Female Nurses were more as compared to males. More than half of the study population (68.3%) were poorly motivated and their job satisfaction level is very poor. Work motivation is highly significantly associated with job satisfaction (p=0.001), (p value is less than 0.005).

Conclusion: There should be an effective Human resource management system for nursing community in every higher level hospital.

Keywords: Motivation, Job satisfaction

Introduction

Motivation can be defined as the processes which account for an individual’s intensity, direction and persistence of effort toward achieving the goal. There are two kinds of motivation, intrinsic or extrinsic. The former are derived from within the individual, e.g. taking pride and feeling good about a job well-done, whereas the latter pertain to rewards given by another person. Job satisfaction, on the other hand, is defined as a pleasurable or positive emotional state, resulting from the appraisal of one’s job or job experiences. Job satisfaction is only achieved if the person is motivated to complete his job successfully.

Psychologists conducted various studies on human motivation extensively and have prepare methodically a variety of theories about what motivates people. Needs-based theories include Maslow’s hierarchy of need, Aldersfer’s theory, Herzberg’s two factor theory and McClelland’s acquired needs theory. Another approach focuses on external factors and their role in

understanding employee motivation (e.g. Skinner’s reinforcement theory). Theories based on intrinsic factors focus on internal thought processes and perceptions about motivation (e.g. Adam’s equity theory, Vroom’s expectancy theory, Locke’s goal setting theory) ¹

The workforce in the health sector has specific features that cannot be ignored and motivation can play an integral role in many of the compelling challenges facing healthcare today ². Most of the studies have been carried out on a combined sample including doctors, nurses including paramedical staff together. Since, the social network varies geographically, hence; the generalization made in developed systems of care can’t be used in India, and ³. Also there is much attrition rate of young nurses in India in both public and private sector, as most of them are going abroad within five years after completing their course. Nurses are called the backbone of health care system, they cannot be ignored and their motivation can play an integral role in many of the compelling challenges facing healthcare today. Employee satisfaction and patient satisfaction both are important from the hospital point of view. Overall work motivation and job satisfaction are important factors to retain hospital employees in the long run specially the nurses. This Quantitative study was designed to assess the work motivation and job satisfaction among nurses in the clinical setting.

**Methodology**

The study is conducted through online survey, target being nurses of Government or a private run hospitals, having minimum bed capacity of more than 500 and staff nurse capacity more than 300 in India. Purposive sampling technique was used to select the study population. A semi structured pre tested questionnaire was used to collect required information. The questionnaire was divided in to 3 parts demographic characteristics, work motivation and job satisfaction.

The questionnaire was sent and randomly selected 100 respondents from the nurse’s community the online questionnaires (prepared in Google Docs) were sent to the nurses through email and Whatsapp. One month time span was given for them to reply to the questionnaire. Further data collected was numerically coded in SPSS software version 16. The data was summarized using descriptive statistics, frequencies and percentages. Statistical differences between categorical variables were assessed using the Chi-square or Fischer exact test (if cell value was less than 5). Means were compared using the Student’s T-test P-value <0.05 was considered statistically significant.

**Result**

Descriptive statistics method and regression analysis were used to analyse the data, the obtained results are being presented in the following tables.

Discussion

The present study was to explore Work Motivation and Job Satisfaction among Nurses in the Clinical Settings. Sample size was 100. The study shows that Work motivation is highly significantly associated with job satisfaction (p=0.001), (p value is less than 0.005). More than half of the study population (68.3%) were poorly motivated and their job satisfaction level is very poor. Only 6.7% of nurses have high motivation and they are having high job satisfaction. 31.8 % of study population were moderately motivated and satisfied with their job. The similar finding had been reported by Lu H et al, Singh Rajkumar G, Hegney, Plank, Parker, Nick Kontodimopoulos and Wangal. Nurses are called back bone of the health care system, they cannot be ignored and their motivation can play an integral role in many of the compelling challenges facing health care today. Nurses will have difficulties in meeing the needs of patients if their own needs are not met. In the present study only the young nurses are taken as samples who are working in patient bedside.

According to Sukhminder Singh Bajwa, Sandeep Singh in the study “In depth analysis of motivational factors at work in the health industry” shows that the demographic profile of all the employees showed only minor differences which were statistically non-significant. Skills, task -identity, task significance, autonomy, feedback, environment, job security and compensation were observed to be the important factors for the motivation of employees. The study were conducted on 100 employees (doctors-40, nurses-40, paramedical-20) by ranking of motivational factors ranging from 0-5. Akambi study showed positive relationship between intrinsic motivation, extrinsic motivation and the workers performance having variables such as intrinsic motivation, extrinsic motivation and employee job satisfaction by taking sample of 100 workers of flour mill of Nigeria. Leshabari MT study on Healthcare Employee Satisfaction Survey reveals they were unmotivated as a result of dissatisfaction with remuneration; opportunities for growth and promotion; working conditions; recognition, rewards and appreciation; as well as benefits and allowances. Research findings indicate that there is a relationship between lack of motivation and stress using Yes or No questions on 106 nursing staffs. The study in Tanzanian health industry reveals that almost half of both doctors and nurses were not satisfied with their jobs, as was the case for 67% of auxiliary clinical staff and 39% of supporting staff.

Most of the studies have been carried out on a combined sample including doctors, nurses including paramedical staff together. They have again been done abroad. Since, the socio-cultural network of abroad is very different, hence; the generalization made abroad can’t be used in India. Also there is much attrition rate of young nurses in India in both public and private sector, as most of them are going abroad within five years after completing their course.

Conclusion

People are always the vital resource of organization. And at times, they are often neglected at their jobs which leads to their failure to perform. Thus here we need to understand what motivates people and how they get satisfied from their job that leads to organizational performance. The present study revealed that more than half of the study population (68.3%) were poorly motivated and their job 39% satisfaction level is very poor. Work motivation is highly significantly associated with job satisfaction (p=0.001), (p value is less than 0.005). There should be an effective Human resource management system for nursing community in every higher level hospital. Top level management will be governed by persons having good knowledge in nursing administration. To increase the job satisfaction level of the employees the Organization should concentrate mainly on the incentive and reward structure besides the motivational session. There should be adequate Rewarding and promotion system to those employees who deserve it. Overall work motivation and job satisfaction are important factors to retain hospital employees in the long run specially the nurses.

Limitation

Lack of time and other resources as it was not possible to conduct survey at large level. While collection of the data many consumers were unwilling to fill the questionnaire. The area for study was limited to specific organizations that are quite a small area to judge job satisfaction level. Online survey.

Recommendation

There should be an effective Human resource management system for nursing community in every higher level hospital. Top level management will be governed by persons having good knowledge in nursing
administration or MBA in hospital management or MHA. To increase the job satisfaction level of the employees the Organization should concentrate mainly on the incentive and reward structure besides the motivational session. There should be adequate Rewarding and promotion system to those employees who deserve it.

Abstract

Metabolic syndrome is a term for risk factors for heart disease and diabetes mellitus. Workers have different lifestyle behaviors and work patterns that can cause metabolic syndrome. Based on medical check-up data in 2016, there were found several cases of dyslipidemia (97.5%), visual impairment (47.8%), BMI> 25 (45.2%), abnormal audiometry (17%), liver enzyme disorder (1.7%), and hypertension (10 %). Among those cases, there are 3 problems which are identified as the components of the metabolic syndrome. This study was conducted to explain the factors related to metabolic syndrome in mine workers to make control and prevention programs. A cross-sectional design was used to obtain workers lifestyle data by analyzing lifestyle questionnaire results and medical check-up data which includes central obesity, triglycerides, HDL, blood pressure and fasting blood sugar. There were significant relationships between physical activities with metabolic syndrome. No significant relationship was found between diet pattern, sleep duration, and knowledge of metabolic syndrome. Promotion and preventive controls are needed to prevent the metabolic syndrome in population, and screening of metabolic syndrome in all workers need to perform by the company to find out the magnitude of the problems.

Keywords: Metabolic syndrome, occupational health, coal mining

Introduction

The metabolic syndrome (METS) consists of five factors for Atherosclerotic Cardiovascular Disease (ASCVD), that is atherogenic dyslipidemia, high blood pressure, dysglycemia, pro-thrombotic state, and inflammatory state, which occurs most often in obese people. The contribution of each component to cardiovascular risk necessarily varies between individuals but, in combination, both multiply the risk of ASCVD\textsuperscript{(1)}.

According to the American Heart Association / National Heart, Lung, Blood Institute update ATP III MS and IDF report, the main purpose for diagnosing METS is to identify patients at high risk of heart disease and type 2 diabetes mellitus who require lifestyle therapy to reduce this risk\textsuperscript{(2)}. Most people with METS are obese and do not settle. Urbanization and access to cheap food create a pandemic of METS. Thus, primary interventions should be lifestyle changes, ie calorie restriction, improved food quality, and increased physical activity\textsuperscript{(1)}.

Some research on METS of International Diabetes Federation (IDF) decided to use the definition of ATP III 2001 as a starting point and modify and update it to reflect the current goals\textsuperscript{(3)}. According to a new definition, a person suffering from METS, they should have central obesity plus two of the other four additional factors. These four factors were elevated triglyceride levels $\geq$ 1.7 mmol / l (150 mg/dl), decreased HDL cholesterol:
<1.03 mmol / l (40 mg/dl) in men and <1.29 mmol / l (50 mg/dl), in women (or specific treatment for these lipid abnormalities), elevated blood pressure (systolic ≥ 130 or diastolic 85 mmHg) or treatment of previously diagnosed hypertension, fasting blood glucose ≥ 5.6 mmol / l (100 mg/dl) or previously diagnosed type 2 diabetes.

METS was found in 22.8% and 22.6% of US men and women. METS was found in 4.6%, 22.4%, and 59.6% of men of normal weight, overweight, and obese, respectively, and a similar distribution was observed in women. Older age, postmenopausal status, Mexican American ethnicity, higher body mass index, smoking, low household income, high carbohydrate intake, and physical inactivity were associated with increased likelihood of METS.(4)

A METS-related study conducted on executive workers in Jakarta in 2011 showed that in general, the prevalence of METS was high (21.6%). The prevalence of METS in male executives (24.7%) was higher than for female executives (11.8%). Demographic, lifestyle, sex, and physical activity characteristics are associated with METS(5).

XYZ is a coal mining company, where the mining processing environment takes place has a health impact. Based on preliminary research by reviewing HIRADC (Hazard Identification Risk Assessment and Determining Control), medical check-up result and clinic visit found that disease that occurs among workers not only related to work environment but related to work behavior and healthy lifestyle.

Material and Method

This cross-sectional study used questionnaire and medical check-up in 2017. This study aimed to describe the prevalence and factors related to METS in coal mining company XYZ. Hypothesis test using Chi-Square test and T-test to see the relation between dietary pattern, physical activity, sleep duration and knowledge with METS. Research conducted at XYZ, a coal mining company operating in South Kalimantan. The study was conducted in January - May 2018. The population study is the workers of XYZ coal mining site of South Kalimantan. From the total of 196 workers, 105 workers selected after adjusting with inclusion criteria. This research was using FFQ to get dietary pattern information, GPAQ for physical activity and questionnaire that develop by the researcher for sleep duration and knowledge.

</tbody>
</table>

Bivariate analysis showed that there was no difference in the proportion of metabolic syndrome in the type of food consumed rarely and often consumed. In the diet often groups as much as 48.8% had METS and on rare diet groups as much as 33.3% had METS. The odds ratio (OR) value obtained at 0.524 (95% CI 0.091-3.012); it means that diet often has a risk for METS of 0.524 times compared with rare diet. The results showed that there was no significant relationship between frequent food intake with METS (p-value = 0.469).

In variable sleep duration, the group that had the highest percentage of METS was the short sleep duration group, which was 57.1% with an OR value of 1,600 (95% CI 0.580-4,412). The OR value for the long sleep duration group was obtained at 0.933 (95% CI 0.304-2.864). However, it can be seen from the p-value, both short sleep duration and long sleep duration are not related to the METS (p-value = 0.364; p-value = 0.904).

The results of data analysis demonstrated that there is a difference in the proportion of METS in both groups of physical activity. The OR value was obtained at 3,030 (95% CI 1.097-8,363); it mean that less physical activity had a risk of METS of 3,030 times compared to active physical activity. P-value showed that there was a significant relationship between physical activity with METS (p-value = 0.032).

### Discussion

Based on the results of research on 92 mining workers XYZ coal mining company located in South Kalimantan found the prevalence of METS in 2017 amounted to 47.8%. When compared with previous research on METS in Indonesia, this result higher than result from Soewondo’s study 28.4%⁶.⁷ According to the consensus of the definition of METS, there was the fact that METS was a progressive disease and increases the risks of ASCVD, for example, some components tend to worsen over time. Some things that usually increase annually are weight gain, gradual loss of muscle mass, stiffness in the arteries, decreased capacity of pancreatic beta cell secretion, mitochondrial dysfunction, and increased inflammatory changes in adipose tissue, and age-related¹.

The largest component of the METS contributing to this study was high blood pressure obtained in 88% of respondents.

### Dietary Pattern

Food intake is a determinant factor in the diet, which is described in the frequency of eating, skips breakfast and eating habits outside the home associated with obesity. It has been agreed that a high-fat diet will increase total energy intake and increase the likelihood of obesity⁷. Assessment of the frequency of food consumption was done using the Food Frequency Questionnaire (FFQ). Food consumption was divided into carbohydrates, animal protein, vegetable protein, vegetables, fruit,
milk and its products, fast food, snacks and soft drinks. After obtaining the overall food frequency data, then the food ingredients are determined which are at risk of causing METS. In this study, diet pattern was not related with METS. This result was not in line with several studies that suggest that diet was related with METS. Dietary patterns characterized by high consumption of fish and foods with whole grains and low consumption of processed products, sugar and sweets and preserved meat are associated with a lower risk of METS with a reduced risk of lower HDL cholesterol concentrations and increased glucose concentration. This might be happening because there was no difference in the variety of food consumed by each worker because the company has provided canteen facilities and meal menu settings.

Physical Activity

Physical inactivity increases the risk of CVD and types 2 diabetes mellitus and other can worsen other risk factors. Increased physical activity promotes weight loss and maintenance in obese people and modifies obesity-related risk factors, including increasing visceral adipose tissue loss, improving insulin sensitivity, increasing HDL cholesterol, and decreasing triglyceride levels. The results of this study showed that workers who were an inactive category (<600 METs-minutes per week) 3 times (OR = 3.030) were at risk of having METS compared with workers who were an inactive category and statistical tests showed that physical activity significantly related with the incidence of METS. These findings are in line with studies showing that the percentage of adults who do most of the sedentary activity was more at risk of developing METS. 21.4% of the participants studied had 3 or more risk factors for METS with low HDL levels as the most risk factor, Moderate-Vigorous Physical Activity (MVPA) with at least 10 minutes per session, Low Physical Activity (LPA) and body mass index explained 16% HDL variation.

Sleep Duration

Sleep duration was not significantly related with METS. Sleep was recognized as an important mediator in an individual’s health status. Given that the number of short and long sleep gradually increases. The results of this study are not in line with some studies that have reported that short sleep hours (generally less than 6 hours per day) or long (generally more than 8-9 hours per day) sleep duration was associated with an increased risk of chronic diseases such as obesity, hypertension, diabetes, and METS. Several studies have reported that short sleep duration was associated with an increased risk of METS, but conversely, long sleep duration was not associated with METS.

In this study, there was no association between short sleep hours and long sleep hours with METS. This was due to the working hours arranged by the company so that very few workers work overtime or leave early. Workers who live in the company accommodation can go straight back home to rest, and workers living outside the company accommodation are provided with shuttle buses so that they return home on time. With a working system like this, it was very possible for a person to return to his place of residence and immediately rest.

Knowledge

Worker’s knowledge was measured using a questionnaire that contained several questions about METS. None of this research results are suitable for groups that are not with METS. The results show that no difference in the scores of knowledge in the group who had METS and did not have METS. This was in line with Kamso et al (2011) research on the groups in Jakarta who see the level of education as the uniqueness of the METS. In the study, there was no significant relationship between education and METS. This was in contrast to several studies that have shown that the level of education has a significant relationship with METS.

Previous studies show that women have a lack of understanding of diet and exercise in reducing CVD. One way to reduce CVD incidence was to improve adherence to healthy lifestyles by educating, filtering, detecting and treating the modifiable risk factors because women do not practice heart-healthy behavior on a regular basis. This attributed to their limited knowledge and lack of attention and knowledge to CVD which can lead to poor motivation to change behavior.

Conclusion

Dietary pattern, sleep duration, and knowledge were not related to METS. Factor contributed to METS in miners based on the results of was physical activity. Promotion and preventive controls are needed to prevent the METS in population. The researcher suggests performing screening of METS in all workers to find out the magnitude of the problems that occur in the company. It is necessary to improve physical activity and exercise.
programs for workers who had METSand all workers.

Conflict of Interest

Hereby the authors declared that there is no conflict of interest in this research with any other parties.

Ethical Clearance

This research has been approved by Ethical Board Committee, Faculty of Public Health University Indonesia and has been approved for ethical clearance by Ethical Board Committee, Faculty of Public Health University Indonesia.

Analysis Of Employee Performance Appraisal System In Primary Health Care

Rokhmah Maulidina1, Widayati Yuli Arini1, Nyoman Anita Damayanti2

1Student of Health Policy Administration Program Study, Faculty of Public Health, Airlangga University, Indonesia
2Lecturer of Health Policy Administration Program Study, Faculty of Public Health, Airlangga University, Indonesia

Abstract

Performance appraisal is an important tool used in measuring the framework established by the organization along with employees. Performance appraisals are useful for monitoring individual performance in order to stay on track to meet organizational goals and to identify individual development capabilities and opportunities. In addition, performance appraisal is also to assess whether organizational goals are achieved and function as future organizational planning and development. A study on the evaluation of performance appraisal system was conducted at Cukir Primary health care, Jombang District. Respondents in this study were all Civil Servants working in primary health care. The instruments used were questionnaires and interviews. The results showed that the performance appraisal system at Cukir Primary health care has been carried out periodically, in accordance with the vision and mission of the institution, and has accurate content and objectives. Respondents identified a gap in the performance appraisal system that no appropriate rewards were given to employees, the appraisal system was not fully explained to the employee, no feedback was given to the employee and the employee was not involved in the formulation of standards and performance targets. It is suggested that the leadership must review the implementation of performance appraisal system at Cukir Primary health care. Performance appraisal should have a positive impact on organizational well-being. If the performance appraisal is done well, then the productivity and performance of employees will increase.

Keywords: Performance Appraisal, Employee Performance Indicators, Primary health care

Introduction

The success of the organization depends on the quality and characteristics of the employees. Employees become an important factor in any organization because without employees, a simple organization can not achieve its goals and objectives1. The long-term success of an organization or company depends on its ability to measure its employee’s performance and use the measurement information for the basis of performing performance improvement efforts in order to always conform to the established standards and the changing demands of the business environment. So the strategic approach of human resource management is to link the organization’s goals with employee performance. Organizational strategic goals are part of the performance management process and implemented in the performance appraisal process. Performance appraisal is a stage of job evaluation that can improve the quality of work for the continuity of organizational activity in it4. Performance appraisal is an important task of the organization, so that the organization knows the extent to which employees are successful or not in the work during the specified period.
From the results of the assessment can be seen organizational performance is reflected by the performance of employees because the performance is a real behavior that displayed each person as work performance generated by employees in accordance with its role in the organization.

Many organizations have implemented performance appraisal systems as key method of development and performance improvement. However, it should also be evaluated whether the performance appraisal system implemented is accurate, effective and of good quality and in line with the organization’s objectives. It is also important to identify the weaknesses or weaknesses of the performance appraisal system and to make continuous improvement efforts to meet organizational goals.

The Government regulates the performance appraisal system for civil servants in Government Regulation Republic of Indonesia number 46 of 2011 on Performance Appraisal of Civil Servants. In the regulation mentioned that the performance appraisal of civil servants is a systematic assessment process undertaken by the appraisal officer against employee work sasarn and employment behavior of civil servants. Employee Work Objectives, hereinafter abbreviated job performance indicators is the work plan and targets to be achieved by a civil servant.

Target is the amount of work load to be achieved from every job performance. Assessment of the performance of civil servants aims to ensure the objectivity of coaching.

Cukir Primary health care is the operational technical officer of Jombang District Health Service in the field of public health services led by a head of the primary health care responsible to the head of the department. The number of human resources at Cukir Primary health care is 80 people, with details of 40 civil servants and 40 non-civil servants.

Performance appraisal is conducted regularly at Cukir Primary health care that is once a year. However, the implementation of performance appraisal applies only to civil servants. Non-civil servants have never conducted performance appraisals. Implementation of performance appraisal is still many shortcomings, among others: employees are not involved in the preparation of standards and performance targets, not monitored in the performance appraisal process, employees do not get feedback or feedback performance appraisal results, and performance appraisals are not used as a basis of reward, training and development needs, planning analysis of human resource needs.

Material and Method

This method of this research was an observational study with cross sectional study design used questionnaires analyzed descriptively. The case study was conducted at Cukir Primary Health Care of Jombang Regency using total sample of all Civil Servants working in Cukir Primary health care which amounted to 40 people.

Researchers distributed questionnaires about performance appraisal system to all civil servants at Cukir Primary health care. The results of the data from the questionnaire were analyzed to determine the knowledge of civil servants (employees) on the performance appraisal system that has been implemented in Cukir Primary health care.

Results and Discussion

Cukir is one of 34 Primary health care in Jombang district. In accordance with the Regent Regulation of Jombang No. 21 of 2012 Cukir Primary Health Care is located as an operational technical implementer of Jombang District Health Office in the field of public health services led by a head of the primary health care responsible to the head of the department. The number of human resources at Cukir Primary health care is 80 people with details of 40 civil servants and 40 local contract workers and puskesmas contracts.

Performance appraisal has been done at puskesmas but only for civil servant. Every civil servant has an employee performance indicator that is evaluated at the end of each year. For non civil servants, there is no performance appraisal method conducted by the head of primary health care. So in this study the questionnaire only provided for civil servants who numbered 40 people. The results are shown in the table below:

Table 1 shows the results of knowledge and the importance of performance appraisal for the respondents. More than 80% of respondents stated that they are neutral, disagree, and strongly disagree that respondents have understood the performance appraisal system held at Cukir Primary health care. Approximately 67.5% of respondents also disagree and strongly disagree that respondents participate actively in performance appraisal conducted.

Approximately 82.5% of respondents agreed and strongly agreed that performance evaluation was conducted over a period of time, 75% strongly agreed and agreed that performance appraisals were used to determine the gap between performance performed against expected targets. 62.5% agreed and strongly agreed that performance appraisal assisted management in organizational control, 67.5% agreed that performance appraisal was a tool to achieve organizational goals and objectives, 45% of respondents stated neutral on the statement of the importance of performance appraisal in building strength and communication with leaders.

A total of 75% of respondents stated neutral, disagree and strongly disagree about the importance of performance appraisal in planning training and development needs as well as human resource planning, employee recruitment, selection and training. From the table above obtained the picture that most employees have not understood and play an active role in the implementation of performance appraisal at Puskesmas Cukir.

In addition, employees also do not know clearly about the importance of performance appraisal system is implemented periodically. This may be because performance appraisal results have not been used as a basis for training planning, development or human resource needs.

</tbody>
</table>
Table 2 illustrates the effect of performance appraisal system on staff at Cukir Primary health care. More than 80% of employees said they disagree and strongly disagree if performance appraisals lead to a decrease in employee competence, 90% of respondents also disagree if this performance appraisal gives a negative stigma to employees.

Performance appraisal also does not provide the effect of decreasing salary, demotion, and dismissal of employees. Respondents also largely disagree if performance appraisals indicate employee weakness. However, as many as 67.5% of respondents agree and strongly agree if in the implementation of performance appraisal there is subjectivity of the leadership.

From table 2 can be obtained information that some respondents already know the effects of performance appraisal system.

The results of the performance appraisal should be used as the basis for payroll, promotion and dismissal of employees, but this has not been done in Cukir Primary health care, so some respondents still do not understand it. Performance appraisal conducted also there is still subjectivity from the leadership. This is because in the performance appraisal system of civil servants there is a performance quality assessment given by the leadership. During this time the value of the quality element is not followed by the evidence of the search used as the basis of the assessment.

Table 3 illustrates employee behavior towards performance appraisal. Approximately 75% of respondents disagree and strongly disagree with the statement that employees are afraid of performance appraisals. Most respondents also disagree on the statement that employees do not like performance appraisals. More than 75% of respondents agreed and strongly agree that poor performance appraisal is done at Cukir Community Health Center.

However, the permanent employees want performance appraisal to be carried out continuously. Respondents also disagree if performance appraisal causes employees to be uninspired in their work. From the table above can be concluded that employees have different behavior on performance appraisal. There are employees who have positive behavior but there are those who behave negatively towards performance appraisal. This may be due to the subjective subjectivity in performance appraisal held at Cukir Primary health care.

Table 4. Contribution of Performance Appraisal of Employees in Cukir Primary Health Care in 2018

<td>7</td>
</tr>
</tbody>
</table>
Table 4 illustrates the contribution of performance appraisals to employees and community health centers. More than 70% of respondents agree and strongly agree if performance appraisals maintain the organization. 70% of respondents also agree that performance appraisals are used as a check and balance of the firm, a similar number of respondents also agree that performance appraisals contribute to increased efficiency and work productivity.

However, most respondents did not agree that performance appraisal conducted so far is used to increase employee salaries. Respondents also agree if the performance appraisal is a tool to improve pehamaman employees against their respective duties, but the number of respondents who do not agree is also quite a lot of about 42.5%. This may be caused by the inactivity of employees in setting SKP targets and targets at the beginning of the year.

Table 5 illustrates the problem of performance appraisal system at Cukir Primary health care. From the table it is known that 90% of respondents stated that there is subjective in performance appraisal, 82.5% stated that performance appraisal is determined without feedback, 70% dissatisfied with performance appraisal system, and 85% said monitoring is still low.

From the result of the research, it is very important to improve the performance appraisal system so that the performance assessment goes objectively, there is feedback given by the leadership to the employee, the employee feel satisfied and the periodic monitoring from the leader accompanied by the evidence of the performance achievement done by the employee.

Conclusions

From the results of simple research conducted at Cukir Primary health care, it is concluded that the performance appraisal system has not been implemented optimally. Employees have not been fully involved either in the process of planning performance standards or performance appraisal processes. The lack of feedback has caused the staff of the public health care to be unaware of the performance outcome for the specified time.

Monitoring of performance appraisal should be done continuously to ensure the quality of the performance appraisal system. The author recommends improvement of performance appraisal system with method “E-Performance based on LAN (Local Area Network) at Cukir Primary health care”.

Abstract

The American Hospital Association (AHA) Board of Trustees stated that patient safety is a strategic priority. In 2004, the World Health Organization (WHO) launched the World Alliance for Patient Safety, a joint program with various countries to improve patient safety in hospitals. The purpose of this study is to know the relationship between knowledge and attitudes of nurses with the implementation of patient safety in Undata General Hospital of Central Sulawesi Province. The type of this research is quantitative with cross sectional approach-based analytical design. The population in this study was the team leaders and implementing nurses in the rooms of Teratai and Catelia pavilions as many as 52 people. The results of Chi Square test with a confidence level of 95% showed the result of statistical test on the knowledge of nurses concerning the implementation of patient safety was \( p=0.021 \) (\( p \) value <0.05) and the result of statistical test on the attitudes of nurses concerning the implementation of patient safety was \( p=0.025 \) (\( p \) value < 0.05). The conclusion obtained is that there is a relationship between knowledge and attitude of nurses with the implementation of patient safety in Inpatient Wards of Central Sulawesi Province’s Undata General Hospital. The hospital is expected to continuously carry out socialization, organizing better in-depth training on the concept of patient safety by emphasizing the importance of the patient safety system.

Keywords: Knowledge, Attitude, Nurse, Patient Safety

INTRODUCTION

The American Hospital Association (AHA) Board of Trustees identified that patient safety is a strategic priority. A report from the Institute of Medicine stated that there were around 3-16% of adverse events in the service of inpatients in hospitals. WHO launched the World Alliance for Patient Safety, a joint program with various countries to improve patient safety in hospitals. Patients, as the users of health services, have the right to obtain security and safety for themselves while in the hospitals1. But there are aspects that also affect the quality of services in a hospital, and it should be a big concern for the hospital as a service provider. Those aspects are patient safety. Patients not only need quality services but also an assuring condition in which the services provided are safe and do not endanger themselves2.

One of the patient safety cultures is communicating mistakes, reporting errors by sticking to patient safety and learning from mistakes and redesigning a better
patient safety system. To solve the occurring problems, an idea of a proactive analysis system was initiated as a strategy to prevent errors. Safety culture is the dominant factor in the effort to succeed in safety and the key to realize quality and safe services. Almost every medical action holds potential risks. The large types of drugs, examinations and procedures, as well as the large number of patients and hospital staffs are potential factors for the occurrence of medical errors. The occurring errors in the process of medical treatment will result in or potentially cause injury to the patient, it can be in the form of Near Miss or Adverse Events\(^3\).

Undata General Hospital of Central Sulawesi Province is a government-owned hospital. It is a top referral hospital or central hospital which getting a Perfect Pass accreditation for Type B Education hospital. This hospital is able to provide specialist and limited subspecialist medical services. This hospital also accommodates referral services from district hospitals. Preliminary studies conducted in Inpatient Wards of Central Sulawesi Province’s Undata General Hospital on 29 April to 10 May 2016 found the number of nurses in catalia ward was 26 people, and the number of nurses in teratai ward was 28 people. As the results of interview with ward chiefs and team leaders, in terms of knowledge about patient safety, the respondents stated that: patient safety is to save patients from adverse events, two respondents stated to maintain patient safety at the hospital, three respondents stated patient safety is the safety of a patient while being treated at the hospital and it must be identified first. In terms of patient safety goals: they stated that it is to avoid unwanted things to happen in order to ensure the patient’s condition is safe, but the three respondents have not yet mentioned the overall objectives of patient safety.

Whereas in terms of attitude: one respondent stated that he/she had begun to implement even though not as a whole yet, two people stated that they had tried to perform but sometimes forgot the way to implement it, the others stated that they had started to improve but there were those who still did not carry it out due to the lack of understanding, so that continuous socialization is needed.

**Method**

The type of this research is quantitative with cross sectional approach-based analytical design. Data collection was carried out on 8 January 2018 in Undata General Hospital of Central Sulawesi Province. The study used total sampling with the number of respondents reaching as many as 54 people consisting of team leaders and implementing nurses in the Teratai and Catelia Wards. During the data collection process, two respondents were forced to leave because they were taking leave.

**Operational Definition and Objective Criteria**

a. Knowledge is everything that is known, understood and applied by nurses starting from the understanding of the goals and objectives of patient safety regarding the implementation of patient safety in Undata General Hospital. The knowledge falls into ‘good’ category if the score of respondents’ answer is \(> 76\%\).

b. Attitude is the response of acceptance given by nurses in the implementation of patient safety in Undata General Hospital. The attitude falls into ‘good’ category if the score of respondents’ answer is \(> 76\%\).

c. Implementation of patient safety is an effort carried out by responsible nurses related to the implementation of patient safety in Undata General Hospital. Implemented if the answer score is 100.

**Data Collection Techniques**

Data was collected by giving questionnaires to research respondents. The questionnaire in this study consisted of: Knowledge questionnaires using 6 points (32 question items) based on gutmen scale, correct answer was given a score of 2 and wrong answer was given a score of 1. Attitude questionnaires consisted of 15 statements based on Likert scale, the answer choices are \(SS = \text{Strongly Agree}, S = \text{Agree}, TS = \text{Disagree}, STS = \text{Strongly Disagree}\). Scoring for respondents’ answers was: given a score of 4 if answering SS, score 3 if answering S, score 2 if answering TS and score 1 if answering STS. The patient safety implementation questionnaires consisted of 5 questions using the checklist sheet, observation techniques were done according to the answers of the nurses related to their activity in the room.

**Results**

1. **Relationship between Level of Knowledge and Implementation of Patient Safety**

Data collection was carried out for 10 days in Inpatient Wards, namely Teratai Ward and Catelia
Ward of Central Sulawesi Province’s Undata General Hospital. Data collection used the technique of filling out questionnaires and observation sheets. This study used chi square test with 95% confidence level. The results of the research, according to the data collected, are presented in table 1.

<table>
<thead>
<tr>
<th>Level of Knowledge</th>

<td>15</td>
<td>28.8</td>
<td>37</td>
</tr>
</tbody>
</table>

Table 1 shows that 80% (4 people) of respondents with lack of knowledge and 23.4% (11 people) of respondents with good knowledge did not implement patient safety. If analyzed based on the percentage, there were more respondents with lack of knowledge who did not implement patient safety than those with good knowledge. The statistical test results obtained $p = 0.021$ (p value $< 0.05$), so that $H_a$ is accepted. It means that there is a significant relationship between the level of knowledge and the implementation of patient safety.

2. Relationship between Attitudes and Implementation of Patient Safety

<table>

</tr>
</tbody>
</table>

Table 2 shows that 58.3% (7 people) of respondents with lack of good attitudes and 20.0% (8 people) of respondents with good attitudes did not implement patient safety. If analyzed based on the percentage, there were more respondents with lack of good attitudes who did not implement patient safety than those with good attitudes. The statistical test results obtained $p = 0.025$ (p value $< 0.05$), so that $H_a$ is accepted. It means that there is a significant relationship between the attitudes and the implementation of patient safety.

Discussions

Relationship between Knowledge and Implementation of Patient Safety in Inpatient Wards of Central Sulawesi Province’s Undata General Hospital

Table 1 shows that the knowledge of nurses regarding patient safety in inpatient wards was already good, as shown by the results of the study, in which the knowledge of each respondent has been good with a total of 76.6%. The results of the statistical test using the chi square test obtained the value of $p = 0.021$ (p value $< 0.05$), which means that there is a significant relationship between the level of knowledge and the implementation of patient safety.

The results of the study showed that, out of 52 respondents, only 5 people (9.6%) had low knowledge about patient safety. Knowledge is an important factor for someone in making a decision, but someone’s knowledge cannot always avoid them from the occurrence of adverse events. For example, a nurse who has good knowledge does not always carry out patient safety properly because all actions that will be taken are at risk of errors.

Based on the results of observation, such condition was influenced by the compliance of a nurse with the Standard Operating Procedure (SOP) that had been given, leadership role of the leader (Head of Hospital Nursing Division) who continued to monitor and evaluate the actions taken by each implementing nurse, as well as good communication between the ward chief and implementing nurses and also among the implementing nurses in each inpatient ward.

Knowledge is the result of “knowing” and it happens after someone has sensed a certain object. Knowledge is the dominant thing that is very important in the formation of one’s actions. According to the experience of several
studies, it turns out that actions which are not based on a good knowledge will not produce good results. Knowledge is obtained from a collection of information that is systematically connected to each other, so that it has a meaning. Information obtained from data that has been processed (sorted, analyzed and displayed in a form that can be communicated through words, graphics or tables), so that it has meaning. Furthermore, this data will be owned by someone and will be stored in the neurons (becoming a memory) of their brain.

In accordance with previous research by Bawelle, there is a relationship between knowledge of nurses and the implementation of patient safety in inpatient wards of Tahuna City’s Liun Kendage Hospital with \( p=0.014 \). According to the research, knowledge is an important factor for someone in making a decision. The results of another study, which also concerning the relationship between knowledge of nurses and the application of JCI standards regarding patient safety by Ginting (2014), showed a significant relationship between those variables, namely knowledge of nurses and the application of JCI standards regarding patient safety with research results of \( p=0.00 \).

Relationship between Attitudes and Implementation of Patient Safety in Inpatient Wards of Central Sulawesi Province’s Undata General Hospital

The results of the study in Table 2 show that the attitudes of nurses related to patient safety in inpatient wards have been good, as shown by the results of the study where the attitudes of each respondent has been good with an overall number of 80.0%. The results of statistical test using the chi square test obtained the value of \( p=0.025 \) (p value <0.05), which means that there is a significant relationship with the implementation of patient safety.

According to the analysis results, 80.0% of nurses have a good attitude towards the implementation of patient safety in the hospital. According to the researcher, there is a relationship between attitude and implementation of patient safety because it can be seen in the results of the study, in which less than half of the respondents or only 12 people (23.1%) had a good attitude regarding patient safety. Based on researcher’ observation, this condition is influenced by the compliance and responsibility of each implementing nurse over the patient’s safety itself.

An attitude does not necessarily manifest in an action (overt behavior) automatically. To actualize an attitude into a real action, it needs supporting factors or allowing conditions, among others is the facility.

According to Bogardus in Azwar, attitude is a kind of readiness to react to an object in certain ways. The readiness in question is a potential tendency to react in a certain way if an individual is faced with a stimulus that requires a response. Allport in Azwar explained that attitude has 3 main components, namely: Belief in ideas and concepts of an object, emotional life or evaluation of an object, and a tendency to behave. These three components together form a total attitude. This complete attitude determination, including knowledge, thoughts, beliefs, and emotions, plays an important role.

Patient safety is a procedure or process in a hospital that provides safer patient services. It is influenced by the knowledge and application of the implementing nurses who prioritize the interests and safety of the patients. This patient safety procedure greatly guarantees quality improvement of a hospital because a hospital can be assumed to be good if the service for patient safety is also good. The first step to improve quality services is safety, while the key to quality and safe services is by developing a patient safety culture. According to Mitchell in Hughes, nurses are a key in developing quality through patient safety. The effort to build patient safety requires commitment which is influenced by knowledge of the nurses. Nurses who have good knowledge of patient safety certainly have a good attitude in improving quality of health services. This is supported by Majid (2011) who argued that knowledge is the basis of attitude, while attitudes will lead to one’s actions.

Conclusion

This study concludes that there is a relationship between knowledge, attitudes and implementation of nurses with the implementation of patient safety in Central Sulawesi Province’s Undata General Hospital, in which all of them fall into ‘good’ category. The hospital is expected to continuously carry out socialization, organizing better in-depth training on the concept of patient safety by emphasizing the importance of the patient safety system. In addition, the responsible nurses are expected to be able to apply the procedures of patient safety targets in accordance with the Operational Standards of the hospital.
Research Permit

This study did not require ethical clearance because there is no treatment on the respondent. Research only equipped with a research permit from the campus (Public Health Faculty Tadulako University) with the number 2467/UN28.1.30/KP/2018 and from the Undata general hospital.

Conflict of Interest

The authors declare no potential conflict of interest in this research.

Evaluation Factors for Non Medical Treatment Failure Patients Tuberculosis Lung Health in Children on Makassar City

Baharuddin K., Bahtiar, Harliani, Muh Basri, Muh Yusuf M, Sitti Rahmatia, Rudy Hartono

1Department of Nursing, Makassar Health Polytechnic, Indonesia
2Department of Nutrition, Makassar Health Polytechnic, Indonesia

Abstract

The purpose of the study, known factors associated with treatment failure patients Tuberculosis in children. The method used is an observational design, cross-sectional study intended to determine the factors associated between the independent variables (independent) and dependent variable (dependent) with the identification of all the variables. Both of these variables can be seen at the time of execution simultaneously. The findings in this study found that low education, low knowledge and disobedience taking drugs is a factor that has a strong risk of treatment failure patients with pulmonary tuberculosis in children, while family support only protective factor (prevention) and not a risk factor for treatment failure patients with TB in children, The conclusion showed that the variables influencing the failure of treatment of TB patients is variable education and knowledge has a value of OR unchanged at 22.752 in CI 95% to the value of the lower limit (LL) = 1.032 and Upper limit (UL) = 501.786 with a significance level of 0.048 <0.05.

Keywords: pulmonary tuberculosis, failure, treatment, children.

Introduction

In 1993 the WHO to declare TB as a global health emergency, because it is a major health problem worldwide cause of morbidity in millions of people each year and recommends the DOTS strategy as a strategy to control TB. TB is regarded as a community health problem of the world despite efforts to control the DOTS strategy has been implemented since 1995 by the WHO report in 2015, in 2014 there were 9.6 million cases of pulmonary tuberculosis in the world, 58% of TB cases are in Southeast Asia and the Western Pacific Region and 28% of cases are African. In 2014, 1.5 million people worldwide die from TB. Tuberculosis is second only to Human immunodeficiency virus (HIV) as an infectious disease that causes most deaths in the world’s population. Indonesia is a country located in Southeast Asia with the second largest number of TB cases in the world after India14. In 2014 TB cases in India and Indonesia, respectively, are 23% and 10% of cases. Based on the WHO report in 2015, the prevalence of TB cases in Indonesia in 2014, including HIV, 647 per 100,000 population1,3.

According to the Global Tuberculosis Report WHO14, estimated the incidence of tuberculosis in Indonesia in 2015 amounted to 395 cases / 100,000 population and a mortality rate of 40 / 100,000 population (of HIV patients with TB are not counted) and 10 / 100,000 population in HIV patients with tuberculosis.models,according to calculations Prediction based on data tuberculosis prevalence survey 2013-2014. Estimates of the prevalence of tuberculosis in 2015 amounted to 643 per 100,000 population in 2016 and estimates as high as 628 per 100,000 populations1,5.

The incidence of pulmonary tuberculosis is still very high and difficult lowered, this was due to tissues non-medical such as; poverty, poor nutritional state, hygiene, low low purchasing power, low education cause
failures and delays in getting a diagnosis.

Although widely available in TB treatment, but current TB treatment failure remains a major health problem worldwide. Therefore, the objective of this study was to evaluate the non-medical factors that influence the rate of treatment failure patients with tuberculosis (TB) in children Lung Health Center.

Material and Method

This study is a quantitative research with cross sectional approach which has been conducted on June-September 2017 in four health centers in the region of Makassar. The population in this study was all mothers of children (aged 5-18 years) who received treatment of pulmonary tuberculosis at the sites. The samples of this study were all patients within 4-6 months of treatment. Our inclusion criteria are Sementra Tuberculosis patients in treatment, willing to become respondents and the age of 5 -18 years, so that a sample size of 42 respondents, taken by total sampling technique.

Data collection instrument was a questionnaire for respondents observe TB treatment failure. Questioners made by researchers and have tested the validity and reliability using the values of $r$ and $\alpha$ values obtained cronbach of 0.82-4. The method of data collection in this study with a total sampling where the entire population of the research sample4.

Data analysis was performed with the statistical test Ratio Prevalence (RP). RP is characterized by a value of the confidence interval (confidence interval) which will determine whether the ratio of the prevalence of significant or not with the parameters: if the confidence interval passes (not including) the number 1 on the starting point, then the risk factors are meaningfully and if the confidence interval below (cover) number 1 at the starting point, it is not a significant risk factor4. Interpretation of the results of the ratio of prevalence at a value confidence interval (CI) is also based on the value ratio Prevalence (RP) with the parameters: if $RP = 1$, meaning that the independent variable is not a risk factor, if $RP>1$ and CI does not include numbers 1, meaning that the independent variable is a risk factor and if $RP <1$, CI no caps a numeral 1, which means that the independent variable is a protective factor or a deterrent. Data processing was performed using SPSS for Windows.

Findings

This study aimed to evaluate the role of non-medical factors against TB treatment failure in Makassar City Regional Health Center. Of the 42 respondents, the majority were in the age group 16 to 18 years (40.5%). Distriubsi sexes, male 25 respondents (59.5%) and women 17 respondents (40.5%). Most of the respondents graduated from high school (junior and senior) of 27 respondents (64.3%).

Discussion

Data analysis of the 42 respondents obtained through data collection in the health center: Minasa, Batua, Antang and Housing Antang Makassar, the results are as follows:

a. Education Level

Table 9. Shows Bivariate analysis of test results that the value of OR = 39,000 with CI = 95%, P-Value = 0.001 < 0.05, and UL LL = 4.116 = 369.510. The value of RR = 16,200, LL = 2.266 and the value UL = 115.841 does not include the value of 1, then it is said to be meaningful and Ho rejected. Results of multivariate analysis showed the educational value of 22.752 with a level of 95% (P = 0.048 < 0.05) value LL = 1.032 and the value UL = 501.786 does not include the number 1. The test results of bivariate and multivariate test results both showed that education has an influence very strong against pulmonary TB treatment failure in children.

Research\(^1\) explains that the duration of TB treatment should be carried out for 6-8 months. Duration of time can cause the patient to become bored and impatient and cause undisciplined and disorganized to take medication that failed in the treatment, but for patients who have a good knowledge will continue to take medication appropriate treatment program. Further\(^10,11,12,13\) explains that the failure of the treatment and cure TB patients contribute directly to the knowledge acquired through education\(^9,14\).

Education can influence attitudes and behavior of someone who is a product of a learning process carried out consciously. Higher education for someone to be able to change the mindset formed a unified awareness in order to change a healthier lifestyle in everyday life. Although the level of education does not always directly Luru with TB disease yng enough education means not always a determinant of treatment success absoluteness of someone who is suffering from tuberculosis disease or illness Another\(^6,12,13\).

b. Level of knowledge

Shows the results of analysis test Bivariat that the value of OR = 39,000 with CI = 95%, P-Value = 0.001 > 0.05, the value LL = 4.116 and the value UL = 369.510, the value of RR = 16,200, the value LL = 2.266 and the value UL = 115.841 not menckup value of 1, then it is said to be meaningful and Ho rejected. Multiavriat test results show the value of the knowledge of 22.752 with a level of 95% (P = 0.048 < 0.05), values LL = 1.032 and the value UL = 501.786 does not include the number 1. Thus both bivariate and multivariate testing both show
that the level of knowledge has a very strong influence of treatment failure.

Knowledge is the result of the know and this occurred after people perform sensing on a particular object\(^9\),\(^11\). Knowledge is very important in shaping the mindset, attitudes and behavior and actions of a person. Health knowledge can help individuals to adapt to the disease, preventing complications and learn to solve problems when faced with a new situation.

Knowledge of TB patients about the disease are factors that affect the incidence of TB suffered by a patient, therefore, a good knowledge of the illness will make the patient aware and determined to do what should be done and so is what should not be done so as to maintain and avoid events worse, and when not protecting and maintaining health, in line with the research. Instead minimal knowledge about the illness, can not in itself raise awareness for the need for regular medical treatment. Within their health development goals to improve public health\(^5\),\(^7\),\(^8\).

c. Noncompliance Drink Drugs

Results show that the value of \(OR = 27.00\) with 95% CI, 0.004 P-Value, the value LL = 2.946 and the value UL = 247.487. The value of \(RR = 13.235\), value LL = 1.842, the value UL = 95.093 does not include the value of 1, then it is said to be meaningful and \(H_0\) rejected. Results of multivariate analysis showed noncompliance value of 18.538 with a level of 95% \((P = 0.049 <0.05)\) value LL = 1.007 and the value UL = 341.215 does not include the number 1. Both bivariate test results multivariate testing results show that the non-compliance has to take medicine strong influence on lung TB treatment failure in children while suffering from tuberculosis.

Compliance TB patients take medication regularly and on time is a crucial factor in the healing process Tuberculosis\(^13\). Compliance includes: schedule time to take medication, taking medications according to the number, type of drug, the dosage is in etiquette drug, drug spending, came to the health center regularly taking medication before the medicine runs out and always remember the advice of health officials. In line with the research that has been done by Muniroh et al that the results show the value of P-Value = 0.001 \((P <0.05)\).

The high rates of treatment compliance due to the high level of motivation, education and knowledge, and understand the importance of health; it is also inseparable from the patient’s awareness of the importance of healthy living. which says that the use of Anti-Tuberculosis Drugs (OAT) improper / irregular or interrupted treatment can lead to drug resistance of Mycobacterium tuberculosis\(^3\),\(^5\),\(^8\),\(^10\). The other variable factors cause patients do not regularly seek treatment even stopped the treatment prematurely, namely the emergence of drug side-effects such as vertigo, nausea, vomiting and headache, which eventually gives rise to non-compliance, trust factor, factor bustle and lacking / not understand the reaction of the drug in the body. TB treatment takes a long time (4-6 months) to achieve healing and with a guide (a combination of) several kinds of drugs, so it is not uncommon patients stop taking medication before the treatment is completed which resulted in treatment failure\(^1\),\(^6\),\(^10\),\(^12\).

Conclusion

There is a relationship with the education level of TB disease treatment failure in bivariate and multivariate analysis at 95% confidence showing OR value and the value of LL and UL> 1 so that the level of education is a risk factor for TB disease treatment failure in children.

There is a relationship with the knowledge level of TB disease treatment failure in bivariate and multivariate analysis at 95% confidence showing OR value and the value of LL and UL> 1 so that a low level of knowledge of a risk factor for TB disease treatment failure in children.

There is a relationship Take medication adherence with treatment failure of TB disease, the bivariate and multivariate analysis at 95% confidence showing OR value and the value of LL and UL> 1 so that non-compliance with taking medication is a risk factor for TB disease treatment failure in children.

There is no family support relationship with TB disease treatment failure, the multivariate analysis showed 95% CI indicates the value of OR and LL and UL<1 so that family support is a protective factor rather than as a risk factor for TB disease treatment failure in children.

Conflict of Interest Statement

This study there was no conflict of interest between the researcher and the subject.
Source of Funding

This research was funded independently by researchers, because they did not get sponsorship from other institutions.

Ethical Clearance

This study received ethical recommendations from the health research ethics commission of the Makassar Health Polytechnic No. 390/KEPK-PTKMK/S VII/2017.

Challenges in Performance Enhancement – Work Related Variables, Performance Link in Indian Manufacturing Sector

S. Umamaheswari

Assistant Professor, School of Management Studies, Sathyabama, Institute of Science and Technology, Chennai

Abstract

Producing of quality products at a reasonable cost mainly depends on the employees enhanced performance. Organizations keen in evaluating the factors most related to enhancement of performance. This study explores the link between the work related factors like work environment, organization commitment and training and development with performance of employees in ceramic sanitary ware factories in India. A sector which is unattended in the context of employee performance. It also verifies relative significance of the factors. Statistical tools were used for analysis. Findings reveal that all the three factors are positively linked to the performance enhancement and training and development is the strongest predictor and work environment is the weakest. Implications, suggestion for future research discussed.

Keywords: Work environment, Organization commitment, Training and Development, performance of employees, performance enhancement

Introduction

The success and failure of an organization mostly relied on the performance of work force in the present competitive business environment. Since Organization’s development is mostly relied on the employees performance as it affects profitability\(^1\) and lack of required performance affects organization’s survival\(^2\), better performance is very important for overall organizational improvement.\(^3\) As economies of business get more complex people, productivity will become an important criterion leading to more pressure on under performers.

World bank alsoindicated thatIndian needs to improve manufacturing sector performance to return to high growth path\(^4\). Industrialization provides more opportunities for high performers job-hops, organizations are necessarily to enhance performance of existing employees. This induced Indian companies to declare war on under performers and performance enhancement become a major challenge for manufacturing industries to find out all possible ways to improve their employee’s performance. Several researchers on performance of employees had been carried out and work related variables like work environment\(^5\), organization commitment\(^6\), training and development\(^7\), performance appraisal\(^7\), engagement and leadership\(^8\) are closely associated with performance enhancement.

This study analyze the linkage of work environment (WE), training and development (T&D) and organization commitment (OC) on performance of employees, working in ceramic sanitary ware factories in India, a sector which is unattended in the context of employee performance (EP), though this industry contributes substantially to national income and provide employment to considerable number of work force and tries to fill-in the gap in the literature.

Motivation to Research

Ceramics is a diverse industry and contains several categories of products, including sanitary ware. Ceramic segment has recorded remarkable growth in the last 20 years and emerged as a major producer and supplier in the world market. The Indian Ceramic

DOI Number: 10.37506/v10/i12/2019/ijphrd/192159
Industry ranks at 8th position in the world and produces around 2.5% of global output. The industry provides employment to 550,000 people, of whom 50,000 are directly employed and accounted for 13% growth and valued approximately INR 10,000 crores in year 2017. Availability of abundant raw materials and availability of labours for lesser pay and opportunities exists in the sanitary ware market, attracted manufacturers and paved way for the new comers to start manufacturing units and also guided the leading players to expand their units in India.

These are all increased the requirement of workforce and performance enhancement of employees has become a major issue to be tackled by this industry and to ascertain the factors which can increase the performance of employees.

**Review of Literature**

**Organization commitment and Employees Performance**

Commitment creates psychological links between organizational goals and employees goals and results in better performance. Because of desirable outcomes organization commitment is gaining more attention now-a-days for the people and organization. It is an emotional reaction towards organization policies and satisfaction over organization policies increases employee’s dedication to work, in turn improves performance. The previous studies relating to organization commitment and performance of employees given evidence that there exists positive relationship between them. The above findings gives evidence that organization commitment is an important factor closely related to employee performance and the hypothesis is as follows.

\[ \text{H1: OC will be positively related to employee performance} \]

**Work environment and Employees Performance**

Motivating environment is necessary to utilize employee’s full potential, and work environment increases employee’s job satisfaction level, consequently the achievement of organization goals. The right environmental factors, both physical and Psychosocial will lead to increased performance and in manufacturing sector also there exists positive impact on employees performance. Several researchers on working environment establish a positive relationship with employee performance.

From the previous studies it is concluded that working environment is an important determinant of employee’s performance and hypothesis is follows

\[ \text{H2: WE will be positively related to employee performance} \]

**Training And Development and employee performance:**

Training improves skills and efficiency of employees results in improved performance hence organizations are investing on training program which will be justified by greater productivity.

Numerous researchers given evidence that training is closely linked to performance of employees as it prepares employees to do the work as desired by the organization. According to, employees technical skills inter personal skills and solid knowledge for performing their works effectively and efficiently increased by training and lack of training results in low performance. Thus T&D plays a recognized role for both work and personal improvement and significant positive relationship with EP.

From the previous studies it is concluded that T&D is an important determinant of employee’s performance and hypothesis is follows

\[ \text{H3: T&D will be positively related to employee performance} \]

**Methodology**

**Sample and procedure**

The study focuses on ceramic sanitary ware factories in India. Given the difficulties in getting permission researcher successfully received permission from 5 factories located in different places in India. After arriving total sample size as 550 and also size for each factory, questionnaire were distributed to employees by researcher with the help of some HR staffs during break hours and 416 usable questionnaire were received back, representing a response rate of 75%. The selection of the respondents was based on the simple random sampling. Around 81% of the respondents were of 25-45 age group and 73% of them possess post graduate and professional qualification while 57% of the respondents falls under
5-15 years of experience. Regarding designation, middle level managers were dominating in the industry and majority of them belong to production department.

**Measurement**

Independent variables proposed in this study are WE, OC and T&D. The outcome variables is EP. Totally 24 questions exists in the questionnaire besides questions related to personnel details.

Work environment was measured utilizing 5 items adopted from\(^\text{23}\). The example items are “overall this organization is a harmonious place to work” and “workers and management get along in this organization”. The reliability coefficient (α) for the items is 0.707 which is above the acceptance level of 0.700 and provides support to the items.

Training and Development was measured using 7 items adopted from\(^\text{24, 23}\). The reliability coefficient for the items (α = 0.800) gives good level of support to the items. Example items are “I have the opportunity to be involved in activities that promote my professional development” and “people are properly oriented and trained upon joining this organization”.

Organization commitment items were adopted from\(^\text{25}\), that consists of 9 items. The reliability coefficient (α = 0.846) gives good level of support to the items. Examples items are “for me this is the best of all possible organizations for which to work” and “I find that my values and the organization’s values are very similar”.

Finally employee performance was measured using 3 items adopted from\(^\text{26}\). Example items are “I met formal performance requirements” and “I performed all tasks that were required of me”. The reliability coefficient for the items is 0.703 which is above acceptable limit of 0.700. Respondents were asked to respond the questionnaire on a likert- scale range from 1- 5, 1 = strongly disagree and 5 = strongly agree. Statistical package for the social sciences (SPSS) has been employed for analyzing the data’s collected.

All the items were subjected to an assessment of content validity as per the procedure described by.\(^\text{27}\) A correlation matrix (item by item) of the data was calculated and that matrix was subjected to principle component analysis. A commonly used rule specifies that only variables with loadings greater than 0.40 on a factor should be considered “significant” and used in defining that factor. The factor loadings of all the items were above 0.40 with no major cross loadings and taken for analysis.

**Results**

<td></td>
<td></td>
</tr>
</tbody>
</table>

*p< 0.05, **p<0.01
To determine the relationship between proposed factors and EP, all the factors regressed simultaneously and the results are tabulated in Table 2. As shown in Table 2, the proposed factors exhibit significant amount of variance in EP ($R^2 = 0.516, p=0.000$). The proposed factors WE and OC were significant predictors of EP and provide support to the hypothesis $H_1$, $H_2$. The strong predictor is T&D ($\text{beta} = 0.515$) and the weak is WE($\text{beta}=0.088$).

**Discussion**

The purpose of this study was to check the impact of WE, OC and T&D over EP among employees of ceramic sanitary ware factories in India.

The Multi linear regression proposing EP as dependent variable and the proposed factors as independent variables show that all the three factors are positively related to employee’s performance. Employees are influenced by present day business environments and this will have reasonable impact on the factors influencing EP. The result of the study indicates that proposed factors explained 51.6% of variance in EP. This signifies that all the proposed factors are influential and crucial and need to be given top priority for better performance of employees. The findings that indicates T&D as the strongest predictor of EP coincides with earlier findings of and can be justified as follows. Training improves skills of employees and training program shapes the employees to work efficiently and effectively to reach the goals of organization results in monetary benefits to employees - This also emotionally induces to work hard, simultaneously increasing their Performance.

The next permanents factor is OC and coincides with, since committed employees feel that they are members of organization and organization is interested on them and this attitude makes them to work sincerely exerting utmost efficiency and this act as a driving force for their better performance.

The next predominant factor positively related to EP is WE and this coincides with previous findings of and this may be due to the fact that employees, while joining, to unfold their capabilities expect favorable working condition. Positive perception towards availability of such favorable working conditions, gives them satisfaction, which leads to dedication in their work, consequentially improves performance.

In summary HR managers need to extent their support to the factors T&D, OC and WE to improve employee’s performance.

**Conclusion, Implication and Future Study**

Although, performance enhancement is very essential, only few studies were carried out in Indian manufacturing industries and practically no research was carried out in the fast growing ceramic sector and this research fills the gap.

The findings provide empirical evidence that T&D, OC and WE are positively related to performance of employees of ceramic sanitary ware factories in India. The research also reveals that T&D is stronger predictor and weaker predictor is work environment. Factory managers are advised to take all measures to provide needed training programs to employees along with providing favorable working conditions. Also periodical meetings may be conducted to generate better understanding and relationship with employees. Future study is proposed for conducting research on other manufacturing industry and using other variables for getting more specific results.

Reliability and Validity of WHOQOL-BREF into Indonesian Version as a Measure of Quality of Life of Tuberculosis Patients

S. N. Anisah\textsuperscript{1}, R. Djuwita\textsuperscript{1}

\textsuperscript{1}Faculty of Public Health, Indonesia University, Depok, West Java, Indonesia

Abstract
Tuberculosis is one of the infectious disease as a public health problem in Indonesia. Tuberculosis causes high pain, disability, and a high level of death. This causes the quality of life of Tuberculosis patients. The WHOQOL-BREF is a special instrument which was widely used to measure the patients’ quality of life. The objective of this study was to assess the validity and reliability the Indonesian version of WHOQOL-BREF for measuring quality of life of Tuberculosis patients. A descriptive cross-sectional design with 30 subjects was conducted at Duren Sawit Public Health Center, East Jakarta, DKI Jakarta, Indonesia. Data collection was carried out on 11 to 15 of July 2017. The validation process included internal consistency, discriminant validity and construct validity. All of the domains met the reliability criteria (Cronbach-\(\alpha\) was \(\geq 0.6\)). The results showed the \(r\) table value>0.361 and the value of Cronbach's Alpha=0.880. The score distribution of each domain from WHOQOL-BREF is symmetrical and there is no floor or ceiling effect. Internal consistency, discriminantand construct validity shows good results from the fourth domain score.

Conclusions: The Indonesian version of WHOQOL-BREF is a valid and reliable questionnaire for measuring the quality of life of Tuberculosis patients.

Keywords: Indonesia.WHOQOL-BREF, Tuberculosis, Validation.

Introduction
Tuberculosis is a diseases that affects many people in the world. In 1992, the World Health Organization (WHO) declared TB as a “Global Emergency”\(^{(1)}\). In Indonesia, Tuberculosis is a disease as the highest contributor to the disease burden. Tuberculosis can affect the patients’ quality of life (QOL), such as psychological, physical, social functioning\(^{(2)}\).

WHO compiled the WHOQOL-BREF which is a short version of WHOQOL-100 that consists of 24 facets covering 4 domains (physical health, psychological, social relationships, and environment) and also measures 2 facets of QOL (overall QOL and general health)\(^{(3)}\). Although the WHOQOL-BREF has been used in 23 other countries\(^{(4)}\), the use of WHOQOL-BREF for Tuberculosis patients is still not widely practiced, especially in Indonesia. The Quality of life of Tuberculosis patients is very important to note because this infectious disease is chronic which has a wide impact on all aspects of life. Chronic illness not only affect the individuals concerned but also the whole family\(^{(5)}\).

With the differences in ethnicity, culture, and language background, it is considered very important to evaluate validity and reliability of WHOQOL-BREF in the Indonesian version. This study aims to assess the validity and reliability of the WHOQOL-BREF to measure the QOL of Tuberculosis patients.

Material and Method
Subjects of this study were patients who diagnosed as new pulmonary Tuberculosis patients bacteriological confirmed at Duren Sawit Public Health Center, East Jakarta, DKI Jakarta, Indonesia, aged more than 15 years,
which had complete medical records and is willing to be a research respondent by signing an informed consent.

The study was carried out using a cross-sectional design. The technique of obtaining samples is by purposive sampling, that is, every Tuberculosis patients at Duren Sawit Public Health Center, which fulfills the research criteria is selected and included as research respondents. Data collection is carried out by 11 enumerators who have received training. The types of data collected are primary data, namely quality of life and other variables related to research. Data collection was conducted on 11-15 of July 2017.

Frequency analysis performed to illustrate the characteristics of respondents. The domain and facets of WHOQOL-BREF data was presented as descriptive data with means and standard deviations (SD), floor and ceiling effects. The floor and ceiling effect>20% of the sample size was significant, indicating that the measurement was limited to a few questions from WHOQOL-BREF\(^{(6)}\).

Internal consistency of each domain was assessed using Cronbach’s Alpha and the contribution of each question to the total Alpha. The Cronbach’s Alpha value is calculated by comparing the r table value for a sample of 30 respondents (r=0.361) with the corrected item-total correlation value\(^{(7)}\) and the reliability test results by looking at the Cronbach’s Alpha value (cut off point=0.6)\(^{(8)}\). The discriminant validity is carried out to determine the ability of the score of each domain to distinguish healthy and unhealthy respondents, tested by using the t-test\(^{(9)}\). According to Hair JF., et al. as cited by Ch. SalimO, et al.\(^{(10)}\) construct validity is tested by using principal component analysis to assess this questionnaire is valid as a questionnaire to measure the QOL. Each question must have a minimum loading factor value of ±0.3. Factor loading ±0.4 is more important (loading), loading >±0.5 is practically significant. Furthermore, the eigenvalue value was used to explain the variations of the question item of the domain, the eigenvalue of >1.0 is meaningful.

Findings

The Indonesian version of the WHOQOL-BREF was created as instruments to measure QOL of Tuberculosis patients. The WHOQOL-BREF in original version was developed as a general psychometric properties by WHOQOL group that would be applicable cross-culturally\(^{(5)}\).

Subjects in this study were new pulmonary Tuberculosis patients bacteriological confirmed at Duren Sawit Public Health Center. Table 1 presents the subjects’ characteristics in this study. Subjects analyzed consisted of 13 (43.3%) men and 17 (56.7%) women and age ranged from 19-69 years with a mean of 40.1 years (SD=14.7). The formal education is mostly 17 (56.7%) with high school education and only 1 (3.3%) uneducated. A total of 14 (46.7%) employed and 16 (53.3%) unemployed. Most married 22 (73.3%) and 8 (26.7%) were not married/divorced/widowed.

Table 2 shows that the mean score of the physical health was 3.2 (SD=0.8), the psychological was 3.6 (SD=0.7), the social relation was 3.4 (SD=0.8) and the environmental was 3.4 (SD=0.6). The value for each domain, the median value is close to the mean value, this means that the distribution of the values of each domain is almost symmetrical approaching the normal distribution. The percentage of floor and ceiling values for each domain is quite low (<20%) ranging from 2.1-18.9%.

Discussion

Based on findings above, women were more found than men in distribution of Tuberculosis patients. Previous study in Pakistan by Codlin AJ., et al. (11) also found more women as Tuberculosis patients than men. According to Nurjana MA. (12), the proportion of Tuberculosis sufferers was found to be almost comparable between male (1.9%) and female (1.8%).

The age of productive patients (15 - 54 years) in this study was 22 years (73.3%). Similar results with research of Hafidah Z., et al. (13) stated that 70% of Tuberculosis patients were in productive age. Ministry of Health Republic Indonesia (1) states that risk factors for pulmonary Tuberculosis are in the productive age (15-54 years).

Formal education of respondents in this study mostly 17 years (56.7%) have the high school education and only 1 (3.3%) uneducated. This result is in accordance with previous research conducted by Adnan, et al. (14), Tuberculosis patients are found at the high school level (45.9%). Likewise also stated by Hafidah Z., et al. (13), that 35% of Tuberculosis patients have high school education. The higher the education of a person, the better knowledge of Tuberculosis, so they can prevent it from being infected and have treatment efforts when infected with Tuberculosis (15).

Respondents in this study were 14 (46.7%) employed and 16 (53.3%) unemployed. The same study by Abror I., et al. (16), 77.3% of Tuberculosis patients do not work after illness. Research conducted by Tinartayu S., et al. (17) also found that the most patients with pulmonary Tuberculosis (72.2%) did not have a permanent job.

Respondents in this study mostly married 22 (73.3%) and 8 (26.7%) were not married/divorced/widowed. In a previous study in Aceh by Hafidah Z., et al. (13), showed that there were many Tuberculosis patients who are married (80%). Research by Abrori I., et al. (16) also found 59.1% of married Tuberculosis patients and 18.2% were unmarried and 22.7% divorced.

In this study, the floor and ceiling effects for each domain are quite low (less than 20%) ranging from 2.1-18.9%. This picture shows that the response of the Tuberculosis patients to the 26 questions of WHOQOL-BREF quite well. A questionnaire must produce a minimal floor and ceiling effect so that it can be recommended to measure a phenomenon (4).
The WHOQOL-BREF shows good internal consistency values, where the Cronbach’s Alpha coefficient of the magnitude domain ranges from 0.742 to 0.860; physical health, psychological, social relation and environmental domains show strong internal consistency (>0.60). The Cronbach’s Alpha coefficient value for each item ranges between 0.828-0.862 for the physical health, 0.741-0.833 for the psychological, for the social relations ranges from 0.529-0.843 and 0.831-0.862 for the environmental. Cronbach’s Alpha value is low (<0.60) if the domain consists of only a few questions. The social relations domain consists of only 3 questions while the physical, psychological and environmental domains consist of 6-8 questions. Non-different results were shown in the study conducted by Ch. Salim O., et al. (10) for the elderly who got the Cronbach’s Alpha coefficient value for each social domain item ranging from 0.10 to 0.69. The results of this study show overall WHOQOL-BREF is reliable (consistent) to measure the QOL in Tuberculosis patients.

Discriminant analysis shows the average score of all four domains in healthy Tuberculosis patients is greater than in those who are unhealthy. Studies conducted in Taiwan(18), in 23 other countries(4) and Ch. Salim O, et al.(10) in Jakarta showed consistent results, WHOQOL-BREF is a valid questionnaire to measure a person’s QOL.

Most of the questions from WHOQOL-BREF have a factor loading value >0.5, meaning that the question is meant to be included in the domain. The four domains of WHOQOL-BREF were able to explain variations of data collected by 53.06-67.88%. These four domains are able to present one’s overall QOL(19). The distribution of the 26 questions from WHOQOL-BREF was symmetrical and the results showed that the WHOQOL-BREF was valid and reliable to measure the QOL in Tuberculosis patients.

Conclusion

Characteristics of Tuberculosis patients were more on productive age, female, high school education, unemployed and married. Overall WHOQOL-BREF is a valid and reliable questionnaire for measuring the QOL Tuberculosis patients. In each domain of the WHOQOL-BREF, the distribution of scores is almost symmetrical and there is no floor or ceiling effect.

Relationship Individual Factors with Sickness Absence in Hospital

Samsul Arifin¹, Abdul Rohim Tualeka²

¹Department of Occupational Health and Safety, School of Public Health, University of Airlangga.
²Department of Occupational Health and Safety, School of Public Health, University of Airlangga.

Abstract

Background: Workers in health industries are more likely to have health problems. Health problems may result in sickness absence. High rate of sickness absence can decrease productivity and consumer satisfaction.

Objectives: To analyse individual factors with types of sickness absence.

Method: Retrospective study design. Data collection was done using secondary data in the form of sickness absence data report of hospital in 2017. A binary logistic regression test was used to identify the significance of correlation of age, sex, years of service and marital status correlation with types of sickness absence.

Results: Of 416 workers, 100 people submitted 163 sickness absence letter with the total of 653 days. Women workers with age range of 26-45, who were married and with 5 years of service were the group with the most sickness absence. Short term sickness absence was the most common type. The results of multivariate binary logistic regression showed that age (p value = 0.659 and Exp (B) = 0.783), sex (p value = 0.929 and Exp (B) = 0.945), years of service (p value = 0.620 and Exp (B) = 0.866), marital status (p value = 0.773 and Exp (B) = 0.837) variables were not significant.

Conclusion: There is no significant relationship between individual factors and type of sickness absence.

Keyword: sickness absence, workers, hospital

Introduction

Based on Canadian Institute for Health Information (CIHI) in 2000, workers in health care are 1.5 times more likely to call in sick or leave work on disability compared to workers in industries other than health care. The average duration of 11.8 days of sickness absence is higher than workers in other fields which is 6.7 days.¹

Unhealthy workers are prone to sickness absence. Sickness absence is divided into 2 types. Short term sickness absence (fewer than 4 days) and long term sickness absence (longer than 4 days). Short term sickness absence is more common than the long term one. Long term sickness absence is generally caused by serious or severe illness.³ It is important therefore to identify individual correlation factors with the types of sickness absence.

The objective of this study is to analyse the individual correlation factors with the types of sickness absence of workers in hospital X in 2017.
Method

This type of research is an observational analysis study with a retrospective research design. The population is workers who call in sick in hospital in Malang, Indonesia. During the period of 2017, the total number of workers was 416 people with 100 workers submitted sickness absence, amounting to 163 sick letters (spell) and 653 days of sickness absence. The research variables studied included the characteristics of workers, namely age, sex, years of service and marital status, and types of sickness absence. Data collection was carried out using secondary data in the form of hospital worker’s sickness absence data in 2017. The data obtained were analyzed descriptively using cross tabulation. Binary logistic regression test was used to test the significance of parameters in a multivariable manner.

Findings

The frequency distribution of hospital workers by age can be seen as follows (see Table 1). Based on table 1 it can be seen that 56 people (56%) who submitted sickness absence were in the age group between 26 to 45 years.

<table>
<thead>
<tr>
<th>Age</th>

<td>4</td>
</tr>
</tbody>
</table>

Most of the workers (79%) submitted short term sickness absence (see Table 5).

Nagelkerke R Square in Table 6 shows a value of 0.16 or 16%. This means that the dependent variable can be explained by 16% independent variables. That is, all independent variables affect the dependent variable simultaneously in the range of 16%, while 84% are influenced or explained by variables not included in this study.

**Discussion**

As many as 56% of workers who submitted sick letters were aged 26-45 years. This is consistent with a cross sectional study conducted on 1200 workers by Sorevi et al (2013) at Mazandaran university hospital, where the frequency of sickness absence was most common among workers aged 38 - 41 years.\(^{(4)}\) Likewise, the study conducted by Isah et al (2008) concluded that the number of sickness absence was significantly correlated with the age of workers.\(^{(5)}\)

Of the 100 people who submitted sick letters, 79% of them were women. This is consistent with a 602 nurse cross sectional study in Brazil in 2008-2012 conducted by Marques et al (2015) which stated that 92.9% of sickness absence were female nurses.\(^{(6)}\) According to Kurniawidjaja (2010), female workers, especially those who are married, are more often called in sick because they have multiple roles, that is, aside from work duties, they also have to provide domestic services to their children and husbands, plus the role of educating children so that they have no problems in their studies.\(^{(6, 7)}\)

About 73% of those who called in sick were married. According to Kurniawidjaja (2010), sickness absence of married workers is related to household problems such as divorce, children and workload. In fact, women who are married have a higher sickness absence or absenteeism in general, and non-medical factors are thought to contribute.\(^{(7)}\)

Workers with the years of service less than 5 years submitted most sick letters, amounting to 61%. This is consistent with the research of Linggarwati et al (2017) which stated that workers with short years of service will be more likely to be absent which may be because they are still adjusting to the environment and workplace conditions. Workers who have worked for years have better attendance because they do not need to adjust to the environment or working conditions.\(^{(8)}\) According to Kurniawidjaja (2010), workers with longer years of service usually have fewer sickness absence than those who have worked for less than a year, presumably because older workers have better working relationships.\(^{(7)}\)

79% of workers submitted short term sickness absence. This is in accordance with Kurniawidjaja’s opinion which stated that 80-90% of sickness absence are short-term ones. Usually, short-term sickness absence is acute and mild in nature, such as diarrhea, red eye disease, common cold or sore throat. However, if it occurs 12 times or more in one year, for example 3 to 6 times in 3 months, the risk factors and pattern need to be analyzed both medically and non-medically.\(^{(7)}\) The study conducted by Tripathi et al (2010) on 385 nurses in India concluded that two-thirds of sickness absence were short-term absences and this was attributed to the low morale of workers.\(^{(9)}\)

Based on variable statistical test, age, years of service, gender and marital status did not significantly influence the types of sickness absence. This was consistent with studies conducted by Mollazadeh et al (2018) in hospital workers in Iran, which concluded that there was no correlation between sex and marital status with workers’ absenteeism.\(^{(3)}\) This result is also supported by a research conducted by Linggarwati (2017) concluding that sickness absence does not have a significant relationship with age, gender, years of service and level of education. From the results of statistical tests, the variables of age, years of service, gender and marital status have an effect of about 16%, while 84% are influenced or explained by variables not included in this study.\(^{(6)}\) According to Kurniawidjaja (2010) there are 3 factors influencing sickness absence, which are individual factors, geographical factors and organisational factors.\(^{(7)}\) The unanalysed factors of this study include geographical factors, comprising of climate, ethnicity, epidemic, insurance system, retirement age. While organisational factors include company scale, work type, occupational hazard, work shift, personal policy, health facility and industrial relationship. While the individual factors that have not been analyzed from this study are job satisfaction, distance of travel to work, social activities.
Conclusions

Based on the results of the analysis it can be concluded that there is no significant relationship between individual factors with the types of sickness absence. Limitations in this study are limited to only a few individual factors. Subsequent research will be better if it is complemented by the inclusion of variables of organizational factors and geographical factors in the analysis of sickness absence.

Conflict of Interest Statement: The authors of this research declare that there is no conflict of interest related to this study.

Source of Funding: All funds used to support this research comes from the researchers themselves.

Ethical Clearance: Because it uses secondary data using an ethical test is not needed.

Does E-health have a role to play in HIV-AIDS programmes?

Shayhana Ganesh*

DUT Research Associate, Faculty of Management Sciences, Durban University of Technology, South Africa

Abstract

The new buzz word in the healthcare industry is Electronic health or E-health. This plays an important role in making services more accessible and person-centred, as well as improving the operations and financial efficiency of health systems. Unequal access to technology means not everyone can benefit from e-health initiatives, so addressing its limitations is also important. E-health interventions can benefit clinicians and patients, enabling outreach to key populations and improving the exchange of information between health service providers and their patients.

Keywords: HIV-AIDS; Electronic health or E-health

Background

Global new HIV infections have declined by just 18% in the past seven years, from 2.2 million in 2010 to 1.8 million in 2017. Although this is nearly half the number of new infections compared to the peak in 1996 (3.4 million), the decline is not quick enough to reach the target of fewer than 500,000 by 2020. E-health interventions are already being used within the global HIV response. Telehealth or telemedicine refers to a practice whereby technology is used to enable a health worker to interact with an individual when they are separated by distance. The uses of digital games that include elements of game playing (gamification) are rapidly becoming an important tool for improving health behaviours and supporting the delivery of care and education. Social media, such as Facebook, Twitter and YouTube, provide interactive platforms for individuals, communities and organisations to share and discuss content, debate issues and promote new ideas.

Methodology

A retrospective literature review of all available local South African data on E-health was conducted to assess enablers and barriers to its use in HIV-AIDS clinics and programmes. Data reviewed showed various levels of E-health utilisation in HIV-AIDS programmes. SMS notifications were common often used as adherence reminders for treatment compliance. Social media was also a key player with interactive programmes for awareness and education campaigns aimed at HIV-AIDS.

Findings

The digital divide of barriers and limitations to technology and e-health in HIV programming is growing exponentially as several patients and service providers make e-health practises part of their daily lives. E-health holds significant benefits to consumers aimed at their disease education, awareness and advocacy. There are also significant benefits to clinicians aimed at enhancing networking and collaboration on difficult patients. A potential drawback of e-health is loss of human contact which is preferred by certain healthcare providers and their patients. It is important to also single out the potential cost and accessibility of internet access to all within their reach. New technologies and new applications of technologies open up a whole range of possibilities for the HIV response with the potential to be extremely effective if they are designed, used and targeted properly. Finally the potential legal issues coupled with privacy issues are also potent reasons for correct corporate governance regarding e-health and programme management, in particular for HIV-AIDS programmes.
Discussion

The use of E-health in HIV-AIDS programmes can result in the generation of tools, frameworks and approaches toward holistic integrated HIV-AIDS care and prevention. If appropriately implemented within the correct regulatory and governance channels-health can be a very beneficial tool to allow optimal treatment outcomes for healthcare workers and patients alike.

Conclusion

E-health has the potential to revolutionise HIV-AIDS healthcare and assist in achieving the UNAIDS Millennium Development goals. It is important to ensure the correct implementation of E-health platforms to allow early gains to be made in the HIV-AIDS prevention arena.

A Feasibility Literature Review, to Explore the Need to Undertake a Study, to Assess the Level of Knowledge and Awareness of HIV Pre-exposure Prophylaxis (PrEP) as an HIV Prevention Modality, Among Young Adults Attending Institutes of Higher Learning in Durban, Kwa-Zulu Natal, South Africa

Shayhana Ganesh*

DUT Research Associate, Faculty of Management Sciences, Durban University of Technology, South Africa

Abstract

HIV-AIDS is an alarming health concern both globally and locally which continues to increase, despite efforts to curb the epidemic. The rate of new infections is the greatest in the younger age group between 18-35 years of age with women being more infected than men. In the absence of a cure for the disease, the mainstay of clinical management involves adherence to lifelong anti-retro viral (ARV) therapy. Another integral component in trying to decrease new HIV infections is enhancing HIV-AIDS prevention modalities. These approaches have grown through the years and range from local to systemic forms either singly or in combination with other therapies. An emerging potentially viable option is Pre-exposure prophylaxis (PrEP). This form of therapy is the ingestion of a type of ARV on a daily basis by an HIV-Negative individual to remain HIV free. There are several clinical trials ongoing and past that have shown efficacy for use in adults and primarily in young adults. The rollout of PrEP as prevention modality globally has commenced and South Africa stands on the brink of roll out for high risk and young adults through the South African Department of Health ARV treatment programme. It is thus imperative that a study to explore the level of knowledge and awareness of HIV pre-exposure prophylaxis (PrEP) as an HIV prevention modality among young adults occurs in order to assess readiness for implementation in order to identify potential challenges with recommendations for smart practices.

Key words: HIV-AIDS; Pre-exposure prophylaxis (PrEP).

Background

South Africa is home to one-sixth of the world’s population living with HIV and has the largest antiretroviral therapy (ART) programme in the world. ART roll out began nationally in late 2003. By the middle of 2008, 568,000 adults and children were receiving ART, and, at present, over 1.5 million children and adults receive antiretrovirals every day. The latest treatment guidelines recommend earlier initiation of therapy for certain patients, thus increasing the numbers eligible for ART and widening the gap between those in need of treatment and those receiving it. Global efforts to end HIV-AIDS have spanned since almost 20 years and still any form of a cure or effective HIV prevention modality remains at large. The newly coined term of HIV-AIDS combination prevention approaches have been shown to increase HIV-AIDS programme effectiveness. These combination prevention packages utilise a variety of prevention mechanisms to best suit the patient and the community concerned, in order to develop a tailor made intervention approach to curb the HIV incidence in that particular community. Several studies have shown that antiretroviral drugs prevent HIV infection. Treatment for prevention in particular provides hope...
as a promising new HIV prevention technology that can empower women to protect themselves from HIV-AIDS\(^2\). The new anti-retroviral drug, Tenofovir, alone or in combination with 200 mg of Emtricitabine can decrease the chances by 50% or more among persons with high adherence to the regimen, with demonstrated efficacy in men who have sex with men, heterosexuals, and injection-drug users\(^3\). Pre-exposure prophylaxis (PrEP) is a daily course of antiretroviral drugs (ARVs) that can protect HIV-negative people from HIV before potential exposure to the virus\(^5\). PrEP has been registered in South Africa for at risk populations and is available at most public health clinics for the general population. Given the high risk of HIV infection among young adults in South Africa, it is imperative to gauge the level of awareness, acceptability and use among young adults in South Africa.

**Methodology**

A retrospective literature review of all available local South African data on PrEP was conducted to assess enablers and barriers to the use of PrEP in young adults in South Africa in order to explore to explore the need to undertake a study, to assess the level of knowledge and awareness of HIV pre-exposure prophylaxis (PrEP) as an HIV prevention modality, among young adults attending institutes of higher learning in Durban, Kwa-Zulu Natal, South Africa.

**Findings**

PrEP is a novel and new area of HIV prevention that will be rolled out to young adults however a paucity of data exists in the level of education, awareness and advocacy in this age group. It is imperative for new studies to be undertaken to inform key decisions regarding education and awareness for this group as well as other institutes of higher learning. Information from these studies can also be provided to the South African National AIDS council in order to inform policy changes as required.

**Discussion**

A great deal can be gleaned from a unique study exploring attitudes and behaviours of young adults attending institutes of higher learning with regard to PrEP. A study of this nature can result in the generation of tools, frameworks and approaches toward holistic integrated HIV-AIDS care and prevention.

**Conclusion**

PrEP is an important tool in the fight against HIV-AIDS especially in the young generation. It is important that surveys, knowledge and awareness studies are conducted to ascertain the gap requiring further enhancement and empowerment to ensure a healthy and productive younger generation.

Husband's Role Related To Wife's Antenatal Care

Sheilla Tania Marcelina1,*, Budi Prasetyo2, Oedojo Soedirham3

1Department of Maternal and Child Health, Faculty of Public Health, Airlangga University

Abstract

Husband’s involvement is essential in overcoming the problem of being late in recognizing signs of danger, making decisions and reaching health care facilities, as well as getting help from health services. Therefore, husband’s involvement facilitates the preparation of labor and seeks for emergency care if needed. Regular check-ups during pregnancy are crucial for detecting risks, so that health experts can carry out antenatal care, prevent complications during pregnancy, so that health experts in health facilities can help and conduct referrals as well as early treatment if obstetric complications occur at the referral site. This study is to analyze the relationship between husband's role and antenatal care. This research is an observational analytic research. This research used cross sectional approach. The data was obtained through interview using questionnaires. The analysis were descriptive and chi-square. Results indicate that the majority of husband and wife respondents are in reproductive age, working husbands, housewives, low education, and there is no relationship between husband's role and antenatal care. Provision of information to husband and family needs to be constantly improved take care of mother and baby health.

Keywords: Husband's role, Antenatal care, Maternal health, Husband's involvement

Introduction

Maternal Mortality Rate in Indonesia still has not reached the 2015 MDGs (Millennium Development Goals) target. It was 305 while the MDGs target was 102 per 100,000 live births1. Sustainable Development Goals (SDGs) is the continuity of Millennium Development Goals (MDGs) on the 3rd purpose of SDGs, which is Good Health. Mother and baby should not die because the actual causes can be prevented. In 2030, MMR is expected to be 70 per 100,000 live births.

Maternal deaths are preventable through access to good antenatal care (ANC). The huge burden of maternal mortality and morbidity and the health systems challenges call for community involvement and strong family or partner support along the continuum of maternal care pathway. One such essential approach is birth preparedness and complication readiness in antenatal care.2

Husbands have an important role to play in antenatal care. The role of husbands in antenatal care should include knowledge of key danger signs during pregnancy, labor and childbirth, and during the postpartum period. Other roles include identifying transportation and health facility, arrangement for a skilled birth attendant, saving money for delivery and emergency, arrangement for blood donor, accompanying wife and making postpartum readiness plan for both the mother and the baby.3

Attention has long been drawn to the absence of men from previous reproductive health initiatives, although men play a major role in influencing women’s reproductive health. Pregnancy and childbirth is regarded as exclusively women’s affair in developing countries. And a male partner is rarely seen at antenatal care. Harsh, critical behavior and language used by health providers, financial constraints, lack of space
to accommodate male partners at ANC clinics, long waiting time during ANC services and opening hours for ANC clinics are associated with poor male participation in ANC attendance. In addition, men have social and economic power, and have more control over their partners. Involvement of male partner becomes even more critical in maternal health services to raising their awareness and engaging them in antenatal care. So this research’s aims is to analyze the relationship between husband’s role and antenatal care.

Materials and Method

This research is an observational analytic research. This research used cross sectional approach. This research was conducted from August to September 2018 in Lumajang Regency, precisely at Gucialit Sub-district, Yosowilangun Sub-district and Ranuyoso Sub-district. Simple random sampling was used to select 221 respondents, namely husbands and their spouse who had just given birth within the past 1 year. Data on husband’s role and ANC were measured by using questionnaires. Questionnaires’ validity and reliability were tested. In examining the relationship of husband’s behavior and ANC, bivariate analysis was conducted by using chi-square with a 95% confidence interval and a significance level of p <0.05.

Findings

Table 1 indicates that the majority of respondents are husbands (67.9%) and wives (69.7%) aged 20-35. Husbands (52.5%) and wives (48.9%) are elementary school graduates. Majority of husbands (97.3%) work and wives (52.9%) do not work or housewives. Husbands have poor knowledge (66.1%) and moderate attitude (86.6%).

**Discussion**

Results indicate that the number of husband and wife respondents aged 20-35 is more than those who aged <20 and >35. This is also related to knowledge, which has a strong contribution on someone in taking attitude or making decision. The results are in line with the research conducted by Bhatta that explored the factors associated with men involvement during ANC and found that uneducated men or elementary level graduates, aged over 25, have higher income and formal job indicate greater involvement. These factors should be considered empathically during the development of maternal health program. The literature indicates that couples whose men have a higher level of education obtain better information and likely involved in birth planning, they are also socially or financially more prepared to make necessary decisions.

Men who are knowledgeable and obtain health education tend to accompany their spouse during ANC visits. The research highlights the reason why husbands do not accompany their spouse during ANC visits. It is the belief that ANC visit is a woman’s duty, the husband is busy with his work and he is embarrassed to accompany his wife.

This study also indicates that the majority of husbands is employee. The majority of wives is housewife. Regarding education, the majority of husbands is in the group of elementary school graduate. While the majority of wives is also elementary school graduate.

ANC examination is crucial as an effort to detect if there is any problem that occurs during pregnancy so that women can receive early treatment. Regarding ANC examination, this study indicates that the majority of respondents undergoes ANC visits well. The majority of husbands is response husband. The majority of respondents has poor knowledge. The majority of respondents have moderate attitude.

Antenatal care (ANC) services can be defined as care provided by skilled health workers to ensure the best mother and baby health during pregnancy. The ANC components include risk identification, prevention and management of diseases related to pregnancy, and the provision of health education and health promotion. ANC directly reduces maternal and perinatal mortality and morbidity, through detection and complication treatment related to pregnancy, while indirectly identifying increasing risks that can develop into complication during pregnancy and delivery, so that early referral can be performed. Pregnant women must have the same right to access affordable and quality health care in achieving optimal health so as not to have any negative impact on both mother and newborn.

This is consistent with the research conducted by Aliyu about the predictors that cause ANC delay in Nigeria, namely the higher the mother’s educational level, the earlier ANC visit at the beginning of pregnancy. Likewise, mothers from high-income families will start ANC in the first trimester compared to those with low income.

Pregnancy check-ups or antenatal care (ANC) is very important for pregnant women and should be conducted at least 4 times, once in the first trimester, once in the second trimester and twice in the third trimester, because it aims to monitor health during pregnancy. Regular pregnancy check-ups can find abnormalities as early as possible so that treatment can be performed as soon
as possible and mother is in a good condition. Some problems that emerge during pregnancy are related to maternal visits by mothers, this is in accordance with research conducted by Bekele et al., anemia in Ethiopia was caused by low family income, less than 2 years delivery distance, iron supplementation and consisted more than 2 people. This is also related to ANC which is not conducted on regular basis.

Several factors related to ANC in the first trimester of pregnancy include age at pregnancy, family income, media exposure, attitude towards pregnancy, knowledge of danger signs of pregnancy, husband’s consent to conduct antenatal care and distance to the health facilities. In addition, reproductive age, behavior, and attitude during pregnancy, birth order, expectation of pregnancy, ideal family size also affect ANC visits. Some factors are related to delay in conducting ANC examination include socio-demographic, such as maternal education, media exposure, place of residence. Maternal education is a strong predictor of antenatal care services usage. The pregnancy checkup timing has a significant effect on pregnancy result, delay in prenatal care at the beginning of pregnancy is associated with poor pregnancy result.

Conclusion

Results indicate that the number of husband and wife respondents aged 20-35 is more than those who aged <20 and >35. This study also indicates that the majority of husbands is employee. The majority of wives is housewife. Regarding education, the majority of husbands is in the group of elementary school graduate. While the majority of wives is also elementary school graduate. ANC examination is crucial as an effort to detect if there is any problem that occurs during pregnancy so that women can receive early treatment. Regarding ANC examination, this study indicates that the majority of respondents undergoes ANC visits well. The majority of husbands is response husband. The majority of respondents has poor knowledge. The majority of respondents have moderate attitude and there is no relationship between husband’s role and antenatal care.

Indicators In Communication Skills of Taman Posyandu Cadres In The Implementation of Tender Loving Care-Based Child Growth And Development Services

Siti Asiyah¹”*, Dewi Retno Suminar³, Moersintowarti B. Narendra⁴, Shrimarti Rukmini Devy⁵

¹Student in Doctoral Program, Faculty of Public Health Airlangga University, Surabaya, Indonesia
²Lecturer in Health Polytechnic of Ministry of Health, Malang, Indonesia
³Lecturer in Faculty of Psychology Airlangga University, Surabaya, Indonesia
⁴Consultant Pediatrician in Dr Soetomo Hospital, Surabaya, Indonesia
⁵Lecturer in Health Promotion and Behavioral Sciences, Faculty of Public Health Airlangga University, Surabaya, Indonesia

Abstract

Child development activities must be based not only to fulfill physical nutrition for children, but also to pay attention to meet the needs of psychological nutrition, such as giving love, attention and affection to children that can be manifested in talk, action, touch and gentle speech to children(1). These are the values of Tender Loving Care (TLC)-based parenting, especially in growth and development services by cadres in Taman Posyandu. This research aims to analyze the dominant indicators in the competence of communication skills of cadres in TLC-based Taman Posyandu. It is a kind of quantitative study with a cross-sectional approach. This research was carried out in 4 districts (cities) in East Java Province with a large sample consisting of 320 Taman Posyandu. The results of this research show that the dominant indicator in the competencies of cadre communication skills is an indicator of understanding the basic communication with children when performing services in Taman Posyandu (0.78). This skill needs to be continuously developed optimally to provide growth and development services in Taman Posyandu, so the services can be implemented properly and wholeheartedly by TLC-based cadres.

Keywords: Health cadres, Communication skills, Tender loving care (TLC)

Background

Cadre is one of the drivers of the success of health programs, especially community-based health programs or community-based health efforts or called Upaya Kesehatan Bersumberdaya Masyarakat (UKBM), one of them is Taman Posyandu. The cadres are believed to be able to make valuable contributions to community development, and can also improve the access and coverage of the community to basic services. There is strong evidence showing that cadres can provide better health outcomes, especially in the field of child health(2). Cadres play an important role in determining the success of children’s growth and development as well as maternal health since the mothers get health information first through the cadres(3), including information about care and fulfillment of children’s needs.

Based on the data obtained from Health Office of East Java Province in 2013, the coverage of detection of child growth in East Java Province is still 70.34%. In addition, monitoring of growth and development carried out at Posyandu has also not been encouraging. Only 49.4% of
toddler who performed monitor growth 4 times or more within 6 months, 23.8% of children under five are not weighed, only 30.5% of children under five have card for health services or called KartuMenujuSehat (KMS) and only 25.5% of children under five have book for mother and child health or called KartuIbuAnak (KIA)\(^4\).

A preliminary study conducted by interviewing 15 cadres in RinginrejoSubdistrict, Kediri Regency showed that 12 cadres (80%) did not have the confidence to be PAUD caregivers since they did not have sufficient knowledge, 13 cadres (87%) had not received training in Taman Posyandu and there had not been any specific guidance from related parties regarding cadre assignments in Taman Posyandu. This shows that the competencies possessed by cadres still need to be improved, particularly related to cadre communication skills in TLC-based services.

TLC is seen as the greatest virtue of dedication in providing professional care\(^5\). It is used to describe how love is shaped and refined to meet the demands of practice\(^5\). Feelings of compassion for others, followed by an empathetic approach, are a requirement for concern for others. Thus, what stands out is the relationship of caring and love\(^6\). This research aims to analyze the dominant indicator in the competence of communication skills of health cadres in TLC-based Taman Posyandu services.

**Material and Method**

This research is a quantitative study with a cross-sectional approach. It was carried out in 4 districts or cities of East Java Province: Blitar, Ponorogo, Surabaya and Jember. The samples were 320 Taman Posyandus spread in 4 districts or cities. The inferential analysis to obtain the measurement model used Confirmatory Factor Analysis (CFA).

**Findings**

**Respondent Characteristics**

The majority of Taman Posyandu chosen as the research sample are in the optimal category (64.06%). Based on the age of the respondents in 320 Taman Posyandu, the majority were ≥ 45 years old, while the least were 30-34 years old. The age group ≥ 45 years old dominates in each city of the research area. All cadres who became the respondents in 320 Taman Posyandu were women. There were no male cadres, even though there was no prohibition for a man to become a cadre. The largest ethnic groups of Taman Posyandu cadres are Javanese people (89.06%), while the remaining 10.94% are Madurese people. The latter was found in Jember (Pandalungan) and Surabaya. Based on education, the majority of Taman Posyandu cadres have high school education. The education background with the least percentage is elementary and diploma or undergraduate. The majority of cadres in East Java have become the Taman Posyandu cadre for more than 5 years (63.44%), except in Blitar with the highest percentage of cadre work period of 3-4 years.

**Cadre Communication Skills**

</table>

Based on output Lisrel as shown in table 5.4, it can be concluded that the index composing the competency of TLC-based Taman Posyandu cadres is a valid index since the value of loading factor is $\geq 0.5$ and significant since the value of $t \geq 1.96$. 
Indicator of Cadre Communication Skills

</tr>
</tbody>
</table>

All communication competencies of TLC-based  
	Taman Posyandu cadres are valid indicators because they  
have a loading value ≥ 0.3. Based on the loading factor  
value it can be concluded that the dominant indicator in  
cadre communication competencies is an indicator of  
understanding the basic communication with children  
when performing services in Taman Posyandu (0.78).  
The lowest competency is the ability to communicate  
with children (0.47) with the overall factors has positive  
influences.

Discussion

Competence is a combination of knowledge, skills  
and behavior so that individuals can do work as expected.  
Cadres are part of the children’s environment who  
contributes to provide and support children by playing a  
role in providing an appropriate environment, fulfilling  
children’s basic needs, security and helping children  
prepare for their future. Therefore it is important for  
cadres to have good competences. Cadres need to have  
knowledge about the reality of society that are able to  
provide learning experiences to children about friendship  
and love(7). TLC-based cadre competencies can be  
improved through caring, responsibility, appreciation,  
and understanding or knowledge in conducting guidance  
and supervision of child growth and development.

Communicate skills is a fundamental thing  
forTamanPosyandu cadres. It is one way to exchange  
information and convey messages related to child  
development, so it should be properly done. The message  
conveyed in communication becomes important because the addresser and addressee can strengthen  
each other through the messages. A good message in  
communication can have a big impact. Communication  
can run well if the addressers, in this research is Taman  
Posyandu cadres, pay attention and understand the  
audience, the target we expect in conveying information,  
the choice of communication channels, the content of  
messages delivered and good control during the message  
delivery process(8). The factors in communication skills  
are consist of 6 indicators.

The dominant indicator in the preparation of  
cadre communication competencies is an indicator of  
understanding the basic communication with children  
when performing services in Taman Posyandu. This  
indicator is also an indicator with the highest loading  
factor compared to counseling and counseling skills.  
Good communication skills with children indicate that  
cadres understand the things needed to communicate  
with children. Implicitly, by understanding how to  
communicate with them, cadres will apply the best  
techniques or ways to communicate so that the feelings  
of TLC will grow and flow inTamanPosyanduactivities.

The least indicator in forming communication is the  
way the cadre communicates with the child. This must  
be performed with full respect to show love for children.  
Respect is acknowledging, appreciating, accepting what  
is, not making fools, openly accepting the opinions and  
views of others without criticizing or judging, opening  
communication, providing psychological security  
and providing experience for success(8)(7). Respect  
emphasizes how to respect and accept objects that are  
loved as they are and do not act as they wish(9). The  
level of one’s sense of respect can be divided into 5  
scales: 1) how to communicate that shows the lack of  
respect; 2) responding to communication, but tend to  
be passive or ignoring; 3) able to show the attention  
and potential of his interlocutor; 4) deeply responding  
giving the addresser the opportunity to be himself); and  
5) paying attention to potential and commit to respect  
the values of others(10).
Conclusion

The dominant indicator in cadre communication competencies is an indicator of understanding the basic communication with children when performing services in Taman Posyandu (0.78). Communication skills must be basically done with full respect to show love for children. Good communication skills with children indicate that cadres understand the things needed to communicate with them. Implicitly, by understanding how to communicate with children, cadres will apply the best techniques or ways to communicate so that the feelings of TLC will grow and flow in Taman Posyandu activities.

Abstract

Background: The effect of increasing the life expectancy is increasing problem of degenerative diseases. One disease caused by a degenerative process is hypertension. This study aimed to analyze the effect of Progressive Muscle Relaxation (PMR) techniques on reducing blood pressure in the elderly.

Method: This research was a quasi experiment with a pre-post test with control group design. The population in this study were all elderly who experienced hypertension. The sample in this study amounted to 30 people, divided into two groups, 15 intervention groups and 15 control groups. Data analyzed using t-test.

Results: There was a decrease in systole pressure after the intervention, with a different mean of 12 mmHg, and the results of statistical analysis showed a significant difference (p = 0.000). The results of the analysis on diastolic pressure also showed a decrease in diastolic pressure after intervention with a mean difference of eight, but the difference was not significant (p = 0.054). Analysis of differences in systolic and diastolic blood pressure in the control group before and after the intervention, both systolic and diastolic blood pressure showed no significant differences between the pre and post measurements. The results of the statistical analysis also showed significant differences in systolic and diastolic blood pressure between the intervention group and the control group (p-value = 0.00).

Conclusions: There was an effect of PMR techniques on reducing blood pressure in both systole and diastole.

Keywords: Progressive Muscle Relaxation Technique, Blood Pressure, Elderly.

Introduction

The various effects of increasing the life expectancy of the elderly, among others, are the increase in the number of elderly people and the increasing problem of degenerative diseases. One disease caused by a degenerative process is hypertension. The onset of hypertension in the elderly is also influenced by psychosocial changes.\(^1\) Psychological changes that occur in old age have negative consequences, changes in the cardiovascular system and psychological stress that pose a risk of hypertension.\(^2\)

Hypertension is responsible for at least 45% of death due to heart disease and 51% of death due to stroke.\(^3\) Based on data from World Health Organization (WHO), hypertension is the biggest cause of death in the population aged 65 years with more deaths in developing countries. General description of hypertension problems in the Southeast Sulawesi Province from year to year has increased. In 2007, the percentage of cases of hypertension amounted to 17% of cases that often occur in the top 10 diseases and increased in 2013 to 22%. The prevalence of hypertension based on measurements is quite high (> 30%) in Konawe Selatan District, Konawe, Kolaka, Wakatobi, and North Kolaka.\(^4\)
Non-pharmacological therapy, such as lifestyle behavior and pharmacology, is needed to decrease blood pressure.\textsuperscript{5,6} The management through lifestyle behavior is very potential in improving blood pressure control and even in decreasing the need for pharmacological management.\textsuperscript{6}

Progressive Muscle Relaxation (PMR) is one technique to reduce stress. The effect of PMR techniques physiologically is to relax tense muscles, the digestive and cardiovascular tract, causing blood pressure to become normal, headaches become lost, digestion becomes normal. Psychological effects are reducing anxiety, eliminating depression, overcoming sleep difficulties and eliminating insomnia.\textsuperscript{7} The previous research showed that muscle relaxation techniques can reduce insomnia complaints effective in reducing pain in clients with glaucoma; and effective against skeletal muscle relaxation and blood pressure stability in hemorrhagic stroke patients.\textsuperscript{8,9}

This study aimed to analyze the effect of PMR techniques on reducing blood pressure in the elderly and developing a PMR Technique Model in the Elderly.

**Method**

This research was a quasi-experiment with a pre-post test with control group design. The study was conducted in September - October 2015 at the Social Home of Tresna Wardha Minaula Kendari. The sample in this study amounted to 30 people, divided into 2 groups, namely 15 intervention groups and 15 control groups. The sampling technique used was a simple random sampling.

The intervention was a progressive technique in the form of contraction and relaxation exercises in each muscle group in sequence according to the guidelines and schedule. The intervention used a booklet that contained instructions for implementing PMR techniques accompanied by pictures of contraction and relaxation movements in each muscle group alternately. The PMR technique in this study was carried out sitting on the floor while leaning against the wall with pillows placed on the back and legs straightened. Its movement is tense the muscle group (muscle contraction) and holds it for 5 seconds then relax (muscle relaxation) for 5 seconds. Each movement is repeated twice. Relaxation techniques were carried out on 10 muscle groups consisting of 1) leg and thigh muscles; 2) wrist muscles; 3) forearm muscles; 4) elbow and upper arm muscles; 5) abdominal muscles; 6) chest muscle; 7) back muscles; 8) shoulder muscles; 9) head and neck muscles; 10) facial muscles. Interventions were conducted twice a day, namely in the morning at 09.00 and in the afternoon at 17.00 for 5 days, so that the total PMR technique carried out was 10 times.

Data analysis using t-test to determine the effect of PMR techniques with blood pressure.

**Results**

Characteristics of respondents shown that the majority 18 people (60\%) of elderly people with hypertension are male (Table 1).

</tbody>
</table>
In table 2 it is shown that in the intervention group the results of the initial systole measurement (pre) obtained the highest percentage were those who experienced mild hypertension (86.7%). Whereas in the results of diastole measurements there were 40% who experienced mild hypertension and 26.7% had moderate hypertension. After the intervention, the second blood pressure (post) was measured and it was found that at systolic pressure 73% of the results were normal and the remaining 20% had mild hypertension. Also seen in table 2 that there was a decrease in the average systolic and diastolic blood pressure in the intervention group. Furthermore, for the control group, pre and post measurements were also carried out. For systolic blood pressure, the highest percentage in the mild hypertension group was 93.3% at the pre-measurement and to 86% at the post-measurement, because there was 1 sample that had increased blood pressure to moderate hypertension. For diastolic blood pressure, the highest percentage of mild hypertension was 80% and in post measurements, there was an increase in mild hypertension to 86.7%, because there were 1 patient whose diastolic pressure increases. In the control group, an increase in the average value of systole and diastole at the final measurement (post).

It shown in table 3 that there was a decrease in systole pressure after the intervention, with a different mean of 12 mmHg, and the results of statistical analysis showed a significant difference (p = 0.000). The results of the analysis on diastolic pressure also showed a decrease in diastolic pressure after intervention with a mean difference of 8, but the difference was not significant (p = 0.054). Furthermore, analysis of differences in systolic and diastolic blood pressure in the control group before and after the intervention shown in table 4, both systolic and diastolic blood pressure showed no significant differences between the pre and post measurements.

Table 5 shows that the mean of systolic and
diastolic blood pressure in the intervention group was lower than the average in the control group. Based on the results of the statistical analysis also showed significant differences in systolic and diastolic blood pressure between the intervention group and the control group (p-value = 0.00). The results of this study indicate that there was an effect of PMR techniques on the reduction in blood pressure of elderly people who have hypertension as indicated by a decrease in blood pressure, both systolic and diastolic blood pressure in the intervention group which was carried out by PMR techniques.

**Discussion**

This study found the majority of elderly people with hypertension were male. This result is in accordance with theory that gender is one of the risk factors for hypertension. The majority of men with hypertension can be caused by active smoking. Smoking habits are associated with an increased incidence of malignant hypertension. Thomas S. Bowman et al, found that the highest incidence of hypertension was in people smoking more than 15 cigarettes per day.\(^\text{10, 11}\)

The intervention of PMR techniques in accordance with the guidelines and schedule is expected to provide a greater relaxation effect and provide a better therapeutic effect in lowering blood pressure in both systole and diastole. This study found that in the elderly who do PMR techniques regularly or according to guidelines (n = 12), which was twice a day for five days showed a decrease in blood pressure is greater, which was equal to 10-20 mmHg, whereas in elderly with hypertension who did not implement PMR techniques according to guidelines (n = 3) only showed a decrease in blood pressure of 0.5-10 mmHg.

This finding is supported by several studies showing that PMR techniques can reduce insomnia complaints, effective against skeletal muscle relaxation and blood pressure stability in hemorrhagic stroke patients.\(^\text{12, 13, 14}\) PMR techniques were first applied to patients in hospitals who experience high blood pressure. Patients are guided to carry out PMR techniques for two to three times a day in a week, the results show that the patient’s blood pressure decreases and within a few weeks the patient’s blood pressure becomes normal.\(^\text{7}\)

Elderly people who live in nursing homes can experience stress due to loneliness or lack of family support. In times of stress, there will be tension in certain body muscle groups that are sometimes not realized. Muscle tension is not always a sign of strength, but can also indicate the presence of energy being discarded. By learning and practicing PMR techniques can avoid unnecessary scattering of energy and store it for things that are needed.\(^\text{15}\) PMR techniques can be used to maintain physical and mental balance and are important competencies possessed by nurses.\(^\text{16}\)

PMR has been applied to patients with various health problems including hypertension, insomnia, headaches, and childbirth.\(^\text{7, 15}\) PMR techniques have been used as a way to deal with stress (stress management) in everyday life.\(^\text{16, 17}\)

Relaxation has a healing effect.\(^\text{18, 19}\) The impact of this intervention is not limited to healing high blood pressure and heart disease, but can also relieve pain.\(^\text{20}\) To get the therapeutic effect of PMR techniques, this exercise must be carried out regularly every day in a systematic order, ie twice a day in the morning and evening for five days, so that the total implementation of PMR techniques is 10 times. This will make individuals aware of the tension in the body muscles and achieve total muscle relaxation. Total muscle relaxation conditions will counteract the negative effects of stress by restoring the balance of the physiological conditions of the body due to the effects of the endocrine system and sympathetic nervous system that occur during stress.\(^\text{15}\)

In this study it was found that the majority of respondents (80%) performed relaxation techniques according to guidelines and schedules, namely twice a day in the morning and evening for five days, so that the total implementation of PMR techniques carried out by respondents was 10 times, while the remaining 20 % only performs PMR techniques 8 times. The implementation of PMR techniques in accordance with the guidelines and schedule will provide a greater relaxation effect and provide a better therapeutic effect in reducing blood pressure in both systole and diastole. This is evident from the results of the study found that in the elderly who do PMR techniques regularly or according to guidelines (n = 12), which is twice a day for 5 days shows a decrease in blood pressure is greater, which is equal to 10-20 mmHg, whereas in elderly with hypertension who do not carry out PMR techniques according to guidelines (n = 3), only show a decrease in blood pressure of 0.5-10 mmHg.
Conclusions

There was an effect of Progressive Muscle Relaxation techniques on reducing blood pressure in both systole and diastole.

Acknowledgements

We give our gratitude to Polytechnic of Health, Ministry of Health, Kendari, that have supported this research. Our appreciation also for all elderly at the Social Home of Tresna Werdha Minaula Kendari that have participated in this study.

Conflict of Interest: The authors have no conflicts of interest to declare.

Ethical approval: This study received ethical approval from the Health Research Ethics Commission of the Health Polytechnic of the Ministry of Health of Yogyakarta with Number: I. B. 01. 01 / KE / LIX / 537/2016.

Abstract

Background: Measles is a major cause of child mortality worldwide. High measles immunization coverage is required in reducing the child mortality. The study aimed to identify the determinants of first dose measles immunization in four districts in Indonesia.

Method: This cross sectional study used secondary data of The Assessment of Second Dose Measles Immunization and Immunization for School Children Coverage in Two Provinces in Indonesia in 2017. Sample were total of 1,200 respondents whose children aged 12-37 months in the survey. Bivariate and multivariate analysis were used to examine the predisposing, enabling, need, and reinforcing factors associated with the immunization.

Results: Factors that statistically associated with the immunization were attitudes toward immunization service quality PR=1,35 (95%CI 1,02-1,79); information on immunization PR=3,17 (95%CI 2,37-4,22); perceived needs of immunization PR=1,55 (95%CI 1,13-2,13); and family support PR=9,07 (95%CI 5,76-14,28). The dominant determinant was the family support.

Conclusion: All the factors associated to the first dose measles immunization have important role in the child immunization. Therefore, stakeholders were expected to intervent all the factors in increasing the immunization coverage.

Keywords: Immunization, First dose measles, Indonesia

Introduction

Measles is an acute, infectious, and highly contagious disease caused by a virus. This disease is one of the main causes of child mortality worldwide. Thus the prevention of measles has a significant role in reducing under-five mortality. Indonesia is a country with high cases of measles. Every year more than 11,000 cases of suspected measles are reported. During 2010 to 2015, it was estimated that there were 23,164 cases of measles in Indonesia. The measles outbreaks still occur every year. The number of outbreaks decreased from 2011 to 2015 (328, 160, 128, 173, 68 cases) but increased in 2016 (129 cases).

Indonesia is committed to achieve measles elimination in 2020 in line with the Global Vaccine Action Plan (GVAP) which targets measles elimination in 5 WHO regions by 2020. High coverage (>95%) is required to maintain high levels of herd immunity through routine and additional immunization. However, the first-dose measles immunization coverage in 2014 and 2015 in Indonesia has decreased. In addition, the percentage of districts that have the first dose of measles coverage >95% also tends to decrease from 45% in 2013 to 28% in 2015.

Immunization coverage for children can be influenced by provider and client factors related
to health services (immunization services). However, some previous studies were only in one area of the primary healthcare (Puskesmas) or only the sub-district and no one had specifically observed the first dose measles immunization as the main outcome so that it did not adequately describe factors related to the first dose of measles immunization in Indonesia. This study was conducted to find out more information and in a wider area, in four districts / cities about determinant factors of first dose measles immunization based on four main factors, namely predisposing, enabling, need, and reinforcing as the theory of Andersen and Green.

Material and Method

The study design was a cross sectional using secondary data of Assessment of Second Dose Measles Immunization Coverage and Immunization for School Children in 2 Provinces in Indonesia 2017 which was conducted on January-May 2017. The population were all children aged 25-37 months in four selected cities/ districts, of Aceh Jaya, Pidie, Bantaeng and Palopo. Samples were children aged 25-37 months who were selected as samples in the survey and the data was well documented (n = 1,200).

The dependent variable was first dose measles immunization was seen from the first dose measles immunization status when the child was before 12 months. Maternal and paternal education were categorized into low if the last education was primary school (up to junior high school) and included to high education if it completed a higher level. Maternal and paternal occupation were categorized as not working and working. Attitudes were measured by respondent’s judgement about health worker’s hospitality, service satisfaction, and cleanliness of the service area (score 0-4). Knowledge was related to the immunization that should be given to children under five and the right age to give the first dose measles immunization (score 0-6). The mean values of these score of each assessment was used as a cut-off point for defining the status of knowledge and attitudes. Family income were also devided by using the mean value. Information on immunization was categorized into ever and never exposed to information. Missed opportunities were categorized into had and had no missed opportunities. Perceived of benefits, barriers and needs (score 1-4) were devided to be less good (<mean) and good (≥mean). Family support included evaluative, instrumental and emotional support to determine which children should be immunized (score 0-7), categorized to be less good and good. Community support was defined as the presence or absence of support from other people (religious leaders, community leaders, neighbors, friends, relatives) to inform or socialize immunization.

Cox regression was performed to calculate the prevalence ratio (PR) with 95% Confidence Interval and to find out the dominant factors associated with the first dose measles immunization.

Results

The proportion of children who had no first dose measles immunization in four districts in Indonesia in 2017 were 19.3%. While children who had immunization were 80.7% or still below the national target (95%). Table 1 showed that based on predisposing factors, non-immunized children had a higher proportion in lower educated mothers and fathers (21.6% and 23.1%), non-working mothers (20.1%), working fathers (19.4%), less good attitudes group (34.8%), and poor knowledge groups (28.5%). Based on the enabling factor, the proportion of not immunized was higher in families with less income (19.9%), in the group that had never been exposed to information about immunization service (61.8%), in the group with missed service opportunity (23.1%). Based on the need factors, not immunized children had a higher proportion in less perceived benefits, barriers, and need groups were 78.2%, 20.1%, and 86.4%. Based on reinforcing factors, not immunized children had a higher proportion in the group with poor family support (43.5%) and in the group with no community (40.2%). Bivariante analysis showed variables which had significantly association with the first dose measles immunization were paternal education, attitudes toward immunization service quality, knowledge about immunization, perceived benefits of immunization, perceived needs of immunization, information on immunization, family support, and social support.

* significant p < 0.05 and entered to multivariat analysis
After removing one by one the independent variables with \( p > 0.05 \) from the first multivariate model, the final multivariate model was obtained (table 2). In the final model of multivariate analysis, it could be seen that the variables which were most strongly associated with the immunization were family support, information on immunization, perceived needs and attitudes toward immunization service.

**Discussion**

This study used a cross sectional study design so it could not establish causal relationship and temporality. Another limitation of study using secondary data was it could not measure all possible variables related to immunization such as the role of health workers and health services which might be strongly associated with immunization.\(^{(20)}\) There was a potential bias in this study due to the use of instruments which were not specifically designed to assess the determinant factors of the first dose measles immunization. The potential bias in measuring the dependent variable was might be a recall bias from the respondent in remembering the first dose measles immunization status. However, this bias had been minimized by checking the Maternal and Child Health Book Record. Measurement of knowledge, attitudes and perceptions of respondents might be potentially cause non-differential-information bias.

This study found attitudes toward immunization service quality as the predisposing factor was significantly associated with the first dose measles immunization. The attitudes of health workers and the immunization services were expected to build positive attitudes to the immunization services quality. Therefore, parents would bring their child for immunization. In this study, poor attitudes and trust would make mothers of the children would not go to immunization services. Poor attitude and trust would make people reluctant and uncomfortable coming to immunization services. This was in line with study by Izza (2017) that parents who had poorly attitudes toward immunization service quality, their children (aged 12-36 months) were more likely to be not getting DPT immunization.\(^{(16)}\)

Information on immunization as the enabling factor was significantly associated with the immunization status. In this study, information was related to facilities and immunization service workers. Group who have obtained information might have better knowledge so they had a positive attitudes toward immunization. This could encourage them to aware and understand about immunization so they would immunize their children. These results were in line with the study by Hijriani (2015) which showed exposure to information was significantly related to the completeness of basic infant immunizations.\(^{(21)}\)

Perceived needs as the need factor was also significantly associated with the immunization. Perceived needs could be seen from respondent’s assumption or judgement that children must be immunized because they really need immunization. This study proved the poor perceived needs was significantly associated with not immunized status. The results were similar to the study in Nepal (2002) that the assessment of immunization service needs was significantly related to the completeness of immunization.\(^{(22)}\) Thus, it was an important factor which influenced parents to immunize their children.

In this study, family support as the reinforcing factor was significantly associated with the first dose measles immunization. The result showed the magnitude of the role of family in health decision making. Families with good knowledge, awareness or understanding of immunization would give positive support in immunization. Many respondents probably lived close to their families so family support influenced determining the immunization of children. Furthermore, this study showed that family support had the strongest role influencing the first dose measles immunization.
This results was in line with some previous studies.\(^{(23,24)}\)

**Conclusion and Recommendation**

The results of this study showed factors that were significantly associated with the first dose measles immunization for under five children were predisposing: attitudes toward immunization service PR 1.35 (95% CI 1.02-1.79); enabling: information on immunization PR 3.17 (95% CI 2.37-4.22); need: perceived needs of immunization PR 1.55 (95% CI 1.13-2.13); and reinforcing: family support PR 9.07 (95% CI 5.76-14.28). Further research was needed with specifically instruments to assess the first-dose measles immunization with a wider area (larger sample), respondents are mothers who have babies (one year old children) at the time of the study, and add variables such as the role of health workers and services so that more valid and complete information will be obtained. All the factors associated to the first dose measles immunization have important role in the child immunization. Therefore, stakeholders were expected to intervene all the factors in increasing the immunization coverage. It could support the increasing of immunization coverage as a strategy to against measles in child.

**Ethical Considerations**

This clearance issued by the ethic committee in Health Research and Development Agency of Indonesia Ministry of Health. The ethic committee had reviewed the study report and independently issued the clearance.

**Conflict of interest**

Both author declared that no competing interest.

Abstract

Background: Adolescent is a period of growth and development as well as transition time from childhood into adult, which need an optimal nutrition intake. Malnutrition during adolescents will give a negative impact on nutrition status of their children in the future. Female adolescents had got impacted more severe compared to male adolescents, because it caused an intergeneration effect. Underweight female or short female tended to give birth a low birth weight infant, and this negative cycle will continue occurred for the next generation. Objective of this study was to analyze association of parents’ body weight to their adolescent height

Method: Using data from Indonesian Family Life Survey (IFLS). Sample inclusion criteria of this study included children aged two to five years old during the IFLS 1, as a biological child, single birth, still alive, living with parents, still alive in IFLS 4, while the exclusion criteria were had incomplete cohort data from 1993 to 2007. This study analyzed 428 individuals out of 847 sample population. Bivariate analysis of Chi-square test had been done followed by multiple logistic regression for independent variables with p value < 0.25.

Result: Multivariate analyses showed that adolescents who had stunted mother had 2.4 times risk of develop stunted.

Conclusions: Adolescent’s height correlate to mother’s heigt.

Keywords: Adolescents height, mother’s height, stunted

Introduction

Adolescent is a time period for growth and development and transition from childhood into adult life and considered as the second fastest growth moment after the first year of newborn life period. Nutrition status is an important contribution during these two period of times. About 50% of body weight and adult body mass frame can be reached during childhood time, and more than 20% of body height of adult can be reached during adolescents¹.

In numerous countries, where half of their adolescents population had short height (z score for height by age according to [HAZ] < –2 SD of WHO Child Growth Standard), it was related to higher risk of negative perinatal outcome to their child in the future. Severe malnutrition was not only contributed to stunting or underweight during adulthood², but it was also impacted their nutrition status. This will lead to intergeneration effects, which were underweight or stunted females tended to give birth a low birth weight infant and will continue in their life cycle for their next generation³, caused constraint on development of their mental,
cognitive, education and economy achievement, increasing risk of raised blood pressure.

A study in Bangladesh, showed prevalence of stunting in adolescents was 46.6% (43.1% in males and 50.3% in females; p value >0.05) . Meanwhile, in Bengal India, indicated that stunting had significantly higher among females child (58.4%) compare to male child (48.7%) . In Africa, the stunting prevalence in adolescents aged 15 to 19 years was 19.1% (22.3% in males and 15.5% in females) . Stunting also known was higher in rural (36.4%) than in urban areas (23.5%) . Within different education background of parents, it showed that prevalence of stunting adolescents was higher in those who had father with low education (illiterate) which was 3.99% compare to father with literate or higher education (12.0%) . In Indonesia, prevalence of stunting in adolescents was relatively high, about 31.4% (7.5% very short and 23.9% short).

Stunting was an indicator of chronic malnutrition that occurred during a long period of time. Interaction between genetic and environment factors was a risk factor for stunting. There were many studies showed the relationship between parent’s height and their child height however, similar study was still needed in different places to confirm result from previous study, in order to obtain most appropriate policy to prevent stunting that specifically meet the need of local population at risk and environment. This study aimed to analyse association of parent’s body height to their adolescent body height.

**Materials and Method**

**Population and Sample**

This study used data from Indonesian Family Life Survey (IFLS). IFLS was a survey conducted in Indonesia by RAND and demographic institution of Universitas Indonesia in 1993, 1997, 2000, 2007. Focus of the survey were fertility, family planning and contraception, health and child survival, migration, occupation, functional health, economic and social of elderly. IFLS is public domain and can be obtained from http://www.rand.org.

This cohort study followed under five children age in 1993 (IFLS 1) until they reached age 16 to 19 years (IFLS 4) and meet the inclusion and exclusion criteria. The inclusion criteria included age of two to five years in ILFS-1, biological child, single birth, still alive, living with parents, and participated in ILFS – 4. Exclusion criteria were incomplete longitudinal data set from 1993 to 2007. Total number of population was 847 (aged two to five years) and we excluded those who had HAZ < -6 and > 6, while individuals who had missing data of parent’s height were excluded. Total number of cleaned sample to be analyzed was 428 individuals.

**Data Manajemen**

This study use data of father’s and mother’s body height, father’s education, mother’s education, environment condition, household economy status, living areas, sex and body height of adolescents. These data was part of data that will be published later on. All of the data were obtained from the IFLS-1 except for adolescents body height was from the ILFS-4.

The IFLS used microtoise to measure the body height. Height measurement result was in centimeter with 0.1 cm accuracy. The height measurement was carried out by trained field workers. The height data of fathers was categorized into two groups based on mean value of body height, which was short < mean 160.5 cm and normal >= 160.5 cm for fathers, while < 150.2 cm (short) and >= 150.2 cm (normal) for mothers. Parent height was defined as short if both father and mother were short; and high or normal if either father or mother was normal. Adolescents body height was defined using Z score based on WHO Anthro Plus 2007, whereas short for those who had height for age (HAZ) < -2 SD of WHO standard median and normal for those who had HAZ >= -2SD of WHO standard median value.

Father’s and mother’s education were grouped into two education status, which were low (less than or equal to junior high school) and high (higher than or equal to senior high school). Living areas were defined as urban and rural.

Living environment were determined using composite variables of house condition (floor, roof, and wall type), electricity source, drinking water source, clean water source, waste discharge, rubbish discharge method, and human feces discharge method. Each of the variables was weighted based on healthy house standard (Minister of Health regulation no: 829/SK/VII/1999). Living environment was defined as healthy if score value was reaching 80% or higher from the highest score and unhealthy environment referred to score value less than 80% of highest score.
Household economy status was measured by percentage of household food expenditure per month per capita. Data was calculated by dividing total food expenditure and total household expenditure (expenditure for food, non-food, education, housing). Poor or low economic status was categorized by percentage of food expenditure ≥ 56.86% from total household expenditure per capita and non-poor or high economic status was defined as percentage of food expenditure per capita < 56.86%. The percentage of 56.86% was based on median value of expenditure in 1993 calculated by Statistic Bureau of Indonesia (BPS).

Data Analysis

Data analysis was completed using a statistic software of SPSS 17.0. Prior to the statistical analyses, the data was tested for normality distribution using Kolmogorov-Smirnoff test. The result showed that the data was not normally distributed, and all variables were modified into two grouped. A univariate analyses was done to describe each variables and bivariate analyses were completed to calculate cross tabulation between each of independent and dependent variables using Chi-square test with 0.05 alpha and 95% CI. Results from the chi-square test were selected independent variables (p value < 0.25) that included in the multivariateanalyze of multiple logistic regression using model prediction analyses.

Results

Table 1 showed 31.8% of adolescents were stunted, male adolescents were higher than females. Half of the adolescents (52.3%) living in rural area. Percentage of adolescents who had stunted mother was 49.3%, and stunted father was 43%, while the percentage of who had both stunted mother and father was 20.8%. Percentage of adolescents who had low educated father was 72.9%, and 81.8% had low educated mother. Percentage of adolescents who had low economic status was 32.7% and 74.8% adolescents was living in unhealthy environment.

Table 2 showed that mother’s height, father’s height, parental’s height, mother and father’s education, economic status and environment were associated with adolescent height (p<0.05), except sex and adolescent resident. Meanwhile all the variables were included in the multivariate analyses (p-value<0.25).

Table 3 showed results of multiple logistic regression. Summary prediction model indicated value of R-squared of Nagelkerke was 19.4%, which assumed that proportion of stunted adolescents can be explained as much as 19.4% from the mother’s height, father’s height, sex and household characteristics (parents education, living environment, food expenditure and residential areas). It was showed under five children (two to five years old) who had stunted mother had higher risk of getting stunted during their adolescents age (OR=2.406, 95% CI= 1.280 - 4.487) compared with those whose mother was not stunted.

Discussion

The statistical analysis showed risk of stunted adolescents was 2.4 times higher among those who had stunted mother after controlling covariates variable. This result in line with other studies\textsuperscript{3,14,13,16}. These facts most likely related to genetic influence as a result of interaction and permanent adaptation of poligen from adolescents’ parent. The genetic factor highly contributed to the adolescents height, after controlled by certain external factors\textsuperscript{17}.

Conclusion

Our finding confirm that mother’s height has association with adolescent height. Hence female adolescent need to maintain their nutritional status in adequate condition to to cut the malnutrition and stunting cycle during adolescents time period.

Abstract

Perception is one of the factors that can determine the attitude and behavior of someone. Perception of safety behavior can be interpreted negatively or positively, workers who have a positive perception will tend to be supportive to behave safely so they can avoid workplace accidents. PT. Kimia Farma (Persero) Tbk. Plant Bandung is listed as a company that has received zero accident awards, meaning that there have never been work accidents that have caused loss of work time. The purpose of this study was to determine the relationship of worker motivation, social support, work experience, and years of service with perceptions of safety behavior of PT. Kimia Farma (Persero) Tbk. Plant Bandung 2017. The type of research used is an analytical survey using a cross-sectional approach. The study population was all production workers I part of PT. Kimia Farma (Persero) Tbk. Plant Bandung. The sampling technique of this study was purposive sampling. The study sample was 51 workers. The data analysis technique uses chi-square. The results of this study indicate that there is a relationship between motivation, social support, work experience, and working period with perceptions of safety behavior. Based on the results of this study it can be concluded that motivational factors, social support, work experience and years of work are related to perceptions of safe behavior.

Keywords: Perception, Safe Behavior, Occupational Safety.

Introduction

Law number 1 of 1970 concerning work safety states that every workforce has the right to get protection from safety in carrying out work and increasing national production and productivity. But the fact that work safety is still not entrenched, this is evidenced by the still high number of workplace accidents and illnesses caused by work that occur both nationally and internationally.¹

According to the International Labor Organization (ILO) every day an average of 6,000 people die, as well as one person every 15 seconds, or 2.2 million people per year due to illness or accident related to their work. The number of men who die two times more than women (Primasari, 2016). In Indonesia the number of occupational accidents recorded in 2011-2014 was the highest in 2013 with 35,917 work accident cases, while in 2011 there were 9,891 cases; in 2012 there were 21,735 cases, and 2014 there were 24,910 cases².

Domino theory Henrich states that workplace accidents are caused by two main things. First is mechanical and environmental factors or unsafe conditions, while the second is unsafe action. Henrich estimates that 85% of accidents are the result of unsafe work behavior (Halimah, 2009). Based on this, it can be said that human behavior plays an important role in the occurrence of accidents and illnesses due to work.³

According to Green, there are three factors that influence individual behavior, namely, basic factors...
(predisposing factors), supporting factors (enabling factors), and reinforcing factors (reinforcing factors). One of the basic factors that influence individual behavior is a perception\(^4\).

According to Robins, there are three factors that can influence perceptions, namely factors originating from perception, target, and situation. Perception includes knowledge, attitudes, expectations, experiences, and motivation. Targets include background, intensity, size, something new and closeness. While the situation includes the environment, social conditions or social support and time or length of observation\(^5\).

OHS programs implemented at PT. Kimia Farma (Persero) Tbk Plant Bandung aims to create a workplace that is safe, comfortable and free from workplace accidents, especially for workers and the community working environment. The K3 Program held at PT. Kimia Farma (Persero) Tbk Plant Bandung is summarized in a program called the zero accident program.

Based on the 2015 zero accident program document PT. Kimia Farma (Persero) Tbk Plant Bandung which shows data from 2011 to 2015 has reached 5,122,353 working hours without losing work time. While for 2016 this company has reached 928,225 working hours without losing work time. So that in 2016 based on the Decree of the Minister of Manpower of the Republic of Indonesia Number PER-01 MEN / I / 2007 PT. Kimia Farma (Persero) Tbk. Plant Bandung received a zero accident award.

The purpose of this study was to identify the relationship between workers’ motivation, social support, work experience and years of service with perceptions of safety behavior in Production I employees of PT. Kimia Farma (Persero) Tbk. Plant Bandung.

### Material and Method

This research is an analytical survey with a Cross-Sectional approach and a method of collecting data at a time (point time approach)\(^6\). The independent variables in this study were worker motivation, social support, worker experience and years of service. The dependent variable in this study is the perception of safety behavior. Variables were measured using a questionnaire with a Likert scale. Alternative answers to questions strongly agree, agree, disagree and strongly disagree\(^7\). Categorization uses median\(^8\). Test the validity and reliability in the production section II, the questionnaire is said to be reliable if the value of Cronbach’s Alpha> 0.60\(^9\). The study sample of 51 production part I workers PT. Kimia Farma (Persero) Tbk. Plant Bandung. Data management through editing, coding, processing, and cleaning\(^10\). The data analysis technique uses the chi-square test.

### Findings

Most workers have a positive perception of safety behavior.

PT. Kimia Farma (Persero) Tbk. Plant Bandung organizes various forms of activities in an effort to provide a positive understanding and understanding to workers of the safety behavior. These efforts include OSH training for workers so as to give a positive impression on workers and workers able to interpret safety behavior properly.

Most workers have a high motivation to behave safely (safety behavior).

The production process requires the production part I worker PT. Kimia Farma (Persero) Tbk. Plant Bandung to interact directly with production components, this certainly has a risk of workplace accidents. This risk is understood by workers as something that can interfere with production and harm safety. Therefore, with the understanding of workplace safety, workers are highly motivated to behave safely.

Most workers get good social support for safety behavior.

According to Sarafino, social support means that there is acceptance from people or groups of individuals that give rise to perceptions in themselves that they are cared for, and helped.

PT. Kimia Farma (Persero) Tbk. Plant Bandung has a morning talk program that is filled with a review of company culture guidelines, the spirit of corporate culture (5-AS), and the fundamental of improvement culture (5R).

So that by doing this a good relationship is established between superiors and subordinates, good relationships are established with fellow co-workers, workers feel support for worker safety from superiors and efforts to remind each other of coworkers. This situation creates harmonization between workers and superiors while in the work environment.

Most workers have good experience with safety behavior.

PT. Kimia Farma (Persero) Tbk. Plant Bandung has implemented national and international standards for workplace safety. All aspects relating to workers and worker safety are well managed. So that workers have good skills in implementing the company’s K3 Standard Operating Procedure (SOP). Good OSH implementation has an impact on workers so that they feel the benefits of K3 and know the OSH aspects well. Fulfillment of these indicators has caused most workers to have good experience with the implementation of OSH in the company.

Almost all workers have long service periods.

Domination of the long working period of PT. Kimia Farma (Persero) Tbk. Plant Bandung is inseparable from the long history of the establishment of this company which began in colonial times, namely in 1896. Previous research on the period of work carried out by Ferlisa showed that the majority of Unit II and III workers at PT. Semen Padang has a long job.11

There is a relationship between the motivation of workers with perceptions of safety behavior.

The results of this study showed 30 workers who were highly motivated, 5 of whom had negative perceptions of safety behavior. This can be caused by the fact that there are still workers who claim that participating in safe behavior is only based on obligations that have been set by the company and solely want to be praised by superiors.

Furthermore, the results of this study also show that of the 21 workers who had low motivation, 11 of them had positive perceptions of Safety Behavior. This can happen because of the company’s efforts to routinely carry out work safety promotions and have an impact on increasing workers’ knowledge and understanding of safety behavior. The author’s statement is based on the theory conveyed by Robins that in addition to the perception factors examined by the author there are other factors that can influence perception, namely knowledge.

There is a relationship between social support and the perception of safety behavior.

According to Notoatmodjo, factors that can influence a person’s perception other than experience can also be influenced by socio-culture. The social aspect that is intended is the existence of good interactions and mutual support between individuals (social support)\(^4\).

The results showed that of 27 workers who received good social support, 4 of them had negative perceptions of safety behavior. This can happen because there are still workers who consider safety behavior only to save production and earn income in order to meet family needs. In addition, this can also be caused by a lack of support from the family towards workers’ safety behavior during the work process. According to Handayani, social support in addition to being obtained from coworkers and superiors can also be sourced from families\(^12\).

The results of this study also showed that of 24 workers who had good social support, 13 of them had positive perceptions of safety behavior. This condition can be caused by the intense work safety promotion carried out by the HSE section so that it increases workers’ knowledge and fosters a supportive attitude from workers towards the perception of safety behavior.

There is a relationship between the experience of workers and the perception of safety behavior.

According to Robbins and Krech, one of the factors that influence a person’s perception of something is experience\(^13\).

The results of this study indicate that there are workers who have a good experience but have negative perceptions of safety behavior. According to Wibowo, this happens because there are several things that can make workers wrong in perceiving something. The good experience obtained by workers can be caused by imitating what other workers do without understanding their purpose. This error is called the halo effect\(^14\).

</table>

There is a relationship between years of service with the perception of safety behavior.

The working period can affect the length of observation or the length of interaction between workers and the work environment. So the longer the workers work somewhere more likely to recognize the surrounding environment\(^15\).

Based on the results of the crosstab, there were 39 workers who had a long working period, 8 of whom had negative perceptions of safety behavior. This can be caused by the cognitive aspects of knowledge of elderly workers who find it difficult to accept positive changes in Occupational Health and Safety held at PT. Kimia Farma (Persero) Tbk. Plant Bandung.

The results of this study also showed that of 12 workers who had new years of service, 5 of them had positive perceptions of safety behavior. Workers with a new working period are classified as teenagers, so they tend to be easier to accept and follow the rules set by the company. So that with health promotion routinely
carried out at PT. Kimia Farma (Persero) Tbk. Plant Bandung workers can immediately understand and interpret safety behavior properly.

**Conclusion**

Based on the results of the study it can be concluded that the majority of workers have a positive perception of the safety behavior, most workers have high motivation, most workers get good social support, most workers have a good experience and almost all workers have long years of service.

There is a relationship between worker motivation, social support, work experience and working period with perceptions of safety behavior at PT. Kimia Farma (Persero) Tbk. Plant Bandung.

Abstract

Employee engagement in organizations is very important, because it provides many benefits, so every employee must have a sense of being engaged. The purpose of this study was to determine the effect of happiness at work on both employee engagement and intention to stay of hospital employees. The current research was an observational analytic. The research design used was cross sectional. The sample size was 154 respondents. The sampling technique used was Proportional Random Sampling. Data analysis was conducted with PLS. Based on the results of analysis and discussion, it is concluded that happiness at work has positive and significant relationship with employee engagement; employee engagement has positive and significant relationship with intention to stay; and happiness at work has no direct relationship with intention to stay, but has relationship through employee engagement.

Keywords: Employee engagement, Happiness at work, Hospital, Intention to stay

Introduction

Health service industry is an industry that has good prospects. Because health services are not only focused on the treatment of diseases, but also provide services for prevention and improvement of health. One of the factors that affect the quality of service in a hospital is the role of human resources (HR) as service providers. The attitude, ability and integrity of HR in the hospital affect the success of establishing relationships between companies, employees and customers. Employee engagement is very important in organizational development. High employee engagement can bring the organization to success, because the current progress of the organization depends on the creativity of its human resources. If the employee has a feeling of being engaged with the company, it will increase three general behaviors, i.e. (3S) Say (talk positively about the organization), Stay (stay in the organization), and Strive (motivated to work more seriously). According to Macey, measurement of employee engagement is done by using a combination of four individual elements with the same weight of importance, i.e. Pride, Satisfaction, Advocacy and Commitment.

The reason for choosing this element is because of employee involvement, which is one of the prides they have, which shows satisfaction with the organization they work in, as well as the intention to stay with their organization.

Employee engagement makes employees have higher loyalty, thereby reducing the desire to leave the company (turnover intention). If turnover intention is low, employee performance will increase. The desire to stay (intention to stay) is the opposite of turnover intention which is defined as when individuals think, plan and want to leave work.

The success of an organization is also marked by employees who are happy at their workplace. Happiness is not only limited to physical aspects, but
also to psychological aspects. This means that happiness will help individuals to control aspects of their lives consciously. Employees who feel happy while working are related to core and contextual performance, customer satisfaction, security, high work presence and retention.

A phenomenon that often occurs is that the good performance of a hospital can be disrupted by various employees’ behaviours that are difficult to be prevented, such as employees’ decision to leave work (turnover). Employees’ decision to leave their previous jobs is preceded by their intention or desire to change jobs (intention to leave)\(^{18}\). The prevalence of nurse turnover events in the world ranges from 10% to 21% per year\(^{13}\).

In Indonesia, the turnover rate is quite high. This can be seen from several studies in class C hospitals, such as Anik’s study. She found that the turnover of nurses at IbnuSina Hospital in Padang from 2010 to 2014 was about 11.95%. The research conducted by Lubis at Zahirah General Hospital in Jagakarsa, South Jakarta, stated that the number of nurse inpatient turnover in 2012 reached 40%. Sources of data obtained from Surabaya Surgical Hospital also showed high turnover rates over the past four years (2011 – 2014), i.e. around 12.22%. At a glance, for the last three years, the turnover rates have shown a decline, but the rates are still above the standard value with an average of 19.6%. Gillies states that the turnover rate is said to be normal if it ranges from 5% to 10% per year and said to be high if it values more than 10%. Therefore, researchers are interested in analysing the relationships between happiness at work on both employee engagement and intention to stay of hospital employees.

**Materials and Method**

The current research was an observational because the process of collecting data did not involve any intervention or treatment\(^3\). This research was an observational analytic because of the nature of the research problem which is a causal relationship and the purpose of this research is to find a model. The design of this study is cross-sectional because data variables were collected in one time period\(^3\).

This research was conducted in the city of Surabaya, i.e. at some private class C hospitals. Data were collected from October 2017 to November 2017. The population in this study was nurses who worked in hospitals. The unit of analysis is nurse. The samples of this study were some nurses who worked in selected hospitals. Sample size in this study was determined by using the estimated stratified sampling formula. Hence, the study used 158 samples from a population of 264. A total of out of 154 questionnaires were feasible to be used in this study.

**Results**

**Individual Characteristics**

The respondents in this study were characterised based on their demographic characteristics, including age, gender, education, marital status and work status as described in Table 1.

**Table 1. Characteristics of Respondents at Four of Class C Hospitals Located in Surabaya in 2017**

| Gender | Male | 5 | 3.2 |
|        | Female | 149 | 96.8 |
|        | Total | 154 | 100 |

| Education | D3 Nursing/Midwifery | 124 | 80.5 |
|           | D4 Nursing/Midwifery | 3 | 1.9 |
|           | Bachelor of Nursing/ Midwifery | 28 | 18.2 |
|           | Total | 154 | 100 |

| Marital status | Married | 124 | 80.5 |
|                | Single | 30 | 19.5 |
|                | Total | 154 | 100 |

| Work status | Permanent employee | 134 | 87 |
|             | Contract employee | 20 | 13 |
|             | Total | 154 | 100 |

Based on the analysis in Table 1, the highest age for respondents was 26–35 years. The number of respondents in this category was 58 respondents (37.7%). Overall, the numbers of respondents under 35 years were more than those over 35 years. Only one person (0.6%)
was aged more than 50 years. The numbers of female respondents were by far higher than male respondents, with 149 (96.8%) of females and 5 (3.2%) of males.

Most respondents were nurses with D3 degree, with 124 respondents (80.5%), followed by nurse with bachelor degree, with 28 respondents (18.2%). Most of the respondents were married, with 124 respondents (80.5%). The numbers of single respondents were 30 respondents or 19.5%. 87% of respondents are permanent employees, while the other 13% are contract employees.

**Outer Model Analysis**

The evaluation of the outer model is performed to determine the validity and reliability that connects indicators with latent variables. Meanwhile the evaluation of the inner model is performed to determine how much influence or causality relationship between variables in a study. The test results of the outer model of the indicators for each latent variable are presented in Table 2.

<table>
<thead>
<tr>

</tbody>
</table>

**Employee Engagement**

<table>
<thead>
<tr>
<th>Variables of indicator</th>
<th>Path Coefficient</th>
<th>T-statistics</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>X2.1 Commitment to the organization's mission</td>
<td>0.825</td>
<td>27.669</td>
<td>Significant</td>
</tr>
</tbody>
</table>

It can be seen from Table 2 that the loading factor of each item for all variables is valued more than 0.5. Thus, the items used in this study have met convergent validity.

**Inner Model Analysis**

The results of the model test of the indicators for each latent variable are presented in Table 3.
Table 3: Inner Loading Values

<table>
<thead>
<tr>
<th>No</th>
<th>Hypothesis</th>
<th>Original Sample (O)</th>
<th>T-statistics</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Happiness at work à Intention to Stay</td>
<td>0.099</td>
<td>1.197</td>
<td>Not significant</td>
</tr>
<tr>
<td>2</td>
<td>Happiness at work à Employee Engagement</td>
<td>0.541</td>
<td>10.660</td>
<td>Significant</td>
</tr>
<tr>
<td>3</td>
<td>Employee Engagement à Intention to stay</td>
<td>0.492</td>
<td>6.136</td>
<td>Significant</td>
</tr>
</tbody>
</table>

Structural or inner model measurement is used to see the relationship between variables, through a bootstrapping process. Individual reflective size is said to be valid if it has a t-statistic value greater than 1.96 (two-side test). If statistical value of a variable is less than 1.96, then the variables do not affect each other.

Table 3 can be explained as follows:

1. Happiness at work does not have a significant relationship with intention to stay, with a t-statistic value of 1.197 (<1.96). The original sample estimate value is positive (=0.099); hence indicating that happiness at work has a positive relationship with intention to stay. Thus the H1 hypothesis in this study which states that “Happiness at work has an effect on intention to stay” is not acceptable.

2. Happiness at work has a significant relationship with employee engagement, with a t-statistic value of 10.660 (>1.96). The original sample estimate value is positive (=0.541); hence indicating that happiness at work has a positive relationship with employee engagement. Thus the H2 hypothesis in this study which states that “Happiness at work has an effect on employee engagement” is acceptable.

3. Employee engagement has a significant relationship with intention to stay, with a t-statistic value of 6.136 (>1.96). The original sample estimate value is positive (=0.492); hence indicating that employee engagement has a positive relationship with intention to stay. Thus the H3 hypothesis in this study which states that “Employee engagement has an effect on intention to stay” is acceptable.

Discussion

The Effect of Happiness at Work Factor on Employee Engagement

The results showed that happiness at work had a direct effect on employee engagement. Happiness at work relates to employee satisfaction, commitment and engagement. Both job satisfaction and employees’ commitment to the organization are strong predictors in improving employee performance and turnover. Previous researchers by some experts have proven that happiness affects performance, including employee engagement at work.

The relationships between happiness and employee engagement are affected by several reasons: First, the construct of happiness contains an understanding of intrinsic motivation in individuals to excel in life in general, both in marriage and in social life. Workers will stay in the organization very much depending on how they see the future in the organization. Furthermore, employees will leave the company if the company they work for cannot provide happiness to their workers. Thus, happiness is a power from within an individual and not based on external factors. The choice to act is not influenced by external factors. If the environment is wrong, the individual continues to act in accordance with his dignity as a person. Second, employee engagement is a motivation for achievement in work in the company. These two psychological constructs basically have a relationship with individual achievement. Happiness is basically an intrinsic motivation to grow, while engagement results in inherent strength in the company. Both constructs basically contribute to employee performance. Consequently, happiness is one of the causes of employee engagement that will influence employee performance.

The Effect of Employee Engagement Factor on Intention to Stay

The results showed that employee engagement has a direct effect on the intention to stay. The variable that has the highest influence as a form of employee engagement factor is satisfaction with the hospital where they work. In addition, inspiring leadership also affects employee engagement. It is undeniable that engagement has an impact on improving financial performance, work quality, employee retention, customer satisfaction and loyalty. Employee engagement is an important contributor to employee retention, customer satisfaction and performance.
Employees who are satisfied with the company will have a low level of stress. Otherwise, they will have a high level of commitment and advocacy. Engaged employees have higher job satisfaction than disengaged employees. Engaged employees have a positive attitude, strong discipline and good work behaviour in the work. The CEO of General Electric described three benchmarks of a healthy organization, i.e. employee attachments, customer satisfaction and positive cash flow.

Happiness in the workplace is very important for employees because employees who are happy at work, have positive feelings that make employees satisfied and productive, which will result on low turnover. As a consequence, happiness at work will create qualified human resources. Basically, employees who are happy at work will have both positive and negative impacts on the organization. By observing both positive and negative effects that are obtained from happy and unhappy employees, the organization can increase employee happiness at work. However, to increase employee happiness at work, it is important to first know the factors that make employees happy at work.

The Effect of Happiness at Work Factor on Intention to Stay

The results showed that happiness at work has no direct effect on the intention to stay, but has effect through employee engagement.

Happiness in the workplace is very important for individuals because individuals who are happy at work, have positive feelings that make individuals satisfied and productive, which will result on low turnover. As a consequence, happiness at work will create qualified human resources. Basically, individuals who are happy at work will have both positive and negative impacts on the organization. By observing both positive and negative effects that are obtained from happy and unhappy individuals, the organization can increase individual happiness at work. However, to increase individual happiness at work, it is important to first know the factors that make individuals happy at work. The factors are (1) positive relationships with others, (2) achievements, (3) physical work environment, (4) compensation, and (5) health. Positive relationships with others are the main factor that makes someone happy at work.

Conclusions

Based on the results of analysis, this research can be concluded as below:

1. Happiness at work has positive and significant relationship with employee engagement;
2. Employee engagement has positive and significant relationship with intention to stay;
3. Happiness at work has no relationship with intention to stay.

Abstract

Background: Patients with chronic disease, including tuberculosis, can easily get depressed. A valid and reliable instrument is needed to detect depression in tuberculosis patients. The Indonesian language version of Zung Self-Rating Depression Scale questionnaire is needed to be proved as a valid and reliable instrument because so many Indonesian people are unable to read the English version.

Objective: The purpose of this research is to obtain evidence on the validity and reliability of the Indonesian language version of Zung Self-Rating Depression Scale questionnaire.

Method: The design of this study is cross-sectional by giving Zung Self-Rating Depression Scale questionnaire that had been translated into Indonesian language to pulmonary tuberculosis patients. Characteristics of the population were presented as mean, standard deviation, and percentage. Corrected Item-Total Correlation table was used for validity test and reliability test result was presented as Cronbach’s Alpha value.

Results: Mean age of the population in this research is 47.75 ± 8.44 years old. Most of all have married (93%). Male and female pulmonary tuberculosis patients are 69% and 31% and 43% only graduated from elementary school. All 20 questions are valid because Corrected Item-Total Correlation values for all the questions are more than r table (>0.195). The questionnaire is also reliable with r Alpha value (Cronbach’s Alpha) 0.887, greater than r table value (>0.195).

Conclusion: Indonesian language version of Zung Self-Rating Depression Scale questionnaire is a valid and reliable instrument to be used for detecting depression in adult pulmonary tuberculosis patients.

Introduction

Tuberculosis (TB) is an infectious disease. It is caused by Mycobacterium tuberculosis. It majorly infects the lungs and known as pulmonary TB, but can also find in other part of the human body and known as extrapulmonary TB. Tuberculosis is one of major global health problems until now. It causes ill health people about 10 million people a year worldwide and become one of the top ten causes of population death. It’s the 9th causes of population death and its ranking is above Human immunodeficiency Virus (HIV)/ Acquired Immunodeficiency Syndrome (AIDS). New cases of Tuberculosis in the world were 6.3 million cases in 2016. Death in Tuberculosis without HIV patients almost 82% reported from WHO African Region and the WHO South-East Asia Region in 2016. Approximately 33% of global deaths in Tuberculosis without HIV patients occurred in India. Indonesia is one of the top 20 countries with the highest incident of TB cases that share 84% of global TB incidence in 2016. TB incidence rate in Indonesia is ≥ 300 per 100,000 population in 2016, Indonesia get the second position after India for countries that have largest incident cases in 2016(1).

Psychiatric problems and mental illness, depression includes mood disorder, may develops in patients with TB. Prevalence of depression have a significant correlation with the severity and duration of disease. The failure of TB control can be caused by many factors, includes the nonadherence to medication that was caused by psychiatric disorders (2). Poor of adherence to medication is a behavioural problem (3). TB and psychiatric disorder have a two way relationship. Severe mental disorder has a positive and significant relation with the incidence of TB, and conversely, the incidence of mental disorder comorbidity increases in TB patients. Researches in England found that 30 – 34% of TB patients were having mental disorder and research in New York found that 20 – 50 % of TB patients were nonadherence to medication because of psychological problems. A research focused on the contagious factors in depression incident of TB patients at Kariadi Hospital in Semarang, Indonesia, found that 51.9% patients with TB were depressed (4).

Valid and reliable instruments needed to detect the psychiatric disorder in TB patients. Zung Self-Rating Depression Scale has been provided by World Health Organization as an instrument to detect depression, but this instrument was written in English language. Not all Indonesian people are able to read and understand English language, so that this instrument should be translated in Indonesian language in order to use it for Indonesian patients, especially Indonesian pulmonary tuberculosis patients. Translation of an instrument needed for a cross cultural research. Translation cannot only be done literally because it can develop cross cultural pitfalls. The challenge is to create a translated version that can be adapted to the local language and culture, but still maintain the original meaning of the items. Translated version of an instrument should be validated for the specific population (5). This research was done to validate and obtain the evidence of reliability of the Indonesian version Zung Self-Rating Depression Scale in pulmonary TB patients’ population.

Materials and Method

This study was approved by Pelita Harapan University Ethical Committee. The design of this study is cross sectional by giving Zung Self-Rating Depression Scale questionnaire that have been translated to Indonesian language to pulmonary tuberculosis patients. Zung Self-Rating Depression Scale questionnaire was translated from original English version to Indonesian language version by one psychiatrist and one clinical psychologist. After being translated from English version, the Indonesian language version was reviewed by one medical doctor with master degree of psychology. The Indonesian language version that has been reviewed then was given to The Faculty of Cultural and Science, University of Indonesia to be back translated to English version by translator that was blinded to the original questionnaire. The result from back translate process was reviewed once again and compared with the original English version to make sure that the back translate version has the same meaning as the original English version. After the reviewer stated that the back translate version has the same meaning as the original English version, the Indonesian language version was given to the pulmonary tuberculosis patients to be tested for validity and reliability (5).

Participants included in the validity and reliability test for the Indonesian language version of Zung Self-Rating Depression Scale questionnaire were 100 patients with pulmonary tuberculosis that were treated as outpatient in Siloam General Hospitals Lippo Karawaci, Puskesmas Kutai and Puskesmas Curug from March to April 2018. The sampling method used was consecutive sampling. Every patient came to the outpatient department was included until we got 100 patients. Informed consents
were given and Indonesian version of Zung Self-Rating Depression Scale questionnaires were filled by patients that have agreed to be participated in this study after they were explained about how to fill the questionnaire.

Inclusion criteria for the patients included in this study are 17 – 66 years old male or female patients with lung tuberculosis who stay in Tangerang and are receiving Tuberculosis drugs regimen therapy. Exclusion criteria in this study are male or female patients who did not agree to participate in this study, and also pregnant female patients. Other data collected from the patients were gender, age, weight, height, educational status, and marital status. All data collected by interviewing the patients.

The data were then analyzed using Statistical Package for the Social Sciences (SPSS) version 23. Numeric variable of characteristics of the population were presented as mean and standard deviation, meanwhile categorical variable of characteristics of the population were presented as percentage. Validity test was done to assess the construct validation. Each question will be declared as a valid question if the corrected item-total correlation value is higher than r table value, so that the validity test result was presented as Corrected Item-Total Correlation table. For reliability test, the internal consistency was evaluated using Cronbach’s Alpha value. The internal consistency will be considered as internally consistent if the Cronbach’s Alpha value is 0.7 or higher, so that the result was presented as Cronbach’s Alpha value\(^{6,7}\).

### Findings

A. Characteristics of Population

Table 2 shows the r Alpha value (Cronbach’s Alpha) is 0.887. This value is higher than 0.7 (>0.7).

Discussion

Psychiatric disorders, including depression, can be experienced by patients with pulmonary TB. There is a significant correlation between prevalence of depression and severity and duration of TB. Psychiatric disorder is one of the factors that cause non adherence to the treatments given to pulmonary TB patients (2). Depression should be detected as early as possible. Zung Self-Rating Depression Scale questionnaire is one of many instruments that can be used to detect depression in TB patients, but this questionnaire is provided in English language.

Many Indonesian people cannot read and understand English language, so that Zung Self-Rating Depression Scale questionnaire should be translated to Indonesian language. Translation to different language can compromise validity of the questionnaire. The translation cannot be done literally because complex inter-cultural problems (5). Validity and reliability evidences in pulmonary TB patients should be obtained for the translated version of Zung Self-Rating Depression Scale questionnaire used. Validity and reliability evidences were obtained by testing this translated questionnaire to 100 pulmonary TB patients.

Almost all patients with pulmonary TB tested in this research have married (93%). Previous study shows that 84.3% patients with pulmonary TB are married (10). Other study in Indonesia, Central java province: Banyumas district, shows that 59.1% patient with pulmonary TB are married (11). Study in Semarang district, also shows that 61% of pulmonary TB patients are married (12). We can see that pulmonary TB happened more frequent in married patients and the same result was found in this study.

Most of the pulmonary TB patients tested are male pulmonary tuberculosis patients (69%). According to World Health Organization (WHO), in 2018 pulmonary TB was generally more frequent to invade male than female, summarize with 64% percentage of the infected population were male patients. In Indonesia, male population might have three times higher chance to be infected by pulmonary TB than female patients. However, the smoking and alcohol consumption habit (which is likely done by male) are also taking part to make the number higher in male patients (8). Other study of the pulmonary TB based on gender issue has shown that 58% of male population were infected (12). The other study describe to about gender issue of pulmonary TB shown that 61.3% are males (13). As several study have been done, the result shown that male population are generally have more tended to get pulmonary TB infection than female population.

Most of the pulmonary TB patients tested were graduated from elementary school (43%), 20% were graduated from Junior High School, 19% were graduated from Senior High School, 9% were Diploma, and the rest were Bachelor. The results from several other studies has shown that the patients with Pulmonary TB were mostly only graduated from primary education as much as 95.5%, and only 4.5% were graduated from higher education (8). Other study of the pulmonary TB based on gender issue has shown that 58% of male population were infected (12). The other study describe to about gender issue of pulmonary TB shown that 61.3% are males (13). As several study have been done, the result shown that male population are generally have more tended to get pulmonary TB infection than female population.

In this research we found that the mean age of the tested pulmonary TB population is 47.75 ± 8.44 years old. The cases in all countries, by age groups, 90% were adults with age > 15 years. In Indonesia, based on data from Indonesian Ministry of Health, in 2018 the prevalence of pulmonary TB is 759 per 100,000 population with age > 15 years old (8). From two data above we can see that pulmonary TB mostly happened in population with age > 15 years old. The result about the population age in this study is almost the same with the data from WHO and Indonesian Ministry of Health (9).
Corrected Item-Total Correlation values for each question in this research are 0.210 – 0.728. Corrected Item-Total Correlation values are more than r table (0.195) for all 20 questions. That means all 20 questions that have been translated to Indonesian language are valid questions, especially to be used to pulmonary TB patients. R Alpha value (Cronbach’s Alpha) for the translated Zung Self-Rating Depression Scale questionnaire is 0.887. This value is higher than 0.7 (>0.7). It means that this questionnaire is reliable and has a good internal consistency.

The limitation of this research are 1) in this research the translated Zung Self-Rating Depression Scale questionnaire only tested in 100 pulmonary tuberculosis patients, so that the adequacy of the sample can be ranked as poor, 2) there was a possibility that the unhealthy patients were too lazy to answer the questions seriously too weak to concentrate, although this possibility had been reduced by giving them informed consent and slowly detailed explanation about how to fill the questions before they started to fill the questionnaire, 3) the questionnaires were given to the patients and filled in the busy and noisy outpatient departments that can distract patient’s concentration in understanding the real meaning of the questions.

Conclusion

The translated Indonesian version of Zung Self-Rating Depression Scale questionnaire is a valid and reliable instrument to detect depression in adult pulmonary TB patients with different educational status.

Abstract

The use of production machinery in the industry is getting higher. Noise due to production machinery disturbs workers, resulting in hearing loss for workers. Deafness due to industrial noise is one of the diseases caused by work. The purpose of the study was to analyze noise intensity and analyze the benefits of earplug on hearing loss. This research is a quantitative study, the design used is a cross-sectional study. The population is workers at PT X who are exposed to noise intensity of 81 - 89 dB of 77 workers. Total population sampling technique. Data analysis using Spearman correlation (rs). The results of the analysis have no relationship to noise intensity with the right audiometry value (p-value = 0.895), there is no correlation between noise intensity and left audiometric measurements (p-value = 0.581). Workers use personal protective equipment so that noise intensity does not affect hearing function. Earplugs used when working are useful as barriers to protect hearing, able to reduce noise intensity by 30 dB. There is a relationship between right and left audiometry (p-value = 0.000). Decreasing the hearing power in the right ear will result in a decrease in hearing the power in the left ear, and vice versa. The auditory structure of the right and left ears has anatomically uninterrupted pathways (interconnected channels). Conclusion Earplugs function effectively to protect the ears from hearing loss, therefore it is highly recommended that you always use earplugs during work.

Keywords: Audiometry, Personal protective equipment, Earplug, Hearing loss, Noise intensity.

Introduction

The World Health Organization (WHO) said that in 2013 as many as 360 million people in the world experienced hearing loss, of which 180 million people who experience hearing loss are in the Southeast Asia region¹. Occupational diseases due to noise exposure rank first in the United States and Europe.

Hidayat et al. (2014) found 63% of employees experienced sensorineural hearing loss, who worked in the production room of PT Alas Kusuma, Kubu Raya Regency. This industry is engaged in wood which produces plywood, block boards, sawn timber and paper overlays, noise intensity of 93.3 dB². The 2018 Regional Health Research notes the causes of hearing loss include: deafness 0.09%, cervical blockage 18.8% and 2.4% secretions in the ear canal¹. Hearing loss causes decreased sensitivity to received sound impulses. Some of the causes that reduce hearing power based on the results of Regional Health Research come from human physiology, not from factors outside the environment or work environment.
Indonesia as a developing country has experienced rapid progress in the field of industry with the availability of industrial machinery for the production process and producing company products. The use of industrial machinery creates noise in the work environment. Unwanted sounds that exceed the ear’s ability to receive them are called noise. Sources of industrial engine noise can result in hearing loss for workers.

Hearing loss occurs due to several reasons, such as age factor, obstruction of the ear canal, secretion in the ear, exposure to noise, long exposure to noise, air pressure and drug use. Industrial noise sources come from production machines. Industries generally use machines that produce noise in the work environment, and this noise is received by workers during their work. The longer workers exposed to the noise the more at risk of experiencing occupational diseases. Aksurali (2010) states that hearing loss is initially temporary, becomes permanent if it is continuously exposed to noise in the workplace which can lead to workplace accidents(3).

Hearing loss due to noise exposure cannot be cured, only can be prevented by noise control efforts(4). One action that can be done is to provide ear protectors or APT (Ear Protector). The use of ear protectors, based on the results of Rahayu’s research (2016), the company provides premolded Ear Protector for workers exposed to noise. The tool is able to reduce noise by 25-27 dB, but workers feel uncomfortable using this type of Ear Protective Equipment, so many workers who do not use Ear Protector Equipment while working, the impact found complaints include: workers feel the ears often buzzing (52%), often dizzy (36%), listening to television with very loud volume (60%), pain in one or both ears (14%) and found 38% screaming when talking(5).

Research at PT X has noise intensity between 81 - 89 decible. Data obtained in the field found 22 workers experiencing hearing loss. Workers are given a personal protective device (PPE), the earplug, workers use PPE but sometimes release the device when the worker. Departing from this problem, it is necessary to analyze the use of earplugs as ear protectors, so as to provide motivation for workers to adhere to the rules and standards of work procedures and support the company to implement health protection for workers. Research problem: does the noise intensity affect hearing? Are earplugs useful to prevent hearing loss? The aim of the study: to analyze the intensity of noise to decrease hearing and analyze the benefits of earplugs to prevent hearing loss.

Material and Method

This research is a quantitative study, the design used is a cross-sectional study. The study was conducted for 6 months, from May 2018 to October 2018. The population of this study was all workers in the PT X production section. The sample was taken by means of the total population, as many as 77 workers in the production section of PT X. Data were collected by directly measuring the noise intensity and worker audiometry examination at PT X by the company doctor.

Data analysis through several stages, namely: Univariate, data analyzed and presented in the form of a frequency distribution of each research variable. The next step is to test the normality of the data, this test is done to determine the next bivariate analysis. If the results of data analysis are normally distributed using parametric tests (product moment correlation), and if the data is not normally distributed using non-parametric tests (Spearman correlation). The next stage is bivariate analysis using Spearman Correlation (rs) because the research data scale is ratio and data is not normally distributed (non-parametric test).

Results and Discussion

The data obtained from this study are grouped in two parts, namely univariate data consisting of the characteristics of the research respondents based on age, years of service, noise intensity, and hearing loss can be seen in the table below:

Table 1. Characteristics of Age and Working Period

<table>
<thead>
<tr>
<th>Age (year)</th>
<th>Frequency (f)</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>24 – 33</td>
<td>12</td>
<td>15, 6</td>
</tr>
<tr>
<td>34 – 43</td>
<td>56</td>
<td>72, 7</td>
</tr>
<tr>
<td>44 – 53</td>
<td>9</td>
<td>11, 7</td>
</tr>
<tr>
<td>Amount</td>
<td>77</td>
<td>100</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Working Period (year)</th>
<th>Frequency (f)</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 5</td>
<td>8</td>
<td>10, 4</td>
</tr>
<tr>
<td>– 10</td>
<td>7</td>
<td>9, 1</td>
</tr>
<tr>
<td>&gt; 10</td>
<td>62</td>
<td>80, 5</td>
</tr>
<tr>
<td>Amount</td>
<td>77</td>
<td>100</td>
</tr>
</tbody>
</table>

Based on age, the majority of workers aged 34-44 years were 56 people (72.7%), 24 - 33 years as many
as 12 people (15.6%) and aged 44 - 53 years as many as 9 people (11.7%). Age is at risk for hearing loss. Decreasing hearing thresholds due to age or presbycusis is the most common cause in developed countries\(^6\). The majority of respondents of productive age hearing function has not decreased, but hearing loss due to noise is very common in the age group > 40 years\(^7\).

Based on years of work, the majority of workers have a tenure of > 10 years totaling 62 people (80.5%), work period < 5 years 8 people (10.4%) and working period of 5 - 10 years 7 people (9.1%). Previous research revealed the prevalence ratio (RP) of hearing loss 2.1 (RP > 1) indicating that working period is a risk factor for hearing loss\(^8\).

Table 2. Respondents Exposed to Noise Intensity

<table>
<thead>
<tr>
<th>Noise Intensity (dB)</th>
<th>Frequency (f)</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal (&lt; 85)</td>
<td>20</td>
<td>26.0</td>
</tr>
<tr>
<td>Noisy (&gt; 86)</td>
<td>57</td>
<td>74.0</td>
</tr>
<tr>
<td>Amount</td>
<td>77</td>
<td>100</td>
</tr>
</tbody>
</table>

The noise intensity is grouped into 2 normal and noisy categories, workers who work in the production section and are exposed to noise > 86 dB as many as 57 people (74%). Exposure to noise received by workers exceeds the appropriate threshold value. Suma’mur (2009) mentions noise intensity in Indonesia which is used as a guideline for hearing protection so that there is no hearing loss which is 8 hours a day for 5 working days (40 hours a week) is 85 dB (A). This provision was agreed upon for 3 decades, and finally became a national standard\(^9\).

Table 3. Hearing Loss experienced by Workers

<table>
<thead>
<tr>
<th>Hearing disorders</th>
<th>Frequency (f)</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>There is no interference</td>
<td>55</td>
<td>71.4</td>
</tr>
<tr>
<td>Hearing disorders</td>
<td>22</td>
<td>28.6</td>
</tr>
<tr>
<td>Amount</td>
<td>77</td>
<td>100</td>
</tr>
</tbody>
</table>

Based on the table above, it was found that hearing loss was experienced by 22 workers (28.6%) and workers who did not experience 55 hearing loss (71.4%). Hearing loss which looks a very common health issue but affects nearly 10% of the world population as indicated by many international studies. Hearing disorders effectively frail sensitivity to the sounds ordinarily heard\(^10\). Liang K et al. (2018) stated that environmental and human activities can be at risk for ear disorders, such as upland residents who carry out daily activities in the lowlands experiencing changes in barotrauma air pressure\(^11\).

Bivariate Analysis

Audiometric measurement data is numerical and abnormally distributed data, so that data analysis is adjusted to the data obtained using non-parametric tests. The following are the results of analysis of Spearman correlation non-parametric test (rs).

Table 4. Correlation of Noise Intensity with Audiometry Measurements

<table>
<thead>
<tr>
<th>Variable</th>
<th>Correlation value</th>
<th>Noise Intensity</th>
<th>Right Audiometry</th>
<th>Left Audiometry</th>
</tr>
</thead>
<tbody>
<tr>
<td>Noise Intensity</td>
<td>Correlation coefficient</td>
<td>1,000</td>
<td>0.015</td>
<td>-0.064</td>
</tr>
<tr>
<td></td>
<td>Significant (p value)</td>
<td>-</td>
<td>0.895</td>
<td>0.581</td>
</tr>
<tr>
<td>Right Audiometry</td>
<td>Correlation coefficient</td>
<td>0.015</td>
<td>1.000</td>
<td>0.647**</td>
</tr>
<tr>
<td></td>
<td>Significant (p value)</td>
<td>0.895</td>
<td>-</td>
<td>0.000</td>
</tr>
<tr>
<td>Left Audiometry</td>
<td>Correlation coefficient</td>
<td>-0.064</td>
<td>0.647**</td>
<td>1.000</td>
</tr>
<tr>
<td></td>
<td>Significant (p value)</td>
<td>0.581</td>
<td>0.000</td>
<td>-</td>
</tr>
</tbody>
</table>

The results of the Spearman correlation noise intensity with the right audiometry obtained a value of \(r = 0.015\) and the value of \(p = 0.895\) showed no relationship between noise intensity and right audiometry. Noise intensity with left audiometry obtained a value of \(r = -0.064\) and the value of \(p = 0.581\) showed no relationship between noise intensity and left audiometry. Increased audiometry results of 22 workers and diagnosed with hearing loss were not caused by noise exposure but were indicated due to other factors not examined such as drug use, cerumen blockage, earwax, lifestyle, smoking behavior and others.

Although workers are exposed to noise but are not related to statistical audiometry values. The results of monitoring workers use Personal Protective Equipment
so that noise does not interfere with hearing power. Ear plugs that are used when working are useful for protecting hearing function. Research by Fredinanta et al. (2013) describes the efforts to reduce noise can be done by controlling at the recipient level. The use of ear plugs provides benefits as ear protectors against the decreased hearing. This tool can reduce noise by + 30 dBA so that the earplug effectively protects the ear from noise exposure(12).

Workers exposed to noise levels 80 - 85 dB are not required to use Personal Protective Equipment, based on Minister of Manpower Decree No. 13 of 2011, because noise sources are at the noise threshold for 8 working hours per day. Workers are advised to use Personal Protective Equipment in this zone, to prevent Occupational Diseases. Measurement of noise intensity at PT X found 12 points above the threshold value (85 - 90 dB) zones must use Personal Protective Equipment(13).

The measurement of right and left audiometry values obtained $r = 0.647$ and the value of $p = 0.000$ means that there is a relationship between the right audiometry and left audiometry and shows a strong and positive pattern, meaning that the higher the right audiometric value the higher the left audiometric value. Decreasing the hearing power in the right ear will result in a decrease in hearing the power in the left ear, and vice versa. Research conducted to prove the ability to hear between the right and left ears, the test involved 41 people aged 19-28 years. Samples are given different information through headphones. The test results found no difference between the functions of the right and left ears in capturing information(14).

Based on the audiogram measurement standard, the classification of deafness is based on audiogram values as follows:

<table>
<thead>
<tr>
<th>Category</th>
<th>Audiometry Value Standard (dB)</th>
<th>Audiometry Value Standard (Person) Measurement Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal</td>
<td>0 – 25</td>
<td>55</td>
</tr>
<tr>
<td>Mild deafness</td>
<td>26 – 40</td>
<td>21</td>
</tr>
<tr>
<td>Being Deaf</td>
<td>41 – 60</td>
<td>1</td>
</tr>
<tr>
<td>Deafness is heavy</td>
<td>61 – 90</td>
<td>0</td>
</tr>
<tr>
<td>Very heavy</td>
<td>&gt; 91</td>
<td>0</td>
</tr>
<tr>
<td>Amount</td>
<td></td>
<td>77</td>
</tr>
</tbody>
</table>

High audiometry value means hearing loss, and the results of analysis based on Spearman test found that the relationship between right ear hearing loss will have an impact on hearing the loss in the left ear. The hearing loss is usually slow in onset but progresses relentlessly for as along as the exposure continues. Indeed, the harmful effects may continue long after noise exposure has ceased. They are irreversible(15). In accordance with the results of the study, the ability to hear the right ear is related to the ability to hear the left ear, the auditory structure of the right and left ears anatomically has an unbroken relationship path (interconnected channels). Sound received by someone, in the form of vibration in the eardrum. Vibration is produced from a number of variations in air pressure produced by the sound source and propagated by the surrounding medium, called the acoustic field. This sound changes from an acoustic signal to an electrical signal and is transmitted by the auditory nerve to the brain(16). Sound localization requires the cooperation of both ears. A sound source close to the right ear will enter the brain earlier than the left ear, but if the sound source is in a straight position it will reach both ears at the same time.

Conclusions and Recommendations

1. The earplug functions to effectively protect the ear from hearing loss, therefore it is very good to still use earplug during work.

2. The decrease in the hearing of the right ear is associated with a decrease in hearing the power in the left ear because the ability to hear the right ear is related to the ability to hear the left ear.

3. There is no correlation between noise intensity and hearing loss, although the intensity of noise in the workplace exceeds the threshold value does not affect the hearing of workers because the earplug can reduce noise intensity + 30 dB (A).

Acknowledgments

Directors, managers and all employees of PT X for the support and permission of the research provided, and willingness to become research respondents.

Study of Deviated Nasal Septum in Vijaywada Population

Chikkala Jagadeesh Babu

1Assistant Professor, Department of ENT Nimra Institute of Medical Science, Ibrahim Patnum Vijaywada-8, Andra Pradesh

Abstract

35 males and 25 female patients aged between 18-40 were studied. There were three types of DNS. Left deviation were 35(58.3%), right deviation were 20(33.3%) and 5(8.3%) were bilateral. The symptoms were bilateral. The symptoms were nasal observation24(40%), nasal discharge 12(20%), headache 10(16.6%), 9(15%) bleeding per nose, 5 (8.3%) had loss of smell. Post–operative complicated were bleeding 1%, residual deforming or deviation was 5.2%, syneche was 5.50% and septal perforation was 0%. Relief after post endoscopic septoplasty were nasal obstruction 94%, headache 82% nasal discharge 84.5%, Hyposmia 86.5%. This study of deviated nasal septum will be quite useful to ENT surgeons, radiologists and physicians to correlate the percentage of relief from various complications after endoscopic septoplasty.

Keywords: Endoscopic septoplasty, DNS-Deviated nasal septum, Vijaywada

Introduction

Nasal septum in the armature of nose It maintains the nose in prominent position over the face. Besides an anatomical function it also helps in physiological function of respiratory system. Deviated nasal septum (DNS) is a rule rather than an exception and is considered to arise out of consequences of trauma(1) either during intrauterine life or thereafter. Though majority of human beings have deviated nasal septum, most of them are asymptomatic and cause little or no any discomfort. However nasal septum may cause nasal obstruction and predispose to various inter related ailments like sinusitis, epistaxis, dysfunction of auditory tube otitis media and upper and lower respiratory tract infections, dental mal alignment leads to poor general health(2) DNS was classified into four different groups, sublaxation, large spurs, caudal deflection and tension septum(3). Endoscopic septoplasty is minimal invasive technique that helps to correct the deformity of the septum under direct visualization using an endoscope. Which is a latest technique as compared to seepoplasty because convention septoplasty has increased morbidity due to poor visualization, relative inaccessibility to poor visualization, relativeinaccessibility, poor illumination hence it is difficult to evaluate exact pathology. Therefore endoscopic septoplasty is used to treat the DNS and satisfactory results were observed(4). Hence attempt was made to prove that endoscopic septoplasty is safer, with least morbidity in both sexes of different age groups.

Material and Method

Sixty (60) patients 35 males and 25 females aged between 18-40 years were selected for study who were regularly visiting ENT OPD of Nimra Institute of medical science Ibrahim patnum Vijayawada (Andra-pradesh)

The patients presenting with complaints due to deviated nasal septum were diagnosed clinically, radiologically and endoscopically. The patients below 17 years, patients with acute respiratory tract infection or other nasal pathology requiring major surgery were excluded from the present study. Their occupation, past history was recorded. Endoscopic septoplasty was done in all the patients of DNS the ratio of the male with females was 1:2. The percentage of male was 58.3% and females were 41.6%. Post
operative patients called for follow up second week after the surgery; There after 90 days, 180 days respectively. If there is any complication like nasal obstruction, nasal discharge, headache, bleeding per nose and hyposmia. Nasal endoscopy was done to rule out the symptoms.

The duration of the study was about three years

**Observation and Results**

Table-1 patients were classified according to side of septal deviation. 35(58.3%) patients had left deviation, 20(33.3%)had right deviation, while 5(8.3%)had bilateral deviation.

Table - 2 patients were classified with different symptoms related to DNS 24(40%) had nasal obstruction, 12(20%)had nasal discharge, 10(16.6%)had headache, 9 (15%)had bleeding per nose, 5(8.3%) had loss of smell.

Table-3 present study of post operative complication were compared with previous studies- bleeding was observed in the study of Sulagavi was 14 %, manjunath 4%, chungetal 0.9%, mohd Nizam 0%, but in presents study 1. Similarly (b) residual deviation or deformity was observed in the study Leena Jain was 13%, suligavi 16%, chungetal 0.9%, mohd Nizam 6.67% but in present study was 5.2%.

(c) Synchae was observed in study of Suligavi was 6% ,Manjunath 4%,Chungetal 2.6%, Mohd Nizam 6.67% but in present study it was 5.50%.

(d) Septal perforation was observed only in the study of chung etal.

Table-4. The present study of relief after post endoscopic septoplasty was compared with previous studies

(a) Relief from Nasal observation was 96% in study of suligavi etal , Gupta etal ,Leena jain etal, Sathyaki, 93.3% and in present study it was 94%

(b) Relief from headache was observed 94.4% in the study ofSuligavi etal, 100% in Gupta etal,Satyak etal was 54%. In the study of Leena Jain and inMohd Nizam 80.9% but in presents study-82%

(c) Relief from nasal discharge was 100% in the study of Suligavi etal and Sathyaki etal 88%, in study of Leena 85%, in the study of Mohd Nizam and in present study it was 84.5%

(d) Relief from hyposmia 100% in the study of suligavi etal , Leena jain and sathayki , 87.5% in the study of Mohd Nizam and 86.5 in the presents study

**Discussion**

In the present study of DNS in Vijayawada population. The male patients were 35(58.3%) and females were 25(41.6%) the left DNS were 35(58.3%) and right DNS were 20(33.3%) and 5 (8.3%) were bilateral (Table-1). Nasal obstruction patients were 24(40%), nasal discharge were 12.(20%) ,headache 10(16.6%), 9(15%) bleeding per nose, 5(8.3%) had loss of smell (Table-2).These finding of DNS and associated clinical symptoms were more or less in the agreement with previous studies.(5)(6)

In the present study of post operative complications, bleeding was 1% residual or deviation or deformity was 5%. synchae was 5.50 %and there was no septal perforation(Table-3).These findings were more or less in the agreement with pervious workers (7)(8). The relief after endoscopic septoplasty was in nasal abstraction was 94 %, relief from headache was 82%, nasal discharge was 84.5%, hyposmia was 86.5. These findings were also more or less in agreement with previous studies (9)(10).

In majority of the casesetiology Could not be established but direct trauma was found to be the one of the factor, moreover these was little role of hereditary factors of DNS but it can be hypothesized that DNS could be admixture of races. Because civilized patients tend to have enlarged facialangle (11) hence DNS may be regarded as one of the disadvantages of racial admixture which needs surgical corrections. Again this admixture of race confirms because DNS will have more clinicalmanifestations in adult hood rather than children. In addition to this occupation of patients will also aggravate the symptoms of DNS.

**Summary and Conclusion**

The present of deviated nasal septum (DNS) of population in both sexes will be quite useful to the ENT surgeons, radiologist to rule out the type of DNS and its post–operative complications and degree of relief from various clinical problems but this demands further embryological,genetic and histo-pathological study of DNS because exact cause and mechanism of growth of DNS is still unclear.
This research work is approved by ethical committee of Nimra Institute of Medical Science. Ibrahim patnan Vijaywada. (Andrapradesh)

Abstract

Clean and Healthy Living Behavior/Perilaku Hidup Bersih dan Sehat (PHBS) is a health behavior by individual, family, and community to help themselves improving health status. The aim of this study was to explain the factors that influence PHBS implementation at household level in Sungai Paring Village. This study was a quantitative by using cross-sectional approach. Population of this study were 2638 households. Technique sampling used purposive random sampling with sample of 91 households. The study was analyzed by chi-square test with CI 95% and significance level 0.05. The results showed that there were no relationship between knowledge (p-value = 0.103), attitude (p-value = 0.172), distance of health care facilities (p-value = 0.089) with the implementation of PHBS. Meanwhile, support from health workers (p-value = 0.001) and community leaders (p-value = 0.010) had relationship with the implementation of PHBS. Health workers, community and stakeholders should strengthen cooperation as an effort to improve the achievement of PHBS program implementation through routine monitoring and evaluation at household level.

Keywords: Clean and Healthy Living Behavior, PHBS program, Household level, Health, behavior, Sungai Paring Village

Introduction

Health degrees are not only determined by health services, but the more dominant ones are influenced by environmental conditions and people’s behavior¹. Household members need to be empowered to implement clean and healthy living behavior or perilaku hidup bersih dan sehat (PHBS) to prevent from infectious or non-infectious diseases².

Ramdaniati (2008) stated that there was an influence of knowledge and attitude toward the implementation of PHBS at household level³. Tumiwa, Rattu and Tucunan’s research (2014) states that the predisposing, enabling, and reinforcing of health behavior, attitude, facilities and infrastructure, such as support from health professionals had a great influence in encouraging members of the household to do PHBS at household level⁴. Budiman et al. (2012) said that knowledge, support and attitude of health workers could illustrate the implementation of PHBS at household level in Cimahi City⁵. Based on several studies, concluded that several factors such as level of education, knowledge, attitude, availability of

facilities, infrastructure and support or attitude of health worker can influence the implementation of PHBS at household level.

The national target achievement of PHBS at household level based on the Ministry of Health’s strategic plan for 2015-2019 is 70%6. Based on data of Indonesian Health Profile in 2014, it was stated that the last achievement only reached 56.58%, it means that the achievement of PHBS at household level was still far from the predetermined target. South Kalimantan Province was one of the provinces that had achievement under the national target (49.74%)7. Banjar Regency had the achievement of PHBS at household level of 52.1% which also did not reached the National target8. Based on data from the Public Health Development Index in 2007 and 2013, Banjar Regency was ranked 13. Based on the result of Basic Health Research (2013) indicating that Banjar Regency can affecting Public Health Development Index of South Kalimantan Province (ranked 31 from 33 provinces). It needs to be a concern because the PHBS achievement data on the household level in Banjar Regency was not reached the target of both provincial and national9.

Data from the Banjar District Health Office in 2014 stated that Martapura Kota District had the lowest percentage of household PHBS in Banjar Regency, which was 37.1%8. Based on data from Martapura 1 Public Health Center, the lowest achievement of PHBS at household level was in Sungai Paring Village as much as 0.87% of 1846 households that had been monitored10. Based on description above, this research was conducted to explain the factors that influence the implementation of PHBS at household level in Sungai Paring Village, Martapura Kota District.

Methodology

This research was an analytic observational study. A cross sectional approach was conducted among community of Sungai Paring Village, Martapura Kota District, South Kalimantan Province, Indonesia. Population of this research were 2638 households. Sampling technique used purposive random sampling with inclusion criteria for families who have children or toddlers as many as 91 respondents. Sample calculation used Stanley Lemeshow’s formula.

Knowledge, attitudes, distance of health care facilities, and support from health workers and community leaders as independent variables. Dependent variable was PHBS implementation at household level. Informed consent sheet was filled in as a form of agreement to be a respondent. The collected data was analyzed by using SPSS software. Analysis was conducted to explain the relationship between independent and dependent variables by using chi-square test with CI 95% and significance level 0.05.

Results

There were the results of univariate (Table 1) and bivariate analysis (Table 2) between knowledge, attitude, distance of health care facilities, support from health workers and community leaders with PHBS implementation at Sungai Paring Village among 91 respondents.

Discussion

There is several factors that affecting PHBS practice at household level. In the results of Hasni, Nurdin and Edward’s research, respondents who have high knowledge and have the willingness to do PHBS, tend to practice PHBS\(^\text{11}\). That results was different with our research. Based on the result showed that knowledge did not have relationship with PHBS practice. This result was similiar with the research of Hapsari (2010) which states that knowledge did not have a significant influence on the practice of clean and healthy living behavior\(^\text{12}\). This research was found that respondent with less knowledge still did PHBS. To behave healthily, the community sometimes not only needs knowledge and positive attitude, or support from facilities only, but it also needs the role model from family or peers\(^\text{13}\). The low level of knowledge in the results of the study might caused by the fact of many people who claim they have never received counseling from health workers around their homes.

Attitude did not have relationship with PHBS implementation at household level. This results was in line with the research of Hanieck (2010) that stated an attitudes do not have a significant influence on the practice of clean and healthy living behavior (p-value = 0.087)\(^\text{14}\). The result of this study was not in line with Mahfudah’s research (2013), said that attitudes can influence individuals in a clean and healthy lifestyle\(^\text{15}\). An attitude has not been automatically realized in an action (overt behavior). The realization of an attitude to be a real action requires a supporting factor or a possible condition\(^\text{16}\). The majority of respondents had positive attitude, but did not implement PHBS can be affected by characteristics of the person such as emotional level\(^\text{12}\). People with high emotional and motivated to behave according to attitudes that have existed within their individually, will strive best for the behavior of clean and healthy living.

Distance of health care facilities was not influencing the implementation of PHBS at household level. This result was in line with the research of Hapsari (2010) which states that distance did not have a significant influence on the practice of clean and healthy behavior\(^\text{12}\). However, in contrast to the results of Ningsih’s research (2014) which states that the distance of health care facilities had an influence on the implementation of PHBS at household level. Ningsih’s research (2014) showed that respondents who had a long distance from
the place of health service allowed respondents to not implement PHBS at household level\textsuperscript{17}. There are certain distance limitations so that people still want to seek health services. Distance limits are significantly influenced by the type of road, type of vehicle, and transportation cost. Road facilities are still adequate and allow people to seek health care facilities even though the distance from the community’s residence is categorized far\textsuperscript{18}.

Support from health workers had influence on implementing PHBS at household level. This result was in line with Hapsari’s research (2010) which states that health worker’s support had a significant influence on the practice of clean and healthy living behavior\textsuperscript{12}. The support can be in the form of counseling or monitoring conducted by health workers in order to create healthy behavior in the community. In Hapsari’s study (2010), respondents who received less category counseling had less healthy living behavior practices\textsuperscript{12}.

Support from community leaders had influence on implementing PHBS at household level. This result was in line with Pratama’s research (2009) which states that the support of community leaders had a significant influence on clean and healthy living behavior, where the higher the role of community leaders in healthy behavior, the higher the motivation of the community to implement PHBS\textsuperscript{19}. Community leaders playing a role in the implementation of PHBS such as mobilizing the potential resources to develop healthy behaviors in the community, collaborating to create a healthy environment, and creating the conducive atmosphere to support changes in healthy behavior\textsuperscript{20}.

**Limitation**

This study was conducted among household in Sungai Paring Village and might therefore not being representative of other village in Martapura Kota District, Indonesia.

**Conclusions**

It can be concluded from this study that knowledge, attitude and distance of health facilities were not influencing someone to apply PHBS at household level. Several factors that influencing PHBS practice at household level were support from health workers and public figures, such as community leader. Community leaders can help activate PHBS programs such as increasing exclusive breastfeeding achievements and making healthy latrines, in several ways such as the formation of exclusive breastfeeding groups, or by forming healthy latrines.

Health workers should work together with community leaders as an effort to improve the achievement of PHBS at household level in Sungai Paring Village community. These efforts can be carried out by health workers socializing to community leaders regarding PHBS practices, so that community leaders can invite the community to implement PHBS at household level. Health workers and community leaders collaborating in order to monitor PHBS implementation at household level.

**Ethical Clearance**

The study was approved and received ethical clearance from the Research Ethics Committee of Public Health Study Program, Faculty of Medicine, Lambung Mangkurat University, Indonesia. We followed the guidelines of the Committee on Public Health Committee on Research Ethics, Faculty of Medicine, Lambung Mangkurat University, Indonesia for ethical permission and informed consent for this study.

**Sources of Funding**

This research was conducted with self funding from Public Health Study Program, Faculty of Medicine, Lambung Mangkurat University, Indonesia.

**Acknowledgements**

We would like to thank all the respondents, the community of Sungai Paring Village, who were helpful in carrying out this research. Gratefully acknowledge also to Public Health Program Study, Faculty of Medicine, Lambung Mangkurat University and government of Banjar District for giving permission to carry out this research.

**Conflict of Interest**

The authors reported no conflict of interest.

Abstract

Universal health coverage is a government program in the health sector with the aim of providing service assistance to the community, however the program has not run smoothly. This was addressed in the presence of several obstacles in the field, and further research is necessary in solving the problems. The purpose of this research is to compile recommendations for improving the compliance of universal health coverage participants in Surabaya from a marketing perspective using the Customer Value method. This activity was carried out in 2017 at the universal health coverage office in Surabaya.

The method used for data collection was by analyzing existing secondary data and primary data obtained using questionnaires given to respondents with the characteristics of payment delinquencies, with a total sample of 30 respondents according to what Cohen (2007) mentioned that quantitative research has a minimum sample of 30.

Conclusions: (1) Group of respondents with the most overdue in universal health coverage payment based on sex was the female group with a percentage of 73.3%. (2) Group of respondents with the most overdue in universal health coverage payment based on the range of age was between 26 to 35 years with a percentage of 36.7%. (3) Based on the Customer Value analysis, the following conclusions were drawn from the participants who were delinquent in paying the premiums: (a) In performance variable, participants stated that universal health coverage services were not satisfying in both emergency conditions and overall services, (b) In service variable, participants stated that the universal health coverage office was difficult to access due to its location and poor service for both old and new participants, (c) In cost variable, the premium price for every service class was still less rational.

Keywords: Universal health coverage, Health Services, Universal health coverage customers.

Introduction

In January 2014, the government established a National Health Insurance program managed by Indonesia Universal Health Coverage¹. However, the program has not been running smoothly. Problems and obstacles were found along the journey. Normatively, government’s main intervention in the management of universal health coverage is both legal and financial power of the company. As an example, its funding is regulated in the Republic of Indonesia Minister of Health Regulation No. 28 in 2014 concerning Guidelines for Implementation of the National Health Insurance Program which regulated the use of the INA CBGs application in setting tariff standards and capitation¹. Law No. 40 in 2004 concerning the National Social Security System which is also a legal basis for universal health coverage has strengthened the position of universal health coverage as a center in implementing the era of National Health Insurance (JKN)². Not only rates and capitation are regulated in the law. The addition of participation in terms of marketing at universal health coverage is also regulated in the Minister of Health Regulation No. 28 of 2014 concerning guidelines for the implementation of
health insurance which also explains participation and additional participation\(^1\).

However, all the legal basis that underlies the sustainability and governance of the Universal health coverage also limits universal health coverage movement in its business development.

For example, data in the field obtained from the division of membership expansion and compliance of universal health coverage in Surabaya (2017) from a total of 85,717 participants, as many as 31,241 participants were delinquent or as much as 36.44% in percentage. Such manners were included as a problem for universal health coverage. In attempt to reduce the delinquency of premium payments every month, universal health coverage conducted routine activities, namely social approaches carried out at every related public place in Surabaya\(^3\).

Based on this background, we were interested in learning all the problems of compliance behavior from the marketing perspective faced by universal health coverage in carrying out the mandate of the National Health Insurance.

**Method of Collecting Data**

Data retrieval during the process was carried out by analyzing existing secondary data and primary data obtained using questionnaires given to respondents with the characteristics of payment delinquencies with a total sample of 30 respondents, according to what Cohen (2007) mentioned in a study that quantitatively a minimum sample is 30\(^4\).

Data collection was also carried out by conducting observations in conjunction with the routine activities of the compliance and participation division of the universal health coverage in Surabaya.

In Table 1 it is explained that as many as 26.7% of respondents who are delinquent in paying premiums are male, while as many as 73.3% are female respondents.

b. **Age**

Characteristics of respondents based on age who are in arrears to pay the Universal health coverage premium will be shown in Table 2 as follows:

<table>
<thead>
<tr>
<th>No</th>
<th>Age</th>
<th>N</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>19 – 25</td>
<td>8</td>
<td>26.7</td>
</tr>
<tr>
<td>2</td>
<td>26 – 35</td>
<td>11</td>
<td>36.7</td>
</tr>
<tr>
<td>3</td>
<td>36 – 45</td>
<td>6</td>
<td>20</td>
</tr>
<tr>
<td>4</td>
<td>&gt;46</td>
<td>5</td>
<td>16.7</td>
</tr>
<tr>
<td>Total</td>
<td></td>
<td>30</td>
<td>100</td>
</tr>
</tbody>
</table>

In Table 2 it is known that the most overdue respondents are from 26 years to 35 years with a percentage of 36.7%. While at least more than 46 years old with a percentage of 16.7%.

2. **Performance Value of Universal health coverage**

On the questionnaire, the performance value is divided into 3 (three) questions regarding the ease of service during the emergency, the provision of affordable care classes, and the overall quality of services provided. The three questions will explain the percentage of the Likert scale in Table 3 as follows:
Table 3. Distribution of Respondents’ Answers Against Variables of Universal health coverage Performance Value for 2017

<td>9</td>
<td>30</td>
<td>10</td>
<td>33.3</td>
<td>6</td>
</tr>
</tbody>
</table>

Information:
VNA : Very Not Agree   NA : Not Agree
D : Disagree           SA : Strongly Disagree

In Table 3, it is known that the frequency of answers to the variable value of the performance of the Universal health coverage first item, as many as 40% expressed their disagreement with the ease of Universal health coverage services during the emergency situation. It can be concluded that as many as 23.3% of participants stated that the Universal health coverage were still not easy to use when in an emergency.

On the other hand, as many as 23.3% of participants said they agreed to Universal health coverage services during the emergency. It can also be concluded that Universal health coverage has made it easier for participants to use it during an emergency.

So that it can be concluded on the question of the first item regarding the ease of emergency services after seeing Table 4.3 on the distribution of respondents’ answers to the variable value of performance Universal health coverage is still not good in case of emergency.

The frequency of the answers on the range of performance values of the Universal health coverage third item concerning the overall quality of services provided, as many as 33.3% stated that they were less agreeing on the quality of the overall Universal health coverage services.

From the three questions on the Universal health coverage performance value variable, it can be concluded that the main cause participants delinquent to pay premiums every month is their emergency services still not properly facilitated when necessary and the whole services as well.

3. Value of Universal health coverage Services

On the questionnaire, the value of service is divided into 4 (four) questions about ease of access, ease of JKN mobile application, service of old participants, and service of new participants. Which will be explained in Table 4 as follows:

Table 4. Distribution of Respondents’ Answers to Variable Value of Universal health coverage Services in 2017

<table>
<thead>
<tr>
<th>No</th>
<th>Question</th>
<th>VNA</th>
<th>NA</th>
<th>D</th>
<th>AGREE</th>
<th>SA</th>
<th>n</th>
<th>%</th>
</tr>
</thead>
<tbody>

<td>14</td>
<td>46.7</td>
<td>9</td>
</tr>
<tr>
<td>2</td>
<td>Ease of JKN mobile application</td>
<td>0</td>
<td>0</td>
<td>10</td>
<td>33.3</td>
<td>6</td>
<td>20</td>
<td>11</td>
</tr>
</tbody>
</table>
In Table 3, it is known that the frequency of answers to the variable value of Universal health coverage services first item, as much as 46.7% of respondents disagree with easy access to the office's location.

The frequency of answers to the second question regarding the ease of use of JKN's mobile application services, as many as 36.7 agreed and felt that the JKN mobile application was enough to help Universal health coverage participants.

While the frequency of the questions in the third item regarding the service of the old participants, as much as 36.7% said they did not agree or it could be interpreted that the service to the old participants was still not good given to the participants.

In the fourth item question concerning the service of new participants, as many as 43.3% disagree or can be interpreted as a service for new participants is still not good. It can be concluded that participants are delinquent to pay referring to the variable value of Universal health coverage services caused by; the location of Universal health coverage services not easy to be accessed by participants, the service provided to the participants is not good and the services that Universal health coverage gives to new participants are not good enough.

4. Health Value of Universal health coverage on the variable price value of Universal health coverage, only one question item is given to the respondents, namely; Affordable premium prices per class of services which will be explained in Table 5 as follows:

<table>
<thead>
<tr>
<th>No</th>
<th>Question</th>
<th>VNA</th>
<th>NA</th>
<th>D</th>
<th>AGREE</th>
<th>SA</th>
<th>n</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Affordable premium prices per class</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>53,3</td>
<td>13</td>
<td>30</td>
<td>100</td>
</tr>
<tr>
<td>Information:</td>
<td>VNA: Very Not Agree</td>
<td>NA: Not Agree</td>
<td>D: Disagree</td>
<td>SA: Strongly Disagree</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In Table 5, it is known that 53.3% of respondents disagree with the price of affordable services. So that we can draw conclusions that participants delinquent in paying premiums still did not agree with the price determined by the Universal health coverage services class.

**Ethical Approval:** Related departments should be assured about the confidentiality of the result of questionnaires

**Conflict Interest:** The authors report no conflict of interest.

**Source of Funding:** Self

**Conclusion**

1. Group of respondents with the most overdue in universal health coverage payment based on the sex was the female group with a percentage of 73.3%.
2. Group of respondents with the most overdue in universal health coverage payment based on the range of age was between 26 to 35 years with a percentage of 36.7%.
3. Based on the Customer Value analysis, the following conclusions were drawn from the participants who were delinquent in paying the premiums:
   (a) In performance variable, participants stated
that universal health coverage services were not satisfying in both emergency conditions and overall services, (b) In service variable, participants stated that the universal health coverage office was difficult to access due to its location and poor service for both old and new participants, (c) In cost variable, the premium price for every service class was still less rational.

Suggestions / Recommendations

1. Improve Universal health coverage services during emergency conditions by simplifying the procedure of admission, so that Universal health coverage participants feel properly facilitated.

2. Improve the overall Universal health coverage services by simplifying each procedure and prioritizing procedures.

3. Facilitate access of participants to the Universal health coverage office by collaborating with the government of Surabaya to add public transportation.

4. Provide training to front office workers regarding hospitality so that services provided to old participants and new participants with various complaints may be accurately fulfilled and affect the quality of services provided.

5. Recalculate premiums per service class so that the expected amounts are more rational.
