1. A Study on Estimation of Chlorine in Drinking Water in an Urban Slum of Guntur District.................1
   K.V.S. Prasad, Anil Kumar Bathula, R. Nageswara Rao, Satya Kishore

2. Exploring the Medical Representatives’ Perception towards Motivational Measures Implemented by Selected Pharma Companies, Chennai City .................................................................6
   A.K. Subramani, N. Akbar Jan, Ashok Kumar Goute, Thangaraja Arumugam

3. Influence of Mastication Rate on Prandial Glycemia among Prediabetics: An Observation ...............14
   Arun Shirali, Nikhil Kenny Thomas, Priyanka Arun Shirali, Prakash Harishchandra, Nitin Joseph, Priya Rathi

4. Predictors of Job Satisfaction: How Satisfied are the Young Generation Doctors in Corporate Hospitals ....20
   Avipsa Padhi, Ayasa Kanta Mohanty, Manoranjan Dash

5. Statistical Analysis of M-Mode Echocardiographic Normal Reference Values in South Indian Adults.......24
   Chaithra N., Madhu B., Balasubramanian S., Sunil Kumar S.

6. Effects of Circuit Training Combined with Different Neuromuscular Activities on Muscular Endurance and Body Composition of School Girls.................................................................30
   K. Sudha, D. Maniazhagu

7. Comparative Evaluation of Mechanical Properties of Ceramic Reinforced Glass Ionomer Cement and Type IX GIC: An Invitro Study........................................................................................................35

8. Anemia among Pregnant Women and its Socio-Demographic and Reproductive Correlates: A Community Based Study............................................................................................................41
   Vinutha Vinod, Pai Divya Venkatesh, AH Suryakantha, Ashwini Kumar

9. Awareness of Knowledge of Saliva as a Diagnostic Tool.................................................................47
   T.N. Uma Mageshwari, Shachi P. Ajmera, S. Mounika

10. Public Health and Environmental Protection Linkages in Law and Practice.....................................50
    Sankalan Porwal, J.K. Mittal

11. GC/MS Analysis of Bioactive Compounds in Aqueous Extract of Cynodon Dactylon.......................55
    Anandaramajayan Nallathambi, Rajesh Bhargavan
   Ashwani Pant, Santosh Kumar

13. Effectiveness of Mind Mapping as an Active Learning Tool among MBBS Phase-1 Students in Biochemistry ........................................................................................................................................ 64
   Deepa S. Sajjannar, G.V. Naregal, S.S. Walvekar

   Kasturi Goswami

15. Developing Health Awareness among the Rural-Urban Fringe Students in the ESL Classroom through Language Activities ........................................................................................................ 76
   M. Samuel Jayakumar, P. Bhaskaran Nair

   M.Z.M. Nomani, Ajaz Afzal Lone, Alaa K.K. Alhalboosi, Aijaj A. Raj, Zubair Ahmed

17. Effects of Migration on the Health of Kashmiri Pandits ........................................................................................................ 89
   Nikita Bhan, Sukhwant S. Bindra

18. Knowledge and Awareness about Nipah Virus Infection among Dentists and Dental Students in Chennai: A Cross Sectional Study ........................................................................................................................................... 93
   Chandrasekaran Krithika, M.R. Sanjana, Chitathoor Sridhar, A. Brighton Maniselvan, K. Ekambareswaran, D. Deepiha, D. Blessy Melba

   Chayanika Goswami

20. Cultural Factors Affecting the Spread of HIV/AIDS among the Women in Jaintia Hills, Meghalaya ........................................ 106
   Monsumi Barooah, P. C. Joshi, Roumi Deb

   Nidhi Kalra, Pratibha Singh

22. Skin Lesion Classification Using Convolution Neural Networks ............................................................................................................... 118
   K.S. Rajasekhar, T. Ranga Babu

23. A Study of Postinfectious Glomerulonephritis in Adults ....................................................................................................................... 124
   Sushanth Kumar, Jayakumar Jeganathan, Nisheeth Kumar, Meenakshi Shetty, Pavan M.R.

24. Outcome of Accelerated Recovery Programme on Occupational Stress among Nurses ........................................................................................................................................... 127
   Hemanathan Rajeswari, Bhaskara Kurup Sreelekha, Seran Nappinai, Udathu Subrahmanyam, Vaidyanathan Rajeswari

25. Healthy Emotional Expression: An Intervention for Anxiety and Suicide Ideation among School Students 133
   Shweta Negi, Roopali Sharma

93. Meat Merchandising in Single Look Produce the Chance of Foodborne Illness: Shoppers Alert!................444
   R. Bhuvaneswari, S. Senith, A. Alfred Kirubaraj, S.R. Jino Ramson

94. A Study to Find Barriers for Physical Activity among Chronic Kidney Disease Patients.......................450
   Anupama Das, S. Sridevi, N. Venkatesh, T. Senthil Kumar

95. Economic Development and Employment Creation in India ........................................................................456
   S. Thangamayan, R. Premalatha, S.N. Sugumar, S. Chandrachud

96. Effectiveness of TMJ Mulligan Mobilization in Individuals with Trismus ..............................................460
   Sameer Sudhir Karpe, Poonam Patil

97. Efficacy of Occlusal Splints in Managing Temporomandibular Disorders..............................................464
   Saranya S.K., Chandrashekar Janakiram, Anil Mathew, Pramod Subash, Priya K. Nair

98. Comparative Evaluation of the Efficacy of Occlusal Splints Fabricated in Different Temporomandibular Positions for Treatment in Temporomandibular Disorder Patients..................................................470
   Ipe Sabu, Saranya S.K., Anil Mathew, Pramod Subash, Chandrashekar Janakiram

99. Effect of Gaze Stability Exercises on Balance Confidence and Mobility in Elderly Population................477
   Peteti Sairam, Latika Gulyani, Saravana Hari Ganesh M.

100. Manifestation of Clinical Symptoms and Associated Complications in Varicose Veins: An Institutional Study........................................................................................................................................481
    Shiksha Sharma, Minakshi Vashist, Madan Gopal Vashist

101. Evaluation of Autonomic Dysfunction in Underweight, Normal Weight, Overweight and Obese Patients with Chronic Obstructive Pulmonary Disease.........................................................487
    Desai Nabil, Jyoti Ganai, Shobitha M., Nabi N.
102. Health Concerns in Elderly: A Survey and Public Education in Bhubaneswar, India

Shreyan Kar, Tushar Kanti Das, Prasanta Kumar Mohapatra, Brajaballav Kar, Anupama Senapati, Nilamadhab Kar

493

103. Biomimics: Skeletal System to Structural System

SindhuNachiar S., Satyanarayanan K.S., Lakshmipathy M.

499

104. Assessment of Performance of Services for Three to Six Years Old Children in Urban Anganwadi’s in Kozhikode Corporation in Kerala: A Cross Sectional Study

Sivakumar D., Deepika

505

105. Incidence and Pattern of Bear Maul Injuries in Mount Abu

Somendra Mohan Sharma, Pratik Patel, Nabajyoti Upadhya

510

106. Physiotherapy Following Extensor Tendon Reconstruction in Zone 5-A Case Study

Angeline R., Soundararajan K., Syed Altaf Hussain, Senthil Kumar T.

515

107. Role of Colposcopy in Diagnosing Potentially Malignant Disorders and Oral Cancer: A Systematic Review

T. Jane Belinda, Sreedevi Dharman

519

108. Alveolar Ridge Dimension and Morphology Measurement in Anterior Maxilla for Immediate Implant Treatment Planning: A Cone Beam Computed Tomography Study

M.A. Fazeelath Banu, Sreedevi Dharman

524

109. A Rare Case of Multiple Osteochondromas with Short Metatarsals and Seizure

N.K. Sundaray, Srikant Kumar Dhar, P.K. Tudu, S.C. Das, Bijendra Mohanty, Gourab Arun

531

110. A Comparative Study to Analyse the Effectiveness of PNF Versus Balance Exercises in Parkinsonism

K. Kamatchi, S. Priya, C.V. Senthilnathan, G. Mohan Kumar, G. Tharani, G. Yuvarani

536

111. Life Skills: A Study on Young Girls Working in Organized Sectors in Coimbatore, Tamil Nadu

K. Umamaheswari, Suja M.K.

542

112. A Descriptive Study to Assess Knowledge and Attitude towards Caesarean Section among Antenatal Mothers in a Selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India

Bindusri Bulbul Babita Mohapatra, S. Shobha, Surekha P. Uke, K. Vanitha

547

113. The Issues Affecting the Correct Practice of Healthcare Waste Management in Lae’s Angau Memorial General Hospital

Keven Gaitu, Kamalakanta Muduli, Harrison Apana, Satyabrata Aich, John Pumwa

551

114. Achondroplasia: A Case Report

Kavitaa Nedunchezhian, Nalini Aswath

557

115. Protocol for Review of “Efficiency of Probiotics”

Kavitha Ramanathan, Nalini Sirala Jagadeesh, Usha Vishwanath, Celina D.

561

116. Mental Health Status among Patients with Breast Cancer Attending a Tertiary Care Cancer Hospital in Mysuru, Karnataka, India

Prakash B., Krishnaveni Y.S., Narayananmuryth M.R.

566
117. Inter Arm Difference in the Blood Pressure and Pulse Rate in Young Adults ......................................................571
   Deepika Madhira, Kumar Sai Sailesh, Ravikanth Manyam, Sudhakara Reddy R, Swathi Movva

118. Knowledge and Hygiene Practices among Mothers While Infant and Young Child Feeding in Raichur, Karnataka: A Cross Sectional Study .................................................................575
   Kusuma, Bheemayya Badesab

119. Internet of Things based Remote Patients Observatory System Using Biomedical Sensors .................................581
   S. Ramani, L. Ramanathan, S. Rajkumar, M. Anbarasi, N. Prabakaran

120. Methicillin Resistant Staphylococcus Aureus (MRSA) Infection: Knowledge, Preventive Practices and Colonisation among Healthcare Professionals of Surgical Units ..................................................587
   Diana D. Mello, Latha T., Janet Alva, Barnini Banarjee, Vandana K.E.

121. A Study on Epidemiological Factors and its Association with Pathological Findings for Precancerous Symptoms of Cervical Cancer ........................................................................592
   Chandana Ray Das, Lipi B. Mahanta, Himakshi Borah, Elima Hussain, Arundhuti Devi, Manjula Choudhury, A.C. Adhikari

122. Trends and Evolution of Telemedicine Research: A Bibliometric Approach ..........................................................598
   Lucia Palacios-Moya, Alejandro Valencia-Arias, Lemy Bran-Piedrahita, Martha Benjumea-Arias, Laura Gaviria-Yepes

123. Human Development in India with Special Reference to Health ..............................................................................604
   M. Ramesh, S. Saravanan, S.N. Sugumar, K. Kalaiselvi, E. Rajarethinam

124. A Study on Welfare Measure of LIC Employees with Special Reference to Salem Division of Tamilnadu 609
   K. Kalaiselvi, P. Jagadeesan, M. Ramesh

125. A Study on Quality of Work of Life Practice in Chemical Industrial Units Sipcot in Cuddalore .................612
   M. Vetrivel, N. Manivanan

126. A Study on Role of Industrialization for Sustainable Development and Poverty Eradication ..................616
   N. Manivannan, M.Vetrivel, A.G. Vijayanarayanan

127. A Study on Occupational Health Hazards among IT Sector Women Employees in Tamil Nadu ............620
   R. Lakshmi, M. Vetrivel, R.V. Suganya

128. Verrucous Carcinoma: A Case Report ...................................................................................................................625
   Malathi L., Masthan K.M.K., Sudha Jimson, Hemasri V.

129. Evaluation of Degree of Relationship of Insulin to LH, Testosterone and SHBG in Various PCOS Groups Categorized on the Basis of Altered LH: FSH Ratios ............................................628
   Malini N.A., Roy George K.

A Study on Estimation of Chlorine in Drinking Water in an Urban Slum of Guntur District

K.V.S. Prasad¹, Anil Kumar Bathula², R. Nageswara Rao³, Satya Kishore⁴

¹Associate Professor, ²Assistant Professor, ³Professor & HOD, Department of Community Medicine, Guntur Medical College, Guntur; ⁴Assistant Professor, Department of Community Medicine, PSIMS & RF, Gannavaram, AP, India

Abstract

Background: The share of urban population to the total population of India has increased from 27.81% in 2001 to 31.16% in 2011. This increase has also been accompanied by rapid growth of slums in cities. The 2011 Census of India reveals that 17.4% of urban households in India live in slums. This survey was conducted in the urban slum area of Anandapet, Guntur.

Objective: estimating the quality of drinking water, storage method at household level and waste disposal of both solid and sewage in that area and also to estimate chlorine levels in the drinking water consumed by the residents in the wake of the recent GE (gastroenteritis) epidemic in Guntur.

Methodology: A community based Cross-sectional study was carried out during May to June 2018 with the objective of estimating the quality of drinking water, storage method at household level and waste disposal of both solid and sewage in that area.

Results: 77(38.5%) houses do not follow any method of disinfection of water. Whereas 70(35%) houses follow boiling. 38(19%) houses use filter, and 15(7.5%) use water purifier for disinfection of water. Among those 70 houses that boil the water, 59 houses use different well maintained vessel for storage of boiled water and 11 houses use same vessel for storage of boiled water.

Conclusions: Majority of the households in the study area had access to improved source of drinking water. But a few households practiced unhealthy storage and treatment practices like cleaning the overhead tank/sumps once a month or once in 15 days, not treating water prior to consumption, dipping the glass into the water drum. Absence of free chlorine suggests the need for attention by the concerned authorities and the households.

Keywords: Sanitation; Slum; Disinfection, Safe Drinking Water; Sanitary Latrine.

Introduction

Access to safe water in adequate quantity is one of the biggest challenges in the recent times. Despite the national commitment to supply safe drinking water, access to water is difficult especially in the rural areas.¹ Water scarcity in terms of quantity and quality has severe implications on the overall development and health of citizens. Factors such as poor availability, affordability and distance between water source and home may lead households to depend on less safe sources and reduce the volume of water used for hygiene purposes² resulting in water-related infections.

Many infectious diseases such as bacterial, viral, and protozoal are result of drinking unclean water. Major etiological agents responsible for more than a million...
diarrheal deaths are *Escherichia coli*, *Rotavirus*, *Vibrio cholerae*, *Shigella*, etc., which spread through unsafe drinking water. Worldwide, diarrhea is the second leading cause of mortality among children < 5 years. In India, pneumonia and diarrhea are responsible for 50% of deaths of children < 5 years and this is because of drinking contaminated water; however, the recent studies from India reported even higher prevalence of water-borne diarrheal disease. In diarrhea, cholera is one of the most virulent and if left untreated, it will lead to fatality rate 25%–50%.[3]

In India, 66% of the rural population practices open air defecation. Despite comprehensive programs like total sanitation campaign, Swacch Bharath Mission open defecation still remains the predominant norm and poses one of the biggest threats to the health of the people.[4]

A significant proportion of water may be contaminated at the source itself and the local geographical conditions may have a role to play in it. Hence, water treatment assumes utmost importance in order to ensure the safety of the water consumed. At the community level, it is the responsibility of the municipalities to chlorinate the water being supplied to the households and public taps. Also it is up to the individual household to ensure that the drinking water they consume is adequately safe.[5]

This survey was conducted in the area of Anandapet, Guntur with the objective of estimating the quality of drinking water, storage method at household level and waste disposal of both solid and sewage in that area and also to estimate chlorine levels in the drinking water consumed by the residents in the wake of the recent GE (gastroenteritis) epidemic in Guntur as several patients were admitted to the Government General Hospital, Guntur especially from the region of Anandapet. The data obtained is for the purpose of getting a clear cut idea about the current situation of Anandapet so that necessary measures can be undertaken to prevent the occurrence of such epidemics in the future.

**Methodology**

A community based Cross-sectional study was carried out during May to June 2018 at Anandapet, Guntur District, Andhra Pradesh with the objective of estimating the quality of drinking water, storage method at household level and waste disposal of both solid and sewage in that area. Approval from the institutional ethical committee was obtained before the start of the study. Initially a pilot study was conducted to assess the chlorination practices in the study area. It was found that 20% of the households used chlorination as one of the method of disinfecting drinking water source.

Sample size was calculated using the formula $4pq/L^2$, considering $p=20\%$ and an allowable error of $6\%$ the minimum sample size was estimated to be 180 which was approximated to 200.

A semi-structured questionnaire was used to collect relevant data from the households regarding the sanitary practices at the household level. Drinking water samples are collected from each house and chlorine levels are estimated with iodometric method of chlorine testing. The results were duly noted, analysed & organized to look up on for easier evaluation.

The final data obtained was analyzed using Microsoft Office Excel 2007 and IBM SPSS statistics 20.

**Results**

Among the 200 households interviewed, majority were Muslims (70%), followed by Hindus (15%), Christians (14%) and others (1%). 39% of the study population was illiterate. The socio-economic grading of the households in the study according to modified Kuppuswamy classification was as follows: upper lower class (19%), lower middle class (46%), upper middle class (29%), upper class (5%) and lower class (1%). Based on the type of family, 63% were nuclear in nature and 37% were joint families.

The main source of drinking water among the households in the study was municipal water 159 (79.5%) houses, followed by mineral water in 34(17%) houses, public tap water by 7 (3.5%) houses and bore well by 1 house(0.5%). The main alternative source of drinking water in the study area was mineral water followed by bore water and water tanker.

About 57.5% of the households surveyed, used buckets/drums to store water. Other method of storage were overhead tanks (35%) and sumps (1%). 6.5% of the study population do not use a proper sanitary method for storing the water. 68% of those who store water in either drums/tanks, clean them once in 7 days. The rest of the population do not have the habit of cleaning the drums/tanks regularly.

77(38.5%) houses do not follow any method of disinfection of water. Whereas 70(35%) houses follow boiling. 38(19%) houses use filter, and 15(7.5%) use...
Among those 70 houses that boil the water, 59 houses use different well maintained vessel for storage of boiled water and 11 houses use same vessel for storage of boiled water.

The method used for dispensing water from stored vessel include dipping glass directly into the vessel by 98 (49%), pouring into the glass by lifting the tumbler 30(15%), by filter tap 35(17.5%) and normal tap by 2(1%).

Among the study population 198 (99%) houses follow hygienic practice of washing the hands with soap after defecation and 197(98.5%) houses responded the importance of washing hands before eating food and after defecation.

Among the houses surveyed, 49 houses (24.5%) had the history of water related diseases in the past 1 year.

Among the surveyed population, all the houses responded that purest form of water is clear water without odour. 184 (92%) houses follow the hygienic practice of disposing the solid waste by segregating it and disposing it by the help of municipal waste collectors. The rest 16(8%) houses are indiscriminately thrown the solid waste outside their houses.

Orthotoludine test was used to test for chlorine in the water samples and it was identified that 100 out of 200 houses were tested negative for OT test. Which predispose them for water related diseases.

Discussion

The majority of study population were Muslims and About 39 % of Head of the families are illiterate. Most of the families belong to lower- middle class (46%) according to modified kuppuswamy classification. 63% of families are of nuclear type. The major source of drinking water to the area is from the Municipal water supply (79.5%) and the major alternate source of drinking water is through Mineral water cans (46%). Buckets & drums are the primary mode of storage of water. In 43% of the houses, residents clean their sumps/ drums daily. 38.5% of household do not follow any method to maintain cleanliness of drinking water while the majority of others follow boiling method (35 %) & candle filters (18%). Almost the entire population knows the importance of washing hands before eating food & post-defecation. 100 homes out of the 200 we surveyed
are being supplied unsafe/unchlorinated water. Around 14 of the homes in Anandpet 2nd line complained of muddy water with bad odour being supplied to their homes. Some of the houses in Anandapet 4th line are lacking water connections as a whole. Most of the GE cases were treated in a government facility, some of them only requiring outpatient treatment whereas others were admitted in the hospital for an average duration of 7 days. All the people who suffered from GE have completely recovered and did not require dialysis during their hospital stay among the houses we surveyed. Majority of the households hand over their solid waste to the Municipal Waste Collector. In conclusion, safe water practices have to be enforced by the municipality and in every house.

**Conclusion**

Majority of the households in the study area had access to improved source of drinking water. But a few households practiced unhealthy storage and treatment practices like cleaning the overhead tank/sumps once a month or once in 15 days, not treating water prior to consumption, dipping the glass into the water drum. Absence of free chlorine suggests the need for attention by the concerned authorities and the households.

**Recommendations:** Health education is very important for better use of existing facilities and also to prevent the incidences of water and sanitation related diseases. Emphasis needs to be given to behavioural change communication to create awareness among the households regarding the importance of water and sanitation practices by using various media for education.

**Source of Funding:** Self

Exploring the Medical Representatives’ Perception towards Motivational Measures Implemented by Selected Pharma Companies, Chennai City

A.K. Subramani¹, N. Akbar Jan², Ashok Kumar Goute³, Thangaraja Arumugam⁴

¹Associate Professor & Head, Department of Management Studies, St. Peter’s College of Engineering and Technology, Avadi, Chennai, Tamil Nadu, India, ²Assistant Professor, Faculty of HR & OB Department, ICFAI Business School, (IBS), Hyderabad (A Constituent of ICFAI Foundation for Higher Education), Hyderabad, Telangana, India, ³Associate Professor, Faculty of HR & OB Department, ICFAI Business School, (IBS), Hyderabad, Telangana, India, ⁴Assistant Professor, VIT Business School, Vellore Institute of Technology, Chennai, Tamil Nadu, India

Abstract

Background: Indian Pharmaceutical industry has significant growth in recent decades and faces hyper competition in the local and international market.

Aim: The primary objective of this research is to explore the medical representatives’ perception towards motivational measures implemented by selected pharma companies, Chennai city.

Method and Material: The primary data of the research was collected through the structured questionnaire. The questionnaire was prepared based on Work Motivation Scale. The final sample size of the survey is 227.

Results: The findings of the study indicates that earnings & benefits given to the medical representatives has highest positive effect on work motivation of medical representatives, which is followed by working conditions, success orientation, task orientation, task orientation, mission orientation, coworker relations, managing others, and supervisor relations. The results of confirmatory factor analysis confirms that all the factors of the conceptual model has significant positive effect on work motivation of medical representatives working in selected pharma companies.

Conclusion: The medical representatives in Pharma industries can be motivated through the adoption of appropriate strategies by considering the right blend of above-mentioned factors.

Keywords: Motivation, Work Motivation Scale, Pharma companies, Medical representative.

Introduction

India being a developing country, it establishes foot prints in all kind of industries in national and international level. India plays a significant role in the international pharmaceuticals sector. India is the leading manufacturer of generic drugs in the globe. India has talent pool of scientists and engineers who drives the industry in par with international standards. In the year 2018, the pharmaceutical exports from India raised at US$ 17.27 billion, which includes the exports of bulk drugs, intermediates, drug formulations, biologicals, Ayush & herbal products and surgical. The medical representatives of pharmaceutical industry play an important role in creating awareness and promotion of the various drugs manufactured by their companies among the doctors, chemists, and patients, therefore the sales turnover, growth, and brand image of the company rests on the shoulders of medical representatives. The competition in pharma industry increases challenges of medical representatives in promoting the company products. The motivation of medical representatives is an important driver which drives them to achieve their sales targets. Therefore, the prime goal of this research is to explore the medical representatives’ perception towards motivational measures implemented by selected pharma companies, Chennai city.
Literature Review: Saroj Kumar et al. (2014), analyzed the influence motivation on the sales force for their sale performance in the selected pharmaceutical industry. The outcome denotes that five factors such as work completion, scope for growth, perspective in career, present internal and no feeling of pressure in work have noteworthy optimistic influence on performance in selling with regards to the pharmaceutical sales force

Wiese & Coetzee (2013), in their research the researcher have analyzed the significance of motivators which are related to non-financial factors with regards to sales representatives working in the chosen pharmaceutical company. From the analysis it is found that ‘being well informed’ and ‘good relationships with customers’ are two significant non-financial motivators and also demographic groups vary in the significance they attach to non-financial motivators.

Amue Gonewa John et al (2012), in their research the researchers have discovered the enhancement of performance in sale by adopting sales force motivation approach. It is found that by setting of sales targets and by providing of financial incentives helps in developing of involvement of salespersons in their job. The outcome of the research proves that there is a robust association among the dimensions of the motivation strategy and performance of sales.

Theoretical Background: In general, the factors motivating a person has been divided in to two set of factors known as intrinsic and extrinsic factors. The extrinsic factors of motivation include - money, status, relationships and network, and other creature comforts (including food, beverages etc). The intrinsic factor - fundamentally responsible for a person’s work habit or a certain way of living/working - is: ‘a deep desire to defend oneself from loss and harm’. If a Medical Representative (MR) knows that lack of involvement in work can cause harm to him in terms of loss of prescriptions, sales and finally his benefits, then the MR will be motivated to work with high involvement (Jack Canfield, 2012)

The motivation of the employees are essential in order to improve their productivity and performance by aligning their individual goal inline with the organizational goal (Suraya and Arif, 2019; Monica et al., 2019). The organizations offers various kinds of monetary and non-monetary measures to motivate their employees to achieve expected performance (Melastuti and Sukartini, 2019)

Source: Work Motivation Scale developed by Bradyd. 2002
Work Motivation Scale: In this context, Bradyd (2002)\(^2\), has developed Work Motivation Scale (WMS) which assist employees discover their values and needs where the main elements that motivate employees not only do perform their job, but also to discover at is faction through it. The Work Motivation Scale contains of eight values measures, or constructs, which has been segmented in to four work drive groups: Hence it is found that earnings & benefits and conditions regarding the working atmosphere are gathered under survival and safety drives, whereas coworker and Supervisor associations lies under association drives, task orientation and handling others lies under self-esteem drives, while the last group like mission and success orientation lies under Fulfillment drive.

The survey questionnaire of the present research was designed based on the work motivation scale. The conceptual model of the research is shown in Figure 1.

![Figure 1: Research Model based on Work Motivation Scale developed by Robert P. Bradyd\(^2\)](image)

Based on the above conceptual model, the following hypothesis can be formulated:

- H1: Earnings & Benefits is having significant positive impact on work motivation of medical representatives.
- H2: Working conditions is having significant positive impact on work motivation of medical representatives.
- H3: Coworker relations is having significant positive impact on work motivation of medical representatives.
- H4: Supervisor relations is having significant positive impact on work motivation of medical representatives.
- H5: Managing others is having significant positive impact on work motivation of medical representatives.
- H6: Task Orientation is having significant positive impact on work motivation of medical representatives.
- H7: Mission Orientation is having significant positive impact on work motivation of medical representatives.
- H8: Success orientation is having significant positive impact on work motivation of medical representatives.

The above mentioned hypothetical relationships are verified using Second order Confirmatory Factor Analysis through Structural equation modeling approach.

Materials and Method

The descriptive research design was adopted in this research to describe the medical representatives’
perception towards motivational measures implemented by selected pharma companies, Chennai city. The primary data of the research was collected through the structured questionnaire. The questionnaire was prepared based on Work Motivation Scale developed by Brady (2002)\(^9\). The population of the research refers to medical representatives working in different Pharmaceutical companies in Tamil Nadu state. The sampling unit of the survey refers to medical representatives working in various pharmaceutical companies located in Chennai city. The survey was done among medical representatives working in top 25 pharma companies in Chennai city. Due to confidentiality and condition imposed by the pharma companies the list of sampling unit is not disclosed in the research paper. The survey includes the medical representatives those who have at least 2 years of experience in the particular pharma company. The researcher contacted 250 samples (10 samples per company), and collected 238 filled questionnaires. Out of 238 questionnaires, it is found that 11 questionnaires were incomplete, so those questionnaires were not considered for the analysis. Therefore, the final sample size of the survey is 227. The pilot study was conducted with the sample of 30 medical representatives. The reliability and validity of the questionnaire is verified based on the results of pilot study.

Table 1 summarizes the reliability coefficient (i.e. Cronbach Alpha) of the various factors used in the work motivation scale of the questionnaire. From the above table it is found that all the factors of work motivation scale are having Cronbach alpha coefficient value more than 0.7, which means the work motivation scale in this research is reliable. In general, Cronbach alpha coefficient value between 0.70 – 0.80 is denoted as “Acceptable”, whereas 0.81 – 0.90 is mentioned as “Good”, and more than 0.90 represents “Excellent”.

### Results and Discussion

The data collected from the main study is entered, tabulated, and analyzed through IBM SPSS 22.0 software. The descriptive and inferential statistical tools are used for the current research.

From the table 2, the below-mentioned inferences are drawn:

- The one-third (33.48%) of the sampled medical representatives are belong to the age group of 36-45 years, slightly higher than one-fourth (28.19%) of them are aged 25-35 years, slightly lesser than one-fourth (23.35%) of them are aged above 45 years, and few (14.98%) of them are aged up to 25 years.

- Around half (49.34%) of them are qualified in B.Pharm (Undergraduate degree), one-third (35.68%) of are qualified in M.Pharm (Post-graduate degree), few (14.98%) of them are qualified only in D.Pharm (Diploma).

- Out of 227 medical representatives surveyed in the research, significant portion (40.53%) of them are having 4-6 years of experience in the present organization, whereas 29.52% of them are having 6-8 years of experience, 18.50% of them are having above 8 years of experience, and only 11.45% of them are having 2-4 years of experience in the present Pharma company.

- Among 227 medical representatives surveyed in the current research, one-third (34.36%) of them are having 8-12 years of total experience in the Pharma industry, whereas 28.63% of them are having 4-8 years of experience, 20.70% of them are having up to 4 years of experience, and only 16.30% of them are having above 12 years of total experience in the Pharmaceutical industry.

Table 3 summarizes the results of descriptive statistical analysis with mean and standard deviation. From the table, it is found that the medical representatives are highly satisfied towards Earnings & Benefits offered by the Pharmaceutical companies with the highest mean score of 4.32 and standard deviation 2.863, meanwhile
least satisfaction is shown towards their supervisor’s relation because of the stress imposed by their supervisors to achieve the targets.

**Structural Equation Modeling (SEM) Approach:**
The second order CFA was executed through SEM approach using IBM AMOS 22.0 software. The figure 3 depicts the second order CFA of the conceptual model based on standardized regression coefficients. The below-mentioned model has 8 observed variables, 9 unobserved variables.

![Structural Equation Modeling Diagram](image)

Figure 2: SEM model based on standardized coefficients

For example, one unit of increase in earnings & benefits increases 0.956 unit of work motivation when other variables are constant. Similarly, all the other factors has significant positive effect on work motivation of medical representatives. The model fit summary of the CFA model is described in table 4.

</table>
The model fit summary of the conceptual model is shown in table 4. The p value of the model is 0.274, which is greater than 0.05 specifies to be good fit and CMIN value is 3.457 displays good fit. Henceforth from table, it is recognized that GFI, AGFI, CFI values are more than 0.90 which denotes excellent fit. Therefore projected value of TLI and NFI are above than 0.95 which signifies good fit and the value of RMR is 0.045 and RMSEA is 0.037 which is less than 0.08 which specifies perfect fit.

### Conclusion

In Indian business context, even in the technological world the employees plays a major role in achieving the better organizational performance. They are the backbones of the industry who runs the organization towards its goals. The Indian Pharma industry is a hyper competitive market with local and international players and it is so dynamic in research, design, manufacture, and deliver the appropriate drugs to the needy people whenever the new diseases are identified based on the guidelines of our Government of India and other international standards. The medical representatives play a significant role in taking the drugs to the target community with shortest span of time. The motivation of the medical representatives with appropriate measures ensures the performance of the Pharmaceutical companies. The findings of the study indicates that earnings & benefits given to the medical representatives has highest positive effect on work motivation of medical representatives, which is followed by working conditions, success orientation, task orientation, task orientation, mission orientation, coworker relations, managing others, and supervisor relations. The results of confirmatory factor analysis confirms that all the factors of the conceptual model has significant positive effect on work motivation of medical representatives working in selected pharma companies.

Abstract

Background: Thorough mastication has the potential to affect postprandial blood sugar levels (BSL) by improving digestibility and absorption of nutrients. Associations between mastication and glucose metabolism in diabetics have been shown in previous studies. However, the association between mastication and BSL in pre-diabetes has not been clarified. Our objective was to examine association between frequency of chewing and BSL in prediabetes population-based cohort.

Method: On attaining Institutions ethical committee clearance, considering all inclusion and exclusion criteria and after taking informed consent, we conducted a cross-sectional study in 95 prediabetic individuals. Subjects recruited to study received a fixed calorific load of 150 calories in form of 25 grams of groundnuts on two successive days. We decided to use groundnuts as substrate for our study as we hypothesized this would result in elevated cephalic phase insulin secretion, since it requires thorough mastication for deglutition and is rich in protein (26%), fat (49%) but little carbohydrate (16%), of which >50% is insoluble fiber. On Day 1 subjects were observed as they were chewing at their routine habituated rates without them being conscious that they are being observed while on Day 2 they were asked to chew each bolus forty times before swallowing. Postprandial BSL were estimated, all parameters and their obtained values were scrutinized on both days and data was statistically analyzed.

Results: On comparing the mean post prandial BSL between normal chewing versus 40 time chewing, statistically significant decrease was observed with respect to 40 chews per bolus (p < 0.000).

Conclusions: These findings support hypothesis that when in pre-diabetic individuals a simple yet effective method of thorough mastication will decrease postprandial BSL vis–a-vis faster chewing and swallowing.

Keywords: Prediabetes, mastication frequency, groundnuts, food, blood sugar.

Background

In India currently prevalence of diabetes has increased tenfold, from 1.2% to 12.1%, between 1971 and 2000. (¹) It was recently estimated that there are 61.3 million people with type 2 diabetes in India and this number is expected to increase to 101.2 million by 2030. Pre-diabetic individuals have a significant risk of progressing to overt diabetes over time, with as many
as 10% progressing to diabetes mellitus per year. Prediabetes comprises of either Impaired Glucose Tolerance (IGT) or Impaired Fasting Glucose (IFG) values. The American diabetes Association (ADA) currently defines IFG as fasting plasma glucose between 100 – 125mg/dL, and IGT as two-hour glucose levels of 140 to 199 mg/dL on the 75-g oral glucose tolerance test. Those with IGT are particularly at higher risk of developing overt diabetes and cardiovascular complications (2). For such individuals a variety of non-pharmacological strategies have been suggested such as increased aerobic exercise, reduced calorie intake and dietary modification. However, these measures are often poorly adhered to by patient population. Hence, there is a need for other simple yet sustainable and effective measures of blood sugar regulation in pre-diabetic population to prevent onset of diabetes. One such potentially useful measure can be ‘thorough mastication’. This study attempts to find out if thorough mastication has any effect on post prandial blood sugar levels - BSL in prediabetic individuals.

**Aim:** To evaluate effect of mastication on post prandial blood sugar levels in individuals with IFG and IGT.

**Materials and Method:** The study protocol was approved by local institutional research ethics committee and all study participants provided voluntary consent before being recruited to the study. It was a cross sectional study carried out in Tertiary Care Medical College affiliated Hospitals. Otherwise healthy individuals of age >18 years with impaired glucose tolerance (2 hours post prandial BSL) or IFG were included. Individuals with acute severe illnesses, hepatic or renal impairment, on medications which are known to alter glycemic levels, recent surgery, trauma or burns, pregnancy and edentulous individuals were excluded.

We designed a simple pre-test post-test quasi-experimental protocol for this study. 95 Subjects recruited to the study received a fixed calorific load of 150 calories in the form of 25 grams of groundnuts on Day 1 and Day 2 each. On Day 1, the subjects were asked to chew in their usual manner and the number of chews per bite was recorded. Subjects were observed as they chew habitually without their knowledge to avoid conscious self-imposed change in chewing frequency and pattern. On Day 2, the subjects were asked to chew each bolus forty times before swallowing. Blood sugar levels were taken on both days immediately prior to the intake of groundnuts and also 2 hours following the meal. Subjects were prohibited from taking any oral caloric consumption/other food bolus 3 hours before the start of the test on both days and also between the meal and post-prandial blood sugar test. They were also told not to engage in any strenuous physical activity and to be preferably at rest. Patients were allowed to drink water during the periods of fasting if required.

Data was collected and analyzed using Microsoft Excel and SPSS version 17. The strength of the association between the variables of interest was evaluated using Chi-square and Student-t tests. A two-tailed p-value of less than 0.05 was defined as statistically significant for all analysis.

**Results**

Our study enrolled total 95 subjects. We had 9 patients with IGT and 86 patients with IFG. Majority of subjects were in the age group of 31-40 years (28.4%). About 26% of the subjects were in the age group of 51-60 years, 24% were in the age group of 41-50 years 12% in the age group of above 60 years and 10% of them were in the age group less than 30 years. In our study, 47% of the subjects were females and 53% were males.

Subjects recruited to the study received a fixed calorific load of 150 calories in the form of 25 grams of groundnuts on Day 1 and Day 2. The average number of chews was 24 on day 1 .All the subjects chewed each bolus forty times before swallowing on Day 2.

</table>
On day 1, there was a drop in BSL two hours after chewing (mean difference 21.147, %change – 18.62) which was statistically significant (p value of 0.000). On day 2, the mean BSL prior to intake of groundnuts was 115.02 and two hours after meal was 127.38. The mean difference was 12.358 with a percentage change of 10.74 % which was highly significant (p value of 0.000). All the subjects chewed each bolus forty times before swallowing (Table 1).

When we analyzed both Day 1 and Day 2, both the pre and post chewing values showed a highly significant correlation (Fig 1) with respect to post prandial BSL.

![Bar diagram](image)

**Fig 1: Bar diagram depicting the comparison between Day 1 and Day 2 mean BSL percentage change of the subjects**

When we analyzed the mean change in sugars age group wise and gender wise, we did not find significant correlation. While considering analysis based on categories of prediabetes following results were obtained.

</tr>
</tbody>
</table>
Mean change in sugar values (table 2 & figure 2) did not show statistically significant correlation when categories of prediabetes namely impaired glucose tolerance and impaired fasting glucose were separately analyzed.

**Discussion**

Our study demonstrates that thorough mastication of 40 chews per bite/morsel/bolus in comparison to routine habituated frequency of mastication in pre-diabetes, results in a statistically significant reduction of post-prandial blood glucose levels.

Although it has been hypothesized that thorough mastication can reduce post-prandial BSL by increasing the cephalic phase of insulin release, previous studies have failed to report consistent or reliable findings with regards to the physiological effects of mastication (Table 3).

In one study, it was found that chewing 30 times per bite caused elevated plasma active GLP-1 concentrations, without affecting the concentrations of blood glucose or serum insulin levels in 10 normoglycaemic subjects but not in type 2 diabetic subjects (3). Another study, however, reported that postprandial BSL significantly decreased following thorough mastication of approximately 30 times per bite in 16 normoglycaemic individuals through potentiation of early-phase insulin secretion (4). The same study also showed that in 10 subjects predisposed to type 2 diabetes, thorough mastication did not potentiate early-phase insulin secretion and elicited higher postprandial
BSL. In a randomized crossover trial of 21 healthy males, it was demonstrated that plasma concentrations of glucose, insulin and GIP were higher with thorough mastication of 40 chews per portion in comparison to 15 chews per portion (5). Another study also showed that thorough mastication of 40 chews in both lean and obese subjects resulted in lower postprandial ghrelin concentrations and higher postprandial glucagon-like peptide 1 and cholecystokinin concentrations (6). Recently, a study in south India (7) demonstrated that thorough mastication of forty-chews improved the postprandial BSL in 86 normoglycaemic subjects but not in 14 dysglycemic subjects, the latter comprising of both type 2 diabetics and pre-diabetic individuals. The results from our study, which was sufficiently powered, shows with considerable statistical confidence that thorough mastication results in reduced post-prandial blood glucose levels in pre-diabetic individuals possibly indicating importance of increased frequency of chewing per morsel as a non-pharmacological intervention in preventing progression to dysglycemic.

However, it is important to note, that this phenomenon was observed in our study in subjects who consumed a substrate (i.e. groundnuts) that was low in carbohydrate content but rich in protein and fat. Results from previous studies suggest that the type of food ingested is important for determining the physiological effects of mastication (Table 3). A study in 1986 demonstrated that chewing a variety of foods including sweetcorn, white rice, diced apple and potato, led to elevated postprandial glucose levels, though the extent to which they rose differed according to the food ingested (8). Conversely, the peak glucose response and the areas under the blood glucose profiles in response to ingestion of these foods, were significantly reduced when the subject swallowed these foods whole instead of chewing them thoroughly. Another study showed significant correlations between the degree of substrate breakdown during mastication and the blood glycemic response for rice (9). The results from the study suggest that individual differences in mastication and masticated particle size distribution may be one of the causes for inter-individual differences in the glycemic response to rice. In a separate randomized, controlled, crossover trial on 15 healthy young subjects, rice chewed 15 times produced a total glycemic response (GR), peak GR and glycemic index significantly lower than when chewed 30 times (10). Groundnuts are readily available, require thorough mastication for deglutition and are rich in protein (26%) and fat (49%) but have a total carbohydrate content of only 16%, of which more than 50% is insoluble fiber. In comparison, 90% of the total dry weight and 87% of the total caloric content of rice is carbohydrate in the form of starch (11). Therefore, we decided to use groundnuts as the substrate for our study as we hypothesized this would result in elevated cephalic phase insulin secretion.

In turn this may result in better glycemic control and reduce progression to overt diabetes in pre-diabetic patients. Although poorly powered, previous studies have shown that higher rates of mastication may actually result in elevated post-prandial BSL when ingesting carbohydrate rich foods such as rice. Studies also show varying effects in diabetic individuals. Hence, we cannot extend our recommendation of thorough mastication to carbohydrate rich foods or in individuals with overt type 2 diabetes. It would be important to qualify the relationship between thorough mastication, carbohydrate rich foods and type 2 diabetes in well-designed future studies.

Our results are statistically robust, based on simple pre-test post-test quasi-experimental study design, rather than a randomized controlled trial (RCT). Hopefully the results of our study will encourage the development of future well-designed RCTs to further qualify the physiological effects of mastication in dysglycemic.

**Conclusion**

Chewing could increase the digestibility and absorption of carbohydrate in several ways; the reduction in particle size would enhance the delivery of food from the stomach to the small intestine the larger surface area of masticated food increases access to pancreatic enzymes; enhancement of salivation associated with chewing would increase digestion of food in the mouth and stomach.

Our study confirms the fact that chewing decreases the postprandial sugars significantly in patients with impaired glucose tolerance and impaired fasting glucose, and also differences may be seen in post-prandial blood sugar level depending on the type of food substrate.

**Implications:** Based on the findings from our study, we would recommend pre-diabetic individuals to employ the simple yet effective method of thorough mastication of approximately 40 chews per bite to lower post-prandial blood sugar levels.

Predictors of Job Satisfaction: How Satisfied are the Young Generation Doctors in Corporate Hospitals

Avipsa Padhi¹, Ayasa Kanta Mohanty², Manoranjan Dash³

¹Research Scholar, ²Professor, ³Associate Professor, Faculty of Management Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar

Abstract
Today corporate hospitals can be successful provided they ensure continuously the satisfaction of their doctors. Job satisfaction comprises the degree of an individual’s feelings towards and satisfaction with present job activities, the accomplishment and responsibilities as well as the degree of an individual’s satisfaction with all aspects that directly or indirectly related to the present job and job content. Hence job satisfaction is the consequence where as job engagement is the antecedents. Fully engaged doctors are more satisfied and will more likely to remain with the hospitals. Keeping in view the above, a thorough understanding of the factors associated with job engagement is much needed where job satisfaction will be playing a major role. Job switching and doctors turnover are becoming recent experience since the young generation doctors enter the corporate hospitals. The study explores the level of job satisfaction and also tries to find the relationship between the individual and job satisfaction related factors on the job satisfaction of young generation doctors working in corporate hospitals. A total of 210 doctors participated in the survey and the findings revealed factors found significantly affect the job satisfaction and the practical implication of the study has great importance to the corporate hospitals in developing their strategies to increase the job satisfaction among the new generation doctors entering the workforce.

Keywords: Job satisfaction, Job Engagement, Workforce, health care sectors.

Introduction

Many earlier studies have significantly contributed to the field of job satisfaction from many angles. Job satisfaction is an attitude towards work related conditions [1]. Job satisfaction was more of a response to a specific job or various aspects of the job. Here it would be appropriate to mention that people, who are fully engaged in job, derive a sense of satisfaction out of it. Many study showed has shown that job performance, absenteeism, turnover and employee relations are influenced by job satisfaction. It is also suggested by other empirical studies that the significant contributor to one’s job satisfaction is the nature of the job itself and it must be material to the individual. Another major factor behind the level of job satisfaction in the stress level associated with work. Job satisfaction is the opportunity for growth and promotion which the organization can afford to offer. A doctor have a strong sense of morality, tend to be patriotic, is willing to fight for freedom and value home and family as they had seen more hardships and disaster at an earlier age than the previous generations. It is suggested through empirical research that they need to be treated differently and organization has to prepare themselves at the time of entry in workforce. Factors that constitute Job satisfaction is similar to earlier generations. Generally people prefer flexibility in getting the work done. They prefer to have challenging career and they also want to grow with the challenges. Clear direction is needed from the employer side as they demand immediate feedback on performance. In the present generation doctors being techno savvy; they also expect organizations to be equipped with current technology. There will be poor outcome and low productivity when the basic

requirements are not provided. Due to advancement in technology and the openness of some of the new and high tech organizations, employees prefer to conduct meetings via video conferencing. Organizations have started providing gymnasium and pool facility to promote active and healthy lifestyle as employees think highly of their work life balance. High job satisfier doctors have greater contribution towards patient care as well as increase productivity performance and more turn over in hospitals.

**Literature Review:** In the present global context it is necessary to understand motivations of present workforce to ensure their participation in ensuring patient satisfaction. It was found doctors derive satisfaction from their work and around two/third doctors are happy with their job and demand a greater increase in the salary will lead to a better professional life [2]. Doctors are dissatisfied in their work due to long hour of work and over loading of work and that can affect the patient care as well as quality health care delivery. Dissatisfaction in doctors was due to night shift duty more than 8 hours and working hours more than 9 hours. A proportion of doctors were dissatisfied due to the working hours as well as salary[3]. Satisfaction of Indian Doctors as well as other doctors from developed countries is almost same. But satisfaction level of Indian doctors are low in comparison top other developed countries [4]. Many doctors are satisfied with their job but many dissatisfied due to workplace and income.[5] Job satisfaction determinants are negatively correlated with the determinants of stress in doctors.[6]. In private practice doctors have more control over their job styles and are responsible for low levels of burnout.[7]. More working hours among doctors more is the stress and less is the job satisfaction [8]. There is a decrease in job satisfaction among doctors but no measurement has been done on the impact on patients [9]. Financial and non financial incentives, leadership, team work and proper coordination of resources are the factors influencing the job satisfaction among doctors. [10]. Opportunity of self development was the factor for the job satisfaction whereas others are organization, nature of work, promotion. Dissatisfaction among doctors are poor utilization of skills, poor promotion prospectus, low pay and allowance and organization policy.[11]. Doctors were found to be dissatisfied with number of working hours, salary and number of night shifts and thus leading to decreased job satisfaction[3][15].

**Research Objectives:**
1. To assess the level of job satisfaction among doctors in corporate hospitals
2. To determine the factors that contributes to job satisfaction among doctors working in corporate hospitals.

**Materials and Method**
Cross section study was conducted for the research period starting from January 2019 to August 2019 using an administered well designed questionnaire. 210 doctors participated in the data collection and randomly chosen from corporate hospitals. Doctors were chosen randomly irrespective of their department. Pilot testing was conducted on 30 doctors initially. Data analysis was done in SPSS package. Reliability of the questionnaire was found to be .675 Likert scale was used as 1 strongly agree to 5 strongly disagree. Factor analysis was done to find out the dimension. The KMO Value was found to be more than .5 which adequate for the factor analysis to be conducted on the data and was significant.

Regression analysis was conducted among the determinants educational level, maturity level, year of experience, salary and growth prospects were taken as independent variable and job satisfaction as dependent variable. $R^2 = .596$ and adjusted $R^2 = .538$. This explains 53% of the variance of the dependent variable is explained by the variance in the independent variable. The results are statistically significant at .000 level. The model was significant and all are found to be significant and $p< .001$

a. Dependent Variable: Job Satisfaction

Conclusion

The study focused on job satisfaction among the doctors working in corporate hospitals and also to determine determinants for job satisfaction among doctors. Study found the factors are educational level, maturity level, year of experience, salary, growth prospects. As doctors grow older they can understand the organization better and their performance can be increased better for quality patient care. Doctor should be appreciated for their work in terms of rewards for recognition for better growth prospect which lead to more job satisfaction. Educational level, year of experience, maturity, salary and growth prospects are found to be statically significant on job satisfaction. Salary is also one of the main motivating factors which directly links with the job satisfaction for which the commitment to the organization and quality patient care delivery will be more.

Ethical Clearance: Not Required (It does not involve any experimental data collected from human as well as Animals. The data is collected from Doctors working in different corporate hospitals in Bhubaneswar which purely is their personal view or opinion which does not violate the ethical standards.)

Statistical Analysis of M-Mode Echocardiographic Normal Reference Values in South Indian Adults

Chaithra N.¹, Madhu B.², Balasubramanian S.³, Sunil Kumar S.⁴

¹Assistant Professor, Department of Water and Health, Faculty of Life Sciences, JSS Academy of Higher Education & Research, ²Associate Professor, Department of Community Medicine, JSS Medical College & Assistant Director Research, JSS Academy of Higher Education & Research, ³Director (Research) and Dean, Department of Water and Health, Faculty of Life Sciences, JSS Academy of Higher Education & Research, ⁴Associate Professor, Department of Cardiology, JSS Hospital, Mysuru, Karnataka, India

Abstract

Background: Normal values for echocardiographic measurements are derived from American Society of echocardiography and European Society of Cardiology/European Association of Cardio-Vascular Imaging and their publications. Indians have smaller cardiac chamber dimensions than the Europeans. However, it has been long felt that reference range from western data cannot be fully applied in our scenario.

Aim: The objective of this study was to develop age and gender-specific normative reference range values for echocardiography measurements.

Methodology: This was a retrospective cross-sectional single-center study conducted on 111 healthy Indian adults who were selected out of the 336 patients aged from 18–76 years, who visited the cardiac medical check-up unit in a tertiary hospital. Echocardiograms were done in participants free of cardiovascular diseases, hypertension, diabetes, high blood pressure or other clinical evident disorders. M-mode Echocardiography in the left parasternal long-axis view was used to measure aorta, left atrium, left ventricle in systole and diastole, right ventricle, interventricular septum, and posterior wall thickness. The 95% reference range of the echocardiographic parameters calculated as a mean±2 “standard deviation for overall and genders specific”.

Results: This study provides a set of data with reference ranges for normal M-mode parameters according to age and gender. Around 58 males and 53 females were classified into the age group from 18-76 years as exclusive class intervals. Age group above of 38 years Indians had higher volume in all the echocardiographic measurements are observed in this study. On examining all our healthy participants, we found that the reference range of most echocardiographic parameters is a highly statistically significant difference as compared with those used in western studies.

Conclusion: The normal reference values for echocardiographic measurements derived from this study could be used for future reference in our local population.

Keywords: Echocardiography normative data; M-mode parameters; Normal reference values; South Indian adults.

Introduction

Echocardiography is the most widely used technique across the globe for the assessment of cardiac chamber dimensions and volumes.¹ In order to detect changes in the structure and function of the heart produced by disease, it is important to determine accurately the effect of normal growth and development on echocardiographic measurements of...
chamber size, thickness, and function. The values for echocardiographic measurements have been presented in several guidelines and statements. The most recent was a joint recommendation for chamber quantification by the European Association of Cardiovascular Imaging (EACVI) and the American Society of Echocardiography (ASE) which had been previously endorsed by several societies, namely the International Alliance Partners of the ASE, Canadian Society of Echocardiography, Indian Academy of Echocardiography, Indonesian Society of Echocardiography, and the Japanese Society of Echocardiography. The interpretation of quantitative data derived from echocardiography is based on comparisons with the predefined age and gender-specific normal reference values. Unfortunately, no reference values are currently available for Indian adults and therefore western data only is used as a reference for echocardiographic interpretations in Indians. Few previous studies have shown that this may be inappropriate as Indians have smaller cardiac chamber dimensions than the western populations and may also have important differences in ventricular functional parameters. The normal reference ranges for echocardiography study aims to obtain a set of normal values for cardiac chamber geometry and function in a cohort of healthy individuals over a widerange of ages (18–76 years) using echocardiographic techniques.

Method

Study design and patient population: This study was performed on 111 apparently healthy adults were selected out of the 336 patients, who visited the cardiac medical check-up unit in a tertiary hospital. A total of 58 male and 53 female echocardiograms were done. Patients who had any cardiovascular disease and their basic echocardiography study was any Congenital, valvular (except trivial regurgitation), Cardiomyopathy (Dilated, Ischaemic, Hypertrophic, infiltrative or restrictive), Ischaemic wall motion abnormalities, Arrhythmias, Diastolic abnormalities, and abnormal systolic left ventricular function were excluded as these could have influenced their echocardiography data. Height in centimeters and weight in kilograms were measured and used to estimate Body Mass Index (BMI) in kg/m², Body Surface Area (BSA) in m² and their ages ranged from 18 to 76 years are considered. The study was approved by the Institutional Ethics committee and informed consent was obtained by all of them.

Echocardiographic Examination: Echocardiographic examinations were performed by an experienced echo technologist using Philips Epiq 7C echocardiography system, Koninklijke Philips, And over, MA, USA, with an X5-1 transducer. Measurements on the echocardiogram were obtained according to the recommendation of the American Society of Echocardiography (ASE) guidelines and Comprehensive Trans-Thoracic Echocardiography examination guidelines by the Indian Academy of Echocardiography. All studies were done with patients lying in the left lateral decubitus position and breathing quietly. M-mode Echocardiography in left parasternal long-axis view was used to measure aorta, left atrium, interventricular septum, and posterior wall thickness, left ventricle in systole and diastole, and the right ventricle. Left ventricular end-diastolic volume (LVEDV), Left ventricular end-systolic volume (LVESV) and Left ventricular Ejection Fraction (LVEF) were measured using Biplane Simpson and two-dimensionally derived dimensions from the parasternal long-axis view. From the papillary muscle level after confirming a true short-axis view that was perpendicular to the centre of the true long axis of the Left Ventricle (LV), measurements for the LV posterior wall thickness at end-diastole (PWd) and interventricular septum at end-diastole (IVSd), LV fractional shorting (FS) was assessed, in addition to, LV ejection fraction (LVEF) which was assessed using the Teichholz method.

Statistical Method

Data were tested for normal distribution with the Kolmogorov-Smirnov test. Continuous variables was expressed as Mean±SD and 25th – 75th Percentile according to data distribution. The coefficient of variation of each assessed parameter was also determined in terms of percentage. To test the difference between the means of male and female were analyzed for statistical significance with the unpaired t-test and examine the mean difference between the sample and ASE/EACVI normal values by using a one-sample t-test. Correlating body surface area to echocardiography measurements and analyze the degree of relationship between continuous variables with age for both genders were performed with Karl Pearson’s correlation coefficient. A probability value p < 0.05 was considered statistically significant and p-value < 0.0001 was considered highly significant. The 95% reference range of the echocardioographic parameters calculated as a mean±2 standard deviation for total and genders. All statistical analyses were carried out using Statistical Package for the Social Sciences (IBM SPSS Statistics 22.0).
Results and Discussion

This study provides a set of data with reference ranges for normal M-mode parameters according to age and gender.\textsuperscript{13,14} A few previous studies have shown that Indians have smaller cardiac chamber dimensions than the Europeans.\textsuperscript{4} Clinicians are using reference range for echocardiographic values from ASE and EACVI recommended measurements and we have tried to compare our results with them, it has been found that average height, weight, BMI and BSA are less in Indians and the reference range of most echocardiographic parameters are highly statistically significant difference as compared with those used in the western studies. In clinical practice, it has been long felt that reference range from western data cannot be fully applied in our scenario.

Descriptive Statistics were used to present the baseline clinical characteristics of the whole cohort are displayed in Table 1. There were no significant differences in age between men and women their mean age for male 46.8±12.5 years and for female was 46.8 9±12.49 years. Males were heavier than females 66.1±12.2 versus 62.9±10.9 kg, taller than females 166.3±6.9 versus 154.3±5.4 cm (t=10.09, p< 0.0001) and consequently had a larger BSA of 1.7±0.2 versus 1.6±0.1 m\(^2\) (t=3.41, p<0.0001). However, they showed a significant difference in BMI (p=0.004) at a 5% level of significance using the independent t-test. The systolic and diastolic blood pressure were similar in men and women, there were highly statistically significant difference regarding Height, BMI, and BSA; however, males generally had significantly larger values compared to females.

The M-mode echocardiographic measurements are presented according to gender, in table 2. Using the widely applied Mean±2SD rule, we propose the normal values for M-Mode echocardiographic measurements for both genders and total. The dimension of the LA (t=2.85, p=0.005), LVID_d (t=2.37, p=0.02), LVID_S (t=3.18, p=0.002), EDV (t=2.83, p=0.005) and ESV (t=3.16, p=0.002) were significantly higher in men. There was no statistically significant difference in AO (p=0.97), RV (p=0.31), IVS_d (p=0.54), IVS_s (p=0.84), LVPW_d (p=0.72), LVPW_s (p=0.46), SV (p=0.14), EF (p=0.68), and FS (p=0.48) using independent t test at 5% level of significance. Data were tested for distribution normality with skewness, all the values lie between -1 to +1. The Quartiles of the echoparameters are presented in table 2. Coefficient of variation of each assessed parameter were also determined, such has the EF, FS, AO and LVID_d had a low coefficient of variation.

Table 3 was analyzed using Pearson’s correlation coefficient (r). A probability value p < 0.05 was considered statistically significant and p value < 0.0001 was considered highly significant. A highly significant positive correlation existed between BSA and each LA (r=0.380, p< 0.0001), RV (r=0.353, p< 0.0001), IVS_d (r= 0.382, p< 0.0001), LVPW_d (r=0.422, p< 0.0001) and there is no significant difference in AO (r=0.184, p =0.054), LVPW_s (r=0.152, p=0.110). This study demonstrated a week negative correlation between body surface area and EF (r=-0.077, p=0.421) also with FS (r=-0.113, p=0.237) was observed.

The mean age of the study subjects was 46.8(years). Average height, weight, BMI, BSA, SBP and DSP were 160.5 cm, 64.6 kg, 25.2 kg/m2, 1.7 m2, 120.8 mmHg, 78.9 mmHg respectively. All these parameters are compared with the mean of EACVI using a one-sample t-test assuming that the means of samples from a population with a finite variance approach a normal distribution regardless of the distribution of the population. In this
study, it was shown that there was highly statistical significance difference in Hight (p< 0.0001), Weight (p< 0.0001), BMI(p< 0.0001), BSA (p< 0.0001) and DBP (p< 0.0001) and no statistical significance difference in age (p=0.37) and SBP(p=0.87) compared to EACVI measurements and mean difference is more in height (-9.7), weight (-4.7) and BSA (-0.1).

We measured several parameters of M-mode echocardiography according to the American Society of Echocardiography (ASE) reference values. On examining all our healthy participants, we found that there was highly significant difference regarding AO (p< 0.0001), LA(p< 0.0001), LVID_d (p< 0.0001) and FS (p< 0.0001) in both genders. Males generally had significantly larger reference values compared to females.

**Conclusion**

The means and range for the M-mode measurements were smaller than the ASE-recommended normal values and also there was a highly statistically significant difference in both genders. On examining all our healthy participants, we found that males generally had significantly larger reference values compared to females.

Effects of Circuit Training Combined with Different Neuromuscular Activities on Muscular Endurance and Body Composition of School Girls

K. Sudha\textsuperscript{1}, D. Maniazhagu\textsuperscript{2}

\textsuperscript{1}Ph.D Scholar, \textsuperscript{2}Assistant Professor, Department of Physical Education and Health Sciences, Alagappa University, Karaikudi, Tamilnadu

Abstract

**Background:** Due to the lack of physical activity now a day’s many youngsters are having health issues to do their regular activities. Muscular endurance and proper body composition are important to enable the person to carry out different type of day to day activities and sport activities all over the life time. The sport training is the way to develop one’s health and physical fitness to live a healthy.

**Purpose:** To identify the 12 weeks training effects of circuit training combined with different neuromuscular activities on muscular endurance and body composition of school girls.

**Method:** This is an intervention study carried out to compare effects of 4 groups. Group 1 (n=15), who trained circuit training (CT), group 2(n=15), who trained circuit training combined with resistance band (CT-RB), group 3(n=15), who trained circuit training combined with skipping rope (CT-SR) and group-4(n=15) control group (CG). The pre and post test data was collected for the muscular endurance and body composition.

**Results:** The difference between pre and post test was significant (p< 0.05) in the intervention groups and insignificant (p>0.01) in control group.

**Conclusion:** The circuit training combined with resistance band and skipping rope produced greater improvement on muscular endurance and reduced percentage of body composition

**Keywords:** Circuit training, Resistance band, Skipping Rope, Muscular endurance, Intervention.

Introduction

Dramatic physiological and psychological changes occur in childhood and adolescence period. This is a critical period of life. The lifestyle, healthy and unhealthy behaviors are develops in this stage. These may influence health behaviors in adult stage. The detailed reviews have conversed about the associations between physical activities and its consequences on health in childhood and adolescence.\textsuperscript{1-6}

Now a day’s fitness is considered as most important health indicators in childhood.\textsuperscript{7} The concept of physical fitness has since evolved to include morphological and metabolic components.\textsuperscript{8} Thus, in the previous decades a number of countries have been promoting physical fitness development among young people in different mode.\textsuperscript{9} In many situation, schools have been measured the best setting in which children with small fitness levels can be recognized and a healthy lifestyle can be carry out.\textsuperscript{7} It is acknowledged that preparation of long-term fitness programme is one of the most excellent ways to improve fitness components.\textsuperscript{10} However in the Physical Education setting these programme cannot lost the entire course or a large part of it since many curricular contents should be developed in a school year.\textsuperscript{11} Therefore, in the physical education setting we require to find short-term programme that could be also helpful for the growth of physical fitness. An excellent methodology that meets these criteria could be the circuit training.\textsuperscript{12-14} This training efficiently reduces the
time devoted to training while allowing and sufficient training volume to be achieved. Furthermore, it allows a higher motor engagement time. Adding together, this methodology has multilevel effects on fitness, particularly in beginners.

Circuit training is often erroneously portrayed as an intensive and stressful form of exercise, with a drill sergeant type in the middle of a circuit bellowing orders at weary recruits. Circuit training is a very versatile and adaptable mode of training that requires the performance of a series of carefully selected exercises. The use of resistance bands and cords as a form of exercise is becoming increasingly popular. In this study, the resistance band and skipping rope training have chosen as a neuromuscular activity.

Resistance band and cords are an effective complement or alternative to any strength and power training workout. Like other strength training exercises, these bands and cords can provide strength gains in both muscle and bones by providing resistance. Rope jumping is one of only a few inexpensive, highly portable and easily learned fitness and sports training exercises that require the precise coordination of several muscle groups.

Method

Participants: Sixty healthy school girls children, 12-14 years old (13.10+0.38 years; body mass

45.29+10.45 kg; body height 1.40+0.03 m; body mass

index 18.35+2.90 kg/m\(^2\)) from ADW Higher Secondary School participated in this study. Children and their legal guardians were fully informed about all the features of the study and were required to sign an informed consent form. The Departmental Research Committee of the Department of Physical Education, Alagappa University approved the study protocol.

**Study Design:** The sixty school girls were divided into three experimental and one control group. The experimental group 1, 2 and 3 were performed circuit training, circuit training combined with resistance band and circuit training combined with skipping rope respectively. The subjects performed their training interventions for the period of 12 weeks. The control group did not entertain any specific type of activity.

Data Collection: The muscular endurance was tested by sit ups test; this is a standardized test for assessing the muscular endurance. The body composition was tested by BMI calculation. The data on muscular endurance and body composition was collected from the participants before and after the training interventions.

Statistics: The analysis of variance was used to analyze the pre and post test development in the groups. The analysis of covariance was used to find the adjusted post test mean differences among the groups. The pair wise comparisons were made by Scheffe’s Post Hoc test.

**Results**

Muscular Endurance:

### Discussions

In this study, circuit training combined with different neuromuscular activities for 12 weeks have significantly improved the capacity of muscular endurance and decreased the percentage of body composition. The training produced relative effect between the study groups. The muscular endurance was better improved in circuit training combined with resistance band and circuit training with skipping rope training than the other training group. The body composition was better altered in the circuit training with skipping rope training than the other training groups.

We confirmed that, twelve weeks of circuit training combined with different neuromuscular activities (i.e.,
resistance band and skipping rope) significantly improved the muscular endurance compared to the control group. The percentage of improvement on muscular endurance for circuit training was 10.03%, circuit training combined with resistance band was 33.27% and circuit training combined with skipping rope training was 32.67%. From the results CT-RB and CT-SR produced more or less same effect on muscular endurance than CT. Both the trainings are suitable for the improvement of muscular endurance. The earlier studies on muscular strength and endurance reveals that 12 weeks of combined exercise or 8 weeks of high intensity circuit training improve the muscular endurance, grip and back strength in obese women. Abdominal muscular endurance and cardiovascular endurance in school children were developed due to the circuit training program. The circuit training alone develops the muscular strength and power better than combined training of resistance and endurance training. We think that the improvement is due to the different type of circuit exercises and neuromuscular activities applied with the time, duration, intensity and recovery. Findings of this study indicate that the circuit training with neuromuscular activities for the period of 12 weeks improves the muscular endurance. The circuit training with different neuromuscular activities is useful for the development of muscular endurance in school going students.

We established that, twelve weeks of circuit training combined with different neuromuscular activities (i.e., resistance band and skipping rope) significantly decreased the body composition compared to the control group. The percentage of improvement on body composition for circuit training was 1.0%, circuit training combined with resistance band was 2.2% and circuit training combined with skipping rope training was 3.7%. From the results CT-SR greatly decreased the body composition than the CT-RB and CT. The previous study findings are in line with the findings of the present study. The positive effects of circuit strength training on body composition parameters were observed. The moderate intensity of circuit resistance training increases lean body mass, bone mineral density and reduces body fat percentage. The circuit weight training and aerobic exercise for the period of 12 weeks resulted in positive effects on body composition. In the present study, the alteration of body composition was due to the gradual increase of intensity of exercise, frequency, repetition and rest of circuit exercises and neuromuscular activities.

Conclusion

In this study, results showed that the circuit training with the combinations of neuromuscular activities conveyed positive effects on the improvement of muscular endurance and reduction of body composition. It improves the health fitness components and helped in the prevention of lifestyle diseases in school students.

The present training protocols very much beneficial for school going children for the anatomical adaptation. Once children well developed in the anatomical adaptations, it leads to the better improvement of health and skill related components of physical fitness. Future studies may be attempted in this area with other training parameters.

Abstract

Background and Objectives: Dental caries is one of the most common problem encountered in pediatric patients. Despite modern advances in prevention of dental caries, many teeth are still lost prematurely leading to loss of function, esthetics, arch length and arch symmetry. Various restorative materials are available for the treatment of dental caries. Physical and mechanical tests were applied to analyze the structural designs of restorative materials. Various researches have been carried out in search of an ideal restorative material. Hence, the present in-vitro study was done to evaluate and compare the mechanical properties (compressive strength, flexural strength and knoop microhardness) of Ceramic Reinforced Glass Ionomer Cement (Amalgomer CR) and Type IX GIC.

Results: The study showed a statistically significant difference in the compressive strength, flexural strength and knoop microhardness of ceramic reinforced glass ionomer cement (Amalgomer CR) and is superior when compared to Type IX GIC.

Conclusion: The study concluded that the mechanical properties (compressive strength, flexural strength and knoop microhardness) of ceramic reinforced glass ionomer cement (Amalgomer CR) is superior to Type IX GIC.

Keywords: Compressive strength, Flexural strength, Knoop Microhardness, Glass ionomer cement, Amalgomer CR.

Introduction

An ideal restorative material requires minimal cavity preparation, have adequate strength and wear properties, be easy to place with a certain amount of adhesion to tooth structure and not be moisture sensitive during placement and setting.¹ Glass ionomer cement (GIC) seems to meet most of these requirements along with particular advantages like ability to leach fluoride, coefficient of thermal expansion similar to tooth, chemical bonding to enamel and dentin, insolubility in oral fluids at intraoral temperatures, excellent biocompatibility, better esthetics and low moisture sensitivity making it highly appropriate for use in children.²

Physical and mechanical tests were applied to analyze the structural designs of restorative materials. From studies of physical and mechanical behavior, shortcomings of structures and materials were observed. To rectify those shortcomings, the process...
of improvement began with the addition of modifiers and studies on various chemical combinations were initiated.\textsuperscript{3}

Although GICs were used as the restorative cements in dentistry, they have disadvantages too. Lack of sufficient strength and toughness limited conventional GIC’s use in stress bearing areas.\textsuperscript{4} Hence for further improvisation in the mechanical properties, a variety of modifiers have been added to conventional GICs and one such material is Amalgomer, which offers the benefits of GIC combined with the strength of amalgam due to ceramic reinforcement in the glass ionomer cement.\textsuperscript{4,5} This tooth-coloured product is proposed by the manufacturer to combine the high strength of a metallic restorative and the esthetics and other advantages of glass ionomers.\textsuperscript{6}

In this context, the present study was designed to evaluate and compare the mechanical properties which includes compressive strength, flexural strength and knoop microhardness of Ceramic Reinforced Glass Ionomer Cement (Amalgomer CR) and Type IX GIC.

**Materials and Method**

72 specimens were be made by using custom made plexi-glass moulds of different dimensions(Figure 1) according to ISO Standard Specifications(ISO 9917). The mechanical properties of the specimens were evaluated in Raghavendra Spectro Metallurgical Laboratory, Bangalore.

**Fig 1: Custom made plexi-glass moulds**

The materials were manipulated according to manufacturer’s instructions and before placing onto the moulds, the walls were coated with petroleum jelly. The mixed cement was then placed by keeping a matrix strip above and below the moulds to achieve a finished surface. After setting, the specimens were removed from the mould and excess was trimmed using Bard Parker blade(#11) and polished with 1200 grit paper. Then the specimens were stored in distilled water at room temperature for 24 hour prior to testing.

In both the groups (Figure 2 & 3);

12 cylindrical specimens of (4 x 6mm) dimension were used to test compressive strength.

12 bar-shaped specimens of (25 x 2 x 2mm) dimension were used to test flexural strength.

12 rectangular specimens of (8 x 4mm) dimension were used to test knoop microhardness.

**Assessment of Compressive Strength:** 12 cylindrical specimens from each group were placed between the plates of Universal Testing Machine (Model PC-2000, Electronic Tensometer). A compressive load was applied along the long axis at a crosshead speed of 5mm/min until the test specimen fracture. The maximum load applied to fracture the specimen was recorded.

**Assessment of Flexural Strength:** 12 bar-shaped specimens from each group were subjected to 3-point bending test on Universal Testing Machine (Model PC-2000, Electronic Tensometer) at a crosshead speed of 5mm/min. The maximum load applied to fracture the specimen was recorded.

**Assessment of Knoop Microhardness:** 12 rectangular specimens from each group were subjected to micro-indentation hardness test in Microhardness Tester (Matsuzawa, Japan/MMT-X7A), where a diamond-intender was pressed onto the surface of the specimens under a load of 100g with a 10sec dwell time. After the load was removed, measurements of the major axis of the diamond marked by the intender on the surface of test specimens were made and used for determining the knoop microhardness.

The values obtained were tabulated and fed in Statistical Package for Social Sciences software (SPSS version 23) for statistical analysis.

**Specimens:**

**Fig 2: Specimens of Amalgomer CR**
Findings: Table 1 shows the mean and standard deviations of the mechanical properties of Amalgomer CR and Type IX GIC.

Discussion

The efficiency of the restorative material to withstand the functional forces is an important requirement for its longevity. Among the mechanical properties, compressive strength and flexural strength are the widely used properties in evaluating the clinical performance of the restorative materials.

Compressive strength is often used as a measure to evaluate the ability of the material to withstand the masticatory force. Flexural strength is used to evaluate the strength of the material and the amount of distortion expected under bending stress. The specimens were subjected to 3-point bending test because it is considered as a representation of the clinical situation as the forces exerted by the opposing cusp. Microhardness can be defined as the resistance of a material to indentation or penetration. Surface hardness tests appears to be appropriate for evaluating the degradation and durability of dental materials.

Various restorative materials have been used since years to preserve the lost tooth structure and maintain form, function and esthetics. Dental amalgam has served as an excellent and versatile restorative material for many years. However, it has many drawbacks like lack of esthetics and the unavoidable use of mercury. This lead to the search of more improved materials and the most commonly used restorative material is GIC because of their fluoride release, biocompatibility and ease of use. However, some deficiencies like moisture sensitivity, short working time, long setting and maturation time, low fracture toughness and poor wear resistance have limited their use to areas which are not subjected to high masticatory stresses.

The physical and mechanical properties of GICs were further improved when a resin portion was added to the original GIC which yielded a hybrid material, i.e., resin modified glass ionomer cement (RMGIC) which was developed to overcome the problems of moisture sensitivity and low initial mechanical strength.
that were typical for conventional glass ionomers and have the advantage of longer working time, less sensitivity to water during setting.\textsuperscript{16,17}

A new generation of glass ionomer, GC Fuji IX, was developed especially for Geriatric and Pediatric patients in late 1990s. It is said to possess high strength, wear resistance, chemical adhesion to tooth, fluoride release, radiopacity, and less sensitivity to saliva.\textsuperscript{18} Last few decades have witnessed efforts increasingly directed towards modifications of the older materials with the addition of various modifiers which were proven to be beneficial.\textsuperscript{4} One such modification made was the incorporation of ceramic particles to GIC. According to Williams et al reinforced materials were significantly stronger than other materials.\textsuperscript{19}

In this context, the present study was done to evaluate and compare the mechanical properties of ceramic reinforced glass ionomer cement (Amalgomer CR) and Type IX GIC by fabricating specimens where were then subjected to subsequent mechanical testing.

The specimens made in the study, failed to have a smooth surface even after placing the mylar strip. It could be due to the irregular surface of the fabricated customized mould. Finishing and polishing of restorative materials always pose a difficulty because particles and matrix differ in hardness and thus cannot be abraded uniformly.\textsuperscript{20,21} For a finishing system to be effective, the cutting particles should be harder than the filler materials. Otherwise, the polishing agent will only remove the matrix and leave the particles protruding from the surface.\textsuperscript{21} GICs’ surface hardness can be affected by the polishing process because it involves polishing of the glass particles and abrasion of the matrix which inturn can compromise the mechanical properties.\textsuperscript{22} Considering this, only gross finishing of the specimens were done.

Once the material is set, they were removed from the mould and immersed in distilled water for 24 hours. Mckenzie et al reported that the physico-mechanical properties of conventional and resin-modified GICs were not significantly different comparing storage in water or saliva upto 1 year. Therefore, water was considered as an acceptable storage medium for the in-vitro analysis of GIC’s properties.\textsuperscript{23} The specimens were then subjected to mechanical testing in the laboratory.

From the results obtained, the mean compressive strength and flexural strength of Amalgomer CR was found to be higher than Type IX GIC which was statistically significant with a p-value less than 0.05. This increase was attributed to the ceramic reinforcement where the ceramic filler in the powder component would react partially with the matrix and forms an altered polysalt matrix thereby enhancing the all round strength of the cement.\textsuperscript{4,5}

The knoop microhardness of Amalgomer CR was higher than Type IX GIC, with a p-value less than 0.05, this increase in microhardness could also be a result of the ceramic reinforcement and due to the improvization inmicronization and treatment of the main glass components, fluoro alumino silico phosphate glass and polyalkenoic acids.\textsuperscript{1} Hence from the present study it was shown that the mechanical properties of Ceramic Reinforced Glass Ionomer Cement (Amalgomer CR) is statistically significant than Type IX GIC with a p-value less than 0.05.

Within the limitations of the present study, Ceramic Reinforced Glass Ionomer Cement (Amalgomer CR) showed superior mechanical properties in terms of compressive strength, flexural strength and knoop microhardness owing to the homogeneous incorporation of ceramic particles in the glass component which further reinforces the material with high strength, lasting durability and high tolerance to occlusal load thereby ensuring it as a restorative material with promising results to be used in pediatric dentistry.

**Conclusion**

The study concludes that mechanical properties of Ceramic Reinforced Glass Ionomer Cement (Amalgomer CR) is superior to Type IX GIC. However, further in-vivo research with more parameters are needed to evaluate the efficiency of ceramic reinforced glass ionomer cement in real environmental circumstances.

**Conflict of Interest:** There is no conflict of interest in the research.

**Funding:** This study has not been funded by any organization.

**Ethical Clearance:** All the clinical procedures were carried out following the protocols approved by the Ethics and Review Committee of Sri Siddhartha Dental College and Hospital, Tumkur (IEC 02/2017).

Anemia among Pregnant Women and its Socio-Demographic and Reproductive Correlates: A Community Based Study

Vinutha Vinod¹, Pai Divya Venkatesh², AH Suryakantha³, Ashwini Kumar⁴

1Assistant Professor, Dept. of Obstetrics and Gynaecology, Melaka Manipal Medical College, 2Associate Professor, Department of Community Medicine, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, Karnataka, 3Former Professor, Department of Community Medicine, S.S Institute of Medical Sciences & Research Centre, Davangere, 4Additional Professor, Department of Community Medicine, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Background: The health consequences of anemia during pregnancy are well documented. The prevalence of anemia among antenatal women is still very high in India and it varies from region to region. Therefore a study was undertaken to assess the relationship between anemia and the contributory socio-demographic and reproductive factors.

Objectives: To study the prevalence of anemia and its contributory socio-demographic and reproductive factors among pregnant women

Method: A cross sectional study was conducted among 400 pregnant women above 18 years and beyond 12 weeks of amenorrhea in the field practice area of a private medical college for a period of one year. Hemoglobin was estimated by strip method using “Color scale test kit”. A predesigned and pretested questionnaire was used to interview the women regarding their socio-demographic and reproductive details. Data was analysed using SPSS ver. 18

Results: Among the 400 pregnant women, 264 (66%) were anemic out of which 32%, 30% and 4% were mildly, moderately and severely anemic. Anemia decreased with age and literacy level. The odds of anemia was 1.69 times more in Muslims as compared to Hindus. Anemia was not associated with any of the reproductive correlates.

Conclusion: Overall prevalence of anemia was high among the women. This calls for an urgent need of imparting health education about anemia. Also all pregnant women should not only be registered as their pregnancy is confirmed but also ensured adequate intake of iron and folic acid supplementation during pregnancy and postnatal period.

Keywords: Anemia, prevalence, socio-demographic, reproductive, factors.

Introduction

Worldwide anemia in pregnancy is a burning issue as it has a detrimental effect on the health of both the mother as well as child. Women during pregnancy are more vulnerable for anemia not only because of the synergistic effects of physiological increase in plasma volume (hemodilution) but also because of increased demand and poor bioavailability of iron in the food, predisposed by social factors like preferential feed for men, women eating last with whatever left, being
deprived of good food, workload of household chores, and other cultural practices \(^{(1,2)}\).

Several studies have shown that almost 40% of maternal deaths in India is indirectly contributed by anemia because of early marriage, rapid succession of pregnancies at closer intervals and loss of blood in each delivery and chronic blood loss due to hookworm infestation and malaria. \(^{(3,4)}\)

The burden of anemia among antenatal women is still very high in India and it differs from region to region. \(^{(5-12)}\) Therefore an attempt has been made to study the relationship between anemia and socio-demographic and reproductive factors contributing to it, to meet the challenge of protecting maternal and neonatal health.

**Aims & Objectives:** To study the prevalence of anemia and its contributory socio-demographic and reproductive factors among pregnant women

**Method**

A community based cross-sectional study was carried out among pregnant women in the field practice area of a private medical college in Davangere, Karnataka.

Inclusion criteria: Pregnant women aged above 18 years and beyond 12 weeks of amenorrhea who were willing to participate in the study were included.

Exclusion criteria: Pregnant women with systemic illness and bleeding disorders, who were non-cooperative, absent on the days of visit or consuming iron and folic acid (IFA) tablets in the past three months were excluded from the study.

**Ethical Clearance:** Ethical Clearance was obtained from the Institutional Ethics Committee.

**Sample Size:** Considering that the prevalence of anemia among pregnant women in India varies from 60-80% (average = 70%), we calculated the sample size using the formula \(n = \frac{4pq}{d^2}\) where, \(n = \text{sample size}, p = \text{prevalence of anemia}, q = 100 - p = 100-70 = 30, d = \text{admissible error} (10 \% \text{of} \text{p}) \text{therefore,} \ \text{n} = 171.4.\) It was rounded up to 210 for urban and 190 for rural pregnant women. Thus the total sample size came up to 400.

**Consent:** Written informed consent was obtained before interviewing the pregnant women.

**Sampling technique** Purposive sampling was employed for the study.

Data Collection tool: All the eligible women were briefed regarding the purpose of the study and were assured of confidentiality and anonymity of information. A predesigned, pretested, semi structured questionnaire was administered to interview the recruited women and data regarding socio-demographic characteristics and reproductive history was taken. Hemoglobin level among the study group was estimated by using “Color Scale for Hemoglobin” device. It is a simple and effective medical device for the accurate estimation of Haemoglobin levels in blood. It comprises a small card with six shades of red that represent Haemoglobin levels at 4, 6, 8, 10, 12 & 14 g/dl respectively. A drop of blood is placed on the test strip provided. After waiting for about 30 seconds the colour of the blood spot is matched immediately against one of the hues on the scale.\(^{13}\)Severity of anemia was classified into four grades, i.e Mild: 10-10.9 g/dl, Moderate: 7-9.9g/dl, Severe:7-4g/dl and very severe :< 4g/dl

**Data analysis:** The data was compiled and analyzed using Statistical Package for Social Sciences (SPSS 18) software. Results were expressed in frequency and percentages. Statistical tests like chi square and Fischer’s exact test were used to assess significance of categorical data. Associations were confirmed using logistic regression and it was expressed using odds ratio with 95% Confidence interval

**Results**

A total of 400 antenatal women were recruited into the study. Their age varied from 18 to 37 years, their mean age being 23.27 ± 3.226 years. Majority of the women were less than 25 years of age (80%) and were predominantly Hindus (49.5%). Most of the study participants were homemakers (85.5%) and almost half of them studied up to secondary school (49.5%). More than half of the women were residing in a joint family (53%) and majority of them were consuming a non vegetarian diet (78%).

The study population was almost equally distributed with respect to the gravida status. Nearly half of them were nulliparous (46.5%). More than half of them had an interval of more than two years between their deliveries (57%). Almost 10% of the women underwent abortions.

Out of 400 pregnant women 264(66%) were anemic. Among them 32% and 30% had mild and moderate anemia respectively. Very few of them had severe anemia(4%) (Fig. 1).
Figure 1: Showing severity of anemia among pregnant women, N = 400

Majority (68%) of women aged less than 25 years were found to be anemic and this was highly significant (p < 0.05). More than three fourth of the Muslim women (77%) were found to be anemic and this difference was highly significant (p < 0.001). Anemia was insignificantly higher in homemakers and agricultural laborers as compared to employed women. The proportion of anemic women significantly decreased as the literacy status increased. Majority of the non-vegetarians (70%) were anemic and this difference was not significant. Anemia insignificantly increased with parity and number of abortions (Table 1).

Discussion

In the present study out of 400 pregnant women 264 (66%) were anemic. Similar findings were observed in other parts of Karnataka as well as in a study conducted in West Bengal (67.8%).\(^{5,6,7,8}\)Comparatively lower proportion of women were anemic in studies conducted in Andaman and Nicobar islands(50.9%) and Southern Punjab (55.2%).\(^{9,10}\) Greater proportion of pregnant women were anemic in the studies conducted in Assam (86.88%) and Solapur(92.38%).\(^{11,12}\) Our findings were almost analogous to the those conducted in Africa (47-62%) and much higher than those in Sri Lanka(16.6%), Indonesia (40.7%) and Nepal (37%).

In our study out of the 66% women having anemia 32%,30% and 4% women had mild, moderate and severe anemia respectively. Almost Similar findings were seen in studies conducted in Kolar, Mysuru, Andaman & Nicobar islands and Jaipur. The proportion of mild anemia was higher in studies conducted by Bisoi S in West Bengal (67.8%). Whereas the proportion of moderate anemia was greater in studies conducted by Taseer et al in Southern Punjab (60.14%) and Biswas M et al (77%)in Assam. The proportion of severe anemia was comparatively higher in a study conducted by Chowdhary HA et. al (11%).\(^{14,15,16,17}\)

In the present study 68% of women aged less than 25 years were found to be anemic and this was highly significant. This hints at the poor dietary intake of iron of these women during childhood and the increased requirements during pregnancy further worsened
anemia. The study findings of HA Chowdhary et al were almost alike. In a study conducted by Bisoi D et al (61.8%) and Kefiyalew et. al (34.6%) the relationship between age and anemia was not significant. In our study it was seen that there was inverse relationship between age and anemia. Contradictory findings were seen in studies conducted by Suryanarayana et.al and Okube OT et al.

In our study 77% of Muslim women were found to be anemic and this difference was highly significant (p < 0.001). The odds of anemia was 1.69 times more in Muslim women as compared to Hindus. Whereas in studies conducted by Bisoi D 80.6% of Muslim women were anemic but this relationship was not significant. Whereas in a study conducted by Okube OT the proportion of anemia was non significantly high in Christians (57.5%).

In our study the proportion of anemia was non significantly more in agricultural labourers (74%) and homemakers (59%). Analogous findings were seen in studies conducted by Lestari S et al and HA Chowdhary et al where 42.6% and 37% of homemakers were anemic. Contradictory findings were seen in studies conducted by Okube OT where anemia was significantly more in employed women as compared to homemakers.

In our study it was seen that as literacy status increased anemia decreased. This may be because literacy has an impact on the utilization of antenatal services as well as following good practices during the antenatal period. These findings were in line with the studies conducted by Bisoi D and Chowdhury HA et al. Contradictory findings were seen in studies conducted by Vindhya et al., Okube OT et al and Kefiyalew F et al where anemia was insignificantly associated with literacy status.

In the present study 70% of women residing in nuclear families were anemic and this relationship was not significant. On the contrary in a study conducted by Bisoi D et al 78.5% of women residing in joint families were significantly anemic. Whereas in a study conducted by Ahmed N et al 76.7% of women residing in nuclear families were found to be significantly anemic.

In the present study 69% of multigravida women were insignificantly anemic. Whereas in a study conducted by Suryanarayana et al anemia significantly increased with gravida status. In a study conducted by Bisoi D et al anemia increased with gravida status and this relationship was not significant.

In our study anemia insignificantly increased with parity. These findings are conflicting with those of Lestari S et al where anemia significantly increased with parity.

In our study women with lesser birth interval were found to be more anemic and this relationship was not significant. Similar findings were found in studies conducted by Lestari S et al and Suryanarayana Et al. Pardoxical findings were seen in a study conducted by Bisoi S where birth interval of lesser than two years was significantly associated with anemia.

In the present study 86% of women with more than two abortions were insignificantly anemic. Ambiguous findings were seen in a study conducted by Ahmed N where the proportion of anemia significantly increased with the number of abortions.

Conclusion

The overall prevalence of anemia was very high among the pregnant women. Anemia had an inverse relationship with age and literacy level. The odds of anemia was 1.69 times more in Muslim women as compared to Hindus.

Recommendations: Intensive health education should be imparted to all pregnant women about the importance of anemia and its outcomes. They should be encouraged to improve their dietary habits with special emphasis on the consumption of foods rich in iron and folic acid. Also all pregnant women should not only be registered as their pregnancy is confirmed but also given iron and folic acid supplementation of required dose and duration during pregnancy and postnatal period. Strict enforcement of 12 by 12 initiative among school girls for their safe motherhood and reproductive health

Limitations: The social correlates like occupation of husband and socioeconomic status were not studied because most of the women were homemakers and did not know the income of their husbands. This was only a quantitative study. Further qualitative studies should be planned to explore the root cause of anemia.

Awareness of Knowledge of Saliva as a Diagnostic Tool

T.N. Uma Mageshwari¹, Shachi P. Ajmera², S. Mounika³

¹Professor, Department of Oral Medicine and Radiology, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, ²Undergraduate Student, DY Patil Dental College, Navi Mumbai, ³Undergraduate Student, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai

Abstract

Aim: Awareness of knowledge of saliva as a Diagnostic tool.

Objective: This survey is done to see the importance & awareness of Saliva tests in India. It was the survey asking about people’s opinion of saliva test and their views about this test in future.

Method and Material: Questionnaire of 14 questions ask to 130 people in Dy Patil dental college from 19-50 years of age.

Reason: To know if this saliva test has a scope of being popular and accurate as blood or urine test in future.

Conclusion: Saliva testing is not that popular, as this study proved that only 51% knew about it. People aren’t aware about the use of saliva test and they aren’t sure about its accuracy level. It should also be reached out to large part of the community by various platforms. The more the research about saliva testing better it will be.

Keywords: Saliva, Diagnostic uses, Awareness, Survey.

Introduction

Over the past 10 years, the use of saliva as a diagnostic fluid has gained attention and has become a translational research success story.

Saliva has the potential to become a first-line diagnostic sample of choice owing to the advancements in detection technologies coupled with combinations of biomolecules with clinical relevance.

Saliva is a unique fluid, and interest in it as a diagnostic medium has advanced exponentially in the last 10 years.¹

There are so many advantages of Saliva that the test is now trending.

Saliva can be used as a diagnostic specimen not only to obtain information more inexpensively and efficiently but also to provide information not readily available from serum testing or other test.²

From genetics to infections and collecting is saliva to accuracy so many papers and reviews have been done on saliva as a diagnostic tool.³

People from all around the world are searching still and spreading the message about saliva testing about its pro and cons.

That’s where this survey comes into the role on assessing the knowledge on saliva being used as a diagnostic tool.

Method and data collection: The survey was conducted with 14 compulsory questions asked to age groups of 18-50 from DY patil dental college Mumbai.

The questions were regarding their knowledge and experience on saliva testing. The questions were based upon opinions, and the future of the test comparing the pros and cons of the urine and blood test.

Saliva test, is not popular as blood or urine test. This survey helped them know that saliva testing is also one way for know that this test is also trending.
The options in the survey was yes and no for most of the questions and for others were maybe option too.

**Result**

The result of the survey was that saliva test, should be more popular and spread. Not many know about the test. Only 6 people out of 130 people have taken the test. Many people feel that more research should be done about it. They aren’t sure about how accurate the results would be and what scope it has for future. Most of the people are curious to know more about the test.

**Discussion**

Diagnostic Saliva test is becoming popular as it can be collected with ease, safety cost effective and non invasive diagnostic approach. Danial Malamud has said that increasingly saliva is used to monitor antibodies (virus and bacteria) drugs is misuse and steroid hormones. He feels the test have already taken a long road in the world of diagnosis e.g some molecules like antibodies, unconjugated steroid hormones, & certain drug techniques are sufficiently to to reflect blood concentrations of the blood accurately.[4]

With a salivary specimen, one can collect multiple specimens from the same individual at the optimum times for diagnostic information. This is of particular value for steroid hormones because many have diurnal or monthly variations. Saliva can be collected in remote sites by unskilled personnel and, with certain collection devices, is stable at ambient temperatures for several weeks.[5]

We believe that this will soon be followed by application of highly informative salivary biomarkers to other high-impact systemic disorders because saliva is composed of various molecules that are filtered, processed, and secreted from salivary gland.[6]

Moreover, as an example An enzyme-linked immunosorbent assay (ELISA) for detection of feline leukemia virus (FeLV) p27 in saliva was tested for its accuracy and sensitivity in diagnosing FeLV infections. Saliva and serum samples from 564 clinical cases were tested with a 99.2% specificity. The overall accuracy of the saliva ELISA reactive to the serum ELISA was 97.9%.[7]

Despite advances in the use of saliva for HIV detection. The advantages of using saliva can be fully realized if it is used in simple but reliable nonlaboratory assay is. One is a preference for less invasive specimen collection techniques (e.g., by use of saliva). It has now been shown that antibodies to HIV from the oral cavity can be detected with a sensitivity and specificity that are essentially identical to those of tests with serum.[5,6,7,8,9,10,11,12]

**Conclusion**

Saliva Testing is only known to 51% from 130 people in the survey. Therefore, 90% people haven’t even taken it. Only 6 from 130 people have taken a saliva test which concludes that it’s not as popular in India as other countries. People haven’t been much aware of this through any means of communication. 92% of the people feel that it will be helpful in the research about genetics (DNA RNA exosomes) They do believe that the test may or may not be accurate and helpful as blood and urine test. Experience of Xerostomia (dry mouth) and excessive salivation was also asked in the questionnaire but they are unaware about if it happened with them like they faced it or not. This the conclusion is Saliva test is not as popular as it should have been people are still unaware about it.

Public Health and Environmental Protection Linkages in Law and Practice

Sunklan Porwal¹, J.K. Mittal²

¹Ph.D Research Scholar, ²Prof. (Guide), Amity Law School, Amity University NOIDA, Uttar Pradesh

Abstract

The field of environmental health and protection and the entire field of public health have repeatedly found themselves isolated from one another, unable to articulate the definition, mission, and goals of public health and the essential role for environmental health and protection in the provision of a healthy ecological and human environment. Environmental agencies often forget that they, too, are public health agencies; public health agencies that have had environmental health functions have divided and abdicated their environmental responsibilities, considering these to be “regulatory” rather than public health. This article reviews the history of environmental health and protection, its involvement within the field of public health, its eventual separation from other public health programs with resulting benefits and consequences, and what the future may hold for environmental health and protection activities as well as for the broader scope of public health of which these activities are a part.

Keywords: Environmental health, Protection, Public Health, Ecology.

Introduction

The world is beginning to acknowledge its natural physical limitations, the relationship between ecological well-being and economic success, and the link between the survival of all nonhuman species and the survival of our own. As this awareness increases, so does the respect for the importance of environmental health and protection activities and for the need to balance development with the environment on both a local and a global scale. Yet even as the importance of environmental protection becomes more clear, the field of environmental health and protection, and indeed the entire field of public health, have repeatedly found themselves isolated from one another, unable to articulate the definition, mission and goals of public health and the essential role for environmental health and protection in the provision of a healthy ecological and human environment. Environmental agencies often forget that they, too, are public health agencies; public health agencies that have had environmental health functions have divided and abdicated their environmental responsibilities, considering these to be “regulatory” rather than public health. Both environmental health and protection agencies and other public health organizations have forgotten how each can enhance and make more effective their combined efforts aimed at creating a healthy public and a quality environment. Since environmental health was one of the very earliest of organized public health activities, how did the field of public health get itself into such a muddle that it no longer recognizes environmental health as a public health activity? This article reviews the history of environmental health and protection, its involvement within the field of public health, its eventual separation from other public health programs with resulting benefits and consequences, and what the future may hold for environmental health and protection activities as well as for the broader scope of public health of which these activities are a part.

Definition of Public Health and Environmental Protection: First, it may be useful to define public health and environmental health and protection. Winslow published his definition of public health in 1923 in The Evolution and Significance of the Public Health Campaign,

“Public health is not a concrete intellectual discipline, but a field of social activity. It includes applications of chemistry and bacteriology, of engineering and statistics, of physiology and pathology and epidemiology, and in some measure of sociology, and it builds upon these
basic sciences a comprehensive program of community service”.

To these today we might add psychology and health education, but public health still remains, as Winslow described it, a program of community service in the improvement of the public’s health.

On the continuum of health services is the organized group of activities known as environmental health and protection. The following definition has been widely used after its review and endorsement by numerous professionals in the field and its publication in the *Journal of Environmental Health* in 1993.

Environmental health and protection refers to protection against environmental factors that may adversely impact human health or the ecological balances essential to long term human health and environmental quality, whether in the natural or human-made environment. These factors include but are not limited to air, food and water contaminants, radiation, toxic chemicals, wastes, disease vectors, safety hazards and habitat alterations.

Today, many professionals in public and environmental health confuse their mission and activities with the titles of the agencies or programs within which they are organized, forgetting that many agencies without the word “health” in their titles are performing public health functions. To assess how this current state of affairs evolved, it is necessary to look at the history of environmental health and protection and its relationship to the rest of the field of public health.

**History and Evolution of Public Health and Environmental Protection:** Environmental health and protection services were some of the earliest public health activities on record. Written mention of the impact of the environment on health dates to Biblical times, with the pronouncements of Leviticus on food safety and quarantine. Winslow describes the awareness of the importance of sewerage, the protection of a public water supply, the regular disposal of wastes, and the effectiveness of isolation and quarantine as long ago as in Rome and in thirteenth century England. Yet he refers to this period as the “Dark Ages of Public Health,” for there was not complete understanding of the mechanisms of disease transmission, nor a policy or methodology for the organized provision of services to protect the public health.

Such a policy developed along with the social reforms of the 1700s and 1800s in England, followed by Massachusetts. Reformers such as Edwin Chadwick in England in the 1840s made the connection between income, living conditions, and health. In London in the 1850s, John Snow traced outbreaks of cholera in populations to their common drinking water source. The 1871 Report of the Royal Sanitary Commission listed 11 essential health activities, most of which were environmental in nature, including “the supply of wholesome and sufficient water for drinking and washing, the prevention of the pollution of water, the provision of sewerage and utilization of sewerage, the healthiness of dwellings, the removal of nuisances and refuse, the inspection of food. Lemuel Shattuck, a social reformer in Boston, published his *Report of the Massachusetts Sanitary Commission* in 1850, calling for similar organized activities on the part of government, a report that led to the founding of the first State Board of Health in Massachusetts in 1869.

There were those among the public health specialists and reformers of the day who envisioned protection of the public health as not only a state but a federal responsibility. They also believed in the importance of strengthening the impact of the combined disciplines within the field of public health through an organized voluntary association of those working daily on public health issues. In 1872, there were established boards of health in only three states and the District of Columbia. Thus, Stephen Smith, an appointed commissioner of the New York City Metropolitan Health Board, invited a group of six men in April, 1872, to discuss the idea of setting up such a professional organization. The result was the first meeting of the American Public Health Association (APHA) in Cincinnati, Ohio, in 1873, with Dr. Smith presiding as President. This professional organization was to be responsible for supporting much of the public health legislation over the next century, and through the concerted efforts of its members in many states was influential in the establishment of boards of health and public health agencies throughout the United States. In fact, at the end of the nineteenth century, 25 years later, full-time health departments existed in 40 states.

Numerous public health gains were made during the decades to follow, including the adoption of local and state public health regulations, an increase in the number of children vaccinated against communicable disease,
widespread provision of water and sewer services, adoption of food protection legislation, housing reforms, protective measures against insects and rodents, and the proliferation of public health laws and programs that made the most significant improvement in history in human morbidity and mortality rates. Mullan’s *Plagues and Politics; The Story of the United States Public Health Service*, provides a history of excellence in leadership and innovative programs that have served as the foundation for many of the programs found nationally today. One such example is that of Dr. Leslie Lumsden, a Public Health Service physician assigned to the State of Washington to reduce the epidemics of typhoid fever, who made it his personal quest to “abolish every insanitary privy, privy vault, cess pool and septic tank in the city and replace those in non sewered areas by sanitary privies” (20). To the environmental protection and hygiene services provided by government were added the personal health services of immunizations and prenatal care, forming the basis of programs for many current local health departments. The above texts provide invaluable historical background on the development of the field of public health over the past century in the United States.

**Provisions Related to Public Health and Environment:** Most human rights treaties were drafted and adopted before environmental protection became a matter of international concern. As a result, there are few references to environmental matters in international human rights instruments, although the rights to life and to health are certainly included and some formulations of the latter right make reference to environmental issues.

The *International Covenant on Economic, Social and Cultural Rights* (16 Dec. 1966), guarantees the right to safe and healthy working conditions (art. 7 b) and the right of children and young person’s to be free from work harmful to their health (art. 10-3). The right to health contained in article 12 of the Covenant expressly calls on states parties to take steps for “the improvement of all aspects of environmental and industrial hygiene and “the prevention, treatment and control of epidemic, endemic, occupational, and other diseases.”

The *Convention on the Rights of the Child* (New York, November 20, 1989) refers to aspects of environmental protection in respect to the child’s right to health. Article 24 provides that States Parties shall take appropriate measures to combat disease and malnutrition through the provision of adequate nutritious foods and clean drinking water, taking into consideration the dangers and risks of environmental pollution. (Art. 24(2)(c). Information and education is to be provided to all segments of society on hygiene and environmental sanitation. (Art. 24(2)(e).

**ILO Convention No. 169 concerning Indigenous and Tribal Peoples in Independent Countries:** (Geneva, June 27, 1989) contains numerous references to the lands, resources, and environment of indigenous peoples (e.g., arts. 2, 6, 7, 15). Part II of the Convention addresses land issues, including the rights of the peoples concerned to the natural resources pertaining to their lands.

Further, governments are to ensure adequate health services are available or provide resources to indigenous groups so that they may enjoy the highest attainable standard of physical and mental Health, (Art. 25(1)), Article 30 requires that governments make known to the peoples concerned their rights and duties.

Two regional human rights treaties contain specific provisions on the right to environment.

The approach of each differs, with the African Charter linking the environment to development, while the American Convention Protocol speaks of a healthy environment.

**The African Charter on Human and Peoples Rights,** (Banjul June 26, 1991) contains both a right to health and a right to environment. Article 16 of the African Charter guarantees to every Individual the right to enjoy the best attainable state of physical and mental health while Article 24 states that all peoples shall have the right to a general satisfactory environment favorable to their development, The distinction between an individual and a people’s right is not made clear.

**The Additional Protocol to the American Convention on Human Rights in the area of Economic, Social and Cultural Rights:** Contains both a right to health and a right to environment, drafted in more detail than in other human rights instruments, Article 10 provides:

1. Everyone shall have the right to health, understood...
to mean the enjoyment of the highest level of physical, mental and social well-being.

2. In order to ensure the exercise of the right to health, the States Parties agree to recognize health as a public good and, particularly, to adopt the following measures to ensure that right:

(a) Primary health care, that is, essential health care made available to all individuals and families in the community;

(b) Extension of the benefits of health services to all individuals subject to the State’s jurisdiction;

(c) Universal immunization against the principal infectious diseases;

(d) Prevention and treatment of endemic, occupational and other diseases;

(e) Education of the population on the prevention and treatment of health problems, and

(f) Satisfaction of the health needs of the highest risk groups and of those whose poverty makes them the most vulnerable.

Article 11 is entitled: Right to a healthy environment. It proclaims:

1. Everyone shall have the right to live in a healthy environment and to have access to basic public services.

2. The States Parties shall promote the protection, preservation and improvement of the environment.

Indian Constitution discuss the Protection of health, Article 48 A ensures that State shall endeavor free environment for good health.

Conclusion

If there were two key themes for the future of environmental health, they would be, focusing on a science-based mission of protecting the public health and the greater ecological system of which we are a part and creating partnerships and linkages with others to insure a healthy environment. Evans, a past President of the American Public Health Association, spoke these words in his 1995 presidential address, “We need partnerships because we don’t have the resources to be successful working in isolation, because working in partnership forces us to define our role and demonstrate our value, because partners hold us accountable for relevant deliverables, and because all of us are smarter than any of us. Partnerships create an interface, a plane in which different disciplines and talents, ideologies, lifestyles, and cultures come together in a way that creates energy, unleashes imagination, and results in mutually beneficial change, Public health leaders must be potent agents of change which must be sustainable and beneficial to society.

In order to lead, professionals in environmental health and protection must be clear on their mission, and advocate for organizing major aspects of environmental health and protection activities together so that the public health world view is maintained. It is the responsibility of environmental health and protection leaders to seek out and support training to enhance the competencies of their staff, and to create dialogue with local educational institutions to strengthen the theory/practice link.

As the separation from other public health functions continues, public health professionals on both sides need to redouble their efforts to keep the linkages strong between all public health functions, especially in light of the drive towards managed care that may promise to provide health care but threatens to replace the vital importance of public health and prevention in the mind of the public.

Abstract

Cynodon dactylon or Arugampul is considered as a sanctified grass in Tamil Nadu, India and used in religious offerings. Its health and nutritional benefits are well documented but very little about its bioactive compounds. Objective of the present study is to determine the bioactive compounds present in the aqueous extract of Cynodon dactylon, using GC/MS as a tool. Hot aqueous extract of Cynodon dactylon was analyzed for its bioactive compounds using gas chromatograph of JEOL GC MATE II and mass spectrometer of quadruple double focusing mass analyzer. Eight bioactive compounds were detected from hot aqueous extract of Cynodon dactylon through GC-MS analysis. The compounds were Alanine, 9,12-Octadecadienoic acid (ZZ), n-Hexadecanoic acid, Oleic acid, Oxiraneoctanoic acid, 3-octly-, methyl ester, trans-, Phytol, Coumarine, 3-(2,4 -dinitrophenyl), 2-Cyclohexen-3,6-diol-1one, 2-tetradecanoyl-.

Keywords: Cynodon dactylon, Arugampul, Bermuda grass, GC/MS Analysis, Bioactive Compounds.

Introduction

Plants are being used as the resources of nutrition and medicines since the beginning of the mankind. Each species of plants produces a mixture secondary metabolites or bioactive compounds. Humans use this property of the plants to make herbal medicines, flavoring substances or recreational drugs. Herbal drugs are effective, affordable and less toxic.¹ Researchers use various types of method/techniques for the metabolite profiling of medicinal plants, but in the recent past gas chromatography mass spectrometry (GC/MS) based metabolite profiling got more acceptance due to its reliability and sensitivity than other method.²

Cynodon dactylon or Bermuda grass is seen in moderate climate all over the world between south and north latitudes. C.dactylon is a stoloniferous, hardy perennial grass, very much variable with long rapid growing, rooting at nodes, forming a dense tuft on the top of the soil. The runners of this plant are usually 2cm long, 0.2-0.6cm broad, flat and convolute. Inflorescence appears on culms 150mm to 1m tall, consisting of 2-12 spikes arranged star like at apex of stem; spikes 25-100mm long with numerous spikelet, arranged in 2 rows on one side of spike.³

C. dactylon is widely used for traditional medical practice in India.⁴ Crude extract of this plant is used for treatment of cancer⁵ obesity, diabetic⁶ gastric ulcers⁷ etc. There are also evidence for its Antihyperlipedemic⁸, Hepatoprotective⁹, Antimicrobial¹⁰ and Antiatherosclerotic¹¹ properties of this plant. But there were a very few documents regarding secondary metabolite profile of C. dactylon. Hence the GC/MS analysis has been done.

Materials and Method

Plant material and extract: C.dactylon plants were collected from the campus of Sri Lakshmi Narayana Institute of Medical Sciences Puducherry. The plant was identified and certified by Dr. R.Sridharan, M.D(S), Nodal officer, Siddha and Consultant Phyto-Medicine, Government of Puducherry.

DOI Number: 10.37506/v10/i12/2019/ijphrd/192194
Collected plants were washed thoroughly with tap water, rinsed with distilled water and air dried in a shady place. Dried plants were pulverized in to fine powder with a grinding machine. To make the aqueous extract, 100gm of plant powder was mixed with 1000ml of distilled water and heated till boiling temperature. The mixture was filtered using Whatmans no 1 filter paper.

**GC MS analysis:** The extract from *C. dactylon* plant was analyzed with JEOL GCmate II GC/MS system (JEOL USA, Inc.), which includes quadruple double focusing mass analyzer. The Column used was HP 5Ms capillary (0.10 – 1.00 µm film thickness) composed of (5%-Phenyl)-methylpolysiloxane. High pure Helium at a flow rate of 1ml/min was used as the carrier gas. The inlet temperature was maintained as 250°C. The oven temperature was programmed initially 50 to 250 @ 10 deg/min. The MS transfer line was maintained at a temperature of 250°C. Mas spectra was analyzed using electron impact ionization at 70eV and data was evaluated using total ion count (TIC) for compound identification and quantification. The spectrums of the components were compared with the database of spectrum of known components stored in the GC/MS library.

**Result and Discussion**

Bioactive compounds from hot aqueous extract of *C. dactylon* was analyzed through gas chromatography–mass spectrometry and compared with the GC/MS library to identify the chemical compounds. Eight peaks were detected in the GC/MS chromatogram (fig-1).

As per the GC/MS library the detected compounds where as follows:

1. First peak was obtained at retention time of 14.9 and the compound was Alanine,
2. Second peak was at 16 and the compound was 9,12-octadecadienoic acid(zz),
3. Third peak was at 16.55 and the compound was n-Hexadecanoic acid,
4. Fourth at 17.48 and the compound was Oleic acid,
5. Fifth at 18.28 and the compound was Oxiraneoctanoic acid,3-octyl- ,methyl ester,trans-,
6. Sixth peak was at 20.05 and the compound was Phytol,
7. Seventh at 21.15 and the compound was Coumarine,3-(2,4-Dinitrophenyl),
8. Eighth peak was at retention time of 23.67 and the compound was 2-Cyclohexen-3/6diol-1-one,2-tetradecanoyl.

These compounds were tabulated with their molecular weight and structural formula in table 1.

Eight different types of bioactive compound were obtained in the GC-MS analysis from the hot aqueous extract of *C.dactylon*. The first peak was obtained at retention time of 14.9 and the compound was Alanine, which is a flavoring agent, antioxidant, cancer preventive, oxidant and it also act as a catalyze in regulating hormonal action. The second compound 9, 12-octadecadienoic acid(zz) was Linoleic acid, is an anti-inflammatory substance, hypocholesterolemic, cancer preventive, hepatoprotective. The third compound - n-Hexadecanoic acid is Palmitic acid by nature which is Antioxidant, Hypcholesterolemic, Nematicide, Pesticide, Lubricant, Antiandrogenic, Flavor, Hemolytic, 5-Alpha reductase inhibitor. Oleic acid is an anti-inflammatory, anti-androgenic cancer preventive, dermatitigenic hypocholesterolemic, Phytol is an Anticancer Antioxidant Anti-inflammatory Diuretic. n-Hexadecanoic acid is an Antioxidant, Hypcholesterolemic Nematicide, Pesticide, Lubricant, Antiandrogenic, Flavor. Oxiraneoctanoic acid, 3-octyl-,methyl ester, trans, Coumarine, 3-(2,4-Dinitrophenyl), 2-Cyclohexen-3/6diol-1-one, 2-tetradecanoyl for these compound the bioactive was not reported but the activity was reported based on main compound (oxiraneoctanoic acid and coumarine).

Climate Change, Public Health and Implementation of Sustainable Development Goals in India-Issues and Challenges

Ashwani Pant¹, Santosh Kumar²

¹Research Scholar, ²Associate Professor, Amity Law School, Amity University, Noida

Abstract

“The Sustainable Development Goals (SDGs) are broad sets of common goals for fair and sustainable health from local to international community. The aim is to end poverty, protect the planet and ensure that all people enjoy peace and prosperity, now and in the future. The goals embody an agenda that is scientifically strong, and widely in-built planned to figure upon the progress recognized by the Millennium Development Goals (MDGs). There is a need for structure wide strategic planning to integrate the economic, social and environmental dimensions into policy and actions. In the era of climate change we need to understand the difference between the MDGs and the SDGs, their implementation and nature of universality and the systems thinking that is needed to deliver the vision. The danger is that individual goals may be prioritized without an understanding of the potential positive interactions between goals. There is an increasing understanding that sustainable development needs a paradigm shift in our understanding of the interaction between the real economy and quality of life. There would be many social, environmental and economic benefits in changing our current model.

The paper basically will focus on: 1) the importance of sustainable developmental goals in the era of climate change in India; 2) Need to develop systems understanding of what supports a healthy environment and the issues & challenges thereof.”

Keywords: Climate Change, sustainable development, public health, implementation, sustainable development goals.

Introduction

“Climate Change which is a long-term change in earth’s climate due to natural, mechanical and anthropological processes which results in emission of greenhouse gases like CO₂, methane, etc. leading to global warming and changing climatic patterns. Shifting of seasons, increasing global temperatures, rising sea levels, changing agricultural patterns have resulted in frequent disasters like landslides, tsunamis, drought, famine, population migration and major health hazards not just for us but also for our children and grandchildren”.¹In view of the serious consequences that “global warming poses for humanity and other life forms, including a rise in a sea levels, an increase in global average air and ocean temperatures, widespread melting of snow and ice, the problem of climate change requires both short term and long term cooperative action by members of the international community to prevent dangerous anthropogenic interference with the climate system inter alia, by reducing concentrations of greenhouse gases within an internationally agreed time framework”².

“Development is a perpetual process enabling humans to expand and realize their potentialities to achieve a greater, better fuller state of living. Utilization of natural resources forms the very basis of sustenance of human life, while nature has only limited regeneration capacity”.³The human civilizations and its development

have been largely dependent on land, water, air and climate which have influenced the evolution of all life forms on earth. From pre-historic times to the present, humankind continues to drive their life and substance on earth in the changing seasons, atmosphere and climate”. It is said that “Earth does not belong to Man but Man belongs to the Earth”. However, mankind has always tried to control and exploit Earth for its own benefits without even blinking once. Increasing world population and the ever-increasing desire of human beings to raise their standard of living has led to technological innovations of all kinds. These innovations have made life more comfortable but at the cost of increased demands for food, air, water, minerals, and energy but at the same time adverse effect on human health”. This article argues that in the era of Climate change that threatens human well-being, not just locally but globally in the present as well as in future. This paper explores such laws, programs and policies of India addressing the public health measures due to climate change in the changing paradigm. To analyze the role of Sustainable Development Goals in mitigating public health issues nationally and globally and what are the issues and challenges in effective implementation of SDG’s towards securing public health.

**Material and Method**

This research is purely doctrinal in nature. Researchers have used both Primary and secondary sources available for this research like Gazettes of India, Acts, Books, Journals, UN website and Newspaper etc.

**Sustainable Development and Public Health Measures:** “The Sustainable Development Goals (SDGs) also called as the ‘Universal Agreement’ with an objective to end poverty, protect the planet habitable, and ensure that all people enjoy peace and prosperity, now and in the future. The Goals were adopted by all member states of United Nations officially in 2015, for the period 2016–30 to address the irresistible pragmatic and scientific evidence that the world needs a fundamentally more sustainable approach. The goals provide a well consulted framework that is sufficiently scientifically robust, politically acceptable, and publicly intuitive. The goals provide us with our best chance of ensuring the necessary collaboration and alignment as we implement global approaches to securing a fair, healthy and prosperous future for ourselves, our children and grandchildren”. Although the 17 goals are supported by targets and indicators- the key learning is that all the goals are intimately interconnected—"a failure to appreciate this will perpetuate an approach which will be non-aligned at best and highly ineffective at worst. Secondly, despite the intuitive nature of interventions that deliver both immediate and long-term ‘co-benefits’ (such as sustainable transport and food systems, or better access to green space), there is a worrying lack of generalizable, quantifiable evidence on the levels of benefit that appeals to policy makers, scientists or practitioners. This inhibits our vision and courage to act in those areas where we should be more specific about health, social and economic benefits. At a global level, we should use the SDGs to highlight the inter-linkage between goals and champion the specific and collaborative actions that create multiple and beneficial outcomes for shared purpose.”

The Sustainable Development Goals are formally the goals of the United Nations’ ‘Transforming our world; the 2030 Agenda for Sustainable Development’, an agenda which sets out the vision, principles and commitments to a fairer and more sustainable world for all. “The Millennium Development Goals (MDGs) were in place from 2000 to 2015 and consisted of eight international development goals. The first three goals covered poverty, education and gender equality; the next three goals addressed ‘health outcomes’ covering child mortality, maternal health and ‘HIV/AIDS, malaria and other diseases. The remaining two goals addressed environmental sustainability and global partnership for development. These eight MDGs were supported by a total of 21 individual targets. The MDGs, although a move in the right direction, were subject to certain criticisms. One was that there was insufficient analysis to justify why these goals were selected as priorities and insufficient information available to be able to compare performance, especially in tackling inequalities within countries”. Nevertheless, “based on data compiled by the Inter-Agency and Expert Group on MDG indicators”, the UN could demonstrate considerable success on some goals, “especially on reducing extreme poverty, reducing both child and maternal mortality, increasing access for people living with HIV to antiretroviral treatment and reducing new HIV infections. However, the report recognized that ‘progress has been uneven across regions and countries’ in the implementation of the MDGs”.
The UN resolution refers to “five ‘areas of critical importance’; sometimes known as the 5 ‘P’s, these are People, Planet, Prosperity, Peace and Partnerships (see Table 1). The goals were launched with the strap-line of ‘Ensuring that no-one is left behind’ with its implication that development and levelling up will be the keys to progress by 2030. How this aspiration is reconciled with maintaining ecosystems and tackling climate change will be a challenge in itself. However, the SDGs do have a clear goal on climate action (Goal 13), which has been strengthened subsequently by the Paris Agreement of the 21st Conference of Parties (COP21) to the United Nations Framework Convention on Climate Change (UNFCCC)”.

Areas of Concern-Impact of Climate Change on Human Health: According to the United Nations Industrial Development Organization (UNIDO), “climate change is likely to have a greater impact on India compared to other countries similarly positioned, on account of the unique combination of its geography, diverse population characteristics and extremely high carbon-related energy dependence”. Climate change is bound to affect the basic requirements for maintaining health- clean air and water, sufficient food, adequate shelter, and freedom from disease given the already high level of poverty, low nutritional levels and poor public health infrastructure in the country. Our personal health may seem to relate mostly to prudent behavior, heredity, occupation, local environmental exposures, and health care access, but sustained population health requires the life supporting “services” of the biosphere. Populations of all animal species depend on supplies of food and water, freedom from excess infectious disease, and the physical safety and comfort conferred by climatic stability. A changing climate is likely to affect all these conditions and hence have a powerful impact on human health and well-being.

Intergovernmental Panel on Climate Change in its fifth Assessment report concluded that “Climate Change is projected to increase threats to human health. Climate Change can affect human health directly (e.g., impacts of thermal stress, death/injury in floods and storms) and indirectly through changes in the ranges of disease vectors, water-borne pathogens, water quality, air quality and food availability. Global climate change is therefore, a newer challenge to ongoing efforts to protect human health”.

Issues and Challenges: Climate change in the global era refers to the statistical variations in the properties of climate system such as change in global temperatures which has drastically altered the distribution and quality of natural resources thereby adversely affecting the livelihood security of the people. The major issues and challenges faced in effective implementation of SDG’s in the global era of climate change are:

1. Adverse impact on crops and quality thereof;
2. Availability and quality of both surface and ground water;
3. Impact on livelihoods, food security and economy;
4. Inadequate drainage resulting in stagnant water and many water-borne diseases;
5. Rising temperatures, “changing patterns of rainfall and more frequent droughts and floods are projected to decrease crop yields causing shortages of food supplies which in result leads to severe malnutrition and under nutrition;”
6. Increasing “traffic and exhaust as well as industrial emissions are raising concentrations of SO2, NO2, O3 and suspended particles resulting into human health hazards;”
7. Unstable population increase is one of the major issue leading to disparity in terms of resource consumption;

**Conclusion and Suggestions**

“From this research what I found is that the greatest long-term danger to human health from climate change will be the disruption of natural ecosystems, which provide an array of services that ultimately support human health. More assessments of the impacts of climate change on health in different tropical zones e.g. Plains, deserts, foothills, hilly and coastal areas are required. In the era of globalization and climate change, to achieve and implement Sustainable Development Goals (SDG’s) related to public health we need focus on – (i) reliable and comprehensive assessments of risks to public health and dissemination of such information; (ii) improving health educational and institutional capacity in urban and rural environment management; (iii) improved efficiency of the water supply management; (iv) establishing of early warning systems and evacuation plans in case of emergency.”

Above all, protection of health from climate change and implementation of Sustainable Developmental Goals should be prioritize and must be a part of a basic preventive approach towards public health. Every generation in history has to faced global challenges. “We Are the First Generation that Can End Poverty, the Last that Can End Climate Change”.

**Conflict of Interest:** Ashwani Pant and Dr. Santosh Kumar declare that they have no conflict of interest.

**Source of Funding:** No funding for this research.

**Ethical Approval:** The study does not require the approval of Institutional Ethics Committee. As the study is the combination of socio-legal issue. No field study is done for this research.

Effectiveness of Mind Mapping as an Active Learning Tool among MBBS Phase-1 Students in Biochemistry

Deepa S. Sajjannar1, G.V. Naregal2, S.S. Walvekar2

1Assistant Professor, 2Tutor, 2Lecturer, Department of Biochemistry, BLDE (Deemed to be University) Shri B.M. Patil Medical College, Vijayapura, Karnataka, India

Abstract

Introduction: Mind mapping, an active learning tool facilitates student learning but remains underutilized in medicine. The present study was conducted with aim of assessing the effectiveness of mind maps as an active learning tool to augment learning in biochemistry and perception of students and faculty of the same.

Methodology: Present cross-sectional study included phase-I medical students (n=140) from BLDEA Shri B M patil medical college. Participants were randomized into study and control group by using computer generated random numbers and intervened by use of mind mapping and conventional assignments respectively. Student performance was measured using multiple choice questions with a maximum score of 25. Feedback was collected from the students as well as the faculty was analyzed.

Results: The mean scores in pre and post test of study group -I and control group-I were (12.19, 12.75) (12.14, 11.73) respectively. After Cross over, the mean scores in the pre and post tests of the study (II) and control groups (II) were (14.98, 16.10) and (14.7, 15.96) respectively. Data was analyzed and compared by Wilcoxon signed rank test and were statistically insignificant in the group –I but highly significant in group-II. Student feedback on mind maps had high positive ratings for longer retention (90%; n=126) and better time management (70%, n=98). The staff perceived that mind maps are helpful when applied for large information as in the medical curriculum (87%) and made students responsible for individualized learning.

Conclusion: Our study concludes that learning to learn becomes more important when there is larger information to be retained as well as analyzed as in medical curriculum and can be effective in making learning abstract concepts as in medical biochemistry more enjoyable and helps integrate basic concepts with other specialties.

It also facilitates lateral thinking and longer retention of concepts which would further help them manage time and to fare better in examinations.

Keywords: Mind maps, Active learning, Medical Biochemistry, lateral thinking, conceptual integration.

Introduction

Medical universities offer anatomy, physiology and clinical biochemistry in the first year of the medical course. Most of the teaching-learning happens through the traditional mode through didactic lectures, tutorials and practicals1. This has been the predominant mode of teaching since the inception of universities. Traditional lecturing defined as “…continuous exposition by the teacher” basically infers that the student activity is limited to taking down the points put across by the lecturer or may be limited to asking desultory and random clarifications or questions to the instructor2. This teacher centric or “teaching by telling approach” is now being challenged by a more student centric mode of instruction which is more benefitting to the construction...
of understanding by the students. The concepts in biochemistry effectively help in understanding the basis of diseases and also in interpreting various investigations requested for the diagnosis or prognosis of the patients but Practicing physicians as well as most of the medical students do consider that learning biochemistry is irrelevant and does little to help their daily practice of medicine. Medical biochemistry should incorporate students’ previously learned knowledge with medical applications and fill in the gaps with new knowledge. This can be achieved by Active learning method which compel the students to do tasks that help indeep learning, to think about what they are doing and also assimilate the information. Active learning is best defined as any instructional method that engages students in the learning process. It strives to involve students in the learning process more directly than in other method and it incriminates them in an activity besides just passive listening. It is the need of the hour to make a paradigm shift from the conventional teacher centered approach to an active, student centric learning experience which will promote reflection, knowledge constructing, inquiry, analytic and critical thinking capacity of the learners. The notion of employing mind maps as an active learning tool will prove to be an ingenious technique to promote student learning. The above method exploits the presentation form of radiant thinking and the inspiration for this strategy hypostatized from the notebooks of Leonardo da Vinci. With the application of mind mapping to learning, ability of student for logical analysis is enhanced. Integration of the left brain capacity in rationalizing and creativity, art and memory endowed with the right brain can be maximized. Adult learners stand for enormous benefit in using Mind maps but remains underutilized in medical education. The magnitude of information that medical students are assumed to master is voluminous and the present need to make the process of teaching-learning evidence based prompted this study.

**Aim:** To document the effectiveness of mind mapping in learning biochemistry among the first year medical students.

**Objectives:**

1. To assess the attitudes of students and faculty regarding mind mapping as an active learning tool using a feedback questionnaire.
2. To assess the effectiveness of mind mapping to augment the students’ learning in biochemistry.

**Methodology:** The present cross sectional study was carried out in BLD (deemed to be university) Shri B M Patil medical college hospital and research centre, Vijayapur over a period of one and half month from August to September 2018. This activity was approved by the university’s institutional review board (IRB) and bears the clearance no: BLDE (DU)/IEC/328/2018-19.

The MBBS phase I (140) students were randomized into study group (I) and control group (I) by using the computer generated random numbers. Both the groups were tested for the chosen topics before their exposure to the learning method by a pre test on MCQs (Multiple Choice Questions) for the chosen topics for a maximum score of 25. This activity was developed as a complementary to the small group teaching activity done during the semester.

The study group (I) was exposed to a detailed 40 minute session of hands on information regarding the origin of mind mapping. They were also trained to construct them for important concepts using characters, symbols, lines, colors, numbers, pictures and keywords for the chosen topics. The idea that mind maps support critical thinking, deep learning, and is creative was also stressed upon before the planned activity was encouraged. In order for the students to demonstrate their understanding of the concepts in a particular topic, assignments for constructing mind maps were administered to the study group (I). The study group (I) was asked to construct mind maps according to Buzan’s guidelines: the minds’ radiation of thought is reflected by the branches of the mind map, key words are used to represent ideas; color is used to highlight and emphasize them. Related thoughts are in the same color creating clarity to enhance recall; and images, symbols and codes are used to highlight ideas and stimulate the mind to make connections. The control group (I) were given the conventional assignments of practicing the topics in a question – answer format to complete.

Students maintained reflective journals to register the process of constructing their mind maps on the very same day and to contemplate on the benefits of it. At the end of the assignments both the groups were observed by a post test comprising MCQs for a maximum score of 25. The scores were tabulated for all the students on their performance before and after the intervention. To test the effectiveness a crossover of the groups was done, after the cross over, the study group (I) formed the control.
group (II) and the previous control group (I) was the study group (II) for the second set of selected topics. The entire process of intervention was repeated and the pre and post test scores for both the groups were tabulated and compared for statistical significance. At the end of study, a feedback was obtained from the students and faculty regarding the perception of mind mapping as a learning tool in biochemistry. The questionnaires were reconstructed for this study based on the available literature and were validated before use. The students’ questionnaire consisted of nine questions rated on a Likert scale with five response categories, strongly agree to strongly disagree to capture the intensity of their feelings for a given item.

Results

The study participants (n=140) were between the ages of 17 to 20 years. When inquired, approximately all the participants have had past college experiences predicated in a traditional passive learning style, while ten percent (n=15) students expressed their familiarity with mind maps and its usage but to a limited extent.

The mean and SD of the scores in the pre and post test of both groups (I) and group (II) were compared by Wilcoxon signed rank test as the distribution was not normal. The mean scores of the study group (I) after the mind mapping activity (12.75) were comparatively more than their mean scores in the pretest (12.19) though statistically insignificant, whereas the mean scores of the students in the control group (I) who had exposure to the conventional small group teaching (11.73) were lower than that scored in pretest (12.14), and also statistically insignificant. After the Crossover, the mean scores of the study group (II) after the mind mapping activity (16.10) were comparatively more than their mean scores in the pretest (14.98) and highly significant. whereas the mean scores of the students in the control group (II) who had exposure to the conventional small group teaching (15.96) was also higher than pretest mean score (12.14) and statistically significant.

| Table 1: Mean and SD of Pre and post test scores of each group (I) |

Figure 2: Comparison of Mean score of Pre and post test of each group(II) after crossover.

Figure 3: Student feedback on the mind mapping activity

Figure 4: Staff feedback on the mind mapping activity
Ninety-two percent (129) of all students agreed that mind mapping requires increased attention and is equally enjoyable even when they applied it for topics which they previously detested. The staff also stated that the students made meaningful use of the activity. Ninety percent (126) of the participants also related that the concepts were retained much longer with the use of their mind map ideas. Seventy percent (98) of the study group felt that mind mapping was good for effective time management, around ten percent (14) disagreed. Seventy five percent (7) of the staff found that the students were motivated for construction of mind maps which made them responsible for individualized learning. Eighty seven percent staff (8) also felt that mind mapping helps specially when applied for large information and should be encouraged as a learning tool. Analysis by results suggests that mind mapping is an effective learning strategy in the population studied.

Discussion

All the MBBS phase I participants implemented mind mapping as an active learning strategy to achieve their specific learning objectives. Some students were anxious of building their own mind maps, and others required an extra week to construct the mind maps.

Buzan\textsuperscript{18} in his seminal work identified that radiant or central thinking is promoted by the use of mind map and it enhanced the multiplicity of the brain. The students opined that the present activity of mind mapping the biochemistry concepts helped them to explore the concept in detail and also its key associations in a standardized, colorful and also in a logical manner. They also found themselves exploring and understanding the concepts of a particular topic. Picton C\textsuperscript{19} also found that the students’ ability to describe their critical thinking process and graphic representation of the concepts was enhanced by reflection which was agreed by our study participants. The staff favorably perceived that students made meaningful use of the mind mapping activity in learning biochemistry concepts. A study by Davies also confirms that learning is facilitated when the information is actively processed, visually and pictorially as in mind mapping of the concepts\textsuperscript{20}. Students have also expressed that mind mapping encouraged team building with their peers, was interesting, stimulating, and also promoted their learning\textsuperscript{21}. Students expressed that mind mapping the concepts taught during lectures were comparatively more enjoyable (Sixty five percent) and particularly beneficial to integrate the subject concepts with other specialties and were also retained longer which would further help them to fare better in examinations and manage their time well. The staff also observed that the study group did not lose interest while deliberating the biochemistry concepts and shared their experiences about the mind mapping activity with enthusiasm. All the students built different mind maps on same concept which made each mind map different and some had better clarity. The reason for this could be multifactorial as participants were novice and inexperienced in constructing mindmaps.

Conclusion

Our findings are in line with many studies\textsuperscript{16,18,22} corroborate the fact that the Mind maps help students remember information, as they individualize the information and create a mental picture which is easier for the mind to reflect and recall but some have documented both positive as well as negative out comes\textsuperscript{22}. Furthermore, mind maps are observed to be effective in creating learning environments which makes the students desirous to learn and recreate the information which is helpful for the learning process\textsuperscript{23}. In view of the aforementioned benefits, there is a need for teachers to include the briefing of the mind map technique so that the students have a meaningful learning than just dispense the information memorized and this is corroborated by conducting such qualitative studies.

Acknowledgment: We would like to thank all the students and the faculty at the medical biochemistry department of BLDEA (deemed to be university) SBMPMC for their active participation.

Conflict of Interest: None.

Funding: Self funded.

The ethical clearance for the study was taken from the institutional ethical clearance committee of BLD (deemed to be university) Shri B M.Patil medical college, hospital and research centre, vijayapura on 21\textsuperscript{st} December 2018 and bears the clearance number, BLDE (DU)/IEC/328/2018-19.

Health and National Competitiveness:
An Empirical Analysis of the BRICS Nations

Kasturi Goswami
Assistant Professor, Department of Economics, Assam Don Bosco University, Tapesia Gardens, Kamrup, Assam

Abstract
The rapid growth of the total health expenditure (THE) is an issue of major concern in most of the countries. Total health expenditure is defined as the sum of both public and private health spending in consideration of the ratio of total population of the country. This paper offers an integrated view of the relationships between health spending, productivity and its effects on gross domestic product. This paper aims to investigate an empirical association between healthcare expenditure out of Gross Domestic Product (GDP) for the BRICS Nations. Data on health expenditure and GDP for the period from 2000 to 2018 from World Bank and WHO was used to analyse the relationship between health expenditure as a percentage share of GDP and GDP of the BRICS countries are used. The data was segregated into two sections and analysed for two decades. The study reveals that in both the decades the total health expenditure as a percentage share of GDP has a direct proportional relationship with GDP for the BRICS nations, except for Brazil in the second decade where an inversely proportional relationship between the two variables is observed.

Keywords: Total Health Expenditure, BRICS Nations, GDP.

Introduction
Health has been considered as one of the remarkable elements that results in the increase in Gross Domestic Product (GDP) for a country. The total government spending, as a share of GDP, can be different according to the country’s priorities which depend on capacity to pay and fiscal constraints of a financial year.1

Atilgan, et al (2017), tried to investigate whether growth and health expenditure are co-integrated or not and found that health expenditure and economic growth have a dynamic causal relationship. Similarly, Bedir (2016) also explained the relationship between economic growth and health care expenditure in emerging markets of Europe and Middle East African and Asian countries. In the study, human accumulation was considered to be very crucial for growth of a country and in order to be to raise capital accumulation, healthcare expenditure was found to be quite influential. Economic growth in a country led to an increase in the healthcare expenditure proportion in outcome of the country, which causes GDP to increase. Again, Halici et al (2016) also found a positive relationship between government spending on health and economic growth which indicates that public health expenditures plays an important role in the determination of economic

Phone Number: 7002339245
growth. Ozturk and Topcu (2014) employed a panel data analysis in order to investigate health and growth in G8 countries. Their findings strongly suggest that there exists a one-way causality between health expenditures and economic growth. On one hand, health expenditures affect economic growth in the short-run and on the other hand economic growth affects health expenditures in the long-run.

The paper has four sections. Section one introduces the subject matter while the second section discusses the methodology. The third section deals with the findings and discussion and the fourth section concludes the paper.

**Method**

The objective of this paper is sought to be fulfilled through the analysis of the secondary data collected from World Bank and WHO. The unit of the study comprises of the BRICS countries. Data on health expenditure and GDP for the period from 2000 to 2018 from World Bank and WHO was used to analyse the relationship between health expenditure as a percentage share of GDP and GDP of the BRICS countries are used. The data was segregated into two sections and analysed for two decades. However there is a limitation of the study as the data of health expenditure as percentage share of GDP was not available for the years 2017 and 2018. The data is analysed and presented in the form of tables and figures.

**Findings and Discussion:** For the present study data on the variables GDP and Health Expenditure as a percentage share of GDP in BRICS Countries for 2000-2010 in the first section and for the years 2011-2018 are presented in tabular and diagrammatic form. The data is analysed and discussed for the same.

Source: World Bank and WHO Database

From Table 1 and Figure 1 it is seen that in terms of GDP China has dominated the 1st decade followed by Brazil. The GDP of China has increased from around 1.21 trillion US dollars in 2000 to around 6.09 trillion dollars US dollars in 2010. The growth throughout the decade of 2000-2010 for China has increased at least by 6 times. However during the same period the total health expenditure as a percentage share of GDP in China has remained more or less constant at around 4%.

Similarly in terms of total health expenditure as a percentage share of GDP Brazil has dominated the scenario and the total health expenditure has increased from 6 to 9 percent, which is evident from table 1 and figure 2. It is followed by South Africa with a total health expenditure pegged at around 7 percent.
From figure 1 it is seen that the growth in GDP shows an upward trend for Brazil, Russian Federation, India and China, with China showing a significant increase with 6.09 trillion dollars US dollars in 2010. However the growth of GDP for South Africa has been stable throughout the decade.

From figure 2 the total health expenditure as a percentage share of GDP has increased for Brazil from around 6 to 9 percent; but for India the total health expenditure as a percentage share of GDP has fallen from around 4 percent to 3 percent. Again for Russian Federation, China and South Africa the total health expenditure as a percentage share of GDP has remained stable at around 5 percent, 4 percent and 7 percent respectively.

Thus from the analysis of Table 1, Figure 1 and Figure 2 it can be concluded that there exists a direct proportional relationship between the total health expenditure as a percentage share of GDP and GDP.
Analysis for Decade 2: It can be seen from table 2 that the data for Total Health Expenditure (THE) as a percentage share of GDP in BRICS Countries for the years 2017 and 2018 is not available.

Source: World Bank and WHO Database

From Table 2 and Figure 3 it is seen that in terms of GDP China has dominated the 2nd decade as well followed by India showing a staggering upward trend. The GDP of China has increased from around 7.55 trillion US dollars in 2011 to 13.61 trillion dollars US dollars in 2018. The growth throughout the decade of 2011-2018 for China has increased significantly.

Similarly in terms of total health expenditure as a percentage share of GDP for the period of 2011-2018 has been dominated Brazil and the total health expenditure has increased from 9 to 11 percent, which is evident from table 2 and figure 4. It is followed by South Africa with total health expenditure at around 7-8 percent.

![Figure 3: GDP (in trillion Dollars) in BRICS Countries for 2011-2018](source)

Source: World Bank Database

It is evident from figure 3 that China has dominated the second decade in terms of GDP. It is followed by India with a staggering and nominal growth in GDP at around 3-3.5 trillion USD. The GDP of Brazil during this decade has been fluctuating and indicates a falling trend towards end of the decade. Similar is the story for the Russian Federation in the 2nd Decade. For South Africa the GDP growth has been fluctuating and pegged at around 1 billion USD.
In the second decade the total health expenditure as a percentage share of GDP has increased for Brazil from around 9 to 11 followed by South Africa where the total health expenditure as a percentage share of GDP is between 7-8 percent. Again for Russian Federation and China the total health expenditure as a percentage share of GDP has remained stable at around 4-5 percent, respectively. But for India the total health expenditure as a percentage share of GDP has been stable at 3 percent.

Thus from the analysis of Table 2, Figure 3 and Figure 4 it can be concluded that there exists a direct proportional relationship between the total health expenditure as a percentage share of GDP and GDP for rest of the BRICS nations except for Brazil. For Brazil the GDP is showing falling trend but the total health expenditure as a percentage share of GDP is increasing, indicating an inversely proportional relationship between the two.

Thus there has been a change in the composition especially for Brazil in a matter of decade. However from the analysis of the data in both the decades it is seen that the total health expenditure as a percentage share of GDP has a direct proportional relationship with GDP for the BRICS nations, except for Brazil in the second decade where an inversely proportional relationship between the two variables is observed. Another point worth noting in the analysis is that in both the decades China is leading in terms of GDP in a significant manner. However, for the total health expenditure as a percentage share of GDP it has been constant around 3-4 percent in both the decades. As such China cannot be termed as a direct indicator to express the relationship between total health expenditure and GDP, not at least in percentage terms. However in real terms for China it can be asserted that as GDP increases the health expenditure also increases i.e. with greater increase in GDP the health expenditure although in percentage terms remained more or less the same, but in real terms total health expenditure’s share in China’s GDP has increased.

Conclusion

There are several arguments that contributes contribute to the idea that health is of substantial importance for growth and productivity. Better health is a labour-augmenting factor that increases the level of individual productivity in terms of healthier individuals and longer expectancy of life. Health Capital theory states a longer life span encourages people to acquire better education which in turn results in more productive people. Thus, it is of utmost importance that there should be expenditures on health as it enhances the individual productivity and in turn promotes growth. Expenditure on health triggers and enhances technological progress in the health sector which in turn promotes productivity of the masses. Thus, both health spending and technological progress acts as a potential source of progress and development by contributing towards
GDP. As a share of GDP, total spending on health care has risen steadily over the past two decades of the BRICS nations. Although increased health spending is expected to positively influence aggregate productivity and growth, evidence on this link is somewhat inconclusive. But a conventional explanation for the rising share of health spending in GDP can be this that in knowledge-based economies human capital is the main driver of productivity and growth. As such health can be considered as an important factor for economic outcomes and carries manifold policy implications.

Developing Health Awareness among the Rural-Urban Fringe Students in the ESL Classroom through Language Activities

M. Samuel Jayakumar¹, P. Bhaskaran Nair²

¹Research Scholar, ²Professor, Hindustan Institute of Technology & Science, No. 1 Rajiv Gandhi Salai, Padur, OMR, Chennai- 603103

Abstract
The Rural-Urban Fringe (RUF) students are not just poor in English language skills but also they lack in their awareness about health, when compared to the privileged group. The low economic background, poor hygiene and congested living spaces together pose a great threat to their health. The purpose of this research is to create health awareness through language activities in the ESL classroom, among the RUF students of Chennai through teacher intervention in teaching methodology and materials. A set of five language activities titled, Drugs and dosages, Importance of hygiene, Danger in smoking, An act of first aid and Danger in dogs was designed and conducted to create health awareness along with enhancing English language skills. A preliminary survey on their general health was conducted to measure the awareness of the students before the program and a post survey was conducted to find the health awareness which the activities created. The continuous performance of the students through regular monitoring and unstructured interview with students clearly proved that health awareness is a must for the RUF students and it can be created successfully through language activities.

Keywords: Health awareness, Rural-Urban Fringe, Language activities, English as Second Language (ESL), Teacher intervention.

Introduction

“To keep the body in good health is a duty… otherwise we shall not be able to keep the mind strong and clear” says Goutama Buddha (¹). The purpose of education is to make the mind strong and clear, but when the need arises to educate on physical health as well, one should not refuse.

The World Cities Report in 2016 says that the slum dwelling population in the third world countries increased from 688 million to 880 million, which is a quarter of the world’s total urban population. It also states that health is a subject of concern especially for people residing in the slum areas of any state or in any country (²). As the urban space expands every day, it gives rise to a new area of living called Rural-Urban Fringe (RUF). The RUF area is defined as the “… structural units (which) include slums and squatter-settlements, built-up dwellings without any proper plan, mixed land uses, areas of agricultural production usurped by lot of industrial units, dispersed location of settlements suffering from urban facilities” (³). It is an area which has a mixed population of rural and urban living within or around the urban area without being economically part of it, and the students from this area are called R-U Fringe students.

The R-U fringe students do not just struggle in English language skills but they also lack in health awareness compared to urban students. Illiteracy of parents, low economic background, studying in regional medium schools and lack of exposure do not just make them linguistically challenged, but also poor hygiene and congested living space are a threat to their health conditions as well. As an ordinary teacher one may not be able to change the family background, economic status, atmosphere and living space or change the curriculum or teaching materials but certainly health awareness can be created through teacher’s intervention in teaching materials. According to Johnston, “English language teaching (ELT) is not merely a matter of training students in a particular set of skills. Rather, the occupation of ELT is profoundly imbued with values…” (⁴) Therefore a set of five language activities was designed titled drugs...
and dosages, importance of hygiene, danger in smoking, an act of first aid and danger in dogs which could be used to develop English language skills and also create health awareness.

This research is the result of the need found among the ESL (English as Second Language) learners of RUF in Chennai, India. The students of these areas are mostly first generation learners and from an economically and socially backward class, awareness about general health and hygiene was found to be lacking compared to urban students. According to Mukherjee, “for any country to develop, it is very essential to target the slum areas which prevail in a vast number and hinder the progress of any nation.” (5)

Creating and using of language activities with health awareness serves dual purpose, which is teaching English and also creating health awareness. It also saves time, energy and effort. Often providing health awareness separately may not be possible, but when it is integrated with language teaching, the students learn a language and also acquire the awareness needed about health.

These activities were conducted in the English classes for 27 tertiary level students for two weeks of time at Hindustan Institute of Technology and Science, Chennai. A primary survey was conducted to find the health awareness and the interest to learn. A post survey was conducted to find the awareness created through the activities. The students’ participation and unstructured interview with students was also considered to study the result.

**Activity 1: Drugs and Dosage.**

The purpose of this activity is to develop intensive reading and create awareness about drugs such as dosage, expiry date, storage information etc.

Instruction: Read the label on a medicine bottle (Fig. 1) and answer the following questions.
Activity 2: Importance of hygiene.

The purpose of this activity is to teach dialogue writing and to create awareness about hygiene.

A. Watch the video ‘A story of Cholera’(6) and fill in the blanks with the right prepositions given. (Prepositions can be repeated)

(after, on, into, from, at, before, through, for, in, by, about, with, to, with, from, throughout)

The Story of Cholera(7)

This is the story of how cholera changed my village.

Tiny germs of cholera – too small to see – spread ……… the river. So small, yet so dangerous.

Without realizing, women carried cholera home ……… the water. Flies carried cholera ……… their feet. Unwashed hands spread it too.

We swallowed cholera germs ……… our water, ……… our food, and ……… our fingers.

It happened so fast. By morning, my father was very sick.

He had diarrhea that looked like gray water and poured out of him. I was so scared.

I went for help.

I never rode so fast.

One look ……… my father and the nurse knew it was cholera. He needed fluids right away. She didn’t have a ready-made packet ……… ORS so we made a special drink to help him.

First we made the water safe – we filtered it ………. cloth and boiled it ……… one minute.

Then we mixed ½ teaspoon of salt and 6 teaspoons of sugar ……… one liter of this safe water. It tasted like tears – not too salty.

I worried my father would die before my eyes. But he soon felt a little stronger. The nurse explained to me that not everyone who swallows cholera germs gets sick like my father, but they can still spread the disease.

Now I needed to take safe water to my village and teach them how to protect themselves from cholera.

I saw a girl carrying water. I told her she could make the water safe ……… adding chlorine drops and waiting half an hour.

There was a man ……….. to eat with unclean hands. I told him to always wash his hands with soap and safe water ……… going to the toilet. Only ……… clean hands could he eat safely.

I saw villagers spreading cholera ……….. our river. I told them we needed to dig latrines far ……….. the river, ……… least 30 meters away. This was important ……….. keep our village clean.

I found a mother preparing unsafe food. I told her: first we must wash our hands ……… soap and safe water. Then we had to wash and peel the food. Cook it and always eat it hot and protect it ……… flies.

I spread the word ……… my village and ran to find my father. I was so happy to see he was better.

Our village became healthy. Now we filter and boil our water to make sure it is safe. We always use latrines, and always wash our hands after.

Food is safe ……… flies, washed and peeled and cooked.

And, we always wash our hands ……… cooking and eating.

We made our village safe from cholera. Spread the word. Your village can be safe too.

B. Write a sentence each using the following prepositions to differentiate each of its meanings.

Example:

among - between

Answer: among – a cow stood among the trees.

between – Anne’s shop is between the library and a restaurant.)

a.  in- at
b. through- to
c. for-from
d. about-throughout

C. Discuss the following with your partner.
   a. How did the father fell sick?
   b. How did the nurse prepare the special drink?
   c. what did the boy do to stop cholera spreading in his village further?

D. List down some of the things people do in your neighborhood that are unhygienic.

   Activity 3: The Danger in Smoking

   The purpose of this activity is to develop writing and create awareness about smoking.

   Materials: How do cigarettes affect the body?

   Instruction: Watch the video and answer the following questions.

A. Discuss the following questions with your partner and write down the answers.
   a. How exactly do cigarettes harm the smoker?
   b. Define active and passive smoking.
   c. Is passive smoking as dangerous as active smoking?
   c. Why do you think people usually smoke cigarettes?

B. Discuss with your partner and map the benefits of quitting smoking in the time frame given (Fig. 2 & 3).

   I. Time Frame 20 min to 1 month.
   - Heart rate and blood pressure begins to return to normal
   - Carbon monoxide levels stabilize increasing the blood’s oxygen-carrying
   - Heart attack risk begins to decrease as blood pressure and heart rates normalize
   - The nerve endings responsible for smell and taste start to recover
   - Lungs become healthier

   II. Time frame: 9 months to 15 years.
   - The delicate hair-like cilia in the airways and lungs restored improving resistance
   - Heart disease risk plummets to half as blood vessel function improves
   - The chance of a clot forming dramatically declines, and the risk of stroke continues to reduce
   - The chances of developing fatal lung cancer go down by 50%,
   - The likelihood of developing coronary heart disease is essentially the same as that of a non-smoker.

   Activity 4: An Act of First Aid

   The purpose of this activity is to develop speaking skills situations through role plays and make students aware of the first aid treatment for common accidents.

   Students were divided in a group of five and each team was given a situation and a reference about the first aid procedures. After learning and practicing the situation they had to enact a skit. The situations given are in Tab. 1.

**Activity 5: The Danger in Dogs.**

The purpose of this activity is to teach paragraph writing and to create awareness about rabies.

1. Observe the picture given ‘Symptoms of Rabies’ *(fig. 4)* and write a paying attention to all the details given.

Figure 4: Symptoms of rabies
Findings: According to the questionnaire administered initially, it was found that 62% of the students were not taught about health and hygiene by their family members. 73% of students reported that no awareness programme of any kind about health and hygiene were conducted in their residential area. Only 37% students had awareness programmes organized in their schools out of which only 19% had attended those programmes. It was also found the nearly 60% of the students were not interested to read any content on health or hygiene. However, 73% of students expressed their interest to learn about health and hygiene in English class room.

Initially, some students who expressed their interest to learn about health in English classroom in their questionnaire were not excited during the classes. They were quite hesitant to participate in the activities. It was found that the reason for their disinterest was not the materials provided or learning about health but shyness, lack of confidence, fear of making mistakes and fear of teacher made them inactive in the classroom. It was also found that use of audio-video materials increased the curiosity of the students and also momentary benefits such as marks, words and gestures of appreciation, fun in group and challenges made the students much interested.

The post-survey questionnaire brought a lot of light on how the students have benefited from this programme. 86% of the students said that the materials that were used were highly useful to learn about health and 81% said they wish to have similar programmes regularly. 68% of students said that they never read any labels on the drugs and now they knew the importance of reading them. 48% were not aware of unhygienic things that were commonly practiced in their area until they watched the video about cholera. 85% of students reported that they hadn’t known the complete details of danger in smoking cigarettes though they knew it was dangerous and they have learnt its danger in detail. Through all the students wanted to help the accident victims, 82% did not knew how to help different kinds of victims until they participated in an act of first aid. Surprisingly, it was also found that 28% of students never knew dogs could bring life threatening disease. Above all, 91% of the students had recommended health awareness in English class to other students.

It was also found, by bridging the gap between the contents of the study materials and real life experience, learner motivation can be enhanced. By turning the learner’s attention more to the reading part of real life (advertisement, prescription, newspaper, film posters etc.), reading becomes an integral part of life. By bridging the gap between casual reading and purposeful (academic) reading, the speed of reading can be enhanced. By linking reading with speaking (as in tasks which ask students to discuss something), oral proficiency gets enriched.

Conclusion

These five activities focusing on health awareness not just provided an opportunity for students to develop their English language skills through participation but also became aware of health. The preliminary survey clearly suggested that there is a need for health awareness programmes and the post survey clearly proved that health awareness based language teaching can empower students and it is the need of the hour.

¹Professor, ²Research Scholar, Faculty of Law, Aligarh Muslim University, Aligarh (U.P., India)

Abstract

Ever since the passing of the Jammu & Kashmir Consumer Protection Act, 1987, the doctor-patient’s relationship came under critical scrutiny, controversy and litigation. The inadequacy of consumer protections laws results in unavoidable contingency, spiralling cost shifting and inordinate health care complexities. It examines health care services as a matter of consumer rights under Consumer Protection Act, 1986, Jammu and Kashmir Consumer Protection Act, 1987 and Consumer Protection Act, 2019. It makes consumers to navigate between hope and despair for access to health care. The paper is driven to analytical study of the inadequacy of consumer laws in dealing effectively deficiency of medical service, insufficiency of health care services, lack of medical professionalism and negligence a case study of Sher-i-Kashmir Institute of Medical Sciences (SKIMS), Srinagar is undertaken by encompassing a legislative survey of consumer laws in inculcating Consumer Right Awareness (CRA) and toning of structural governance of grievance redressal mechanism. The gap between the precept and practice of consumer justice and compensation in health care services is identified for adoption of a robust infrastructural and schematic revamping.

Keywords: Health Care Services, Consumer Right Awareness, Grievance Redressal Mechanism, Consumer Justice and Compensation.

Introduction

The health care facilities to the people of the erstwhile state of Jammu and Kashmir (J & K) is marred by constraints of financial resources, difficult topography and terrain, poor road connectivity, low presence of private sector, low accessibility and affordability by underprivileged segments of the population. There has been a gradual decay in the health services of J & K over the last three decades. The state is under shadows of infectious diseases like tuberculosis, RTI, UTI diarrhea disease.¹ There is growing shadow of chronic diseases like hypertension, coronary artery disease, cancers, and diabetes. Factually speaking there are 3,807 health care institutions in the state which is considered the highest number of hospitals in the country. The annual budget for the health sector in J & K is Rs. 2,423-crore. The per capita spending under plan, non-plan and centrally sponsored schemes is estimated at Rs. 1,931 crore.² According to the State’s Economic Survey Report, 2017, there were 4,433 government health institutions in J & K at the primary, secondary and tertiary levels with 6,674 doctors.³ The paper examines the efficacy of J & K Consumer Protection Act, 1987 to give effect to Consumer Protection Act, 1986 to take care of consumer right awareness among patients for robust health care services in Union Territories of J & K under Jammu and Kashmir Reorganisation Act, 2019.

Materials and Method

The material and method applied for the study include analytical method of legal research by undertaking the legislative survey and scrutiny of consumer laws at central and state levels. These laws are studied under Parsonian Effect theory in the context of health care services.⁴ The comparative consumer law study of Consumer Protection Act, 1986, J &
1987 and 1986 forms the basis of 1986, 7 1986, 5 2019 is based on established canons of statutory interpretation. The material and method partakes an empirical framework of SKIMS, Srinagar a premier medical institution in J & K state. The case study is based on Consumer Right Awareness (CRA) under four major parameters which include consumer right awareness, redressal against medical negligence, and recourse to deficiency of medical service and compensation and consumer justice.

Findings

It is important to note that the both Consumer Protection Act,1986, J & K Consumer Protection Act,1987 and Consumer Protection Act, 2019 are public welfare legislation and has been designed to avoid procedural technicalities, delays, and requirement of court fees to protect consumers availing medical facilities and health care services. It contains three-tier consumer disputes redressal system at the District, State and National levels along with Central Consumer Appellate Authority (CCAA) including right to health and environment.

Central Consumer Protection Act, 1986: The Consumer Protection Act,1986 forms the basis of J & K Consumer Protection Act, 1987 therefore a perusal of this law in brief is imperative. The Act seeks to promote and protect the interest of consumers against deficiencies and defects in goods or services. It also seeks to secure the rights of a consumer against unfair trade practices, which may be practiced by manufacturers and traders. The Act applies to all goods and services unless specifically exempted by the Union Government and covers all sectors, whether private, public, or cooperative. It ordains simple, speedy and inexpensive machinery for redressal of consumer’s grievances, the marketing of goods and services to consumers, as well as the relationships, transactions and agreements between the consumers and the producers, suppliers, distributors, importers, retailers, service providers and intermediaries of those goods and services. The application of Consumer Protection Act,1986 to health services derives life breath and sustenance from Supreme Court ruling in Indian Medical Association v. V.P. Shantha. In this case the question raised was whether the treatment provided by medical practitioners to their patients would constitute “service” under the meaning of the Act and whether patients would be treated as ‘consumers’ under the same Consumer Protection Act,1986 The court noted that the issues arising in the complaints against medical negligence can be speedily disposed of by the procedure being followed by consumer disputes redressal agencies. Thus the Consumer Protection Act, 1986 is pioneering law in protection of consumer from the standpoint of health, environment and consumer justice.\(10\)

J & K Consumer Protection Act, 1987: The J & K Consumer Protection Act,1987 aims to provide effective safeguards to the consumers against defective goods, deficient services and unfair trade practices. The Act provides speedy redressal to consumer complainants by setting up of a District Consumer Redressal Forum and State Commission having jurisdiction to claim of Rs. 10 lakhs and Rs. 30 lakhs respectively. The State Commission will be vested with appropriate appellate and revisional powers. It shall apply to all goods and services except those which are specially exempted by notification by the state government did not specifically exempted health care services provided by government hospitals. It seems profitable to refer section 2(1)(0) as under:

“Service” means service of any description which is made available to potential users and includes the provision of facilities in connection with banking, financing, insurance, transport, processing, supply of electrical or other energy, board or lodging or both, entertainment, amusement or the purveying news or other information, under a contract of personal service.

The necessary penal and punitive provisions have been incorporated for effective redressal of unfair trade practices, defect in the goods, and deficiency of services. The Consumer Commissions are authorized to impose penalties on trader or person against whom complaint is made if he fails to comply with the order of the redressal agency.

J & K Government Doctors (Relaxation of Restrictions on Private Practice) Rules, 1987: It will be appropriate to see the application of J & K Consumer Protection Act, 1987 and J & K Government Doctors (Relaxation of Restrictions on Private Practice) Rules, 1987 in holistic perspective in regard to doctor patient relationship and health care services. This is also important to see this law in the context of penalty or punishment may involve imprisonment for a period not more than 3 years or a fine or both. The complaint mechanism by a consumer voluntary organization, registered society, company and state government will also be scrutinised in pragmatic discourse. Therefore,

### Discussions

The study of health care services under consumer protection laws of J & K health institutions is an empirical study of SKIMS with 900 bedded tertiary care hospital and undergraduate medical college with intake capacity of 100 students. According to survey there are total 1648 health institutions in J & K State.\(^{13}\)

**Selection of Area of Study:** SKIMS being premier medical institution in India, it provides additional services including prevention, treatment, rehabilitation, obstetrics, substance abuse, health education, and screening for cancers and other diseases.\(^{14}\)

### Consumer Right Awareness & Health Care Services

By this analogy persons who are rendered free service are “beneficiaries” and as such come within the definition of “consumer” under the *J & K Consumer Protection Act, 1987* and *J & K Government Doctors (Relaxation of Restrictions on Private Practice) Rules, 1987*. Located in Soura area of Srinagar, this is the largest medical Institute under *Sher-i-Kashmir Institute of Medical Sciences, (Grant of Degrees) Act, 1983*.\(^{15}\) The *J & K Consumer Protection Act, 1987* is not applicable to government hospitals because of free medical care services to patients. But the medical services rendered by doctors and hospitals falls within the ambit of a “service” as defined in Section 2(1) (o) of the Act.

Source: Field work

The above table clearly shows that 22% respondents have knowledge about consumer law or redressal agencies while as 79% respondents said that no they were not having any knowledge about consumer laws however 9% respondent didn’t said anything about the information of consumer laws. The legal literacy about the complaint mechanism for the deficiency in medical services is also in abysmally low. When we asked patients about the deficiency of medical services gives rise to grievance redressal at appropriate consumer forum almost 2/3 respondents feign ignorance about it.

The medical negligence on as the part of health care provider is frequent in J & K that is why the patient affected by medical negligence have faint idea about the complaint mechanism as victims. The Table II shows that 21% respondents have knowledge about complaints in consumer forums on the basis of data received from respondents 69% respondents said that they were not aware about the concept of complaints in consumer forums, however 10% respondents didn’t say anything about the complaints in consumer forums.

The Comptroller and Auditor General (CAG) of India has reported that ‘even the emergency medicine department has been found to be not fully equipped to deal with cases of road traffic accidents having multiple organ injuries including orthopedic injuries.’ This is also pathetic to note that ambulances meant for patients have been found mis-utilized to the extent of 40 to 47 per cent during 2008-12.  

Health Care & Medical Negligence: The knowledge regarding negligence in health care services reveals that 23% respondents were aware about the complaints mechanism. The ordinary prudence about medical negligence depicts that 66% respondents don’t have knowledge about grievance redressal and 11% remain indifferent to liability of doctors and hospital authorities.

Compensation & Consumer Justice: The compensation in case of medical negligence to the patients and their kith and kin also represent empathic and ignorance. The patient interviewed regarding their response to compensation in case of medical negligence reveals that 21% respondents show that they have knowledge about penal provisions against doctors. Still majority of patients to the tune of 71% said that they were not having any information related penal provisions whereas 8% are either ignorant or indifferent didn’t say anything about penal action can be initiated in the case of medical negligence on part of hospital and doctor.

Source: Field Work

The apex court ruling has played seminal role in curbing medical malpractice and making compensation an integral part of consumer justice that 17% respondents have knowledge about compensation given by consumer forums and 74% said that they were not having any information related compensation related consumer forums however 09% respondents didn’t say anything about compensation provided by consumer courts. This places the consumer justice in a conundrum especially in the aftermath of Supreme Court decision.

Conclusion

The analysis of health care services under consumer laws of erstwhile J & K state now Union Territory of J & K under Jammu and Kashmir Reorganisation Act, 2019 reveals that health status of the people has not been able to keep pace with the national targets. The state has a considerable segment of population living below poverty line, inadequacy of healthcare and burden of disease in an environmentally benign setting. The J & K Consumer Protection Act, 1987 has not achieved consumer right awareness and assertiveness in realisation health care services. The health services and disease overburden needs proper regulation. This becomes more important in the wake of unrest of decades has worsened the health status of people especially of population living below poverty line. The only salacious aspect is to note that the purpose and object with which the J & K Consumer Protection Act, 1987 has been passed has substantially achieved in the ambit of patient’s rights notably compensatory justice. But the SKIMS have been found inadequately equipped to deal with accidents and trauma prevention and mis-utilisation of ambulance services despite rich infrastructure. The most significant and equally multifaceted as well complex service in the field of consumer grievances is that of medical malpractice and the doctors of SKIMS and other government hospitals of state need to be more circumspect and careful towards medical services to patients to enlarge the realm of consumer justice, access to health and compensatory jurisprudence.

Effects of Migration on the Health of Kashmiri Pandits

Nikita Bhan¹, Sukhwant S. Bindra²

¹Doctoral Student, Amity Institute of Social Science, ²Director Research,
Amity Institute of International Studies, Amity University Sector 125, Noida, Uttar Pradesh, India

Abstract

Kashmiri Pandits (KPs), the Hindu community from the state of Jammu & Kashmir of India, are distinct from rest of the Hindu community of India. They have their own customs and rituals that broadly differ from the customs that are prevalent in the Hindu community. The community has its own language, social customs and a rich cuisine. The community had to migrate in the late 1980’s due to the onset of conflict in the state. They had to live in refugee camps in Jammu where the sanitation facilities were minimal. It caused a lot of health issues among the migrants. The change in the geographical environment led to the KPs suffers with skin diseases. There was a major difference between the climatic conditions of Jammu and the valley. Valley being cold and Jammu warm. The current study focuses on the health conditions of Kashmiri Pandits after migration.

Keywords: Internally Displaced People, Kashmiri Pandits, Migration, Refugee camps, Health conditions.

Introduction

Kashmiri Pandits (KPs), the Hindu community from the state of Jammu & Kashmir of India, are distinct from rest of the Hindu community of India. They have their own customs and rituals that broadly differ from the customs that are prevalent in the Hindu community. The community has its own language, social customs and a rich cuisine. Their culture is very different from the rest of Hindus in India, their customs and rituals vary to a great extent. They follow the traditions of sanatan dharma, also known as Hinduism. They belong to the small caste of saraswatbrahmans known as Pandits.

The community had to migrate to different parts of India as a result of conflicts that arose in the Valley due to self-determination in Kashmir valley by the Kashmiri Muslims. This self-determination process gave rise to selective killings of Kashmiri Hindus as a result of which the Kashmiri Hindus, primarily the KP community had no other option but to leave their homes in order to protect themselves from this crisis. This conflict had its roots in the disputes that arose between India and Pakistan at the time of partition in 1947. This political war between both the countries since partition had resulted in large scale bloodshed. This has affected all the communities of Kashmir including the Hindus, Sikhs, Muslims and Buddhists till date. The late 1980’s was the period when large scale migration of Kashmiris, especially Hindus had occurred in various parts of India as a result of the conflict prevalent in the valley at the time. The KPs had no other option but to migrate solely for self preservation. KPs migrated to different parts of India and concentrated mostly in the states of Delhi and Jammu. Immediately after migration many of them had to live in refugee camps in Jammu which made their lives miserable. The camps were in inhabitable conditions and did not provide proper infrastructure during extreme weather conditions as a result of which there was a visible impact on the health of the community, mostly the children in particular. The total number of families that have migrated from Kashmir is 59,452 families. In Delhi the total number of families is 19,338 including Hindus, Sikhs and Muslims. (Relief organisation Migrants, Jammu, Government of J & K).

The KPs are officially termed migrants by the Indian government. The KP community, however has raised objections for using such terms because this migration was not voluntary. They wished to be called Internally Displaced People (IDP) Malhotra 2007. IDPs are those who do not cross the borders to find a safe place to live, unlike refugees they are on the run from their own home. They stay within the country under the protection of their government even if that government is responsible for their displacement. According the UNHCR guidelines
on internally displaced persons; those persons who have migrated within their country should be given the status of internally displaced persons. However, the fact of the matter remains that in India there is no protection extended to these displaced persons. India did not sign the UNHCR convention 1951 and Protocol 1967. In the absence of refugee and IDP laws, the condition of these migrants was and shall remain wretched to say the least. Malhotra attempted to clarify the concept of IDP’s and refugees, where the refugees cross the international borders but not internally displaced people. The study defines how Kashmiri people can be identified as internally displaced people. The assumption used in the study was that internally displaced people bring about new modes of social organisation, which uses various response strategies to integrate in the host community and how that try to adjust socially and culturally which is beyond just physical survival. The paper also pointed out the fact that the displacement has impacted the social organisation of the Kashmiri people. The field research area of the study included 5 camps in Jammu region and apartments in Noida. The research focused on the determinants with which the displaced people integrate with the local population, these determinants includes ethnic, family and religious affiliations. The observation of the research shows how the internally displaced people living in Jammu camps are more miserable than the people living in Noida, as in Noida there are proper housing facilities where as in Jammu only one room tenements were available to the internally displaced people. A more peculiar feature was that the people living in Jammu camps belonged to the villages or rural areas of Kashmir such as Kulgam, Kupwara, Anantnag, Barramulla, on the other hand people living in Noida were from Srinagar city.

**Condition After Migration:** Migration led people to move to different parts of India. Most of the KPs moved to Jammu in the refugee camps. The camps were in miserable conditions and were not apt for living. Migrants were living in tents initially in the 1990’s and later on in 1994 these tents were transformed into one room tenements (ORTs). Theses tents did not protect them from the various weather conditions, dust storms were a major issue as it affected the beam of the tents. Another major issue was that of snakes. The land where these tents were established was isolated and more of a jungle. Many deaths happened because of the snake and scorpion bites. Various diseases caught migrants because of the unhygienic conditions in the camps.

Many migrants went into depression. Privacy was also a major concern in this arrangement. The couples specially lacked the private spaces.

In 2006, an elaborate report on the impact of migration on the socio-economic conditions of Kashmiri displaced people was published. It is an extensive empirical study conducted by J & K centre for minority studies. The findings of the study indicated that insecurity of life and honour were the chief causes of migration of KPs. It was found that 9 per cent migrant families moved out of Kashmir valley from January 1990 to May 1990. Migration took place from both rural as well as the urban areas of Kashmir including people from all occupational groups i.e. farmers, professionals, government servants, agriculturists, traders and self-employed. The study pointed out that there is no comprehensive policy on the issue of return and rehabilitation. The government policy clearly stated that the migrants will be returned with dignity and honour however nothing of the sorts has happened till now.

In another study, based on interviewing 50 migrants from refugee camps in Jammu, on migrant KPs observed that 90 per cent of the migrants were not happy with their incomes as they were able to make more in the valley. Unemployment among the youth became a major cause of concern. The study further pointed out that the hygiene conditions were miserable. It was observed that children were using Hindi or English for communication rather than speaking Kashmiri hence making the Kashmiri language vulnerable.

A study on effects of displacement on the Kashmiri migrations aimed at understanding the problems faced by Kashmir families after migration that were living in refugee camps in Jammu. It was found out that the camps were low on providing even the basic necessity to the migrants. There was no proper drainage system, water facilities or electricity. Changes in the climatic conditions also added to their miseries. The lack of basic amenities such as drinking water, drainage and sewerage, absence of proper lavatory facilities, poor housing, overcrowding, and extremes of climate, lack of healthcare, joblessness, idleness, depression, disease and death. They were accustomed to live in cold climates but a sudden change of the climatic condition caused skin and other air borne diseases to the migrants. The economic condition of the community was dwindling as migration left the people with no property of their own. The author noted that migration affected on the entire
social order of the community and that the cultural values have diminished. The author pointed out that the majority of respondents are willing to move back to the valley if they are assured of a peaceful environment in the valley. [11]

The emotional stress during displacement takes a toll on the physical as well as mental health. Large numbers of mental health problems are reported among IDPs. Psychological and mental disorders are epidemic in proportion. Reactive depression and nervous breakdown are very common in the youth. [12] Majority of the people of this community were having either hypertension or depression which is because of the separation of their relatives, friends and near and dear ones. [13]

Few migrants were able to get out of those camps in the early 1990’s and got themselves settled in Delhi or other states. They got good opportunities in the city as they were possessing knowledge and degrees. Few of them had their relatives already settled in the city which became a blessing. The city also helped them in achieving better standard of living.

The community has suffered a lot after the migration. Government at the centre and the state level did not address the problems of these people as required. The initial phase for the community was an arduous journey but they were able to settle themselves well in the city. Settling in a different place with new people was equally tough for the community. The reaction of the host community was also not welcoming. [6] The community had no choice but to adapt themselves with the host community and accept changes in their culture. Besides this the youth find it difficult to identify themselves with the Kashmir and its culture as they have lived most of their lives outside of Kashmir. Toshkhani argues that the youth are abandoning the culture and language which in turn is resulting in the fading away of the rich culture of Hindus of Kashmir. [14]

Further the studies found out that Incidence of child abuse was reported as higher since migration. Girls disliked camp living more than boys. [3]

**Conclusion**

The consequences of migration were hard for the Pandits. They had to leave behind their property and businesses. They had to live in refugee camps in Jammu where the sanitation facilities were minimal. It caused a lot of health issues among the migrants. The change in the geographical environment also led to the KPs suffers with skin diseases. There was a major difference between the climatic conditions of Jammu and the valley. Valley being cold and Jammu warm. The youth was unemployed and the education facility was not proper which lead to loss of education in children. The community also faced a lack of community sense; there were a lot of socio cultural changes which they had to go through. KPs suffered a lot after migration and are still struggling to get back their share in the valley. The cultural shock post migration has impacted them in certain aspects, the most important being the physical and psychological aspect. Migration to hotter places caused a lot of health issues, specially skin related problems as they were not accustomed with the hot and humid climate. Psychologically and emotionally they have felt isolated and neglected which impacted the overall performance of youth in achieving the best in life. However, the community adapted themselves with the host environment quite well and has also made peace with the said change, because of their adaptive quality.

They are now settled and have adapted the new environment; it has been almost twenty seven nine since they parted with their homeland. Some of them mentioned that they do not want another migration by returning to their homelands because they are not ready for another emotional turmoil and there are few who are haunting to go back.

**Ethical Clearance:** As secondary data was used for this research study, no ethical issues were involved and therefore no ethical clearance was taken.

Abstract

Background: Nipah virus infection is a zoonotic epidemic that has gained worldwide attention due to its high pathogenic potential, case fatality rate and lack of therapeutics or vaccines. Considering the recent outbreaks in Kerala and the fact that it is potentially contagious through saliva, awareness is an absolute necessity among all health professionals including dentists.

Aim: To evaluate the knowledge and awareness regarding Nipah virus infection among dentists and dental students

Materials and Method: A cross-sectional study was conducted among 100 dentists and 100 dental students. A structured questionnaire comprising of 18 questions assessing knowledge and awareness about Nipah virus infection was distributed to the participating dentists and dental students through Google forms. Data obtained from both groups (dentists and dental students) were compared and analysed using SPSS software version 16.0.

Results: The results revealed that 92% of the respondents had heard about Nipah infection earlier. Social media was found to be the most common source of information among both dentists (41.7%) and dental students (39.8%). The mean (SD) score obtained were 10.8±2.6 for dentists and 8.9±3.0 for dental students. The dentists were considerably more knowledgeable and aware of Nipah infection than dental students and the difference was statistically significant (p< 0.05).

Conclusion: Our study is one of the first of its kind to evaluate the knowledge and awareness about Nipah virus infection among dental professionals. Continuing education programs should be conducted among dental professionals and students to improve awareness as well as to ensure protection of personnel and prevent spread of infection.

Keywords: Nipah virus, dentists, awareness.

Introduction

Nipah virus infection is an epidemic that has gained worldwide attention in the recent past due to its high pathogenic potential, case fatality rate and lack of therapeutic interventions and vaccines[1]. It is a zoonotic infection caused by Nipah virus (NiV), a paramyxovirus that is mainly transmitted by a particular type of fruit bat that belongs to Pteropus species but has also shown high incidence of human to human transmission [2]. This deadly infection was first isolated and identified in September 1998 in Malaysia. The first outbreak in India was in Siliguri, West Bengal in 2001[3]. The outbreak in Calicut, Kerala in 2018 and its more recent emergence
in 2019 has sparked a renewed interest in studying this disease and also emphasizes why awareness is an absolute necessity among all health professionals including dentists. Since Nipah virus infection can be transmitted through saliva, dental surgeons have a responsibility to protect themselves and other patients from contracting the infection. The aim of this study is to evaluate the knowledge and awareness regarding Nipah virus infection among dentists and dental students.

**Materials and Method**

A cross-sectional study was conducted among 100 dentists and 100 dental students randomly selected from various dental institutes in south India from July to August 2019. An informed consent was obtained from all the participants and approval was obtained from the Institutional Review Board (IRB) prior to the commencement of the study.

A structured questionnaire comprising of 18 questions measuring knowledge and awareness towards Nipah was developed in English, and validity and reliability of the questionnaire was assessed among a pilot sample of 20 dentists and dental students not involved with the study. Further three epidemiologists specialized in public health were provided with the questionnaire, they assessed it for the face and content validity (CVI-0.86) and found it to be satisfactory. Test retest was used to assess reliability and was found to be acceptable (k=0.74).

The dentists and dental students were invited to participate through email and those who consented were provided with the questionnaire by Google forms. Awareness of participants about Nipah infection was assessed based on the respondent’s knowledge on aetiology, modes of transmission, clinical features, diagnostic tests and preventive measures. The data obtained was entered into excel worksheet. Each correct response by the participant was given a score of 1, every incorrect response was given a score of 0 and finally the overall score of each participant was also calculated and tabulated. Data obtained from both groups (dentists and dental students) were then compared and analysed for statistically significant difference using SPSS software version 23.0 (IBM, Chicago, IL). T-test was performed with 95% confidence interval and a value of P < 0.05 was considered to be statistically significant.

**Results**

**Awareness of the existence of Nipah (Chart 1 and Chart 2):** Out of the total 200 participants, 16 participants did not know about the infection. These participants were thus eliminated from knowledge assessment and the rest of the study was based on the responses of the remaining 184 participants which consisted of 52% dentists and 48% dental students.

**First source of information (Chart 3):** Out of the total 184 respondents, 75 (40.7%) stated social media, among which 40(41.7%) were dentists and 35(39.8%) were dental students. This was followed by 66(35.8%) participants who stated television, 29(15.7%) participants who stated newspapers and 14(7.6%) participants who responded that they had first received information about Nipah from friends/relatives.

**Causative organism (Chart 4—all other questions):** 159(86.4%) participants in this study were aware that it was a viral infection. Out of this, 91(61.6%) respondents were dentists and 68(42.76%) were dental students. The knowledge of dentists with regard to this question was found to be significantly higher than dental students. (**p value:0.001**)

**First outbreak in the world**

A total of 80(43.4%) participants that included 52(65%) dentists and 28(35%) dental students correctly responded that it was in Malaysia. There was a statistically significant difference between dentists and dental students with regard to knowledge about this question (**p value: 0.002**)

**Most Recent Outbreak in India:** Majority of the participants 137(74.4%) were aware of the most recent outbreak in Kerala, out of which, 78(56.9%) were dentists and 59(43.06%) were dental students. The dentists were found to have better knowledge than dental students with regard to this question as well. (**p value: 0.029**)

**Previous outbreak of Nipah in India (Chart 4):**

Out of the total 184 respondents, only 97 (52.7%), which included 50 dentists and 47 dental students, knew that there has been a previous outbreak in India. There was no statistically significant difference between dentists and dental students with regard to knowledge about this question (**p value: 0.858**).
**Main Reservoir Host of the Organism:** Among respondents, 155 (84.2%) participants correctly identified bats to be the main reservoir hosts of Nipah virus among which, 86 (55.4%) respondents were dentists and 69 (44.5%) respondents were dental students. Among those who responded correctly, there was a slight statistically significant difference between dentists and dental students \((P \text{ value: } 0.041)\).

**Average incubation period of the organism (Chart 4):** 72 respondents (39.6%) responded correctly that it is 4-14 days. There was no statistically significant difference between dentists and dental students \((P \text{ value: } 0.051)\).

**Main diagnostic test:** 100 (54.3%) participants correctly responded that it was ELISA and PCR tests. Out of this, 63 (63%) were dentists and 37 (37%) were dental students. Dentists were found to have significantly higher knowledge than dental students on this question \((P \text{ value: } 0.001)\).

**Vaccines to prevent Nipah infection:** For this, majority, 124 (67.3%) participants knew about the lack of such vaccines. Among those who responded correctly, 69 (55.6%) were dentists and 54 (43.5%) were dental students. There was no statistically significant difference between dentists and dental students with regard to knowledge about this question \((P \text{ value: } 0.133)\).

**Main clinical manifestations:** The main clinical manifestations of Nipah are fever, myalgia, respiratory distress and encephalitis. Out of the total 184 participants, 112 (60.8%) participants which included 68 (60.7%) dentists and 44 (39.3%) dental students responded correctly. Dentists were found to have a significantly higher knowledge about the various clinical features than dental students \((P \text{ value: } 0.004)\).

**The fatal complication of Nipah:** Out of 184 participants, 122 (66.3%) participants knew that encephalitis was the fatal complication of Nipah. Out of this, 74 (60.6%) were dentists and 46 (37.7%) were dental students. This question showed a statistically significant difference between dentists and dental students \((P \text{ value: } 0.001)\).

**Possibility of Nipah transmission through saliva:** When asked if Nipah could be transmitted through saliva it was found that most of the participants 132 (71.7%), including 69 (52.3%) dentists and 63 (47.7%) dental students were aware of such a possibility. There was no statistically significant difference between dentists and dental students with regard to knowledge about this question \((P \text{ value: } 0.966)\).

**Role of frequent hand washing and disinfection in limiting spread of Nipah:** The responses indicated that majority \([143(77.7%)]\) of the participants were aware about the importance of hand washing and disinfection in protection against Nipah. There was no statistically significant difference between dentists and dental students with regard to this question \((P \text{ value: } 0.234)\).

**The case fatality rate of Nipah infection:** Out of the total 184 participants, 76 (41.3%) respondents were aware that it was 40-70%. There was no statistically significant difference between dentists and dental students with regard to this question \((P \text{ value: } 0.623)\).

**Possibility of relapse in Nipah infection:** For this, out of the total 184 participants, majority \([107(58.2%)\]) of the participants, including 55 (51.4%) dentists and 52 (48.6%) dental students were aware of such a possibility. There was no statistically significant difference between dentists and dental students with regard to knowledge about this question \((P \text{ value: } 0.806)\).

**Mean overall score (Chart 6):** The mean overall score for each candidate ± standard deviation was calculated and based on this, the mean overall knowledge of dentists and dental students was analysed and it was 10.8 ± 2.6 for dentists and 8.9 ± 3.0 for dental students and it was thus inferred that there was a statistically significant difference between dentists and dental students \((P \text{ value: } 0.0005)\).
Chart 1: Group distribution (dentists and dental students)

Chart 2: Distribution of respondents based on whether they have heard about Nipah previously

Chart 3: Distribution of the various sources of information among dentists and dental students
Charts 4 and 5: The charts given above represent the distribution of the question-wise correct responses given by dentists and dental students. The questions highlighted in yellow showed a high statistically significant difference between dentists and dental students with regard to that particular question. Those highlighted in green showed a slight statistically significant difference between the two groups. The remaining questions showed no statistically significant difference between dentists and dental students.

Chart 6: Comparison of the mean overall score between dentists and dental students.
Discussion

This study shows the knowledge and awareness level about Nipah infection among 100 dentists and 100 dental students. 8% of the participants had never heard of Nipah and were excluded from knowledge assessment. This could indicate the need for awareness about Nipah infection. To our knowledge, there is no similar study in literature to test the knowledge about Nipah infection among dental students and dentists.

In our study, social media and television were the dominant sources of information among both dentists as well as dental students which possibly indicates the direction for communication of urgent information and guidelines in future. In a study on awareness regarding Nipah infection among health-care workers in a Medical College Hospital in Kerala by Varghese et al., newspapers were the most common source of information.

In our study, 86.4% appeared to know about Nipah being a viral infection. This was similar to a study done by Binub K in 2019 among medical students of Malappuram District where a higher proportion (95%) of the study population knew that Nipah was a viral infection, probably because the study was done in the same area where there was a recent Nipah outbreak and also because it was done among medical rather than dental students.

In our study, less than 50% were aware that it was first discovered in Malaysia and about a previous outbreak in India. In contrast to this, other studies have shown between 60% to 83.5% of the participants knew about previous outbreaks. In our study, 74.4% of the study population knew about its recent outbreak in Kerala while in other studies, it was reported as 94%.

In our study, majority (84.2%) were aware that bats were the reservoir hosts. Other studies showed lower numbers- 40% and 72% of the participants to be aware about the reservoir host of Nipah. Less than 40% of the participants knew about the average incubation period of Nipah in our study. A previously done study showed that 66% of the participants knew the right answer. In our study, 54.3% of the participants knew about the confirmatory tests for Nipah. An even lesser number of the study population (44%) knew about the confirmatory tests in another study. In our study, more than half of the participants knew that no vaccines/medications were available to prevent Nipah infection.

The most prominent clinical picture is that of fever, myalgia, respiratory distress and encephalitis with encephalitis being the fatal complication. Over 60% of the participants in our study were aware of this. The correct responses in earlier studies also ranged from 60-70%. In our study 66.3% were aware that encephalitis was the fatal complication of Nipah infection. Another study showed only 37% of the participants knew about this.

In this study, over 70% of the population was aware that Nipah has the potential to be transmitted through saliva. In our study only 31.5% of the participants had knowledge about the use of Ribavarin to control Nipah infection. In contrast to this, a previous study had 67% participants who were aware of this. In this study, 79.3% of the participants were aware that the use of personal protection equipment. However, studies done in the past had 90 to 95% participants who were aware of the correct answer.

In our study, only 77.7% were of the opinion that frequent hand washing and disinfection of equipment can contribute to reducing spread of Nipah. In the study by Varghese et al., 85% knew that maintaining proper hand hygiene can help to limit the spread of Nipah. In our study, only 41.3% of the participants knew the case fatality rate of Nipah infection. Similarly, only 37% of the participants in the study by Binub K had knowledge about this. In our study, 51.2% were aware about the possibility that Nipah infection could relapse.

The Dental surgeons had considerably more knowledge and better awareness about the etiology, clinical features, transmission potential, prevention and management of Nipah infection as compared to dental students, highlighting the need to educate dental students periodically about prevalent epidemics and their implications in dental practice.

Conclusion

Nipah Virus is a deadly infection with a high case fatality rate and it is imperative for health professionals to be aware of the prevailing health epidemics not just in their locality but also those at a global level. Nipah infection is of particular interest to dentists as it is an infection that can be transmitted through saliva. Our study is one of the first of its kind to evaluate the knowledge and awareness about Nipah virus infection among dental professionals. Dentists must therefore protect themselves and all those in the dental operatory
by deferring treatment for suspected cases. Considering the nonspecific initial symptoms of Nipah infection, adequate knowledge regarding this disease could be crucial in dealing with suspected cases in the dental operatory. Continuing education programs should be conducted among dental professionals and students to improve awareness as well as to ensure protection of personnel and prevent spread of infection.

Factors Influencing Nutritional Status of Children Attending Integrated Child Development Services (ICDS) Programme: A Study on Kamrup District of Assam

Chayanika Goswami

Research Scholar, Dept of Economics, Gauhati University, Assam

Abstract

Children are the most valuable asset of a nation; their good nutrition is the cornerstone for survival, health and development for current and succeeding generations which guarantee the sound and sustained economic development. The nutritional status of children impacts their health, cognition and educational achievements. But underweight and malnutrition are most prominent in India (According to NFHS-3 & NFHS-4). Therefore, government of India has initiated several schemes to develop the health status of people including the children on priority. Integrated Child Development Services (ICDS) programme, which was launched in 1975 with target to prevent the incidence of severe malnutrition of children under the age of 6 years in the country. This scheme also includes pregnant women, nursing mothers and adolescent girls in close combination with the health services for the improvement of health status and overall development of children and other beneficiaries. As a standard practice, it is expected that the proposed objectives of ICDS should be achieved; it is only the monitoring and evaluation which reflects the clear picture of the reality/situation at the ground level. The present study has made an attempt to examine the factor influencing nutritional status of children attending ICDS programme. This study may be able to provide a baseline data in effective implementation of the ICDS programme and improvement of nutritional status of children in future.

Keywords: Child nutrition, Health status, malnutrition, Growth, Development, ICDS, Kamrup.

Introduction

The most valuable asset of a nation is children; their good nutritional status impacts on cognition, health and educational attainment. In India, 20 per cent of children under five years of age suffer from wasting due to acute under nutrition; more than one third of the world’s children who are wasted live in India and has recorded the highest number of low birth weight babies per year at an estimated 7.4 million. Indian constitution were made provision for the improvement of nutritional status and standard of living of people. In India, people are facing problems mainly on famines, inadequate food supply, florid nutritional deficiency disorders, malnutrition, high infant mortality rate, illiteracy, ignorance, lack of awareness etc. Thus, to eliminate these problems and to raise welfare of the people, the Government of India has launched many programmes and schemes. Integrated Child Development Services (ICDS) Scheme aims at adopting an integrated approach to contributing towards human resource development and variety of socio-economic problems affecting both child and mother. The target group of ICDS is not only the population of Scheduled Castes(SC) and the Scheduled Tribes (ST), but also other people living below the poverty line and also include those people who needed to be protected from all kinds of injustice. Thus, Government of India has launched a unique, comprehensive and integrated programme for early childhood care and development and named it as “The Integrated Child Development Services (ICDS)”. The main motive behind the introduction of ICDS scheme is to enhance all round development of the children, especially for the weaker and most vulnerable sections of the society.

The ICDS scheme launched in 1975 including children, pregnant women, nursing mothers and adolescent girls in close combination with the health services for the improvement of health status and overall development of children and other beneficiaries.
**ICDS Beneficiaries and services:** The beneficiaries’ are:

- Children below 6 years,
- Pregnant and lactating women,
- Adolescent girls,
- Other women in the age group 15-45 years.

**Services:** The services provided under ICDS scheme are:

- Supplementary nutrition
- Pre-school non-formal education
- Nutrition & health awareness
- Immunization
- Medical check-ups
- Referral services

In Assam, ICDS scheme was introduced in the year 1975 in Dhakuakhana Development Block on experimental basis, along with 32 other blocks in the country. According to Integrated Child Development Service (ICDS) Scheme report 2012-13, the State APIP for Assam has been expanded to 223 blocks comprising 230 projects and 58,118 AWCs are in operation till 31st March of 2012. According to Census 2011, it is found that 26,395 numbers of villages of the state have AWCs.

**Statement of the Problem:** According to National Family Health Survey report, underweight and malnutrition are most prominent in India. The percentage of underweight children in India is 35.7 percent. Many schemes are developed to improve the health status of people. ICDS is launched to overcome the problem of malnutrition among children in the age group of 0-6 years. Although the ICDS programme appears to be well-designed and well-placed to address the multidimensional causes of malnutrition in India but there are several mismatches between the programme’s design and its actual implementation. Therefore, an attempt has been made to study on the factors affecting nutritional status of children attending ICDS programme.

**Objective:** To find out the factors influencing nutritional status of the children.

**Methodology:** The present study is based on both primary as well as secondary data. The secondary data are collected from different government reports and organizations. The main sources of secondary data are— The Department of Social Welfare, Government of Assam, National Family Health Survey -3 (NFHS-3), National Family Health Survey - 4 (NFHS-4), Census reports, Health and family welfare reports, Statistical Handbook of Assam, Nutrition Policy reports of Government of India etc.

The primary data are collected through sample survey. The samples are drawn by following multistage sampling technique, both random and purposive. The sample design involves the following stages:

**Selection of District:** This research study was conducted in Kamrup district, which is selected purposively. It is a pioneer district to have this project. From the secondary sources it has been observed that the nutritional status of children in Kamrup district is not very satisfactory. The stunted rate, wasted rate, severely wasted rate and underweight rate is higher in Kamrup district in comparison to many other districts of Assam. Therefore, Kamrup district is selected for conducting the present study.

**Selection of Development Blocks:** In Kamrup District, there are 17 developmental blocks and out of these 17 development blocks 5 blocks are selected randomly for the purpose of the study.

**Selection of Sample Villages:** From the selected development blocks, 4 villages are selected from each development block. Therefore, a total of 20 villages are selected for the study. The total number of villages of each Block is available on statistical hand book. The villages are selected through lottery method of random sampling.

**Selection of Anganwadi Centre:** From the selected 20 sample villages, 20 Anganwadi Centers are selected for the study one from each village.

**Selection of Beneficiaries:** The total number of beneficiaries in 20 AWCs is 312. Out of these 312 beneficiaries, 50% beneficiaries i.e. 156 beneficiaries are selected randomly for the purpose of the study.

**Method**

Weight-for-age is an indicator that is used to assess the nutritional status of children. According to WHO, this indicator is most prominent because it is caused by lack of nutritious food. Therefore, in the present study growth evaluation has been done by using weight-for-
age indicator with the help of growth chart. It provides a measure of extent of under-nutrition in the community. Directorate of Social Welfare and in collaboration with UNICEF has introduced three growth monitoring measure of children through ICDS scheme by AWWs. The nutritional status of the children is categorized as:

- normally weighted (denoted by green colour)
- moderately underweight (denoted by yellow colour)
- severely underweighted (denoted by orange colour)

The norms and standard of these three categories can be classified as:

| Table 1: Measurement of Nutritional Status of Children from birth to 5 years |
|-----------------------------|-----------------------------|-----------------------------|
| Age            | Normally Weighted (in Kg) | Moderately Under Weighted (in Kg) | Severely Under Weighted (in Kg) |
| 0-1 year       | 2.5 to 9                   | 2 to 7                       | 1 to 6.3                      |
| 1-2 years      | 9 to 11.5                  | 7 to 9                       | 6.3 to 8                     |
| 2-3 years      | 11.5 to 14                 | 9 to 10                      | 8 to 9                       |
| 3-4 years      | 14 to 16                   | 10 to 12                     | 9 to 10                      |
| 4-5 years      | 16 to 18                   | 12 to 13                     | 10 to 12                     |

In order to identify the different factors influencing the nutritional status of children, multinomial logistic regression is used. When the dependent variable is categorical in nature, it is not possible to use formal regression statistical tests like multiple regression. This calls for use of other tests such as logistic regression which is also known as binomial logistic regression which predicts the probability that an observation falls into one of two categories of a dichotomous dependent variable. Multinomial logistic regression is an extension of the binomial logistic regression, and is used to predict a nominal dependent variable given one or more independent variable. In the present study, the dependent variable (nutritional status of the children) is divided into three categories: normally weighted, moderately underweight and severely underweight. So, multinomial logistic regression is used to study the factors influencing nutritional status of children.

The Multinomial Logistic Regression model for determining the nutritional status of children is as follows:

\[ Y_i = B X_i + e_i \]

Where, \( Y_i \) is the dependent variable, named nutritional status measured by the weight of the children having three categories – normally weighted, moderately underweight and severely underweight. The categories are taken as 2, 1 and 0 respectively.

\( X_i \) is the vector of independent variables.

\( B \) represents co-efficient of independent variables.

\( e_i \) is the error term.

**Results and Discussions**

In the present study, multinomial logistic regression model is used to study the various factors determining the nutritional status of children. For this, nutritional status of children is taken as dependent variable which is categorized into following three categories:

Based on the review of literature the following independent variables are included in the analysis:

\[
\text{Nutritional status} = \begin{cases} 
0 & \text{Severe} \\
1 & \text{Moderate} \\
2 & \text{Normal}
\end{cases}
\]
Description of Independent Variables used in the model:

***p<0.01 **p<0.05 *p=0.10 RC- Reference Category, Cox and Snell $R^2 = .756$, Nagelkerke $R^2 = .895$, Goodness of fit (Chi-square) = 220.276 (not significant)

As shown in the above table ‘severely underweighted’ children are taken as the reference category. The estimated model compares ‘normally weighted’ children in reference to ‘severely underweighted’ and ‘moderately underweighted’ children in reference to ‘severely underweighted’ children. Based on the significance level of the Wald statistics it is found that in case of ‘normally weighted’ in reference to ‘severely underweighted’, three variables came out to be significant at 5 percent namely, husband’s employment, household monthly
income and supplementary nutrition service. Again, in case of ‘moderately underweighted’ in reference to ‘severely underweighted’, mother’s education, father’s education and pre-school education came out to be significant at 5 percent while father’s employment came out to be significant at 10 percent.

Factors affecting ‘normally weighted’ children in reference to ‘severely underweighted’ children: The β coefficient of father’s employment reveals that other variables remaining constant, having father who work in the primary sector is associated with a 0.206 decrease in the relative log odds of having normally weighted children than severely underweighted children. The odds ratio of father’s employment is 0.814. This indicates that controlling for other variables; children whose father works in the primary sector are .814 times less likely to have normally weighted children than severely underweighted children compared to those whose father are not engaged in the primary sector.

The β coefficient of household monthly income reveals that other variables remaining constant, increase in household income by 1000 rupees is associated with a 4.102 increase in the relative log odds of having normally weighted children than severely weighted children. The odds ratio of household monthly income is 60.461. This indicates that controlling for other variables; with increase in household monthly income, children are 60.461 times more likely to become normally weighted than severely underweighted.

The β coefficient of supplementary nutritional service reveals that other variables remaining constant, full availability of supplementary nutritional service is associated with a 1.001 increase in the relative log odds of having normally weighted children than severely weighted children. The odds ratio of supplementary nutritional service is 2.721. This indicates that controlling for other variables; children who have been availed full supplementary nutritional services are 2.721 times more likely to become normally weighted children than severely underweighted compared to those who have not been availed full supplementary nutritional service.

Factors affecting ‘moderately underweighted’ children in reference to ‘severely underweighted’ children: The β coefficient of pre-school education reveals that other variables remaining constant, regularly attending pre-school educationis associated with a 3.006 increase in the relative log odds of having moderately weighted children than severely weighted children. The odds ratio of pre-school education is 20.206. This indicates that controlling for other variables; children who regularly attending pre-school education is 20.206 times more likely to become moderately weighted than severely underweighted than those who don’t attend pre-school education regularly.

The β coefficient of mother’s education reveals that other variables remaining constant, increase in mother’s education by one unit is associated with a 0.245 increase in the relative log odds of having moderately weighted children than severely underweighted children. The odds ratio of mother’s education is 1.278. This indicates that controlling for other variables; with increase in years of schooling of mothers, children are 1.278 times more likely to become moderately weighted than severely underweighted.

The β coefficient of father’s education reveals that other variables remaining constant, increase in father’s education by one unit is associated with a 1.014 increase in the relative log odds of having moderately weighted children than severely weighted children. The odds ratio of father’s education is 2.757. This indicates that controlling for other variables; with increase in years of schooling of fathers, children are 2.757 times more likely to become moderately underweighted than severely underweighted.

The β coefficient of father’s employment reveals that other variables remaining constant, having father who works in the primary sector is associated with a 3.516 decrease in the relative log odds of having moderately underweighted children than severely underweighted children. The odds ratio of father’s employment is 0.029. This indicates that controlling for other variables; children whose father works in the primary sector are .029 times less likely to become moderately underweighted than severely underweighted compared to those whose fathers are not engaged in the primary sector.

Conclusion

The present study is an attempt to explore the nutritional status of children & its various determinants. The study reveals that various socio-economic factors like parents education, employment status, household monthly income have a significant impact on the nutritional status of childrens. Again, apart from it, the study also shows that ICDS programme influence the nutritional status of children. The present study found
that the supplementary nutrition service and pre-school education programme under ICDS scheme is positively related to the nutritional status of children which is statistically proved.

Cultural Factors Affecting the Spread of HIV/AIDS among the Women in Jaintia Hills, Meghalaya

Monsumi Barooah\textsuperscript{1}, P. C. Joshi\textsuperscript{2}, Roumi Deb\textsuperscript{3}

\textsuperscript{1}Ph.D., Research Scholar, Amity Institute of Anthropology, Amity University, Noida, Uttar Pradesh, \textsuperscript{2}Professor of Social Anthropology, Department of Anthropology, University of Delhi, New Delhi, \textsuperscript{3}Director, Amity Institute of Anthropology, Amity University, Noida, Uttar Pradesh, India

Abstract

Despite years of study and lack of empirical evidence, assumptions about culture as a co-factor in the spread of HIV/AIDS still persist. In recent years, more and more ideas about cultural causality have been called into question, and often disproved by studies. Thus, in light of new evidence, socio cultural causes of the disease, is both warranted and long overdue. The overall objective of this paper is to unravel the socio-cultural factors contributing to the spread of HIV/AIDS among the Jaintia women of Meghalaya. The study adopted mixed research methodology, both qualitative and quantitative. The research designs employed were explorative, descriptive and contextual. The findings revealed that social cultural factors which include gender issues, violence, presence of risk beahviours, stigma and discrimination lead to HIV infection in the study area. Other issues which emerged include lack of information about HIV/AIDS, poverty, unsafe sexual practices, ignorance and cultural beliefs.

Keywords: Socio-cultural factors, HIV/AIDS, Jaintia Women, Meghalaya.

Introduction

The role of socio-cultural factors in the fight against HIV/AIDS has been the subject of much research in the last decade.\textsuperscript{1} Culture varies in different parts of the world and is one of the many reasons influencing human behavior, value systems, credences, and practical erudition. It is deeply rooted in all aspects of a society, including local perceptions of health and illness seeking behaviours. However, in the broader sense, it includes traditions and local practices, taboos, religious affiliations, gender roles, marriage and kinship patterns, and so forth.\textsuperscript{2} From this, it is clear that it influences attitudes and behaviours related to the HIV/AIDS epidemic: risk of contracting HIV, access to treatment and care, shaping gender relations and roles that put women and men at risk of infection, being supportive towards or discriminating against people living with HIV/AIDS and their families, etc. It encompasses all duties, rights and behaviours a culture considers appropriate for men and women. Hence, in social invention gender gives us a sense of personal identity as male or female. This creates notions of masculinity and feminity which in turn brings unequal power relations between men and women. Moreover, cultural norms prevent them from seeking information or admitting their lack of knowledge about sex or method of protection. To contextualize this even more, there is an unequal balance of power between men and their sexual partners – an imbalance whose detrimental effects have resulted in women becoming the face of HIV/AIDS. Lack of power by women in relationships means that they have very limited decision-making abilities in the relationship and are unable to negotiate safer sex and therefore risk infection to please the men.

Young women and adolescent girls aged 15-24 years are particularly affected with HIV infection. Globally, in 2015 estimated 2.3 million adolescent girls and young women living with HIV, that constitute 60 per cent of all young people infected with HIV years.\textsuperscript{3} Several studies on HIV infection among the women between age group 15-49 years were conducted globally (for both men and women). In view of high prevalence of HIV infection among the women in reproductive and sexual active group and availability of limited information on HIV particularly among young women, the present study focused on the young women belonging to the age group.
15-35 years with the aim to understand various social and cultural factors that reinforce women’s vulnerability to HIV/AIDS.

**Materials and Method**

The present cross-sectional study was conducted amongst tribal women of Jaintia Hills, Meghalaya covering East and West Jaintia Hills districts. Data was collected from 320 women of all the five blocks (Thadlasken, Laskein, Amlarem, Saipung and Khlehriet) of East and West Jaintia Hills, Meghalaya (The sample size of 308 was calculated using online sample size calculator http://www.surveysystem.com/sscalc.htm, giving prevalence estimates with 95% confidence level and within 5% confidence interval for a total number of people living with HIV (PLHIV) in Meghalaya, which is 1,541., Meghalaya AIDS Control Society, 2014). All the participants belonged to the age group 15-35 years. Interview schedules, in-depth interviews, focus group interviews were used to collect data to understand the social and cultural factors behind the HIV/AIDS infection. Information was gathered regarding marriage pattern, gender issues, violence against women, risk behaviour, stigma and discrimination and the cultural beliefs. Data was collected by interacting with the women and building rapport by developing mutual trust with them. This was supplemented with living in the community, participating in their activities and constantly observing what the women actually do in specific situations.

**Results**

In the present study, the decision making power of the family regarding what to eat everyday varies in different families. It is observed that in majority of the families the women decides what to be cooked and which school their children should go. However, the decision regarding sex and use of condom in most of the cases is taken by the male partners (74%). The percentage of women having power over household chores is 61% and men is 39%. The Jaintia society of Meghalaya is commonly known as matrilineal where authority, title, inheritance, residence after marriage and succession are traced through the female line (mother or maternal ancestors). The decision of divorce depends on both women and men. It is observed that the percentage of men deciding on divorce is more as compared to that of women (men 60% and women 40%). The study revealed various reasons of divorce like refusing sex, unfaithfulness, HIV infection, failure to support family and violence against women. (Table 1).

</table>

Moreover, the study also highlighted several forms of violence against women in Jaintia Hills, Meghalaya. It was found that the Jaintia women do not consider the harmful behavior by men as violence because these acts are considered to be normal in their society and they occur so often that they seem normal. The overall percentage of Jaintia women under study who faced violence of any form is 94%. In some cases, this has led to low self esteem, depression, and some women were even suicidal. There are few cases where the Jaintia women equally abuse their husband and physically assault them. In the present study 4% of the women agreed that they have had hit their husband when they come home drunk and start getting abusive and violent. (Fig. 1).
Another form of violence against women in Jaintia tribal society is to cope with an alcoholic husband who drinks away half his salary, comes home to inflict violence on his wife and children and then dies prematurely leaving his family to eke out a desperate living for themselves. The trauma of being members of a society where marriage is so brittle is that women often remarry with the hope that the second time they would be lucky to find a man who would look after their mental, physical and financial needs. Hence, their children from the first marriage are forced to accept a stepfather in their life. The study also revealed that in many cases the stepfather rape the stepdaughter.

The other kind of violence is the women having no control over their wombs and how many children they wish to have. Several women reported that in the different villages of Jaintia Hills, the women think they can keep their husbands only if they have unlimited sexual relationship. As a result, women have as many as seven, eight or ten children. They are poor and are unable to give each child proper food and education.

Early marriage severely increases young girls’ vulnerability to HIV as they are most likely to be forced into having sexual relationship with their (usually much older) husbands. Young girls have softer vaginal membranes which are more prone to tear, especially on coercion, making them susceptible to HIV and other STIs. Older husbands are more likely to be sexually experienced and HIV infected. The dramatic rise in young married girls’ exposure to unprotected sex is driven by pressure to bear children and their inability to negotiate safe sex. The significant age gap in spouses also further intensifies the power differential between husband and wife, which in turn discourages the open communication required to ensure uptake of voluntary counseling and testing for HIV, sharing test results and planning for safe sexual relations throughout the marriage. The Jaintia women are victims of early marriages which make them vulnerable to the disease. In the present study, the total number of early marriages i.e. before 18 years (legal age at marriage) amongst the Jaintia women is 46. The percentage of married women at the age of 15 years, 16 years, and 17 years is 4.3%, 6.5% and 3.4% respectively. (Fig. 2).

Risk behaviors among the Jaintia tribal women include unprotected sex and multiple sex partners. It was found in the study population that married couples never use condoms because of reproductive purposes. Furthermore, there was lack of knowledge regarding the use of condoms indicating their level of ignorance. Some women believed that continuous use of condoms was a sign of lack of trust or love. Married women had no decision on safe sex though they knew that their husbands have extramarital relationship. Risk behaviours such as having multiple partners increases HIV/AIDS infection in the community. (Fig. 3).
who are infected with HIV/AIDS are reluctant to adopt behaviour that might signal their HIV-positive status to others. So, it was observed in the present study that married HIV-positive men do not use a condom to have sex with his wife; an HIV-positive mother continues to breastfeed her baby. It was also found in the present study that people do not want to get tested for HIV/AIDS fearing that they might be diagnosed with HIV and that would lead to the discrimination in their society. It was reported that 61% women agreed that if a person is infected with HIV/AIDS they should be expelled from the community and be ashamed of themselves. They should not stay in the community as other people will get infected by them. For the betterment of the community, these people should leave the pleasures of family life. (Fig. 4).

![Stigma and discrimination related to HIV/AIDS among the Jaintia women](image)

**Fig. 4: Showing the stigma and discrimination related to HIV/AIDS among the Jaintia women**

Among the Jaintia women, certain prevalent cultural norms and practices related to sexuality contribute to the risk of HIV infection. For instance, negative attitudes towards condoms, as well as difficulties negotiating and following through with their use. Condoms also have strong associations of unfaithfulness, lack of trust and love, and disease in the study area. The importance of fertility among them hinders the practice of safer sex. Young women under pressure to prove their fertility prior to marriage become pregnant and therefore do not use condoms or abstain from sex. Every family has many children which are also seen as a sign of virile masculinity among the men of Jaintia Hills. Men tend to have more sexual partners and to use the services of sex workers. Urbanisation and migrant labour expose the Jaintia to a variety of new cultural influences, with the result that traditional and modern values often co-exist. Therefore, traditional values that could serve to protect people from HIV infection, such as abstinence from sex before marriage, are being eroded by cultural modernisation.

**Discussion**

This paper sought to ascertain the socio cultural factors facilitating HIV/AIDS among the women of Jaintia hills, Meghalaya. Unsafe sexual practices have been considered the main cause of HIV transmission worldwide. In the present study, none of the women were found to be using condoms when having sexual intercourse with their partners. Previous studies also reported unpopularity of HIV-preventive method like use of condom, among sexual partners, suggesting that people do not view them as source of HIV risk. The study suggested that young women may be entering into sexual relationships without full knowledge that their partners have other relationships or that they know but want to solicit some benefits from these extra partners, such as money or gifts. Such multiple sexual relationships are very conducive to the spread of STIs, especially HIV. The findings are consistent with the previous studies on youths. Another study revealed the prevalence of multiple concurrent partnerships among the sexually active university students. Domestic violence and sexual abuse are important correlates of HIV risk especially among women. World Health Organization has defined domestic violence as physical abuse (e.g. slaps, punches, kicks, assaults with a weapon, homicide), emotional verbal and psychological abuse e.g. belittling the woman, preventing her from seeing family and friends, intimidation, withholding resources, preventing her from working or confiscating her earnings) and sexual abuse (e.g. rape, coercion and abuse includes use of physical force, verbal threats, and harassment to have sex, unwanted touching or physical advances, forced participation in pornography or other degrading acts that often persist over time and are accompanied by threats on part of the perpetrator). Various studies have reported that the women lacked the ability to control sexual activities (including condom use) making them powerless in abusive relationships with HIV-positive men leading to high HIV risk behavior and abstaining the infected to obtain treatment for HIV/AIDS. The prevalence of violence was reported by 94% of the women, posing a risk to studied population for HIV infection.

Despite of the presence of HIV risk behaviors, the personal perception of HIV risk was found to be only 8% amongst the women of the present population. Although
one percent of women thought that their partner’s sexual behavior put them at risk of HIV infection. Similar findings have been reported among general population as well as high HIV risk groups like MSM and black Africans suggesting it as a major health issue. Studies have reported that a relatively good awareness of HIV did not always translate to a perception of individual risk, possibly because of lack of symptoms, assumptions about monogamy or a lack of acknowledgement of risky behaviours. This added to the reasons of low perception among the currently studied population. Low risk perception was found to be a barrier to HIV testing in many previous studies.

Mobile Learning among Physiotherapy Undergraduates: An Evaluation of Current Status, Dispositions and Performance

Nidhi Kalra¹, Pratibha Singh²

¹PhD Scholar, Assistant Professor, ²Professor, Faculty of Applied Sciences, Manav Rachna International Institute of Research and Studies, Faridabad, Haryana

Abstract
Mobile phones have become an almost essential part of daily life since their inception. They offer a lot of advantages especially offering participatory learning for the students. Their ability to provide learning apparatuses beyond the time and space dimension makes them all the more acceptable for current millennial generation. Thus this study tries to find out whether physiotherapy students are inclined towards the usage of mobile leaning and how is it affecting their academic performance.

Method: The study was conducted on 120 Bachelor of Physiotherapy students who were using smart phones from at least a year through a self reported questionnaire.

Result: Majority of the participants perceived m learning as advantageous though there were some disadvantages and barriers perceived as well. As anticipated, both by users and from the literature, universal internet access and screen size were a major limitation to device use.

Conclusion: M-learning devices can have a positive impact on the learning experiences of physiotherapy students. The results supported the feasibility of providing mLearning devices to support learning. However, universal internet and screen size are the fundamental limitation to optimal device utilization.

Keywords: Mobile learning, Physiotherapy students, Learning and study skills, Information and communication technology.

Introduction
Information and communication technology (ICT) is a ground-breaking technique which offers the possibility to create imaginative learning methodologies by giving more extravagant chances and encounters to the present age of students.¹ Presenting ICT inside the learning condition expels conventional study hall boundaries, and gives online development, which therefore can improve the present understudy commitment.² It gives a spot where students cooperate and support each other as they use a collection of devices and learning resources to their greatest advantage of learning destinations and critical thinking exercises.³

Noteworthy changes in higher education including the medical sciences have occurred because of ceaseless imaginative movements.⁴

Studies indicate increasing utilization patterns of ICT among health care professionals and learners.⁴

One of the ICT tools which is seeing rapid advancement is mobile phone.

Mobile phones have become an almost essential part of daily life as well as necessary medium of communication since their rapid growth in popularity in late 1990s.⁵

These latest portable electronic gadgets (advanced cells, tablet PC) have been obscuring the learning limits among study hall and home, just as limits between the
idea of PC and cell phones. The utilization of PDA and tablet has been soaring for the last a couple of years. Youthful grown-ups having a place with this age in India spend all things considered of more than 2.2 hours daily on their PDAs. As needs be, this conduct should prompt change or adjustments in instructive practices by establishments in order to guarantee that they keep their students connected with and what’s more, give a quality learning knowledge just as administration that will both fulfill contemporary understudies and pull in new ones.

The multifunctional flexible advancement enable learners to get to the Web pervasively for finding and looking information, messaging, examining digital books, and in fact shopping. The flexibility has in addition enabled adapting free of region and whenever without a doubt out of classroom education option.

Portable advancements give an instructive stage that is dynamic, taking into account more development, and challenge. Their advantages are showed in various aspects of training, including shared learning among friends, setting explicit learning, and the assistance of a functioning, valuable learning process. Also, portable based learning gives information - based learning apparatuses that permit learning outside the study hall. Learning is flexible as far as space, i.e., it occurs at the workplace, at local, and at spots of unwinding; it is versatile between assorted scopes of life, i.e., it might identify with work demands, personal development, or unwinding; and it is convenient concerning time.

The capacities of compact devices and their wide setting of utilization add to their inclination to develop community oriented and total learning works out, enabling students to share data, records and messages in groups.

It additionally fills in as a connection among information and aptitude based practice by giving prompt access to learning, and accordingly improves clinical thinking abilities. It additionally, incomprehensibly, advances self-learning, joint effort and in particular security of the student.

An instructor can convey a fixed number of ideas inside a constrained time, most study hall exercises are restricted to just the underlying introduction of the subject and practice is dominantly left to the understudy to do as homework. Hence, there are no open doors for issue goals until the following class. This is ideal situation for the utilization of a portable application (App) outside the study hall, and which additionally gives a chance to an instructor to change his or her job from only an area master to that of an arbitrator of the substance.

Physiotherapy is a gifted social insurance discipline that utilizes development based answers for treatment of pathologies, debilitations and incapacities. Physiotherapy examination, determination, and arranging of treatment conventions requires the broad investigation of various conditions, their related patho-mechanics, and the appraisal and the executives of conditions utilizing the most recent helpful method, for which physiotherapists need to rehearse widely to sharpen their aptitudes. In like manner, physiotherapy understudies need introduction of learning past a formal, instructional methodology in the homeroom and with a broad spotlight more on viable sessions. Appropriately, it is basic that physiotherapy learning expand well past the customary study hall setting and include broad self-learning and practice, which can undoubtedly be met utilizing versatile application learning and which can spur students to focus on the data introduced and hold it better.

Despite of all the advantages there have been studies that reveal practical and social limitations towards the usage of such versatile devices. Thus through this study we are trying to gather feedback from the students about their experience while using m learning.

**Method**

**Aims:** This study aimed to evaluate the impact of m learning devices on student attributes and academic performance by gathering feedback from a group of students, in a naturalistic setting. The objectives of the study were:

1. To identify students perceived impact of m learning as an adjunct to learning.
2. To identify whether m learning devices have an impact on studying efficiency.
3. To identify the perceived influence of smartphone on academic performance
4. To identify any significant limitations to the use of devices.

**Sample, Data Collection and Study Period:** The study was conducted in October 2018 on 120 Bachelor of Physiotherapy students who were using smart phones from at least a year. After taking written consent
participants were given a statistically validated survey questionnaire that had 3 parts and contained a mixture of likekt scale questions assessing perceived advantages and disadvantages, simple yes/no responses and free text boxes framed after an extensive literature review.

Questionnaire consists of 2 parts:

• First part consisted of participant’s demographic data.
• Second part consisted of questions related to the effect of mobile phone on academic performance and perceived advantages and disadvantages
• Third part consisted of free text boxes explaining the barriers or limitations of mobile learning.

Analysis: A self-reported questionnaire, based on a review of the literature, was used to understand the opinions of undergraduate physiotherapy students towards the use of smartphones, their advantages, disadvantages, barriers and effects on academic performance. Data were compiled in an MS Office Excel spreadsheet.

Descriptive statistics were utilized to describe participants and the mobile devices benefits and barriers.

Results

Both male and female students of age between 18-25 years were surveyed.

**Perceived Disadvantages:** Participants were asked a series of questions concerning the disadvantages of the use of mobile devise. Answers were rated on a 5 point Likert scale from Strongly disagree (1) to Strongly agree (5).

High cost of device (36%), accessibility of information due to absence of internet connection (39%), lack of proof of quality and accuracy of available apps (28%) and risk of accessibility of personal data (23%) are the major disadvantages of mobile usage.

**Limitations or Barriers in mobile learning:** Students indicated that the most commonly discussed
type of obstacle in mobile learning is the insufficient size of device screens (50%) followed by network accessibility (39%). 14% of the students also felt it as being a distracter. Learning style was discussed as a minor barrier that might affect management of mobile learning (2%).

Discussion

Education is impactful and a major vehicle for change in society\textsuperscript{17}, therefore should be imparted smartly.

Effective learning strategies can be developed by innovative and creative teaching method, which interestingly benefit both students and teachers alike, motivating them to learn innovate and retain knowledge more efficiently. It should make an observable change in the learner, and which leads to greater engagement, understanding and/or a measureable impact on student learning\textsuperscript{18-19}.

Mobile learning being one such ICT tool which is already deep rooted in the lives of current millennial generation and is helping by creating opportunities for the collaboration and eliminating barriers on and off the campus.\textsuperscript{20}

The advantages participants of our study have perceived are in consonance with H Amruta and her co authors who has beautifully explained that how m learning can bridge the distances in learners and how portability in learning has the capacity to hook the generation Y\textsuperscript{21, 22}.

Elia, 2011\textsuperscript{23}, Crescente and Lee, 2011\textsuperscript{24} claim that m learning helps in improving the literacy rate by increasing the participation rate and offering a learning stage in the user’s hand which supports our study well where our participants (69%) are too agreeing that m learning is helping in improving learning processes, thus their academic performance and saves time, also supported by findings of Blanka in 2015.\textsuperscript{25}

Thus, it seems that use of smartphone for academic purposes and for learning skills has the potential to help students to learn efficiently if it is carefully integrated into the classroom and outside the classroom. So according to their positive answer, we can assume that smartphone has positive effect on academic performance and learning skill among the students of physiotherapy.

Quicker access to the web is viewed as a noteworthy advantage of mLearning gadgets\textsuperscript{28} and even after expanded availability, our outcomes demonstrated understudies still felt restricted by web get to\textsuperscript{29}. These outcomes propose that web network in clinical spaces will assume a noteworthy job in limiting the capability of such gadgets for position based training and is referenced by Deutsch and partners (2016) as a key factor in arranging before usage of a m Learning program.\textsuperscript{30}

Therefore better planning, preparation, and updated policies would improve learning processes in the area of mobile learning.

Limitations: Given the setting, the research question and the naturalistic methodological approach the main limitation was the lack of control group. The anonymous nature of the questionnaire made it impossible to identify and followup the survey non-responders. The general is ability is also limited by performing the study at a single site. Finally, there is a danger of recall bias as students were asked to self-report their usage.

Conclusion

Physiotherapy students embrace mLearning devices for their academics. The devices had a positive effect on the perceived efficiency of students’ work. However, as is commonly reported elsewhere, small screen size and limited internet access mainly inhibit them to use them extensively.

Skin Lesion Classification Using Convolution Neural Networks

K.S. Rajasekhar¹, T. Ranga Babu²

¹Research Scholar, Department of ECE, ANUCET, ANU; ²Professor, Department of ECE, RVR & JC Engineering College, Guntur, A.P., India

Abstract

Skin cancer is one of the deadliest disease found in humans. These skin cancers are of various types like Basal Cell Carcinoma (BCC), Melanoma, Nevus, Seborrheic Keratosis (SK), Squamous Cell Carcinoma (SCC). Some of the skin cancers can be identified visually, but in order to diagnose a skin cancer patient should have to undergo for a biopsy test and it takes a long time to diagnose. To overcome this an automated skin lesion classification system has to be developed. In this work, a basic architecture of the Convolution Neural Network (CNN) model is used to classify different skin lesions. The proposed model achieved better accuracy for SCC Vs SK, BCC Vs SK, Melanoma Vs Nevus and Melanoma Vs SK are 0.9741, 0.9867, 0.9506 and 0.9734 respectively for 25 epochs when compared to the other related works.

Index Terms: Skin cancer, Basal Cell Carcinomsa, Melanoma, Nevus, Seborrheic Keratosis, Squamous Cell Carcinoma, CNN, Training Accuracy, Validation Accuracy.

Introduction

The occurrence of cancer has been increasing over the past 20 years. Cancers are of different types, one of the most common type of cancer is the skin cancer. A skin cancer may be of two types melanoma and non melanoma. Every year globally 1,32,000 melanoma and about 2 - 3 million non melanoma skin cancers are occurring[1]. Even though the skin cancers are visually identified, the diagnostic accuracy achieved by an unaided expert is around 60% only.

A modern technique of aided visual inspection is Dermoscopy, which magnifies both the skin and elements surface reflection. The skin cancer images are digitally acquired by using dermoscopic technique. These dermoscopic images are used as inputs to the CNN. An enormous work has been done using CNN on skin cancer dataset. A conventional Computer Aided Diagnostic(CAD) system involves 3 phases-segmentation, feature extraction and classification.

In this work CNN is considered in order to eliminate the tedious process of pre-processing, segmentation and feature extraction, since it is having capability to work with raw data. CNN dramatically improves the classification of skin lesion in categorization and detection process by handling a large variations in the dataset.

Bi, Lei, et. al.,(2017)[2] have done classification of skin lesions as melanoma, seborrheic keratosis and nevus using deep residual networks achieving an average AUC of 91.50.

Matsunaga, Kazuhisa, et al.,(2017)[3] have proposed lesion classification using Deep Neural Networks. The CNN are fined tuned with the training samples using generic object recognition in Keras with RMS Prop and AdaGrad optimization achieving an AUC of 0.924 with Melanoma classifier and 0.993 with Seborrheic Keratosis classifier.

Boman, Joakim, et. al.,(2018)[4] evaluated the performance of the CNN during classification of skin lesions. Using Transfer learning, Inception v3 was trained for different skin lesions achieving an AUC of 0.71 for Melanoma versus Nevus, 0.91 for Basal Cell Carcinoma versus Seborrheic Keratosis, 0.91 for Squamous Cell Carcinoma versus Seborrheic Keratosis,
0.84 for Seborrheic Keratosis versus Melanoma, 0.83 for Solar lentigo versus Melanoma respectively.

Harangi, Balazs et al., (2018)\textsuperscript{[5]} have done skin lesion classification using ensemble of features extracted from different pretrained models GoogLeNet, AlexNet, ResNet, VGGNet. The accuracy achieved for classifying melanoma, nevus, and seborrheic keratosis is 0.891.

Mahbod, Amirreza, et al. (2019)\textsuperscript{[6]} proposed a fully automatic computerized method for skin lesion classification using deep features extracted from different CNN and abstraction levels. Three pre-trained deep models AlexNet, VGG16 and ResNet-18, are used as deep feature generators. An AUC of 83.83% for melanoma classification and 97.55% for seborrheic keratosis classification was achieved respectively.

M A Albahar (2019) et. al., \textsuperscript{[7]} have proposed a CNN with novel regulizer for skin lesion classification achieving an Area Under the Curve (AUC) of 0.77, 0.93, 0.85, and 0.86 for Melanoma against Nevus, Basal Cell Carcinoma versus Seborrheic Keratosis, Melanoma versus Seborrheic Keratosis, Melanoma versus Solar Lentigo respectively.

Hence, in this paper work is done on classification of two class skin lesion classification using Convolution Neural Network. Section 2 gives a brief introduction about Convolution Neural Network. Section 3 gives a description about the subset of skin lesion database and explains about the application of CNN to the dataset. Section 4 presents the results for classification of skin lesions. Section 5 gives conclusions.

Convolution Neural Networks: For an image classification CNN’s are very much useful because of their high accuracy. CNN was first proposed by computer scientist by LeCunn et.al.,\textsuperscript{[8]} that uses a hierarchical model to get a fully connected layer, in which all the neurons are connected to each other to process the output. A CNN is constructed by combining convolutional, pooling and fully connected architectures. A simple CNN model consists of two hidden layers (convolution layers). To create feature maps CNN uses various kinds of kernels to convolve the input image which results in the output matrix of a convolution layer.

\[
Q_i = A_f \left( b_i + \sum_{M=1}^{N} I \ast K_{m_i} \right) 
\]

(1)

Where the input image I is convolved with kernel \( K_{m_i} \). The bias \( b_i \) is added to each element obtained to the sum of all convoluted matrices

The size of the input image ‘I’ should be increased by padding with zeros to maintain the output image same as that of the input image. The output of the convolution consists of both negative and positive values. The negative values are removed using Activation or Non linear functions such as Hyperbolic, Softmax, Rectified Linear Unit (ReLU), Exponential Linear Unit (ELU), Scaled Exponential Linear Unit (SELU) which are given in the Equations 2,3,4,5 and 6 respectively.

\[
f(x) = \frac{1}{1+e^{-x}}
\]

(2)

\[
(z_i) = \frac{e^{x_i}}{\sum_j e^{y_j}}
\]

(3)

\[
f(x) = \begin{cases} 
0 & \text{for } x < 0 \\
1 & \text{for } x \geq 0 
\end{cases}
\]

(4)

\[
f(x) = \begin{cases} 
\alpha(e^x - 1) & \text{for } x < 0 \\
\alpha & \text{for } x \geq 0 
\end{cases}
\]

(5)

\[
sef(x) = \lambda \begin{cases} 
x & \text{for } x < 0 \\
\alpha(e^x - 1) & \text{for } x \geq 0 
\end{cases}
\]

(6)

The convolution layer is followed by pooling layer which is used to reduce the size of the feature maps and parameters of the network that increases computational speed. Max pooling is used widely to select the maximum of the value. The hyperparameters of pooling layer are filter size, stride and max pooling.

Regularization method need to be used to introduce dropouts not only on the training data but also on the new entries to reduce the problem of overfitting. Loss function gives the difference between the output and target variable which helps in the connection of various inputs to the next layer independently. The architecture of CNN is shown in Figure 1.
Methodology: The dermoscopic raw images are given to the input layer of CNN. First the inputs are convolved using a kernel. To capture different properties of input data one or more number of kernels can be used on each convolution layer. A stride is applied to perform the convolution by shifting the Kernel K with N input elements. Finally the output of the convolution is applied to the sigmoid activation function. This helps in the connection of various inputs to the next layer independently.

Dataset: The dataset for the present work is obtained from International Skin Imaging Collaboration (ISIC) ISBI 2017 challenge[9] which is shown in Figure 2. There are 2000 training, 600 testing and 150 images for validation. The dataset also includes 586 skin lesions of Basal Cell Carcinoma, 2169 skin lesions of Melanoma, 18566 skin lesions of Nevus, 419 skin lesions of Seborrheic keratosis and 226 skin lesions of Squamous Cell Carcinoma.

Results

The main objective of this work is skin lesion classification using convolution neural networks. The size of the skin lesions obtained from the ISIC archive ranges from 4288 X 2848 to 722 X 542 approximately. The size of the input images which are given as input to the CNN are reduced to 128 X 128 to keep the computational cost low. Convolution is used to extract the features from the given data. It acquires the features using the relationship between pixels by learning image features using small squares of input data. The stride and filter size should be specified in order to perform convolution.

Convolution is done by placing the filter on the image matrix and the respective digits are multiplied by each of them which are further added to make a value. In the present work, Layer 1 is convolution with 256 filters of size 3 X 3 and stride of 1 is used. Convolution layer is used with an activation function in order to remove the negative values while multiplying using activation functions. The activation function used is this work Sigmoid.

Layer 2 is the Max pooling which is used to reduce the spatial volume of the image so that the computation
becomes relatively simple. Max pooling is the process of obtaining the maximum value among the given matrix when a filter is placed over the given matrix. Max pool of size 2 X 2 with stride 2 is used in this work. Layer 1, layer 2 can be used multiple times by changing the parameters if needed and these layers are called hidden layers.

Flattening is performed to make the multi dimensional images(matrix) to vector form. The vector is thus fed into the fully connected layer having a neural network with a dense layer containing 64 neurons. The output layer consists of 2 neurons to classify the skin lesions into different categories.

The two layer feed forward neural network consists of 16384 input neurons in the hidden layer and two neurons in the output layer. In this work Adam optimizer is used. The SPARSE categorical cross entropy is used for updating the weights by back propagating the error backwards.

Skin lesion classification of Melanoma Vs Nevus, Melanoma Vs Seborrheic Keratosis, Seborrheic Keratosis Vs Squamous Cell Carcinoma and Basal Cell Carcinoma Vs Seborrheic Keratosis is done using Convolution Neural Network. Binary classification of the skin lesions is done and the graph of accuracy against epochs was shown in Figures 3.
The skin lesions from the ISIC Archive are augmented by rotating, flipping and zooming the images which are given as input to the Convolution Neural network. The over fitting problem can be overcome by data augmentation and regularization through dropout.

The hyper parameters for the present work are shown in shown in Table 1.

Table 1: Hyper parameters used in binary classification

The skin lesions from the ISIC Archive are augmented by rotating, flipping and zooming the images which are given as input to the Convolution Neural network. The over fitting problem can be overcome by data augmentation and regularization through dropout.

The performance of classification was evaluated using metrics such as training and validation accuracy as shown in Table 2. The number of epochs used were only 25 above which the classification may lead to under fitting and there is a reduction in the training and validation accuracy.

The detection of skin cancer in early stages is a challenging task. Due to the lack of proper early detection system skin cancer diseases are becoming non curable and leads to death. In this paper, skin classification is done using basic architecture of Convolution Neural Network achieving a good accuracy when compared to the other complex algorithms. In future the accuracy may be improve by considering different architectures like GoogLeNet, AlexNet, ResNet, VGGNet in the future work. The training and validation accuracy may be improved using external data for cross validation. The best structure of CNN model can be evaluated using optimization algorithms to find out the best parameters of the network. Extensive data augmentation needs to be done to the input data to cross validate the accuracy of the result.

**Conclusion**

A Study of Postinfectious Glomerulonephritis in Adults

Sushanth Kumar¹, Jayakumar Jeganathan², Nisheeth Kumar³, Meenakshi Shetty², Pavan M.R.²

¹Associate Professor, Dept of Nephrology, ²Associate Professor, Dept of Medicine, ³Resident, Dept of Medicine, Kasturba Medical College-Mangalore, Manipal Academy of Higher Education, Karnataka, India

Abstract

Introduction: To study the clinical presentation and outcome of postinfectious glomerulonephritis in adults.

Materials and Method: This was a prospective study of 50 cases of post-infectious glomerulonephritis. All patients were followed up for 18 months. The mode of presentation, history of sore throat or skin infections were documented. Serum creatine, Urinary proteinuria, C3 level, and ASO titre were performed. All these patients were followed up every two weeks after discharge for six months and four weekly thereafter for one year. Outcomes were classified as complete remission, partial remission and development of end stage renal disease.

Results: In their presentation to the hospital Oedema was present in 98% of the cases. 84% of patients had oliguria, Gross haematuria was present in 24% of patients and hypertension was present in 92% of the patients. ASO titre was positive in 16% of the patients. Most patients (82%) had proteinuria between 2.5-3.5 gm/24hrs. Complete remission was achieved in 84% of the patients. Partial remission in 12% of the cases and 4% of the patients went on to develop end stage renal disease (ESRD). The presence of gross haematuria and nephrotic range proteinuria correlated with the development of end stage renal disease.

Conclusion: Gross haematuria, nephrotic proteinuria, impaired renal function and presence of crescents in kidney biopsy at initial presentation are poor prognostic indicators of post-infectious glomerulonephritis in adults.

Keywords: Glomerulonephritis, postinfectious, proteinuria, outcomes, prospective.

Introduction

Post-infectious glomerulonephritis is an immune complex mediated glomerulonephritis caused by different organisms. The characteristic renal histopathology is diffuse, proliferative glomerulonephritis, often exudation with IgG and C3 subepithelial and mesangial deposits. The more extensive use of renal biopsies highlighted atypical histological forms of the disease. There is however little information about the long term prognosis of glomerulonephritis associated with infections in adults. Although the majority of patients make a complete clinical recovery, a significant number, especially the elderly continue to exhibit urinary abnormalities including sub- nephrotic range proteinuria, hypertension, and abnormal urine sediments. In the recent years only a few studies with a small number of patients and relatively short follow-ups have been reported and its long term prognosis remains undefined. Hence we decided to study the clinical presentation and outcome of post infectious glomerulonephritis in adults.

Materials and Method: The main aim of this study was to study the clinical presentation and outcome of postinfectious glomerulonephritis in adults. This was a prospective study. Clearance was obtained from the Institutional ethics committee. Informed consent was obtained from all the participants. All patients with post-infectious glomerulonephritis in adults presenting with low C 3 and normalizing within 8 weeks of presentation and biopsy proven post-infectious glomerulonephritis were included in this study. Glomerulonephritis in
children, other glomerulopathies and chronic kidney disease patients were excluded. A detailed history especially history of sore throat and skin lesions in the past two to three weeks were elicited and examination was done to look for oedema, hypertension in all participants. Investigations done included urea, creatinine, ASO titre, 24hrs urine protein, Serum C 3. Extracapillary proliferation (crescents) on kidney biopsy was considered present when it involved > 30% of glomeruli. All these patients received antibiotics, antihypertensives, and anti-oedema measures according to their clinical presentation. Patients with crescents received intravenous pulse methyl prednisolone one gram for three consecutive days followed by oral steroids of 1 mg/kg/day for one month and gradually tapered. All these patients were followed up every two weeks after discharge for six months and four weekly thereafter for one year. Investigations like serum creatinine, urine routine and microscopy, 24 hour urinary protein, serum C3 were repeated at the end of 8 weeks after initial presentation.  

Complete remission was diagnosed when plasma creatinine was < 1.2 mg/dl, Proteinuria < 0.2 gm/24 hrs and urinary red blood cells < 5/HPF.  

Partial remission was diagnosed when serum creatinine > 1.2 and < 5 mg/dl, proteinuria between 0.21 and 3.5 gm/ 24 hrs and / or urine red blood cells > 5/HPF. End stage renal disease (ESRD): chronic renal insufficiency requiring maintenance haemodialysis.

Results

A total of 50 participants were included in the study. 34 (68%) patients were males in the study. 16(32%) patients were females in the study. The maximum number of patients in our study were between the ages of 25-35 years. Mean age of presentation was 31.71 ± 6.75 years. The four cardinal features of post-infectious glomerulonephritis including oedema, oliguria, gross haematuria and hypertension were studied. The occurrence of these clinical features along with the preceding history of sore throat or skin lesions are shown in Table 1. The level of proteinuria among the subjects are shown in Table 2. Most of our patients had proteinuria between 0.2-2.5gm/24hrs. The mean 24 hour urine proteinuria in our study was 1158.6± 837.22 mg/24hrs ranging from a minimum of 255 mg/24hrs to a maximum of 3678 mg/24 hrs. The mean serum creatinine at presentation was 1.7 ± 1.4 ranging from a minimum of 0.6 mg/dl to a maximum of 7.2 mg/dl. ASO titre was found to be positive in 16% of the patients. All patients received antibiotics, antihypertensives, and anti-oedema measures according to their clinical presentation. The outcome of the patients is shown in Table 3. The mean number of weeks for complete remission was 19.31± 6.45 weeks ranging from a minimum of ten weeks to a maximum of 36 weeks. In eight patients, kidney biopsy was performed due to worsening renal function. Out of these, four showed diffuse proliferative glomerulus with IgG and C3 deposits. These patients received temporary haemodialysis and three underwent partial remission at eighteen months, whereas one progressed to end stage renal disease on maintenance haemodialysis. Two patients showed crescents and were treated with steroids and temporary haemodialysis. One of them had partial remission after eighteen months after initial presentation and the other patient progressed to end stage renal stage on maintenance haemodialysis.

Discussion

In our study, post-infectious glomerulonephritis was found predominantly in the third decade. Nattachai Srisawat et al found that most of the cases in their study were in the fifth decade. 1 Our study showed a male predominance which is consistent with other studies. In our study the typical prior history of sore throat were observed in only six patients and prior history of typical skin lesions in two patients and these eight patients had
high ASO titre. In our study ASO titre positivity was only observed in 16% of the patients with post-infectious glomerulonephritis. Gabriella Moroni et al observed ASO positivity in 47% of their patients. In our study the mean range of proteinuria was 1.2gm/24hrs and nephrotic range proteinuria was seen in only 4% of the patients. Gabriella Moroni et al found that 16% of their patients had nephritic range proteinuria and the mean proteinuria was 3.7g/24hrs. After a follow up of fifty patients for 18 months, 84% of our patients had complete recovery, 12% entered partial remission and 4% progressed to end stage renal disease on maintenance haemodialysis. Montseny et al in contrast found complete remission in only 26% of their adult cases. However, the short follow up of that study with a mean duration of 9 months may have precluded the observation of late recoveries in other patients, since complete remission occurred after a median of 12 months in that study. In our study complete remission occurred after a median of five months. Hinglais N et al, who studied the prognosis of post streptococcal glomerulonephritis found that it took a median period of 12 months for complete remission. At the end of 18 months, in our study, partial remission was observed in 12% of the patients. Gabriella Moroni et al observed partial remission in 20% of their patients. In our study only 4% of the patients progressed to end stage renal disease after a follow up of 18 months showing a relatively better prognosis of post-infectious glomerulonephritis in adults. Gabriella Moroni et al found 37% of their patients progressed to chronic renal insufficiency suggesting that the long term prognosis of post-infectious glomerulonephritis was worse in adults. In our study the presence of oedema, oliguria, hypertension at presentation did not correlate with the outcome. However gross haematuria at initial presentation showed a significant correlation with the development of end stage renal disease. Montseny JJ et al showed that nephrotic range proteinuria at onset was associated with adverse outcome. Similarly our study has shown that presence of nephrotic range proteinuria at initial presentation has a significant risk of developing end stage renal disease.

**Conclusions**

Gross haematuria, nephrotic proteinuria, impaired renal function and presence of crescents in kidney biopsy at initial presentation are poor prognostic indicators of post-infectious glomerulonephritis in adults.

**Ethical Clearance:** Taken from the institutional local ethics committee before the start of the study.

Outcome of Accelerated Recovery Programme on Occupational Stress among Nurses

Hemanathan Rajeswari1, Bhaskara Kurup Sreelekha2, Seran Nappinai3, Udathu Subrahmanyam4, Vaidyanathan Rajeswari5

1Professor & HOD cum Vice Principal, Department of Mental Health Nursing, Narayana College of Nursing, Chinthareddypalem, Nellore, Andhrapradesh, 2Vice Principal, Department of Medical Surgical Nursing, Faculty of Nursing, Sri Ramachandra Institute of Higher Education and Research (DU), Porur, Chennai, Tamil Nadu, 3Consultant Psychologist, Department of Psychiatry, Meenakshi Medical College Hospital & Research Institute, Enathur, Kanchipuram, Tamil Nadu, 4Professor, Department of Statistics, Narayana College of Engineering, Chinthareddypalem, Nellore, Andhrapradesh, 5Former Principal, Sree Narayana Nursing College, Chinthareddypalem, Nellore, Andhrapradesh, India

Abstract

Introduction: Among all the health care professions, Nursing is very stressful. Many studies identified that nurses suffer from moderate to high stress from the workplace. The objective of the study was to measure the outcome of the Accelerated Recovery programme in reducing occupational stress among Nurses.

Materials and Method: Quantitative research approach with Pretest posttest control group design was adopted to conduct a study among 120 nurses in Narayana Medical College Hospital, Nellore. By random allocation, nurses were assigned into study group (SG=60) and control group (CG=60). Index of Clinical Stress was used to gather data. For nurses in the study group, Accelerated Recovery programme with routine activities was executed and nurses in the control group underwent routine activities for five weeks. Posttest was conducted I (5th week), II (3rd month), III (6th month), IV (9th month), and V (12th month). Data were analyzed using descriptive statistics like mean (M) and standard deviation (SD) inferential statistics like Wilcoxon signed-rank test, Mann Whitney U test and repeated measure ANOVA.

Results: Repeated measures of the clinical stress over a period of time within [(SG: F= 597.142, p < .001), (CG: F= 0.558, p< .05)] and between (F= 159.345) the study and control groups showed statistical significance at p< 0.001. It is evident that the level of clinical stress has decreased significantly in the study group than the control group.

Conclusion: The results have confirmed that ARP is effective in decreasing the occupational stress among nurses. Building resilience is essential to enhance both personal and professional wellbeing.

Keywords: Nurses, Occupational stress, Job stress, Workplace stress, Resilience, Guided Imagery, Neurolinguistic Programming, Personal narrative.

Introduction

Among all the health care professions, Nursing is very stressful(1). The backbone of any health industry is the nurses. A report by US Occupational Safety and Health Institute states that among 130 professions which was studied for mental health problems related to work, nursing ranks 27th place as nurses work beneath constant pressure and stress than other medical professionals(2).
The demands of the job needs the nurses to be with energy levels, mental alertness, soaring skills, empathy toward patient and families, round the clock patient care, collaboration with other health care team members, in an environment where there are limited resources, and staff shortage which adds to the exhaustion.

The prevalence study conducted in India revealed 87.4%, a different study in Saudi Arabia reported 45.5%, a study in Iran identified 57.4% nurses had occupational stress. A Pilot study in the USA reports 92% of nurses have moderate-to-very high stress levels and a study in South West Ethiopia reports 58.46% job-related stress.

Out of ten jobs, the nursing profession is considered to have a maximum intensity of job-related injury or illness which necessitates the absenteeism from the occupation. In 2010, the median number of absenteeism days from work due to musculoskeletal disorders was seven. Five percent of injuries to the registered nurses were mainly ascribed by the physical attacks on the job, and they are always uncovered for exceptional dangers.

Today, there are numerous studies are carried out on the prevalence of occupational stress, factors influencing, injuries related to work, job satisfaction, and the problems related to the shortage of nurses. Managing stress at the right time will improve the quality of life and the patient care as well. Accelerated Recovery programme (ARP) is a package that includes self care measures, guided imagery, Neurolinguistic programme, and thought field therapy. The objective of the study was to measure the outcome of Accelerated Recovery programme in reducing occupational stress among Nurses.

Materials and Method

Study Design: The present study was carried out from April 2015 to March 2017 in Narayana Medical College Hospital, Nellore, India which is a tertiary care multi-speciality teaching hospital. The study adopted a Quantitative research approach with Pretest posttest control group design.

Population and Sample: Using power analysis, the sample size was calculated, which was 117 and was rounded off to 120. Nurses were first screened for Secondary traumatic stress. Then nurses who scored >30 in Index of clinical stress were recruited for the study. Nurses who already participated in Neurolinguistic programming, Cognitive behavior therapy, and stress management were excluded from the study. By random allocation, nurses were assigned into the study group (SG=60) and control group (CG=60).

Measures: Index of Clinical Stress (Abel, 1991) has 35 items which measure the level of subjective individual stress. The responses are expressed on an eight-point rating scale which is rated as 1= none of the time, 2= very little, 3= a little of the time, 4= some of the time, 5= a good part of the time, 6= most of the time, 7= all of the time. Out of 35 items, four items have reversed scoring. The total score ranges from 0 to 100. The obtained score is interpreted as 0-30: No stress and >30: Significant stress.

Ethical Consideration: Permission from Institutional Ethics Committee, Narayana Medical College was obtained. Also, permission was taken from the Director, Medical Superintendent, and Nursing Dean, Narayana Medical College Hospital. By explaining the nature and the purpose of the study, informed consent was obtained from nurses. The confidentiality of information was maintained.

Data collection procedure: After the work schedule, nurses were met by the researcher who fulfilled the inclusion criteria. Nurses were made to sit comfortable in a separate room where the study was carried out. On day one, using Index of clinical stress, pretest data was collected. For nurses in the study group, ARP with routine activities was executed and nurses in the control group underwent routine activities for five weeks. ARP is an individualized standard treatment protocol for five-weeks with five sessions, each lasting for 90-120 minutes. The session involves listening to audios, didactic and experiential training. The first session is assessment of the condition with the practice of guided imagery. Second session involves the construction of a personal and professional time-line. Session three, involves development of a self-management plan, thought field therapy and Neuro-linguistic. Session four focuses on supervising the self where the ‘Letter from the Great Supervisor’ is read by the nurse. Session five evaluates the programme goals address the pathways for recovery and closure. (Baranow sky and Gentry 2010). For the nurses in the study group, continuous reinforcement was given by follow-up telephonic calls. Posttest was conducted I (5th week), II (3rd month), III (6th month),
IV (9th month), and V (12th month) for both study, and control groups.

**Data Analysis:** Data collected was coded, tabulated and were analyzed using SPSS version 16.0. Descriptive statistics like mean (M) and standard deviation (SD) was used to find the effect of ARP on the index of clinical stress and Inferential statistics like Wilcoxon signed-rank test, Mann Whitney U test and repeated measure ANOVA to determine the impact of the ARP on index of clinical stress within and between the groups and over a period. Statistical significance was set at p< 0.05.

**Results**

Most of the nurses were in the age group of 21-30 years (SG: 58.4%, CG: 53.4%), were females (SG: 90%, CG: 83.3%), mostly unmarried (SG: 86.7%, CG: 71.7%), have B.Sc(N) as the professional qualification (SG: 68.3%, CG: 73.3%), work in ICU (SG: 83.3%, CG: 86.7%), half of them have an experience < 1 year (SG: 50%, CG: 56.7%), work as staff nurse (SG: 85%, CG: 90%), and less than half of them use listening to music (SG: 48.3%, CG: 46.6%) as their coping strategy.

Significant change is distinguished in the mean scores of clinical stress within the SG (Z: 6.762, 6.745, 6.738, 6.458 which is statistically significance at p < .001 and in CG (Z: 0.541, 0.081, 0.837, 0.217, and 0.260) which is statistically significance at p < .001(Table 1). Between-group comparison shows that during pretest, the means scores of the clinical stress, in the study and control groups was 72.45, 73.78 whereas means scores of the clinical stress during posttest I (32.2, 72.85), posttest II (33.67, 74.03), posttest III (36.35, 75.13), posttest IV (40.28, 73.98), and posttest V (43.03, 74.52) with (Z: 0.767, 9.475, 9.456, 9.456, 0.947) which is statistically significant at p < .001(Table 2).

Repeated measures of the clinical stress over a period of time within [(SG: F= 597.142, P < .001), (CG: F= 0.558, p< .05)] and between the study and control groups (F= 159.345) showed statistical significance at p< 0.001 (Table 3).

Discussion

The results of the study suggest that the intervention of ARP had a positive outcome in diminishing the nurse’s clinical stress from baseline to post-intervention with continuous reduction from one to 12 months. The socio demographic data reveals that half of the participants were in 21-30 years, four fifth of them were females which substantiate that nursing is female dominated profession. More than half of them are graduates. Three fourth of them are junior nurse working in Intensive care units with minimal experience in the hospital. Less than half use listening to music as their coping strategy. A study on the experience of clinical stress among novice nurses in a tertiary care teaching hospital reported high level of stress with a significant association on variables like age, marital status, educational qualification, area of work, and duration of work at p< .001(16). In a study to examine nurses level of occupational stress and the coping strategies, the age group of < 30 years, less than one year experience and perceived work-related issues and patient demands are felt to be stressful (17). An institutional study to identify the level of occupational stress and the determinants reported that 51% of the nurses reported moderate stress and 3% reported severe stress(18).

The present study adopted intervention such as guided imagery, NLP, thought field therapy, debriefing which has made the outcome of stress reduction. The findings are supported by various such studies which are conducted as individual intervention. An evaluative study on the impact of online guided imagery training on stress and anxiety reported that the stress level has reduced from 17.8 to 13.5, anxiety mean scores reduced from 56.4 to 54.3 at p < .001 which is similar to the present study finding (19).

A pilot study determined the effectiveness of EFT on perceived stress and anxiety among nursing students reported a decrease in the perceived stress and anxiety with a decrease in somatic symptoms which was significant at p< .05(20). The result of Emotion regulation training proved to reduce the mean scores on occupational stress from 136.6 to 113.02 which is significant at p< .05 in nurses working in the critical area(21).

A study investigated the effectiveness of Neuro-linguistic programming (NLP) on occupational stress where in the experimental group, the baseline score was 121.36 which has come down to 64.53 after the intervention whereas the control group had a baseline score of 120.88 and in post-test, the score is 120.96 and statistically significant difference at p = .0001(22).

As the researchers has offered the package of intervention which could have benefitted the nurses which has been identified that the effect was found till one year.

Conclusion

The results have confirmed that ARP is effective in decreasing the occupational stress among nurses. Further research is needed to identify which intervention had an intense effect in reducing occupational stress. A balance between stress and job satisfaction will enhance the professional quality of life thereby preventing the long term effect of compassion fatigue. Building resilience is essential to enhance both personal and professional wellbeing. Health care facilities have to provide adequate resources for work which will condense stress levels in nurses and assist balance in work-life.

Acknowledgements: The authors are thankful for the Management, Director, Medical Superintendent, Nursing Dean of Narayana Medical College Hospital for their permission and support to conduct the study and all the nurses for their participation and cooperation during the study. Healthy Emotional Expression: An Intervention for Anxiety and Suicide Ideation among School Students

Shweta Negi¹, Roopali Sharma²

¹Research Scholar, ²Professor, Amity Institute of Psychology & Allied Sciences, Amity University, Noida, Uttar Pradesh

Abstract

The present study has been performed to understand the effectiveness of intervention among the school students who were experiencing anxiety and suicide ideations. It was assumed and asserted that an interactional therapy which consist of Relaxation, written expression and verbal expression is a mean of healthy expression of emotions. Results proves that interactional therapy is found to be an effective method to reduce the level of anxiety and suicide ideation among school students. The scores of anxiety and suicide ideation is found to have gone down in both the age groups i.e 13-15 years and 16-18 years when compared after the intervention.

Keywords: Anxiety, Suicide ideation, Written expression, Relaxation, Verbal expression.

Introduction

The ever dynamic world has become a major challenge for all of us. With time the obstacles are also evolving. The present paper is an effort to understand the most suitable way to deal with challenges of human lives. Gross in 1998, 1999 defined Emotional expression as how one conveys emotional experience through both verbal and non-verbal behavior¹. Elliotts & Jacobs, 2013 explained expression as the act of presenting one’s thoughts, ideas and feelings via speech, writing, or through any other method.²

Types of Expression: Frank (2001) stated that facial expression is a form of expression where individual shows his/her feeling through verbal and non-verbal behaviour.³

Linguistics: Kristen A. Lindquist, Jennifer K. MacCormack, and Holly Shablack (2015) explained expression is fixed i.e a form of word is presented with some specific meaning to it.⁴

Anxiety: Browne (2018) said anxiety is a feeling of uneasiness, worry, tension about the things whose results are uncertain. There are multiple symptoms of anxiety through which one can understand that if an individual is experiencing anxiety for example., heart palpitation, restlessness, muscle tension etc.⁵

Types of Anxiety Disorders (APA): Individuals who experience GAD are always in the hunt of danger in the space and are very observant. they become overly concerned with everyday hassles. Generalized anxiety disorder is “characterized by chronic excessive worry accompanied by three or more of the following symptoms: restlessness, fatigue, concentration problems, irritability, muscle tension, and sleep disturbance”.

Phobias: According to National Institute of Mental Health Worldwide between 5% and 12% of the population suffers from phobic disorders. The basis of phobias are irrational and irrelevant and they believe in the idea as anyone else.

There are 3 types of Phobias:

- Specific Phobia
- Social Phobia
- Agoraphobia

Panic Disorder: According to taylor Panic disorder refers an abrupt surge of intense attack rising to a peak when thoughts of particular stumble are present. In this disorder person experiences brief attack of intense terror which results in physical symptoms such as dizziness, nausea, difficulty in breathing or sweating C Barr Taylor 2006.⁶
Post-Traumatic Stress Disorder: Post-Traumatic Stress Disorder is a result of Traumatic experiences in an individuals’ lives (Caroline Vaile Wright, Linda L. Collinsworth, Louise F. Fitzgerald, 2009). According to DSM – V some of the common symptoms include hyper-vigilance, flashbacks, black outs, lack of concentration, avoidant behaviors, anxiety, anger and depression.

Separation Anxiety Disorder: It occurs when children are separated from their parents children tends to experience Separation Anxiety Disorder (G Masi, M Mucci, S Millepiedi - CNS drugs, 2001). It is considered as disorder as the level of anxiety among the children is excessive and inappropriate.

Suicide: It is a process of ending one’s life and is one of the important reason of death worlds wide (Matthew K. Nock, Guilherme Borges, Evelyn J. Bromet, Christine B. Cha, Ronald C. Kessler, Sing Lee, 2008). This phase of life also involves a feeling of hopelessness and helplessness. According to Timothy J. Legg, 2018 symptoms of suicide ideation includes sleeplessness, loss of appetite or doesn’t feel hungry, social withdrawn alone etc.

Suicide Ideation: According to Nock, M. K., & Favazza, A. R. (2009) it is a deliberate effort to destroy one’s body tissues. Inability to deal with one’s life circumstances create a cycle of negative thoughts and the person end up ending their lives in the process. According to M. David Rudd, 1989, problem of youth suicide is a great concern.

Healthy Emotional Expression: Facing challenges and obstacles in life journey is natural and common across all human existence but how we manage the state of mind in those dire circumstances decides the mental health of an individual. Edward J. Murray Daniel L. Segal, 1994 has stated that by practicing relaxations method like, yoga, meditation etc, last but not the least by letting those disturbing emotions go and by not pondering upon them again and again it is recommended that one shall strive for healthy means of expressing emotions.

Davide Margola, Sara Molgora, Tracey A. Revenson 25 march 2014 the aim of this research was to study the Effects of Benefit-Focused Versus Standard Expressive Writing on Adolescents’ Self-Concept During the High School Transition. To do this research two groups of expressive writings were made namely benefit – focused versus standard expressive writing. It was found out that in the initial 5 years 201 male students wrote about the potential benefits of school transition. It was found out that benefit focused group found to have better short – term academic self – concept.

Gian Mauro Manzoni, Francesco Pagnini, Gianluca Castelnuovo and Enrico Molinari (2008) worked on the topic ‘Relaxation training for anxiety: meta-analysis done for ten-years’. From 1997-2007 all the studies which consist of relaxation training specifically Jacobson’s Progressive Relaxation, Autogenic training, applied relaxation and meditation were evaluated. There were 27 studies which qualified. Results shows relaxation training contributes in the reduction of Anxiety.

Caroline Smith, Heather Hancock, Jane Blake-Mortimer Kerena Eckert (2007) did a study on A randomised comparative trial of yoga and relaxation to reduce stress and anxiety. This study was conducted for 10 to 16 weeks to find the effectiveness of the yoga and meditation on stress and anxiety. 10 weekly one hour sessions of either relaxation or yoga were given to the participants. In the end of the research it was found out that though both the method are crucial for the betterment of patients with stress and anxiety but yoga is found to be more effective.

Sheese, B. E., Brown, E. L., & Graziano, W. G. (2004) did the research on Emotional expression to figure out the effectiveness of emotional expression through E- mail. It emphasises upon the effectiveness of the e-mail based writing treatment. For this study the 546 participants were randomly distributed into long and short term traumatic writing. By repeating this procedure for 5 weeks it has been found out that e-mail based writing treatment helps to produce positive physical and mental health.

Stacey H. Kovac PhD, Lillian M. Range (2002) gave their contribution when they found out that when an individual writes about their negative/ suicidal emotions, the intensity of those emotions reduces. They did the work on more than 100 college students for 2 weeks, wherein students were asked to express their emotions on pen and paper. This practice was repeated for 20 minutes till 4 days. Eventually the researchers could claim that this process is reducing the suicidal thoughts in the participants.

Material and Method

Study population, sample size and data: The
study started diagnosing 400 children with suicide ideations and anxiety of various severity levels, who were attending schools at Delhi/NCR, of which there were 340 drop outs from the further plan due to exclusion criterion. The prospective study finally comprised of 60 students classified as Early and Late adolescents, of which 30 were girls constituting 50% of sample and remaining 30 boys making up rest 50%.

Independent samples t-test - allows us to compare two groups of observations, all of which have come from the different group of people but possibly with a different mean for each condition. One has two experimental conditions and has used different participants in each condition. Systematic improvements in the parameters are noticed with corresponding magnitude of such effect in the population of interest. Systematic variations were assessed using experimental condition comparison; mean ($\bar{X}$) and corresponding difference were supported by 95% confidence interval for every possible significant statistics or otherwise. Further to support the significance of such comparisons, effect size is duly reported for every experimental phase evaluation using $r$ (Rosenthal, 1991; Rosnow & Rosenthal, 2005), $d$ (Cohen’s d). Mean differences are evaluated using p-value, t statistics, error bar graph and box - whisker distribution, all the comparisons denoted by $p < .01/.05$ or *** are highly significant at both the levels of significance 1%, and 5%

**Intervention Plan:** For 3 and a ½ months children with anxiety and suicidal ideation issues were called for 1 hour for one to one interpersonal therapy sessions (30 adolescents for each group – 13-15yr and 16-18yr). The intervention focused on enhancing social support, decreasing interpersonal stress, facilitating emotional processing by attacking anxiety and improving interpersonal skills. The plan is for the student to become more aware of his or her ability to deal with interpersonal problems that have kept him or her from being able to actively manage the symptoms of anxiety and suicide ideation. Three method were used to unburden the emotions, they are as follows:

- Relaxation Therapy
- Written Expression
- Verbal Expression

**Tools:** State–Trait Anxiety Test by Sanjay Vohra and Suicidal Ideation Scale by S. Sisodia & V. Bhatnagar

**Results**

Significant at both the levels (0.05 and 0.01)

**Discussion and Conclusion**

The current study is an attempt to understand if relaxation therapy, written expression and verbal expression is repeated for 3 months of time in regular interval will it have effect results in two age groups, i.e. 13-15 years and 16-18 years. Students with Anxiety and suicide ideations were identified to proceed the research work. Despite of having a clear criteria for the selection of participants, researcher faced huge difficulty in gathering the students and collecting the consent of parents as well as students. Students who are unable to manage their life circumstances are highly judged by their peers.

Results of the present study shows improvement in anxiety scores as the (Mdiff- 13.93) with 95% CI, p < .000) for pre-post intervention for 13-15 years of school students. Whereas mean difference for 16-18 years is 12.46, 95% CI and p< .000) which is a highly significant score. Mean Scores obtained on pre-test suicide ideation for age 13-15 years is 78.87 and the post test mean scores are 58.53. Mean difference obtained for the same is 20.33 with 95% CI, p < .000. The results
clearly indicates significant improvement in the anxiety and suicide ideation and intervention is found to be very effective for 13-15 years of age group. Mean score for 16-18 years school students pre-test suicide ideation is found to be 85.30, whereas for post-test it is 70.07. The mean difference for the 16-18 years school students is 15.23 with 95% CI, p < .000. Therefore the results are promising in its nature.

It can be concluded that if students are individually exposed to the same 3 step process to reduce the Anxiety and Suicide Ideation, there will be a significant difference in the level of anxiety and suicide ideation. It can also be said that therapy is going to be effective irrespective of the age of the school students.

Conflicts of Interests: Authors declares no conflict of interest.

Funding: Self

Ethical Clearance: This study was entirely done for the benefit of the children. Prior consent was taken from the parents as well as from the schools to conduct the research procedure.

Measures to Assess Standing Balance in Individuals with Spinal Cord Injury: A Review

Meenakshi Singh¹, Aparna Sarkar², Chitra Kataria³

¹Ph.D. Scholar, ²Professor, Amity University, Amity Institute of Physiotherapy, Noida, U.P., ³HOD Rehabilitation, Indian Spinal Injuries Centre, Delhi

Abstract

Background/Aim: Standing balance after the spinal cord injury is one of the major rehabilitation goals to improve the community participation. Measurement of realistic goal of standing balance requires the use of validated scales in population with spinal cord injury. The study aimed to identify and review the psychometric properties of outcome measures used to assess standing balance in spinal cord injury.

Method: Multiple databases were searched from the earliest records to March 2019. Reliability, validity and clinical utility of measures of standing balance were extracted.

Results: Seventeen outcome measures were identified and out of these only six measures- Smart Balance Master, Berg Balance Scale, Activity-Based Balance Level Evaluation (ABLE) scale, Mini BES Test, Functional Reach Test (FRT), and Community Balance & Mobility (CB & M) Scale are direct measurements of standing balance in SCI population with reported psychometric properties.

Conclusion: There is a need for reliable and valid tests to comprehensively assess standing ability in people with SCI, which encompass a range of tasks that have relevance to ADLs.

Keywords: Spinal Cord Injury, Standing Balance Assessment/Measurement, Paraplegia, Rehabilitation, Reliability, Validity.

Introduction

Primarily, the spinal cord injury results from a complete or incomplete damage to the spinal cord, thus leading to variable loss of motor, sensory and autonomic function. While during the rehabilitation, one of the biggest concerns of an individual with spinal cord injury is the scope of standing and walking. Standing is perceived to be a much more realistic goal than walking as it gives various benefits to the individual like prevention of contractures in lower limbs, minimization of osteoporosis, stimulation of circulation, reduction of spasticity and improvement in renal function¹. Hence, for the individual with SCI, the ability to stand and walk is discerned to be the most significant priority.

Balance or postural control can be defined as the ability to control the centre of mass in relation to the base of support and subsequently requires complex interaction of musculoskeletal and neural systems²,³. Standing balance is determined as the measurement which is used for the assessing of the balance and its ability to perform functional activities in standing position. The control of the balance can be divided into three main elements, the ability to maintain a posture, keep control of balance during voluntary movements (proactive) and regain control after unforeseen loss of balance (reactive)²,³. These elements are influenced by many factors, thus affecting the standing balance of a subject with SCI including the lower extremity motor score, spasticity, age, height, sensations in lower extremity, trunk control,
upper limb strength, cardiorespiratory fitness and self-motivation to stand and walk.

To make a good evaluation of balance control in subjects with SCI, it is vital to assess varying elements required for maintenance of posture during static and dynamic movements. Although a customized standing balance and gait training protocol are designed for individuals with spinal cord injury, there are very limited tools to evaluate standing balance of this population.

**Objective:** To identify and review the psychometric properties of the current clinical and biomechanical outcome measures used to assess standing balance in population with spinal cord injury.

**Method**

The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines have been used for the present review study. Also, the review has no registered protocol.

**Search Strategy:**

**Study Selection Criteria:** Inclusion criteria:

- Adult Participants with acute, subacute, and chronic SCI;
- ASIA Impairment Scale AIS (A-D);
- Measure of balance along with
- Information on its psychometric properties using individuals with SCI

**Exclusion Criteria:** Non-English articles

**Data Sources:** MEDLINE/Pubmed, Research Gate, Scopus, Cochrane from the earliest records to March 2019 were searched for the collection of relevant data. The search items were standing balance measurement/assessment/evaluation, postural stability and spinal cord injury/injuries, paraplegia, and tetraplegia.

**Study Selection:** All three researchers selected the papers after searching with the relevant keywords. Overall, ninety nine articles were extracted for inclusion and exclusion criteria. One author identified twenty one duplicated articles. The other author screened and excluded twenty three articles after exploring and reading the title and abstract. Out of remaining fifty five full text papers, fifteen articles were excluded as those papers mentioned the sitting balance measurement in spinal cord injury. Overall, the screening of the remaining forty full text articles was done by all the three researchers to prevent disagreement. Lastly, references for the selected studies were also searched manually for additional information.

**Data Extraction:** All the articles were scrutinized and read thoroughly in order to extract the relevant information regarding the properties of scale, domain of balance assessed by the scale, scoring criteria, and the subject characteristics on which the scales were utilized. Majorly, reliability and validity were the main psychometric properties which were studied for the scale. Reliability implies whether a scale gives consistent results in a given population. Moreover, it includes internal consistency and reproducibility. While validity is the ability of an instrument to measure an outcome to the degree to which it is intended to measure. The detailed properties of all the instruments/scales were thus explored and highlighted in the study.

**Results**

The search yielded one posturographic parameter- Smart Balance Master along with sixteen clinical outcome measures with varying psychometric properties that directly or indirectly measured standing balance in SCI individuals- Berg Balance Scale (BBS), Walking Index for Spinal Cord Injury-II (WISCI-II), Activity-based Balance Level Evaluation (ABLE) Scale, Functional Independence Measure (FIM), Spinal Cord Injury- Functional Ambulatory inventory (SCI-FAI), Six Minute walk tests(6MWT), 50 foot walk test, Ten meter walk test (10mWT), Two minute walk test (2MWT), Timed up & Go test (TUG) and Mini-Balance Evaluation System’s test (Mini-BESTest), Functional Reach Test (FRT), Community Balance and Mobility Scale (CB & M), Walking Romberg, Timed Standing and Tandem Stance.

Out of these, eight measures were omitted as these were determinants of walking function- (WISCI-II, SCI-FAI, 10mWT, TUG, 6MWT, 2MWT, 50 foot walk test) and measures of functional independence (SCI-FAI, FIM).

Another three clinical measures of balance namely walking Romberg, timed standing with eyes closed and tandem stance were also removed as there is no mentioning of psychometric characteristics in population with SCI.
The remaining six measures were divided into clinical and biomechanical measures of standing balance. For the clinical measures, Berg Balance Scale, Activity-based Balance Level Evaluation scale, Mini-Balance Evaluation System’s test, Functional Reach Test, and Community Balance and Mobility Scale are included. While biomechanical measure was measuring the balance using Smart Balance Master System.

Clinical Measures of Balance: Berg Balance Scale was developed initially to assess balance in elderly population on a set of predetermined tasks. Few studies have established the psychometric properties of the BBS in the SCI population. Recently, one of the crucial studies examined the concurrent validity and interrater reliability of the BBS in the chronic SCI population. In this study of 42 participants, it was discerned that the scores of BBS correlate with Falls Efficacy Scale and motor scores of individuals. Moreover, interobserver reliability was high with reference to each item as well as final score. However, BBS failed to identify difference between fallers and non fallers.

With reference to SCI population, BBS exhibits excellent interrater reliability and concurrent validity with WISCI-II, SCI-FAI, TUG and 10 MWT. In one study, the researcher tried to establish the concurrent validity of the Berg Balance Scale in a sample of 32 ambulatory subjects with AIS D SCI. The validity of BBS was established with WISCI-II, SCI-FAI, 10MWT and TUG. Subsequently, the correlation was high but still BBS showed ceiling effects supplementation of which requires the need of its use along with 10MWT or 2MWT.

ABLE scale is a recently developed scale for the SCI population to assess sitting and standing balance as well as walking abilities. The standing sub scale has 13 items for assessing static and dynamic components of balance. Content validity was established through expert opinion and discriminant validity through the Bonferroni Post hoc comparison.

The MINI BESTestscale (derived from BESTEST) measures the ability of balancing anticipatory and reactive postural control sensory interaction and dynamic gait. Additionally, the components of MINI BESTest were found to strongly correlate with BBS, TUG, SCIM- mobility items and 10 MWT. Also, it could identify individuals walking with without the use of assistive aids, and those who had high/ low concerns about falls. The items were correlated in individuals with Chronic SCI.

The Community Balance and Mobility Scale (CB & M) is designed to assess balance in ambulatory patients who suffer from balance impairments. Furthermore, the scale has been assessed for its use in incomplete SCI but as a retrospective assessment. The scale was perceived to have high correlates with the scores of 6 MWT and moderate with 10 MWT & BBS scores. High internal consistency was further evaluated. CB & M was shown to be a valid measure in SCI patients with high functioning levels.

Standing Functional Reach Test (FRT) has been used to assess the forward and lateral reach in spinal cord injured subjects. The distance reached is thereby measured and assessed as a predictor of balance and falls. Consequently, the test assesses dynamic balance through a single test. Studies show the efficacy of FRT as a measure to predict falls in spinal cord injury subjects along with good intertester reliability.

Biomechanical measure of Standing Balance: The Smart Balance Master System measures static balance, limit of stability and dynamic balance. It uses a force platform to identify a person’s COG and thereby the stability is checked by change in percentage of limits of stability, movement time and path sway. Concurrent validity of SBM was established with BBS in incomplete SCI. High level of association was found with BBS. Consequently, it was concluded that LOS tests of Smart Balance Master system may be used along with BBS to assess dynamic standing balance-ability.

Discussion

Standing, being one of the most integral aspects of function and a major rehabilitation goal after the spinal cord injury is assessed via different tools. Although, the Berg Balance Scale is reported to be the most commonly used one in this population, however, there are few items which are not suited for subjects of SCI. BBS has been widely used and recommended only for patients with AIS C & D. Also, it shows ceiling effects and does not permit the use of assistive devices. Thus, the researchers cautioned that the BBS should be used in with walking tests when assessing a patient for appropriate assistive device use.

ABLE scale showed minimal floor & ceiling effects with multiple overlapping item’s difficulty levels.
Although the scale is able to distinguish individuals after SCI on the basis of functional mobility. Further research will be required to establish the reliability and validity of the scale with existing scales for widespread usage.

MINI Bestest was compared with BBS for assessing balance of walking subjects in SCI. Author recommended MINI Bestest over BBS as no ceiling effect was observed. But the test has only been assessed in AIS D individuals who have the highest functional level in the SCI population along with need for further validation.

Smart Balance Master (Neurocom) assesses balance function during stance with the help of force platform. The researchers have claimed that LOS test of SBM is a relevant balance evaluation tool; however, it has been used in AID individuals. Furthermore, testings required to find test retest reliability of the SBM tests.

Functional reach tests have been proven as a good screening tool for fall risk prediction in ambulatory individuals with spinal cord injury. However, the test measures only dynamic balance. Therefore, it is needed to complement the test with other measures to evaluate all aspects of standing balance.

Community Balance & Mobility Scale is determined as a strong measure of balance in incomplete SCI subjects with high level of functioning which limits its usage in early stages of rehabilitation. Herein, the balance training is initiated and simple components for balance assessment is required. The researchers have thus recommended the testing of CB & M scale in prospective studies in order to check overall efficacy of the items.

Study Limitations: Though the study tried to incorporate all the assessment tools used for standing balance assessment, however, the exclusion of Non-English articles limits the incorporation of all scales. Also, the study does not include assessment of standing balance in paediatric SCI population.

Conclusion

Although Biomechanical and clinical measures of standing balance have been used in individuals with SCI, with BBS being the most commonly used tool in the population. However, there is a need for the development and establishment of psychometric properties of a clinical tool to measure the standing balance in spinal cord injury including the factors that contribute to the achievement of safe, and independent standing in varying environmental contexts.

Medical Tourism and its Scope in India

Arup Deka

Ph.D., Scholar, Department of Economics, Gauhati University

Abstract

Indian healthcare sector is one of the fastest growing sectors. The growth of trade in health care services through medical tourism has led India as an affordable destination. Patients from foreign countries come to India for surgical purposes due to low cost and high quality of hospital services. The country has huge potential to grow up and also expected to grow at a compound annual growth rate of 17 percent from the year 2011 to 2020.

Keywords: Health, healthcare, trade, medical tourism, cost, quality.

Introduction

Privatization of healthcare sector is a strategy for reducing government burden and this strategy was first adopted by USA. Under the pressure of international agencies like World Bank (WB), World Health Organization (WHO), other countries also thumbs up the mercerization policy. In parallel direction, globalization has opened up the scope for trade in healthcare sector. Trade in health care sector intrinsically linked with globalization.

The health care sector is divided into four sub sectors. These sectors are medical and dental services, nursing and midwifery, hospital services and other health services. According to general agreement of trade and services (GATS), there are four modes of doing trade in health care services, such as cross border provision of services, cross border movements of consumers or consumption abroad, commercial presence, cross border movement of service providers. The main focus of the study is concentrated in mode two which is popularly called health tourism or medical tourism.

Researchers have pointed out the global recession as the responsible factor behind commercialization, corporatization and marketisation of health care sector. The process received a boost during the late 1970s and early 1980s and the process was accelerated during the 1980s and 1990s with the growth of the pharmaceutical and medical equipment industries.

People from developed countries and other Asian countries come to India for medical treatment and people from India also go abroad for same purposes. This movement of patients from one place to another place is called as medical tourism. People travel to other countries because they are sick and need medical treatment to get healthy; such treatment includes organ transplant, surgery, dental treatment, medical therapy.

Indian health care is one of the fastest growing sectors. Trade in health care services is a billion dollar profitable industry for India in the twenty first century. Growth of trade in health care services through the medical tourism has led India as an affordable destination. It provides first class world medical care at third world prices.

Patients from foreign countries come to India for surgical purposes due to low cost and high quality of hospital services. The country has huge potential to grow up and expected to grow at a compound annual growth rate of 17% from the year 2011 to 2020.

The paper is explorative in nature. It is a contribution to the existing literature on medical tourism. The main objective of the paper is to find out the influencing factors of medical tourism and also explores the potentiality of medical tourism in India through a brief survey on existing literatures and based on secondary data.

Following the introduction part the paper has two sections, section two contains literature review, and section three contains importance of the study.

Literature Review: This section covers four sub sections including summary and conclusion.
Defining Medical Tourism: World tourism organization (WTO) defines tourism as travelling to and staying in places outside domestic environment for more than one consecutive year for leisure, business and other purposes. Traditionally tourism means travel for pilgrimage to holy places in country side. But in modern concept tourism means travel for leisure, pleasure, business and health. There are different forms of tourism like dark tourism, ecotourism, heritage tourism, health care tourism, medical tourism, space tourism and many more evolving day by day. Health tourism and medical tourism is not same. Medical tourism is a part of health tourism. Health tourism is composed of wellness tourism and medical tourism. The act of travelling abroad to obtain medical, dental and surgical care is called medical tourism. Medical tourism in correct term is the medical, surgical or dental interventions.

Medical tourism is a component of health care tourism. Health care tourism implies travelling outside ones local environment for the maintenance, enhancement and restoration of an individual’s well being in mind and body. It involves relaxation, exercise, massage, cosmetic surgery, operation and reproductive procedures.

Influencing Factors of Medical Tourism: There are many factors both from supply and demand sides which lead the growth of medical tourism. Researchers have finger out some pull factors (supply) for example, country environment like condition of economy, image of the country and status of tourism and healthcare industry and push factors (demand) factors for example, age, gender, income, education, insurance coverage. Moreover, economic, political and regulatory factors like Visa, Tax, as demand side factors and cost, time, quality, and affordability of travelling abroad are supply side factors of medical tourism.

New marketing strategies and innovative technique like telemedicine, internet has predominant impacts on medical tourism. Many hospitals in the world have partnership with travel agencies. It promotes the benefits of various turnkey packages of medical tourism services. Another evidence shows that internet as a driving factor in outsourcing healthcare services and making medical travel a global phenomenon.

Other literatures have shown that Cost and quality of services of medical care is a major factor which leads to growth of medical tourism. For example, study on Bangladesh healthcare system explains about the country’s dependency on India in case of medical care. The study starts with a brief overview of hospital sector has found that about 57 percent of total Bangladeshi patients seeking treatment abroad especially in India in 1999. This is because medical services facilities in Bangladesh are inadequate, and the services quality in India is relatively better than in Bangladesh. It is found that maximum number of patients do not seek visa on medical grounds in order to avoid hassles and take tourist visa to enter India for medical treatment. Another study on India gives a comparative picture of Indian medical care facilities with the world. The topic is starts with a general overview of Indian medical tourism. The author has compared the cost of surgery in India with that of Uk and USA. It shows that India has ability to do a knee replacement surgery at a least cost if we compare it with UK, USA. It also adds that India has same expertise of doctors and same infrastructure as UK, USA. The paper states that Non Resident of India (NRI) has been taking the advantage of Indian medical market because they avoid long waiting lists. Finally the paper wants to state that India offer world class treatment at an economical rate. Thus low cost, high quality and easy access medical alternatives for people across globe are the driving factor of medical tourism. Apart from low cost, other factors like information technology, shorter waiting time and convenient legal issues are the prime factors for the development of medical tourism.

Emergence of Medical Tourism in the world: Travelling abroad for treatment has increased dramatically in the 21th century and is one of the fastest growing exports of trade in healthcare services by the private corporate hospitals. Many places have been growing as an important medical tourism destination in the world.

United States of America is considered as one of the most technically advanced medical health care.
The American healthcare system is the most expensive system in the world\textsuperscript{22}. The Deloitte Centre for health solution report 2015 states that the inbound medical tourism to the United States is approximately $5 billion annually and patients come from the countries like North America, the Caribbean, Europe and the Middle East\textsuperscript{23}. Moreover availability of advanced medical technology and sophisticated training of physicians is the major factors for growth of medical tourism in US\textsuperscript{23}. However the economic recession has had a negative impact on patient’s ability to afford medical care in America\textsuperscript{24}. Therefore, many people from United States started to move outside of the country and consequently Mexico has become the popular destination for the American\textsuperscript{25}. Stomach surgery, eye exams and routine checkups are among major services that Americans are seeking in Mexico\textsuperscript{26}. Another important destination for medical tourism is Malaysia. This country is a primary destination of medical travelers in the ASEAN region around 75 percent of medical tourists from ASEAN region\textsuperscript{27}. Most international patients come from neighboring countries with less developed medical infrastructure such as Indonesia\textsuperscript{27}. From this industry the country has gained a good amount of revenue and it is expected that the revenues from this sector will grow at a compound annual growth rate of around 37 percent during 2012-2016\textsuperscript{28}. There has been increasing cross border trade and travel for health care services to countries such as India, Thailand, Malaysia, Indonesia and Mexico, patients from developed and developing countries for diagnostic, surgical, non- surgical treatment in search of value for money\textsuperscript{29}. The main cause of patients flow from outside is the low medical cost compared to that of developed countries. Foreign patients are motivated to come to developing countries like India, Thailand because of low cost of surgery, less or no waiting time, technology and facilities, quality of services\textsuperscript{30}

**Emergence of Medical Tourism in India:** In Indian history it is found that many learned people from China, Tibet, Greeks, Afghans and Persians came to India to learn curing and preventive therapy. Ayurvedic is a popular medical care method and is world famous. Yoga and Ayurvedic medicine were most popular in India as early as 500 years ago and there was a constant flow of medical voyagers and spiritual students to India to seek the benefits of Yoga and Ayurvedic healing method\textsuperscript{31}. Ayurvedic texts were translated in many foreign languages. Europe, Paracelsus known as father of modern western medicine, but the system of modern medicine is borrowed from Ayurvedic\textsuperscript{31}. The rising cost of health care services and complexity of the procedures in developed countries has given the opportunity for growth of medical tourism in India. India has huge potential to grow up medical tourism sector\textsuperscript{10}. It becomes a new channel for the transfer of medical services from the developed world to developing world\textsuperscript{11}. Evidence shows that American and Europeans frequently travel to India and Thailand for heart and knee replacement surgery\textsuperscript{31}.

Source: Indian Tourism Organization annual report, 2005

Medical tourists travel to India for surgical purposes which enhance the scenario for medical tourism in India. In India there are several hospitals with quality certification, English speaking staff and highly trained physicians and has cost advantage over developed countries. For example; the treatment like cardiology procedures (CABG) surgery cost US $ 7390 in India, cost US $ 15300 in Singapore, cost US $ 10093 in Malaysia and cost US $ 19360 in Thailand. When we compare the cost of CABG treatment in above mentioned countries with that of India, international patient can save 51.7%, 26.8%, and 61.8% respectively. Similarly, the cost of treatment for pace maker single chamber in India is US $ 5394 and that of in Singapore, Malaysia, and Thailand is $ 7450, $6857, $9500 respectively. Thus an international patient can save money in India. The medical cost advantage in Indian medical treatment is an important factor\textsuperscript{2}. 

**Conclusion**

The increasing demand of health care has positive impact on medical tourism industry. Low cost, high quality and easy access medical alternative for the people across world are the driving factor of medical tourism. In India Many patients from developed countries come to India because of low surgical cost. However the country must care about the availability of healthcare resources like doctors, nurses, hospital equipment so that medical tourism can grow at a sustainable way.
Likely Contribution of the Study: Medical tourism is growing in many developing countries. It has provided employment generation and has created an opportunity to grow up other subsidiary services like hotel, restaurant, shopping mall etc.

Medical tourism for healing human body: pain and trouble of human being can be removed through medical care. Medical care facilitates to enjoy a disease free life. Thus development in medical facilities is prerequisite of human life.

Medical Tourism as an Income Source: Medical tourism can be an important source of export income. It helps the country to earn foreign income and the earning income can be used for the development of the economy.

International and Interregional Cash Flow: medical tourism is a global industry. It is an important source of interregional and international cash flow. A recent survey stated that medical tourism fetches an annual growth rate of 25-30 percent annually at global level.

Efficiency: Medical tourism improves the efficiency of business structure and hospital administration. Moreover it promotes professional attitude among hospitals and challenging and rewarding employability.

Abstract

Background: The knowledge of bacterial and candidal interaction and its adhesion to different dental materials is an important factor to be considered before using it in the oral cavity for rehabilitating any hard or soft tissue. In this study an evaluation and comparison of adherence of three different species of oral microflora on three different dental alloys is seen on broth and artificial saliva as a medium.

Materials and Method: The purpose of this study is to evaluate the effect of different dental alloys on microbial growth in two different mediums (Broth and Artificial saliva). Three different dental alloys: Titanium, nickel chromium and cobalt chromium are selected for the study. A total of 180 samples are taken. They were then autoclaved and studied for microbial adherence of streptococcus mutans, Enterococcus faecalis and candida albicans species. The adherence of the samples tested was checked in ELISA reader at 545nm.

Results: Group 1 Artificial saliva and Group 2 SDA and BHI broth showed Statistical significant values of adherence between the C. albicans, S. mutans and E. Faecalis when compared with titanium, nickel chromium and cobalt chromium dental alloy.

Keywords: Oral microflora, Dental alloys, Adherence, Antibacterial, Antifungal.

Introduction

In advanced dentistry casting alloys like nickel chromium, cobalt chromium and commercially pure titanium (Cp Ti) are widely used for removable or fixed dental prosthesis. Whether it is a cast partial denture, fixed dental prosthesis or implant supported removable or fixed dental prosthesis¹. As per literature, reports state that these dental materials may cause local tissue response such as local allergic reaction, gingivitis, periodontitis in the oral cavity.¹

The knowledge of bacterial interaction and its adhesion to different dental materials is an important factor to be considered before using it in the oral cavity for rehabilitating any hard or soft tissue. Comparative studies done by Antonio et al and other authors on the various microflora and their effect on various dental alloys shows adhesion and antimicrobial activity of dental alloys towards the oral microflora². Dental biofilm also known as dental plaque or oral biofilm caused by oral microflora act as a major etiologic factor in causing gingivitis and periodontitis³. Biofilm formation and bacterial colonization is a continues process which takes plays in oral cavity³. The resultant increase in microbial numbers and its adhesion at the surface have shown to increase and advance the maturation rate of plaque formation⁴. Microbial adhesion towards the surface can be due to Initial non-specific interactions such as electrostatic interaction, vander walls forces and acid base interactions,and also specific interactions such as receptor-lingand binding⁵.
This in vitro study involved a comparison of the degree of bacterial adherence and biofilm formation on three different species of oral microflora on prosthetic dental alloys, thus enabling us to determine which biomaterial had minimal proclivity toward bacterial adherence and biofilm formation.

Materials and Method

Three different dental alloys: Titanium, nickel chromium and cobalt chromium are selected for the study. A total of 180 samples are taken. The samples are divided into two groups each group 1 and group 2. Each group is then further divided into subgroups group 1: a, b, c and group 2: a, b, c.

Fabrication of casting samples: 180 wax pattern samples were fabricated from crown wax on a metal die measuring 2mm in thickness and 1cm in diameter (Figure 1). The wax patterns are casted as per manufacturers instructions. (Figure 2)

Microbiological study: The samples are then suspended in two different materials of Sabaroud dextrose and artificial saliva for testing candida albicans, Broth heart infusion and artificial saliva for E. faecalis and Broth heart infusion and artificial saliva for streptococcus mutans respectively. Each microorganism is then inoculated into their respective culture media and incubated for 18 hours at 37°C. cells along with the samples are then harvested and washed three times in pbs (phosphate buffered saline). The samples are then taken and suspended in the fresh broth medium. and the test species with the test samples are incubated at 37°C for 24 hours. After 24 hours the test tubes containing the microorganism are vortex until the microorganisms are diffused in the medium. The broth is discarded and the samples are again rinsed in pbs (phosphate buffered saline) for three times.

Each sample is then suspended separately in 0.1% Crystal Violet solution and let it stand for 15 mins. The crystal violet solution is then discarded and samples are rinsed in pbs (phosphate buffered saline) for three times. The samples are then dried. after drying the samples are now de-stained using 33% acetic acid (Figure 3). The de-stained solution is then transferred to the ELISA Plate. The absorbance of the de-stained solution Is read at 540 A in ELISA reader. (Figure 4)

Discussion

Dental plaque and biofilm formation on the surface of different dental alloys whether it is a polished surface or and rough surface is s being a major and prime etiologic factor for various dental diseases like dentinal caries and periodontitis\textsuperscript{2,3,6-8}. Colonization of this various bacteria and the initial biofilm formation and then maturation of the plaque starts as soon as this dental material come in contact with oral environment\textsuperscript{9,10,11}. The early plaque formation or acquired pellicle on any surface area mainly contents of various salivary proteins and bacterial enzymes. The process of adhesion begins with a process of interaction of the various bacteria with the salivary proteins at a distance. Also the electrostatic repulsive forces along with van-der-waals attractive forces helps in initial adhesion of the microorganism to the surface\textsuperscript{5,11}. Nickel chromium, cobalt chromium and titanium are the material of choice in doing most of the prosthetic rehabilitation. This material is used in prosthodontics starting from simple cast partial denture to the titanium used for implant supported prosthesis. Their strength, biocompatibility and their ability to form a good bond with the oral environment have kept them in market since ages. Even though research is being carried out on numerous other material like zirconium, ceramic, poly-ether-ether-ketone etc. still these materials are not able to replace the titanium and other dental alloys due to their disadvantages\textsuperscript{13-15}. In the following study conducted we have chosen nickel chromium, cobalt chromium and titanium to check the adherence of various bacteria and fungi species and to evaluate their antibacterial and antifungal activity. In the following study conducted we have chosen nickel chromium, cobalt chromium and titanium to check the adherence of various bacteria and fungi species and to evaluate their antibacterial and antifungal activity. Numerous study was done on nickel chromium alloy for its cause as an allergic reactant. The result showed that the allergic reaction was due to the beryllium content. Hence for this study we have used a beryllium free nickel chromium alloy\textsuperscript{13-15}. Implanted supported prosthesis are a boon to dentistry and implants are replacing various other options of prosthetic treatment whether it is complete denture or removable or fixed dental prosthesis. Among this various factors plaque formation around implants and bacterial adhesion over implant surface has lead it to marginal bone loss around implant. If not treated it further lead to peri-implantitis and thus implant failure\textsuperscript{2,15}. Riley and Meein 1982 examined the activity of bacteroides species against similar metal. The study was conducted on Comparison between activities of cobalt, nickel, mercuric and chromium chlorides these samples were tested against all the microorganisms and it was seen that all the test showed similar activities\textsuperscript{14}. In the present invitro study done may be of clinical importance as the adherence of candida albicans, E. Faecalis, Streptococcus mutans tested on titanium alloy samples showed a statistically significant lower values of adherence when comparison was done between nickel chromium and cobalt chromium alloy samples. This might be stated that titanium has an inhibitory effect on various different microorganisms\textsuperscript{16}. Also a three-year study done by Adell et al 1986 on titanium abutment and teeth gave the result that the microflora appearing on the titanium abutment were different from the microflora appearing on the human dentition. They concluded as surface energy and its characteristics of the titanium dental alloy may influence the accumulation of the oral microflora. In the following study conducted comparison of titanium dental alloy with different dental alloys was done. The comparison wherein the result showed a statistical significant values\textsuperscript{17}. Our present study mimics the oral environmental condition such as oral microorganism and saliva. Also the factors which influence the bacterial adhesion to the surface such as culture medium used, condition of the culture, culture of the species of microorganism, incubation time, environment of the culture medium after inoculation and the growth of the microorganism were also considered. The result of this study showed interaction between the nature of the microorganisms studied, the culture medium i.e. artificial saliva and broth medium (sda broth and bhi broth) and the dental alloy. The role of each microorganism in the oral environment plays a major role whether to create the oral environment into the disease state or maintain the oral environment into biologically healthy state when any restorative material is suspended into this environment. Considering E. Faecalis in particular, this microorganism plays a major role in peri apical lesion or apical periodontitis. previous studies have shown that E. Faecalis enters the root canal space via the dentinal tubules which may also lead to infection of the root canal space. This Studies have also contributed in stating that these species can also spread infection to the treated root canal teeth at the apical region of root.
From the prosthodontic point of view it is an important consideration applied while restorative the prosthesis from crown and bridge, as this microorganism have the ability to enter via dentinal tubules. The prosthetic part replaced in the oral cavity should have all the ability to resist the adherence of such species. Present study showed the effect of adherence of E. faecalis on titanium, nickel chromium and cobalt chromium in two different medium. The result showed a statistically significant value when all the three factors were considered the least adherence of E. faecalis were seen with titanium alloy followed by cobalt chromium alloy. Whereas the highest adherence value was seen nickel chromium alloy. Considering the nickel chromium and cobalt chromium there was no statistical significant relation was seen. Hence titanium alloy can be considered as a metal of choice for fabrication of restorative materials like custom made post or copings fabricated for single crown and fixed dental prosthesis.

Antimicrobial activity of various metals have been studied with different species of microorganisms. One of the study done by Hwang et al to see the antimicrobial activity on orthodontics appliances showed a positive result on S. mutans bacteria. Streptococcus mutans is involved and designated to form decay. When silver ion were studied with streptococcus mutans the result showed that the adherence of S. mutans was very less also the silver ion showed an antimicrobial effect on this species. In the following study the same effect has been studied to see the antibacterial effect of Streptococcus mutans on titanium, nickel chromium and cobalt chromium dental alloy. There was stastical significant result was seen of the adherence of the S. mutans on the dental alloys being studied. When comparision was done least adherence value was seen with respect to titanium alloy followed by nickel chromium. The highest value of adherence was seen with the cobalt chromium alloy. This indicates that there may be more antibacterial effect seen by titanium alloy followed by nickel chromium and cobalt chromium alloy.

Formation of dental plaque is a multifactorial facet. With initialization of biofilm formation on tooth surface and the restorative surface of the dental alloys used in fabrication of these prosthesis. The present study result showed a statistical significant value of adherence of the microorganism to the dental alloys, irrespective of the surface of the dental alloys being polished or not polished.

### Conclusion

The results of the present study showed that microbial adherence is seen least with titanium alloy compared to nickel chromium and cobalt chromium alloy.

- Estimating the metal as a factor adherence was more for cobalt chromium alloy flowed by nickel chromium alloy and least for titanium alloy.
- Estimating the microorganism as a factor least adherence was seen with candida albicans and highest adherence was seen for Streptococcus mutans followed by E. faecalis.
- Estimating the medium as a factor highest value of microorganism was seen in saliva medium compared to broth medium.

Within the limitation of this study it can be concluded that the antibacterial and antifungal effect seen with titanium alloy was more compared to nickel chromium alloy and cobalt chromium alloy.

Quality of Life and Quality of Sleep among Post CABG Patients

Ambina K.¹, Shalimol U.S.², Anjana A.P.³

¹Second Year M.Sc. Nursing Student, ²Asst. Professor, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi, India

Abstract

Introduction: Coronary artery bypass grafting (CABG) surgery is one among the most common procedures performed in the world, and it is one of the possible treatments for coronary artery disease (CAD). A study to assess the quality of life and quality of sleep among post coronary artery bypass grafting (CABG) patients was done in Amrita Institute of Medical Science, Kochi. Objectives of the study were to (1) identify quality of life among post CABG patients (2) identify the quality of sleep among post CABG patients (3) find out the correlation between quality of life and quality of sleep among post CABG patients (4) Find the association between quality of life and selected demographic variables among post CABG patients (5) Find the association between quality of sleep and selected demographic variables among post CABG patients.

Methodology: A quantitative approach with a descriptive correlational design using a non-probability convenience sampling technique was used to collect data from 101 post CABG patients. The setting used for the study was CVTS OPDs at AIMS, Kochi. A standardized quality of life questionnaire and quality of sleep (Pittsburgh sleep quality index) tool was used for the assessment along with a semi-structured questionnaire to assess socio-demographic and clinical data.

Results: The study result showed that the majority of samples (97%) had good QOL with mean score of 69.22. PCS (96%) showed higher value than MCS (68.3%). Considering sleep 61.4% expressed good quality of sleep. There was a significant weak negative correlation between QOL and quality of sleep (r = -0.246). Hence as QOL increases and quality of sleep increases. Also a significant association found between QOL and socio-demographic variables like occupation (p=0.018), association between sleep and socio demographic variables like occupation (p=0.05).

Conclusion: Overall QOL and quality of sleep improved after CABG.

Keywords: Quality of life, Quality of sleep, CABG.

Introduction

Coronary artery bypass grafting (CABG) is an established and highly effective therapy for coronary artery disease. CABG has been effective than the medical therapy, for the relief of angina pectoris(1).

The first coronary artery bypass operation in human being was using a saphenous vein graft and coronary artery anastomosis was performed in November 1964 by Garrett and Debakky(2). In spite of general decline worldwide, off-pump coronary artery bypass grafting (CABG) surgery is performed in more than 60% of patients undergoing CABG in India; mainly because of shorter operative time and reduced procedure cost(3).

Sleep is considered as an altered state of consciousness in which the individual’s perception and reaction to the environment are decreased. Normal sleep required for an adult is 6-8 hours. The person having coronary artery disease may show sleep disturbances.
This cause changes in quality of life, behavioural pattern, loss of appetite and mood changes. The common sleep disorders identified among post CABG patients are insomnia, sleep apnoea, circadian rhythm, sleep disorders, restless leg syndrome, sleep disorders secondary to medical and surgical disorders.

Pain, stress, anxiety, and sleep disorders are common after surgery. All of these factors can compromise treatment and quality of life following surgery. Evidence indicate that patient’s quality of sleep after heart surgery is frequently poor, particularly during the postoperative period and that patients experience high level of sleep disruption, irregular sleep cycles, and reductions in slow wave sleep.

Although the effectiveness of coronary artery bypass grafting (CABG) is being evaluated in terms of mortality, complications or recurrence of symptoms, empirical studies assessing the change in patients quality of life (QOL) after CABG need to be studied as findings keep changing as time progress. A systematic analysis of how well the patient is considering a multiple variable need to be studied which has greater impact in improving the overall performance of the patients after CABG.

Behrouz far, Nezafati (2009) conducted a descriptive study to assess the relationship between sleep patterns and the quality of life in CABG patients at Iran. 91 patients selected for the study, Samples were selected in three phases 24 hours before surgery, as well as 6 and 10 weeks after surgery. Interview checklists were used for data collection. Three scales were used, Pittsburgh sleep quality index, Epworth sleepiness scale and sleep log and quality of life was measured with 36 short forms. The first two interviews were done at the hospital clinic and the last through telephone. The result showed that mean score of sleep in all three stages were normal and mean score of quality of life was in the mid one-third of 0-100 scale. No significant differences were found between on-pump and off pump groups in their sleep patterns and quality of life. All three stages, sleep quality positively and significantly correlated with quality of life p< 0.001, p=0.002 and p=0.004 respectively. The significant positive correlation existed between sleep efficiency and quality of life p< 0.001, p=0.002 and p=0.005 respectively. Finally, the researcher concluded that a significant and positive correlation between sleep pattern and quality of life in CABG patients.

Material and Method
Quantitative research approach with descriptive correlational design was used to identify the QOL and sleep among post CABG patients. The study was conducted among 101 post CABG patients after one year of surgery and coming for follow up in CVTS OPDs of Amrita Institute of Medical science, Kochi. The subjects were selected by non-probability convenience sampling technique. The data were collected using semi-structured questionnaire to assess the socio-demographic characteristics, SF-36 standardized tool to assess the quality of life of post CABG patients and PSQI standardized tool to assess the quality of sleep of post CABG patients. The content validity was obtained from 7 experts. The tool was found to be valid. Informed written consent was obtained from the samples after explaining the purpose of the study. Data was collected in CVTS OPD. Anonymity and confidentiality of samples were maintained. A pilot study was conducted among 10 samples who met the eligibility criteria. It was found that the research design was appropriate, research tools were valid and reliable and the study was amendable to statistical analysis. The data was analyzed using descriptive and inferential statistics.

Results
Section I: Description of sample characteristics:
In this study the majority of sample 65(64.4%) were under the age group of 61-70 years. In gender, majority of sample were male 92 (91.1%). Most of the sample 58(57.4%) were married & 46 (45.5%)were having high school education. The data illustrated that most of the samples were unemployed, retired 27(26.7%) and 25(24.8%) were private employed. When considering the food habits most of the 80(79.2%) sample were non vegetarian. The majority 92(91.1%) of the sample were belongs to nuclear family. Among 101 samples the common types of surgery were OFF pump 85(84.2%). Consider the indications of surgery majority were having triple vessel disease 76(75.3%) and were having normal EF 78(77.2%). Regarding smoking habit majority of the samples were ex-smoker 65(64.4%) and 62(61.4%) were ex alcoholic. Among the samples 95(94.1%) had normal BMI. Considering the complications majority 60(59.4%) were had no complications after CABG. Considering the hours of sleep per day most of them had 6-8 hours of sleep.

Section V: Association between quality of life and selected demographic variables: The association between QOL and selected demographic variables like age, gender, marital status, education, income, diet pattern and type of family were not statistically significant with p value of 0.05 level. Whereas occupation showed statistically significant (0.05).

Discussion

The first objective was to identify the quality of life among post coronary artery bypass grafting patients: The results from the present study showed that overall quality of life of post CABG patients 97% had good quality of life with mean score of 69.22 and standard deviation 9.368. Considering the physical component summary 96% samples had good quality of life with mean score 77.98, and mental component summary 68.3% samples had good quality of life with mean score 57.07. That means PCS higher than MCS.

The similar findings were observed in a descriptive study conducted by Anastasios Merkouris, Dimitrios Pistalos to assess the QOL after CABG patients at Greece in 2008. The findings showed that the overall QOL of patients was improved, good level of QOL with an average score of 80.4.\(^{(8)}\)
The present study findings are contradictory to a study findings done by Lee GA conducted a cohort study to assess the patients reported health related quality of life five years post CABG at Australia in the year 2008. The findings showed that good level of QOL with an average score of 66.02%. MCS (53.6) was higher than PCS (45.8). PCS had poor QOL and MCS had good QOL(9).

The second objective was to identify the quality of sleep among post coronary artery bypass grafting patients: The results from the present study showed that good quality of sleep was observed in 61.4% and 38.6% had poor quality of sleep with a mean score 5.02.

Hikmet Yilmaz, Ihsan Iskesen conducted a descriptive study to assess the Sleep Characteristics of Patients After Cardiac Surgery at Turkey in 2015. The finding showed that immediate post-operative period sleep quality was poor, after 6 weeks that improve the sleep after CABG(10).

The third objective was to find the correlation between the quality of life and quality of sleep among post Coronary Artery Bypass Grafting patients: The present study result found that there is a significant weak negative correlation (r=-0.246) between QOL and quality of sleep. Thus referred as the quality of life increases with increase quality of sleep. Negative correlation means quality of life increases quality of sleep decreases, but in this study quality of sleep questionnaire (PSQI) had reverse scoring, that means lowest score of sleep indicate good quality of sleep and highest score of sleep indicate poor quality of sleep. Majority of the samples had lowest score, that shows that good quality of sleep.

The above findings were supported by the quantitative descriptive study conducted by Ulla.M. Edell, Jerker to assess the sleep and QOL among post CABG patients at Sweden in 2000. The study include 38 male patients aged 45-68 underwent CABG. The Nottingham Health Profile (NHP) instrument demonstrated that 6 months after surgery the QOL was significantly improved. The findings showed that improve the sleep one month after CABG(11).

The forth objective was to find the association between the quality of life and with selected socio demographic variables

Taghipour H.R conducted a descriptive study to assess the QOL one year after CABG at Iran in 2011. The result showed that mean age of patients was 61.4, most of them were males. On pump surgery had better general health than off pump surgery 47.9 (p=0.024). Negatively correlated with EF r=-0.220. Chi-square value is 0.19(12).

Conclusion

Overall quality of life and quality of sleep improved one year after CABG. Majority of the samples expressed more physical wellbeing than of emotional wellbeing hence forth, there is an alarming need to give a holistic care for patients.

Effectiveness of Sublingual Versus Oral Misoprostol for Induction of Labour at Term

Rekha Parimkayala\textsuperscript{1}, Shraddha Shetty K.\textsuperscript{2}

\textsuperscript{1}Registrar, Department of Obstetrics & Gynecology, Rainbow Hospitals, Currency Nagar, Vijayawada, Andhra Pradesh, \textsuperscript{2}Associate Professor, Department of Obstetrics & Gynecology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Karnataka, India

Abstract

Objective: To compare the efficacy and safety of 50 microgram (\(\mu\)g) sublingual Misoprostol with 50 microgram (\(\mu\)g) oral misoprostol for labour induction at term.

Method: One hundred twenty women with medical or obstetric indication for induction of labour at term with unfavorable cervix were randomized to receive 50mcg of misoprostol either orally or sublingually. Primary outcome was number of women delivering vaginally within 24hrs of induction. The need for oxytocin, mode of delivery, doses of Misoprostol required and neonatal outcomes were analyzed and compared between the groups.

Results: Induction to vaginal delivery time was < 24hours in 43(71.7\%) in sublingual group and 36(60\%) women delivered vaginally in < 24hours in oral group. No significant difference was found in the number of women delivering vaginally within 24hrs of induction among both the groups. Time from administration of first dose to delivery in sublingual group was lesser compared to oral group. 46.7\% of women required oxytocin in sublingual groups, whereas 75\% in oral group which was statistically significant. Sublingual group had lesser number of women requiring more than 1 dose of misoprostol compared to the oral group.

Conclusion: Sublingual misoprostol seems to be having better efficacy than the oral misoprostol and has lesser induction to delivery interval. Hence can be considered to induce labour at term for ripening of cervix.

Keywords: Sublingual administration; oral administration; misoprostol; induction; labour.

Introduction

“Induction of labor is defined as intervention designed artificially to initiate uterine contractions leading to progressive dilatation and effacement of the cervix and birth of the baby”.\textsuperscript{(1)} Induction is indicated when the mother and fetus are benefited with higher chance of healthy outcome than the birth being delayed. \textsuperscript{(1)} Misoprostol is commonly used for induction of labor as it is stable at room temperature and has rapid onset of action. It can be administered in oral, sublingual or rectal routes. The efficacy of misoprostol varies with different routes of administration due to change in their pharmacokinetics. Sublingual route has better efficacy compared to other routes as it bypasses enterohepatic circulation and has lesser hyperstimulation rates.\textsuperscript{(2)} The objectives of the study were to compare the efficacy of 50microgram of sublingual Misoprostol with 50microgram of oral misoprostol for labor induction at term, number of women delivering vaginally within 24 hours of the induction, induction to delivery interval and adverse effects and neonatal outcomes in two groups.

Method

This hospital based non blinded randomized comparative study was conducted in the Department of Obstetrics and Gynecology department in a medical college in Karnataka over a period of one year six months between September 2014 and March 2016 after approval from the Institutional Ethical Committee of Kasturba Medical College, Manipal University, Mangalore. Informed and written consent was obtained from the women on a predesigned consent form.

Statistical Analysis: Sample size was taken as 120 women with term gestation with indications for labor induction 60 in each group. Fisher’s exact test and chi square test were applied for the statistical analysis. A statistical package SPSS version 17.0 is used to do statistical analysis. P value < 0.05 is considered to be significant.

Women were admitted in the hospital after satisfying the inclusion criteria. Demographic details such as age, height, weight, parity, gestational age and amniotic fluid index (AFI) and indication for induction were noted. They were randomized to receive either 50 mcg of sublingual (Group A) or 50 mcg of oral misoprostol (Group B) every 4th hourly till a maximum of three doses. A pelvic examination was done to assess the Bishop’s score which was followed by a 20 minute Non stress test (NST) to rule out non-reactive fetal heart rate. Fetal and maternal monitoring was done by clinical auscultation of fetal heart rate and monitoring uterine contractions. Vaginal examination was done every 4 hours to assess Bishop’s score. The dose was repeated every 4 hours, a maximum of 3 doses were given. No significant difference was found between the two groups. Most of the participants were in the age group of 18-26 years i.e. 45 (75%) and 37(61.2%) in Group A and Group B respectively. Most of the patients were nulliparous accounting to 80% in sublingual group and 70% in oral group. Induction to vaginal delivery time was < 24 hours in 43(71.7%) in sublingual group and 36(60%) women delivered vaginally in < 24 hours in oral group. No significant difference was found in the number of women delivering vaginally within 24hrs of induction among both the groups (Table 2). Time from administration of first dose to delivery in sublingual group was 11hrs 16min with standard deviation of 4hrs 15min, while in oral group the mean time from induction to delivery was 15hrs 15min with standard deviation of 6hrs 30min and was found to be statistically significant. These observations suggest that there was increased induction to delivery interval when misoprostol was used by oral route compared to sublingual route (Table 3).

Inclusion criteria were women in the age group between 18-35 years, live singleton pregnancy at term gestation (gestational age of > 37 weeks) with medical or obstetric indication for induction, cephalic presentation, unfavorable cervix (Bishop’s score ≤ 6) and reassuring fetal heart tracing. Exclusion criteria were cephalopelvic disproportion, history of caesarean section or any uterine surgery, multiple gestations, malpresentation, hypersensitivity reactions for prostaglandins, contra indications for prostaglandins usage (e.g. Asthma) and parity > 4.

The Primary outcome studied were number of women delivering vaginally within 24 hours. The Secondary outcome analyzed include time interval between induction to vaginal delivery, number of misoprostol doses required, patients requiring oxytocin augmentation, failed inductions, number of caesarean section, neonatal outcomes-meconium stained amniotic fluid, non reassuring fetal heart status, Apgar score at 1 and 5 min and NICU admissions and side effects like uterine hyperstimulation, gastrointestinal disturbances and pyrexia.

Results

A total number of 120 women with term pregnancy were included and 60 women were assigned to receive a 50 mcg sublingual misoprostol and 60 women are assigned to receive a 50 mcg oral misoprostol.

Table 1 shows the indication of labor in both the study groups. Main indications for labor induction were postdatism and premature rupture of membranes. No significant difference were found between the two groups. Most of the participants were in the age group of 18-26 years i.e. 45 (75%) and 37(61.2%) in Group A and Group B respectively. Most of the patients were nulliparous accounting to 80% in sublingual group and 70% in oral group. Induction to vaginal delivery time was < 24 hours in 43(71.7%) in sublingual group and 36(60%) women delivered vaginally in < 24 hours in oral group. No significant difference was found in the number of women delivering vaginally within 24hrs of induction among both the groups (Table 2). Time from administration of first dose to delivery in sublingual group was 11hrs 16min with standard deviation of 4hrs 15min, while in oral group the mean time from induction to delivery was 15hrs 15min with standard deviation of 6hrs 30min and was found to be statistically significant. These observations suggest that there was increased induction to delivery interval when misoprostol was used by oral route compared to sublingual route (Table 3).

In sublingual group, 45 (75%) required a single dose of Misoprostol for labor induction compared to 31 (51.7%) in oral group. In oral group, 29(48.3%) of the women required more than 1 dose of misoprostol compared to the sublingual group with p value of 0.029 which was statistically significant. In sublingual group, 53.3% of women did not need oxytocin for augmentation...
of labor where as in Oral group, 75% of women required oxytocin (Table 4).

In sublingual groups, failed induction was observed in 8(13.3%), where as in oral group it was 9 (15 %) and the result was not statistically significant. Number of women delivered vaginally was 44 (73.3%) in sublingual group and 40 (66.7%) in oral group. Cesarean delivery was 26.7% in sublingual group and 33.3% in oral group with a p value of 0.426 which was not statistically significant.

Most common indication for Cesarean delivery was failed induction in 8 (50%) in sublingual and 9 (45%) in oral group which was not statistically significant. Other indications were meconium stained amniotic fluid, non reassuring fetal heart status and secondary arrest of descent. Table 5 compared the neonatal outcome in both the groups. Meconium stained amniotic fluid, non reassuring fetal heart status, meconium stained amniotic fluid, non reassuring fetal heart status, low APGAR scores and NICU admissions were the neonatal outcomes and there were no statistical significance found among the two groups.

The most common side effects among both the groups were GI disturbances in 2(3.3%) sublingual and 6(10%) in oral group and pyrexia in 1(1.6%) sublingual and 3(5%) in oral group which was not statistically significant. There was no hyperstimulation noted in any of the cases in both the groups.

### Discussion

The present study was a prospective study designed to study the effectiveness of the sublingual and oral misoprostol for term induction of labor. Post-datism and PROM were the most common indications for induction. Similar indications for induction of labor were noted in other studies.\(^{(3-5)}\)

Forty three (71.6%) women delivered vaginally within 24hours of induction with sublingual misoprostol compared to 36 (60%) women in oral group. According to the study conducted by Bartusevicius and colleagues, there was no statistical difference noted among women delivering vaginally within 24hours of induction with 50 mcg of sublingual misoprostol or 25 mg of vaginal misoprostol. 58 women (83%) in the sublingual group and 53(76%) in the vaginal group delivered vaginally within 24 hours.\(^{(4)}\)
In the present study, time from administration of first dose to delivery in sublingual group was 11hrs 16min, in oral group the mean time from induction to delivery was 15hrs 15min and was found to be statistically significant. These results suggested that induction to delivery interval was increased when misoprostol was used by oral route compared to sublingual route. Similar results were observed in other studies.(4,5) Humaira Zaman Malik and colleagues compared 100 µg oral misoprostol with 50 µg sublingual misoprostol for induction of labor, they observed that 92% women delivered within 12 hours of induction in sublingual group and 84% of women in oral group.(6) In sublingual group, 45 (75%) required a single dose of Misoprostol for labor induction compared to 31 (51.7%) in oral group. In oral group, 29 (48.3%) of the women required more than 1 dose of misoprostol compared to the sublingual group. In sublingual group, 53.3% of women did not need oxytocin for augmentation of labor where as in Oral group, 75% of women required oxytocin. These results were comparable to other studies.(4–7)

In sublingual groups, failed induction was observed in 8(13.3%), where as in oral group it was 9 (15 %) and the result was not statistically significant however in H.Z.Malik study, there were no cases of failed induction in both the groups.(6) Number of women delivered vaginally was 44 (73.3%) in sublingual group and 40 (66.7%) in oral group. Cesarean delivery was 26.7% in sublingual group and 33.3% in oral group with a p value of 0.426 which was not statistically significant whereas Bartusevicius and colleagues observed in their study, that there were no difference in the mode of delivery among both the groups. Seven(10%) in the sublingual group and 8(11%) in the vaginal group underwent emergency cesarean section for non reassuring fetal heart status.(4) In a study conducted at Mashhad University of Medical Sciences, where 25 µg vaginal misoprostol was compared with 25 µg sublingual misoprostol for induction of labor, women underwent cesarean section due to non establishment of active labour.(8)

The most common side effects among both the groups were GI disturbances in 2(3.3%) sublingual and 6(10%) in oral group and Pyrexia in 1(1.6%) sublingual and 3(5%) in oral group which was not statistically significant. There was no hyperstimulation noted in any of the cases in both the groups. In a study done by Sedigheh A and coworkers, Tachysystole, vomiting and abdominal pain were the common side effects in both the groups. Abdominal pain and vomiting were more in sublingual group than vaginal group.(9)

Meconium stained amniotic fluid, non reassuring feta heart status, low APGAR scores and NICU admissions were the neonatal outcomes and there were no statistical significance found among the two groups. Similar results were noted in other studies.(5,6,10,11) According to Bartusevicius and colleagues, neonates were admitted in NICU for neonatal respiratory distress syndrome in the sublingual group and congenital infection and neonatal respiratory distress syndrome in the vaginal group.(4)

Conclusion

Sublingual misoprostol has better efficacy than the oral misoprostol and has shorter induction to delivery interval. It can be considered for ripening of cervix before induction of labor in high risk conditions and prolonged pregnancies.

Abstract

Introduction: Risk factors for spread of Tuberculosis such as overcrowding and unhygienic environment, poverty and social taboos are more prevalent in urban slums. Hence, to assess awareness about TB in slum community becomes important in program planning as awareness plays vital role for Tuberculosis prevention and control.

Objectives: To study the knowledge and awareness about Tuberculosis among urban slum dwellers.

Methodology: This community based cross-sectional study was conducted in four urban slums of Wardha district, Maharashtra during three months (January-March 2019). We visited house to house in the slum areas; and dwellers available at home and willing to share their knowledge on TB were involved. Total 169 people were interviewed with the help of pre-structured questionnaire which includes awareness about symptoms, mode of spread, prevention, and treatment of TB.

Result: Among 169 dwellers, 111(65.68%) were male and 58(34.32%) were female. About 20(11.83%) respondents never heard about TB. Those 149(88.17%) who heard about TB; for 87(51.48%) dwellers, commonest source of information was friends and family, followed by mass media. Most of them, 132(78.11%) knew that TB spreads through air inhalation of droplet. Cough is a main symptom of TB was informed by 128(75.74%) respondent whereas 56(33.14%) replied for fever >2 weeks. Notably, 150(88.76%) participants indicated that government PHC/CHC/District Hospital is the place for management, whereas 37(21.89%) responded towards private practitioners. Awareness level was significantly high among male than female and among literate than illiterate.

Conclusion: Slum dwellers are vulnerable to get infected with TB or converted to disease status. Although awareness level for TB was found to be relatively satisfactory among the most of the slum dwellers, it was not absolute. There is scope to increase knowledge by conducting awareness activities or augmenting community visits by health workers in slum areas. This will increase the knowledge of habitat female group and illiterate which was observed to be significantly less satisfactory.

Keywords: Tuberculosis (TB), Awareness, Urban Slum community

Introduction

Tuberculosis is an ancient disease, and drugs are discovered so long back, still we are struggling to eliminate it. As per Global TB report of 2015, its incidence has dropped by an average of 1.5% per year since 2000, and effective diagnosis and treatment of TB
In 2015, worldwide incidence of TB cases was 104 lakh and; in India, it was 28 lakh. India accounts for highest number of mortality; global mortality due to TB in 2015 was 14 lakh; whereas in India, it was 4.8 lakh. As per Global TB report 2016, the highest burden of both TB and MDR TB was estimated in India. its incidence in India was about one fourth of the global burden. Globally, in 2017, 10.0 million people developed this disease, where India contributed incidence about 27%.

The Global Plan to Stop TB; first in 2001–2005 and the second in 2006–2015 were an important step in achieving the ultimate goal of ‘Elimination of TB by 2050’ i.e. one case per million. The Stop TB Strategy acts as a framework to channel national program for effective control. TB program strategy seeks to strengthen health systems (infrastructure), capacity building of health workforce, engage all care providers (Private stream and NGO), promote research and funding; and empower people with TB and communities.

Tuberculosis is more prevalent in marginalized community such as urban slums or tribal regions. Risk factors for spread of TB such as overcrowding, unhygienic environment, poverty; along with social taboos are more prevalent in urban slums. TB spread can be prevented, if community knows about its mode of spreading. TB can be easily controlled if people are able to recognize at least common symptoms. National health programs playing vital role in prevention and control of TB, however community awareness for basic knowledge on TB such as mode of spread, symptoms, progress and treatment availability is equally important to accelerate the programs goals. Hence, we planned to assess awareness about Tuberculosis in slum community.

Objective: To assess the knowledge and awareness about Tuberculosis among the urban slum dwellers.

Methodology: Study Design and settings: This community based cross-sectional study was conducted in urban slum of Wardha district, Maharashtra during three months (January-March 2019). Four slum areas beside railway station and track (Tarfail, Fulfail, Station Fail, and Itwara) was covered.

Study Participants: Participants were adult above 20 years of age & residents of slum area.

Sample Size and Sampling Technique: There were total 226 houses in these slum pockets and was decided for complete enumeration. Visited house to house in these slum area, and collected the information from adult (>20 years) resident who were available at home and willing to share their knowledge on TB. Total 169 adults shared information on TB in these slum areas, whereas others refused to talk on TB.

Data Collection Tools and Technique: Participants were interviewed with the help of pre-structured questionnaire after informed consent. This tool included questions on awareness about mode of spread, symptoms, prevention, and treatment of TB.

Results

Out of 169 participants, male respondents were 110 (65.09%) and female were 59(34.91%), whose mean age was observed to be 43.27 (+14.37 SD) and 41.44 years (+17.21 SD) respectively. About 85.21% interviewed dwellers were literate and 82.84% were married.

About 128 (75.74%) of the interviewed dwellers were aware about cough more than 2 weeks as a symptom suggestive of TB and 56 (33.14%) response obtained for fever more than 2 weeks.

Cough more than 2 weeks is a main symptom of TB was informed by 128 (75.74%) participants whereas 56 (33.14%) replied for fever more than 2 weeks. 28 (16.57%) dwellers didn’t respond for this question.

Among the participants, 132 (78.11%) responded for air inhalation of droplet nuclei as a mode of spreading Tuberculosis.

Table 4: Knowledge about Tuberculosis among urban slums dwellers

</table>

Most of the participants 137 (81.07%) knew that TB spread from one person to another and 124 (73.37%) knew that TB can be prevented whereas 145 (85.80%) pointed that TB is treatable disease. Very few dwellers 51 (30.18%) were having Knowledge that TB can involve any other organ than lungs.

Fig. 1: Place for the diagnosis and treatment for TB available (multiple responses allow)
Notably, 150(88.76%) participants indicated that government PHC/CHC/District Hospital is the place for diagnosis and treatment followed by 37(21.89%) responded towards private practitioners. Very few participants 05 (2.96%) were recognized medical colleges accessible place for TB management.

Association of gender and education status with overall TB awareness level: We assessed the awareness level of participants by scoring the six important questions such as i) Symptoms suggestive of TB, ii) Does TB spread from one person to another? iii) Mode of spreading, iv) Does TB involve any other organ than lungs? v) Does TB can be prevented and vi) Is TB treatable?

Total score is six for correct response. We considered, if score is ≥4 then awareness is satisfactory and ≤3 then unsatisfactory. It is observed that out of 110 male, 91 (82.73%) were having satisfactory awareness and out of 59 female, 40 (67.80%) were having satisfactory awareness. This Gender wise difference i.e. male were more aware about Tuberculosis was observed to be statistically significant. Awareness level was observed high among literate dwellers than illiterate and this difference was observed to be statistically significant.

Discussion

Main source of information in studied urban slums was family and friends, similar findings were observed in Mysore slum dwellers by Archana Basavaraju, et al. Another common source of information for these studied community was media which includes Television [News & advertisement], Radio and newspaper.

Health workforce can provide proper and definite information about TB. This present study observed that doctors and health workers contributed very less (only 15%) as a source of information, which can be increased by interaction between slum dwellers and health staff. Other studies conducted in India observed near about similar proportion of health professionals as a source of information.

In present study, participants identified cough more than two weeks as predominant symptom suggestive of TB followed by fever and then weight loss; whereas study conducted in Surat by Hetvi Mahida, et al, fever was recognized by participants as the most common symptom, followed by weight loss and then cough.

Gender wise difference was observed. In present study setting, satisfactory level of knowledge and awareness about TB was observed significantly more among male than female. When same determinant was studied in Pondicherry by Palanivel Chinnakali, et al similar gender wise awareness level difference was observed whereas, in Mysore, no such significant difference was observed.

Proportionately low literacy level was found among slum dwellers for higher secondary and above education. Overall TB awareness level was significantly satisfactory among the literate and same findings were noted in Mysore and Pondicherry slums. Literacy improves the knowledge as well as quality of life. Hence, awareness level can be increased in slum area by improving the education facilities and motivating the community for literacy. Female literacy can be promoted to increase the awareness level, so that gender wise gap of knowledge which was observed extensively can be abridged. Various IEC campaign and health awareness program were conducted in different part of India and has provided evidence for increase in knowledge among the beneficiaries.

When we compared the findings of present study (Wardha, Maharashtra) and some of the studies in Chhattisgarh, Mysore, Surat and Pondicherry among the slum dwellers, it is noted that more than 80% community from all these settings were aware that TB spread from one to another person. However, satisfactory proportions (91%) of slum dweller of Mysore were acknowledged about mode of spread as compare to the other study areas, including the present study. About half of the participants were aware about correct mode of TB spread in Surat. Awareness about TB prevention and treatment was observed to be satisfactory among slum community in Wardha, Chhattisgarh and Puducherry as compare to Mysore.

Pulmonary involvement is the most common mode of tuberculosis infection. Studied slum community was quiet sensitive about respiratory illness due to TB; however there is need to improve the awareness level about involvement of any other organ than lungs due to TB which is observed among very few participants.

Different types of Government health facilities such as Primary Health Center, Rural Hospital, Sub-district
Hospital and District Hospital were recognized as places for diagnosis and treatment of TB. This indicates that slum community was responsive towards the public health facilities and identified it as an approachable sector for TB. It is noted that about 50%-80% of the TB patients access the private health facilities for TB treatment.[14,15] Private sector was recognized by very less proportion of studied population, though it can equally contribute in TB management through Public Private Partnership.

Conclusion

Knowledge and perception regarding a TB help these slum dwellers as well as the patients in taking right help at the right time which direct them to take preventive and control measures. In present study, although the level of knowledge was found to be relatively satisfactory, it was not absolute. Very few dwellers responded for Health stakeholders (doctors and health workers) as a source of information.

Slum dwellers are vulnerable to get infected with TB or converted to disease status owing to their lifestyle, socioeconomic and environmental conditions. There is scope to increase knowledge by conducting awareness activity or augmenting community visits by health workers in slum areas, which will again helpful to increase knowledge of habitat female group and illiterate which was observed to be significantly less satisfactory than male and literate respectively.

Abstract

Dengue virus infection is being recognised to manifest with various systemic impairments. WHO has coined ‘EXPANDED DENGUE’ to denote such complications and atypical presentations. Here we present a case of Dengue who presented with PUO, bleeding, pain abdomen, vomiting and itching. She was noted to have fever, tachycardia, anaemia, thrombocytopenia, deranged liver function, acute pancreatitis, urinary abnormalities, rhinorrhea and pruritus. Her hospitalisation period was a stormy one posing both diagnostic and therapeutic problem. While recovering she exhibited neutropenia suggesting concomitant Evans syndrome. The different haematological and biochemical parameters also mimic that of HELLP syndrome.

Introduction

Dengue fever caused by Dengue virus 1-4 presents with an initial febrile phase of 3-5 days which is followed by a critical phase of 1-2 days and a recovery phase of 2-3 days duration unless complications arise. WHO in 2009 classified the infection as dengue without warning sign, with warning signs and severe dengue. Latter refers to cases with significant bleeding(dengue haemorrhagic fever), compensated or profound shock(dengue shock syndrome). It also includes patients with expanded dengue syndrome a term coined by WHO in 2012 to include all such complications and atypical presentations involving nervous system, eyes, heart, liver, kidneys, skin, muscles(myositis), colon (acute inflammatory colitis), SLE, hemophagocytic syndrome etc. [1] The diagnosis of dengue infection is based on clinical features and confirmed by detection of dengue virus NS1 antigen or by RT-PCR during initial febrile period, thereafter by detection of dengue IgM antibodies from 5th day onwards in primary infection which remains positive upto 90 days. While primary infection confers life long immunity against the infecting serotype, it confers immunity only upto 3-4 months for other serotypes. [1] Since it’s recognition in 1946 in India dengue infection has spread to almost all parts of the country, from urban to rural areas, affecting adults more than children, has involved all serotypes and is manifesting more in increasing severity. The clinical presentations are being noted to be more atypical. (2)Cross-reactivity with chikungunya, malaria, typhus, leptospira, typhoid fever, H1N1 virus, HepatitisA, Zika virus is also being noted. (3)(4)

We are reporting a case of dengue who presented to us with prolonged fever, upper gastrointestinal bleed and pain abdomen. During her hospitalisation she had exhibited features of involvement of various systems/ organs such as heart (tachycardia) blood (anaemia, thrombocytopenia, leucopenia, neutropenia), Liver (deranged liver function), Kidney (urinary abnormality), pancreas (pain abdomen, ultrasound evidence of swollen pancreas), skin (urticaria) nose (rhinorrhoea, sneezing). The findings of haemolytic anaemia(anaemia, raised LDH, positive direct coomb’s test), immune thrombocytopenia and neutropenia refers to Evans syndrome. Haemolytic anaemia, elevated liver enzymes, low platelets would refer to HELLP syndrome. Though the hospitalisation period was a stormy one posing both diagnostic and therapeutic challenges, she recovered

with supportive therapy after two weeks and is under regular follow up.

**Case report:** Mrs NS a 42 years old housewife from a rural area presented to us on 10 May 2017 with complaints of fever of 20 days duration, passage of black stool of two days duration and one episode of bilious vomiting in the morning same day. The fever was of moderate severity, remittent in character associated with headache, bodyache, muscle pain for which she was treated at home. Subsequently it became intermittent, mostly marked towards evening and early hours of the morning. At times it was associated with chills and temperature varied from 99 to 103°F for which she was treated at a hospital for about a week. When she noticed her stool to be black for two days she reported to us. Along with fever and malaena she felt diffuse pain all over the abdomen but more marked over the epigastrium and right hypochondrium. She had no past illness except that of polyarthralgia eight years back lasting for about two months. She had two uneventful home deliveries, no abortions. Last child was born 17 years back. Her periods are regular. Last mensturalflow was three weeks back. On examination she was a middle aged lady, thin built, height-158 cm, weight-46 Kg, BMI-18.4. She had pallor, no icterus/cyanosis/lymphadenopathy/thyromegaly/raised JVP/clubbing or oedema feet. Slightly pigmented patches were noted over both malar regions. Pulse-138/minute regular, BP-110/70 mmHg over right arm on lying position, temperature-102°F. Examination of heart-and lungs-unremarkable, Abdomen-soft but diffusely tender, more marked over epigastrum, other examination-no abnormality. With a provisional diagnosis of PUO with antipyretic induced upper GI bleed she was managed with IV pantoprazole, PRBC, fluids and a broad spectrum antibiotic. Investigations-Hb-7.9 gm/dl, TWBC-4290/cmm, Polymorph-55%, lymphocyte-37%, monocyte-7%, platelets-54000/cmm, peripheral smear-Bicypopenia, stool occult blood positive, urine-protein 70mg/dl, WBC-normal, plateletsreduced, reticulocyte count-0.3%, serum haptoglobin 133mg/dl (normal-16-200mg/dl), thyroid function tests normal, LFT-SGOT and PT INR-1:121 raised, Direct coomb’s test positive, ANA—negative, Antiphospholipidantibodies. IgA, IgG, IgM negative, AntiB2 glycoprotein IgA, IgG negative but IgM was positive(40.75 u/l, Normal<20u/l), Antiphospholipidantibodies. IgA, IgG, IgM negative, AntiB2 glycoprotein IgA, IgG negative but IgM was positive(40.75 u/l, Normal<20u/l), Antiphospholipidantibodies. IgA, IgG, IgM negative, AntiB2 glycoprotein IgA, IgG negative but IgM was positive(40.75 u/l, Normal<20u/l).
which further supported the diagnosis of Evan’s syndrome. To confirm a repeat TWBC three days later showed a count of 4100/cmm with polymorphs 10% (Absolute neutrophil count-410), lymphocytes 67%, monocytes 18%. Since she was asymptomatic with stable vitals with normal LFT and urine report she was thought to have recovered from this spectrum of expended dengue and was discharged with advice of regular follow up. A repeat blood count 4 weeks later has shown Hb9.2gm/%, TWBC-4450/cmm, polymorphs-32.6% (ANC-1424) lymphocytes-57.65, thus qualifying the criteria of concommitant neutropenia of Evans syndrome.

Discussion

The patient with fever, bleeding and thrombocytopenia presenting during dengue endemic period and being positive for dengue IgM antibodies fits to be a case of dengue. The prolonged fever, late manifestation of bleeding(UGI and subconjunctival) with a platelet count of 54000/cmm and subsequent other systemic manifestations suggest expanded dengue syndrome under severe dengue category. These atypical presentations could be a spectrum of dengue related immune dysregulation. The factors responsible for thrombocytopenia in dengue are multifactorial like transient marrow suppression, platelet aggregation, hemophagocytosis and immune destruction.(1) Thus immune reaction initiated by dengue virus can explain persistence of fever, sustained thrombocytopenia (could be immature/ineffective also) which caused the bleed though the count of platelets were not that low. Immunoglobulin and complement, tumour necrosis factor alfa, interleukin-8 studies would have been helpful but could not be carried out. The anaemia in this case in absence any knowledge of pre-illness Hb value, being normocytic normochromic could be due to bleeding and/ or immune mediated. Autoimmune haemolytic anaemia (AIHA) is defined as a Hb level of 11gm/dl or less at diagnosis with features of haemolysis(low haptoglobin level and/or elevated LDH and/or bilirubin levels) and a Positive direct antiglobulin test (DAT).(5) Our patient had elevated LDH and a positive Direct antiglobulin test, thus qualifying as having AIHA. Immune thrombocytopenic purpura otherwise known as Idiopathic thrombocytopenic purpura(ITP) refers to acquired immune mediated destruction of platelets and possibly inhibition of release of platelets from the megakaryocytes. It is termed as secondary if associated with an infection.(6) Absence of splenomegaly, adequate number of megakaryocytes in bone marrow aspiration and presence of antiBeta-2GP IgG suggests immune destruction(7). In our case, the infection is dengue infection. During the course of the disease neutropenia had been noted. Immune neutropenia refers to a neutrophil count below 1500/cmm on two separate occasions at least a week apart without any obvious cause(5). Our patient had a neutrophil count of 410/cmm on 3rd week of hospitalisation and 1424/cmm a month later, thus qualifies to the definition.

Evans syndrome (ES) first described by RS Evans in 1951 is a rare autoimmune disorder characterised by simultaneous or sequential presence of autoimmune haemolytic anaemia, immune thrombocytopenic purpura and/or immune neutropenia. It classified as secondary when associated with other autoimmune disorder/ malignancy/infection. Hepatitis C has been reported to be associated with ES(5). It is a rare and dreaded disease and many a time refractory to treatment but spontaneous remission is known.(8) Our case is on spontaneous remission and will be followed up.

HELLP (haemolysis, elevated liver enzymes, low platelets) syndrome is pregnancy related, the haemolysis is microangiopathic, LDH level is equal or higher than 600 iu/l.(9) Our patient was nonpregnant, haemolysis was autoimmune and had LDH level-598iu/l. Contrary to negative history occurrence of subclinical Eclampsia and HELLP during her pregnancies can not be denied. Amongst different pathogenetic mechanismsof HELLP syndrome genetic and epigenetic nature has been stressed(9). Elsewhere dengue infection in pregnancy with multiorgan failure has been reported to mimic HELLP syndrome.(10) Hence findings in our patient may be accepted as a mimic of HELLP syndrome and could be an epigenetic manifestation under influence of dengue related immune dysregulation of an inherited predisposing gene.(9)

Cardiac abnormalities in dengue have been reported as high as 36.7 % of cases in one study and comprised of sinus tachycardia, bradycardia, atrial fibrillation, first degree heart block, RBBB, Nonspecific ST-T changes, elevated troponin-I, CPK-MB, hypotension, pericarditis, myocarditis, myocardialinfarction, cardiomyopathy, S–A and A-V block. Our patient had sinus tachycardia.(11)

Gastrointestinal manifestations. Abdominal pain is an warning sign and has been a feature in 40% of cases. Our patient had prominent pain abdomen, diffuse
as well as epigastric and right hypochondriac. The gastric and duodenal erosions, hepatic involvement, renal involvement and acute pancreatitis (as evidenced by swollen pancreas on ultrasound) all contributed to pain abdomen in our case. Hepatic dysfunction in dengue has been reported to show raised SB in 25%, SGOT in 76%, Alkaline phosphatase in 43% of cases. It is different from other virus involvement in that here SGOT is increased more than SGPT. (12) Our patient had marginal derangement in SGOT and in PT _INR. It has also been suggested that elevated SGOT may serve as an early indicator of dengue infection. Other manifestations are fulminant hepatic failure, acalculous cholecystitis, acute pancreatitis, acute appendicitis, diffuse peritonitis and splenic rupture.

Renal manifestations described as AKI, IgA nephropathy, Rhabdomyolysis, Myoglobinuria acute renal failure, haemolytic uremic syndrome. Our patient had shown variable cellular and sedimentary findings which have been reverted to normal on recovery.

Dermatological manifestation—Our patient had itching which subsided on recovery.

Nose. The patient while in hospital during second week had running nose along with sneezing with pale nasal mucosa which recovered within 3-4 days.

Nervous system. Neurological manifestations are varied involving the neuroaxis, spinal cord, nerve root, peripheral nerves and muscles. (2) Our patient did not have any demonstrable involvement except that of myalgia.

**Conclusion**

Cases of dengue are presenting with many atypical features and complications. Our patient not only posed diagnostic and management problems but also exhibited varied manifestations of varied severity, Evans syndrome with spontaneous recovery as well as showed features to mimic HELLP syndrome.

Strategies Influencing with Holding of Women Employees in IT Sector in Chennai, Tamil Nadu

Shakila Devi A.R., Rabiyyathul Basariya S.

Abstract

The increasing rate of employee attrition and the problems the employers and the HR managers face in retaining ‘good’ and ‘performing’ employees in the absence of a set of women employee retention strategies are simply compounding in IT companies. Women executives are ambitious and, like men, say they are ready to make some sacrifices in their personal lives if that’s what it takes to occupy a top-management job. Many, however, are not sure that the corporate culture will support their rise, apparently with some justification. Although a majority of organizations we studied have tried to implement measures aimed at increasing gender diversity among senior executives, few have achieved notable improvements. This research article throws light on the need and importance of retaining women employees and the strategies enhanced to influence retaining women employees in Chennai IT Hub.

Keywords: Retention strategies, need and importance, IT hub in Chennai.

Introduction

Employee retention refers to the various policies and practices which let the employees stick to an organization for a longer period of time. Every organization invests time and money to groom a new joinee, make him a corporate ready material and bring him at par with the existing employees. The organization is completely at a loss when the employees leave their job once they are fully trained. Employee retention takes into account the various measures taken so that an individual stays in an organization for the maximum period of time.

Research says that most of the employees leave an organization out of frustration and constant friction with their superiors or other team members. In some cases low salary, lack of growth prospects and motivation compel an employee to look for a change. The management must try its level best to retain those employees who are really important for the system and are known to be effective contributors. It is the responsibility of the line managers as well as the management to ensure that the employees are satisfied with their roles and responsibilities and the job is offering them a new challenge and learning every day.

Need And Importance Of Retaining Female Employees: In a competitive business climate, retaining key employees is vital for the health of the company. But when these key employees are women, many corporations and industries continue to be befuddled as to how to retain this valuable cohort. Indeed, it’s surprising how many supposedly modern institutions are caught in a time-warp. Unfair compensation, gender imbalance in senior management positions, inflexible schedules and even active discouragement of female employees continue to plague companies large and small.

The good news is, a few simple steps can vastly improve conditions for female employees. And the benefits of maintaining a women-friendly environment far outweigh the costs. Retaining employees male or female, is just good business sense when you consider both the obvious and hidden costs of a high rate of employee turnover. One of the more obvious steps is fair compensation. Indeed, it’s surprising how many supposedly modern institutions are caught in a time-warp. Unfair compensation, gender imbalance in senior management positions, inflexible schedules and even active discouragement of female employees continue to plague companies large and small.

The good news is, a few simple steps can vastly improve conditions for female employees. And the benefits of maintaining a women-friendly environment far outweigh the costs. Retaining employees male or female, is just good business sense when you consider both the obvious and hidden costs of a high rate of employee turnover. One of the more obvious steps is fair compensation. It should go without saying that, after years of being treated as second-class employees, women first and foremost want to feel as equally valued as their male counterparts. Fair wages are just a start.

Fair compensation should also include bonuses and benefits. And women don’t want to feel like they will be punished for wanting a work/life balance. The lack of a flexible schedule is cited as the number one reason employees leave for other jobs, so companies should ensure they are able to accommodate their workers’ need to spend time with family or on other
projects. Telecommuting, a compressed work week, collaborative scheduling and self-scheduling can all factor into employee happiness and job satisfaction. Maternity benefits, childcare, and maternity leave should be included in employment packages.

Greater gender balance in the workplace, especially in leadership positions, can pave the way for women to feel that they too can succeed. When women see other women rising within a company, they realize that it is possible for them to rise to senior positions as well.

To this end, the smart employer will consider introducing mentorship programs to encourage high-potential female employees to aspire to senior leadership roles. Women’s networks can be critical retention tools as well, particularly for employees at their mid-career level. Retraining and reentry training for women who have temporarily left the workforce are also valuable tools in your retention box. Professional development, career coaching, and grooming for bigger projects and promotions, as well as guidance regarding each woman’s career trajectory, are invaluable in retaining female employees.

Executive presence training is one option to consider. A 2016 Forbes article cited a study by the non-profit New York organization Center for Talent Innovation that said being perceived as leadership material is essential to being promoted into leadership positions. The article went on to say that “the 268 senior executives surveyed said ‘executive presence’ counts for 26% of what it takes to get promoted”. Women who are trained to develop an executive-type persona in terms of gravitas—that is, confidence, poise under pressure and decisiveness—as well as communication and appearance become more confident and are better able to command a room, thereby clearing a path to high-stakes and high-visibility positions. By utilizing some or all of these ideas, companies can benefit from a healthier and more balanced work environment. It just makes sense.

Objectives Of The Study
1. To understand the existing strategies for retaining women employees in IT industry
2. To identify the organizational challenges faced by the women compelling them to discontinue career

Strategies For Retaining Women Employees:
- Work should never become monotonous and must offer a new learning each day. An employee should be able to upgrade his skills and enhance his knowledge at the workplace. Employees leave the organization whenever there are no chances of further growth. An individual must be made to do something which really excites him and most importantly matches his background. The
employees must be asked to accomplish the tasks in the most innovative way for them to enjoy their work. No one should be asked to do anything out of compulsion. The team leader must not force anyone to work. Let them accept assignments willingly. The moment work becomes a burden for the employees, they look for a change.

• Every individual should enjoy privacy at the workplace. The superiors must ensure that no employee interferes in each other’s work. Team members sitting at adjacent desks should not overhear their colleague’s conversation or check any confidential documents. These things lead to severe demotivation and prompt an individual to look for a change. Discussion is important but one should not irritate anyone. The team manager should also not make his team member’s life hell. Just give them deadlines and ask them to complete the assignments within the desired time frame. Motivate them to deliver their best but don’t be after their life. Remember everyone is mature enough to understand that work comes first, and everything later.

• Every employee should be treated as one irrespective of his designation. Sexual harassment is against the law and is a strict no no at the workplace. The male workers should respect their female counterparts and make them feel comfortable. Don’t ask any female employee to stay back late. Leg pulling, back stabbing, lewd remarks must be avoided at the organization to retain the employees.

• The management must formulate employee friendly policies. The employees must be allowed to take one or two leaves in a month so that they get time to rejuvenate. Don’t call the employees on weekends. Let them enjoy. The human resource department must take the initiative to celebrate birthdays of employees at the workplace. This way people come closer, make friends, develop trust and are thus reluctant to go for a change. Major festivals should also be celebrated at the organization for employees to get attached to the organization.

• Incentives, cash prizes, trophies, perks should be given to deserving employees to motivate them to perform up to the mark every time. The salaries of the high potential employees must be appraised from time to time as monetary dissatisfaction is one of the major reasons for employees quitting their jobs. The hard work of the workers must be appreciated. The slow learners must not be criticized but should be inspired to gear up for the next time.

• The performers must be made to participate in the decision making process. They should have a say in the major strategies of the organization for them to feel important and trust the management.

Have more women leaders: The first thing that gives a woman confidence at her workplace is having women leaders to look up to. This also indicates that the company offers them an environment conducive to scale the corporate ladder. It would be more beneficial if women leaders took on the role of mentors in mentorship programmes that are already at work in certain companies.

Empower Female Employees to Shape Company Culture: Startup land has become famous for offering a fraternity-like atmosphere: free beer, video games, and personalized hoodies. While it’s not fair to say women don’t like these perks, tech companies should include women on the teams that are shaping company culture. Expanding the activities beyond those evoking college dorm rooms will help attract talented women who don’t feel connected to those traditions.

Finally, it should go without saying that the best way to attract female talent is to offer competitive wages and excellent benefits that will support them in their life choices regardless of if they decide to have children or not. While the grand gesture of Facebook and Apple will surely help their recruitment efforts, our corporate culture as a whole needs to focus on making small, but important, everyday changes and sticking with them

Conclusion

The study throws light through valuable suggestion to increase the female employees’ retention in the organization. This study can help the management to find the weaker parts of the female employee feels towards the existing organization retention strategies and also helps in converting those weaker part in to stronger by providing the optimum suggestions or solutions.

Abstract

Purpose: The goal of the paper is to evaluate the human asset measurement of national wellbeing mission in India. It intends to report and investigate human asset administration (HRM) practices and make proposals to enhance representative and wellbeing framework results.

Method: The paper draws from a substantial report that utilized a blended techniques way to deal with evaluate execution of India’s Ministry of Health (MoH). It utilizes information gathered through record examination and top to bottom meetings of key witnesses involving approach creators, ranking staff of NHM and its partner associations and doctor’s facilities.

Findings: Public wellbeing segment HRM in India has discovered deficient arranging, poor organization and underutilization of staff. Absence of far reaching maintenance procedures and poor working conditions added to the inability to draw in and hold talented faculty.

Suggestion: Associations with both formal and casual conditions influenced HRM execution. While report audit was a noteworthy wellspring of information for this paper the shortcoming in the HRIS constrained accessibility of information. This exploration gives a framework—wide arrangement way to deal with wellbeing HRM in India. It adds to the writing and confirmation expected to control HRM approach choices and practices.

Keywords: National Health Mission, Human Resource Management, Institutional Theory, Public Health Sector.

Introduction

This paper looks to comprehend the human asset administration hones in the general wellbeing part in India (Odisha). As other poor state Odisha encounters various human asset challenges like perpetual staff lack, restricted abilities, and poor inspiration and maintenance are some of significant dangers to conveyance of administrations and generally execution of the wellbeing framework. Broadly the thickness of wellbeing work force per 10,000 populaces has been ceaselessly low by International standards. The World Health Organization sees staff as the most reproachful of all wellbeing framework assets. Nations with less wellbeing laborers can’t convey benefits adequately or scale up intercessions basic for accomplishing wellbeing objectives. HRM frameworks include the arrangements, techniques, forms, methodology and practices utilized in the administration of individuals in the working environment. There is broad confirmation that HRM hones affect hierarchical and worker execution in numerous segments. Nonetheless, the attention on HRM and its capability to add to enhanced execution of wellbeing frameworks, human services associations, patient and representative results is simply developing. There is a developing acknowledgment that HRM frameworks exist inside associations which are social elements. These associations and their outside surroundings impact the structure and working of the HRM frameworks. In the perspective of this reality, this paper utilizes institutional hypothesis as a focal point to
comprehend HRM in India’s wellbeing segment. Based on this hypothesis, it is presumed that HRM rehearses in the general population area wellbeing division to a substantial degree mirrors the qualities, standards and convictions of people in general segment and India as a bigger setting.

**Literature review:** Institutional Theory has been connected to HRM for over 10 years. This hypothesis allows a more sweeping, framework wide perspective of HRM inside wellbeing. Associations in Institutional hypothesis are seen as social substances that always adjust to their surroundings with a specific end goal to increase social acknowledgment (legitimacy). The situations are portrayed as involving rules, standards, benchmarks, and prerequisites that apply weight on associations affecting their structures, procedures and practices. These creators recognized three classes of Institutional weight: administrative, (for example, lawful and government prerequisites which tend to in the associations be considered “imagine”): intellectual which are “regular learning” and desires for gathering of experts in the associations and “regulating” which mirrors the qualities, convictions and standards of the more extensive society Meyer et. al 1983 contends that the qualities and conviction frameworks in the association’s outside surroundings are fantasies as in they depend for their adequacy and reality on the way that they are broadly shared by people and gatherings that have been given the privilege to decide such issues. A bunch contemplates have been led in the NHS on the HRM execution connect. A portion of these will be inspected here. Michael A West and J.F Dawson analyzed the connection between modernity of evaluation, complexity of preparing and level of staff working in groups and patient mortality in 61 intense healing facilities in England. By asking HR Directors inside the doctor’s facilities to finish a study they could set up doctor’s facility execution in medicinal services associations arrangement regarding these key factors. Analysis uncovered that complexity of examination had the most grounded negative association with quiet mortality, yet that level of staff working in groups and refinement of preparing likewise had noteworthy negative associations with tolerant mortality. This was the primary investigation to set up connections between HRM practices and execution in intense trusts in the NHS. The creators recognize a few restrictions including little example measure, cross sectional research outline and utilization of HR Directors as respondents.

**Understanding HRM Practices:** The regularizing and intellectual weights can be condensed as “casual” establishments that take care of the more profound and stronger part of social structures while administrative weight can be described more as “formal” foundations. The general wellbeing segment in India exists inside people in general administration which gives its prompt outside condition. The Directorate of Public Service Management (DPSM), which is a body under Ministry of state President set up through open administration demonstration of 1998 has the statutory duty regarding the administration of open administration. The DPSM obligation involves arrangement of strategy structure and creating and improving methodologies to open administration execution. In the perspective of relatedness, it tends to be presumed that the HRM rehearses in the general wellbeing segment are to a bigger degree an impression of more extensive open administration. Similarly people in general administration exists inside the country, state or society (Scott, 2004) which shows the more extensive financial and political setting which may likewise impact the HRM hones. The state as an element has power and specialist over associations. Its inborn real imagine power can assume a huge part in molding the general population benefit structure and conduct which thus impact HRM frameworks in the wellbeing segment.

While there are constrained HRM thinks about utilizing Institutional hypothesis in the general wellbeing segment in creating nations, investigation into business and improvement associations propose that there are two expansive institutional weights in the area. One is formal administrative condition vital for basic leadership and usage of strategy. This can be undermined by poor vote based process, absence of responsibility and acknowledgment of fantastic debasement. The second contains the casual institutional qualities of the network including the working of a casual economy, the resistance of frivolous defilement, not really including financial gain but rather organizing the enthusiasm of family or neighborhood network over the prerequisite of the working environment. Of significance for this exploration is that India is viewed as fair nation since autonomy India has an appropriate place for the execution and administration of viable HRM hones. This paper underscores the part of open administration and the state in molding the HRM hones in the general wellbeing segment.
Method

The part of the Human Resource technique that identifies with expanding quantities of key staff in consonance with IPHS and guaranteed administrations has just been displayed as a subcomponent of office fortifying. Numerous regions of expertise improvement are introduced as a major aspect of particular RCH and transferable and non-transmittable infection control programs. This segment centers around the general procedure for HR improvement. NHM will likewise center around making organizations for building limit at state and sub state and territorial levels. States will be upheld to create solid HR administration frameworks with enhanced practices for decentralized enrollment, reasonable and straightforward frameworks of postings, convenient advancements, money related and non monetary motivations for execution and administration in underserved zones, measures to decrease proficient seclusion by provisioning access to proceeding with restorative instruction and expertise up graduation programs, give profession chances to bleeding edge laborers and use the colossal adaptability accessibility under the mission.

NHM will bolster in-benefit programs, both private and through separation instruction mode on family solution, the study of disease transmission, general wellbeing administration and such different aptitudes and specializations as required. In benefit preparing will likewise underscore building authority aptitudes among key functionaries. Uncommon accentuation is required for family drug projects to enhance the pro holes at optional care levels and give a superior quality and scope of administrations at both essential and auxiliary levels.

NHM would empower improvement of extension courses for ASHA s to wind up ANMs/GNMs and for ANMs to end up medical attendants and attendants to end up nurture specialists. NHM will bolster advancement of a course for B.Sc in network wellbeing for mid-level clinical care supplier. Graduates from various clinical and paramedical foundations like drug specialists, B.Sc Nurses and so forth would likewise have the capacity to acquire this capability through fitting scaffold courses. The plan and length of the scaffold course would rely on an appraisal of the hole amongst present and wanted abilities. Local based determination, an extraordinary educational modules of preparing near where they live and work, contingent authorizing and a positive practice condition will guarantee this new unit is specially accessible where they are required most, i.e. in the underserved zones. Medical caretakers will fill in as the foundation of clinical offices and NHM will bolster the extension of their part as clinical care providers. NHM will bolster propelled preparing of attendants, including multi skilling and undertaking moving keeping in mind the end goal to empower and enable them to go up against more up to date benefit regions. They will likewise be upheld to get instructive headway through extension courses and other preparing.

NHM visualizes the utilization of telemedicine to help proceeding with medicinal and nursing training and at work support to suppliers working in proficient detachment in rustic and remote areas. NHM would likewise bolster methodologies to enlist and send talented wellbeing laborers in country and remote zones. These systems would incorporate money related and non-monetary impetuses, administrative measures, workforce administration and measures to lessen proficient and social confinement.

For the staff of program administration units, enhanced execution will be empowered through setting clear expectations, undertaking general execution checking and founding an appropriate examination framework. Furthermore preparing in view of holes distinguished through ability appraisal and strong supervision will empower specialist organizations to accomplish their execution objectives. One related issue is the irreconcilable situation circumstances that emerge when government specialists are likewise associated with private practice. This ought to be debilitated and appropriate motivating forces made accessible to such suppliers to invest additional energy out in the open administration in people in general healing center. Anyway numerous states would need to begin by concentrating on irreconcilable circumstance circumstances, for example, private practice on open time, cross referral to their own facilities and different deceitful practices.

Data Collection: Two wellsprings of information were utilized for the investigation: archive examination and key witness interviews. Archive examination included National improvement designs (NDPs), NHM vital and yearly execution designs and different types of reports, government and MOH approaches and related reports from different offices, for example, WHO. Key sources were purposely chosen and met. These contained strategy creators, senior administration and
staff of the MOH including nine resigned representatives distinguished through a snowballing procedure and senior officers from different partner associations, for example, the Ministry of Local Government, mission, healing centers, administrative bodies, proficient associations and worldwide offices working in India (Odisha).

Findings: HR strategy: The requirement for a thorough HR arrangement was recognized amid the 1983 hierarchical survey, with duty regarding its advancement relegated to the Department of Health

HR arranging

A utilitarian HR plan: The Ministry of Health tried noteworthy endeavors to create HR designs. The principal plan was produced in 1987 and the second in 1992\textsuperscript{10}. These designs were, be that as it may, condemned for inability to address enough the HR needs of the nation, the staffing needs of redesigned offices and to connect with wellbeing area advancement designs.\textsuperscript{9}

A HR data framework: The absence of powerful and productive wellbeing data frameworks that can give information to encourage arranging and basic leadership is a proceeding with issue\textsuperscript{9}. Deficiencies in the enrollment procedure both at NHM and services have been referred to as one of the contributing components to high opening rates. Availability and adequacy of HR maintenance methodologies. The general wellbeing division profits by fascination and maintenance techniques acquainted from time with time by the Government.

Conclusion

Regardless of the issues confronting HRM in India, there was no sign in any of the meetings that the wellbeing part was liable to political control. While the WHO structure HRM markers gave the structure to understanding the HRM framework in India, utilization of institutional hypothesis in the examination gave further bits of knowledge into the logical variables that shape HRM rehearses in the general wellbeing division. Considering the centrality of HRM to the workforce and wellbeing framework execution, wellbeing framework analysts need to embrace more research around there to advise HRM arrangement and basic leadership. In perspective of fitting hypothesis with robotic structures frequently utilized in contemplating HR matters in the wellbeing segments.

Prevalence of Type A Personality in Employees of Healthcare Institution

Yogita A. Pawar¹, Suraj B. Kanase²

¹Intern, ²Associate Professor, Department of Neurosciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Background: Healthcare institution is a public or nonprofit organization that provides services for 24 hours per day and 7 days per week. So this work pattern has direct or indirect impact on their health. Stressful life style leads to many health problems. As personality plays a vital role in dealing with the stress and competition. It is essential to know your personality to prevent all the further complications associated with it for a better living. The study is done to find out these type of personalities and aware them about the further health problems.

Objectives: To find out the proportion of Type A personality individuals in particular institution. 2) To find out the association between the personality and related diseases.

Method: Ethical Clearance was obtained from the Institutional Ethical Committee. 100 consecutive individuals aged between 30 to 50 years both male and female were interviewed. They were selected according to the inclusion and exclusion criteria. They were allowed to fill the Questionnaire-OB-360-TYPE A BEHAVIOUR SCALE. According to which conclusion was made.

Result: A statistical analysis for type A personality was significant and for correlation between personality type and health diseases/disorders was not significant (p 0.417).

Conclusion: The majority of participants showed type A personality. The study concluded that there is no significant difference between personality type and health condition. The maximum number of female employees comparatively male employees were more prone for health conditions due to their personality type.

Keywords: Type A personality, employees, healthcare institution.

Introduction

Health is state of complete physical, mental and social well being and not merely absence of disease or infirmity.¹ Healthcare professionals play an important role in delivering quality healthcare service. The demand of these healthcare professionals has been increased.

Even the sensitivity of work at hospitals have increased the level of job stress on the individuals working in it.²

Due to such kind of occupation the health risk factors are increased among healthcare workers.³ Stressful work pattern make healthcare staff and doctors more susceptible to physical and emotional morbidity.⁴ Studies have revealed that the cause of stress among healthcare professionals include-emotional and physical needs of patients, inadequate staffing levels, long working hours, exposure to infectious diseases and hazardous substances leading to illness or death, demands of the job and lack of communication, career development, problems with patients, problem with work or home interface and social life, working environment and the workload.⁵,6,7,8,9

The stressful things may vary in number and type and one’s physiological, psychological and social makeup are associated with stress, which stimulate and excite to some, whereas may feel stressed and burned.\textsuperscript{10} Individuals are with one temperament profile, which has different character outcomes. Personality development is characterized by relative stability alternating with more rapid transition to new adaptation.\textsuperscript{18}

There is difference in response to similar stressor under similar work conditions and situations which is attributed to the personality of the individual and particularly to the type of the personality.\textsuperscript{11} Personality is defined as a deeply ingrained pattern of behaviour that includes modes of perception, relating to and thinking about oneself and the surrounding environment.\textsuperscript{3} Personality combines the stability, organization of person’s characteristics, temperature, intellect and physique and adjustment to the environment.\textsuperscript{11}

There are many factors which lead to increase stress, anxiety and occupational health outcomes in different areas of medicines which contribute to the perception of job dissatisfaction and stress.\textsuperscript{12} Numerous lists of personality traits describing an individual’s behaviour have developed. Recent research has examined people using extensive lists of personality dimensions and has distilled them into big five.\textsuperscript{13}

Famous researchers Friedman and Rosenman divided people into two basic types of behavior or personality, type A and type B.\textsuperscript{14}

People who are more competitive, outgoing, ambitious, impatient, aggressive, rigidly organized, highly status conscious, anxious, concerned with time management are labeled as type A personality. People with type A personalities are often high achieving “workaholics”. They push themselves with deadlines and hate both delays and ambivalence.\textsuperscript{15} They are in hurry and appear to be driven.\textsuperscript{16} They always need to win and have rage ensues.\textsuperscript{1}

People who have type B personality do not appear to be driven. Their job ambitious do not dominate their entire lives. They are less aggressive, more relaxed and set fewer deadlines.\textsuperscript{16} They find time for their family and friends.\textsuperscript{15}

Type A behavior pattern was found that the coronary patients behave in similar pattern: they are extremely competitive, high achieving, impatient, restless. Type B more relaxed pattern of behavior and low risk of coronary heart disease.\textsuperscript{17}

Famous researchers Friedman and Rosenman divided people into two basic types of behavior or personality, type A and type B.\textsuperscript{14}

The main factors predicting occupational behavior-ability, motivation, intelligence and demographic factors. The relationship between personality and work-occupational variables (attitude to work, belief about work, behavior at work and psychological measures), personality characteristics (biological, cognitive dimension, decision and thinking style, coping patterns), organizational behavior (structure, selection procedure, approval procedure), and psychological process (mechanisms and phenomena).\textsuperscript{17}

**Aim:** To find out the proportion of Type A personality individuals in a particular institution.

**Objectives:** To screen the individuals of a Krishna Institution of Medical Sciences Deemed To Be University, Karad. To find out that how many of them lie in that category. To find out the association between the personality and related diseases.

**Need for Study:** Healthcare institution is a public or nonprofit organization within the state that provides health care and related services, including but not limited to be provision of inpatient and outpatient care, diagnostic and therapeutic services, laboratory services, medicinal drugs, nursing care, assisted living, elderly care and housing including retirement communities and equipment used or useful for the provision of healthcare and related services.

They provide services for 24 hours per day and 7 days per week. So this work pattern have direct or indirect impact on their health. Even in healthcare institution competition has increased now a days to maintain their status and fulfill their daily needs.
As world is changing at an extraordinary pace. And in today’s competitive landscape, there are survival skills that young people need to master so that a measure of success can be assured. To master these skills people are living stress full life.

Stressful life style leads to many health problems. As personality plays an vital role in dealing with the stress and competition. It is essential to know your personality to prevent all the further complications associated with it for a better living. The study is done to find out these type of personalities and aware them about the further health problems.

Materials and Methodology

Type of study- Observational study, Study design-Survey, Place of study-Krishna institute of medical sciences deemed to be university, Sample size-100, Sampling method-simple random method, Duration of study-3 months

Materials: Forms, Pens.

Inclusion criteria: The individuals of Krishna Institute of Medical Sciences Deemed to be University, Karad, Age group-30 to 50 years, Both males and females.

Exclusive Criteria: Individuals not willing to participate, Individuals with personality disorders.

Outcome measures: Questionnaire-OB-360-Type a behaviour scale

Procedure: 100 subjects aged between 30 to 50 years both male and female were selected for the study. Individuals not willing to participate and with personality disorders were excluded. Written consent was taken from subjects those willing to participate. The conclusion was done based on the Questionnaire-OB-360-TYPE A BEHAVIOUR SCALE filled by the subjects.

Results

The majority of participants showed type A personality. The study concluded that there is no significant difference between personality type and health disorders in males. The maximum number of female employees were more prone for health disorders due to their personality type.

Discussion

This study ‘PREVALENCE OF TYPE A PERSONALITY IN EMPLOYEES OF HEALTHCARE INSTITUTION’ was conducted to find out the type of personality in employees of healthcare institution and find out the association between the personality and related diseases.

Healthcare institution is a public or nonprofit organization within the state that provides health care and related services, including but not limited to provision of inpatient and outpatient care, diagnostic and therapeutic services, laboratory services, medicinal drugs, nursing care, assisted living, elderly care and housing including retirement communities and equipment used or useful for the provision of healthcare and related services.

They provide services for 24 hours per day and 7 days per week. So this work pattern have direct or indirect impact on their health. Even in healthcare institution competition has increased now a days to maintain their status and fulfill their daily needs.

As world is changing at an extraordinary pace. And in today’s competitive landscape, there are survival skills that young people need to master so that a measure of success can be assured. To master these skills people are living stress full life.

Stressful life style leads to many health problems. As personality plays an vital role in dealing with the stress and competition. It is essential to know your personality to prevent all the further complications associated with it for a better living. The study is done to find out these type of personalities and aware them about the further health problems.

The objectives of this study were to find the individuals of Krishna Institution Of Medical Sciences Deemed To Be University, Karad. To find out that how many of them lie in that category. To find out the association between the personality and related diseases.

The study was conducted with 100 subjects from Krishna institute of medical sciences deemed to be university, Karad. Subjects were selected according to the inclusion and exclusion criteria and written consent was taken. Both the males and females subjects were equally included for study. Subjects were explained about the procedure of the study. Then they were asked to fill the questionnaire accordingly. Survey was done according to the results obtained and hence conclusion was given.

The study shows 51% female and 49% male subjects participated. Personality type obtained in the study is 57% type A and 43% type B personality. In which type A personality included 22 males and 35 females and type B personality included 27 males and 16 females. The study shows 15 of them have health diseases/disorders and 85 do not have health diseases/disorders. In which 12 females have health diseases/disorders and 39 females do not have health diseases/disorders and 3 males have health diseases/disorders and 46 males do not have health diseases/disorders.

Earlier studies have shown the type A personality subjects correlate their personality pattern with hospitalized patients for coronary artery diseases. There are studies showing the correlation between job stress and job performance among house officers with type A personality characteristics is high.

The study shows there is negative correlation between personality and health conditions but it also shows the health conditions are more prone to female group of population. ($r$ value= 0.082, $p$ value= 0.417).

Conflict of Interest: The authors declare that there are no conflicts of interest concerning the content of the present study.

Source of Funding: This study was self funded.

Ethical Clearance: The study was approved by the Institutional Ethics Committee of KIMSDU.

Impact of Physiotherapy Treatment in Children with Cerebral Palsy Aged Between 6 Months to 5 Years

Sukanya V. Jadhav¹, Suraj B. Kanase²

¹Intern, ²Associate Professor, Department of Neurosciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad, Maharashtra, India

Abstract

Background: Cerebral Palsy has various structural and functional impairments which can lead to inability to walk, move independently which impairs their overall growth and development physiotherapy treatment in these subjects is a routine practice. Its applicability and outcomes is still an upcoming research area. This treatment has a longer duration of application for better outcomes. It is a big challenge for parents to do so due to many reasons. The impact of physiotherapy should be found out for all the age groups irrespective of their pathology and presentations. This study is an effort to do so.

Objective:

1. To study the types of cerebral palsy.
2. To assess the children with cerebral palsy.
3. To study the impact of physiotherapy on levels of gross motor function in children with cerebral palsy.

Method: Ethical Clearance was obtained from the Institutional ethical committee. 64 cerebral palsy children were selected aged between 6 months to 5 years divided in 3 groups according to their age both girls and boys were selected. They were assessed using Gross Motor Function Classification System scale which was recorded for a duration of 3 months. According to which conclusion was derived with appropriate statistical method.

Result: Group A shows maximum in level IV, Group B shows maximum in level I and II and Group C shows maximum in level III.

Conclusion: We found that level of Gross Motor Function was improved in the age group of 2 to 4 years and above when compared with age below 2 years after receiving physiotherapy treatment.

Keywords: Gross Motor Function, Cerebral Palsy, Motor development.

Introduction

Development is termed as maturation of functions which is needed for attainment of variety of skills for optimal functioning of child. It mainly deals with maturation and myelination of the nervous system. Although sequence of the development is similar for all, rate of Development differs¹.

Gross motor, fine motor, social and language functions are four different domains in any child’s developmental process. Influence of multiple factors including prenatal maternal illness, bad obstetric history etc., may cause detrimental effect on child’s normal developmental process¹.

Developmental process can be broadly classified into four stages comprising of infancy, early childhood,
middle childhood and late childhood. Infancy is a stage starting from birth up to 1 year of child’s life. Early childhood lasts up to 6 years which includes Toddlers from 1 to 3 years and Preschool period of 3 to 6 years. Middle childhood is the school-going age between 6 to 12 years. Late childhood is the adolescent period ranging between 13 to 18 years.

**Cerebral Palsy (CP):** CP is a collection of disorders affecting the development of movement and posture leading to activity limitations that are credited to non-progressive disturbances occurring in the developing fetal or infant brain. CP is the commonest childhood neuromuscular condition occurring in about 2 to 2.5 per 1000 live births. Any injury or developmental abnormality of immature brain causes cerebral palsy.

**Gross Motor Function (GMF):** They are the ones which require whole body movements involving large muscles of the body to perform activities of daily living. Standing, walking, running and jumping, sitting are some of the gross motor functions. It also includes activities like throwing, catching, kicking requiring eye-hand coordination.

**The prognosis for GMF in CP very inconstant:** Motor development: Motor development includes dynamic movements requiring voluntary control. They help us to maintain an erect and stable posture based on the posture so that it aids to carry out other finer movements. Motor development is based on the growth and development of CNS, genetic factors and environmental factors.

**Aim:** To determine the impact of physiotherapy treatment in children with cerebral palsy.

**Objectives:** To study the types of cerebral palsy. To assess the children with cerebral palsy. To study the impact of physiotherapy on levels of gross motor function in children with cerebral palsy.

**Need for Study:** Gross Motor Functions are those which require whole body movements and which involve the large muscles of the body to perform everyday functions, such as standing and walking, running and jumping, sitting. They also includes eye-hand coordination such as throwing catching kicking.

Cerebral Palsy children have impairments such as inability to walk, vision impairment and even inability to sit independently at 2 years of age.

Children who has undergone physiotherapy treatment in past years, in those patients there is need to find the present status of the child. The amount of recovery who has undergone treatment should be noted and follow up must be done.

It is important to find out the exact level of impairment of gross motor function to avoid further complications and it will easy to set the treatment protocol accordingly.

Hence there is need to study the impact of Physiotherapy treatment in children with cerebral palsy aged between 6 months to 5 years.

**Materials and Methodology**

**Type of study:** Observational study, Study design - Analytic study, Place of study - Krishna institute of medical sciences deemed to be university, Sample size - 64, Sampling method - simple random method, Duration of study - 3 months

**Materials:** Assessment charts, Pens, computers.

**Inclusion criteria:** 1. Children diagnosed and received physiotherapy treatment for cerebral palsy. 2. Age group - 6 months to 5 years, 3. Both sex.

**Exclusion criteria:** Children with other neurological diseases, cardiovascular or musculoskeletal problems.

**Outcome measures:** Gross Motor Function classification system.

**Procedure:** 64 subjects aged between 6 months to 5 years both male and female were selected for the study. They were classified into A, B and C group according their age group. Children with other neurological, cardiovascular and musculoskeletal disorder were excluded. Written consent was taken from the parents of subjects. they were assessed as per the scale accordingly. The conclusion was done based on the Gross Motor Function Classification System.

**Findings:**

Conclusion

We found that level of Gross Motor Function was improved in the age group of 2 to 4 years and above when compared with age below 2 years after receiving physiotherapy treatment.

Discussion

This study “Impact of physiotherapy treatment on children with cerebral palsy aged between six months to five years” was conducted to study exact level of gross motor function in children with cerebral palsy who undergone physiotherapy treatment.

Gross Motor Functions are those which require whole body movements and which involve the large muscles of the body to perform everyday functions, such as standing and walking, running and jumping, sitting. They also includes eye-hand coordination such as throwing catching kicking. Cerebral Palsy children have impairments such as inability to walk, vision impairment and even inability to sit independently at 2 years of age. Children who has undergone physiotherapy treatment in past years, in those patients there is need to find the present status of the child. The amount of recovery who has undergone treatment should be noted and follow up must be done. It is important to find out the exact level of impairment of gross motor function to avoid further complications and it will easy to set the treatment protocol accordingly.

The objectives of the study are To study the types of cerebral palsy. To assess the children with cerebral palsy. To study the levels of gross motor function in children with cerebral palsy.

64 subjects were selected according to the inclusion and exclusion criteria. They were classified into A, B and C group according to their age group. Group A includes children aged before 2 years. Group B includes children aged between 2 to 4 years. And Group C includes children aged between 4 to 6 years. Both boys and girls were selected for the study. Then they were assessed as per the scale accordingly. Result was as on level of gross motor function of the child. Conclusion were made according to the result obtained.

The study shows different levels of gross motor function in the subjects. 16% children are under level I, 22% children are under level II, 22% children are under level III, 26% children are under level IV, and 14% children under level V participated in the study.

Comparison between the groups were done according to the level of gross motor function. Group A showed maximum IV level of gross motor function that is the poor prognosis is seen. Group B shows maximum II level of gross motor function that is the good prognosis. Group C shows maximum III level of gross motor function that is better prognosis.

Hence there is need to study the impact of Physiotherapy treatment in children with cerebral palsy aged between 6 months to 5 years.

Prevalence of Poly Cystic Ovarian Syndrome (PCOS) in Obese Females in a Tertiary Care Centre in South India-An Observational Study

Swetha T1, Yasodha S1, Prabhu Ravi2, Rajalakshmi Veda. S.3

1Assistant Professor, Department of OBG, 2Assistant Professor, Department of Surgery, 3House Surgeon, Department of OBG, Sri Lakshmi Narayana Institute of Medical Sciences (SLIMS), Affiliated to Bharath Institute of Higher Education and Research, India

Abstract

Background: Poly cystic ovarian syndrome (PCOS) is more common among obese females. It has many dimensions which is still being explode many studies have tried to characterise the exact presentation of the disease. This study analysed the prevalence of PCOS in obese females. Along with this, the prevalence of acanthosisnigricans which is a surrogate maker of insulin resistance and Hirsuitism has been simultaneously studied.

Methodology: It was a cross sectional study which is carried out among medical students in a tertiary care centre in South India for one year. Questionnaire was designed and study was done. It comprised sample size of 113 females. All these candidates had high Body mass index (BMI) and all of them fall under obese category. The candidates who were participating in this study were aware of the PCOS condition and a brief session on PCOS was given before the start of this study. Along with this, Cutaneous manifestations were also assessed based on the severity of the symptoms.

Results: This study found that the prevalence rate of PCOS among obese females was 85.8%. More than half of the study patients has acanthosisnigricans (57.5%) and Hirsuitism (59.2%). These results were based on Rotterdam criteria. In this 93.8% of hyperandrogenism, 57.5% had Acanthosisnegucans and 59.2% had hirsuitism. In this study 50.4% had fulfilled all three criteria according to Rotterdam criteria according to Rotterdam and 35.3% has fulfilled 2 out of 3 criteria and 14.1% faced to fulfillatleast 2 criteria(Figure 3). Thus from the above study we conclude that there is great prevalence rate for PCOS in obese females aged 18 to 22.

Conclusion: With 85.8% prevalence rate of PCOS among obese females, it strongly proves that there is a association between the two. Thus increase in BMI causes increased risk of PCOS among females.

Keywords: PCOS, obesity, BMI, Hirsuitism, hyperandrogenism, acanthosisnigricans, oligomenorrhea.

Introduction

In 1935, Irving Stein and Michael Leventhal, both working at the Department of Obstetrics and Gynecology, Michael Reese Hospital, Chicago, USA, described the clinical, the macroscopic characteristics and histological features of polycysticovarsyndromefor the first time. The definition of the polycysticovarymorphology has also varied over the years. The first definition was the one by Stein and Leventhal and they described the macroscopic appearance ofpolycysticovariess as usually bilateral, enlarged, tense ovaries that were often distinctly globular in shape. The histological description was that of the presence of multiple cysts, rarely larger than 15 mm and these cysts were lined by a hypertrophic theca cell layer. It was also noted that the tunica albuginea,
which is the collagen-rich stroma immediately below the ovarian surface epithelium, was much wider than in normal ovaries and that the ovaries were devoid of corpora lutea.

**Methodology:** Present work was a non comparative cross sectional study which was carried among medical students in a tertiary care centre in South India. It was done over a period of one year. It included a sample size of 113 patients. It is a questionnaire based study. Here we explained the candidates about PCOS, its clinical manifestation, investigation, diagnosis and management. Institute Human Ethics Committee (IEC) approval and informed consent was obtained. Entire information recorded was kept confidential, and patient was given full freedom to quit from the study at any point. The following are the criteria based on which study was carried out.

**Inclusion Criteria:**
1. Young female about 18-22 years willing to participate
2. Unmarried women
3. BMI more than 25kg/m²

**Exclusion Criteria:**
1. Pregnant and married women
2. Age less than 17 and more than 22

**Result**

In this study, with sample size of 113 obese females the prevalence of PCOS was 85.8% and all these people were diagnosed under Rotterdam criteria, 14.1% found without PCOS and were not fulfilling the Rotterdam criteria. (Figure 1).

Table 1 shows distribution of age and BMI calculation in mean and standard deviation is 20.43+2.58 and 28.36 + 4.27 respectively.

</table>

**Fig 2: Rotterdam criteria**

In this study 92% were found to have menstrual irregularity and 93.8% were found to have features of hyperandrogenism. In which, 56.6% had Acanthosisnigricans and 58.4% had hirsuitism and 44.2% had acne. In this study 50.4% had fulfilled all three criteria according to and 35.3% has fulfilled 2 out of 3 criteria and 14.1% failed to fulfill at least 2 criteria (Figure 2). Thus from the above study we conclude that there is great prevalence rate for PCOS in obese females aged 18 to 22.

**Fig 1: Shows prevalence rate of PCOS**
Discussion

Poly cystic ovarian syndrome (PCOS) is traditionally thought of as a triad of oligomenorrhea, hirsuitism and obesity. But now it is recognized as a heterogenous disorder that results in overproduction of androgens, primarily from the ovary and is associated with insulin resistance. (1) The hypothesis of the origin of PCOS by environmental factors is based on the beneficial results observed by weight loss. This condition worsens with increase in weight.2

The Major criteria of PCOS proposed in the consensus of the National Institutes of Health in Bethesda were hyperandrogenism, oligoovulation, exclusion of other known disorders and possibly the characteristic morphology of polycystic ovaries on ultrasound.3

At the Rotterdam consensus, the presence of two out of three following criteria was considered as diagnostic for PCOS Oligoovulation or anovulation, clinical and/or low chemical signs of hyperandrogenism, and polycystic ovaries by ultrasound, after exclusion of other related disturbances.4

PCOS is a common gynecologic condition with an estimated prevalence of 7% inwomen of reproductive age groups11, it is often not diagnosed for several years12. Hence, reports investigating the prevalence of PCOS in adolescents are rare. The prevalence of diagnosed PCOS in Northern California of adolescents aged 15–19 years was 0.81%13. In an Iranian study, the prevalence of PCOS regardless of diagnosis was estimated to be 3% based on a questionnaire assessing PCOS symptoms14. However in our population, the prevalence was 0.76% for diagnosed PCOS and 0.56% for diagnosed and confirmed PCOS. However, the prevalence of PCOS was 1.14% when combining diagnosed and undiagnosed PCOS with clinical features and phenotypes based on NIH criteria.

PCOS has a strong association with obesity. The prevalence of PCOS varies between populations, as does the strength of association between PCOS and obesity. Findings from some small clinical studies, in Northern california suggest that the metabolic risk associated with PCOS is mostly due to obesity and that PCOS does not independently increase the metabolic risk of adolescents15. Obese adolescents or women may be more commonly associated with the diagnosis of PCOS leading to a potential bias in studies based on diagnosis codes that may result in an overestimation of the association with obesity. On the other hand, women without obesity and different metabolic risk seem to be less likely to be diagnosed which may bias studies aiming to identify potential high metabolic risk phenotypes of PCOS if criteria other than diagnosis codes cannot be used.

Abdominal visceral adipose tissue has been identified as a better marker of metabolic health than body weight which suggest that adipose tissue and tissue-specific inflammation play a crucial role in the development of PCOS. Because White women tend to have significantly higher visceral fat than Black women16.

The key pathophysiologic components may appear to include androgen excess, abnormal gonadotropin dynamics, and IR. Excess androgen production in the ovary affects follicle maturation, leading to follicular atresia and decreased reproductive function. In addition, the resultant hyperandrogenemia may produce clinical hyperandrogenism and underlying primary hypothalamic defect in the gonadotropin releasing hormone (GnRH) pulse generator or a secondary effect of low levels of progesterone resulting from oligo-or anovulation17.

Insulin also plays a central role in PCOS pathophysiology, acting to increase androgen levels by direct and indirect mechanisms19. Insulin resistance in women with PCOS is independent of body mass. However, obesity in PCOS is associated with greater insulin resistance and a higher incidence of dyslipidaemia6. Many mechanisms have been proposed for insulin resistance in PCOS women. These mechanisms were peripheral target tissue resistances, reduced hepatic clearance or increased pancreatic sensitively7. In obese individuals, free fatty acids and tumour necrosis factor alpha released from adipose tissue may play a key role in pathogenesis of insulin resistance.8

If PCOS is suspected, a complete medical history, physical examination, blood tests, and a pelvic ultrasound should be performed[20] which includes weight gain, menstrual cycle abnormalities, male-pattern hair growth, skin changes, and elevated blood pressure (BP). Blood is drawn to assess hormone, glucose, and lipid levels, and a
pelvic ultrasound is performed to scan for ovarian cysts. During the assessment period, other potential causes associated with reproductive, endocrine, and metabolic dysfunction should be excluded. Physicians should rule out adrenal hyperplasia, Cushing’s syndrome, and hyperprolactinemia before a PCOS diagnosis is confirmed.

After PCOS is diagnosed, studies show that more than 50% of patients develop prediabetes or diabetes, and there is an increased risk of myocardial infarction (MI), dyslipidemia, hypertension, anxiety, depression, endometrial cancer, and sleep apnea. Moreover, pregnant women with PCOS should be informed of the increased rates of miscarriage, gestational diabetes, pre-eclampsia, and premature delivery.

Since the primary cause of PCOS is unknown, symptomatic treatment is always better. Few treatment approaches improve all aspects of the syndrome, and the patient’s desire for fertility may prevent her from seeking treatment despite the presence of symptoms. Treatment goals should include correcting anovulation, inhibiting the action of androgens on target tissues, and reducing insulin resistance. Weight reduction for obese patients with PCOS is beneficial in many ways. Weight loss helps to decrease androgen, luteinizing hormone (LH), and insulin levels. It also helps to regulate ovulation, thereby improving the potential for pregnancy.

To manage patient with PCOS, it is recommended that 30 min of exercise on at least 5 days of the week to maintain weight and for healthy lifestyle. Recent studies showed that 60-75 min of moderate to high intensity of physical activities promotes a greater long term (i.e.) up to 12 months, weight loss compared with the conventional recommendation for optimum health. Dietary modifications are also recommended. In which dairy products like cheese should be avoided and more vegetables and fruits should be included.

Apart from this, many drug therapies are used for the treatment of PCOS including Gonadotropins, antidiabetic agents, aromatase inhibitors, antiandrogens, OCP’s, and statins are also tried.

**Conclusion**

In this study we conclude that as physicians, we should be aware of our role in not only treating this PCOS clinical features but also to remove the stress and emotional instability of the patient which arises due to this complex clinical presentation. Thus our first line treatment should be encouraging the patient to do regular exercise. We must also recommend the patient to have a healthy lifestyle modification which involves dietary modifications. Certain drugs can provide promising results whereas treatment of long term consequences of PCOS should also be kept in mind. As a result, future studies on PCOS in adolescent girls should also be considered in order to get the best outcome results.

To Study the Morphological Changes of Coracoacromial Arch in Various Shoulder Disorders

Tejashree S. Kumbhar¹, G. Varadharajulu²

¹Intern, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India, ²Dean, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Objective: To determine the morphological changes of coracoacromial arch in various shoulder disorders.

Method: An observational study was done, which included 100 subjects. They were selected by simple random sampling method as per the inclusion and exclusion criteria of the study. The inclusion criteria were, all clinically diagnosed shoulder disorders. The exclusion criteria were, coracoacromial ligament injury, post-traumatic stiffness of shoulder, post-operative conditions, recurrent dislocations and subluxations. The study was conducted at physiotherapy OPD of Krishna institute of medical sciences deemed to be university karad for a duration of 6 months. The ethical clearance for the study was taken from institutional ethical committee of KIMSDU Karad.

Result:

1. Shape of acromion-out of 100 subjects 34 subjects were having flat morphology, 35 subjects were having curved morphology and 31 subjects were having hooked morphology.

2. Acromion angle-In this study 34 subjects with flat morphology were studied and 100% subjects showed alteration in acromion angle. 100% subjects were having acromion angle greater than 12 degrees where normal range is 0-12 degrees. 35 subjects with curved morphology were studied and 91% subjects showed alteration in acromion angle. 91% subjects were having angle more than 27 where normal range is 12-27 degrees. 31 subjects with hooked morphology were studied and 16% subjects showed alteration in acromion angle. 16% subjects were having angle less than 27 where normal range is more than 27.

3. Lateral acromion angle-amongst 100 subjects 79% subjects showed alteration in lateral acromion angle. 79% subjects showed more than 99 degrees of lateral acromion angle where normal range is 64-99 degrees.

4. Acromion index-out of 100 subjects 92% subjects showed acromion index less than 0.7 where normal value is more than 0.7.

Conclusion: The results of this study conclude that morphological changes of coracoacromial arch causes various shoulder disorders. The study further conclude that 79% subjects showed altered lateral acromion angle, 92% subjects showed altered acromion index. 100% subjects with flat morphology showed altered acromion angle, 91% subjects with curved morphology showed altered acromion angle, 16% subjects with hooked morphology showed altered acromion angle.

Keywords: Coracoacromial arch, Shape of the acromion, Acromion angle, Lateral acromion angle, Acromion Index.

Introduction

Coracoacromial arch is formed by coracoid process, the acromion and inferior surface of acromio-clavicular joint. It forms osteoligamentous vault over humeral head and protects from superior translatory forces thus preventing it from dislocation superiory. Although
beneficial to joint stability, contact of humeral head with the undersurface of the arch can simultaneously cause painful impingement or mechanical abrasion of structures within the subacromial space.

The supraspinatus tendon is particularly vulnerable because of its location beneath all of the potentially impinging structures except the coracoid process. Suprahumeral space has been quantified by measuring the sup-to-inferior acro-humeral interval on radiographs. As the acromiohumeral interval decreases, it must accommodate the soft tissue structures within it, as well as the articular cartilage and the capsuloligamentous structures. For this reason, Flatow & Colleagues suggested that even during normal motion into humeral elevation, there is some contact of rotator cuff with the coracoacromial arch(2).

The morphology of the acromion has been considered the main cause of subacromial disease (impingement syndrome, tendinitis and rotator cuff pathologies) (3,4,5). Bigliani et al(6) described the existence of three forms of acromion (flat, curved, hooked), associating the morphology found in the lateral radiographic view with the prevalence of subacromial disease. The vector resulting from the force which originates in the lateral projection of acromion which, in turn, related to the deltoid insertion, causing the humeral head to rise up and impinge against the subacromial surface during the abduction of upper limb.(7,8,9)

According to the study by Bigliani et al (6) showed that 70% of rotator cuff injuries were associated with type II acromion, and 80% were associated with hooked type of acromion. And he found no injury in type I acromion (4,6). Snyder et al reported that acromion thickness, in its anterior third, to an etiological role in the subacromial disease. (10)

There are certain shoulder disorders in which morphological changes are noticed. It is necessary to know what exact changes occur in shoulder disorders. So as to plan for a particular targeted treatment for certain shoulder disorders. Hence the present study is conducted to study the morphological changes of coracoacromial arch in various shoulder disorders.

**Materials and Methodology**

An observational study was conducted on 100 subjects selected with simple random sampling method as per the inclusion and exclusion criteria of the study. The inclusion criteria were all clinically diagnosed shoulder disorders. The exclusion criteria were coracoacromial ligament injury, post-traumatic stiffness of shoulder, post operative conditions, recurrent dislocations and subluxations of the shoulder joint. The study was conducted at physiotherapy OPD of Krishna institute of medical sciences deemed to be university karad for a duration of 6 months. The ethical clearance for the study was taken from institutional ethics committee of KIMS DU karad.

**Procedure:** Ethical Clearance was obtained from institutional ethical committee KIMS DU, Karad. Subjects diagnosed clinically by Orthopaedic surgeons with shoulder disorders were included in the study. Shoulder disorders–impingement syndrome, adhesive capsulitis, rotator cuff tear, bursitis, tendinitis were studied in this study. Diagnostic tools used were AP view of shoulder X-ray. The acromion index and the angle of lateral projection were calculated through the angular and geometric measurements, using a goniometer, determined by measurements on the radiographs, according to Nyffeler et al (7) and Banas et al (9), respectively. The values were compared with normal ranges.

Materials used for this study are X-ray of shoulder and data collection sheet. AP view of shoulder is taken for this study.

**Normal ranges are**-

1. Shape of acromion-Type I-Flat
   - Type II-Curved
   - Type III-Hooked
2. Acromion angle-type I-0-12 degrees
   - Type II-13-27 degrees
   - Type III-More than 27 degrees
3. Lateral acromion angle-64-99 degrees
4. Acromion index-GA/GU= more than 0.7

Any deviations from normal range are noted.

**Result and Statistical Analysis**

1. Shape of acromion-out of 100 subjects 34 subjects were having flat morphology, 35 subjects were having curved morphology and 31 subjects were having hooked morphology.
2. **Acromion angle**—In this study 34 subjects with flat morphology were studied and 100% subjects showed alteration in acromion angle. 100% subjects were having acromion angle greater than 12 degrees where normal range is 0-12 degrees.

35 subjects with curved morphology were studied and 91% subjects showed alteration in acromion angle. 91% subjects were having angle more than 27 where normal range is 12-27 degrees.

31 subjects with hooked morphology were studied and 16% subjects showed alteration in acromion angle. 16% subjects were having angle less than 27 where normal range is more than 27.

3. **Lateral acromion angle**—amongst 100 subjects 79% subjects showed alteration in lateral acromion angle. 79% subjects showed more than 99 degrees of lateral acromion angle where normal range is 64-99 degrees.

4. **Acromion index**—out of 100 subjects 92% subjects showed acromion index less than 0.7 where normal value is more than 0.7.

**Discussion**

This study was conducted to study whether various shoulder disorders cause morphological changes in coracoacromial arch or not. Coracoacromial arch provides stability to shoulder joint, also protects the shoulder superiorly from direct trauma. Arch also acts as physical barrier to superior translator forces acting on humeral head, preventing it from dislocating superiorly (1). Due to tremendous force and repetitive stress, coracoacromial arch is prone for damage and dysfunction of shoulder joint.

The objective of this study was divided into 4 parts, firstly to the shape of acromion process, secondly to study the acromion angle according to its morphology, thirdly to study the lateral acromion angle and lastly to study the acromion index. 100 subjects were included in this study. Out of 100 subjects there were 44 males and 56 females. All clinically diagnosed shoulder disorders were taken with no age limitations. Subjects with coracoacromial ligament injuries, posttraumatic conditions, postoperative conditions, recurrent shoulder subluxations and dislocations were excluded from the study.

Prior informed consent was taken from the subjects. They were explained with necessary information before handing them with the forms. The form consisted 2 sections firstly demographic data, information, outcome measures, secondly the consent form. The outcome measures used in this study was radiograph of the shoulder. AP view of radiograph was selected. Shape of the acromion, acromion angle, lateral acromion angle and acromion index were measured on the radiograph. These values were measured to study the morphological changes of coracoacromial arch. Shape of the acromion was studied and subjects were categorized into flat, curved and hooked category of morphology (6). 34 subjects with flat morphology were studied in that 100% subjects showed alteration in acromion angle, having ranges more than 12 degrees where normal range is 0-12 degrees (11). 35 subjects with curved morphology were studied in that 91% subjects showed acromion angle more than 27 degrees where normal range was 13-27 degrees (11). 31 subjects with hooked morphology were studied in that 16% showed acromion angle less than 27 where normal range was more than 27 degrees (11).

Lateral acromion angle was measured and 79% subjects showed alteration in angle that was more than 99 degrees where normal range is 64-99 degrees (11). Acromion index was measured and 92% subjects showed altered acromion index which was less than 0.7 (normal range more than 0.7). in this study 66 subjects with adhesive capsulitis, 27 subjects with tendinitis, 3 subjects with impingement syndrome, 3 subjects with rotator cuff tear and 1 subject with bursitis were studied. This study found that changed morphology of coracoacromial arch is one of the causes for various shoulder disorders. An also changed morphology of coracoacromial arch is the predisposing factor for shoulder dysfunction. Study showed that morphological changes cause various shoulder disorders.

**Conclusion**

The results of this study conclude that morphological changes of coracoacromial arch causes various shoulder disorders. The study further conclude that 79% subjects showed altered lateral acromion angle, 92% subjects showed altered acromion index. 100% subjects with flat morphology showed altered acromion angle, 91% subjects with curved morphology showed altered acromion angle, 16% subjects with hooked morphology showed altered acromion angle.

Quality of Life of Patients Underwent Midfoot Amputation at a Tertiary Care Hospital in Kochi

Thanu KM1, Anju Reghunath2, Anupriya S2

1Assistant Professor, 2IV Year B Sc Nursing students, Amrita College of Nursing, Amrita Vishwa Vidyapeeth, Kochi, India

Abstract

Midfoot amputations are commonly seen among patients with diabetic foot ulcers, which may cause impaired physical mobility and can affect their quality of life. The purpose of this study was to assess the quality of life of patients who underwent midfoot amputation.

Materials and Method: A quantitative approach with descriptive research design was used for the study. It was conducted among 55 patients who underwent midfoot amputation and were attending the endocrine and podiatry OPD of a tertiary care hospital. Sample selection was done using non-probability convenience sampling technique. The socio-demographic and clinical data were collected by a semi-structured questionnaire and the quality of life was assessed using SF-36 questionnaire. Analysis was done using chi square test.

Results: Majority of the subjects (98%) had poor quality of life with a mean score of 31.18±6.62. Among the 8 domains of quality of life, role limitation due to physical health was the poorest with a mean score of 8.19±14.47. Physical component summary (PCS) and mental component summary (MCS) of SF-36 were also poor with mean scores of 29.35±8.60 and 30.72±11.85 respectively. No significant association was found between the quality of life and selected demographic variables of the midfoot amputated patients.

Conclusion: The result of the study highlights poor quality of life among midfoot amputated patients. It was also found that the major problem that led to poor quality of life was the role limitation due to physical health. Therefore, there should be more focus on the rehabilitation of patients after midfoot amputation to improve their quality of life.

Keywords: Quality of life, midfoot amputated patients.

Introduction

Amputation is the removal of whole or part of an extremity. It can cause loss of function, body image disturbances, and psychosocial disruption. Diabetic foot and other vascular complications are the most common causes of surgical amputation. Amputation of the limbs has been reported to be a significantly stressful event for an individual. 1

Statistics say that the main causes of limb loss are vascular disease including diabetes mellitus and peripheral vascular diseases, trauma, and cancer. It was also projected that the amputee population will be more than double by the year 2050.2,3

A study was conducted on body image and self-esteem in lower limb amputees in Austria. The purpose of the study was to analyze the impact of lower-limb amputations on aesthetic factors such as body image and self-esteem as well as quality of life. This cross-sectional study in three centers included 298 patients. This study showed that lower-limb amputations significantly influence the patient’s body image and quality of life.4,5
Majority of the non-traumatic lower limb amputations occur in people diagnosed with diabetes. Most of the amputations can be prevented by educating the patients about foot care and lifestyle modification which will help to prevent diabetic foot ulcer.

A recent study says that the knowledge and self-care practice of diabetic patients should be improved to reduce complications such as amputation. An amputation can disturb the physical and mental capability of human body. It can affect the quality of life due to problems with mobility, pain, and appearance of the amputated part.

Materials and Method

The study was conducted among 55 midfoot amputated patients and the research design used was non-experimental descriptive research design. The subjects were selected by non-probability convenience sampling technique based on inclusion criteria and rapport was established with them. After obtaining permission from institutional ethical committee, researcher explained the purpose of the study and obtained informed consent from them and the tools were administered. The demographic data was obtained from the subjects themselves and the clinical data was collected from the medical records. SF-36 questionnaire was used to assess the quality of life of midfoot amputated patients. The factors assessed in quality of life mainly included general health, physical problems, emotional problems, pain, etc. The data obtained was analyzed using descriptive and inferential statistics and the association was assessed using chi square test.

Results

Most of the subjects in this study were within the age group of 50-60 (41%). In that, most of them were males (75.5%), 83.6% of patients were married. Majority (96.4%) of the subjects underwent midfoot amputation due to diabetic foot ulcer. None of them were using prosthesis.

Description of quality of life of patients underwent midfoot amputation

The figure shows that 98% (54) of the subjects have poor quality of life and only 2% (1) have good quality of life.

<td>Emotional wellbeing</td>
<td>0</td>
<td>64</td>
<td>39.85</td>
<td>15.700</td>
</tr>
</tbody>
</table>

The table III shows that among the mental components majority had role limitation due to emotional problem with a mean score of 10.91±24.04 whereas the other two components such as energy and fatigue and emotional wellbeing also was poor with mean scores of 41.39±11.24 and 39.85±15.70 respectively.

Association between demographic variables and quality of life: The demographic variables such as age, gender, education, occupation, income, duration of amputation, and reason for amputation did not show any association with the quality of life of midfoot amputated patients.

Discussion

Results of the present study shows that the majority of samples are males (74.5%), the cause of amputation is diabetes mellitus, and the quality of life of the subjects is poor. The PCS and MCS scores of the subjects are also poor. A study conducted in Egypt showed that most of the participants were males (59%) and the major cause of amputation was diabetes mellitus. Most of the subjects had a change in quality of life after amputation and also the most affected aspects were the physical and mental components. Another study conducted by Johannesson et al. also showed that the individuals with diabetes mellitus have an increased rate of amputation than the general population.

In our study there was no significant relation between the quality of life and demographic variables such as age, gender, education, occupation, and cause of amputation.

In a study conducted in Egypt showed that there was no statistical significance with educational level, work, or cause of amputation, but there was significant association between quality of life and gender. The result obtained in our study might be because of the smaller sample size.

In the present study, the lower physical and mental component scores contributed to the poor quality of life among midfoot amputated patients. Physical function, role limitation due to physical and emotional problems, energy and fatigue, emotional wellbeing, and social function were the areas found to have more problems experienced by the participants. It is related to the results of a study conducted in a rehabilitation center which showed that the SF-36 physical component and mental component scores were significantly lower for amputees when compared with general population.

Conclusion

Amputations are not uncommon nowadays. However, minor amputations also have a larger impact on the quality of life of the individuals. The result of the study highlights poor quality of life among midfoot amputated patients. It was also found that the major problem that led to poor quality of life was role limitation due to physical health. It is important to consider the physical as well as the mental functioning after the amputation. For that, the health care workers should give importance on rehabilitation of the patients and also provide education to the family members about the importance of psychological support that needs to be given to them.

Bronchoscopic Study in Diagnosing of Carcinoma of Lungs in Telangana Population

Ramkrishna Reddy M¹, Nalini N²

¹Associate Professor, ²Assistant Professor, Department of Pulmonary Medicine, Medi Citi Institute of Medical Sciences, Ghanpur, Medchal, Telangana

Abstract

In the Bronchoscopic study of lung carcinoma 39 adult patients aged between 28 to 65 years old, of both sexes were studied. The history was 13 (33.3%) were smokers, 12 (30.7%) were former smokers, (9.23%) were exposed to dust, 5 (12.8%) were non-smokers. The types of lesion were 16 (14%) had partial endotracheal obstruction, 11 (28.2%) had complete endotracheal obstruction, 8 (20.5%) had mucosal irregularities, 4 (10.2%) had external compression. The histopathological observation were 17 (43.5%) had squamous cell carcinoma, 7 (17.9%) had small cell carcinoma, 13 (33.3%) had adeno carcinoma, 2 (5%) had mixed cell carcinoma. This various Bronchoscopic presentations of Bronchogenic carcinoma will be quite useful to chest and pulmonary physician, pathologist and onco-surgeon to treat such patients efficiently and prevents the morbidity and mortality of the patients because early detection of carcinoma can be treated and increase the survival of such patients.

Keywords: Ca= Carcinoma, FOB=Fiber optic Bronchoscopy, histopathology, Telangana.

Introduction

According to the National cancer institute (ministry of health) Ca of lung is most common neoplasm and highest mortality rate(1)(2). It is estimated that, death due to lung ca is 1.2 million globally (including both sexes) every year(3). The most affected were adults. In industrialized countries, the lung ca an epidemic disease among men. However it has become more common in woman also. The principle risk factor is smoking, which causes 10-30 times greater risk of developing lung neoplasm, other traditionally accepted factors are exposure to dust, chimneys of industry in urban areas, family history of lung cancer are aggravating factors to cause ca of lung(4).

Most diagnoses are confirmed when the disease become advanced, locally or disseminated, since early stage tumours do not usually produce symptoms that warrants investigations. This indicates that, early detection measures are particularly important since surgical resection, which constitutes, the only therapeutic approach that offers a potential cure, is effective only in early clinical stages. Hence attempt was made to study the lung ca with FOB and histopathologically to detect the lung ca at various stages causes obstructions at various degrees.

Material and Method

39 adult patients of both sexes aged between 28 to 65 years who were regularly visiting chest and pulmonary OPD of Mediciti Hospital of Ghanpur, Medchal-501401, Telangana.

Who were diagnosed bronchogenic carcinoma, histopathologically were selected for study. The age, gender, smoking history of every patient was recorded individually. Apart from routine blood examination, CT.BT(Clotting and bleeding time). ECG was also studied and atropine 0.6mg IM and Inj phenergan 25mg IV was given. Bronchoscope was performed with flexible, fiber optic Bronchoscopy (FOB), through trans–nasal or trans oral route under tropical anesthesia (2% xylolcaine) multi para monitor was attached to heart rate, Blood pressure, respiratory rate, ECG and oxygen

DOI Number: 10.37506/v10/i12/2019/ijphrd/191940
saturation. During and soon offer procedure oxygen was administrated to maintain oxygen saturation more than 90%. Samples were collected from bronchoscopic aspiration, brushing and biopsy obtained and sent for further confirmation.

The HIV, HBsAg patients and patients with cardiac neurological problems were excluded from the study. The clinical features, history of patient, bronchoscopic findings and histo-pathological observation were grouped with percentage to correlate the types and degree of carcinoma. The ratio of male and female were 3:1

During the study was about three years

Observation and Results

Table 1. History of bronchogenic carcinoma patients 13(33.3%) were smokers 12(30.7%) were former smokers 9(23%) were exposed to dust, 5(12.8%) were non-smokers

Table 2. Types of endobronchial lesions 16(41%) had partial endotracheal obstruction, 11(28.2%) had complete endotracheal obstruction, 8(20.5%) had mucosal irregularities, 4(10.2%) had external compression

Discussion

The present study of Bronchoscope in the diagnosing of carcinoma of lung in Telangana population. The history of lung ca patients was 13(33.3%) were smokers 12(30.7%) were former smokers 9(23%) were exposed dust, 5(12.8%) were non-smokers (Table-1). The endobronchial lesions were 16(41%) had partial endotracheal obstruction, 11(28.2%) had complete endotracheal obstruction, 8(20.5%) had mucosal irregularities, 4(10.2%) had external were, 17 (43.5%) had squamous cell Ca 7(17.9%) had small cell ca 13(13.3%) had adeno Ca, 2(5%) had mixed cell Ca (Table-3). These present values were more or less in agreement with previous studies (5)(6)(7).

It was observed that higher prevalence of lung Ca in males than females, because in India males are more smokers than females(8) moreover adult of both sexes were more prone for lung Ca. In the study of endobronchial lesion the right lower lobe bronchus followed by right lower lobe was common site of lesion but most of the foreign studies have right upper lobe was common site of lesion(9). However right lung was common site of any infection including tuberculosis or Ca because of short and straight bifurcated trachea towards right side while left bifurcated trachea was long and oblique hence left lung is rare to get infected.

In the histo pathological study squamous cell Ca, was highest in present study (43.5%) but in some other studies of Indian studies adeno-carcinomawas highest but in abroad study squamous cell Ca was quite common(10). In general adeno-carcinoma and squamous cell Ca were quite common globally.

It has been also reported that, passive exposures to cigarette smoke were also more prone for lung Ca because passive smoke contains a complex mixture of various mutagenic and carcinogenic agents(11). It has been postulated that, endogenous and exogenous estrogens play a role in the development of adno-carcinoma.
As the common symptoms of the lung Ca concerned 54% of the patients reported cough as initial manifestations of the disease. Although hemoptysis is common, it is rarely severe. Early dyspnea or chest discomfort affected 60% of the patients at the time of diagnosis\(^{(12)}\). But in India cough and dyspnea or chest discomfort are thought to be common symptoms of respiratory tract infection and rarely go to physician to get treatment hence Ca will be almost pre dominant during treatment of lung Ca, other correlative factors like body weight loss, fever were also taken as common phenomena due malnutrition and frequent changes in climatic conditions and reduced immunological factors.

**Summary and Conclusion**

The present bronchoscopic diagnosis of Ca of lungs in Telangana population will be quite helpful to the chest and pulmonary physician, pathologist and oncological surgeon for resection of broncho pulmonary segments for long survival of patients but for delayed diagnose of Ca, both patients and doctors to be blamed because exact cause and mechanism of Ca is yet to be known.

This research paper was approved by ethical committee of Mediciti Institute of medical Sciences, Ghanpur, Medchal-501401, (Telangana).

Study of Different Feeding Patterns in Children of Telangana

Surayanarayana Regidi¹, Pradeep Reddy M²

¹Assistant Professor, ²Associate Professor Department of Pediatrics, Mediciti Institute of Medical Sciences Ghanpur, Medchal, Telangana

Abstract

80 (Eighty) school children aged between 6 months-18 months were selected for the study of different pattern of feeding. The inception of first feeding were in 38(47.5%) was (< 6 hrs 22(27.5) were 7-12 hours. 11(13.7%) were 13-24 hrs 7(8.75%) were 25-48 hrs 2(2.5%) were 49-72 hrs. In the pre-lacteal feeding 18(22.5%) used honey, 39(48.7%) sugar solution (water added with sugar), 14(17.5%) plain water, 9(11.2%) milk. The causes of stoppage of breast feeding was 24(30%) insufficient breast milk, 18(22.5%) maternal sickness, 15(18.7%) infant sickness, 14(17.5%) maternal employment, 9(11.2%) subsequent pregnancy.

This pragmatic study of different patterns of feeding, inception of first feeding and various cases of stoppage breast feeding will be quite useful to pediatrician to treat such children efficiently to prevent morbidity and mortality in children.

Keywords: Feeding, lactation, breast feeding, Telangana.

Introduction

Understanding children eating attitudes and behavior is important in terms of children’s health. Dietary habit acquired in childhood persists throughout to adulthood (1)(2). Globally under nutrition is one of the most important public challenges. Under nutrition is associated with more than one third of global disease. It is estimated that 35% death in children due to under nutrition associated with in appropriate feeding practices during early childhood(4). Poor feeding result into repeated infection suboptimal breast feeding leads to ill-health in children. Maximum infants’ children deaths due to diarrhea and pneumonia were observed in excluded breast fed(5). The first two years of life is the critical window of opportunity for the child growth. It was observed that, there is hindrance in the child growth in India and abroad well. Hence attempt was made to study the children at different age of months and their feeding pattern, types of diet and various causes of stoppage of breast feeding.

Material and Method

80 (Eighty) children aged between 6 months-18 months, regularly visiting pediatric OPD of Mediciti Institute of Medical Sciences Ghanpur, Medchal-501401, Telangana were selected for study. The detailed history of feeding pattern was collected from their mothers. The different feeding patterns, pre-lacteal feeding time of inception, causes of stoppage of breast feeding, were studied with percentage.

The children having congenital anomalies, low birth weight were excluded from the study. The ratio of male and female kid was 2:1. The duration of study was about two years.

Observation and Results

Table-1—Study of inception of first feeding in children 38 (47.5%) < 6 hours, 22(27.5%) 7-12 hours, 11(13.7%) 13-24 hours, 7(8.75%) 25-48 hours, 2(2.5%) 49-72 hours.

Table-2—Study of pre-lacteal feeding in children: 18(22.5%) honey, 39(48.7%) sugar solution (water+ sugar) 14(17.5%) plane water, 9(11.2%) milk.

Table-3—Causes of stoppage of breast feeding in children 24(30%) insufficient breast milk, 18(22.5%) subsequent pregnancy.
maternal sickness, 15(18.7%) infant sickness 14(17.5%) maternal employment 9(11.2%) subsequent pregnancy.

**Discussion**

The present study of different feeding pattern, in Telangana children. In the study of inception of first feeding in children 38(47.5%) < 6 hrs, 22(27.5%) 7-12 hours 11(13.7%) 13-24 hrs, 7(8.75%) 25-48 hrs, 2(2.5%)49-72 hrs (Table-1). In the study of pre-lacteal feedings in children 18(22.5%) was honey, 39(48.7%) was sugar solution (water added with sugar), 14(17.5%) plane water, 9(11.2%) milk (Table-2). The causes of stoppage of breast feeding 24(30%) Insufficient milk, 18(22.5%) maternal sickness, 15(18.7%) Infant sickness, 14(17.5%) maternal employment 09(11.2%) subsequent pregnancy (Table-3) This findings were more or less in agreement with previous studies\(^6\)(\(^7\))(\(^8\)).

Breast milk alone is capable of meeting all children’s requirements up to 6 months, but after this period it must be complemented with adequate foods in order to supply nutritional requirement and prevent infant’s mortality and morbidity including malnutrition and over weight\(^9\). Any food other breast milk that is given to breast feeding child is defined as complimentary food.

From nutritional point of view premature introduction of complimentary food can be disadvantages because it reduces the duration of breast feeding, interferes with absorption of important nutrients from breast milk and it increases, the risks of contamination and allergic reactions, on the other hand by complimentary food has disadvantages because children energy requirements will not be met, resulting in deceleration in growth and increased risk of malnutrition and micro nutrients deficiencies\(^10\).

Excessive milky diets have been identified as one of the causes of anemia during first years of life. Liquid cow milk is itself poor source of iron and can also inhibit absorption of the iron present in some other foods if given concomitantly, in addition to provoking micro-hemorrhages in the intestinal mucosa of children less than 1 years old\(^11\). It was also noted that both parents and children diet consisted many unhealthy snacks food such as crisps, chocolate and biscuits.

**Summary and Conclusion**

The present study of different feeding pattern in children of Telangana is useful to pediatrician, nutrition expert because apart from frequency of feeding, nutritious digestible food is also necessary for proper growth of children in their early life, during breast feeding mother must consume nutritious, balanced diet which be suitable for infants heath and body growth.

But this study demands further awareness building programmes about child care and feeding practices must be included in antenatal care, postnatal care, because blind beliefs and superstition are still prevailing regarding feeding patterns and diets in children due to illiterate and orthodox parents, society which keeps away the children from nutritious and balanced-diet.

Study of Urinary Tract Infections in Patients with Catheter a Teaching Hospital Study

Purushothama Acharya

Assistant Professor, Department of General Surgery, Srinivas Institute of Medical Sciences, Mukka, Suratkal Mangalore, Karnataka

Abstract

96 patients (all males) aged between 50-80 years with urinary tract infection with indwelling catheters for more than 2 weeks were studied. The reasons for catheterization - 62(64.5%) had BPH, 7(7.2%) had cancer of prostate, 9(9.3%) had urethral stricture, 11(11.4%) had CVA, 2(2%) had penile cancer, 2(2%) had poly trauma, 3(3.1%) had C.V.D. Only those with monomicrobial isolates were selected for the study. The isolated organism from urine culture in a calibrated wire loop delivering 10/41 urine sample was used to inoculate blood, Mac conkey and agar plates and incubated aerobically at 37 c for 24-48 hours. Isolated colonies were biochemically identified. All isolates were tested for susceptibility to commonly used antibiotics on Mueller-Hinton agar by standard Kirby–Bauer disc diffusion method. There were 57(59.3%) e.coli, 15(15.6%) Klebsiellaspp, 7(7.2%) Enterobater sp., 5(5.2%) Acinetobacter, 12(12.5%) p. Aeruginosa infections. The susceptibility of isolated bacteria to antibiotics was studied. This practical study of urinary tract infections associated with catheterization will help the urologist to treat such patients efficiently to avoid the risk of morbidity and mortality.

Keywords: BPH= Benign prostate Hyper trophy, catheter, MacConkey and CLED, Kirby-Bauer Disc.

Introduction

Urinary tract infection (UTI) is the most common site of nosocomial infection accounting for more than 40% of nosocomial infections in India and abroad. (1) Incidence can be as high as 60 to 86% depending upon method and duration of catheterization, the quality of catheter care and host susceptibility. (2) Host factors which appear to increase the risk of acquiring catheter associated UTI include advanced age, debility and immunity as well as reason for the need of catheter. Catheter associated UTI are caused by a variety of pathogens, including E. coli, Klebsella, proteus, enterococci, pseudomonas, enterobacter, serratia, and Candida. Many of these microorganisms are part of the patients endogenous bowel flora but they are also be acquired by cross contamination from other patients or hospital personnel or by exposure to contaminated solutions or non–sterile equipments (3). Moreover Catheter associated UTI in healthy patients is often asymptomatic and is likely to resolve spontaneously with the removal of catheter. Occasionally infection persists and leads to such complications as prostatitis, epidyymitis, cystitis, pyelonephritis, and gram negative bacteriacemia particularly in high risk patients. Hence attempt was made to study the microbial pathogens associated with UTI in catheterized patients and determine their susceptibility patterns to commonly used antibiotics.

Material and Method

96 patients (all males) aged between 50 to 80 years who regularly attended urology department or admitted in different wards of Srinivas Institute of Medical Sciences hospital, Suratkal, Mangalore between july 2012 to june 2016 were selected for the study. Catheters were usually changed after 2 or more weeks or changed when there were clinical symptoms of fever, dysuria, cloudy urine, blockage or other symptoms of urinary tract infection (UTI). Catheters were removed when they were deemed no longer necessary.
By using aseptic technique urine sample was collected form distal end of catheter into a sterile container. A calibrated wire loop delivering 10 ml urine sample was used to inoculate blood, MacConkey and CLED agar plates and incubated aerobically at 37°C for 24-48 hours. Isolated colonies were biochemically identified using recommended guidelines.\(^4\)

Only those with monomicrobial isolates were selected for the study. All isolates were tested for susceptibility to commonly used antibiotics on Muller Hinton agar by standard Kirby Bauer disc diffusion method. The zone diameter of inhibition for each antibiotic was interpreted according to National committee for clinical laboratory standards (NCCLS) Interpretive table. The patients with symptoms or proven UTI prior to catheterization were excluded from the study. The organisms resistant to particular antibiotics were classified and treated accordingly.

**Observation and Results**

**Table-1**  Age group classification of patients -16(16.6%) were between the age group of 50-60 years, 45(46.8%) were between 60-70 years of age and 35(36.4%) were above 70 years of age.

**Table-2**  Clinical diagnosis of diseases of patients with catheter i.e. infections - 62(64.5%) had BPH, 7(72%) had cancer of prostate, 9(9.3%) had urethral stricture, 11(11.4%) had CVA, 2(2%) had cancer of penis, 2(2%) had poly trauma and 3(3.1%) had CVD.

**Table-3**  prevalence of isolated organism in urine culture -57(59.3%) were E.coli, 15(15.6%) were Klebsiella, 7(7.2%) were Enterobacteria sp, 5(5.2%) were Acinetobacter sp, 12(12.2%) were p. aeruginosa.

Discussion

The present study is of UTI in patients with catheter, in teaching hospital of Srinivas Institute of medical sciences Mukka, suratkal–Mangalore.

96 patients (all males) aged between 50 to 80 years with urinary tract infections associated with catheters were studied. 62(64.5%) had BPH, 7(7.2%) had ca prostate 9(9.3%) had urethral stricture, 11(11.4%) had CVA, 2(2%) had cancer of penis, 2(2%) had poly trauma, 3(3.1%) had CVD (Table-2). The isolated organisms in the urine culture of the patients were 57(59.3%) E.coli, 15(15.6%) were Klebsiella, 7(7.2%) Enterobacteria, 5(5.2%) were Acinetobacters, 12(12.5%) were p. Aeruginosa. Antibiotics susceptibility to gram negative bacteria were also studied (Table-3). These present findings were more or less in agreement with previous studies.(6)(7)(8)

Urinary catheterization is generally indicated to relive urinary tract obstruction and urinary retention, to permit urinary drainage in patients with neurogenic bladder dysfunction, to aid urologic surgery and to obtain accurate measurement of urinary output in critically ill patients. If the Catheter is placed for more than one week, the rate of colonisation can be as high as 80 to 90%.9) Hence more attention should be placed on the catheter care and in the prevention of errors in the closed drainage. Also, use of catheter should be limited to carefully selected patients so as to reduce the size of population at risk. The majority of UTI are due to gram negative bacteria and many of these pathogens are part of the patient’s endogenous bowel flora but some may have been a acquired by cross-contamination from other patients or hospital personnel or by exposure to contaminated solution and unsterile equipment or even the hospital environment. Catheter associated UTI is frequently polymicrobial.10) The antimicrobial susceptibility pattern confirms that most of the UTI isolates in our environment are resistant to the commonly used antibiotics including broad spectrum antibiotics. This high resistance pattern could have resulted from poorly guided antibiotic prophylaxis after catheterization and empiric therapy of catheter associated with UTI. In particular the high resistance of the gram negative isolates to the fluoroquinolones is worrisome as these are reserve drugs for treating resistant infections. This may be due to rampant misuse of these drugs with consequent development of resistance. Hence indwelling urinary catheters should be used only when absolutely necessary and they should be removed as soon as possible. Catheter should be inserted only by adequately trained personnel. Urinary catheters should be aseptically inserted utilizing proper sterile technique. Personal care should be taken for catheterized patients.

Summary and Conclusion

The present study of UTI in patients with Catheter will be quite useful to the urologists and other doctors as well as other hospital personnel since bacteriuria is almost inevitable on long term catheterization.

Though prophylactic systemic antibiotics have been known to delay onset of bacteriuria in catheterized patients, all the possible preventive measures have to be taken during catheterization. This study demands further histopathological, immunological and microbiological study because little is known about exact proliferation, mechanism and activation of these organism which cause morbidity and mortality if untreated or if there is delay in treating.

Evaluation of Multi Drug Resistance Tuberculosis During the Study of Pulmonary TB in Telangana Population

Nalini N1, Ramkrishna Reddy2

1Associate Professor; 2Assistant Professor Department of Pulmonary Medicine Mediciti Institute of Medical Sciences, Ghanpur, Medchal, Telangana

Abstract

Out of 89 adults (aged between 25 to 75 years old) of both sexes of pulmonary Tuberculosis 4 (4.4%) were multi drug TB patients detected. The 89 patients history was 24(26.9%) were Tobacco smokers, 19(21.3%) had exposed to air-pollution, 11(12.3%) had high dosage of cortico steroids, 6(6.7%) had haemodialysis, 7(7.8%) were diabetes mellitus, 8(8.9%) had alcohol use, 5(5.6%) had chronic liver diseases, 9(10.1%) were HIV positive. Reasons for discontinuation of TB treatment was, 29(32.5%) had false sense of cure, 12(13.4%) had non-co-operation of paramedical staff, 11(12.3%) had domestic problems, 14(15.7%) had migrated for labor, 9(10.1%) cost of transport, 14(15.7%) had adverse drug reactions. The rate of resistance in single and poly drug therapy was. Rifampicin, pyrozinamide, ethambutol streptomycin had 0% rate resistance. Ioniazide + streptomycin, Isoniazide + streptomycin + rifampicain, Ethambutol + streptomycin had 0.5% resistance rate. Isonizide + Ethmubutol had 2.2% resistance rate. Isonizide had 1.8% resistance. This study of pulmonary tuberculosis with MDRTB patients with different history and different rates of immunity will be quite useful to pulmonary medicine physician to treat such patients efficiently because pulmonary tuberculosis is one of the main causes of morbidity and mortality in India and abroad.

Keywords: PT=Pulmonary Tuberculosis, MDRTB=Multi Drug Resistant tuberculosis, immunity, Telangana.

Introduction

Pulmonary Tuberculosis is one of the immune-compromised disease because due to urbanization there will be more exposed to polluted air, lack of nutritious food, poverty, migration to urban cities are the key factors for the PT. The prevalence of PT is estimated about 35%, globally (including India and china)(1). The to most potent anti TB drugs are Isonizide (H) and Rifampicin (R). MDR-TB, treatment response is poor and the mortality rate is high in adult as compared to children(2)(3). It could be due to the drop-out of treatments and this in complete treatment may leads to MDRTB(4).

Poor adherence to prescribed treatment increases the risk of morbidity, mortality and spread of disease in the community (5). Though TB/DOT services are provided by free of charge by government yet many patients are not successfully treated. Hence attempt was to study the patients of PT having different history and resistance, so that this study comprise of various rates of immunity will be helpful to chest physician to prevent the morbidity, mortality and spread of the disease.

Material and Method

89 adult patients aged between 25 to 75 years of both sexes visiting to mediciti medical college hospital Ghanpur Medchal-501401, Telangana, having pulmonary tuberculosis were selected for study. Out of 89 patients 4.4% patients diagnosed as MDRTD. All 89 patients belongs lower-middle socio-economic status. Every patients of PT were studied thoroughly with their past and present history, so that there should not be any recurrence of disease. Radiological, pathological biochemical investigation were done to confirm PT.
The patients with cardiac and neurological complication were excluded from the study. The ratio of male and female was 2:1.

The duration of study was adult five years,

Every patients, history, clinical manifestation, Drug resistance were classified and grouped with percentage.

Observation and Results

Table-1. History of PTin Telangana populations were 24(26.9%) were tobacco-smokers, 19(21.3%) were exposed to air-pollution 11(12.3%) had high dosage of cortico-steroids, 6(6.7%)had hemo dialysis, 7(7.8%) had D.M, 8(8.9%) had alcohol use, 5(5.6%) had chronic liver disease, 9(10.1%) had HIV positive.

Discussion

The present study of evolution MDRTB in PT Telangana population. The history of PT patients was 24(26.9%) were smokers, 69(21.3%) were exposed to air pollution, 11(12.3%) had high dosage of corticosteroids 6(67%) had haemodialysis, 7(7.8%) were DM, 8(8.9%) were alcoholic, 5 (5.6%) had chronic liver disease, 9(10.1%) were HIV positive patients (Table-1). The reason for discontinuation of TB treatment at TB/ DOTS, center was 29(32.5%) were at false sense of cure 12(13.4%) were due to non-cooperative of para-medical staff 11(12.3%) had domestic problems, 14(15.7%) migrated for labour, 9(10%) cost of transport, 14(15.7%) adverse drug reactions (Table-2). The rate of resistance in single and poly drug study, Rifampician, pyrazamidse ethambutol, streptomycin were 0%while Isonized + streptomycin, Rifampicin Isonized + streptomycin were 0.5% Isconoized + Ethambutol rate of resistance was 2.2% and Isonized was 1.8% (Table-3) This present prevalence of MDRTB study was 4.4% (Table-4). These obtained values were more or less in agreements with previous studies(6)(7)(8).

MDR-TB Caused by mycobacterium tuberculosis that is resistant both isonized and Rifampicin with or without resistant to other drugs is a phenomenon that is threatening to destabilize global tuberculosis control (9).In the present study ratio male and female was 2:1, hence it is important to evolve gender specific motivation strategies to reduce the default(10). Moreover default has been linked to length and complexity of treatment. It has been also any new tuberculosis chemotherapeutic agents which can further reduce the length of treatment will ultimately improve global tuberculosis treatment success rates(11).

The major hindrance of present study is the small size of patients hence not representing populations at large but Indian scenario is, it stands 22nd ranks high TB burden country(12). The risk or aggravating factors are genetic HIV infection. Diabetes mellitus, use of immune nodular drugs has been associated with the development of fatal TB in rheumatoid of arthits, tobacco smoking, poverty, economic attitude towards the nutritious food which creates immunity against such fatal diseases.

Summary and Conclusion

The present study of evolution MDR-TB in the study of PT will be useful to chest or pulmonary physician to present morbidity and mortality. It is suggested long and complex way treatment has to be reduced and simplified on the other hand awareness about fatal TB disease has to be created among people but this study warrants further pharmacological, genetic, histopathological, immunological study because exact formation of mycobacterium tuberculosisbacilli and their mechanism of spreading, gravity of resistance is still unclear.

Abstract

96 patients (78 males and 18 females) aged between 18 to 45 years had fractures of mandible -62(64.5%) had road accident, 17(17.7%) had assault, 12(12.5%) sports injury, 5(5.2%) due to falls. The anatomical sites of fractures were 32(33.3%) had symphysis menti and parasymphysis, 15(15.6%) had body of mandible, 13 (13.5%) had angle, 10(10.4%) had ramus, 7(7.29%) had condyles, 19(19.7%) had alveolar fractures. 46(47.9%) had isolated fractures and 50(52.0%) had multiple fractures. Types of treatment method were 3(3.1%) were un-treated, 19(19.7%) had IMF (inter maxillary fixation 5(5.2%) had circummandibular wire with an occlusal splint, 9(9.3%) had Risdon wining 46(47.9%) had MPO= mini plate osteo synthesis. 14(14.5%) had reconstruction plates. This study will be quite use full to oral and maxilla facial surgeon because morpho metric study of mesoderm is un-certain

Keyword: IMF= Inter maxillary fixation, MPO= mini plate osteo synthesis, Isolated fractures Multiple fractures.

Introduction

Fractures of mandible do occur and form a significant part of facial bone fractures encountered by the practicing dental surgeons. The occurrence of facial injuries tends to be high compared to injuries in other body areas because face is without any protective covering, and the mandible is one of the prominent bone of the face. deporting on the direction and force of the trauma, fractures of the mandible commonly occur at different sites, one classification of fractures by anatomic location. However the presence of teeth in the mandible is the most important anatomical factor which makes its fracture different from fractures elsewhere in the body. Hence attempt was made to study the fractures of mandible at different sites in the adults because adults are more prone for accidents, sports injury etc.

Material and Method

96 patients (78 males 18 females) aged between 18 to 45 years had mandibular fractures were brought to Nimra institute of medical sciences hospital Nimra Nagar Ibrahim patnum. Jupidi Vijaywada (District) Andrapradesh–521456 were selected for study

The anatomical sites of fractures were noted X-ray MRI was taken, Blood examination was also done to rule out Routine blood examination RBS (Random blood sugar) and to know any previous diseases like Rhumatoid arthritis, cardiac diseases. etc. History of each patient was studied in detail.

The patients were classified as per the anatomical sites of fractures and treated with different suitable method. Ratio of the male sand females were 4:1 HIV, congenital heart diseases patients were excluded from the study. The duration of this study was about three years.

Observation and Results

Table-1 Distribution of causes of mandibular fractures 62(64.5%) had road accidents 17(17.7%) had assault 12(12.5%) during sports, 5(5.2%) due to falls

Discussion
In the present study, of different sites of fractures of mandible, in Andrapradesh population. 62(64.5%) had fractures due to road accident, 17(17.7%) had assault, 12(12.5%) had sports injury, 5(5.2%) due to falls. (Table-1). The Anatomical sites of mandible fractures were 32(33.3%) symphysis menti and parasympysis menti 15(15.6%) body of mandible 13(13.5%) angle, 10(10.4%) ramus, 7(7.29%) had condyles, 19(19.7%) had alveolar (Table-2). Types of fractures were 46(47.9%) isolated, 50(52%) multiple fractures (Table-3) Types of treatment method were 3(3.1%) untreated and kept on observation, 19(19.7%) had IMF, 5(5.2%) circummandibular wire with an occlusal splint, 9(9.3%) had ridson wiring. 46(47.9%) had MPO (mini plate osteosynthesis) 14(14.5%) had reconstruction plates (Table-4). These findings were more or less in agreement with previous studies.

The present study the patients were aged between 18 to 45 years old who had fracture of mandible the reason could be un-aware of traffic rules or no fear of penalty or punishment, drunk and ride, bad roads, hurry and worry moreover assaults, sports are also common factors in young and adults age only. The conservative approach to the fractures of the mandible is justified because in the young’s and adults there is adequate blood supply to heal the fractures A soft diet is necessary so that mastication must be minimal during conservative treatment

The condylar process of the mandible and symphysis menti and parasympysis menti are weakest

point of the mandible hence more prone for fracture. Condylar processes are independent parts because they have to articulate with cranium to form Temporo-mandibular joint while symphysis menti is a meeting point of two independent bone hence symphysismenti or parasymphyssis are the weakest point of mandible tooth-bearing portion form 2/3rd of the mandible while non-tooth bearing portion forms remaining 1/3rd part of the mandible. The alveolar part is also major part of the fracture because of position of the patients during accidents assault or falls.

The patients were successfully treated between three to eight weeks with regular follow-up. In weak or mal-nutritious patients calcium supplements were also given to enhance rapid healing of fractures

**Summary and Conclusion**

The present study of fracture of mandible indicated that tooth bearing, symphysis menti body, ramus are most commonly prone for fractures. Hence awareness of traffic rules. Construction of good and safe roads, severe punishment for culprits, moreover night journey and long journey in rainy season should be avoided

Evaluation of Impaired Renal Function in Critical Care Units of Telangana Population

P. Dasharatham¹, Sudhirchalasani²

¹Associate Professor, ²Associate Professor Department of General Medicine Mediciti Institute of Medical Sciences Ghanpur Medchal Telangana

Abstract

42 patients (30 males and 12 females) aged between 30 to 65 years having renal impaired functions were studied the clinical manifestations were 16 (38%) had fatigue, 9(7.1%) had clubbing, 9(21.4%) had anemia, 2(4.7%) had cyanosis, 5(11.9%) had joint pain 4(p.5%) had dyspnea with excretion, 3(7.1%) had dyspnea without excretion. The associated diseases were 11(26.1%) had hypertensive, 19(45.2%) had diabetes mellitus, 8(19%) had cardiac diseases, 4(9.5%) had urinary tract infections. The GIT manifestations were 4(9.5%) had mouth ulcer, 9(21.4%) had change in taste, 11(26.1%) had anorexia, 6(14.2%) had nausea, 7(16.6%) had vomiting, 5(11.9%) had hiccup. The CNS and PNS manifestations were in 12(28.5%) conscious state, 9(21.4%) were in confused state (poor attention), 7 (16.6%) had slurred speech, 6(14.2%) had ataxia, 5(11.9%) had tremours, 3(7%) had burning sensation of feet and hand. The GFR status according to cock‑craft Gault formula method 6(14.2%) were in stage I, 11(26.1%) were in stage II, 17(40.4%) were in stage III, 8(19%) were in stage IV. This study of analysis of impaired functions of kidney will be quite useful to physician, Uro‑surgoen, to treat such patients efficiently to prevent morbidity and mortality because about 90000 Indian patients develop renal failure every year.

Keywords: GFR= Glumulo Filtration Rate, DM= Diabetes mellitus HTN= Hypertension, UTI= Urinary tract infection.

Introduction

Kidneys bear a huge responsibility in the survival of human body. They keep our internal environment in balance and play on essential role in the maintenance for normal homeostasis. It therefore comes as no surprise that renal impairment results into decline in kidney function can seriously affect essentially every organ of the body system. GFR is the best quantification of kidney function can be measured by estimating the concentration of serum or urinary clearance of filtration marker. The impairment of renal disease has multiple clinical manifestation which involves cardio-vascular, hormonal, Central and peripheral nervous system GIT, skeleto-muscular system etc. which especially affects older adults because there is a progressive decline of renal function with advance of age. Hence attempt was made to study the various clinical manifestation in adults so that, physician can take pre-cautionary measures to avoid wide-spectrum of clinical complications like congestive heart failure(1) And anemia of chronic kidney disease may reflect dys-regulated erythropoietin release and loss of peritubular cells which leads to un-corrected hypoxia.(2) Ends into mortality of patients.

Material and Method

42 patients (30 males and 12 females) aged between 30 to 65 years admitted at mediciti institute of medical sciences Ghanpur medical Telangana. Most of the patients belonged to middle socio-economic status. Every patients history was studied in detail. The USG, KUB, X-Ray, blood and urine investigation was done to rule out s. creatinine, Blood urea, RBS, and lipid profile was also carried out in Hypertensive patients. Estimated GFR (e GFR) was calculated using cock croft
Gault formula (CG/e GFR CG). And chronic kidney disease Epidemiology collaboration equation (CKD–EPI/e GFR CKD-EPI) equation the mGFR-24 hr urine-cr-cl was calculated as follows:

\[
\text{Creatinine clearance} = \frac{U \times V}{p} \times 1.73/A
\]

\(U\) = urine creatinine, (mg/dl)

\(V\) = urine volume/minute ie total volume/24*60

\(P\) = plasma, serum creatinine (mg/dl), 1073= avarage body weight

\(A\) = height 0.73 (cm) * weight (kg) * 7.1*10^{-3}

11 the eGFR was calculated using eGFR CG, eGFR MDRD. And eGFR CKD-Ep equation

\[
\text{Ccr} = \frac{(140-\text{age}) \times \text{weight}/72 \times \text{scr} \times (0.85 \text{ in females})}{\text{where creatinine clearance (cer) is expressed in milliliters per minute age in years, weight in kilograms and serum creatinine (Scr) in milligrams per decilitre}}
\]

HIV and congenital kidney anomalies patients were excluded from the study

The duration of the study was about two years

**Observation and Results**

**Discussion**

The present study of evaluation of impaired renal function of Telangana population the clinical manifestation of patients were 16(38%) had fatigue, 3(7.1%) had clabbing, 9(21.4%) had anemia, 2(4.7%) had cyanosis, 5(11.9%) had joint pain, 4(9.5%) had dyspnea with excretion, 3(7.1%) had dyspnea without excretion. (Table-1). The associated diseases were 11(26.1%) had HTN, 19(45.2%) D.M, 8(19%) had cardiac disease, 4(9.5%) had urinary tract infection (UTI) (Table-2) GIT manifestation were 4(9.5%) had mouth ulcer (9.5%) 9(21.4%) had change in food taste, 6(14.2%) had nausea, 7(16.6%) had vomiting 5(11.9%) had hiccough, 11(26.1%) had anorexia (Table-3). The central nervous system (CNS) and peripheral nervous system (PNS) manifestation were 12(28.5%) were conscious, 9(21.4%) were in confused state, 7(16.6%) had slurred speech, 6(14.2%) had ataxia, 5(11.9%) had tremors 3(7.1%) had burning sensation of feet and hand (Table-4). The GFR status according to cock-craft Gault formula 6(14.2%) were in stage-I 11(26.1%) were in stage II 17(40.4%) were in stage III, 8(19%) were in stage IV, (Table-5). These findings were more or less in agreement with previous studies. (5)(6)(7)

The patients have renal function impairment associated with multiple diseases like HTN, DM, Anemia, CVD, malnutrition, UTI hence it is imperative to the clinician to rule out the kidney disease at the beginning so that morbidity and mortality of such patients can be prevented. (8) The kidney disease may reflect stronger influence of the other factors such as use of ACE inhibitors. Because use of ACE inhibitors in progression of kidney disease is fairly established (9) Because kidney disease of patients having ischemic heart disease (IHD) and other CVD risk factors have been reduced considerably by the use of ACE inhibitors because stage IV or Vth (Table-5). The serum creatinine may not be as strong marker for the mortality of the patients moreover patients having associated complication (Table-2). Can be put for dialysis.

Anemia of renal impairment arises primarily from progressive failure of kidney endocrine function, peritubular cells in the kidney cortex function as oxygen sensors controlling red cell mass. Renal tissue hypoxia triggers hypoxia inducible factor signaling which in turn, up-regulates erythropoietin production. (10) To stimulate division and differentiation of red cell precursors. Anemia of kidney disease leads to left ventricular hypertrophy, congestive cardiac failure (CCF), coronary artery disease, and untreated anemia of kidney also cause progressive renal impairment.

**Summary and Conclusion**

The present study of renal function impairment evaluation will be quite useful to predict the complications of kidney disease because early diagnose of kidney disease will present the morbidity and mortality. But the present study demands farther patho-physiological, genetic, nutritional, embryological and immunological study because little is known about exact mechanish, duration and filtration rate (Glumulo filtration).

Study of Tympanoplasty in Vijaywada Population

Chikkala Jagadeesh Babu
Assistant Professor, Department of ENT, Nimra Institute of Medical Science, Ibrahim Patnam, Vijaywada, Andrapradesh

Abstract

33 males and 12 female patients were selected for tympanoplasty either righter left harvesting of the tragal cartilage graft with a thickness between 0.2 to 0.4 mm and techniques used were underlay techniques and lateral to the hand of malleus supported by gel foam on both sides. During the study mean value of diameters of external canal in 21 males (63.6%) was 1.2 mm, and 12 males (36.3%) it was 1-4mm. In females 7 females (58.3%) the diameters of external canal was 1.2mm and in 5 females (41.6%) it was 1.3mm. The size of perforating gap in tympanic membrane Air borne gap range and average range study. 20 males had 1-2 mm perforations, air borne range was 10-31 dB and average range was 22dB. In 10 males the perforation size was upto 1mm, air borne range was -0.25mm, the average range was 11dB.In 3 males air borne range 17-31dB and average range was 23 dB. In females study 7 females had 2-3mm perforation, air borne range was 14-36 and average was 24 dB, In 3 females perforation was upto 1mm, air borne range was 0-25 dB and average was 9 dB, In 2 females had 3-4mm perforation, air borne range was 17-31 dB and average range was 23 dB. This study of tympanoplasty by tragal cartilage will be certainly helpful to junior ENT surgeons and biotechnologist to invent such similar technique in future.

Keywords: Tympanoplasty, Tragal cartilage. Perforation, Air borne range.

Introduction

As tympanic membrane is developed from all three germ layers hence it is resistant to negative middle ear pressure, stable and elastic until it is not perforated hence long term aim of tympanoplasty its reconstruct the tympanic mechanism and the sound conducting mechanism since the introduction of tympanoplasty(1) numerous graft materials like skin, fascia lata, temporaries fascia, vein, perichondrium, durametre have been used for closure of the defective membrane(3)(4) but in most of the cases there were recurrent perforations reported due to severe attical and or posterior uncontrolled retraction pockets with cholesteatomatus formation, atelectasis of tympanic membrane, fascia and perichondrium have been shown to undergo atrophy and subsequent failure regardless of the placement of techniques used (5) In the present study used cartilage as grafting materials an account of its increased stability and resistant to negative middle ear pressure, even in the cases with chronic Eustachian tube dysfunction because cartilage is well tolerated by the middle ear and shows long term survival. Hence attempt was made to study tympanoplasty in Vijayawada Population of sexes and satisfactory result was observed.

Material and Method

45 patients aged between 22 to 35 years who were visiting to Nimra Institute of medical Sciences hospital Ibrahim PatnamVijayawada, AP–521456, were selected for study. The selected patients diagnosed clinically as chronic supportive to its media, with loss hearing, constant liability of infection Tinnitus and dizziness. Pre-operative assessment included a puretone audiogram and a tympanogram. They consented for cartilage tympanoplasty either right or left and harvesting of the tragal cartilage, graft with a thickness between 0.2 to 0.4mm and technique used were underlay technique and
lateral to handle of malleus supported by a gel form an both sides.

The patients had middle ear pathology viz tympanic sclerosis, cholesteatoma, fibrosis were excluded from the study. Out of 45, patients 12 were females. (the ration of male and female was about 3:1)

All the patients have minimum three month post operative tososcopical and audio metric follow up and if any complication treated immediately. The duration of the study was about three years.

Observation and Results

Table-1: In 21 males (63.6%) the mean value of external canal was 1.2 mm and in 12 males (36.3%), the mean value of external canal value was 1.4 mm. In females 7 females (58.3%) The mean value of external canal was 1.2 mm and 5 females(41.6%), the mean value of external canal was 1.3mm

Table-2: The study of size of perforation and airborne gap range and average range. In 20 males the perforation size was between 1-2 mm, air borne range was 10-31dB and average was 22 dB. In 10 males it was upto 1mm, the airborne range was 0.25dB and the average range was 11 dB. In 3 males the size of perforation was 3 to 4 mm, the airborne range was 17-31 dB and average was 23 dB. In 3 females the perforation of tympanic membrane was upto 1mm, air borne was 0.25dB and average range was 9 dB. In 2 females the perforation size was 3 to 4 mm, the air borne range was 17-31 dB and average range was 23 dB.

Discussion

In the present study of 33 males and 12 females of Vijayawada population were studied. The mean value external canal was in 21 males (63.3%) was 1-2 mm and 12 males (36.3%) the mean value of external canal was 1-4 mm. In females study 7 females (58.3%), the mean value of external canal was 1-2 mm and in 5 females (41.6%), the mean value of external canal was 1-3 mm (Table-1). These findings were more or less in agreement with previous studies[6][7]

In the present study of size of perforation of Tympanic membrane, air borne range and average range study 20 males had perforation size was 1-2 mm, air borne range was 10-32 dB and average range was 22dB. In 10 males the perforation size was upto 1mm, air borne range was 0-25 dB and average range was 11dB. In 3 males the size of perforation was 3-4mm, airborne range was 17-31dB and average range was 24 dB. In 3 females the perforation of tympanic membrane was upto 1mm, air borne was 0.25dB and average range was 9 dB. In 2 females the perforation size was 3 to 4mm, air borne range was 17-31 dB and average range was 23 dB. These findings were also more or less in agreement with previous studies[8][9]

To avoid the failure of the graft, dry remnant tympanic membrane was avoided, because it was vascular, hence graft was not adhering to the remnant tympanic membrane. All dry preparation was converted to subtotal perforation by removing atrophic portion of tympanic membrane. Overall graft take rate was 99.30% was successful. It was in previous studies also[10][11] but the procedures may vary in different countries.
Summary and Conclusion

The present study of tympanoplasty in both sexes of Vijayawada Population is quite helpful to junior surgeon to follow moreover further studies should be conducted to ascertain the effect of demographic characteristics on audiology cal outcomes after cartilage tympanoplasty. This study also demands further histo-pathological, embryological and bio-mechanical study because grafted cartilage is being mesodermal and received tympanic membrane is developed from all three germ layers hence stability of tymponoplasty remains ambiguous.

Study of Depressive (Psychiatric) Problems in Elderly Population of Telangana

Sudhir Chalasani1, P. Naveen Chandra Reddy1

1Associate Professor, Department of General Medicine, Mediciti Institute of Medical Sciences, Ghanpur, Medchal, Telangana

Abstract

In the present study 95 male and 83 female elderly Depressive (psychotic) patients aged between 65 to 75 years studied in males 45(47.3%) were dementia, 25(26.3%) had depressive illness, 11(11.5%) were manic, 10(10.5%) were anxiety, 4(4.2%) had paranoid psychosis. In female 36(43.3%) had dementia 20(24) had depressive illness 8(9.6%) had paranoid 4(4.8%) had hallucination 9(10.8%) had anxiety. Apart from this disease associated with geriatric psychotic patients were also studied in males. 20(21%) D.M, 26(25.2%) had osteo–arthritis, 7(7.3%) had constipation 22(23.1%) had family conflicts, 1(13%) had death of life partners or close relatives. 9(9.4%) had a sudden loss in business. In Female geriatrics 30(36.1%) D.M, 23(27.7%), 22(26.5%) had family conflicts, 8(9.6%) had death of life partner or close relative. In the study of suicidal tendencies due to severe depression 65(68.4%) of males, 60(72.2%) female had suicidal ideation, and 30(31.5%) male 23(27.7%) females were attempted for suicide. This study of various psychotic patients will certainly help the psychiatrist to treat the old aged patients efficiently and meticulously, and it conveys a massage to surgeons, and physicians to take opinion of psychiatrist during the treatment of geriatric patients so that they can be cured physically and mentally and live with confident and face the challenges of the geriatric problems.

Keywords: Dementia, depression Geriatric, Anxiety.

Introduction

35 to 48% elder patients suffer with psychiatric problems. Their psychiatric disorders were mainly dementia and depression is the most common problems. The elderly patients is no different from younger individuals however, in the respect of both can develop acute psychiatric or medical disturbances that may be superimposed on a chronic medical or mental condition. (1) during evaluation a geriatric patient/present confusing array of symptoms to the physician. The patients past and present history it may be long rambling tale with frequent disgression. Dementia is a chronic process with a loss of intellectual abilities that interferes with social or occupational functioning. Dementia a evidence of organic etiology or the disorder does not fit the criteria for other organic mental disorder. (2)

Depression is one of the most common problems of aged next to dementia. The geriatric patients are debilitated because of severe depression. Majority of the patients were misdiagnosed depressed elderly patients usually experience fatigue, listlessness, constipation and decreased appetite; They typically have disturbed sleep and may actually appear to be quite sad. Their sadness may be overlooked by young healthy care taker who believes that, any one would be sad about being that old. One can reveal their problems with brief conversation that, They have recurrent thought of death, illness and hopelessness. They see their lives as futile and separation from their families as lonely and unending. (3) Hence attempt was to study the various psychiatric problems in elderly population of both sexes.

Material and Method

1. 95 males 83 females aged between 65 years to 75 subtending with psychiatric illness who were regularly visiting General medicine OPD of mediciti institute of medical sciences Ghanpur Medichal–50140 Were selected for study. In addition to this most of male and female geriatrics were referred by medicine surgery orthopedic due to their anxiety disorders, These patients were councilled thoroughly and evacuated their past and present history of disease and diagnosed and treated accordingly, viz dementia, psychosis, mood disorder includes depression, mania, generalized anxiety disorders associated with medical and surgical (pre and post surgical). The duration of this study was about two years.

Observation and Results

Table-1 Study of different psychiatric illness in male geriatric patients out of 95.45(47.3%) were dementia, 25 (26.3%) were under major depression 11(10.5%) were suffering with anxiety 4(4.2%) had paranoid psychosis

Table-2 Study of different psychiatric illness in female geriatric patients out of 83, 36(43.3%) had dementia, 20(24%) were under depression 8(9.6%) had paranoid psychosis, 4(4.8%) had hallucination 6(7.2%) were manic anxiety

Table-3 Diseases associated with psychotic geriatric male patients out 95 20(21%) were diabetic mellitus, 24(25.2%) had osteoarthritis 7(7.3%) had constipation 22(21.1%) had family conflict 13(13.6%) death of life partner or close relatives 9(9.4%) sudden or unexpected loss in business

Table-4 Diseases associated with psychotic geriatric female patients out of 83, 30(36.1%) were diabetic mellitus 23(27.7%) had arthritis, 22(26.5%) had family conflicts 8(9.6%) had problem of death of their life partners or close relatives

Table-5 Study of social tendencies due to major depression in geriatric patients of both sexes, a) in males out 95, 65 (68.4%) and in females out 83, 60(72.2%) had suicidal ideas frequently. B) in males out of 95 30(31.5%) and in females out of suicide but did not succeed.

Discussion

In the present study of psychiatric problems in elderly patients of Telangana population of both sexes. In males Dementia were 45(47.3%) depressive illness 25(26.3%) manic 11(11.5%) anxiety 10(10.5%) and paranoid psychotic were 4(4.2%) (Table-1) in female patients also dementia were 36(43.3%) depressive illness were 20(24%) paranoid psychosis were 8(9.6%) hallucinated 4(4.8%) manic 6(7.2%) and anxiety were 9(10.8%) (Table-2) The diseases associated with male psychotic patients of old age were diabetic mellitus 20(21%) osteo orthotic 24(25.2%) constipation 7(7.3%) family conflicts 22(23.1%) death of life partner or close relative 13(13.6%) sudden loss in business 9(9.4%) (Table-3). In female psychiatric patients associated diseases were diabetic mellitus 30(36%) osteoarthritis 23(27.7%) family conflicts 22(26.5%) death of life partner or close relative 9(9.6%) (Table-4).These findings are more or less in agreement previous studies.[4][5] Due to sever or major with depression these psychotic elderly patients have suicidal ideations or/and commit suicidal attempts in males 65(68.4%) had suicidal ideations in females 60(72.2%) had also suicidal ideations. Moreover 30(31.5%) males and 23(27.7%) attempted for suicide (Table-5)

Dementia is a chronic organic mental disorder characterized by a) impairment of memory, b) intellectual function c) deterioration of personality with lack of personal care d) there is impairments of judgment, impulse control, and impairment of abstract thinking. In the dementia there are degenerative brain damage if defuse may lead to dementia. There will be enlarged cerebral ventricle widened cerebral sulci and shrinkage of cerebral cortex. When viewed gross anatomically but in microscopic study senile plaques, neuro fibrillary tangles, cortical nerve cell loss and granulo vacuolar degeneration, moreover there is marked decrease in brain choline acetyl transferes with similar decrease in brain acetylcholinesterage (Ach E).[6] Manic or hypomania patients in present study ie, 11(11.5%) in males, 6(7.2%), (Table-1 & 2) near half of the patients give the history of manic attach episodes in the earlier year During the manic period the patient was elated, expansive or irritable, hyperactivity, pressure of speech, flight of ideas, inflated self esteem and decreased need for sleep were features of manic episodes. The patients often exhibited grandiose delusions and some time persecutory delusions, paranoid psychosis or reaction in the present study was 4.2% in males and 9.6% in females (Table-1 & 2). Female are more prone to this psychotic disease than males. It is due to lack of family cohesion and feelings of loneliness are significant features observed in the present study. Moreover paranoids associated with several bizarre complaints and hallucinations of voices, smell, but intelligent is usually well preserved.[7][8] Anxiety disorder 10(10.5%) males 9(10.8%) in female (Table-1 & 2) Anxiety in old age often mixed with depression and hopelessness anxiety may occur due to anticipation of yet additional onis fortunes, guilt feelings might arouse anxiety. If the planned ventures, were not fulfilled anxiety may occur but chronic neurotic anxiety carryover from earlier years. The patient suffer from anxiety such as restlessness, term or of hands and poor sleep suicidal ideas may be present in the severe cases of delusion of nihilism, hypochondriasis is and depressive with physical illness.[9] Depressive ideation had 3 common types of disorders, a) Hopelessness-due to pessimism b) helplessness feeling lonely c) worthlessness feeling of inadequacy, inferiority, guilty feelings, self approach. Although depression was common in both sexes but quite obvious in females widowed and belongs to lower socio-economic groups. Death of spouse was the most stress full event often leading to radical changes in lifestyle, loss of personal care and general loss of life satisfaction. Elderly man suffer reduction in income due to retirement or inability to work due to health reasons. poor socio-economic results multiple stresses such as in adequate diet, deficient and poor medical care and family disorganization, all these combine to produce depression.[10] Social isolation or living alone is one of the important factor causing depression in elderly. It may be due to retirement and lack of social contact or due to physical illness and inability to move about or due to children moving away from the family for the reason of employment.[11]

Summary and Conclusion

The present study of psychiatric/depression problems in elderly populations of Telangana will certainly help the physician to diagnose the patients with different, present and past family history because a behavioral problem in elderly patient is too often diagnosed a being a natural result of old age. Hence every surgeon or physician must take an opinion from psychiatrist during treatment of aged patients because most of the diseases are non organic and result of depression, or psycho-somatic factors. However this study demands farther genetic study because most of anxiety, depression schizophrenic are genetic hence they can be treatable not curable.

Study of Umbilical Hernia in the Patients of Andrapradesh

Ravi Dasyam

Assistant Professor, Department of General Surgery, Nimra Institute of Medical Sciences, Nimra Nagar Jupudi (v), Ibrabimpatnam, Krishna (Dist) Andhrapradesh

Abstract

63 adult patients (40 males and 23 females) aged between 30 to 70 years of umbilical hernia were studied. 13(20.6%) were alcoholic, 10(15.8%) were HTN, 7(11.1%) were smokers, 9(14.2%) had coronary artery diseases, 11(17.4%) were DM, 8(12.6%) were DM, 8(12.6%) were obese, 5(7.9%) were tobacco chewers, the clinical manifestation was 17(26.9%) had severe pain, 16(25.3%) had abdominal distention, 20(31.7%) had swelling, 8(12.6%) had irreducible hernia, 2(3.1%) had vomiting. Blood investigation study included sodium in 45mm/dl (66.6%) patients had 134‑136, mg/dl, 21(33.3%) had 137‑138. mm. In serum albumin study‑39 (61.9%) mg/dl patients had 3.2 to 5.1 mm and 24(38%) had 6.1 to 7 mg. In serum creatinine study 44(69.8%) patients had 1.2 to 1.3 mg/α and 19(30.1%) had 1.5 mg/d In serum Bilirubin study 48(76.1%) patients had 1.8 to 1.5 mg/dl and 15 (23.8%) had 2.2 to 2.4 mg/dl In WBC count study 43(68.2%) patients had 6.2 to 6.9 20(31.7%) had 7.1 to 9.2. In platelet count study 44(69.8%) patients had 145.7 to 149, and 19(30%) had 150 to 160 the percentage of post operative infection were 11(17.4%) had wound infections in anatomical group, 8(12.6%) patients had wound infections in mesh group, 9(14.2%) had seroma in anatomical repair, 7(11.1%) had seroma in mesh repair. The percentage of recurrence of umbilical hernia were 9(14.2%) had anatomical repair, 8(12.6%) had mesh repair.

Keywords: Necrotic mass, strangulated hernia, Mesh repair, HTN= Hyper tension.

Introduction

Hernia is a word derived from a Greek word heron, meaning a branch or protrusion. Hernia is the bulging of the part of the normal contents of the abdominal cavity through a weakness in the abdominal wall.(1)

Hernias of the abdominal wall that arise room 3cm above to 3cm below the umbilicus are defined as umbilical hernia.(2) Cirrhosis of liver is one of the major cause of umbilical hernia, as cirrhosis leads to rise in intra abdominal pressure while obesity in females causes herniation.(2) The treatment with cirrhotics with umbilical hernia is quite complicated because umbilical hernia is associated with ascetic fluid, peritonitis, evisceration, incarceration of the content of hernial sac. (3) Moreover weakness of the muscles of the anterior abdominal wall secondary to poor nutrition and recanalised umbilical vein includes restoration of supraumbilical fascial defect. (4) Long standing as citis will lead to umbilical hernia. Hence attempt was made to evaluate the practical challenges and complications of umbilical hernias at different ages in both sexes, because umbilical hernia has tendency to be associated with high morbidity and mortality in comparison with inguinal hernia because of higher risk of incarceration and strangulation that requires emergency repair.

Material and Method

63 adult patients with umbilical hernia aged between 30 to 70 years, including both sexes (40 males and 23 females). Who were regularly visiting to department of general Surgery. Nimra Institute of medical sciences, Nimra Nagar Jupudi (v) Ibrahimpatnum, Krishna (dist) – 521456, Andhrapradesh were selected for study. History of every patient was recorded. Radiological and blood investigation was carried out to know the severity of hernia and to study the associated clinical manifestations of the patients.
Out of 63 42 were necrotic mass and 21 were strangulated umbilical hernia and pathologically benign. Small defects of hernia were sutured and larger defects were closed by mesh repair

HIV and malignant patients having umbilical hernia were excluded from the study. The duration of the study was about four years

Discussion  
In the present study of umbilical hernia in the patients of Andrapradesh. 63 adult patients of different age groups. Among them 13(20.6%) were alcoholic, 10(15.8%) were HTN, 7(14.2%) had coronary artery disease 11(17.4%) had diabetes mellitus (DM) 8(12.6%) were obese 5(7.9%) were tobacco chewers (Table-1). 14(22.2%) patients were aged between 30-40 years, 29(46%) patients were between 41-50 years 15(23.8%) were aged between 51-60, 5(7.9%) were aged between 61-70 years of age (Table-2). The clinical manifestations of these patients with umbilical hernia (UL) was–17(26.9%) had severe pain, 16(25.3%) had abdominal distention 20(31.7%) had swelling 8(12.6%) U.L. were irreducible, 2(3.1%) had vomiting (Table-3) blood investigation of U.L patients the serum sodium level in 42(66.6%) had 134-136 mm/L 21(33.3%) had 137-138 (mm/l). the serum albumin level in 39(61.9%) had 3.2 to 5.1, 24(38%) had 6.1 to 7. S.creatinine. 44(69.8%) had 1.2 to 1.3, 19(30%) had 104 to 105, In S.Bilirubin study 48 (76.1%) had 108 to 1.9, 5(23.8%) had 2.2 to 2.4 in mean WBC count study 43(68.2%) had 6.2 to 6.9, 20(31.7%) had 7.1 to 9.2. in platelet count study 44(69.8%) had 145.7 to 149, and in 19(30.1%) 150 to 160 (Table-4) The postoperative infections in UH was 11(17.4%) in wound infection in anatomical group 8(12.6%) wound infections in mesh repair, 9(14.2%) in seroma in anatomical repair, 7(11.1%) in seroma in mesh repair (Table-5) Recurrence of U.H–9(14.2%) in anatomical repair 8(12.6%) in mesh repair (Table-6). These obtained values were more or less in agreement with previous studies. 

Hernias commonly cause pain and are distressing to patients more aesthetically. These concerns, and the risk of incarceration, are the most common reasons patients seek surgical repair of hernia. The treatment U.H in cirrhotic is quite challenging. Control of ascites forms the main stay of treatment as this leads to reduced hernia recurrence and post operative complications like wound dehiscence, infection evisceration and peritonitis. Use of diuretics, paracentesis at regular intervals and transjugular intrahepatic port system shunt (TIPS) are often necessary to control ascites TIPS done preoperatively in these patients may allow better control of ascitis and in turn make them more amniable for herniorraphy. The laboratory values of the present study showed high levels of morbidity and preoperative sepsis and treated with antibiotics moreover large with wide openings are difficult to manage by anatomical repair, as it may result into recurrence due to undue tension resulting in tissue necrosis such hernias asw treated with prosthetic mesh repair. In which material was implanted in the abdominal wall that could add strength, and avoiding excessive tension created by large and wide UH. These large and wide UH. Defects bridged by prosthetic mesh. This mesh repair has low morbidity and less recurrence rate. The mesh bridge has laparoscopic approach.

Summary and Conclusion  
The study of umbilical hernia in the patients of Andrapradesh is quite useful to the surgeon because wide and large umbilical hernias(UH) were closed by mesh repair which method has lower recurrence because UH has recurrence is quite common. Owing to intra-abdominal pressure and muscles of the abdomen are antigravity muscles but this study demands further biomechanical, patho-physiological, nutritional,myological study because umbilicus is a meeting point of many systems of the body. Hence it is more weakened and easily allow the herniation. and little is known about the degree of intra-abdominal pressure and strength of muscle which prevent the herniation.

Assistant Professor Department of Obstetrics and Gynecology G.S. Medical College, NH24, Near Petrol Pump, Peeplabandapur, Pilkhuwa (UP)

Abstract

In the present study, 40 females of primary infertility and 40 females of secondary infertility aged between 18-40 years were studied, primary infertility females grouped as group-A and secondary infertility females grouped as group-B. In group A, the duration of marriage of 21 (52.5%) was 1 to 5 years, 12 (30%) had 6 to 10 years, 7 (17.5%) had more than 10 years. In group B, 11 (27.5%) had 1-5 years of marriage duration, 16 (40%) had 6-10 years and 13 (32.5%) had more than 10 years of marriage period. The menses history in group A was: 13 (32.5%) had regular menses, 19 (47.5%) had oligomenorrhea, 5 (12.5%) had amenorrhea and 3 (7.5%) had menorrhagia. In group B, 12 (30%) had regular menses, 17 (45.5%) had oligomenorrhea, 9 (42.1%) had oligomenorrhea, 9 (22.5%) had amenorrhea and 2 (5%) had menorrhagia. In group A, serum prolactin level in 17 (42.5%) females was 0-20mg/ml, 23 (57.5%) was 21-100mg/ml. In group B, 26 (65%) had 21-100mg/ml and 1 (2.5%) had >100 mg/ml. In group A, TSH level in 3 (7.5%) was <0.4, 27 (67.5%) females had 0.4-4.7, 10 (25%) females had >4.7 µIU/ml. In group B, 2 (5%) females had <0.4 µIU/m, 33 (82.5%) females had 0.4-4.7 µIU/m, 5 (12.5%) females had >4.7 µIU/ml. This correlative study of S. prolactin and TSH hormones will be quite useful to obstetrics and gynecologist, endocrinologist, to rule out proper cause and treat the infertility efficiently, because due to increased rate of infertility majority of couples are finding surrogative mothers which are quite expensive and may lead to legal complications.

Keywords: Serum Prolactin, Thyroid stimulating Hormone.

Introduction

Infertility is defined as the failure of a couple to achieve conception (regardless of cause) after one year of unprotected and adequately timed inter course(1). It could be primary i.e. a couple has never conceived despite cohabitation and exposure to sexual activity over a period of years, secondary infertility is when couples have achieved a pregnancy, previously but regular unprotected sexual intercourse has not resulted in second pregnancy (2). Human infertility is a complex problem, which has numerous consequences depending on the society and cultural background, gender, lifestyle, sexual history of the people it affects. Infertility is a global public health concern. This is partly due to complexity in aetiology as well as difficulty in preventing, diagnosing and treating it.

Hormonal disorder of female’s reproductive system is comprised of a number of problems resulting from aberrant dysfunction of hypothalamic-pituitary-ovarian axis. These relatively common disorders often lead to infertility (3). Measurement of prolactin and thyroid hormones especially TSH has been considered an important component of infertility work up in females (4).

Hence attempt was made to study these both hormonal assays and correlate their profile in both primary and secondary infertile females.

Material and Method

80 infertility woman aged between 18 to 40 years who were regularly visiting Obstetrics and Gynecology department, G.S. Medical College, NH24, near petrol...
pump, Peeplabandapur, Pilkhuwa-245304 (UP) were selected for study. Among 80, 40 were primary infertility and 40 were secondary infertility hence primary infertility females were, grouped as A and secondary infertile were grouped as B group.

Complete haemogram, ESR, USG perineum and abdomen, chest x-ray, thyroid function test, serum prolactin test, Histosalpinography and diagnostic laparoscopy was carried out whenever indicated.

Blood examination was done for hormone probably on 3rd day of menstrual cycle. TSH and prolactin assay levels were measured using Beckman coulter Access-II Immune assay analyzers.

Male factor infertility-congenital anomaly of urogenital tract, diabetes mellitus patients with cardiac and neurological disease were excluded from the study. The duration of study is about two years (from September 2016 to December 2018)

For the patients of group A and group B, duration of marriage, menses history, hormonal level assay were classified in percentage and studied.

Discussion

In the correlative study of prolactin level and hypothyroidism in both primary and secondary infertility females of Uttar Pradesh, in group A, the duration of marriage of 21 (52.5%) was 1 to 5 years, 12 (30%) had 6 to 10 years, 7 (17.5%) had more than 10 years. In group B, 11 (27.5%) had 1-5 years of marriage duration, 16 (40%) had 6-10 years and 13 (32.5%) had more than 10 years of marriage period (Table-1). The menses history in group A was: 13 (32.5%) had regular menses, 19 (47.5%) had oligomenorrhea, 5 (12.5%) had amenorrhea and 3 (7.5%) had menorrhagia. In group B, 12 (30%) had regular menses, 17 (45.5%) had oligomenorrhea, 9 (21.5%) had oligomenorrhea, 9 (22.5%) had amenorrhea and 2 (5%) had menorrhagia (Table-2). In group A, serum prolactin level in 17 (42.5%) females was 0-20mg/ml, 23 (57.5%) was 21-100mg/ml. In group B, 26 (65%) had 21-100mg/ml and 1 (2.5%) had >100 mg/ml (Table-3). In group A, TSH level in 3 (7.5%) was <0.4, 27 (67.5%) females had 0.4-4.7, 10 (25%) females had >4.7 µIU/ml. In group B 2 (5%) females had <0.4 µIU/m, 33 (82.5%) females had 0.4-4.7 µIU/m, 5 (12.5%) females had >4.7 µIU/ml (Table-4). These findings were more or less in agreement with previous studies (5)(6)(7).

Hyper prolactin adversely affects the fertility potential by impairing pulsative secretion of GnRH and hence interfering with ovulation (12). This disorder has been implicated in menstrual and ovulatory dysfunctions like amenorrhea, oligomenorrhea, anovulation, in adequate corpus luteal phase and galactorrhea.

Summary and Conclusion

The present correlative study of serum prolactin
level and hypothyroidism in both primary and secondary infertility of females in Uttar Pradesh will be quite useful for obstetrics and gynecologist endocrinologist physician to treat such infertility. Hence assessment of serum TSH and prolactin levels must be mandatory in the treatment of infertile women especially those presenting with menstrual irregularity. But this study further warrants, genetics nutritional, neurological, endocrinological study because exact quantum of hormonal secretion, mechanism of stimulating factors which exactly increase or decrease the hormonal secretion is still unclear.

Abstract

90 adult patients (48 males and 42 females) aged between 25 to 50 years were studied pre-operative clinical manifestation were 35(38.8%) had protruded hemorrhoids, 18(20%) had bleeding, 17(18.8%), had painful hemorrhoids, 11(12.2%) had hemorrhoids with discharge 9(10%) had hemorrhoids with pruritis.

In the comparison of grade-II with grade-III MXSP mean value of grade-II was 102 and grade-III was 120 (p<0.01) and t test was–109, MSP of grade-II mean value was 73 and grade-III was 96.5 (p<0.01) and t test was–147. In RBL study before and after treatment all parameters like MXRP MXSP MRP MSP, VFS MXTV were highly significant (p<0.01). In monometric study of electro therapy before and after electro therapy all the parameters viz MXRP, MRP, MSP, VFS, MXTV. Were found to be highly significant p value (p<0.01). In the study of haemrroidectomy before and after haemorroidectomy all the parameters viz, MXRP, MRP, MSP, VFS, MXTV were found to be highly significant (p<0.01).Post operative conditions of haemorroidectomy, RPL and electrotherapy were compared. Post operative pain was severe (6%) at haemorroidectomy moderate (4%) at RBL and mild (2%) at electrotherapy. Thrombosized external haemorrhoids was 1% at haemorroidectomy, 2% at RBL and nil at electro therapy. Urinary retention was highest (5%) at haemorroidectomy, 1% at RBL and nil at electro therapy. Post–operative discharge was 3% at haemorroidectomy, 2% at RBL and nil at electrotherapy. This comparative study has pragmatically proved that, electro therapy approach for grade–II and grade–III haemorroid treatment is safer than other method

Keywords: RBL= Rubber Band ligation, Electro therapy, Haemorrhoidectomy manometer.

Introduction

Hemorrhoids are abnormally enlarged and cushions containing intravenousatreo-venous anastomosis, traditionally described as occurring in 3.7, and 11 ‘o’ clock positions. The vascular supply is from branches of superior rectal artery, which are drained by veins (internal venous plexus) emptying into superior rectal vein. Internal hemorrhoids, which originate from above the dentate line of the anal canal, occur when these and cushions are dragged down the canal. They affect millions of people around the world, and represent medical and socio-economic problem. Multiple factors have been claimed to be the etiologies of haemorrhoidal development, including constipation and prolonged straining. With advancement of age connective tissue replaces the matrix of the muscle, there by leads to loss of elasticity, and tonicity of muscle to anchor the blood vessels. Which form anal cushion will be lost and leads to protrusion of blood vessels which are abnormally enlarged. The risk factors of hemorrhoids are constipation, straining and also diarrhea, straining which sitting for long in a toilet with an unsupported and relaxed perineum leads to engorgement of the anal cushions and increases the downward shearing force upon them. Along with loss of supporting muscle fibers the venous plexus distends causing the hemorrhoids to bulge. Hemorrhoids are common in the later stage of pregnancy and may be due to the gravid

uterus causing compression on the pelvic venous system may be the aggravating factor. It is established fact that, anorectal physiology changes with the development of hemorrhoids and associated with abnormally raised resting and squeezing pressure.\(^{(4)}\) Treatment modalities also can change the physiological parameters. Hence attempt was made to compare these resting and squeezing pressure before and after treatments of RBL, electrotherapy and haemorroidectomy so that surgeon can predict the risk factors and adopt the safest method to approach hemorrhoids.

**Material and Method**

90 adult patient (48 males and 42 females) aged between 25 to 50 years suffering with haemorroids, regularly visiting surgery department. Nimra institute of medical sciences. Nimra nagar. Jupidi. (v) Ibrahimprtrum(m) Krishna (district) Andrapradesh‑521456 were selected for study. The diagnosis and grading of haemorroids was confirmed by history, physical examination, and anoscopy. 45 patients had grade-II and 45 patients had grade-III haemorroids grade-II haemorroids had prolapse with spontaneous reduction, bleeding, seepage, grade-III had prolapse with bleeding, seepage. 30 patients selected for RBL (rubber band ligation), 30 for electrotherapy, 30 for haemorroidectomy, The manometric readings of these three groups were recorded, pre- and post treatment and were compared statistically. Moreover clinical manifestation of the patients before and after the treatment were also recorded.

The HIV and malignant patients suffering with haemorroids were excluded from the study. The duration of the study was about four years.

**Observation and Results**

**Table 1** Pre-operative clinical manifestation of patients of haemorroids-35 (38.8%) had protruded haemorroids, 18 (20%) had haemorroids with bleedings, 17 (18.8%) had painful haemorroids, 11 (12.2%) had discharging haemorroids 9 (10%) had haemorroids with pruritis.

**Table 2** Mean value of MRP in grade-II haemorroids was 34.62 (SD±0.61) and mean value of MRP in grade-III was 53.19 (SD±0.94) t test value was -109 and p value (p<0.01) was highly significant, in MSP study mean value of Grade-II was 73.3 (SD±0.63) and grade-III was 96.5 (SD±0.84) t test value was -147 and p value (p<0.01) was highly significant. In MXSP study mean value of grade-II haemorroids was 102.2 (SD±0.48), and grade-III was 120.5 (SD±0.97), t test value was -111.9 p Value was (p<0.01) was highly significant.

**Table 3** Study of manometric changes in RBL. (Before and after RBL) treatment. In MXR study mean value before RBL was 78.5 (SD±0.94) and after RBL was 82.00 (SD±1.23) t test value was 11.6 and p value was highly significant (p<0.05). Mean value of MXSP before RPL was 117.7 (SD±1.26) and after RPL was 114.2 (SD±1.14) t test value was 7.08 p value was highly significant (p<0.01). MXRP mean value Before RBL 52.8(SD±0.94) t test value was 17.5 and p value was highly significant (p<0.01). In MSG study mean value RBL was 99.46(SD±1.01) and after RBL was 119.8 (SD±0.69) t test value was 85 and p value was highly significant VFS mean value before RPL was 29.9 (SD±0.54) and after was 30-9 t test value was 9.87 and p value was highly significant in MXTV study mean value before RPL was 121.3 (SD±0.51) t test value was 134.8 and p value was highly significant (p<0.01).

**Table 4** Manometric changes at Electrotherapy (Before and after) in MXR study mean value before electrotherapy was 78.7(SD±0.63) and after electrotherapy 75.9 (SD±0.63) t test value was 16.2 and p value was highly significant (p<0.01). In MXP study mean value before electro therapy was 120 (SD±0.85) After electro therapy 114(SD=1.0) t test value was 26.4 and p value was highly significant (p<0.05) in MRP study mean value before electrotherapy was 50.7 (SD±0.78) and after electrotherapy 46(SD±0.69) t test value was 25.7 and p value is highly significant (p<0.05) in MSP study mean value before electrotherapy was 93.8 (SD±0.52) and after electrotherapy 88.9 (SD±0.57) t test value was 33.3 and p value was highly significant. In VFS study mean value before electro therapy 29(SD±0.42) and after electro therapy 27.9(SD±1.02) t test value was 5.31 and P value was highly significant in MXTV study mean value before electro therapy was 116(SD±0.76) and after therapy 119.8(SD±0.67) t test value was 19.4 and p value was highly significant.

**Table 5.** Manometric changes at haemorroidectomy (before and after). In the MXR study mean value before haemorrectomy was 86.6(SD±0.78) and after haemorroidectomy 73.7(SD±0.59), t test value was 73.9 and p value was highly significant (p<0.01) in MXP study mean value before haemorroidectomy was 126.4 (SD±0.58) and after haemorriedectomy 110.7 (SD±0.89) t test value was 106.2 and p value was highly significant (p<0.01) in MRP study mean value...
before haemorroidectomy 57.7(SD±0.48) and p value was highly significant (p<0.01) in MSP study mean value before haemorroidectomy was 103.4 (SD±0.67) after haemorroidectomy 118.5(SD±0.9) t test value was 20.5 and p value was highly significant (p<0.01) In MXTV study, mean value before haemorroidectomy 122.7 (SD±0.76) after haemorroidectomy 122.2(SD±1.16) t test value was 2.15 and p value was significant (p<0.05).

Table-6 Post operative condition of haemorroidectomy RPL and electrotherapy were compared (1) severe pain (6%) at haemorroidectomy, moderate pain (4%) at RBL and mild (2%) at electrotherapy, (2) urinary retention was observed 5% in haemorroidectomy patient and 1% at RBL but none at electrotherapy post–operative discharge was observed 3% at haemorroidectomy and 2% at RBL but none at electrotherapy.

Table 4: Manometric changes at Electrotherapy before and after treatment
## Discussion

In the present study of haemorrhoids and comparison between electrotherapy, Rubber band ligation therapy and haemorrhoidectomy in the patients of Andrapradesh population. The pre-operative clinical manifestation were 53(38.8%) had protruded haemorrhoids 18(20%) had bleeding haemorrhoids, 17(18.8%) had severe pain 11(12.2%) had discharge, 9(10%) had haemorrhoids with pruritis (Table-1) comparison of 45 grade-II and 45-grade-III were compared with manometric changes. MRP mean value in grade-II was 34.6(SD±0.61) and in grade-III was 53.1 (SD±0.94) t test was 109.5 and p value was highly significant MSP mean value in grade-II was 73.3(SD±0.62) and grade-III was 96.5 (SD±0.84) t test was-147.8 and p value was highly significant (p<0.01) (table-2) study of manometric changes in RBL before and after RBL was compared with various parameters like MXRP, MXSP, MRP MSP VFS, MXTV and found statically significant p value (p<0.01) similarly manometric changes before and after electrotherapy were studied and various parameters like MXRP, MXSP MRP, MSP, VFS, MXTV were compared statistically and highly significant p value was observed (p<0.01) (Table-3) study of manometric changes in RPL., Statistically MSP, VFS and MXTV values significantly increased after applying method (P<0.01). The post operative conditions of all three approaches to haemorrhoids were compared. Post-operative pain was severe (6%) in haemorrhoidectomy moderate (4%) at RBL and mild (2%) at electro therapy.

Manometric changes in RPL., Statistically MSP, VFS and MXTV values significantly increased after applying method (P<0.01).
thromosized external haemorroids were observed in 1% in haemorroidectomy, 2% at RBL and nil at electrotherapy. Urinary retention was observed in 5% haemorroidectomy and 1% at RBL post–operative discharge was observed 3% in haemorroidectomy 2% RBL and nil at electrotherapy (Table-6) these observed values were more or less in agreement with previous studies(5)(6) The very purpose of this comparative study to compare the physiological changes after the treatment of haemorroidal disease using three different approaches. Raised anal pressure was documented in grade III and all three method before treatment due to prolapsed hemorrhoids causing vascular hypertension of and cushion(7)(8)

It was also observed that MXP MXSR decreased significantly after haemorroidectomy. Moreover grade II had significant lower MRP and MSP than patients with grade III haemorroids RBL and electrotherapy did not cause any significant changes in anal pressure compare to haemorroidectomy. Increased VFS which develops in parallel to the development of prolapsed hemorrhoids elevated after haemorroidectomy could be due to scar formation after surgery VFS was higher in all three types patients after treatment but patients did not have any complications. Among three treatment haemorroidectomy caused most significant changes in anal physiology. Hence haemorroidectomy must be avoided in grade–II and grade–III hemorrhoids because there will be over tonic contraction of anal sphincter muscle. When post treatment of RBL and electro therapy was compared electro therapy was quite safer in the treatment of grade–II and grade–III hemorrhoids.

Summary and Conclusion

The present study of haemorroids, comparison between electro therapy, RBL and haemorroidectomy will be useful to decide the pros and cons of RBL, haemorroidectomy and electrotherapy. This study clearly indicates that, electrotherapy is ideal and safer treatment for grade–II and grade–III haemorrhoids because electrotherapy has least post of operative pain and complications and had least changes in anorectal manometric parameters. But this study demands further biomechanical, haemo-dynamic, patho-physiological, genetic, nutritional studies because little is known about anorectic physiological changes.

Study of Recurrent Abdominal Pain in Children of Telangana

Pradeep Reddy M.,1, Surayanarayana Regidi2

1Associate Professor, 2Assistant Professor Department of Pediatrics, Mediciti Institute of Medical Sciences Ghanpur, Medchal, Telangana State

Abstract

83 school going children aged between 6-15 years of both sexes were studied for Recurrent abdominal pain (RAP) the height of 49 (59%) children was the 148 to 150 cm, 34(40.9) children was 151 to 157 cms. The weight of the 47(56.6%) of children was 42 to 44 kg and 36(43.3%) children had 45 to 48 kg weight BMI of 46 (55.4%) children has 18.2 to 19.2, 37 (44.5%) had 19.3 to 20.2. The dietary habit of children 16(19.2%) were purely vegetarian, 18 (21.6%) were non vegetarian, 49(59%) were both vegetarian and non-vegetarians. The clinical manifestation were 16(19.2%) had constipation, 19(22.8%) had mesenteric lymphadenopathy, 14(16.8%)had urinary tract infection, 24(28.9%) had pallor, 6(7.22%) had hapatomegaly, 4(4.81%) had splenomegaly.

This pragmatic approach to children having various clinical manifestation will be quite helpful to pediatrician, Radiologists physician to treat such patients efficiently and to avoid morbidity and mortality because, there is always over protection and over caring towards children health.

Keywords: Recurrent abdominal pain, mesenteric lymphadenopathy, UTI, pallor.

Introduction

Recurrent abdominal pain (RAP)is the perhaps the most common painful health problem in the school going children about 10-20% of children suffer with RAP It was named as RAP syndrome by British pediatrician, J. Apley because of its repeated episodes and severe enough to affect their activities over a period longer than three months(2). The condition has remained poorly being implicated in the causation. The investigations seldom show organic disease. Treatments, strategies are very and little basis in evidence.

As many as, half of the children do not see the doctor about RAP (3). Although the pain is often as severe as in those who do, presumably the patient or family regards the symptoms as trivial because of mild severity or transient nature(4). Usually when the impacts on the functionings of child or family, then medical help was sought. Hence attempt was made to study the RAP in children at different ages to avoid morbidity and mortality among the children because abdomen has various systems of body hence it is popularly called as magic box.

Material and Method

83 school going children aged between 6-15 years of both sexes were visiting to pediatric OPD of Mediciti Institute of Medical Sciences Ghanpur, Medchal-501401 (Telangana) Hospital were selected for study. Blood examination CBC (complete Blood count) RBE (Routine Blood Examination) LFT(lever function test) urine analysis, culture, stool examination for cyst ova, parasites, In same patients x-ray abdomen, USG Abdomen and lower GIT were carried out various causes of recurrent abdomen pain, “Red flags” in history and examination of recurrent abdominal pain (RAP), moreover classification of RAP by symptomsatology according to Rome–II criteria viz functional dyspepsia, IRBS (Irritable Bowel Syndrome), functional abdominal pain, abdominal migraine, Aerophagia was also taken into consideration causes of recurrent pains mentioned below were also taken into consideration.
The children having HIV positive cardiac and neurological disease were excluded from the same. The duration of study was about 3 years. The ratio of male and female children was 2:1.

Discussion

The present study of RAP in children between 6 to 15 years of age both sexes. The height of children in 49 (59%) had 148 to 150, in 34 (40.9%). In study of weight 47 (56.6%) had 42 to 44 kg, 36 (43.3%) had 45 to 48 kg, The BMI in 46 (55.4%) had 18.2 to 19.2 and 37 (44.5%) had 19.3 to 20.2, the dietary habits study 16 (19.2%) were purely vegetarian 18 (21.6%) were non-vegetarian (Table-1) the clinical manifestation were, 16 (19.2%) had constipation, 19 (22.8%) had mesenteric lymphadenopathy, 14 (16.8%) UTI, 24 (28.9%) pallor 6 (7.22%) Hepatomegaly (Table-2). These findings were more or less in agreement with previous studies (5) (6) (7).

The pallor was associated with tiredness, anorexia, dizziness, headache, vomiting, fever diarrhea and constipation also (8). In fact RAP is and does not lend itself a single model of causation. Organic pathology cannot be identified in majority of children having RAP (9) (10). Organic disorders observed in RAP were UTI inflammation (crohn’s disease) or distention of abdomen and intestinal parasites also.

It can be also hypothesized that repeated eating habits consumption of junk foods, over burden of school studies may be the causative factors of RAP. Hence apart from treating RAP by pediatrician psychiatric counseling and sparing of time by the parents for kids may prove effective treatment for RAP.

Summary and Conclusion

The present pragmatic study of RAP in Telangana children will be useful to pediatrician radiologist psychiatrist because 90% of RAP is due to psychosomatic disorders. Hence affection by the teachers, mentors and parents is mandatory to treat such complicated non organic diseases.

Study of Surgical Site Infections in Patients in a Tertiary Care Hospital

Purushothama Acharya
Assistant professor, Department of General Surgery, Srinivas Institute of Medical Sciences, Mukka, Suratkal Mangalore, Karnataka

Abstract
There were 192 patients (110 males and 82 females) who underwent surgeries which were considered clean pre operatively (not contaminated or infected). Of these, 15(7.8%) had surgical site infections. Among 15 patients, 2(13.3%) had DM with obesity, 4(26.6%) had obesity only, 5(33.3%) had D.M. only, 2(13.3%) were anemic and 2(13.3%) had hypoalbuminemia. The surgeries in which infections observed were 4(26.6%) hydrocoelectomy, 2(13.3%) Thyroidectomy, 3(20%) Hernioplasty, 2(13.3%) lumpectomy, 2(13.3%) lipoma excision and 2(13.3%) mastectomy. The organism observed in surgical site infected area were 2(13.3%) klebesella, 5(33.3%) staphylococcus, 8(53.3%) had E.coli. Prevalence of surgical site infection varies with duration of hospital stay, increased duration of surgery, age, type of wound, electivity of procedure etc. Obesity and diabetes were also more prone to cause surgical site infection.

Keywords: SSI = Surgical site infection DM = Diabetes mellitus, Nosocomial organism.

Introduction
Surgical site infections could be hospital acquired and/or due to less immunity of patients like advanced age, D.M. etc. Apart from harming the patients, these health care associated infections can affect nurses, physicians, visitors and custodians of patients. Despite many advances in infection control practices including improved operating room ventilation, sterilization method, barriers, surgical technique and antimicrobial prophylaxis, SSI still cause substantial amount of morbidity and mortality among hospitalized patients. Prevalence of SSI are reported to be between 0 to 15% depending upon the reason for operation, the site, the approach, use of instruments, experience of surgeon etc. Study of surveillance of these infections is a vital step as it provides an insight into the magnitude of problem and helps the concerned authorities to take radical measures and curtail these infections. Hence attempt was made to study the incidence, types of SSI and associated factors so that this pragmatic approach will be helpful to treat such patients efficiently and avoid morbidity and mortality.

Materials and Method
192 patients of both sexes (110 males and 82 females) of different age groups regularly visiting to Srinivas Institute of Medical Sciences, Mukka, Suratkal, Mangalore–574146 (Karnataka) between August 2012 and July 2016 were studied. These patients had undergone variety of surgeries, viz. thyroidectomy mastectomy, lumpectomy, hernioplasty etc. Out of 192 patients 15(7.8%) patients had surgical site infections. Their infection pattern was studied along with culture and organisms were identified and treated accordingly. Moreover, history of surgically infected patients was also noted and their hematological and radiological examination was repeated to rule out and predict the secondary infection risk which may result in morbidity and mortality. Patients having infections before surgery were excluded from the study. The types of surgeries which had infections, the types of organism observed and the possible reasons were studied. The duration of the study was four years.
Observations and Results

Table 1: History of the patients of surgical site infections. 4 (26.6%) were obese, 5 (33.3%) had Diabetic mellitus, 2 (13.3%) had DM with obesity, 2 (13.3%) were anemic, 2 (13.3%) had hypo albuminemia.

Table 2: Surgeries in which surgical site infections were observed. 4 (26.6%) had undergone hydrocoelectomy, 2 (13.3%) had undergone thyroidectomy, 3 (20%) had hernioplasty, 2 (13.3%) had lumpectomy, 2 (13.3%) had lipoma excision and 2 (13.3%) had mastectomy.

Table 3: Study of prevalence of organism observed in surgical site infections. 2 (13.3%) klebesilla, 5 (33.3%) staphylococcus, 8 (53.3%) E.Coli.

Discussion

In the present study of SSI in the patients of Srinivas Medical college, Suratkal (Mangalore), Karnataka state, the history of these patients was 4 (26.6%) were obese, 5 (33.3%) had D.M, 2 (13.3%) had obesity with DM, 2 (13.3%) were anemic, 2 (13.3%) had hypo albuminemia. The surgeries in which infection occurred were 4 (26.6%) had undergone hydrocoelectomy, 2 (13.3%) had undergone thyroidectomy, 3 (20%) had hernioplasty, 2 (13.3%) had lumpectomy, 2 (13.3%) had lipoma excision and 2 (13.3%) had mastectomy. The organism observed in the SSI were 2 (13.3%) had klebesilla, 5 (33.3%) had staphylococcus, 8 (53.3%) had E.coli. These findings were more or less in agreement with previous studies. It was also noted that prevalence of infection rate was higher with advancement of age. Other factors are, increased severity of acute illness and decreased host response to bacterial invasion associated with reduced immunity and prolonged hospital stay. Diabetes mellitus is an important risk factor for the development of wound infections as compared to non-diabetic patients. It was also observed that emergency surgery had lower rates of SSI than elective surgeries. This is counter-intuitive as emergency operation should be at higher risk because of suboptimal pre-operative preparation. Moreover stay of elective operation patients was longer than emergency operation. This may be because, majority of the emergency operative patients were of younger age group than elective operations. It was also analyzed that surgeries done by junior surgeons will have more rate of SSI as compared to experience surgeon. Apart from this those with anemia, malnutrition and obesity had more chances of SSI.
Summary and Conclusion

The present study of SSI will be helpful to have better knowledge of causative factors in reducing the incidence of such complications and helps to take preventive and precautionary measures which will prevent the risk of morbidity and mortality. But this study warrants further patho-physiological, immunological, nutritional, nosocomial patterns because exact formation and mechanism of infections of the surgical sites are still un-clear.

Study of Factors Affecting Low Birth Weight of Newborn in Uttar Pradesh

Ambri Agarwal¹, Prashant Tomar

¹Assistant Professor, Department of Obstetrics and Gynecology, ²Assistant Professor, Department of Paediatrics, G.S. Medical College, Peeplabandapur, Pilkhuwa (UP)

Abstract

82 (Eighty two) pregnant ladies aged between 16-30 years were studied. The maternal history was- qualification, 38(46.3%) were illiterate, 28(34%) were primary school educated, 16(19.5%) were secondary school educated. The habits were, 4(4.87%) were smokers, 36(43.9%) were passive smokers, 42(51.2%) were Tobacco chewers. Socio-economic status was 12(14.6%) were house wives, 17(20.7) were shop keepers, 53(64.3%) were laborer. The material age was, 38(46.3%) were aged between 16-19 were, 29(35.3%), were aged between 20-25,15(18.2%) were aged between 26-30. The clinical manifestation during pregnancy was -14(17%) had PIH, 4(4.87%) had pre‑eclampsia, 2(2.43%) had eclampsia, 6(7.31%) had gestational diabetes, 24(29.2%) had APH, 32(30%) had PROM. The obstetric factors were 30(36.5%) were prim pares, 52(63.4%) were multiparous, 62(75.6%) had history of LBW, 38(46.3%) had history of miscarriage, the period of amenorrhea was ‑22,(26.8%) had 28 to 37 weeks, 53(64.3%) had 38‑40 weeks 7(8.53%) had above 40 week 5(6.09%) had multiple pregnancy. This pragmatic approach study of LBW will be quite helpful to obstetrics and gynecologist, pediatrician, physician to treat such patients actively to prevent morbidity and mortality of low birth newborn which is a great threat and challenge to the medical fraternity globally.

Keywords: PIH-pregnancy Induced Hypertension, APH = Ante partum Hemorrhage, PROM = premature rapture of membrane, LBW = Low Birth weight.

Introduction

LBW (low birth weight) defined as weight at birth which is less than 25000gm usually measured in the first hour of life irrespective of the gestation age (¹). LBW is the major cause and contributes to about 60% to 80% of all neonatal deaths (²). Based on epidemiological studies, infants weighing less than 2500 gm, are more, likely to, die than normal weight babies. Global occurrence of LBW is 15.5% which amounts to about 20 million low birth weight infants each year. 96.5% of them in developing countries (³). Many of the LBW newborn become the victims of protein energy malnutrition (PEM) and infection. The causes of LBW are socio-economic status, poor nutrition during pregnancy, education level, and awareness of health condition. LBW is one of the most serious challenges for mother and child health. It has number of public health consequences such as mental retardation, congenital anomalies, morbidity and mortality. Moreover very high cost of special care and intensive care unit (⁴). Hence attempt was made to study the different causes of LBW because there is increase of neonatal death every year globally.

Material and Method

82 (Eighty two) pregnant ladies aged between 16-30 years, regularly visiting to obstetrics and gynecology department of G.S medical college hospital NH24 near Dhoori petrol pump, Peeplabandpur, Pilkahuwa-245204 (U.P), were selected for study. They were admitted as per their expected delivery date (EDD). History of every patients was noted individually. The history clinical manifestations of pregnancy and obstetrics problems were noted and classified with percentage The LBW babies were referred to neo-natal department for
further investigation. The patients having neurological complications, HIV, HbSAG and mothers having still born babies were excluded from the study.

The duration of the study was about 2 years (from September-2016 to December-2018).

**Observation and Results**

**Table-1-Maternal history in LBW fetal study–**

1. Qualification study 38(46.3%) were illiterate, 28(34%) were qualified upto primary school, 16 (19.5%) up to high school. (Secondary school)
2. Habit study-4(4.87%) were smokers, 36(43.9%) were passive smokers, 42(5.2%) were Tobacco chewers.
3. Socio-economic status-12(14.6%) were house wives, 17(20.7%) were shop keepers, 53(64.3%) laborer.
4. Age of maternal was, 38(46.3%) were between 16-19 years, 29(35.3%) were between 20-25 years 15(18.2%) were aged between 26-30.

**Table-2-Study of clinical manifestation during pregnancy–**

14(17%) had PIH (pregnancy Induces Hyper tension),4(4.87%) had Pre-eclampsia, 6(7.31%) had gestational Diabetes mellitus, 24(29.2%) had APH(Antepartum hemorrhage),32(39%) had PROM(premature rapture of membrane).

**Table-3-Obstetric factors affecting LBW–**

30(36.5%) were primiparous, 52(63.4%) were multiparous, 62 (75.6%) had previous history of LBW, 38(46.3%) had history of miscarriage.

The period of amenorrhea at delivery, 22(26.8%) had 28-37, weeks, 53(64.6%) had 38-40 weeks, 7(8.53%) had above 40 weeks,5(6.09%) had multiple pregnancies.

**Discussion**

In the present study of factors, affecting LBW of newborn in Uttar Pradesh. The maternal history was qualification 38(46.3%) were illiterate, 28(34%) were studied till primary school. 16(19.5%) were educated
till secondary school. The habits were 4(4.8%) were smoker, 36(43.9%) were passive smokers, 42(51.2%) were Tobacco chewer (like Gutaka). The Socio-economic status was 12(14.6%) were house wife, 17(20.7%) were shop keepers, 53(64.3%) were laborer. The age of pregnant mothers was 38(46.3%) were between 16-19 years, 29(35.3%) were aged between 20-25, 15(18.2%) were 26-30 years old. (Table-1). The clinical manifestation of pregnant mother was 14(17%) PIH (Pregnancy induced Hyper tension HTN), 4(4.87%) had pre-eclampsia, 2(2.43%) had eclampsia, 6(7.3%) had gestational diabetes 24(29-2%) APH (Ante partum hemorrhage), 32(39%) had PROM (Premature Rupture of Membrane) (Table-2). The obstetric factors were - In parity study 30(36.5%) were primiparous, 52(63.4%) were multiparous, 62(75.6%) mothers had previous history of LBW, 38(46.3%) mother had history of miscarriage. The period of amenorrhea was 22(26.8%) had 28-37 weeks, 53(64.6%) had 38-40 weeks, 7(8.53%), had above 40 weeks, 5(6%) mothers had multiple pregnancies. This finding were more or less in agreement with previous studies (5)(6)(7).

The socio-economic conditions such as poverty, education level, violence during pregnancy, passive smoking (because her husband or father in law, family members could be smokers) early marriages are also contributing factors for LBW. Infectious agents have potential to penetrate through uterus in lesser immunity females and cause inflammation in uterus and placenta. Cytokines are released in response to the inflammation by the body immune system resulting in preterm initiation of labor which results in LBW. Adolescent when become pregnant before their own growth is completed faces difficulty in fulfilling their own and nutritional requirement (8). It has been also reported that passive smokers exposure to beedi or cigarettes smoking contains a complex mixture of various mutagenic which endogenous to growing fetus (9).

LBW individuals experience many health complication throughout their life which can cause long and short terms consequences including hypothermia, perinatal asphyxia respiratory problems, Hyperbilirubinemia, anemia, infection, neurological problems. Ophthalmic complications, hearing defects, sudden infant death syndrome, coronary artery disease, immune-system problems (10). LBW could be due to serious placental problems leading to insufficient transport of nutrient and oxygen to fetus. Hence expecting mother must have proper nutritional intake and regular medical check-up moreover expecting mothers should not take self-medicine without advice of physician or obstetrics and gynecologist.

Sometimes premature LBW babies need to be born to save mothers life due to other complications like anomalies of placenta, severe bleeding etc. It is also hypothesized that, violence during pregnancy leads to stress and strain on growing fetus may impair or retard the growth of fetus lead to LBW with de-arrangements of cardio-vascular and central nervous system. The LBW babies suffer with this de-arrangement in their future life, such children will be burden to whole family and society as well.

During pregnancy, apart from proper nutrition, regular medical check-up, expecting mothers should be treated, sympathetically and amicably for healthy growth of fetus.

**Summary and Conclusion**

The present study of factors affecting LBW of newborn in Uttar Pradesh will be quite useful to obstetric and gynecologist, physician pediatrician to avoid the morbidity and mortality of newborn. It is necessary improve the maternal health through nutrition and education because maternal malnutrition and anemia have significant association with LBW but this study further demands genetic, immunological, nutritional and embryological study because exact function of placental barrier and duration of formation of germ layers is still un-clear.

This research paper was approved by ethical committee of G.S. Medical College, NH24, Near Petrol Pump, Peelabandapur, Pilkhuwa-245304(UP)

A Study to Assess the Effectiveness of Video Assisted Teaching Programme on Knowledge Regarding Breast Self-Examination among Adult Women in Selected Hospital in Bangalore

Uma Parvathi¹, Rinu Mathew²

¹Professor and HOD, ²Lecturer, Department of OBG (N), Krupanidhi College of Nursing

Abstract

Breast self-examination is an important screening method used to detect early breast cancer. Studies have reported that awareness and practice of breast self-examination is an important method of prevention of breast cancer as it is one of the public health problem.

Aims: The main aim of the study was to assess the effectiveness of video assisted teaching on knowledge regarding the breast self-examination among adult women.

Materials and Method: Descriptive research approach which was evaluative in nature with one group pretest and post test design was used for the study. Purposive sampling technique was used to select the subjects of 30 adult women in vanivillas women and children hospital Bangalore. The tool used for the study was self-administered questionnaire and video assisted teaching regarding breast self-examination.

Results: The study reveals that majority 26 (86.7%) of the subjects had inadequate knowledge during pre-test. In post-test, 5 (16.7%) of the subjects had adequate knowledge and 22 (73.3%) had moderately adequate knowledge. It shows that there was a significant difference between pre-test knowledge score (8.63) and post-test knowledge score (15.20). Paired t test was used in order to assess the effectiveness of video assisted teaching programme on knowledge regarding breast self examination and was found to be effective (t=12.679 p<0.05) at 0.05 level of significance.

Conclusion: Video assisted teaching is effective in improving the cognition and confidence of the adult women.

Keywords: Video Assisted Teaching (VAT), Breast Self Examination (BSE), Effectiveness, Knowledge, Adult women.

Introduction

Every country in the world is progressing towards the destiny of “Health for all”. Breast is the important organ for each woman as these are the symbol of motherhood and women hood. The breast is susceptible to numerous benign and malignant conditions. Breast cancer is probably the most feared cancer in women because of its frequency and psychological impact. It affects the perception of sexuality and self-image to a degree greater than any other cancer. The incidence of breast cancer is rising in every country of the world especially in developing countries such as India[1].

Breast cancer begins in the breast tissue. In breast cancer, the cell of the breast grows in a chaotic way. Instead of going and dividing in a regular and expected other, they grow out of control. If the cancer is not treated, the cell can spread can spread within the breast or even break off and metastasis to other part of the body[2].

India is likely to have over 17.3 lakhs new cases of cancer and over 8.8 lakhs death due to the disease by 2020 by cancer of breast, lungs and cervix topping the list, a premier a medical research body said. In its projection, the Indian council of medical research (ICMR) said in 2016 the total number of new cancer cases is expected to be around 14.5 lakhs and figured is likely to reach nearly 17.3 lakhs in new cases in 2020. Over 7.36 lakhs people are expected to succumb to reduce in 2016 while the figure is estimated to shoot up to 8.5 lakh by 2020. Data also revealed that only 12.5 % of patient comes for treatment in early stages. The northeast reported the highest number of cancer in both male and female[3]. Among females, breast cancer topped the list and among male mouth cancer, the studied said.

Breast Self Examination is an important screening measure for detecting breast cancer among women; those who correctly practiced BSE monthly can detect a lump in the early stage of its development and treated for a better survival rate. Nurses play a pivotal role in teaching the BSE to the women to identify the breast abnormalities. The nurses who can promote monthly BSE should be perfect by supporting realistic beliefs about early detection and prevention of breast abnormalities as well as demonstrating BSE, so that women can do it themselves without consulting physician[4]. Thus the investigator was interested to educate the adult women about breast self examination in a view to prevent the breast illness in the advancing age and the best method to reach the adult women would be VAT (video assisted teaching). Therefore this study aims to evaluate the effectiveness of VAT on cognizance of BSE among adult women.

Materials and Method

Research Approach: In order to accomplish the objectives of determining the level of knowledge and assessing the effectiveness of VAT on breast self-examination among women, evaluative research approach was adopted for the study.

Research Design: The research design selected for this study was one group pre-test and post-test design.

Variables: Variables are qualities properties or characteristic of a person, things, situation that vary or change in qualitative research an activity is aimed at trying to understand how or why things vary and to learn how or one variables is related to others[6].

In this study, three types of variables were identified.

Independent Variables: In this study, the independent variable is video assisted teaching (VAT).

Dependent Variables: In this study, the dependent variable is the knowledge of adult women regarding breast self-examination.

Extraeous Variables: Any uncontrolled variable that greatly influence the result of the study is called as extraneous variables. The extraneous variables considered in this study are

- Age
- Gender
- Religion
- Family history
- Dietary pattern
- Previous source of information regarding breast self-examination.

Population: The population is the present study consisted of adult women admitted in selected hospital at Bangalore.

Setting of Study: The present study was conducted in Vani villas women and children hospital at Bangalore.

Sample: The 30 adult women who were admitted in Vanivilas women and children hospital, Bangalore who fulfilled the inclusion criteria were selected as samples.

Sampling Technique: In this study, purposive sampling technique was used to select the subject.

Inclusion Criteria: In this study, the inclusion criteria consisted of the women who are:

- Married women
- Who are willing to participate in study and available at that time of the study.
- Able to communicate in Kannada, Hindi and English.

Exclusive Criteria: In the present study, the exclusion criteria consist of women who are;

- Not willing to participate.
- Absent while administering the intervention.
**Data Collection Task/Instrument:** Data collection tools are the procedures or instrument used by the researcher to observe or measures the key variables in the research problem. The data collection instrument for the present study consisted of self-administered questionnaire with two sections.

**Section-1:** Demographic Performa

**Section-2:** Questionnaire to assess the knowledge regarding breast self-examination among adult women.

**Development of The Tool:** The tools were prepared on the basis of the objective of the study. The researcher did an extensive review of literature to collect the relevant materials and based on it, the two was selected for the study.

The following steps were understood to prepare the final tool. Tools was developed based on the related literature and expert suggestions.

**Description of The Tool:**

**Section 1: Demographic Data:** It consists of the details related to age, education, religion, gender, family history, dietary pattern, previous source of information of the breast self-examination among the adult women.

**Section 2: Questionnaire:** Self-administered questionnaire to assess the knowledge on breast self-examination among adult women.

A self-administered questionnaire was prepared to assess the effectiveness of video assisted teaching on knowledge regarding the breast self-examination among adult women in selected hospital in Bangalore. It compromised of 24 items with 4 choices. This was prepared by investigators. Each correct answer was given a score of 1 and wrong answer was given a score of 0. The maximum score was 1.

**Content Validity:** Content validity is the criterion for evaluating the quality of measures or an instrument. Content validity refers to extent to which an instrument adequately encompasses the pertinent range of subject matter \(^7\). Content validity of the tool for the present study was established by 7 experts in the field of nursing. The tool was given along with the objectives of the study and blue print of the tool was also provided. Modifications were made based on the suggestions given by the experts, after consulting with guide

**Validity Of The Tool:** The tool was distributed to the experts in the field of nursing and the appropriate correction was made according to their opinion with references to guides.

**Data Collection Procedure:** The data collection for the main study was done on 30 adult women in Vani Vilas women and children Hospital at Bangalore. Formal written permission was obtained from the concern authorities before data collection.

The researcher introduced themselves to the mother and the purpose of the study was explained to them. Confidentiality was assured and the consent was taken from the admitted adult women. Pre-test was conducted for 3 days (each day 10 sample) followed by Video assisted teaching. And the post-test was conducted after 3 days of VAT.

The subjects were asked to give base line information after which the pre-test measurement was taken by using self-administered questionnaire.

The investigator observed that many subjects were motivated to participate in the study. The data collection was completed by thanking the subjects for their participation and co-operation. The data collection was compiled for analysis.

**Plan For Data Analysis:** A master scoring sheet was prepared by the investigator to organize the computed data. The data would be analyzed using descriptive and inferential statistics.

**Findings**

**Major finding of the study:**

**Section 1: Description of baseline characteristics of the adult women:** This section deals with the description of the baseline characteristic of the subject in terms of frequency and percentage such as Age, Gravida, Religion, Family income, education and previous source of information regarding the breast self-examination. The majority subject belongs to the age group 19-22 year (50%) and it was also inferred that majority of the subjects were primipara i.e. (64%). The majority of the subjects were Hindus i.e. (74%) and also majority of the subjects were attained secondary education i.e. (40%). The majority of subject family income is in between 7323-9787 i.e. (33.33%). The result shows that 70% of women reported as never having practiced breast self-examination.
Section 2: Comparison between pre-test and post-test knowledge scores on breast self-examination:
The majority of subjects had inadequate knowledge during the pre-test i.e. 26 (86.7%). In post-test, 16.7% of subjects had adequate knowledge i.e. 5 (16.7%) and 22 (73.3%) had moderately adequate knowledge.

The effectiveness of teaching method in promoting women’s breast self-examination in breast self-examination teaching clinic. The sample was composing of 130 women. Demonstration was used with the comparison group while the experimental group 1 was taught by demonstration and practice, the experimental group 2 was provided by demonstration and self and reminding, and the experimental group 3 was provided by demonstration and reminding from friends. The result of study shows that the least change of breast self-examination behaviour was found among comparison group at highest change of breast self-examination behaviour was found among the experimental group 1, but the significant difference was not found between the women’s breast self-examination behavior [8].

Section 3: Effectiveness of video assisted teaching on knowledge regarding breast self-examination:
Paired t test was conducted in order to assess effectiveness video assisted teaching programme on knowledge regarding the breast self-examination among adult women. The calculated t value t=12.679 was found to be greater than the table value t1=2.05 at p<0.05 level of significance. Hence it was inferred that video assisted teaching programme was effective in increasing the knowledge among adult women regarding breast self-examination.

A descriptive study was conducted in southern Iran in 2009 to determine the knowledge and attitude of breast self-examination in women. A self-administered questionnaire was developed to collect information from 60 women in the age group of 30-50 years. The results showed that 46.7% of participants didn’t perform breast self-examination and that almost all of those who did perform breast self-examination did it in correctly [9].

Section 4: Association of pre-test knowledge scores on breast self-examination with their selected demographic variables: There was no significance association between the pre-test knowledge score and the selected demographic variables.

Conclusion

Breast is the important organ for each woman as these are the symbol of motherhood and womenhood. The breast is one of the target organs for various hormones, of a particular oestrogens, progesterone and prolactin. As such many a breast related complaint or disease is associated with endocrine dysfunctions [10]. It is important to examine the breast of female and male clients. A small amount of glandular tissue, a potential site of for the growth of cancer cells, is located in the milk breast. In contrast, the majority of the female breast is glandular tissue. The breast is susceptible to numerous benign and malignant conditions. Among the various breast problems, breast cancer is one of the most common malignancies in women [11].

The samples consist of 30 adult women whom are admitted to Vani villas women and children hospital, KR. Market, Bangalore. The consent was taken from the admitted adult women. Pre-test was conducted for 3 days (each day 10 sample) followed by VAT. And the post-test was conducted after 3 days of VAT.

The data collected were subjected to analysis using descriptive statistics in term of frequency percentage, mean, SD, and inferential statistics using paired t test.

The following conclusions were drawn based on the finding of the study:

- Majority of the subjects were in the age group between 19–22 years among adult women.
- Majority of the subjects were Hindus.
- Majority of the subjects were primipara mother.
- Majority of subjects were not practicing Breast self-examination regularly.
- Majority of subjects were secondary level of education.
- The present study concluded that the video assisted teaching programme which was found to be effective in increasing the knowledge among adult women. (t=12.679 at p<0.05) The results showed a significant
difference between the pre-test knowledge scores 
\( x_1 = 8.6333 \) and the post-test knowledge score 
\( x_2 = 15.2000 \) after administration of video assisted 
teaching programme and was tested using paired ‘t’ test analysis. The computed chi-square values showed that, there was a significant association between the pre-test and the post-test knowledge.

- The present study concluded that there is no significant association between pre-test knowledge score and demographical variables like age, parity, religion, education, family income and practicing BSE.

**Limitation:**

- The study made use of self-administered questionnaire only to assess the knowledge of adult women.
- The study was limited to only one hospital at KR. Market, Bangalore.
- The study was confined to only 30 adult women.

**Recommendation:** On the bases of the findings of the study following recommendation has been made for the further study.

- The study can be replicated on the larger samples for the generalization of finding.
- A similar study can be conducted in different hospital setting.
- A similar study can be conducted for a longer duration.
- A similar study can be done focusing on different age group.
- A comparative study can be conducted both in urban and rural female population.

**Source of Funding:** Funding for the study was done by self.

**Ethical Clearance:** Ethical Clearance was obtained from the institutional review and ethical board.

**Conflict of Interest:** There are no conflicts of interest.

An Observational Study to Analyse the Neuromotor Control and Endurance of Neck Muscles among Physiotherapy Students

Nabeena N.¹, V. Rajalaxmi²

¹Faculty of Physiotherapy, ²Vice Principal, Dr. MGR Educational and Research Institute, Velappanchavadi, Chennai, Tamil Nadu, India.

Abstract

Aim: To analyze the neuromotor control and the neck muscle endurance among the student population.

Background Of The Study: Recent studies shows that poor posture habits causes the neck muscles to continuously overwork to counterbalance the pull of gravity causing imbalance between the agonist and antagonist.

Materials And Method: The study design is observational study. Female subjects within the age group of 18-25 years were included and Subjects with migraine, tension type headache and neck pain were excluded from the study. After getting consent from the 100 samples, CCFT and jull's test were performed.

Conclusion: The study revealed that there is reduced neck muscle endurance and motor control among the subjects.

Keywords: CCFT, Jull’s test, Endurance, Neuro motor control.

Introduction

The neck muscles, including Sternocleidomastoid and trapezius are responsible for the gross motor movement in the muscular system of the head and neck¹. The deep neck flexor is made up of the longus colli, longus capitis, rectus capitis anterior. Not like the superficial neck flexor muscles, the deep neck flexors are responsible for maintenance of cervical lordosis and inter segmental stability during the activities of daily living².

Neck muscles are responsible for head movement, stabilizing the upper region of the body, assisting in swallowing and also to elevate the ribcage during inhalation or more. The neck supports the weight of the head and is highly flexible and turns in all directions. They move the head in every direction, pulling the skull and jaw towards the shoulders, spine and scapula. Working in pairs on the left and right sides of the body, these muscles control the flexion and extension of head and neck. Individually these muscles rotate the head or flex the neck laterally to left or right. These diverse tasks require both strong, forceful movements and some of the fastest, finest and most delicate adjustments in the entire human body. The deep cervical muscles are rich in muscle spindles and have been thought to play a relatively more prominent role in sensory motor function of this region. Neck muscles contract to adjust the posture of the head throughout and thereby require the greatest endurance of the muscles.

The concepts of “postural health” and “optimal posture” have been discussed in the healthcare professionals community for decades and broadly accepted that “good” and “bad” postures exist³,⁴. The Posture Committee of the American Academy of Orthopedic Surgeons (AAOS, 1947) defined healthy posture as the state of muscular and skeletal balance.
which protects the supporting structures of the body against injury or progressive deformity and poor posture as a faulty relationship of the various parts of the body which produces increased strain on the supporting structures. The prolonged periods of repeated motions or remaining fixed in one particular position commonly leads to the adaptation of poor posture habits. This postural adaptation causes the muscles of upper back to continuously overwork to counterbalance the pull of gravity on forward head and ultimately causes faulty posture adaptations like rounded upper back, neck muscle tightness and neck pain.

Based on existing evidence physiotherapists would select mainly upright postures, as these optimal postures were safe and natural when in cases of treating patients. However it is necessary that the therapists themselves should also concentrate on the importance of maintaining the strength of their neck muscles to prevent strain and other related problems. This study aimed to analyze the neuro motor control and endurance of the neck muscles among the physiotherapy students.

**Materials and Method**

The study was carried at the Faculty Of Physiotherapy, Dr. MGR Educational and Research Institute, Chennai. The study was approved by the institutional review board, among 125 volunteers 100 samples were selected based on the inclusion and exclusion criteria. The study included only the female subjects between the age group of 20-25 years, Subjects with migraine, tension type headache and neck pain were excluded from the study. As the study was an observational study type the samples were clearly explained about the procedure that they have to undergo. The informed consent was duly signed by the samples and the physiotherapist.

**Outcome measures:** The samples were asked to perform two tests, Jull’s test and Cranio cervical flexion test (CCFT). Jull’s test was performed to assess the endurance of neck muscles and CCFT were performed to analyse the motor control of the neck muscles.

Jull’s test is a cervical spine examination procedure that tests for deep neck flexor muscle weakness or deconditioning. Subjects should be awake and cooperative during a Jull’s Test. The subjects should be positioned in supine lying and tries to maintain the neck in flexion for 5-10 sec. This test can be performed in 2 positions, one in supine lying and the other involves the head about 3 cm off the table in full neck flexion. A positive Jull’s test is seen when there is noticeable chin jutting or excessive shaking when the subject maintains a flexed position.

The CCFT tests the neuromuscular control of the control of the deep cervical flexor muscles, the longus capitis, and colli. It can also be used as a clinical indicator of impaired activation of the deep cervical flexor muscles, to measure the muscle activity of the deep and superficial cervical muscles or as a therapy approach. The intra-and inter-reliability for the CCFT was between “fair to good” and “good to excellent” (ICC: 0.63 to 0.86).

The patient is positioned in a supine crook lying position, with the neck in a neutral position. The neutral position of the neck can be visually determined by maintaining a horizontal face position between the forehead and chin, before performing the test, an uninflated pressure sensor (= PBU or pressure biofeedback unit) must be placed beneath the occiput. The pressure sensor is inflated to a stable baseline pressure of 20 mmHg.

The patient is instructed to move the head vertically. The movement is performed gently and slowly. This nodding action causes the pressure in the inflated pressure sensor to increase. For the first stage of the test the pressure should increase by 2 mm Hg and asked to maintain this position for 5-10 seconds. Then the patient relaxes back to 20 mm Hg to increase the pressure again this time to 24 mm Hg using the same action and hold for five seconds. The patient has to do this until he/she has reached a pressure of 30 mm Hg. This test should be repeated twice without substitution or fatigue. Flexion of the neck requires activation of the deep cervical flexors. It is necessary to pay attention to compensatory strategies like Loss of the neutral position of the neck and head and Palpable or visible contraction of the sterno cleido mastoid and scalene muscle.

**Data Analysis:** Data was analysed using SPSS 21.0 and Microsoft Excel. All responses received were included in the analysis along with the average values of the trials; therefore results are reported accordingly. Mean and standard deviation were used for continuous data.
Table 1 The values achieved by the subjects when performing the Jull’s test and CCFT

</tr>
</tbody>
</table>

The median pressure level while performing the CCFT was 26 mm Hg. P value < 0.001

Result

According to the data analysis, the average values of both the Jull’s test and CCFT values were calculated. The mean value of Jull’s test in normal position is 3.20 and when it was 3cm off the table is 1.76. The mean value of CCFT is 5.62. The p value of both the scores when calculated is 0.000*. Based on the p value scores, it suggests that there is a significant difference among the subjects when the neck muscle endurance and neuro motor control activity was assessed. The normative baseline for CCFT was considered to be 26 mmHg. This study revealed that on assessing the Jull’s test and CCFT endurance of and the motor control of the neck muscles are reduced among the student population (physiotherapy students).

Discussion

Reduced activity of the the deep cervical flexor muscles goes hand in hand with an increase in activity and neuromuscular inefficiency of the superficial muscles even under low load and even with non-functional tasks. Patients with neck pain also struggle to relax the superficial neck flexor muscles even after an activity has ceased. Changes in function in the deep cervical muscles has an influence in function as it affects the support and control of the cervical spine and could lead to overload on specific segments. Falla et al (2004) revealed that any deficits in neuro-motor control could play an important role in the development of recurrent or chronic neck pain.

McKenzie and Haughie et al have proposed that nonspecific neck pain results from poor posture, arising through the sustained, long-term, abnormal physiological loads that such postures impose on the neck, with a consequent reduction in neck muscle strength. Petty et al. noted that weakened deep flexor muscles and consequentially decreased adjustment ability activated the superficial muscles, sterno cleido mastoid muscle and scalenus anterior muscle, and triggered excessive movement of the chin and the head resulting in excessive extension of the upper neck bone and shortening of the posterior muscles of the neck, reducing the stability of the neck. An obliteration of the cervical lordosis and a compensatory tilting back of the head at the atlanto-occipital joint, stretching of the posterior cervical muscles and weakness of semispinalis cervicis and overaction with ultimate shortening of semispinalis capitis thereby, the head shifts anteriorly from the line of gravity, the scapulae may rotate medially, a thoracic kyphosis may develop and overall vertebral height may be shortened. This ultimately leads to a forward head posture.

Conley et al. reported that deep muscles of cervical vertebrae maintain cervical lordosis and play an essential role in adjusting the movement of spinal segments. Much research has focused on the correlation between the stability of the cervical spine and the deep flexor muscles. Heo JG observed that impairment of the deep flexor muscle in patients with chronic neck pain weakened the strength of static muscles and severely weakened the endurance of the muscles. The role of the longus capitis and longus colli, deep flexor muscles of the neck, is considered important in postural adjustment and maintaining stability of the neck. They jointly cooperate to support the weight of the head while moving the head in various directions and provide stability during low-intensity static muscle endurance exercise, but not during high-intensity exercise, for which strong muscle contraction is required.

Based on the recent trends, physiotherapists play a major role in advising the importance of posture correction and its impact in the working areas, thereby it is also necessary for the therapist themselves to concentrate on the posture. Thereby it is necessary to emphasize on exercise training for the neck muscles and to counter balance equally over the muscles and pull of gravity. When exercises are followed regularly it helps in maintaining the properties of the muscles to reduce the strain over the neck muscles and other neck related problems.
The limitations of this study were the small number of participants in the study, the inclusion of female students only, and the lack of information on their levels of activity, all of which make it difficult to generalize the results. Future research should include a greater number of subjects and make gender comparisons.

**Conflict of Interest:** None

**Ethical Considerations:** The manuscript is approved by the Institutional Review board of faculty of physiotherapy. All the procedures were performed in accordance with the ethical standards of the responsible ethics committee both (Institutional and national) on human experimentation and the Helsinki Declaration of 1964 (as revised in 2008).

**Declaration of patient consent:** The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.

**Funding:** Nil, This is a self-funded study.

Abstract

Introduction: *Staphylococcus aureus* is one of the most common human pathogen capable of causing a wide range of infections. *Staphylococcus aureus* is a common cause of both community and hospital infections. It was the endemic microorganism in several reports of nosocomial infections which induced high mortality and morbidity. This microorganism is a virulent bacterium that can cause serious infections including skin and soft tissue infections, wound infection, bacteremia, pneumonia and endocarditis. It is estimated that *Staphylococcus aureus* has developed the ability to acquire resistance to all classes of antimicrobial agents and methicillin-resistant *S. aureus* (MRSA) has become a major problem in many hospitals worldwide. Hospital acquired infection (HAI) due to multidrug resistant bacteria like MRSA are a growing problem in many health care institutes. Materials and Method A total of 568 clinical isolates of *Staphylococcus aureus* were isolated from various clinical specimens received in the Department of Microbiology, Sri Lakshmi Narayana Institute of Medical Sciences, Pondicherry from April 2014 to December 2017, were included in the study. Isolation and identification of *Staphylococcus aureus* was done by standard conventional microbiological method. Identification of MRSA was done as per standard guidelines of CLSI by using Oxacillin broth microdilution method. Antibiogram was determined by Kirby-Bauer disc diffusion method on Mueller-Hinton agar with zones of inhibition.

Results: *Staphylococcus aureus* was susceptible to Vancomycin (94.7%), followed by Teicoplanin (91.7%), Linezolid (88.5%), Amikacin (85.7%). In case of MRSA all the isolates showed 100% susceptibility to vancomycin, followed by Teicoplanin (97.5%), Amikacin (84.7%) linezolid (80.3%) and Clindamycin (54.8%). In case of MRSA all the isolates were 100% susceptible to vancomycin followed by teicoplanin (97.5%), amikacin (84.7%) linezolid (80.3%) and clindamycin (54.8%).

Conclusion: MRSA infections are emerging as a serious health problem in health care set up. Joint efforts by clinicians, clinical microbiologists, hospital management and public health authorities are required to meet the challenge of MRSA on the forefront.

Keywords: *Staphylococcus aureus*, MRSA, Oxacillin, Vancomycin.
localized infection and septicemia, including the use of animal models for infection.²

*Staphylococcus aureus* has emerged as one of the main important human pathogens, and has over the past decades, been a leading cause of hospital and community-acquired infections. Staphylococcal infections give rise to a wide spectrum of symptoms and diseases in humans. The bacterium is well characterized and known to have a diverse arsenal of virulence factors that causes a prominent inflammatory response.³ This pathogen affects both immune competent and immuno compromised individuals, frequently resulting in high morbidity and with complications, which constitute problem to health care institutions. *S. aureus* has been reported by several studies as the causative agent of wide variety of diseases of supportive infections such as boil, wound infection, pustule, subcutaneous and sub-mucosa abscesses, osteomyelitis, mastitis, impetigo, septicemia, meningitis, bronchopneumonia, food poisoning, a common cause of vomiting, diarrhea, and urinary tract infections.⁵

*S. aureus* was discovered in 1880, its effective treatment was started in 1940, penicillin was the only drug used for treatment of the infections caused by this bacterium. After in late 1940 and throughout 1950, *S. aureus* developed resistance mechanism to penicillin. Introduction of Methicillin was done in 1961 to treat these resistant strains and within a year or later, clinicians had encountered methicillin-resistant *Staphylococcus aureus* which became a big threat. Now strains of MRSA are simultaneously resistant to a list of different groups of antibiotics, including vancomycin which is often considered our last line of antibacterial defence. Methicillin-resistant *Staphylococcus aureus* (MRSA) has been recognized as one of the major pathogens in both hospital and community settings.⁶

In 1961, British scientists discovered MRSA, the first case of this “superbug” in the United States occurred in 1968.⁷ MRSA is due to the acquisition of *mecA* gene that carried on a large mobile genetic element, the staphylococcal cassette chromosome, and which encodes a low affinity penicillin-binding protein 2a (PBP2a) to β-lactam antibiotics. The *mecC* gene when present, may also mediate methicillin resistance. The *mecA* complex also contains insertion sites for plasmids and transposons that facilitate acquisition of resistance to other antibiotics.⁸ Hospital acquired MRSA is frequently multidrug resistant. This limits the therapeutic options to a few antimicrobials, which are toxic, complicated to administer and expensive. As a consequence patients have to be hospitalized for a longer duration, treatment costs are increased and associated mortality also rises. This has a significant impact on individual patients and institutions. An additional concern of grave significance is the emergence of vancomycin intermediate *Staphylococcus aureus* (VISA) and more recently vancomycin resistant *Staphylococcus aureus* (VRSA).⁹,¹⁰

Hence this study was conducted to evaluate antibiotic susceptibility pattern of *Staphylococcus aureus* and to determine methicillin-resistant *Staphylococcus aureus* (MRSA) isolates from various clinical specimens.

**Materials and Method**

A total of 568 consecutive, clinically significant, non-repetitive clinical isolates of *Staphylococcus aureus* were isolated from various clinical specimens (pus, urine, wound swabs, sputum, ear swabs, body fluids, throat swabs, catheter tip, nasal swabs, blood) received in the Department of Microbiology, Sri Lakshmi Narayana Institute of Medical Sciences, Pondicherry, during the period of April 2014 to December 2017 were included in this study.

**Specimen collection:** The specimens were collected in sterile containers following aseptic measures and transported to the laboratory without delay and processed immediately. All the specimens were inoculated on 5% sheep blood agar and Mac Conkey’s agar and plates were incubated aerobically at 37°C.

**Identification of *Staphylococcus aureus*:** Colony morphology, Gram reaction, pigment production, catalase, and mannitol fermentation tests were performed and allocated to appropriate genera to the isolates. Golden yellow colored colonies on nutrient agar were noted and slide coagulase and tube coagulase was performed for differentiation of *S. aureus.*¹¹

**Identification of Methicillin-resistant *Staphylococcus aureus* by Cefoxitin disk diffusion method:** The MRSA strains were identified by using Cefoxitin (30μg) disc on Muller Hinton agar (Hi-Media Laboratories, Mumbai). Zone size was interpreted according to CLSI criteria, susceptible, >22 mm; resistant, <21 mm.¹²

**Identification of MRSA by Oxacillin broth dilution method:** MICs of oxacillin for all isolates showing reduced zone of inhibition by cefoxitin disk
diffusion were determined by broth microdilution method as described by Raghabendra Adhikari et al\textsuperscript{13} and CLSI guidelines\textsuperscript{14}. The concentrations of oxacillin used were 0.0125 µg/mL to 128 µg/mL.

**Antibiotic susceptibility:** Antibiotic sensitivity was tested using the Kirby-Bauer disc diffusion method (1966) on Mueller-Hinton agar according to antibiotic Clinical and Laboratory Standards Institute disc susceptibility testing guidelines(2013).\textsuperscript{14} Bacterial suspension equivalent to 0.5 McFarland was prepared by mixing 3-5 well isolated colonies in 3-4 ml of sterile physiological saline. Each suspension was inoculated on Muller Hinton agar (Hi-Media Laboratories, Mumbai) using sterile cotton swab and antibiotic disks were applied and incubated aerobically at 37°C. Antibiogram was determined for the following antibiotics Teicoplanin (30µg), Vancomycin (30µg), Gentamicin (50µg), Amikacin (30µg), Linezolid (30µg), Ciprofloxacin (10µg), Cefotaxime (30µg), Clindamycin (2µg), Cotrimaxazol (25µg), Erythromycin (15µg), Penicillin (10units), Tetracycline (30µg) (Hi-Media Laboratories, Mumbai).

**Results:** Out of 568 clinical isolates, 321 (56.5%) patients were from male and 247 (43.4%) were female. Majority of the patients were of age 41-50 (17.2%) as shown in (Table-1 and Table-2). Distributions of various clinical specimens were given in the (Table-3) of the 568 Staphylococcus aureus recovered, 366(64.4%) exhibited resistance by Cefoxitin disk diffusion method and 361(63.5%) were found to be MRSA by broth microdilution method and the cutoff value is 4µg/ml. Among them 127 had high level resistance with MIC of >128µg/ml. The MIC of Oxacillin for *S. aureus* isolates ranged from 0.064 µg/ml to 256 µg/ml.

*Staphylococcus aureus* was susceptible to vancomycin (94.7%), followed by teicoplanin (91.7%), linezolid (88.5%), amikacin (85.7%).

In case of MRSA all the isolates were 100% susceptible to vancomycin followed by teicoplanin (97.5%), amikacin (84.7%) linezolid (80.3%) and clindamycin (54.8%).

Discussion

Staphylococcus aureus is one of the most infectious agents with high prevalence in various communities and healthcare institutions. MRSA is recognized as a major cause of nosocomial infections which result in significant morbidity and mortality rates. It is a very common cause of infection in hospitals and is most liable to infect newborn babies, surgical patients, old and malnourished persons and patients with diabetes and other chronic diseases. The important reservoirs of MRSA in hospitals are infected or colonised patients and transient carriage and hands of health care workers is the predominant mode for patient to patient transmission.\(^{15}\)

In our study prevalence of MRSA was found to be (63.5%), similarly such percentages have previously reported in studies from verma et al. (80.89\%), Suresh Jaiswal et al. (72\%),\(^ {17}\) Dr. S. Kulkarni et al. (70.3\%),\(^ {18}\) Tiwari et al. (69.1\%), Joshi S et al.\(^ {19}\) and Ali et al. (68\%),\(^ {20}\) Yadav et al. (66.84\%),\(^ {21}\) Shilp Arora et al. (59.3\%),\(^ {24}\) Chandrasekhar et al. (56.7\%),\(^ {23}\) Anupurba et al. (54.8\%),\(^ {22}\) Rijal. Ket al (51.6\%).\(^ {2}\)

MRSA strains were predominantly isolated from pus samples (72.3\%) which correlates with Yadav et al. (86\%),\(^ {21}\) Dr. S. Kulakarni et al. (64.67\%),\(^ {18}\) Bandaru S Rao et al. (64.38\%),\(^ {23}\) in contrast Ankur Kumar et al.\(^ {27}\) and Bilal Ahmed Mir et al.\(^ {28}\) reported (21.42\%) and (27.5\%).

Staphylococcus aureus was susceptible to Vancomycin (94.7\%), followed by Teicoplanin (91.7\%), Linezolid (88.5\%), Amikacin (85.7\%). All the MRSA isolates were 100% sensitive to Vancomycin in the present study. The sensitivity followed by Teicoplanin (97.5\%), Amikacin (84.7\%), Linezolid (80.3\%) and Clindamycin (54.8\%) correlates with Bhatt CP et al.\(^ {29}\), Gitau et al.\(^ {30}\), Ankur Kumar et al.\(^ {27}\) and Bandaru S Rao et al.\(^ {26}\)

Conclusion: MRSA is emerging as a potential threat to our hospitals with a predilection for critically ill patients. Regular surveillance of hospital acquired infections, promotion of infection control precautions and formulation of definite antibiotic policy can be helpful in preventing MRSA infections from acquiring an alarming proportion. Good basic hygiene measures are extremely important, not only for hospital staff but also for patients and visitors, and it has a positive impact in infection control.

Abstract

Xylene is an important component of petrol and 98% of Xylene is derived from the petroleum refining industries. When human get expose to xylene, which is one of the major genotoxicant, which may induce with a range of acute/chronic diseases but occurrence of cancer is still not available in literature. Taking into our mind that our study aims to investigate and correlate the micronuclei in exfoliated oral epithelial cells with urinary methylhippuric acid level estimation among petrol pump workers.

Aims & Objectives:

• To evaluate occupational exposure of xylene in petrol pump workers by assessing urinary methylhippuric acid level.

• To determine the correlation between the level of urinary methylhippuric acid and the micronuclei of exfoliated epithelial cells of buccal mucosa.

Materials and Method: Urine samples and oral buccal mucosa smears were collected from 30 healthy individual (control) and 30 petroleum pump workers (case) working in petroleum station. The urinary methylhippuric acid (MHA) level was analysed by using Shimadzu UV-Visible Spectrophotometer procedure. The smeared slides were stained with PAP stain and analyse the micronuclei of exfoliated epithelial cells by using Axio Vision SE64 Rel 4.9.1. Ink Software.

Results: The urinary Methylhippuric acid level was substantially higher in cases than in controls (p<0.001). The Micronuclei (MN) frequency was drastically increased in cases than in controls and was statistically highly significant (P<0.0001). The frequency of MN gradually increased along with increased urinary MHA level in petroleum pump workers.

Conclusion: The urinary MHA level and MN frequency is a useful index to recognize the occupational exposure to the petroleum product. Thus, our study emphasizes that appropriate precaution and regular bio-monitoring must be taken among petrol pump workers which shall help to reduce their potential levels of risk associated with the occupation.

Keywords: Xylene, Exfoliated buccal cells, Micronuclei, Occupational Exposure, Urine Methylhippuric acid level.

Introduction

Health is very precious and the work environment plays an important role in one’s health. Air, noise, heat, and radiation are the main source of environmental pollution especially in urban areas.¹

Millions of workers in a variety of occupational settings have the potential to be exposed to hazardous
substances, important among which are petroleum derivatives. Many toxicological effects may be associated with the exposure to petroleum component such as benzene, toluene, ethylene and xylene, which are also known as volatile organic compounds (VOCs). Petroleum derivatives constitute a complex mix of chemicals and are well known genotoxic agents especially xylene. Exposure to petroleum vapours is classified by the International Agency for Research on Cancer as Group-2A (‘probably’) carcinogen to humans, mainly on the basis of well-established carcinogenicity. The presence of xylene in petrol and as an industrial solvent can result in widespread emissions to the occupationally exposed petrol pump workers. Xylene is a colorless, flammable liquid that smells like gasoline. It is found in both natural products like coal tar and petroleum and also in manufactured products like inks, insecticides, and paints. Xylene is also used as a solvent to make other chemical compounds. People might be exposed to xylene in many ways including breathing air, particularly in areas near factories or petrol pumps.5

The mechanism(s) of xylene as a carcinogenic agent has not yet fully understood but the hypothesis of xylene acting as an indirect genotoxic carcinogen is well-documented in literatures. Cytogenetic damage, including structural aberrations, micronuclei (MN) and sister chromatid exchanges (SCEs), are demonstrated in bone marrow cells, splenocytes, peripheral blood lymphocytes and oral mucosal cells of mice exposed to benzene but not proven in humans. Among all the cytogenetic biomarkers, micronuclei have been extensively used to gauge rates of chromosomal damage to genotoxic agents.6

Exfoliated oral buccal cells have been used non-invasively to successfully show the genotoxic effects of various lifestyle factors, medical treatments and occupational exposure to potentially mutagenic and/or carcinogenic chemicals.

Methylhippuric acid is a principal metabolite of xylene and hence its level in urine can be used to monitor external exposure in petrol pump workers. Although xylene is present at low level in urine of exposed individuals, trying to find some sensitive methodology of direct determination of trace amount of this environmental and industrial pollutant can be a suitable alternative way to overcome the problems may associate with the determination of its metabolite (methyl hippuric acid) in urine.7

Petrol pump workers are chronically exposed to petroleum derivatives primarily through inhalation of the volatile fraction of petrol during vehicle refueling. Taking into our mind that occupational exposure to such derivatives may possess genotoxic risk. Hence our study aims to investigate and correlate the cellular changes in exfoliated oral epithelial cells using PAP stained oral smears with the UV-spectrophotometric urinary methylhippuric acid level estimation in petrol pump workers.

**Materials and Method**

The study population selected from various petrol pumps according to inclusion and exclusion criteria and control population were healthy individuals who were not exposed to petrochemical product.

**Inclusion criteria:**
- Persons giving their written consent to participate in the study.
- Male employees who is above 18 years of age, working in the Mysuru city limits.
- Workers who are working in shifts not less than 8 hrs.
- Workers should not have the habit of consuming any form of tobacco/alcohol.

**Exclusion criteria:**
- Person with history of any systemic condition or disease.
- Person with history of any chemotherapy/surgery/radiation therapy.
- Person having any lesions/ulcer/tumour/trauma in the oral cavity.

Urine samples were collected from 30 healthy individual and 30 petroleum pump workers working in petroleum station who are above 18 years of age. The urine was collected before exposure/work shift and after completion of a work shift. The urinary methylhippuric acid (MHA) level was analyzed by using Shimadzu UV-Visible Spectrophotometer procedure. (Fig.1)
Oral buccal mucosa smears were also collected from the same individuals and smeared slides were fixed in the alcohol and coded it. These smeared slides were stained with PAP stain and 100 cells were analyzed in zig-zag manner by using bright field microscope under 40X magnifications. So that, overlapping/same cells should not be taken for consideration. Cytomorphometric changes like micronuclei of exfoliated epithelial cells were studied by using Axio Vision SE64 Rel 4.9.1. Ink Software. (Fig. 2)

The following criteria for scoring micronuclei:

- Rounded, smooth perimeter suggestive of the membrane.
- Less than a third the diameter of the associated nucleus, but large enough to discern shape and colour.
- Staining intensity similar to that of a nucleus.
- Texture similar to that of a nucleus.
- The same focal plane as a nucleus.
- An absence of overlap with, or bridge to, nucleus.

The obtained data were collected and statistical analysis method were applied like descriptive statistics, one sample t-test, Pearson’s correlation.

Result

In the present study, the urinary MHA level was in cases 87.8 μg/ml and 30.8 μg/ml in controls was found as shown in Table I. The urinary MHA level was high in cases than the control population.

The correlation of urinary MHA level and micronuclei (MN) among cases, the p-value was 0.000 which was significant in Table-II. The urinary MHA level increase along with the increase in the number of micronuclei.

The comparison between urinary MHA level and micronuclei in cases and controls, the p-value was 0.000 which was highly significant as shown in Table III.

Discussion

Xylene is an important component of petrol and a widely distributed environmental contaminant. About 98% of Xylene is derived from the petrochemical and petroleum refining industries. Petrol station attendants are chronically exposed to petroleum derivatives primarily through inhalation of the volatile fraction of petrol during vehicle refuelling. Therefore occupational exposure to xylene in humans generally takes place in factories, refineries; petrol refuelling and other industrial settings. When humans get exposed to one of the major genotoxicants like xylene have been associated with a range of acute/chronic diseases/cancer depending upon the concentration and time of exposure.

Methylhippuric acid is a principal metabolite of xylene and hence its level in urine can be used to monitor external exposure in petrol pump workers. Based on this, our study attempted to investigate any correlation between cellular changes in exfoliated buccal epithelial cells that were obtained and the urinary MHA level among petroleum pump worker.

The present study consisted of 30 petroleum pump workers (case group) and 30 healthy individuals with no known exposure to petrochemical products (control group) all of the above 18 yr old male population. All the subjects who met the inclusion and exclusion criteria were subjected to a pair of oral buccal smear sampling and collection of the urine sample for estimation of MHA levels. The oral buccal smears were stained with Rapid PAP stain to assess the micronuclei of exfoliated cells and the estimation of urinary MHA level was done using UV-spectrophotometer.

In our study, the urinary MHA level was found to be more in case population (87.8 μg/ml) than control population (30.8 μg/ml). Our study is in accordance with studies by Celik A et al. (2003), Singaraju et al. (2012), Koschisoruret al. (2000), Vermaet al. (2001), Hein et al. (1989), were also reported that the urinary MHA level in petrol station workers was significantly higher than controls. Engstrom K et al. (1978) who reported that a determination of methylhippuric acid concentration in urine samples was found to be high at the end of the workday for evaluating the xylene exposure. Thus our study found that occupational exposure to xylene is associated with increased MHA level in urine.

The analysis of micronuclei (MN) has gained popularity as biomarker assay for human genotoxic exposure and effect of xylene. Hence, we analysed the micronuclei along with urinary MHA level in both case and control group. In our study, the urinary MHA level and micronuclei (MN) showed highly significant in the case group than control group.

In our study, we try to identify the relation between urinary MHA level and micronuclei frequency in epithelial cells. The frequency of MN gradually increased with increased urinary MHA level in petroleum pump workers. Hence, the micronucleus test in exfoliated epithelial cells and the urinary MHA levels in urine seem to be a useful biomarker of occupational exposure to xylene.

As demonstrated in this study, MN frequency is a useful tool to identify the level of petroleum product, but we could not able assess the relationship between urinary MHA level and cytormorphometric analysis of epithelial cells among petrol pump workers. The urinary MHA level and MN frequency is a useful index to recognise the occupational exposure to a petroleum product. Further studies may require knowing the effect of the xylene over the oral epithelial cells with a time of exposure in the larger population. Molecular studies are required to identify the effect of the xylene over the oral epithelial cells in a larger population.

Xylene has a significant role in humans, and act as carcinogenic agent, it may initiate the carcinogenic process often to do damaging the cellular DNA. Thus our study emphasises that appropriate precaution and regular bio-monitoring must be taken among petrol pump workers about their health which may reduce their levels of risk associated with the occupation.

Conclusion

The hazards of xylene are well documented, but the substitutes are not so thoroughly evaluated. It may not be good to get expose to petroleum product on daily basis to larger the volume. One must be aware these petroleum products are the main pollutant that is responsible for the genotoxic effect. The result obtained
in this study suggests that exposure in these workplaces may induce genotoxic effects. It is important to control and reduce the exposure to petroleum products as much as possible and it is necessary to educate the petrol pump workers about its hazardous effect to ensure the safety and healthy working atmosphere for the petrol pump workers. Hence, the petrol pump worker should use a proper personal protective equipment like protective clothes (Buna-N-Rubber or Vilton gloves), impervious apron, face mask or full-face organic respirator, safety goggles, organic inhaler etc. so that they can prevent the hazardous effect of xylene on individual health.

Strategical Career Planning to Combat Career Plateau

Shakila Devi A.R.¹, Rabiyyath Basariya S.²

¹Research Scholar; ²Associate Professor, Bharath Institute of Higher Education And Research, Chennai, India

Abstract

A career planning is the route map of a person’s work life. It is the sequence of positions a person occupies during his lifetime. Earlier it was based upon the advancement and promotion of an individual in an organisation but in recent scenario it is defined in a holistic way to include a person’s attitude and experience based on this approach and extensive research conducted. It has been identified that a person goes through four different career stages during his adult growth and development. Plateau is a stage where an employee get stagnated at a position for a long time with no opportunities for growth in career. Planning the career in right way will avoid the career plateau for any employee.

Keywords: Career planning, career stages, learner, solid citizen’s deadwood.

Introduction

Career planning involves setting career objectives by assessing one’s capabilities, values and goals followed by examining alternative career options. Making a choice and planning how to progress in chosen career path. Career planning process involves identifying the individual needs and aspirations, the second step is analyzing career opportunities, third step is to align the individual needs and opportunities and the final step is related to action planning and periodic review.¹

Career Planning: The career is defined as the sequence of jobs that constitute what a person does for a living. It involves setting career objectives by assessing one’s capabilities, values and goals followed by examining alternative career options making a choice and planning how to progress in chosen career path.² A career plan is an individual’s choice of occupation and career path.

Features of Career Planning:

- Attracting talented person to the organisation.
- Identifying the person’s positive characteristics.
- Developing healthy way to deal with conflicts, emotions and stress.

Stages Incareer Planning:

Establishment stage: (Age 20 to 26) in this stage when an individual is not sure about his competence and potential they depend upon their subordinate for guidance support and feedback. At this situation they commit themselves to a specific career, organisation and job. Gradually they explore themselves and their capabilities.

Advancement stage: (Age 26 to 40) in this stage employees become independent contributors and are forced on achieving and moving up in their career. At this stage they need very little guidance: moreover they have a clear view of what they want to do in their career. At this phase they settle down in their career and so it termed as settling down stage.

Maintenance stage: (Age 40 to 60) in this stage the individual holds on to the career due to the success which he experienced in his stay. During this phase many people have achieved advancement whereas it could be conflictual and depressing for those who are dissatisfied in their career progress. Such types of employees try to find out alternate careers and there arises career plateau. In olden days career plateau raised maximum during this...
phase only but in recent times due to industrialization and globalization sometimes career plateau arises in the advanced stage itself.

**Withdrawal Stage:** (Age 60 and above) in this stage individuals want to leave their career. At this stage the individual slowly loses all attachment to the organisation and gets ready for retirement. Such people contribute by imparting knowledge and skill to others. The people who have found success in their career feel satisfied and fulfilled.

**Benefits of Career Planning:** The most relying beneficial factor is that it creates the path to avoid the career plateau.

**Important benefits**
- Laborturnover is reduced.
- Ensures constant supply of promotable employees.
- Creates reserve talent to meet any emergency.
- Improves the loyalty of the employees.
- Organisational growth and development is encouraged.
- Discourages the supervisors who suppress growth of subordinates.

**Career plateau:** Career plateau is defined as a point in one’s career where their likelihood of additional hierarchical upward mobility i.e. promotion is very low. There are four main principal career states they are.

**Learner:** Individuals who have high potentials less than the standard level.

**Stars:** Individual who perform outstanding work and are having high potential with fast track career paths.

**Solid citizens:** Individuals present performance is outstanding and has a little chance of future advancement.

**Deadwood:** individuals have a little potential for advancement and also their performance is not up to the level satisfaction.

**Career plateau has both subjective and objective aspects:** A subjective aspect includes self-perceptions, assessment and reaction towards present work situation.

An objective aspect includes observation and analyse the facts that are observed.

**Factors determining career plateau**

The following factors determine the career plateau stage of an employee

- Lack of intrinsic motivation
- Perception of individual
- Familial factors
- Locus of control
- Perseverance of work
- Lack of individual skill and ability
- Lack of organization’s innovative climate
- Business strategy
- Individual needs and values
- Slow organizational growth
- Lack of extrinsic rewards

The behaviour of each individual is influenced by several factors; these are classified as environmental, personal, organizational, psychological factors. Individual behaviour forms the basis of organizational behavior. Perception is an important factor influencing behaviour and as a process it involves steps such as receiving, selecting, organizing, interpreting, checking and reacting. Perception is influenced by the factors such as perceiver perceived and situation. Learning is yet another variable in human behaviour. Knowledge of learning is vital for understanding organizational behaviour. There are various sources of acquiring attitudes and in organisations there are work related attitudes.

**Environmental factors:** An environmental factor includes variables such as economic, social and political. These factors are mainly external and will influence individual behaviour. It is a synthesis of several factors such as employment level, wage rates, economic outlook and technological change.

**Personal factors:** Every individual brings to the workplace a variety of personal characteristics and attributes like age, sex, education dependents, abilities and similar related factors.

**Organizational system and remarks:** individual behaviour is also influenced by physical facilities. Organizational structure and design leadership and reward system.
Psychological factors: psychological factors are individual mental characteristics and attributes that can affect behaviour. There are several psychological factors but the more prominent among them are personality, perception, attitudes, values, and learning.

Career plateau relates to significant variance in three outcomes: career satisfaction, job satisfaction, and turnover intentions. All these three are interrelated with one another. The study of individual behaviour forms the basis of career plateau. Perception is a factor which influences the behaviour of individuals. Perception is the unique interpretation of a situation by an individual. Perception is composed of six processes: receiving, selecting, organizing, interpreting, checking, and reacting to sensory stimuli or data. These processes are influenced by the perceiver and situation.

Career satisfaction: Career satisfaction is a set of pleasurable feelings with which employees view their work. It is also referred to as a positive emotional attitude resulting from the evaluation of one’s job or job experience.

Job satisfaction: There are many factors which lead to job satisfaction, the most important job elements which contribute to job satisfaction. These are: wage structure, nature of work, promotion chances, quality of supervision, work groups, and working condition.

Turnover intentions: If an employee experiences career satisfaction and job satisfaction in his profession, automatically turnover intention gets vanished.

Professional plateau: Every individual will face the stagnating career in their duration of life. Stagnating career of professionals is an unavoidable phenomenon in organizational setting. Stagnation of an individual arises due to the lack of proactive planning. A career plateau from the organization’s points arises due to new business strategy and organizational restructuring.

Stagnation in the new business strategy or in the organizational restructuring are characterized into:

- When the employee’s competencies could not meet the requirements of the new organizational strategy.
- When the employees skill lacks against the market opportunities.
- When the employees possess outdated knowledge.
- When the professionals expertise becomes unimportant for the company anymore.
- When the employees face discrepancy between the effort and remuneration received by them.

These five categories are the important causes for the stagnation of an employee. Flexibility programmer and development plan should be designed to increase the professional’s career. Specific intervention should be designed in order to develop the organization. In an organizational process fleet review which is meant as a structural intervention is used to trace current position and to prevent future stagnation.

Plateaued professionals become aware of their own responsibility in managing their development in the changing business context. An explicit and focused collaborative effort can be of great importance in making plateaued professionals flexible and prevent a lot regarding personal damage and organizational damage related to career plateauing.

Conclusion

Career planning in an organisation encourages the employees towards having ambitions and working towards fulfilling them. Career planning involves setting career objectives by assessing one’s capabilities, values and goals followed by examining alternative career options making a choice and planning in accordance to it will definitely bring success in every employee’s life. Factors that are determining career plateau should be taken care while planning for career development so that the plateau can be avoided in one’s career.

Knowledge and Practice on Current Regulatory Requirements for Members of Ethics Committee amongst Dental Colleges in India

Vini Mehta¹, Sahana Hegde-Shetiya², Pradnya Kakodkar², Nitin Gupta³

¹MDS, ²Professor, ³Assistant Professor, Dr. D.Y. Patil Dental College and Hospital, Dr. D.Y. Patil Vidyapeeth, Pune

Abstract

Introduction: Regulatory guidelines have been made stringent to safeguard human rights, integrity, safety and welfare.

Aim and Objective: The present study was designed to elucidate the knowledge and practice of current regulatory requirements for the members of ethics committee (EC), amongst dental colleges in India.

Materials and Method: A cross sectional survey was conducted amongst the ethics committee members of various post graduate dental colleges representing North, South, East, West and Central zones. A validated closed questionnaire was framed in accordance with the Schedule Y of Drugs and Cosmetic Rules 1945 and Indian-GCP guidelines, which was sent through an e-survey using Google forms.

Results: The response rate was found to be 40%. Less than 50% participants correctly answered about guidelines of biomedical research, composition of EC, serious adverse effect and vulnerable population. 16.3% of the participants had registered EC and only 28.7% applied universal ethical principles.

Conclusion: Despite the presence of ethics committee in the dental institute, the knowledge and practice regarding current regulatory requirements was found to be insufficient for proper functioning.

Keywords: Ethics, current regulatory requirements, dental colleges.

Introduction

Due to an enormous rise in research on human subjects in dental teaching institutions today, it is important for ethics committee members to address the ethical concerns of the subjects involved in the research. According to Indian Council of Medical Research (ICMR) it is compulsory for any biomedical research to be approved by the Institutional Ethics Committee (IEC)/Institutional Review Board (IRB), before its initiation. This is supported by the revised Schedule Y in Amendment 2005 of the Drugs and Cosmetics Act, 1940.¹ According to this Act, all the institutions undertaking research should have their IEC accredited to a central agency.²

The horizons of dental research are widening with time but individual and institutional research ethics capabilities are not improving in the required and ideal proportion.³ ICMR and the World Health Organization (WHO) conducted a survey on 223 IEC in India which shows that maximum committees did not meet regulatory requirements in terms of composition and function. Recently a survey was conducted to assess the existence, structure and functioning of IEC in dental teaching institution in Kerala found that out of 17 colleges, 13 had a functioning IEC and only 4 colleges were accredited to a central agency.⁴

Regulatory guidelines have been made stringent to safeguard human rights, integrity, safety and welfare.⁵

Also, there is an insufficient interaction between researchers’ and ethics committee members leading to misconduct in implementing ethical guidelines. It is imperative that ethics committee members should have the requisite knowledge on current regulatory requirements which is in accordance with Schedule Y of Drugs and Cosmetics Act. The present study was designed to elucidate the knowledge and practice on current regulatory requirements for members of ethics committee amongst dental colleges in India.

**Materials and Method**

The study was approved by the institutional review committee of Dr. D.Y. Patil Vidyapeeth, Pune, India.

**Study setting:** A cross sectional questionnaire-based study was conducted amongst the ethics committee members of various post graduate dental colleges representing North, South, East, West and Central zones through an e-survey using Google forms between September to December 2017.

**Study population and sampling technique:** State wise list of post graduate dental colleges was obtained from the Dental Council of India (DCI) website. A list of the email addresses of ethics committee members was collected through convenience sampling. Sample size was calculated using EpiInfo software based on results from Deolia S where knowledge was 43.3%. The final sample size was 300 and e-mails were sent to 750 members through google form.

**Study tools and Data collection:** The 18-item closed questionnaire was framed in accordance with Schedule Y of Drugs and Cosmetic Rules 1945 and Indian-GCP guidelines. Lawshe’s method was used for content validity using judgments from a panel of 10 subject matter experts (SMEs). The reliability was also established by test–retest amongst 20 volunteers of similar population. The kappa value was 0.9, which indicated high reliability. This was followed by pilot testing amongst 10 volunteers who were asked to answer the questionnaire and provide feedback on content, clarity and brevity of the questionnaire.

Check boxes were provided and participants had to click on any one option for each question. Care was taken that one person could answer the questionnaire only once and all questions were mandatory. The responses were directly recorded through google forms. Since this was an e-survey, the informed consent was included in the Google form.

**Statistical analysis:** The online recorded information was converted into codes and analyzed using Statistical Package for Social Sciences (SPSS) Version 20 software package (SPSS inc., IBM, and Chicago, IL, USA). Analysis was done using descriptive statistics and expressed in the form of frequency and percentages.

**Results**

Out of 750 EC members, 300 responded giving a response rate of 40%. 37% of the participants belonged to South zone. Only 38.6% of the participants received training in research ethics. Table 1 presents the characteristics of the study participants.

Nearly 64% had adequate knowledge about informed consent, but only 14.7% knew about the continuing review of an approved protocol. 46.3% of EC members were aware of the ICMR guidelines on ethics for research and only 11.3% of the participants knew about the current regulatory requirements. Table 2 presents the responses to questions on their knowledge.

Only 16.3% of the participants had registered ethics committee and 39.3% of the participants would review all research studies at least annually. Less than 50% of the participants maintained confidentiality and applied universal ethical principles while reviewing a protocol. Table 3 shows the EC members responses regarding their practice.

A statistically significant association \[p<0.001\] was found between training received in research ethics and number of years of experience in ethics committee with knowledge.

A statistically significant association \[p<0.001\] was found between the training received in research ethics and the number of years of experience in ethics committee with practice.

Discussion

India is considered as an ideal, cost-effective location for undertaking clinical trials and for meeting international regulatory requirements. Ethics committee members are responsible for the safety of research participants. In India, institutional mechanisms for ethical review of research involving human subjects are weak and vulnerable, collaborative effort is required to strengthen them to fulfill their stated missions. Due to an inherent need for strengthening the ECs, ICMR has started promoting the establishment of ECs and providing training modules for EC members and researchers in ethics. In our survey, we included only post graduate institutions because there is an enormous increase in the number of research projects carried out in these institutions. In addition, numerous independent studies are also undertaken by the faculty as a part of professional enrichment. We had a response rate of 40% which was better than (24.8%) reported by Mirzae A.

A study found that only 23.5% of IECs were accredited to Central Drugs Standards Control Organization (CDSCO), 91.6% had more than one dentist as clinicians. The results of the present study also indicate that only 16.3% of the EC are registered and 46.3% of the respondents had MDS degree which suggests that findings in this study are not necessarily generalizable because sometimes dental institutions have sub-committee which function at college level.

In a study conducted to check the competence of ethics committees, a survey questionnaire was developed and sent to 20 EC representing various parts of the state. 83% said that the decision to approve/reject the protocol was taken during the meeting with all members participating in the final decision making and 93% of the members said that periodic ethics review of ongoing trials was conducted. The results obtained in our study are in contrast where only 32.6% of the members were aware about the ICMR guidelines on final decision making and 14.7% of the members knew that continuing review of an approved protocol should be done at least annually.

A survey found that only 23.5% of IECs were accredited to Central Drugs Standards Control Organization (CDSCO), 91.6% had more than one dentist as clinicians. The results of the present study also indicate that only 16.3% of the EC are registered and 46.3% of the respondents had MDS degree which suggests that findings in this study are not necessarily generalizable because sometimes dental institutions have sub-committee which function at college level.
whereas the university have IEC/IRB which is probably registered with CDSCO.

The present study sheds light on the fact that only 34% of the members invited expert in special area similar to a study done in compliance with Schedule Y/ICMR Guidelines 2006 where legal experts were not present in approval meetings. It was observed that in most institutes, the chairperson was affiliated to the same institution like in the present study. 39.3% of the respondents said that the chairperson was from the same institution which could potentially induce a conflict of interest while reviewing the proposals.

Members who had received training in ethics showed adequate knowledge and good practice, which was similar to this study showing that training is significantly (p<0.001) associated with knowledge and practice of the EC members. The overall knowledge regarding various regulatory requirements was found to be discouraging amongst EC members in this study justifying the requirement for compulsory training and upgradation in knowledge.

In a study, it was observed that higher qualifications (p=0.004), those with more than 20 years of research experience (0.023) and those with more experience of working with ECs (p=0.032) were more likely to attend meeting. Results obtained in this study, showed the number of years of experience in ethics is significantly associated with knowledge and practice.

Practice of the EC members might not have been evaluated appropriately because some of the questions were not based on individual decisions rather policies made by institutions. However, this survey from dental colleges in India is an effort to capture the existing level of knowledge of EC members about current regulatory requirements, which can be validated further by undertaking a larger study across India in the near future. This study highlights the need for mandatory training for EC members in the form of workshops and lectures to keep abreast with the current regulatory requirements and appropriate institutional support to IEC for proper functioning.

**Conclusion**

Despite the presence of ethics committee in the dental institute, the knowledge and practice regarding current regulatory requirements was found to be insufficient for proper functioning. This study was attempted to bring awareness amongst members of EC to follow ethically high standards that will help in safeguarding and protecting the health and welfare of the research participants in particular and the nation as a whole.

Forcing Gender Issues and Challenges Affecting Women Employees to Continue their Career in IT Industry

A. Nafeesa Begum1, G. Brindha2

1Research Scholar, Department of Management Studies, Bharath University, 2Professor & Head, Faculty of Management Studies, Dr. Mgr Educational and Research Institute University, Chennai

Abstract

Despite the major advancements women have made in becoming a significant part of the workforce, they are still facing important career development issues. Although many women achieve lower and middle management positions, they seem to hit the “glass ceiling” in many organizations and are denied the most senior levels of upper management. The reasons are multi-dimensional; some women lack the confidence to apply for senior positions; some lack the necessary education or training; and others find themselves excluded from the top positions because of systemic gender bias that exists in some companies. There are plenty of statistics tracking the percentage of women in the workforce, their qualifications and their salaries. But the data doesn’t show us the whole picture. It doesn’t assess how women feel, how they fare in their day-to-day business, the challenges they encounter. And that is why the research embarked on a global task, asking more than 9,500 women across the G20 to identify the top five issues faced at work especially in IT industry.

Keywords: Women Retention, Issues and Challenges, Career Advancement, Gender Discrimination, Strategies to Overcome.

Introduction

Despite progress in employment gender equality, men continue to substantially outnumber women in terms of employment in the tech industry. Many analysts attribute the gender disparity in technical fields to the fact that women study science, technology, engineering and mathematics (STEM) at a lower rate than men do. Some experts suggest that cultural expectations also influence the gender divide causing women to feel pressured to pursue careers in other industries1.

Regardless of having equal or superior skills to their male counterparts, women often feel like societal pressure and cultural norms work against them while seeking employment and advancement in tech careers. Many companies have taken a proactive approach toward gender bias in tech employment by adopting inclusive and collaborative policies that mandate equal treatment for men and women. However, the following three challenges still exist in many settings, but women in IT can overcome them as they pursue a fulfilling and successful career.

Inequality and Discrimination: Statistics indicate that women working in IT positions report gender inequality at a higher rate than the overall average among employed women. Networking opportunities and promotions go to men in tech careers at a higher rate than to women2. Company events and trade gatherings often provide settings where male tech workers exhibit sexist attitudes and behaviours toward their female colleagues. Meanwhile, employees in the work environment often question whether a woman has the ability to address and resolve technical issues.

Gender discrimination, though illegal, still exists in the job market. Interviewers ask questions about marital and parental status to three-quarters of female applicants. Even when not directly quizzed about their family status, a stunning forty-percent of all women feel like they must carefully guard details about their family during job interviews. When women (or any employee) feel like outsiders in the workplace because of their unique qualities or differences (e.g., gender, race/ethnicity, nationality, age, religion, sexual orientation), they feel excluded. Exclusion comes at a great cost to
organizations in the form of lowered job satisfaction, reduced work effort, diminished employee voice, and greater intention to leave. Building an inclusive workplace means creating a culture that fully engages and supports all employees.

Women who experience discrimination and inequality in the workplace should talk about the issue openly and report it to their supervisor. The company’s responsibility will, then, be to address the issue properly. To prevent such situations from occurring again, business owners need to educate their personnel about gender discrimination and teach them how to recognize and deal with it.

Moreover, business owners and managers who have a healthy attitude toward women in the workplace should set an example for the entire company by behaving in ways that respect all workers and treat everyone working in IT fairly, regardless of gender. Such behavior will also respectfully treat all employees that become mothers and make them feel comfortable and secure while taking leave. Similarly, employers need to adopt flexible scheduling so working mothers don’t feel as though they must neglect their responsibilities to keep their job.

**Not Fitting in:** Women in male-dominated fields such as IT often lack self-confidence and suffer from feelings of inferiority. In a workplace where the great majority of employees are male, women often feel as though they don’t fit in. A drastic number of approximately 60 percent of women working in tech report sexual harassment. Although such problems can exist in fields with a higher degree of gender equality, the problem seems worse in IT. Female tech workers have a higher incidence of sexual harassment in IT because fewer targets exist in that profession. The fact that one-third of women IT workers feel unsafe at work illustrates the severity of the problem. This is a serious issue and women should never hesitate to report it to their supervisors.

Additionally, not having a college degree in engineering or computer science can also lead to a workplace atmosphere where women feel as though they don’t fit in. Some women can also experience difficulty staying up-to-date with the latest trends in technology, leading to a skill gap that adds to the challenges they face. Still, women can do IT jobs just as well as men can, as long as they make an effort to develop and maintain their proficiency in required skills.

Lucky enough, the IT industry usually operates as a meritocracy where employees who deliver consistent results receive favorable treatment regardless of their gender or background. Women can overcome the obstacles they face while working in IT by letting their performance speak for them. Although the strategy doesn’t eradicate gender-based prejudice and discrimination, it allows women to achieve upward mobility.

**Lack of Support and Understanding:** Female IT employees often report feeling as though they don’t have the full support of their co-workers. They also feel a lack of support at home in cases where their family members and friends still embrace cultural biases regarding women in the workforce. Attitudes about the role of women at home often prevent female IT workers from achieving a healthy work-life balance. Also, new mothers often cut short their paid maternity leave because they feel as though they will lose their job or promotion because of their absence.

Handling inequality and discrimination in the workplace is hard on its own, but handling it without any support for the chosen career makes things even harder. Working on improving the quality of family communication can go a long way in making sure that every female IT worker’s family member understands that their job in the IT industry is important to them.

**Flexible Work Arrangements and equal pay:** Flexible work arrangements (FWAs) define how, where, and when employees’ work, allowing them to best manage their career and personal priorities. Once seen as an employee benefit or an accommodation for caregivers (primarily women), flexible work arrangements are now an effective tool for organizations to attract top talent as well as a cost-savings measure to reduce turnover, productivity, and absenteeism.

**Equal Pay-it’s 2018, and women still make less than men.** Women around the world continue to face a wage gap. In fact, women on average will need to work more than 70 additional days each year just to catch up to the earnings of men. Our research shows that even after taking into account prior experience, time since degree, job level, industry, and global region, women MBA graduates were paid $4,600 less than men in their first job after graduation.

**Children and career:** Almost half of the women polled are optimistic about the prospects of having a
child and a career. Women in emerging countries led by Brazil—where maternity laws are generous and family ties are close—are the most confident. By contrast, women in some of the richest countries—Germany, the UK and France—are least confident and feel having a family might wreck their careers.

According to the Denver Women’s Commission, even though most women work outside the home, they are still the primary caregivers for their young children as well as elderly or infirm relatives. Consequently, many women can only pursue their careers on a part-time basis, resulting in fewer promotion opportunities. Unlike their male colleagues, women consider the ages of their children and the amount of time they have available before they decide to pursue a career path.

**What Else Can Be Done?**

IT companies need to recognize and admit to the problem of gender inequality in their IT workforce. They need to diligently transform their corporate culture into one that respects all employees, regardless of gender, and make discrimination and harassment socially unacceptable.

Employers need to create and enforce policies that protect women when they become victims of sexual harassment and discrimination. However, they also need to go beyond forced compliance to fully eliminate gender-related IT employment issues.

Technology exists for men and women and so does IT employment. As companies and families work to erase gender-based prejudices, more women will aspire a career in the tech industry. Girls need positive male and female role models so that they will never consider their gender as a negative attribute.

**Conclusion**

Women can overcome gender-based challenges in IT right now by focusing on their skills and staying current with industry trends. Still, cultural norms need to change in employment, family and educational settings to permanently eliminate the problem of gender discrimination, so every woman can feel confident, supported and safe as they pursue their dreams. As an atmosphere of equality permeates the workplace culture, women will feel confident because they know their skills and performance determines their success rather than their gender and college degree.

Emerging Trends of IT Industry Policies for Ensuring Women Employee Retention

A. Nafeesa Begum¹, G. Brindha²

¹Research Scholar, Department of Management Studies, Bharath University, ²Professor & Head, Faculty of Management Studies, Dr. Mgr Educational and Research Institute, Chennai

Abstract

Today, behaviour of women employees has changed the environment of the private organization. Young women employees always ready to switch over whenever she dissatisfy with any reason in the job. Retention strategy is a powerful recruitment tool. Private organizational issues matters as lost knowledge and training time. HR managers should identify the needs of the women employee and then devises the retention strategies. As different individuals have different priorities does not fit one strategy. HR professionals face the vital challenge to retain talented women employees. Retention strategies are fall into four categories- job enrichment, salary, working conditions and education, addressing these issues this article demands a specialized approach that emerge new fangled women friendly policies which foster gender neutral workplace in developing retention strategies.

Keywords: Retention strategies for female employees, scope, trends and policies.

Introduction

“New-Fangled Women Friendly Policies which Foster Gender Neutral Workplace”

The fast developing knowledge economy coupled with the information technology during the last two decades has totally changed the complexion of our business and employment relations. The globalized economy and the labour market have further added new dimensions to this phenomenon. India has taken advantage of this growing trend entering the IT sector of economy and industry¹. Though the Indian is fast responding and taking the challenge head on and competing effectively in the new IT dominated global market the industrialist-employer in the IT industry are facing another challenge, namely, finding suitable people to recruit to the jobs being generated by them. When and where they are able to find people who can meet their expectations, they are facing the new challenge that this is coming their way in the form of retaining the people working with them. In fact, recruitment and retention are two sides of the same coin. Economically and financially employee retention, of late has acquired greater significance.² It is much more costly and time consuming to find the right replacements. Resultantly the employee retention has turned out to be a critical challenge to the employers. They have become very sensitive to the problem of employee retention. Researchers also are seized of the situation and getting involved in this challenge.

Researchers have found that workplace culture and women’s personal character traits play major roles in retention. So what are the things that make a difference? Women prefer workplaces that are collaborative rather than hierarchical, explains Heather Metcalf, director of research and analysis at the Association for Women in Science³. And they are more apt to stay in work environments that allow for creativity and flexibility, she says. Conversely, women are fleeing companies that encourage employees to practically live at work, she says. While 71 percent of women with young children work outside the home, according to the Pew Research Center, women still shoulder more responsibility for child care and elder care than men. So living at the office to show they are committed to their jobs is not an option. “Creating workplaces that have a lot of flexibility, that allow for people to work in a way that fits best with them, boosts creativity and job satisfaction,” Metcalf says, and these are the settings where women stay and thrive. No matter what type of organization women work for, large or small, public or private, their relationships with their immediate bosses are critical.
to whether they feel engaged and content. The ideal supervisor is committed to his or her subordinates’ advancement and development, assigns stretch projects, and provides necessary support and feedback to help them be successful, Bilimoria says. And workplaces that employ women in higher levels are more apt to retain women at the lower levels.

Objectives of the Study

1. To identify the emerging trends and policies for retaining women employees in IT industry
2. To identify the scope of ensuring women retention in IT industry
3. To suggest new policies that are women friendly and that will foster gender neutral workplace

Scope of the Study: Keeping in view the critical problem the organizations in the IT industry have been facing ever since the IT industry came into existence in India to retain their performing employees at different levels, this study seeks to understand the different strategies of different organizations for retaining their employees and examine whether those strategies have any universal base and comparison with the experiences of high-tech organizations or organizations depending on the knowledge workers or professional employees and if so what are these common employee retention strategies being in practice in different organizations in the IT industry in Chennai.

The scope of this study is confined to IT industry in Chennai. The study throws light through valuable suggestion to increase the female employees’ retention in the organization. This study can help the management to find the weaker parts of the female employee feels towards the existing organization retention strategies and also helps in converting those weaker part in to stronger by providing the optimum suggestions or solutions. This study is a clear guide for the solution seeker about the factors which induced women employees to stay back in the same organization. Special attention has been shown in this research about their empowerment in the society economically as well as professionally. Career development is an existing trend to be stay in their organization and how these factors induced them; all those answers will be make this research unique and an find an enhanced approach towards balancing gender at workplace.

Emerging Trends for Retaining Women Employees:

More Women Leaders: The first thing that gives a woman confidence at her workplace is having women leaders to look up to. This also indicates that the company offers them an environment conducive to scale the corporate ladder. It would be more beneficial if women leaders took on the role of mentors in mentorship programmes that are already at work in certain companies.

Sexism-Free Work Culture: Every workplace must offer a safe and secure environment for employees that help them grow personally and professionally. But it is a sad reality that this is not always true in India. Some of the biggest companies here lack sexual harassment cells and policies against discrimination at the workplace. Create a culture that does away with sexism at work by educating your employees about ‘unconscious biases’ and ‘benevolent sexism’.

Pay men and women equally: When you hire talented women, understand that they put in the same amount of hard work and time as the men and acknowledge that with equal pay. Offer them equal opportunities and trust them with responsibilities similar to what their male counterparts are given to foster increased confidence and professional growth.

Transparent Performance Evaluation Policy: Make it clear to all employees how they are going to be evaluated and about the requirements to be met to make career advancements. It is commonly seen that most organisations promote men on potential and women only on measurable and proven performance. Check your talent management systems and do away with such biases.

Flexible Work Schedules: Many Indian companies already offer flexible schedules to their employees, but most often they turn out to be only the freedom to choose their shifts. True flexibility means allowing your employees to adjust their work schedules to maintain a healthy work-life balance without being penalised. As long as they turn in their work on time and are producing results, their physical absence from office shouldn’t be a concern. Having flexible schedules end up in happier, more satisfied and extremely productive employees. Good intentions, alone, are not enough to make women employees want to work for your company. Treat
them well, provide them opportunities for professional development and create a culture that values their talents and respects them as individuals.

**Paternity Leave:** Reputation being known as a company that promotes gender equality will go a long way in attracting top female talent. And offering a generous paternity leave policy is one of the most effective ways to demonstrate a commitment to women and working families. While paternity leave is designed for men, it ultimately benefits working mothers and children. Furthermore, since most states don’t require it by law, implementing paternity leave shows that an employer is willing to go above and beyond to promote equality and inclusion.

**Empower Female Employees to Shape Company Culture:** Startup land has become famous for offering a fraternity-like atmosphere: free beer, video games, and personalized goodies. While it’s not fair to say women don’t like these perks, tech companies should include women on the teams that are shaping company culture. Expanding the activities beyond those evoking college dorm rooms will help attract talented women who don’t feel connected to those traditions.

Finally, it should go without saying that the best way to attract female talent is to offer competitive wages and excellent benefits that will support them in their life choices regardless of if they decide to have children or not. While the grand gesture of Face book and Apple will surely help their recruitment efforts, our corporate culture as a whole needs to focus on making small, but important, everyday changes and sticking with them.

**Career Development Program:** Every individual is worried about her career. You can provide them conditional assistance for certain courses which are beneficial from your business point of view. Conditional assistance means the company will bear the expenses only if she gets an aggregate of certain percentage of marks. And entrance to that course should be on the basis of a Test and the number of seats to be limited. For getting admitted to such program, you can propose them to sign a bond with the company, like they cannot leave the company for 2 years or something after the successful completion of the course.

**Timely increments:** Timely Increments in salary makes talented employees to stick to the organisation for long time. Many researchers have found that the salary and increments were the core reasons behind leaving of employees to other organisations and competitor organisations attracts talent by showing sole monetary benefits, indeed most of the talent is getting attracted for this reason. It is universal fact and one has to accept that the monetary benefit is the core reason for an employee decision-making on retention in the organization.

**Conclusion**

In a competitive business climate, retaining key employees is vital for the health of the company. But when these key employees are women, many corporations and industries continue to be befuddled as to how to retain this valuable cohort. Indeed, it’s surprising how many supposedly modern institutions are caught in a time-warp. Unfair compensation, gender imbalance in senior management positions, inflexible schedules and even active discouragement of female employees continue to plague companies large and small. The good news is, above few simple strategies can vastly improve conditions for female employees. Women who are trained to develop an executive-type persona in terms of gravitas that is, confidence, poise under pressure and decisiveness—as well as communication and appearance become more confident and are better able to command a room, thereby clearing a path to high-stakes and high-visibility positions. By utilizing some or all of these ideas, companies can benefit from a healthier and more balanced work environment. It just makes sense.

Back Stretch Exercise vs Pelvic Tilt on the Backache among Antenatal Mothers

Pallavi Shinde¹, Merlin Suji²

¹Tutor, Tehmi Grant Institute of Nursing Education, 3, Tadiwala Road, Pune, Maharashtra, ²Tutor, Symbiosis College of Nursing, Symbiosis International (Deemed University), SB Road, Pune, Maharashtra

Abstract
Back pain is a very common discomfort during pregnancy. The reasons are weight gain, expanding sacroiliac joints and mal-position of the fetus¹. The present study aimed to compare the effect of back stretch exercise versus pelvic tilt on the backache among antenatal mothers in selected hospitals of Pune. Pre experimental two group pretest and post test design was used for the study for 30 antenatal mothers with the back pain in selected multi specialty hospital. To select the samples Non-Probability purposive sampling technique was used. After Pretest both exercises were taught to different samples and the post test was carried out after 7 days. Result shows that back stretch exercises were more effective than the pelvic tilt exercise.

Keywords: Back stretch exercise and Pelvic tilt exercise.

Introduction
During the childbearing year, woman’s body undergoes extensive changes which frequently necessitate many adaptations. While back pain during pregnancy interfere with work and daily activities². A strong back is essential for good posture and for proper balance during pregnancy; it can be achieved by Stretching exercise which helps in improving range of motion, flexibility, circulation, decreases stress, and releases tension. While experiencing pregnancy back pain, gentle exercises, such as stretching and light movement will decrease spasm of the muscles, and help decrease back pain¹. Throughout the pregnancy this exercise release endorphins (naturally occurring chemicals in brain) which relieves backaches improve posture by strengthening and toning the muscles in back, buttocks, and thighs. It reduces constipation by accelerating movement in intestine. Prevent wear and tear of joints and which become loosened during pregnancy due to normal hormonal changes by the lubricating fluid in joints, and help to sleep better by relieving the stress and anxiety.

Many women feel uncomfortable with the idea of working out during pregnancy. By doing exercise, women likely to have an easier labor and get back into shape more quickly after giving birth⁴. One way to strengthen the pelvis is to do pelvic tilt exercises regularly. These easy pregnancy exercises strengthen abdomen muscle, soothe backaches during pregnancy and labor, improve posture, and ease delivery⁵.

Statement of the Problem: A comparative study to assess the effect of back stretch exercise vs pelvic tilt on the backache among antenatal mothers in selected hospitals of Pune.

Objectives of the Study:
1. To determine the level of backache among antenatal mothers.
2. To determine the effect of back stretch exercise on backache among antenatal mothers.
3. To determine the effect of pelvic tilt exercise on backache among antenatal mothers.
4. To correlate between selected demographic variables and backache among antenatal mothers.

Operational Definitions:

Back Stretch Exercise: In this study it refers to the activities performed to pull tightly and releasing the back muscles in sitting position to reduce the pain and increase the flexibility. This activity will be carried over for 20 to 30 sec and repeated twice per day for a period of 1 month.
Pelvic tilt exercise: In this study it refers to the activity performed to pull tightly and releasing the back muscles in standing position to reduce the pain and increase the flexibility. This activity will be carried over for 20 to 30 sec and repeated twice per day for 1 month.

Assumption
- Antenatal mother may suffer from backache
- Back stretch exercise may have significant effect on backache among antenatal mothers.
- Pelvic tilt exercise may have significant effect on backache among antenatal mothers.

Research design: The selection of research design is the most important step as it provides the framework for the study.

<tr>
<td>O2</td>
<td>X</td>
<td>O2</td>
</tr>
</tbody>
</table>

Keeping in view the objectives of the study, the researcher selected for the study was pre experimental two group pretest and post test design (O1 x O1), (O2 x O2). In the present study, the base measure will be the assessment of pain on numerical pain scale and the experimental variable will be the demonstration of back stretch exercise and pelvic tilt exercise depicted as ‘X’.

In this study the independent variable is the back stretch exercise and pelvic tilt exercise. The dependent variable in the study is backache among antenatal mothers.

Setting of the study is multispecialty hospital in PCMC Area.

Population: The population of this study comprises of women who are suffering from backache among antenatal mothers of selected hospital of Pimpri, Pune.

Sample and sampling technique: A non probability-purposive sampling technique was used for selecting 30 postnatal working women who met the set criteria during the period of data collection.

The following criteria were set for the selection of samples:

Inclusion Criteria:
1. Antenatal mothers in second and third trimester
2. Antenatal mothers who were suffering from backache
3. Antenatal mothers who were willing to participate in this study

Exclusion Criteria:
1. Antenatal mothers who were at high risk due to medical and surgical condition.
2. Antenatal mothers who were in 1st trimester.

Data collection technique and instruments: A study aimed at assessment of comparison of back stretch exercise vs pelvic tilt exercise on backache among antenatal mothers. Hence, numerical pain scale and observational checklist was used for collection of data.

Development Of the tool

Observational checklist was prepared to assess the effect of back stretch exercise vs pelvic tilt exercise on backache among antenatal mothers

Description of the tool

Section I: Socio demographic profile which consists of age, education, occupation, gravida and monthly income.

Section II: Standardized pain scale (numerical Scale) to assess intensity of backache.

Section III: Profile for back stretch exercise which contains the profile of the exercise step wise.

Section IV: Observational checklist for profile for back stretch exercise.

Section V: Profile for pelvic tilt exercise which contains the profile of the exercise step wise.

Section VI: Observational checklist for profile for pelvic tilt exercise.

Content validity: To ensure content validity of the tool it was submitted to 24 experts. Twelve from Obstetrics and gynaecological nursing, four from Obstetrics and gynaecology department, three from community health nursing departments, three from medical surgical department and two from physiotherapy. The experts were selected based on their clinical expertise, experience and interest in the problem being studied. They were requested to give their opinion on the appropriateness and relevance of items in the tool. As a whole the suggestions and comments of experts included grammatical corrections of the sentences. The modified tool contained 10 items after incorporating
the suggestions. After validation of content, an expert in Marathi language translated the tool from English to Marathi.

**Reliability:** Reliability was assessed using inter-rater method. Cohen’s kappa was found to be 0.80. Hence the tool is reliable.

**Data Collection:** On day one (pre-test day) the purpose of the study was explained to each antenatal mother and the confidentiality of her response was assured. After pre-test on the same day back stretch exercise to 15 selected samples and pelvic tilt exercise to selected 15 samples was administered to the subjects. Post-test was taken on the 7th day using the same tool, and again post-test was taken on 7th day using the same tool.

Analysis of data related to comparison of effect of pelvic tilt exercise vs back stretch exercise on the backache among antenatal mothers.

Two sample t-test for comparison of effect of pelvic tilt exercise vs back stretch exercise. Mean change in pain score in back stretch exercises group were 1.4 and 3.4 in session two and session three. For pelvic tilt exercise group, the mean effect was 0.7 and 2 in second and third sessions. T-values for this comparison were -3 and -5.1 with 28 degrees of freedom. Corresponding p-values were 0.003 and 0.000, which are small (less than 0.05), the null hypothesis is rejected. The pain scores decreased significantly better for back stretch exercise group as compared to that of pelvic tilt exercise group. Hence the back stretch exercise proven to be more effective than pelvic tilt exercise in reducing backache among antenatal mothers.

</tbody>
</table>
Since all the p-values are large (greater than 0.05), there is no evidence against null hypothesis. None of the demographic variable was found to have significant association with backache among antenatal mothers.

**Ethical Clearance:** Ethical clearance was taken from Dr. D.Y. Patil Hospital authorities before conducting a study. Personal consent was taken from the antenatal mothers before conducting the study.

**Source of Funding:** Self.

**Conflict of Interest:** There is a genuine need for continuing education for nurses, particularly for those who are working in hospital departments dealing with antenatal care. There is a need for extensive and intensive nursing research in this area so that strategies for educating people on the exercises which can give a better motherhood. The nurse researcher should be able to conduct the research on various aspects of awareness about the maintenance of body postures which will help to prevent or reduce the backache.

**Recommendations:**
- A similar study may be replicated on large samples; thereby findings can be generalized for a large population.
- A comparative study may be conducted using different antenatal exercises for backache.
- A similar study may be conducted to find out the knowledge regarding effects of different exercise on backache.
- A similar study may be conducted to find out attitude towards antenatal exercise.

**Conclusion**

The result shows, pain scores decreased significantly better for back stretch exercise group as compared to that of pelvic tilt exercise group hence the back stretch exercise proven to be more effective than pelvic tilt exercise in reducing backache among antenatal mothers.

Does Serum Ferritin Concentration Influence Antioxidant Vitamin C in Type 2 Diabetes?

Swati N. Tikare¹, Mohamed Siddiq¹, Kusal K. Das², Saeed Yendigeri³, Salim A. Dhundasi¹

¹Department of Physiology, ²Department of Physiology, Shri B.M. Patil Medical College, BLDEA University, ³Department of Pathology, Al Ameen Medical College, Bijapur-586103, Karnataka, India

Abstract

Background: Iron a known pro oxidant was found to have a link between ferritin and pathogenesis of type 2 diabetes, but the mechanism is still not clear. The role of Iron in the electron transport chain has been postulated to be a major pathway of tissue damage by generating excess amount of free radicals. Vitamin C is an important co-factor for iron metabolism whether the serum ferritin level has any role in the vitamin C influenced diabetes or ferritin influenced diabetes or both is still not well established.

Aim and objectives: The present study is aimed to assess the link between serum ferritin and type 2 diabetes in perspective of vitamin C among the population of North Karnataka

Method: A study was conducted on known type 2 diabetes patients (n=28) and their age matched control group (n=28). Serum ferritin was estimated by ELISA technique and serum vitamin C level was assessed by Roe and Kuether method in both the groups. Basal parameters and lipid profile were measured and analyzed by standard method in both the groups.

Result: The serum ferritin level was found to be significantly higher (p= 0.0012) in the diabetics as compared to control group by 61%. Whereas the serum vitamin C level was lower in diabetics by 14.1% in comparison to controls, although the values were not statistically significant. No significant correlations were found among serum ferritin with vitamin C, fasting blood glucose with serum ferritin and fasting blood glucose with serum vitamin C in diabetics or in control subjects.

Conclusion: Significantly increased serum ferritin in type 2 diabetes in our study maybe due to pathophysiological changes in liver, which maybe independent of antioxidant vitamin C induced iron metabolism.

Keywords: Type 2 diabetes, serum ferritin, serum vitamin C, north karnataka.

Introduction

The precise molecular mechanisms underlying the pathogenesis of iron-overload-related diabetes have not been identified but the initial glucose abnormalities include insulin resistance and hyperinsulinaemia, followed by impaired insulin secretion[1]. Type 2 diabetes is a disease marked by chronic inflammation, and altered Iron metabolism maybe one of the causes. A link between type 2 diabetes with elevated ferritin levels and inflammation has been established[2].

Iron is an essential element in many vital processes, but intimately linked to oxidative stress. Iron participates, through the Fenton reaction, in the formation of highly toxic free radicals, such as hydroxide and the superoxide anion, which are capable of inducing lipid peroxidation[3]. Iron is essential for a number of biochemical reactions in the body including the electron transport chain, gene
regulation, regulation of cell growth and differentiation. The role of Iron in the electron transport chain has been postulated to be a major pathway of tissue damage. Iron in excess generates free radicals which have the ability to damage membrane lipids, proteins and also DNA. This ultimately leads to cell death including the beta cells which subsequently causes altered glucose homeostasis[4].

Several studies report a relationship between diabetes mellitus and vitamin C. Vitamin C is an important co-factor for iron metabolism, hence its influence on glucose and iron homeostasis may be considered[5]. The serum ferritin linkage with vitamin C found in various studies, were unable to come out with a definite conclusion whether ferritin influenced diabetes or diabetes influenced ferritin, or vitamin C was influenced by both these factors. There were a lot of research findings indicating the role of Iron in free radical mediated type 2 diabetes mellitus, hence our study intended to find out a link between serum ferritin and type 2 diabetes among the population of north Karnataka region. The study further aimed to assess the relationship between antioxidant vitamin C level and serum ferritin levels among the type 2 diabetics of the same populations.

Materials and Method

The study was conducted on twenty eight type 2 diabetes mellitus patients (more than five years since diagnosis) and same number of age and sex matched control subjects from the outpatient department of a tertiary care hospital. The protocol was explained to the subjects and patients, included in the study. Informed consent was obtained from each of the participant. The exclusion criteria were presence of anemia, inflammatory disorders, smoking, vitamin supplementation, hormone replacement therapy or evidence of infection at the time of sampling for the study. Both the controls and the diabetic patients were from the same geographic area of Northern Karnataka. They belonged to the lower socio economic group with similar cultural and dietary habits which was vegetarian in nature. The experimental protocol was approved by the Institutional ethics committee.

The basal parameters recorded were pulse rate, body mass index (BMI), blood pressure and body temperature and also the haematological parameters were analysed. Fasting and post prandial blood glucose was measured by routine laboratory method to confirm their diabetic status or otherwise. Lipid profile of both the groups were measured and analyzed by standard method. Serum ferritin level was estimated by Immunoenzymometric method. Serum was separated from samples collected in the pilot tubes after 1 hour and stored at -20°C. The serum ferritin was estimated in batches of samples by ELISA technique using commercial ELISA kit, FerritinAccubindTM ELISA test system from Monobind Inc. USA. The test values were read from the standard curve. The Serum Vitamin C level was estimated using Roe and Kuether method[6].

Statistical Analysis: The Mean±SD values of all parameters of control and diabetic group were calculated. unpaired ‘t’ test was done to compare data between controls and diabetics. Pearson’s Correlation test was done to correlate the biochemical parameters in controls and diabetic individuals. The Statistical Analysis was done using Graphpad Instat 3.

Results

Table 1 shows the comparison of mean values and standard deviation of physical anthropometry and haematological parameters of controls and type 2 diabetic patients. Table 2 depicts biochemical parameters, serum ferritin, serum vitamin C and lipid profile of controls and diabetics. The glycemic status was significantly different among the control and the diabetics. The fasting blood glucose and post prandial blood glucose were significantly higher (p=0.0001, p=0.0001) in the diabetics than in control subjects. Serum ferritin level in diabetics was also found to be significantly higher (p= 0.0012) as compared to the controls. Although the serum vitamin C levels in diabetics did not show any statistically significant change, but a decrease of 14.1% in serum vitamin C level was found in diabetics. The Total Cholesterol, Triglycerides, LDL and VLDL values were statistically higher and HDL level statistically lower in diabetic group as compared to the control group. Table 3 shows the Pearson’s correlation between fasting blood glucose and serum ferritin, fasting blood glucose and serum vitamin C and serum ferritin and serum vitamin C in controls and in diabetic group. The present study did not find any significant correlations among any of the parameters either in the controls or in the diabetic group.
Discussion

The bidirectional relationship between iron metabolism and glucose homeostasis is increasingly recognized. Several pathways of iron metabolism are modified according to systemic glucose levels, whereas the insulin action and secretion are influenced by changes in relative iron excess.

In present study we aimed to find serum ferritin and vitamin C level in diabetics and controls in North Karnataka region. The study also liked to emphasize the possible influence of serum ferritin concentration in relation to serum vitamin C level in control and type 2 diabetic patients. The hematological parameters did not show any significant differences in the diabetics except RBC count.

Increased serum ferritin levels in the diabetic patients in the present study, were indicating diabetic induced alteration of hepatocellular pathology. Iron is predominantly stored in the liver. Hepatocytes take up transferrin bound iron from the bloodstream through TfR1, expressed on the sinusoids, when iron load exceeds the iron-binding capacity of ferritin. The liver can maintain iron homeostasis within a narrow physiologic range by secreting hepcidin. Hepcidin senses a number of pathophysiological changes that control iron homeostasis, and it responds by downregulating the expression of iron transporter Ferroprotin-1(FPN-1) on the enterocyte. FPN-1 undergoes phosphorylation, internalization and degradation under the influence of hepcidin. This factor inhibits the duodenal absorption of iron. There is overexpression and release of hepcidin in proportion to the increased level of circulating ferritin.

Iron overload is found to exert an important effect on glucose homeostasis by impairing the response to insulin in the liver, muscle, and adipose tissue. Excess iron, once stored in the liver, interferes with glucose metabolism, causing hyperinsulinemia via both decreased insulin extraction and impaired insulin signaling Hyperinsulinemic status, on the other hand, favors the intrahepatic deposition of iron. Thus iron overload appears to cause hyperinsulinemia and insulin resistance. A study revealed that insulin and iron induce oxidative stress synergistically.

Increased serum ferritin concentration in diabetics of our study indicates a poorly controlled type 2 diabetes associated with hyperferritinemia, which maybe suggestive of possible oxidative stress. Our study further corroborated with an American cohort study where plasma ferritin levels were found to be higher by 28.7% in the diabetics. While an elevated plasma ferritin level may be a causal factor for diabetes, it is also possible that the moderately increased ferritin levels of diabetic patients are just a marker for the metabolic alterations that ultimately result in diabetes, without a causal role in diabetes development.

Our observations were further supported with a strong association between clinically raised ferritin in incident diabetes patients, independent of known risk factors like age, BMI, sex, family history, physical inactivity, smoking, etc.

In our study the serum vitamin C level was lower in diabetics by 14.2% in comparison to controls without having any statistical significance. Evidence suggests that Insulin favour hyperglycemia inhibits ascorbic acid uptake by cells. Thus the plasma levels may remain normal while tissue levels are low, a condition termed “tissue Scurvy.” This observation on vitamin C is further corroborated with a study by Schorah CJ and et al. Thus in the light of all these evidences we suggest that both plasma and intracellular vitamin C levels must be evaluated simultaneously to get a clear idea regarding vitamin C status in diabetics specifically.

No significant correlation between fasting blood glucose and serum ferritin, fasting blood glucose and serum vitamin C and serum ferritin and serum vitamin C, were found in our study which differs from the observation of Eshed. et al. (2001) were a positive correlation between plasma ferritin concentration with insulin resistance and with the risk of acquiring type 2 DM were found. Ershed et al., also found no correlation between plasma ferritin level and glycemic control. The alteration of lipid profile in the diabetics our study indicate diabetes related dyslipidemia.

Implication: Hence it maybe concluded from the present study that increased serum ferritin in type 2 diabetes maybe due to pathophysiological changes in liver, which is independent of antioxidant vitamin C. Although vitamin C is considered as an important factor for regulation of iron metabolism but possibly it does not influence ferritin regulation in type 2 diabetes. Small sample size was a limiting factor in our study. Further studies such as a prospective cohort study with large sample size would be required to evaluate the causal role of Iron overload, if any in our geographical area.

An Epidemiological Study of Acute Respiratory Tract Infections among Under Five Children Attending Urban Health Centre of a Medical College

Hafsa Jabeen1, MSK Swarupa2, A. Chandrasekher3
1Post Graduate Student, 2Professor, 3Professor & Head, Dept. of Community Medicine, Deccan College of Medical Sciences, Hyderabad

Abstract

Introduction: In India, an estimated 26 millions of children are born every year.1 As per Census 2011, the share of children (0-6 years) accounts 13% of the total population in the Country. An estimated 12.7 lakh children die every year before completing 5 years of age.1 15% of the mortality in them is due to Acute respiratory Infections (ARI). The occurrence of ARI is related to various risk factors in the child and in the environment. Many of these risk factors are amenable to corrective measures.2 Therefore, the present study undertook to identify the prevalence and various risk factors for acute respiratory tract infection in under-five children.

Objectives:
1. To study the prevalence of ARI in under five children.
2. To study the risk factors associated with ARI.

Method: A cross sectional facility based study in Urban health centre of Deccan college of Medical Sciences. All under five children attending health centre during the study period of 6 months (November 2017–April 2017)

Results: The present study showed 56% of ARI prevalence. Majority (55.3%) of study subjects were females. More number of subjects(35.5%) belongs to 0-12 month age group. Least number of children belongs to 49-60 months age group. Majority (41.8%) of study population belongs to SES-III (according to Kuppuswamy classification). Only (47.7%) of the subjects were fully immunized.

The present study revealed that there is statistically significant association between age, type of family, socioeconomic status, Mothers education, Vitamin-A supplementation, Over-crowding, presence of separate kitchen and Family h/o parental smoking p=<0.05 with occurrence of ARI.

Conclusions: The present study found that age of the child, type of family, socioeconomic status, Mothers education, Vitamin-A supplementation, Over-crowding, presence of separate kitchen and Family h/o parental smoking were the significant risk factors responsible for ARI in under-five children.

Keywords: Acute respiratory infections (ARI), under five children, type of family, socioeconomic status Mothers education, Vitamin-A supplementation over-crowding, parental smoking.

Introduction

In India, an estimated 26 millions of children are born every year.1

As per Census 2011, the share of children (0-6 years) accounts 13% of the total population in the
Country. An estimated 12.7 lakh children die every year before completing 5 years of age. The international consultation on control of acute respiratory infections, December 1991 reported that there are links between environmental risk factors (such as smoke, outdoor and indoor pollution, passive smoking, overcrowding) and risk factors in the child (such as low birth weight, malnutrition, measles, breast feeding and vitamin ‘A’ deficiency) with acute respiratory infections. Many of these risk factors are amenable to corrective measures.

Therefore, the present study undertook to Study the prevalence and various risk factors for acute respiratory tract infection in under five children.

AIM & Objectives:
1. To study the prevalence of ARI in under five children.
2. To study the risk factors associated with ARI.

Methodology

Study Design: A cross sectional facility based study

Study Area: Urban health centre of teaching institute

Study Population: All under five children attending health centre during the study period

Study Duration: 6-months (November 2017–April 2018)

Inclusion Criteria: All under five children attending health centre during the study period.

Exclusion Criteria: Parents or guardians of patients not giving consent.

Data Collection: Informed parental consent was taken before enrolling in the study. Socio-demographic and epidemiological information of the cases were collected by interviewing the parents or guardian of the child using a pretested proforma. The operational definition of an ARI was based on a child having at least one of the following symptoms (cough, running nose, ear discharge, sore throat which might be associated with fever, chest retractions and fast breathing).

Statistical Analysis: The detailed data was entered into the Microsoft Excel 2010 spreadsheets and analyzed by using SPSS 23.0. Results were presented in the form of tables and figures and subsequently analyzed statistically using percentages, Chi-square test. For all the statistical tests, a ‘p value’ of less than 0.05 was considered as statistically significant.

Results

Socio-demographic profile of children: The study includes 600 under-five children. The number of female children were slightly more (55.3%) than the number of males. More number of subjects (35.5%) belongs to 0-12 month age group. Least number(13%) of children belongs to 49-60 months age group. Majority of study population belongs to SES-II & III (63.2%) followed by IV (36.8%) (according to Kuppuswamy classification). In nearly 55.5%of the houses kerosene is used as a source of fuel followed by LPG (39.7%). Only 47.7 % of children are fully immunized.

</table>
The present study showed 56% of ARI prevalence. More percentage of children with ARI are living in joint families (61.3%) than nuclear families (51.5%). Almost equal percentage of children with ARI are from upper and lower middle (64.1%, 60.2%) and upper lower classes (46.6% each). More number of children’s mothers are literate (69.4%). Slightly more (54.8%) number of children with ARI are having a birth weight of $\geq 2.5$ kg when compared to children without ARI (45.2%). Only 51.5% of children with ARI received vitamin A supplementation. Only (47.7%) of the subjects were fully immunized.

## Discussion

**Socio-demographic profile of children:**

Majority (55.3%) of study subjects were females. In a study done by Islam F et al., females were more than males. More number of subjects (35.5%) belongs to 0-12 month age group. Least number of children (13%) belongs to 49-60 months age group. In a study done by Zaman K et al., ARI is seen mostly in 18-23 month olds followed by 6-11 months. Singh MP, Nayar S also found high rate for infants. Majority (41.8%) of study population belongs to SES-III followed by IV (36.8%) according to Kuppuswamy classification. Similar findings were observed by Sebastian SR et al., but Goel K et al. found 10%, 20% in class I & II and 20% 67.7% in class III & class IV. This may be due to variation of the socioeconomic strata in different regions. Only (47.7%) of the subjects were fully immunized.
ARI Prevalence: The present study showed 56% of ARI prevalence which is similar to the study done by Kapil Goel et al5 in meerut district and Kumar SG et al13 found the prevalence to be 52%and 63.7%, but in the study done by Walke SP15 et al found the prevalence to be 35.4% and 34.3% respectively which are less compared to our study. It may be due to the variation of study settings.

Table no 1: Risk factors: The present study revealed that there is a statistically significant association between age (X^2=10.63), type of family (X^2=5.77), socioeconomic status (X^2=13.0), mothers education (X^2=17.87). In a study done by Madhav S.M et al6, Arnold monto S, Ulman B.M et al7 and Savitha MR et al11 also found significant association between maternal education and occurrence of ARI which is similar to our case findings. The study also found statistically significant association between vitamin A supplementation (X^2=11.10), presence of separate kitchen (X^2=12.577), overcrowding (X^2=3.696) and h/o parental smoking (X^2=3.773) and the occurrence of ARI which are proved to be their risk factors of ARI.

In a study done by Goel K et al5 (78.12%), Jha et al4 (75.3%) observed significant association of ARI with parental smoking and overcrowding. Other studies done by Kumar SG et al13 (OR=1.49) & Vinod K. Ramani et al12 (OR=1.84) also found significant association of ARI with overcrowding and history of parental smoking similar to the present study.

The factors like birth weight and immunization status are not found to be associated with the occurrence of ARI

Conclusion

The present study found that the age of the child, type of the family, socioeconomic status, mothers education, vitamin A supplementation, presence of separate kitchen overcrowding, and H/O parental smoking were the found to be statistically significant risk factors associated with the occurrence of ARI in under-five children. Based on the findings, occurrence of ARI could be reduced by improved living conditions (housing standards) and environmental conditions. There is a need to improve vitamin A supplementation, immunization and birth weight of the baby. Mother’s education may add to improvement in the socioeconomic conditions thereby living conditions of the family.

Risky Driving Behaviour among the Motorized Two Wheeler Novice Riders in Davanagere City, Karnataka

Nandini V.1, Kumar Sumit2

1Department of Public Health, Manipal Academy of Higher Education, 2Assistant Professor, Department of Public Health, Manipal Academy of Higher Education

Abstract

Road traffic accidents (RTA) account for greater mortality and morbidity rates worldwide, resulting in considerable global burden. In India motor vehicle accidents are one of the common reasons for mortality among young riders. The present study provides insight to different aspects of risky driving behavior from individual attitudes, and psychological factors like, anger, mood and emotions. Road traffic accidents are the third leading cause of death among young people. If timely actions are not taken, road traffic accidents are predicted to become the fifth leading cause of death in the world. Considering the issue and concern about younger age group, this study was carried out to understand risky driving behaviour among young novice two wheeler riders. A cross sectional study was conducted among college students, findings from this study says young males are more involved in risky driving behavior. Finally, the results focus on the role that risky driving behaviour plays in two-wheeler motor vehicle accidents and suggests the need for further research in this area of risky driving behaviour to improve road safety education and law enforcement policies that focus upon ensuring good driving behaviours.

Keywords: Davanagere, Novice, Riding behaviour, Younger riders.

Introduction

Road Traffic Accidents (RTAs) are a major cause of death and injury and an increasing public health problem globally, causing more than 1.2 million deaths annually1. In India, the motor vehicle population is growing at a faster rate with growing number of fatal crashes it is due to “Human factors”, “Vehicle factors”, and “environmental factors”2. The physical characteristics of the vehicle coupled with unsafe behavioral factors of the rider expose the two-wheeler to high risks.

RTAs are most commonly affect the economically productive age group and is the leading cause of death among young people aged between 15 and 29 years3. According to the World Health Organization (WHO), RTAs are the sixth leading cause of death in India with a greater share of hospitalization, deaths, disabilities and socio-economic losses in the young and middle-aged population2. Young riders are at an increased risk of road traffic crashes and the reasons for higher rate of road traffic crashes amongst young riders are due to minimal information about road safety, not being aware about the dangers on the road, limited practice and an inexperience particularly in the necessary safe driving. Apart from these, young riders are having risk-taking behavior like negligent driving, speeding and mobile phone usage. There is a probable gap which remains to be addressed to change the behaviour of motor vehicle riders. The current study was investigated the risky driving behaviours like speeding, non-usage of helmet, mobile phone usage, anger, not following traffic rules which is present among the young motorized two-wheeler riders of Davanagere city and the findings of the study can be taken up by local authorities (RTO, Traffic police) to design behaviour specific intervention programmes.

Evidence from various national reports (NCRB, SRS, MCCD) as well as few independent studies indicate that RTAs and fatalities are five times higher in males (82-86%) compared to females, due to greater exposure to unsafe traffic environments as well as due to their greater risk-taking behaviours.

By the Ministry of Road Transport and Highways (MoRTH) for the year, 2016 shows 1, 50,785 people were killed and another 4, 94,624 were injured in 4,
80,652 road crashes in India. The numbers of road crash deaths have increased by 31% from 2007 to 2017 and fatal road crashes have increased by 25.6% during the same period.3

Davanagere is the sixth largest city in Karnataka and it is being recognized as knowledge city because the city is home to the headquarter of Davanagere University and several educational institutes providing general, professional, management and training courses including medical and engineering courses. Apart from this Davanagere is a commercial and trading center located in central Karnataka. According to 2011 census, Davanagere had 4,30,129 population and now it has crossed 5 lakh population. In the same period, Davanagere had 1,06,365 vehicle population of which 79,473 were motorcycles.4 In Davanagere, motor vehicle accidents are the most common contributory factors to trauma because of increased population with multiple vehicles, increased density of traffic especially at peak hours, faulty roads and traffic signals, poor maintenance of vehicles and Other contributory factors leading to motor vehicle accidents are speeding, mobile phone usage, consumption of alcohol and other drugs, including physiological condition such as fatigue, depression, stress and an immaturity among youths. In 2014 Davanagere was ranked second highest in Karnataka on the list of traffic violation and it had recorded 34,739 cases.4

**Materials and Method**

A cross sectional study was conducted among college students in Davanagere city, Karnataka between the age group of 18 years to 25 years who are holding learner’s license and permanent driving license from two years in Davanagere city. A sample size of 150 was calculated by considering proportion of the event in the population (P=50%), value at a specified level of confidence (Z=95%), the proportion of population risky driving behaviour among novice rider was estimated as 50%, the confidence level was estimated at 1.96. The desired precision of 8% was taken, considering response rate as 8%. Colleges were selected based on administrative permission. Colleges and classes were selected through purposive sampling method and then students from all classes were invited to participate in the survey, study purpose and their role in the study was explained. Students were enrolled after written informed consent and closed ended structured questionnaire was administered to collect quantitative data, participants were questioned about their involvement in risky driving behaviours over the period from age 18-25 years, using a rider behaviour questionnaire. A total of 150 forms were distributed and collected in all 6 colleges. A data was entered and analyzed in excel and SPSS version 16. Association among gender and age between various domains of risky driving behaviour was done by using chi-square statistical analysis test.

**Result**

A study was conducted in Davanagere city among college students, of the 150 participants 106(70.67%) and 44(29.33 %) males and females, respectively and 125(83.33%) were belong to 18-20 years of age, 25(16.67%) were belong to 21 and above age. Of 150 participants 26(17.33%), 11(7.33%) ride fast and aggressive respectively.

**Table 1: Various domains of risky driving**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

In table 2, we look into various domains under risky driving behaviour. 75.3% of students drive fast when they get late to college or any work, 52% of participants crossed city speed limit, 35.3% of participants raced when lights went green in the traffic signal and 33.3% of participants overtook vehicle from left side, 118(78.67%) get angry when delayed to work/college due to the traffic jam. This shows that risky driving behavior is most common among novice riders. Among 150 participants 18(14.4%) aged between 18-20 years have never used a helmet while riding a two-wheeler. Based on these results, participants in the age group of 18-20 years are shown to nonuse of helmet. Then this study confidentially says that age was associated with helmet use. After performing Chi-Square test among these variables, it shows significance with a p-value of 0.044. Of 150 participants 11(25.6%) of females and 67(62.6%) of males have crossed city speed limit. Based on these results, males are shown to cross city speed limit. Then this study confidentially says that gender is associated with speeding. After performing Chi-Square test among these variables, it shows significance with a p-value of 0.001.
males and 0(0%) of females sent or read a text in mobile while driving. Based on these results, males are shown to send or read a text while driving. Then this study confidentially says that gender is associated with mobile phone usage while driving. After performing Chi-Square test among these variables, it shows significance with a p-value of 0.002. Among 150 participants, 2(4.7%) of females and 35(32.7%) of males talk in mobile and 18(41.9%) of females, 75(70.1%) of males use mobile phones to get direction based information while riding. Based on these results males are shown to use a mobile phone while riding. After performing Chi-Square test among these variables, it shows significance with a p-value of 0.001. Among 150 participants, 9(20.9%) of females and 50(46.7%) of males carrying more than one pillion in their two-wheeler. Based on these results males are showed that they carrying more than one pillion in their two-wheeler. After performing Chi-Square test among these variables, it shows significance with a p-value of 0.003. Among 150 participants 10(23.3%) of females and 45(42.1%) of males tried racing along with their peer in their two-wheeler. Based on these results males are showed that they racing along with their peer. Chi-Square test among these variables, it shows significance with a p-value of 0.031. Among 150 participants 10(23.3%) of females and 45(42.1%) of males driving are influenced by bad road condition. Based on these results females are showed that their driving is more influenced by bad road condition. Chi-Square test among these variables, it shows significance with a p-value of 0.003.

Discussion

The findings from this study says that there is a risky driving behaviour among young novice riders. In the present study, prevalence (24.67%) of mobile phone usage for talking while riding is high compared to the similar studies done in India so far. A study was done in Surat city by Mittal P, Garg R. (2013), reported prevalence of talking on cell phone while riding is 3.02%, these differences could be due to the variability in time demographic composition studied in these surveys.

The present study says, about 18(12%) of riders and 130(86.67%) of pillions never used a helmet while travelling in a two-wheeler. A report from National Institute of Mental Health & Neuro Sciences (NIMHANS) says that on an average about 100-120 two-wheeler riders and pillions sustain head injuries every month out of which 10-12 succumb to death.

In this present study male drivers are more commonly involved in risky driving behaviours than females. A study from S. Jafarpour. et al. says male drivers often show more aggressive violations than females. A study from G. Gururaj. et al. 2014 RTIs is a leading cause of mortality, morbidity and disability among the young and predominantly males and this study says, nearly 80% of RTIs occurred in the age group of 15-44 years, predominantly among males and those less educated, an observation that is similar to global findings.

Out of this study recommendations are behavioral change intervention strategies among the novice riders by involving local stakeholders like traffic authorities, parents and head of the educational institutes. Road safety knowledge and awareness can be created amongst the young population through education, public talk campaigns and in colleges, showing visuals of harmful effects of risky riding and unsafe riding behaviour, in collaboration with local stake holder. Awareness regarding safe driving among the youths can be created through the use of most popular used social media. Limitations of this study was, some colleges had exams schedules during the study period. The non-response rate was more among postgraduate college students.

Conflict of Interest: Data collected during the study is not disclosed and it is confidential.

The Prevalence of Potentially Malignant Disorder (Leukoplakia) among Tobacco Users

Nashwah Hinaz¹, Gheena S.²

¹Undergraduate Student, Saveetha Dental College, ²Reader, Department of Oral Pathology, Saveetha Dental College, Saveetha University, 162, Poonamallee High Road, Chennai, Tamil Nadu, India

Abstract

Introduction: Leukoplakia is the most common premalignant or potentially malignant lesion of the oral mucosa. The annual percentage of malignant transformation varies as a result of differences in tobacco and dietary habits. For both genders, cancer of the mouth and pharynx ranks sixth overall in the world. In industrialized countries, men are affected two to three times as often as women, largely due to higher use of alcohol and tobacco.

Methodology: Archives from the past 2 years (2017-2018) were accessed from Saveetha Dental College. The inclusion criteria was the type of leukoplakia, site affected, age and sex of the patient. The exclusion criteria were the non-tobacco users. The data was collected and statistically analysed.

Results: There exists a male predilection to the occurrence of leukoplakia among the screened population. A correlation between gender and leukoplakia had a positive correlation for the male gender and types 1,4 leukoplakia and had a slight positive correlation.

Conclusion: The incidence of leukoplakia among tobacco users is high as compared to the non tobacco users. The male population is at a higher risk. More incidences of homogenous and speckled leukoplakia has been reported within the 2 years.

Keywords: Premalignant; leukoplakia; lesion; homogeneous; tobacco.

Introduction

Cancers of the oral cavity and oropharynx represent approximately three percent of all malignancies in men and two percent of all malignancies in women all over the world [1]. Squamous cell carcinoma, which arises from the oral mucosal lining, accounts for over 90 percent of these tumors [2-4]. These start as premalignant lesions and if not treated in time they may turn malignant and lead to cancers of the oral cavity. Oral cancer most commonly occurs in middle-aged and older individuals, although a disturbing number of these malignancies is also being documented in younger adults in recent years [5-7].

One of the most common pre malignant lesions of oral cavity is Leukoplakia. Recently, WHO (2005) changed the definition of leukoplakia as “a white plaque of questionable risk having excluded (other) known diseases or disorders that carry no increased risk for cancer. Despite advances in surgery, radiation, and chemotherapy, the five-year survival rate for oral cancer has not improved significantly over the past several decades and it remains at about 50 to 55 percent [8]. The strong association between cancers of the oral cavity and pharynx with tobacco use is well established.

Epidemiological studies show that the risk of developing oral cancer is five to nine times greater for smokers than for nonsmokers, and this risk may increase to as much as 17 times greater for extremely heavy smokers of 80 or more cigarettes per day [8-13]. The percentage of oral cancer patients who smoke (approximately 80 percent) is two to three times greater than that of the general population. Snuff and chewing...
tobacco have also been associated with an increased risk for oral cancer\textsuperscript{[14]}. In India and Southeast Asia, the chronic use of betel quid (paan) in the mouth has been strongly associated with an increased risk for oral cancer\textsuperscript{[15-17]}.

Early oral cancers and precancerous lesions are often subtle and asymptomatic. Therefore, it is important for the clinician to maintain a high index of suspicion, especially if risk factors such as tobacco use or alcohol abuse are present. Invasive oral squamous cell carcinoma is often preceded by the presence of clinically identifiable premalignant changes of the oral mucosa. These lesions often present as either white or red patches, known as leukoplakia and erythroplakia. As the cancer develops, the patient may notice the presence of a nonhealing ulcer. Later-stage symptoms include bleeding, loosening of teeth, difficulty wearing dentures, dysphagia, dysarthria, odynophagia, and development of a neck mass\textsuperscript{[18]}.

**Materials and Method**

Archives from the past 2 years (2017-2018) were accessed from Saveetha Dental college. A total of 150 patient reports were assessed and data was collected accordingly.

**Inclusion criteria:**

- **type of leukoplakia**
  - homogeneous leukoplakia
  - Nodular leukoplakia
  - Verrucous leukoplakia
  - Speckled leukoplakia

- **site affected**
  - buccal mucosa
  - Tongue
  - Hard palate
  - Soft palate

- **age**
  - sex of the patient
    - Male
    - Female

**Exclusion criteria:**

- non-tobacco users

The data was collected and statistically analysed using various statistical tests.

**Results**

After a statistical analysis it can be seen, from chart 1, that there is a male prediction to the occurrence of leukoplakia among the screened population, Pearson correlation Test was run to check the and type of leukoplakia, it was observed that relationship between the site there was a negative correlation but the correlation was very weak with an R value of 0.0652 (Chart 2).

A correlation between gender and leukoplakia had a positive correlation for the male gender and types 1,4 leukoplakia and had a slight positive correlation with an R value of 0.0256. (chart 3).
Discussions

Leukoplakia is one of the most common form of premalignant lesions in India. Out of the various types of leukoplakia, Erythroplakia and speckled leukoplakia are oral precancerous lesions that have a high potential for malignant transformation.

The term erythroplakia is used to describe a red plaque or macular lesion in the mouth for which a specific clinical diagnosis cannot be established[19,20]. Lesions are named erythroleukoplakia, leukoerythroplakia or speckled leukoplakia when red and white areas are associated or white patches are present over the red plaque[21].

Risk factors for oral carcinoma, such as alcohol use and smoking, diets lacking antioxidants (such as vitamins C, E, and beta-carotenes), occupational exposure to carcinogens, viral infections, and genetic and hereditary factors, may affect how these precancerous lesions become established and develop[22].

Most of the patients with leukoplakia are over 40 years of age, mainly seen in fifth to seventh decades with average age to be 60 years. Its prevalence is higher with age in males. Leukoplakia is commonly seen on lips, buccal mucosa, tongue and gingiva. The site varies with the form of tobacco habit, like in beedi smokers the site is anterior buccal mucosa whereas in patients who chew tobacco, seen on the posterior buccal mucosa and is generally seen as gray, white or yellowish white in color[23].

Leukoplakia presents a diverse clinical appearance and with time its appearance often changes. Usually it takes about 2.4 y to diagnose the lesion. Initially the lesion appears as a thin, slightly elevated gray or grayish white translucent plaque. The lesion is characteristically soft and flat and is sometimes wrinkled or fissured. The borders of the lesion are usually sharply demarcated but rarely some lesions blend gradually into adjacent normal mucosa. Some authors have designated the term preleukoplakia to this early stage, few others have preferred to use this stage as thin leukoplakia[24].

Later, the lesions become thicker, extend laterally and become more whitish in colour. The fissures may become deep and leathery on palpation. This stage is referred as thick or homogenous leukoplakia. Some severe lesions develop surface irregularities and are designated as granular or nodular leukoplakia. Verrucous leukoplakias show sharp or blunt projections. The red and white lesions have designated terms erythroleukoplakia, speckled leukoplakia or non homogeneous leukoplakia. These lesions have been shown to have a higher malignant transformation rates[25].

Conclusion

Oral leukoplakia is the most common potentially malignant disorder. The lesion can be diagnosed with the history and clinical examination. Biopsy of such lesions should be carried out and it should be differentiated with other white lesions. Early detection of leukoplakia is necessary as it shows high malignant transformation rates. New non invasive method such as salivary markers in the detection of transformation should be carried out to control this lesion.

Esthetic and Prosthetic Rehabilitation of Maxillary Lateral Incisor: A Case Report

Neetha J. Shetty

Associate Professor, Department of Periodontology, Manipal College of Dental College, Mangalore, Manipal Academy of Higher Education

Abstract

The key factors in achieving successful outcomes after implant placement immediately after tooth extraction is a correct diagnosis and treatment planning. The efficacy of immediate implant placement has been established and shown to be predictable if reasonable guidelines are followed. The reasons for tooth extraction may include but not limit to: insufficient crown to root ratios, remaining root length, periodontal attachment levels, periodontal health of teeth adjacent to the proposed implant sites, unrestorable caries, root fractures with large endodontic posts and questionable teeth in need of endodontic retreatment. The most esthetically challenging in implant placement is the maxillary anterior region. The reason being that tooth loss leads to resorption of bone and collapse in gingival architecture leading to esthetic compromise and inadequate bone for implant placement. Also, the advantages of placing Immediate implant into freshly extracted socket reduces the treatment time, cost, and increases the patient comfort. This case report describes the procedure for immediate implant placement in fresh extraction socket. Clinical and radiographic examination revealed width and length of the tooth for selecting implant size and design. Implant was successfully loaded and was functional during 24 months follow up period.

Keywords: Immediate implant placement; fresh extraction socket; immediate loading.

Introduction

Hard and soft tissue preservation becomes a crucial goal once an implant treatment is initiated. One of the ways of achieving this is by immediate implant placement. Immediate implant placement also reduces the treatment timing. However, to achieve a successful result, an immediate implant requires a precise case selection. In situations where immediate implant is not conducive, a delayed implant placement can be considered. Along with a precise case selection, an appropriate surgical treatment, clinician’s experience and the restorative procedures play an important role when placing immediate implants.

Clinical Case: In 2017, a healthy 25-year-old male reported for evaluation of a fractured upper right lateral incisor (figure-1). On consultation with an endodontist, it was decided to extract the tooth and go for an immediate implant placement as the patient was very much concerned about esthetics. Patient was in good systemic as well as periodontal health. A thorough clinical evaluation and a CBCT was recorded (figure-2) and analyzed, after which the patient was posted for implant placement as he did not have any facial plate deformity. The patient was explained about the procedure and a consent form was duly signed by the patient. The area of interest was anaesthetized with 1:80,000 lignocaine hydrochloride. With a no. 15 scalp blade, the supracrestal fibers were dissected. This was followed by the use of a periotome to sever the periodontal ligament fibers from the alveolar bone so that the tooth becomes loose, thereby extracting the tooth atraumatically. The walls of the alveolar socket were found to be intact after extraction (figure-3). The socket was degranulated and curetted for any remnant of periapical lesion. Osteotomy was performed in a palatal position so as to not perforate the labial cortical bone, about 2mm apical to the apex. An implant of length 13mm and diameter 4.5mm was placed (figures 4-5).
primary stability was achieved with a torque of 20Ncm/2 was achieved. since the torque achieved was less, it was decided to go for delayed loading and a gingival former was placed. Post–operative instructions were given ad antibiotics (amoxicillin 200mg, thrice daily for 5 days) and analgesics (divon plus twice daily for two days) were prescribed.

After 5 months, an IOPA was taken to evaluate the implant and bone interface (figure-6). The gingival former was removed revealing a good soft tissue contour. Impressions were taken for prosthetic rehabilitation using putty with light body for the maxillary arch and an alginate impression for the mandibular arch. The final ceramic crown was cemented after 1 week. After 1 year, radiographic and clinical follow up demonstrated successful result, meeting aesthetic and functional requirements (Figure 7).

Discussion

A mandatory requirement when placing an immediate implant is atraumatic extraction. The best healing conditions is provided by attempting this\(^1\). Despite all the efforts, extracting a tooth results in severing the collagen fibers and blood vessels to the periodontal ligament causing trauma to the bundle bone. Extraction of tooth with or without flap elevation is a surgical consideration. Extracting a tooth with or without elevating a flap, is a surgical aspect that must
be considered. Covani et al affirmed that flap elevation may cause alveolar bone resorption in the exposed area, whereas a flapless technique reduces patient discomfort, alterations in alveolar crest dimensional alterations, and better soft tissue quality around implant. This also reduces post-surgical trauma, and by preserving the vascular supply integrity, as the periosteum is maintained. The stages of alveolar healing are initiated as soon as the tooth is extracted. It has been postulated that there is a horizontal resorption of bone dimension that amounts to 56% immediately after extraction.

Also, when an implant is inserted immediately after an extraction, there is a void created between the buccal wall and the implant. Some authors suggest the filling of this void with a biomaterial in order to maintain hard tissue contour. The clinician also has to consider that soft tissue will also go through the process of remodeling following implant placement.

Immediate implants require a complicated and precise soft tissue management. Moreover, De Rouck et al. demonstrate that using single immediate implants with instant provisionalization, can help optimize esthetics. It was concluded that this can limit the amount of midfacial soft tissue loss, being this area the most critical in aesthetic implant dentistry. Nevertheless, if primary stability is not achieved, or the patient’s case does not fit the ideal requirements for immediate provisionalization, this should not be done, and therefore, a different type of treatment should be considered.

Conclusion

Based on the outcomes of the present report, it can be concluded that immediate implant placement may be a viable treatment option for cases requiring earliest restoration of teeth to be extracted. However, this approach is considered highly technique sensitive and requires expert dental implant team for its execution. Careful selection of cases, proper treatment plan and follow-up of surgical and prosthetic protocols are the keys to success.

Psychosocial Problems and Coping Strategies Among Peri-Menopausal Woman

Nethravathi Venkataswamy Reddy¹, Dayananda Bittenahalli Omkarappa²

¹Professor, Department of OBG, ²Associate Professor, HOD, Department of Psychiatric Nursing, Kempegowda College of Nursing, K.R. Road, V.V. Param, Bangalore

Abstract

Context: Peri-menopausal period is characterized by a continuous decline in ovarian function due to which women are vulnerable to various physical and psychosocial symptoms affecting their quality of life. There will be a chance that if their problems were left unnoticed they might become mentally ill in the future.

Aims: To assess the psychosocial problems and coping strategies among peri-menopausal women and to find out the correlation between psychosocial problems and coping strategies.

Method and Material: A cross sectional descriptive Survey research design was adopted for the present study. 200 women were recruited by Convenience sampling technique at selected PHC area, Bangalore urban and data was collected from June to December 2017. Psychosocial problems rating scale and checklist were used to assess psychosocial problems and coping strategies.

Statistical analysis used: Data were analyzed using Statistical package for the social Sciences software package (Version 23).

Results: The findings shows that 12% of respondents are having severe psychosocial problems, 28% of respondents are having moderate psychosocial problems and 30% of respondents are having mild psychosocial problems. With regards to coping strategies 40% of respondents are having Poor coping strategies, 38% of respondents are having moderate coping strategies and 22% of respondents are having good coping strategies. Psychosocial problems are negatively correlating with coping strategies.

Conclusion: The study concludes that peri-menopausal women are at risk for psychosocial problems and a negative correlation was observed between psychosocial problems and coping strategies.

Keywords: Psychosocial problems, Coping strategies and Peri-menopausal women. Psychosocial problems and coping strategies among peri-menopausal woman.

Introduction

Women experience various turning points in their life cycle, which can be developmental or transitional. Menopause is a major turning point in life of a woman which is directly related to her womanhood.¹ The exact age of menopause varies from woman to woman. In normal women, the menopause occurs between 45 to 50 years of age. It is characterized with cessation of menstruation and implies inability in child bearing capacity and aging.² Peri-menopause is a term used to specify “the time around menopause”.³ The World Health Organization defines peri-menopause as the period (2-8 years) preceding menopause and the one-year period after final menses, resulting from the loss of ovarian follicular activity.⁴ Approximately 70% of women experience some adverse symptoms during the peri-menopause stage that are caused due to the loss of estrogen.⁵
Peri-menopausal period is characterized by a continuous decline in ovarian function due to which women are vulnerable to various physical and psychosocial symptoms affecting their quality of life. Most of the women experience varying degrees of adverse symptoms such as vasomotor instability, headaches, hot flushes, and dizziness, diaphoresis, drying of the skin, sleeplessness and loss of hair. Several psychological factors were related to the process of physiological change. A woman may experience a fear of losing her appearance, uncertainty about her purpose in life as middle-aged woman, sadness at the passing of the fertile time of life. These feelings may even outweigh the physical discomfort caused by the complex hormonal changes.6-9

Peri-Menopausal women may be experiencing psychological problems like anxiety, depression, fear and anger, loss of memory and lack of concentration.10 The study conducted by Bromberger JT et al shows that women were two to four times more likely to experience major depression episode when they were perimenopausal or early postmenopausal11 and study conducted by Afshari P et al showed that 59.8% of the 1280 samples were depressed; in particular, 39.8% had mild depression, 16% moderate depression, and 4% severe depression among menopausal women.12

An explorative study conducted on Bio-Psychosocial Problems and Coping Strategies adopted by the Menopausal Women of the age group of 40–50 Years showed that women experienced mild to moderate Bio-Psychosocial problems and used both positive and negative coping strategies. The result also revealed there was significant but low negative correlation between the bio psycho social problems and coping strategies used by the menopausal women.13 The studies have shown that about one-third of the women suffered from decreased psychological well-being.14 Therefore, emotional balance, tolerance level, adjustment process and other personality attributes were under great threat, which negatively affect the mental health. There will be a chance that if their problems were left unnoticed they might become mentally ill in the future. Some suitable interventions and modifications in their life style and coping strategies especially during these periods of life may help to improve and maintain their good health.15 Hence, the investigator is interested to undertake this study to assess the psychosocial problems during perimenopause, with the view that this study might help the healthcare professionals to gain an insight in to the psychosocial problems faced by the peri-menopausal women.

The Objectives of the Study:
1. To assess the psychosocial problems and coping strategies among peri-menopausal women.
2. To find out the correlation between psychosocial problems and coping strategies among perimenopausal women.
3. To find out the association between psychosocial problems scores with selected socio-demographic variables.

Method

A cross-sectional descriptive Survey research design was adopted for the present study. 200 women were recruited by Convenience sampling technique at selected PHC area, Bangalore urban and data was collected from June to December 2017. The study included perimenopausal women who are willing to participate in the study and able to read and write English/Kannada. The study excluded Peri-menopausal women who are mentally ill. The study protocol was approved from Intuitional ethical committee. Formal permission was obtained from Medical Officer and informed consent was taken from subjects. Data were analysed using Statistical package for the social Sciences software package (Version 23) and results were presented in table form.

Data collection Instrument

1. Socio-demographic proforma: It includes questions on their age, marital status, educational status, occupational status, religion, type of family, family income, dietary pattern, number of children and age at menarche.

2. Rating Scale: It consists of 30 questions to assess the psychosocial problems among peri-menopausal women with possible scores ranging from 0 to 60. Each item is scored as follows: 0 = “Not At All” 1 = “some extent” 2 = “very much”. A total score of 15-30 are classified as mild, 31-45 as moderate and above 45 as severe psychosocial problems.

3. Checklist: It consists of 16 items which assess the coping strategies adopted by women during the peri-menopausal stage. The scores assigned are “always-2”, “sometimes-1” and “never-0. The maximum score is 30. A score of 1-15 consider as
Poor coping strategies, 16-22 as Moderate and 23-30 as Good coping strategies.

**Results**

In the present study, Majority (65%) of the respondents were in the age group 45-50 years, most of them were married (90%). Majority (70%) of the respondents were Hindus and majority (39%) of the respondent’s educational qualification is No formal education. Majority (65%) of the respondent’s occupation is House maker and Majority (60%) from Joint family. Highest number (65%) of the respondent’s family monthly income is Rs 5000-9000 and Majority (60%) of respondents’ dietary pattern is mixed. Majorities (70%) of the respondents are having two children and Majorities (62%) are attained menarche at age of 13-16 years.

The findings shows that 12% of respondents are having severe psychosocial problems, 28 % of respondents are having moderate psychosocial problems and 30% of respondents are having mild psychosocial problems. With regards to subscale majority (47%) of respondents scored positive for generalized anxiety followed by social problems (38%) and lowest number (10%) of respondents scored positive for depression problems. The overall mean for psychosocial problems is 26±1.26. With regards to coping strategies 40% of respondents are having Poor coping strategies, 38% of respondents are having moderate coping strategies and 22% of respondents are having good coping strategies. The mean for coping strategies is 13±2.43.(Table 1)

Pearson’s correlation was calculated to examine the relationship between the psychosocial problems and coping strategies. Psychosocial problems is negatively correlating with coping strategies (-0.45), indicating that as Psychosocial problems are increasing coping strategies will be decreased. Chi-square was calculated to examine the association between psychosocial problems with selected demographic variables. It is revealed that there is significant association found between psychosocial problems with age, occupation and age at menarche. No association was found between remaining demographic variables.

**Discussion**

The study revealed that 12% of respondents are having severe psychosocial problems, 28% of respondents are having moderate psychosocial problems and 30% of respondents are having mild psychosocial problems. Our findings echo previous research evidence which shows that menopausal women suffered from psychosocial problems more than twice the rate of women and those who reported their first severe depression episode were also affected by severe anxiety disorders and physical problems. Rates of persistent mood symptoms were higher among early peri-menopausal women (14.9%–18.4%) than among menopausal women (8%–12%) and early peri-menopausal women had higher odds of irritability, nervousness, and frequent mood changes. The study conducted by Yazdanpanhi et al shows that there is higher risk of stress, anxiety and depression among women who are experiencing menopausal symptoms. An Indian cross-sectional study shows that level of syndromal depression and anxiety was found to be 86.7% and 88.9%, respectively among women aged 40–60 years. The present study revealed that
Psychosocial problems is negatively correlating with coping strategies and this is supported study conducted by Lam shows that low negative correlation between the bio psycho social problems and coping strategies.13

There is a need to create nationwide public awareness campaign through media, newspapers, radio programs, involvement of non-governmental organizations, schools and colleges, and integrating distribution of public education materials with multipurpose workers so that early detection of psychosocial problems among menopausal women is possible at the grass route level and future complication can be prevented.

**Limitations:** The study is limited to small sample size (200) and small number of subjects limits generalization of the study.

**Conclusion**

The study findings shown that peri-menopausal women are at risk for psycho-social problems and peri-menopausal women are using poor coping strategies to overcome the psychosocial problem. A psycho-social problems can results in major psychiatric illness, so early identification by health care team is very important for prevention of complications. Further research is needed to identify effective strategies for treating psycho-social problems among menopausal women.

Comparative Study of Laproscopic Cholecystomy with Drain Versus no Drain

Nooruddin W. Ansari

Associate Professor Department of General Surgery Mamata Academy of Medical Sciences, Bachupally, Telangana State

Abstract

Out 50 patients of laparoscopic cholecystomy 25 patients group as LC with drain and 25 patients without drain and post laparoscopic colostomy (LC) complications of both groups of were noted. In group A(drain) 14 (56%) had infection of wound and in group B (No drain) had 2(8%), 9(36%) pain in group A and 3(12%) in group B (No drain)7(28%) of group A(drain) had blockage in pipe and 7(28%) patients had more length of stay at hospital and 3(12%) of group B had long stay at hospital 5(20%) morbidity in group A (drain) and 2(8%) morbidity in group B 4(16%) of group A (drain) had chest infection. This study was unable to prove that, drains were useful in reducing complications in laparoscopic cholecystomy.

Keywords: LC = Laparoscopic cholecystomy, GB = Gallbladder, Group A (drain) Group B (No drain).

Introduction

Study Gall bladder (GB) is a pear shaped temporary reservoir of bile situated on the inferior surface of the liver partially covered by peritoneum(1). G.B by virtue of its anatomical position at the gateway to the hilum of liver and by the virtue of its embryological development including its numerous variations is the commonest component of gastrointestinal tract, after the appendix requiring surgical invention. Gall stone disease is of the commonest biliary tract disorders known since ages require surgical intervention for total cure. In India gallstone are most common and costly digestive disease and major cause of hospitalization(2)(3).

Cholecystectomy without sub hepatic drainage was first described in 1913, and since then surgeons were divided weather to use it as a routine drainage or not in uncomplicated cases(4). Most surgery continues to use routine sub hepatic drain for the fear of bile leak and bleeding(5). Such complications invariable occurred in spite of sub-hepatic drainage. Easier convalescence decreased rate of complications and shortened hospital stay were the advantages of no drainage(6). Laparoscopic cholecystectomy (LC) after the advent in 1987 rapidly established itself as the gold standard method of gall stones. Arguments of drainage from open era continue into laparoscopic era, also. Hence attempt was made to compare the post-LC complications in drain and no drain patients groups.

Material and Method

Total numbers of 50 patients were selected for Laparoscopic cholecystectomy (LC). The selected patients were suffering with ACute cholecystitis with cholelithiasis. Acute cholecystitis with GB sludge. A calculus cholecystitis, symptomatic cholelithisis, chronic calculus cholecystitis, patients were divided 25 each as group A and B. Group A was choosen for LC with drain. Romovac suction drain was inserted after LC in sub-hepatic space and no drain tube was for group B patients. Post operatively both groups were treated with same antibiotics.

The patient had cholelethiasis withcholedocolithiasis with Juinside, carcinoma of G.B, Pyogenic mucocele G.B, cholecystohepatic duct, congenital anomalies of GB were excluded from the study.

The pre-anesthetic check-up and fitness for all 50 patients were carried out. LC was done by standard four port method. Post operatively all the patients were given broad spectrum antibiotics, analgesia injections. The purpose is to study the pros and cons of placing a routine drain in the case of LC and evaluate the complications. Patient’s tolerance, comfort and morbidity, length of hospital stay.

The complications of drain and no drain were classified with percentage. The duration of the study was adult 2 years and 6 months.

**Observation and Results**

**Table-1 Comparative study of post LC complicate patients–14(56%) had infection in would in group A (Drain) patients while 2(8%) had infection in Group B (No drain), 9,(36%) had pain in group A (drain) and 3(12%) had pain in group B (No drain) 7(28%) patients had blockage in tube of drain, 7(28%) of the patients had long stay at hospital and 3(12%) had to stay long in hospital 5(20%) had morbidity in group A (drain) and 2 (8%) had morbidity in post LC surgery 4 (16%) had chest infection in group A (drain).

**Discussion**

In the present study of laparoscopic cholestectomy drain versus, no drain, 14(56%) of infection of wound observed in group A(drain), 2(8%) in group B(no drain) 9(36%) pain in group A(drain) and 3(12%)in group B(no drain)7(28%) blockage of drain in group A(drain), 7(28%) patients of group had to stay in hospital for longer time and 3(12%) in group B(no drain) had to stay for longer time in hospital, 5(20%) post LC morbidity in group A (drain) and 2(8%) in group B (No drain), 4(16%) chest infection in group A(drain) (Table-1). This findings were more or less in agreement with previous studies (7)(8).

It was also observed that quantity of sub hepatic fluid collection in both drain and no drain patients after LC was insignificant (9) and pain was very less in no drain patients as compared to drained patients.

Any drain, regardless of type is a foreign body that maintains a fistulous communication between a given tissue plane or cavity space and external environment.

Drain being a foreign body local infection is more likely consequences. In addition there is a threat of erosion into some adjacent structure, such as major blood vessels or on intestine. When in place the drain keeps tissue along the entire length of its passages separated and there by permits the egress of accumulated fluid and smaller matter.

Moreover the tract created is not a one-way street, for bacteria can migrate inward and colonize or supplant the microbial flora at the deepest extremely of drain(10). Hence the role of prophylactic drainage is much more uncertain. Despite being an established part of surgical practice there is little evidence to support the routine use of prophylactic drainage. In areas of gastro intestinal surgery evidence exists that drain placement has no demonstrable benefits.

**Summary and Conclusion**

The present study of comparison between laparoscopic cholecystectomy with drain versus, no drain can be concluded that there is no any practical benefit of post operative drain insertion in the patients with laparoscopic cholecystectomy. It offers no benefit in terms of post operative abdominal pain reduction shoulder pain reduction, nusea vomiting and fever in post-operative period. On the other hand it prolongs the hospital stay can also increase the chances of infection. In addition to pain and discomfort on the drain site so drain is not recommended as routine practice in LC.

This research paper was approved by ethical committee of Mamata Academy of Medical Sciences, Bachupally-500090 (Telangana)

Correlation of Glycaemic Control, Age and Duration of Disease with the Quality of Life in Type 2 Diabetes Mellitus Patients in the Field Practice Area of a Medical College

Novmeet¹, Varsha Parihar², Anshu Mittal³, Parul Sharma⁴

¹Assistant Professor, Department of Community Medicine, MMMC & H, Kumarhatti, Solan, H.P., ²Tutor, Department of Community Medicine, MMMC & H, Kumarhatti, Solan, H.P., ³Professors and Head, Department of Community Medicine, MMIMSR, Mullana, Ambala, ⁴Statistician, M.Sc. 2nd Year, Kurukshetra University, Kurukshetra

Abstract

Diabetes is a chronic progressive endocrine disease characterized by elevation of blood glucose level. This disease is associated with decreased life expectancy; increased morbidity and diminished quality of life. Measuring QOL is important, because by doing so we can predict the patient’s capacity as well as ability to manage the disease and to maintain overall well-being and the long-term health. The objective of the study was to study the correlation of glycaemic control, age and duration of disease with quality of life in patients with Type 2 Diabetes Mellitus.

Material and Method: A cross-sectional study was conducted 200 patients, 100 each from rural and urban centers, at field practice area of Department of Community Medicine, MMIMSR, Mullana. The survey has been conducted with the help of pretested, semi-structured questionnaires. The softwares used for the data-entry and the analysis of the data are Microsoft Excel and IBM SPSS (Statistical Package for Social Sciences) version 21. FINDINGS: 42% of the subjects were between 61-70 years of age. 55.5% were males and 44.5% were females. 24% were having the disease for last 11-15 years. Males had higher QOL scores than females. Scores were more for the patients of rural areas than urban areas, those patients who did not develop any complications or co-morbidity, patients who were employed. Scores were also better for those patients who had HbA1c level less than 7. Scores were minimum for those subjects belonging to the age group of >70 years and belonging to upper socio-economic class.

Conclusion: Poor QOL was associated with increasing age, duration of disease and poor glycaemic control.

Keywords: Type 2 Diabetes Mellitus, Quality of life, HbA1c.

Introduction

Diabetes is a chronic progressive endocrine disease characterized by elevation of blood glucose level leading to various complications which further lead to morbidity and mortality. According to WHO, Diabetes Mellitus is defined by the level of hyperglycaemia giving rise to risk of microvascular damage (retinopathy, nephropathy and neuropathy). Abnormal high level of blood glucose is called as Hyperglycaemia which, if severe, acute and untreated, can be life threatening. It is associated with decreased life expectancy, increased morbidity, increased risk of macrovascular complications and diminished quality of life. Type 2 diabetes is characterized by insulin resistance in peripheral tissue and a delay or deterioration of insulin secretion, due to gradual deterioration of β-cell function. The onset of this
The current WHO diagnostic criterion for fasting plasma glucose is \( \geq 7.0 \text{mmol/l} (126 \text{mg/dl}) \), Blood Sugar (F): Shows the Fasting blood sugar of the respondent. The current WHO diagnostic criterion for post prandial (two hours after meal) plasma glucose is \( \geq 11.1 \text{mmol/l} (200 \text{mg/dl}) \), HbA1c: To check the Hemoglobin A1c to detect the glycaemic control of the patient. We took the cut off level of HbA1c as 7%. Section C: This section contained the SF 36 Questionnaire which is a generic questionnaire accommodating 36 items which measures Quality of Life (QOL) across eight subscales, which are both physically and emotionally based. For each subscale, scores are transformed to a scale from 0 (worst health) to 100 (best health). The eight different subscales or domains that the SF36 measures are as follows: Physical Functioning, Role Limitations due to Physical Health, Role Limitations due to Emotional Problems, Energy/Fatigue, Emotional Well-being, Social Functioning, Pain, General Health. STRATEGY: All the eligible patients were interviewed after taking due consent. The observations were noted as told. Height and weight for each of the patient was noted. After this, patient underwent laboratory investigation for FBS, PPBS and HbA1c to know the control. The findings regarding the investigations were noted from the lab. ANALYSIS OF DATA: The softwares used for the data entry and the analysis of the data are Microsoft Excel and IBM SPSS (Statistical Package for Social Sciences) version 21. Quantitative data has been presented as mean and standard deviation. Qualitative data has been presented as percentage to depict proportions. T-test and ANNOVA tests were applied to show the difference of scores among various categories of a particular variable, P value less than 0.05 was taken as significant at 95% confidence interval. Before getting the proforma filled, due consent was sought from all the subjects. Those not willing were respectfully excluded from the study. The study did not impose any financial burden in form of any drug usage or conduction of laboratory tests etc. Confidentiality was maintained throughout the study.

**Material and Method**

STUDY AREA: The area under study was Ambala and it was conducted in the Field Practice area of Department of Community Medicine, MMIMSR, Mullana. The health services in this area are catered through three rural and one urban health centres. STUDY DESIGN: Cross-Sectional study. STUDY PERIOD: Conducted over a period of one year from January 2015–December 2015. STUDY POPULATION: Inclusion Criteria: Subjects aged 20 years or above who had been diagnosed to have Type II DM attending the OPD of Urban and Rural health centers of the Community Medicine Department were included in the study. Exclusion Criteria: Those not willing were excluded. SAMPLE SIZE: 200 patients of Type II DM: 100 each from rural and urban centers. Previous experience showed that annually more than 100 patients of Type II DM reported to each of the health centers. Hence, it was decided to study at least 100 patients from each centre. STUDY TOOLS: Questionnaire The survey has been conducted with the help of semi-structured questionnaires. The questionnaire was divided in the following three sections: Section A: This section contained the socio-demographic profile of the study participants. The social demographic profile consisted of following areas: Age: The age of every subject was recorded to the nearest completed year. Sex: It determined whether the subject is male or female, Address: The address of the subject was also entered to ensure the area of the study. Section B: In this section the information was ascertained about the variables related to the disease. The variables are as follows: Duration: It shows that for how many years the subject is suffering from the disease, Blood Sugar (F): Shows the Fasting blood sugar of the respondent. The current WHO diagnostic criterion for fasting plasma glucose is \( \geq 7.0 \text{mmol/l} (126 \text{mg/dl}) \), Blood Sugar (PP): Shows the post prandial blood sugar of the respondent. The current WHO diagnostic criterion for post prandial (two hours after meal) plasma glucose is \( \geq 11.1 \text{mmol/l} (200 \text{mg/dl}) \), HbA1c: To check the Hemoglobin A1c to detect the glycaemic control of the patient. We took the cut off level of HbA1c as 7%. Section C: This section contained the SF 36 Questionnaire which is a generic questionnaire accommodating 36 items which measures Quality of Life (QOL) across eight subscales, which are both physically and emotionally based. For each subscale, scores are transformed to a scale from 0 (worst health) to 100 (best health). The eight different subscales or domains that the SF36 measures are as follows: Physical Functioning, Role Limitations due to Physical Health, Role Limitations due to Emotional Problems, Energy/Fatigue, Emotional Well-being, Social Functioning, Pain, General Health. STRATEGY: All the eligible patients were interviewed after taking due consent. The observations were noted as told. Height and weight for each of the patient was noted. After this, patient underwent laboratory investigation for FBS, PPBS and HbA1c to know the control. The findings regarding the investigations were noted from the lab. ANALYSIS OF DATA: The softwares used for the data entry and the analysis of the data are Microsoft Excel and IBM SPSS (Statistical Package for Social Sciences) version 21. Quantitative data has been presented as mean and standard deviation. Qualitative data has been presented as percentage to depict proportions. T-test and ANNOVA tests were applied to show the difference of scores among various categories of a particular variable, P value less than 0.05 was taken as significant at 95% confidence interval. Before getting the proforma filled, due consent was sought from all the subjects. Those not willing were respectfully excluded from the study. The study did not impose any financial burden in form of any drug usage or conduction of laboratory tests etc. Confidentiality was maintained throughout the study.

**Findings:** A total of 200 Type 2 Diabetes Mellitus patients participated in the study. Majority (42%) were between 61 to 70 years of age. 30% were between 51 to 60 years, 15.5% were between 41 and 50 years of age, 7.5% were above 70 years and 5% were 40 years and below. 55.5% were males and 44.5% were females.
Majority (24%) were having the disease for last 11-15 years, 23% were having the disease for less than 5 years, 22.5% were having the disease for last 6-10 years, 19.5% were having the disease for last 16-20 years and 11% of all the subjects were having the disease for more than 20 years.

</table>

In this study 55.5% subjects were males and 44.5 were females. Similarly, in the study conducted by Mathew et al (2014), 53% were males and 47% were females. In role limitation due to physical health domain better results were observed in the age group of 41-50 years and the difference was significant. Similarly, in role limitation due to emotional problems domain better results were observed in the age group of 41-50 years but the difference was statistically significant this time. Again, in the Energy/fatigue domain, better results were observed in the age group of 41-50 years and the difference was statistically significant. For the rest of the domains, age group ≤40 years had better results and the difference was significant. Spasić et al (2014) also concluded that patients in the younger age groups had better QOL as compared to their older counterparts and
this association was significant. These findings were in agreement with the study conducted by Papadopoulos et al (2007) in Greece, in which they found that the patients from younger age groups scored higher for all the eight domains. In the present study it was observed that with increase duration of disease quality of life tends to decline for all the domains with highest scores for the subjects having disease for less than 5 years and lowest for those having the disease for >20 years. It was also found that this association was significant for all the domains except role limitations due to emotional problem domain where these results were not significant. Similarly, in the study conducted by Thommasen et al, they found that as the duration of the disease increased, declines in “physical functioning,” “role physical,” and “general health” scores was observed. In this study we found that scores were better for patients who had HbA1c level less than 7 than those who had it more than 7. Similar observations were also found in the study conducted by Imran et al (2010) in Malaysia, in which they found that patients with poor glycaemic control had the lowest scores in all the scales of the SF-36. The two scales that were most severely compromised were the Physical Functioning and Role Physical scales. Similar trend was observed for all the remaining domains. The difference was statistically significant. This observation shows that good control of diabetes plays important role in improving the quality of life. Similarly, Akinci et al (2008), in a study they conducted in Turkey, found that the patients with higher levels of HbA1c had poor quality of life scores than the patients with low HbA1c levels.

**Conclusion**

Type 2 diabetes mellitus is linked to a poorer perception of health-related quality of life. Diabetic patients have comparatively poorer quality of life than non diabetic population. QOL is especially affected with increasing age, increased duration of disease and poor glycaemic control. Therefore, it must be kept in mind that diabetes have a great impact on patient’s life that cannot be measured solely by the quantification of objective clinical parameters (like morbidity and mortality). We recommend that efforts should be put on to improve the QOL in combination with medical treatment in order to achieve the overall wellbeing and health status of the patients.

Tuberculosis and Mental Health: The Interface

Paramita Barman

Assistant Professor in Economics, Faculty of Commerce & Management, St. Xavier’s University, Action Area IIIB, Plot No. IIIB/1, New Town, Kolkata

Abstract

In the era of the Sustainable Development Goals and the ambitious End TB Strategy, it is vital to recognize that only the microbiological cure of tuberculosis (TB) will not be adequate for bringing this public health adversity under control, let alone its eradication. Mental disorder which is an important risk factor as well as a ramification of TB, very often escapes attention during deliberations and discourses on TB. Mental illness in its various forms contributes significantly to the global burden of death and disability. The comorbid conditions of TB and mental health add to the challenges that already prevail in the management of each. This study tries to look into the inter-linkage between TB and mental health by exploring existing literature and identifying the pathways through which each becomes a fuelling factor for the other. Designing of policy to effectively address each of these health conditions within the conceptual as well as technical and operational framework for dealing with the other is the need of the hour.

Keywords: Tuberculosis, Mental health, Comorbidity, Burden of disease.

Introduction

Tuberculosis (TB) remains a public health emergency. It currently stands as the leading cause of death from a single infectious agent, ranking above HIV-AIDS and substantially contributing to the global burden of disease. India, bearing a staggering 27 per cent of incident TB cases worldwide, tops the list of the 30 high TB burden countries and accounted for a glaring proportion of ‘missed cases’ globally, reflecting a mixture of under-diagnosis and under-reporting of TB cases. TB was declared a public health emergency by the WHO in 1993 followed by most countries adopting the DOTS strategy in their national TB control programmes. The standard treatment regimen for drug sensitive TB comprises a six months course of four first-line anti-TB drugs. Treatment default has been one of the prime reasons for the rampant emergence of multi drug-resistant TB which takes a longer treatment span with second line drugs that are both more toxic and expensive. TB is strongly related to the socioeconomic gradients of a population. The association between TB and poverty is well documented. Although not exclusively a disease of the poor, deprivations typically associated with poverty like malnutrition, crowded and unsanitary living conditions, substance abuse and lack of disease related awareness due to illiteracy substantially increase the risks of infection and disease. The disease also happens to be associated with severe social stigma.

Several medical conditions present risk factors for TB like HIV, diabetes, silicosis, use of tobacco and alcohol abuse and are also responsible for detrimental TB treatment outcomes. Also, TB can make the course of such diseases more complex. Either way, prevalence of such comorbidities in the population adds to the burden of TB. An important comorbidity associated with TB but less deliberated on is mental disorder. The inter-linkage between mental health and TB often escapes attention in practice and in policy prescriptions while each continues to contribute to the dilemma in management and control of the other. The paramount significance of mental health has been quite succinctly brought out through the definition of ‘health’ by the WHO as constituting a state of complete physical, mental and social well-being and not just the absence of disease or infirmity. Mental illnesses in varied forms like anxiety disorders, depression, schizophrenia and dementia to name a few are responsible for nearly 13 per cent of the global burden of disease, besides being important catalysts for other diseases. The low and middle income countries are home to 80 per cent of people living with some mental disorder and the increasing burden may be traced to factors like paucity...
of resources allocated towards mental health particularly in these settings and underutilization of existing services due to lack of awareness as well as stigma attached to mental illness\textsuperscript{9}. A plethora of social, psychological and biological factors are responsible for preserving the mental health of an individual at any point of time. People with mental health conditions are often deprived of opportunities of education and income, impeding their scope for socioeconomic development and resulting in marginalisation and increased vulnerability.

The liaison between TB and mental health, despite its implications on the disease burden of each condition, remains a largely under-researched area.

**The interface: mental health implications of TB:**
The impact of an infectious disease of chronic nature like TB with a typically lengthy duration of treatment transcends mere physical impairment. According to the WHO, “depression has been an invisible burden for people with TB” and “the mental well-being of TB patients during their treatment has often been overlooked”.

TB affects people mostly in their productive years of life resulting in grave socioeconomic consequences for the household. In the developing countries that bear the major brunt of TB, despite availability of free of charge diagnostic and treatment services provided by the national tuberculosis programmes directed towards TB control, barriers like geographical distance of health facility from patient’s residence, direct costs of travel, food and accommodation, inconvenient timings of DOTS clinics, indirect costs of foregone earning and lack of information about service availability compel patients to fall back on easily accessible private sources of care both formal and informal as they navigate through not so efficiently functioning health systems seeking relief from symptoms. This often results in a ‘medical poverty trap’ situation for households particularly the economically vulnerable ones, even before such patients can be put on effective treatment\textsuperscript{9,10}. TB is thus not only a result but also a cause of poverty. Financial hardship in the household following catastrophic expenditures on diagnosis and treatment of TB on one hand and dwindling income due to inability to work for reasons of physical incapacity caused by the disease is a pressing reason for development of stress and anxiety in the patient particularly if he or she happens to be the sole bread winner in the family. Studies hint at exposure to chronic and stressful life events and financial predicament as important mediators in stimulating mental ill health\textsuperscript{11}.

Strong social stigma shrouds TB. Studies have highlighted the social implications of getting diagnosed with TB or being under TB treatment as constituting rejection from family, friends and neighbours, social ostracisation, discrimination and fear of being thrown out of job on revelation of positive TB status. Stigma affects health seeking behaviour as people with symptoms hesitate to go for diagnosis, patients tend to conceal their disease status from family and relatives and those on treatment face difficulties in continuing with it. Social adversities are felt more by women with diagnosed TB, in the form of difficulties in getting married, harassment by in-laws and other members of family, broken marriages and dismissal from work\textsuperscript{12,13,14}. Getting diagnosed with TB or undergoing treatment for the same has been found to be associated with mental anguish, depression, feelings of loneliness and uselessness, anxiety and low self-esteem. It has been documented in the context of another communicable disease, HIV, that stigma and discrimination in all forms are ultimately linked with depressive traits among people living with HIV\textsuperscript{15}. The potential pathways through which a physically impairing condition like TB may culminate into a mental affliction thus seem to be economic crisis and social crisis. The impact of TB on mental health may be analysed at two levels—first, at the level of diagnosis of the disease where the perceived social stigma associated with TB instils in the patient fear of social isolation, estrangement from kins and job loss; additionally, perception of self as transmitter of infection leads to a sense of guilt and inferiority that in turn reinforces stigma. The burden of stigma itself jeopardises mental well-being. The second level constitutes the treatment phase where common side-effects of anti-tubercular drugs like gastrointestinal complaints, vertigo, nausea, headache, skin rash, dizziness and mood disorders cause irritability and depression among patients. Several anti-TB medications like cycloserine, isoniazid, ethionamide and linezolid may trigger severe forms of mental disorders. Drug-induced psychosis can potentially fuel self-harming thoughts like suicide. Mental illness, in particular severe depression, are highly prevalent among patients undergoing multi drug resistant TB treatment\textsuperscript{16}. Studies conform to poor quality of life of TB patients with frequent bouts of depression, feelings of anxiety on diagnostic disclosure and as well as development of drug-induced psychiatric symptoms in patients under treatment ultimately leading to extreme outcomes like suicidal deaths\textsuperscript{17,18}. Also, physical weakness resulting from the disease and side-effects of drugs lead to
frequent absence from work and loss of income. Besides travel, accommodation and the like during the course of treatment, nutritious food constitutes an indispensible component of expenditure which adds to financial burden and consequently mental strain.

Mental disorders have been estimated to be prevalent among 40 to 70 per cent of people with diagnosed TB. Presence of the comorbid condition of mental illness in TB patients, if left unscreened and untreated, leads to poorer outcomes of TB treatment and adds to the burden of disease and disability.

Mental disorders as a risk factor for TB:
Patients with mental illnesses are also at an increased risk of exposure to TB infection with higher rates of homelessness, poor nutrition, addictions to smoking and alcohol and co-morbidities like diabetes and HIV. Limited and mostly crowded accommodation options for patients with mental disorders like group homes and rehabilitation centres rather provide a congenial environment for an outbreak of TB. Studies have identified that patients with depression are at a significantly higher risk of pulmonary TB as compared to those without depression while controlling for age, sex and comorbidities. Patients with mental illness are more likely to exhibit inadequate health seeking behaviour due to a number of reasons like inability to recognize disease related symptoms, lack of clarity regarding who in the family or otherwise is responsible for the healthcare of such patients and ineffective communication between the patients and their providers about symptoms and risk factors. These contribute to diagnostic delays among patients suffering from mental disorders resulting in prolonged periods of transmission of infection in the family and community with subsequent outbreaks of TB.

Discussion
TB management and control strategies particularly in the high burden developing countries mostly remain preoccupied with symptoms remission, drug regimen and treatment. With excessive emphasis on only the medical aspect of the disease, ancillary facets like individual care and counselling of the patient and family members, psychological assistance, provision of treatment adherence support and nutritional support that are equally significant for ensuring desired treatment outcomes, have taken a back seat. Counselling constitutes an inevitable part of TB treatment by providing the much needed support system to patients to help them cope with the woes of lengthy and sometimes expensive treatment, reduced income due to inability to work, responsibilities in the family, perceived loss of social standing and similar unsettling factors. Also, side-effects of anti-tubercular drugs in the form of physiological disturbances, anxiety, mood fluctuations and even depression can potentially hamper the effectiveness of treatment. Experiences of discomfort often induce TB patients to abandon treatment midway, the moment they start feeling better. Treatment non-compliance can have serious consequences for community health including continued transmission of infection and emergence of multi drug-resistant and extensively drug-resistant strains of TB. At the level of the patient, quitting treatment leads to development of drug resistance with greater morbidity and mortality. Timely health seeking and treatment adherence are additional challenges for patients living with TB and mental illness with consequent unfavourable treatment outcomes. Family support assumes a greater role in TB control as the duration of treatment is an extended one as compared to other clinical conditions so that patients are expected to be requiring greater care as well as nutritional and livelihood support. Compassion and cooperation of family members become extremely important in helping the patient tide over disease related mental anguish and cope with the stresses of diagnostic revelation and treatment. Educating the patient’s family and community at large about TB, its mode of transmission, prevention, importance of treatment compliance and curability of TB are vital besides medical intervention as it helps raise disease related awareness on one hand and reduce stigma and negative attitudes about TB on the other. Adopting means to ensure greater acceptability of TB patients in the mainstream of society should essentially constitute an important element in TB management and control efforts so that their mental health can be preserved along with restoration of physical health. In India for example, the Revised National Tuberculosis Control Programme (RNTCP) has largely been target oriented focusing on detection and cure of TB, with little attention to mental health. Scarcity of official data on depression and other mental health complaints or even suicidal attempts by TB patients bears testimony to this gap in the treatment regime. Nevertheless, the RNTCP lays down counselling as a vital component of treatment in the guidelines that it provides for the management of drug resistant TB. Scaling up of professional counselling services and the ratio of counsellor to patients which may serve as an effectiveness index, needs to be addressed.
Concluding Remarks: Both TB and mental illness have substantial individual contributions towards the global burden of disease. Further, each constitutes an important comorbidity factor for the other, adding to the challenges that already exist in the management and control of each. Mental ill health, besides being a disabling factor in the individual concerned, also results in poor treatment outcomes for TB patients with greater morbidity, mortality, treatment default and resistance to drugs and increases transmission in the community. Yet, there remains a dearth of measures in the TB control programmes across developing countries in particular to adequately address their mental health care needs. Lack of a compulsory and in-built mental health support apparatus undertaking routine delivery of screening and counselling services constitutes a conspicuous lacuna in the TB management and control efforts that requires to be urgently looked into. Detection and proper management of mental and behavioural disorders improve patients’ quality of life as well as ensure better attainment of treatment objectives. That caring for the mental health of TB patients is intrinsic to their treatment of TB needs to be recognised, promoted and implemented at the earliest. This calls for physicians treating TB patients and psychiatrists addressing mental aberrations in patients to be aware of the pathways of interaction between these two conditions, particularly with respect to drugs administered in the treatment of each. Synergy between national TB control programmes and mental health campaigns in countries can be an effective step and is important for accommodating and addressing the disease burden caused by comorbid conditions of mental ill health and TB. Collaborative endeavours like the “Let’s talk about depression and TB” campaign as part of the broader “Depression: let’s talk” campaign launched by the WHO are optimistic developments that can guide nations towards this end. Without the alignment of consolidated efforts directed towards regular detection and management of mental disorders within TB control programmes and screening of patients with mental health complaints for TB, the ambitious targets of the End TB strategy and the Sustainable Development Goals calling to ensure healthy lives and well-being for all at all ages will be hard to achieve.

Emerging Trends of Pharma Industry Policies for Ensuring Women Retention

A. Nafeesa Begum¹, G. Brindha²

¹Research Scholar, Department of Management Studies, Bharath University, ²Professor & Head, Faculty of Management Studies, Dr. MGR Educational And Research Institute, Chennai

Abstract

Today, behaviour of women employees has changed the environment of the private organization. Young women employees always ready to switch over whenever she dissatisfy with any reason in the job. Retention strategy is a powerful recruitment tool. Private organizational issues matters as lost knowledge and training time. HR managers should identify the needs of the women employee and then devises the retention strategies. As different individuals have different priorities does not fit one strategy. HR professionals face the vital challenge to retain talented women employees. Retention strategies are fall into four categories—job enrichment, salary, working conditions and education, addressing these issues this article demands a specialized approach that emerge new fangled women friendly policies which foster gender neutral workplace in developing retention strategies.

Keywords: Retention strategies for female employees, scope, trends and policies.

Introduction

“New-Fangled Women Friendly Policies Which Foster Gender Neutral Workplace”

The fast developing knowledge economy coupled with the information technology during the last two decades has totally changed the complexion of our business and employment relations. The globalized economy and the labour market have further added new dimensions to this phenomenon. India has taken advantage of this growing trend entering the Pharmaceutical sector of economy and industry¹. Though the Indian is fast responding and taking the challenge head on and competing effectively in the new Pharmaceutical dominated global market the industrialist-employer in the Pharmaceutical industry are facing another challenge, namely, finding suitable people to recruit to the jobs being generated by them. When and where they are able to find people who can meet their expectations, they are facing the new challenge that this is coming their way in the form of retaining the people working with them. In fact, recruitment and retention are two sides of the same coin. Economically and financially employee retention, of late has acquired greater significance.² It is much more costly and time consuming to find the right replacements. Resultantly the employee retention has turned out to be a critical challenge to the employers. They have become very sensitive to the problem of employee retention. Researchers also are seized of the situation and getting involved in this challenge.

Researchers have found that workplace culture and women’s personal character traits play major roles in retention. So what are the things that make a difference? Women prefer workplaces that are collaborative rather than hierarchical, explains Heather Metcalf, director of research and analysis at the Association for Women in Science³. And they are more apt to stay in work environments that allow for creativity and flexibility, she says. Conversely, women are fleeing companies that encourage employees to practically live at work, she says. While 71 percent of women with young children work outside the home, according to the Pew Research Center, women still shoulder more responsibility for child care and elder care than men. So living at the office to show they are committed to their jobs is not an option."Creating workplaces that have a lot of flexibility, that allow for people to work in a way that fits best with them, boosts creativity and job satisfaction," Metcalf says, and these are the settings where women stay and thrive. No matter what type of organization women work for, large or small, public or private, their
relationships with their immediate bosses are critical to whether they feel engaged and content. The ideal supervisor is committed to his or her subordinates’ advancement and development, assigns stretch projects, and provides necessary support and feedback to help them be successful, Bilimoria says. And workplaces that employ women in higher levels are more apt to retain women at the lower levels.

Objectives of the Study
1. To identify the emerging trends and policies for retaining women employees in Pharmaceutical industry
2. To identify the scope of ensuring women retention in Pharmaceutical industry
3. To suggest new policies that are women friendly and that will foster gender neutral work place

Scope of the Study: Keeping in view the critical problem the organizations in the Pharmaceutical industry have been facing ever since the Pharmaceutical industry came into existence in India to retain their performing employees at different levels, this study seeks to understand the different strategies of different organizations for retaining their employees and examine whether those strategies have any universal base and comparison with the experiences of high-tech organizations or organizations depending on the knowledge workers or professional employees and if so what are these common employee retention strategies being in practice in different organizations in the Pharmaceutical industry in Chennai.

The scope of this study is confined to Pharmaceutical industry in Chennai. The study throws light through valuable suggestion to increase the female employees’ retention in the organization. This study can help the management to find the weaker parts of the female employee feels towards the existing organization retention strategies and also helps in converting those weaker part in to stronger by providing the optimum suggestions or solutions. This study is a clear guide for the solution seeker about the factors which induced women employees to stay back in the same organization. Special attention has been shown in this research about their empowerment in the society economically as well as professionally. Career development is an existing trend to be stay in their organization and how these factors induced them; all those answers will be make this research unique and an find an enhanced approach towards balancing gender at workplace.

Emerging Trends For Retaining Women Employees:

More Women Leaders: The first thing that gives a woman confidence at her workplace is having women leaders to look up to. This also indicates that the company offers them an environment conducive to scale the corporate ladder. It would be more beneficial if women leaders took on the role of mentors in mentorship programmes that are already at work in certain companies.

Sexism-Free Work Culture: Every workplace must offer a safe and secure environment for employees that help them grow personally and professionally. But it is a sad reality that this is not always true in India. Some of the biggest companies here lack sexual harassment cells and policies against discrimination at the workplace. Create a culture that does away with sexism at work by educating your employees about ‘unconscious biases’ and ‘benevolent sexism’.

Pay men and women equally: When you hire talented women, understand that they put in the same amount of hard work and time as the men and acknowledge that with equal pay. Offer them equal opportunities and trust them with responsibilities similar to what their male counterparts are given to foster increased confidence and professional growth.

Transparent Performance Evaluation Policy: Make it clear to all employees how they are going to be evaluated and about the requirements to be met to make career advancements. It is commonly seen that most organisations promote men on potential and women only on measurable and proven performance. Check your talent management systems and do away with such biases.

Flexible Work Schedules: Many Indian companies already offer flexible schedules to their employees, but most often they turn out to be only the freedom to choose their shifts. True flexibility means allowing your employees to adjust their work schedules to maintain a healthy work-life balance without being penalised. As long as they turn in their work on time and are producing results, their physical absence from office shouldn’t be a concern. Having flexible schedules end up in happier, more satisfied and extremely productive employees. Good intentions, alone, are not enough to make women
employees want to work for your company. Treat them well, provide them opportunities for professional development and create a culture that values their talents and respects them as individuals.

**Paternity Leave:** Reputation being known as a company that promotes gender equality will go a long way in attracting top female talent. And offering a generous paternity leave policy is one of the most effective ways to demonstrate a commitment to women and working families. While paternity leave is designed for men, it ultimately benefits working mothers and children. Furthermore, since most states don’t require it by law, implementing paternity leave shows that an employer is willing to go above and beyond to promote equality and inclusion.

**Empower Female Employees to Shape Company Culture:** Startup land has become famous for offering a fraternity-like atmosphere: free beer, video games, and personalized goodies. While it’s not fair to say women don’t like these perks, tech companies should include women on the teams that are shaping company culture. Expanding the activities beyond those evoking college dorm rooms will help attract talented women who don’t feel connected to those traditions.

Finally, it should go without saying that the best way to attract female talent is to offer competitive wages and excellent benefits that will support them in their life choices regardless of if they decide to have children or not. While the grand gesture of Face book and Apple will surely help their recruitment efforts, our corporate culture as a whole needs to focus on making small, but important, everyday changes and sticking with them

**Career Development Program:** Every individual is worried about her career. You can provide them conditional assistance for certain courses which are beneficial from your business point of view. Conditional assistance means the company will bear the expenses only if she gets an aggregate of certain percentage of marks. And entrance to that course should be on the basis of a Test and the number of seats to be limited. For getting admitted to such program, you can propose them to sign a bond with the company, like they cannot leave the company for 2 years or something after the successful completion of the course.

**Timely increments:** Timely Increments in salary makes talented employees to stick to the organisation for long time. Many researchers have found that the salary and increments were the core reasons behind leaving of employees to other organisations and competitor organisations attracts talent by showing sole monetary benefits, indeed most of the talent is getting attracted for this reason. It is universal fact and one has to accept that the monetary benefit is the core reason for an employee decision-making on retention in the organization

**Conclusion**

In a competitive business climate, retaining key employees is vital for the health of the company. But when these key employees are women, many corporations and industries continue to be befuddled as to how to retain this valuable cohort. Indeed, it’s surprising how many supposedly modern institutions are caught in a time-warp. Unfair compensation, gender imbalance in senior management positions, inflexible schedules and even active discouragement of female employees continue to plague companies large and small. The good news is, above few simple strategies can vastly improve conditions for female employees. Women who are trained to develop an executive-type persona in terms of gravitas that is, confidence, poise under pressure and decisiveness—as well as communication and appearance become more confident and are better able to command a room, thereby clearing a path to high-stakes and high-visibility positions. By utilizing some or all of these ideas, companies can benefit from a healthier and more balanced work environment. It just makes sense.

Shetty Memorial Institute of Dental Sciences, Mangalore, 5Assistant Professor, Department of Orthodontics and
Orthopedics, Subbaiah Institute of Dental Sciences, Shivamogga, Karnataka, India

Abstract

Aim: To determine the prevalence of molar incisor hypomineralization among school children aged 9 to 12 years in virajpet, Karnataka.

Method: This cross-sectional descriptive study consisted of 1600 school children aged 9-12 years selected by stratified cluster sampling procedure. The European Academy of Pediatric Dentistry criteria were followed for MIH diagnosis. Chi-square test was used to analyze the categorical data. \( P \leq 0.05 \) was considered for statistical significance.

Results: The prevalence of MIH is 13.12 % with no gender predilection. 10 year old children showed the highest prevalence (15%) among all the age group. Majority of children with MIH (70.2%) have lesions in both molars and incisors with demarcated opacities and atypical restorations being the most frequent defect type.

Conclusion: Prevalence of MIH was 13.12% in the 9-12 year child population in Virajpet. There is a need for a proper planned preventive and restorative program with regard to the increasing prevalence of MIH.

Keywords: First permanent molar, Developmental Defects, Hypomineralization, Post eruptive breakdown, Incisors.

Introduction

Dental enamel has a number of properties making it a unique tissue. It is the hardest tissue in the body and has a very high proportion of inorganic matter, mainly hydroxyapatite. The ameloblast has a limited reparative capacity; therefore disturbances occurring during the mineralization of enamel will remain as permanent marks. Defects in enamel quality or in other dental hard tissues are important implications for the understanding of evolution, function, origin and relation to etiological factors behind developmental disturbances but also how environmental factors may influence on the mineralization of the dental hard tissues. These unique properties of teeth have been widely used in research within biology, anthropology, archeology and several other areas.\(^1\)

\(^{1,2}\) The molar incisor hypomineralization (MIH) is defined as a qualitative defect of the enamel characterized by the progressive and simultaneous hypomineralization of the enamel structure of the first permanent molars which is of systemic origin, which may be associated frequently with incisors.\(^3\)
It was first defined by Weerheijm et al. in 2001. It is also called as “hypomineralized permanent first molars (PFMs)”, “idiopathic enamel hypomineralization”, “nonfluoride hypomineralization” “dysmineralized PFMs” and “cheese molars”. Knowledge about the magnitude of MIH seems desirable as it is vulnerable for consequences like rapid caries development, early enamel loss, soft structure and sensitivity.  

MIH is recognized as a global dental problem and epidemiologic reports from all over the world are continuously published. The global prevalence of MIH ranged from 2.4% to 40.2%. Majority of the studies that reported MIH were from European countries with a prevalence range of 3.6% to 37.5%. Prevalence in middle and South East Asian countries ranged from 9.25% to 20.2%. Prevalence data from India were scant and reported a prevalence of 6.31% to 9.46%. The prevalence is almost 40% percent in Denmark and Brazil. As many as 5% of the children in a Swedish population have a severe form of MIH and will experience extensive and difficult treatment. It has been reported that children with MIH have ten times more dental treatment compared with a group of children with clinically healthy first molars.  

The prevalence of MIH was not well documented due to several diagnostic classification in the literature. The various indices used are Alaluusua et al. criteria (1996), developmental defects of enamel index (DDE), Kemoli criteria (2008), Koch et al. criteria (1987), and the European Academy of Pediatric Dentistry (EAPD) 2003 criteria. Knowledge about the magnitude of MIH seems desirable as it is vulnerable for consequences like rapid caries development, early enamel loss, soft structure and sensitivity.  

Severe clinical manifestations and their consequences associated with MIH, indicates the need for research to increase knowledge about its prevalence and risk factors in developing countries. Thus, the aim of this study was to evaluate the prevalence MIH in a group of children aged from 9 to 12 years in Virajpet, Karnataka, India.  

Material and Method  

The present, descriptive cross sectional study conducted during January 2018–March 2018, the study population comprised of 9 to 12 year old School children belonging to Virajpet taluk. Total numbers of school students were 9792. Sample size was estimated and obtained as 400 per each age group and among 4 age groups (9, 10, 11 and 12 years) the total of 1600 samples. Stratified Cluster Sampling Method was followed. Total of 171 schools in Virajpet taluk was divided into 10 clusters based on location. Each cluster contains 17 schools. Considering 10% of schools from each cluster 2 schools were chosen randomly. Total schools considered were 20. Considering the number of schools included and the sample size (400 per age group), 20 students from each age group from each school was taken. Subjects who were willing to participate and whose parents/guardians have given written informed consent and children having fully erupted all permanent first molars and incisors were included in the study. The children with amelogenesis imperfecta, dentinogenesis imperfecta, white spot lesions, tetracycline stains, erosion, fluorosis and Turner’s tooth, with appliances, undergoing orthodontic treatment, Restorations and Crowns on any of the first permanent molars and incisors were excluded. Ethical clearance was obtained from the Institutional Review Board of Coorg Institute of Dental Sciences, Virajpet. Diagnosis of MIH was done using EAPD Criteria 2003.

An examination for MIH should be performed on wet teeth after cleaning. Teeth to be examined are the 4 first permanent molars (occlusal, buccal, lingual/palatal surfaces) and 8 permanent incisors (incisal, labial, lingual/palatal surfaces) following Type III Clinical examination with adequate natural light. The oral examination of all the study subjects was carried out by a single investigator. Each participant was meticulously examined and the findings were compared to know the diagnostic variability agreement. The agreement was found to be 80%.  

The data was collected and transferred from pre-coded proforma to computer. The data will be analyzed using SPSS (IBM) version 23. Descriptive statistics included mean, standard Deviation, Frequency and Percentage. Inferential statistics included Chi square test. The level of significance was set at 0.05 at 95% confidence intervals.  

Results  

Distribution of study subjects comprised a total of 1600 (100%) participants. Among them, 786 (49.1%) were males and 814 (50.9%) were females. MIH was found to be present in 210 (13.12%) subjects and the rest 1390 (86.87%) subjects were unaffected. Among
210 subjects affected with MIH, 58 (14%) subjects were 9 years, 60 (15%) subjects were 10 years, 49 (12.25%) subjects were 11 years and 43 (10.75%) subjects were 12 years of age.

Discussion

The study recruited children aged 9 to 12 years for the assessment of MIH. Garg N et al\textsuperscript{12} stated that at this age, most children would have had all four first permanent molars and the majority of incisors, but these teeth would not have been exposed to the oral environment long enough to develop dental caries.

In the present study, prevalence of MIH was 13.12% among 9-12 year old children. This is in accordance with the study conducted by P.C. Calderara\textsuperscript{13} among school children aged 7.3–8.3 years living in Lissone, Northern Italy, wherein the prevalence of MIH was 13.7%. In a study conducted by Sulaiman Mohammed Allazzam\textsuperscript{14} in Jeddah, Saudi Arabia, prevalence of MIH was 8.6% among a group of 8-12-year-old children. In a study conducted by Rahil Ahmadi\textsuperscript{15}, the prevalence of MIH in a group of Iranian children aged 7-9 years was 12.7%. A study conducted by H.T
in Mangalore, Karnataka among 6-12 year school children, prevalence of MIH was found to be 17.2%. In a study conducted by ShubhaArehalli Bhaskar¹⁶ done among school children aged 8-13 years from Udaipur, Rajasthan, MIH prevalence was 8.9%. The prevalence in another study conducted by M Kirthiga et al⁴ among children aged 11-16 years of a city in Karnataka, Davangere was 8.9%. According to study conducted by SavithaDeepthiYannam et al¹¹ in the child population aged between 8-12 years residing in Chennai, the prevalence of MIH was 9.7%. The study conducted by Cervantes Mendez MJ et al¹⁷, in South Texas, among 6-14 years subjects showed a prevalence rate of 29.5% which is on the higher side. According to Cho Syet al¹⁸, the difference in MIH prevalence seen in various parts of the world may be due to the heterogeneity in ethnic and age groups being studied and the retrospective nature of the studies conducted.

In the present study, 10 year old subjects showed comparatively higher prevalence (15%) than the other age groups and the least prevalence of MIH (10.75%) was seen in 12 year old children. These results are in accordance with the study conducted by SavithaDeepthiYannam¹¹ among the age group of 8-12 years, wherein the prevalence of MIH was highest among 10-year-old children (12.9%) and least prevalence of MIH (7.4%) was seen in 12-year old children. In a study conducted by Cristiane Maria Da Costa-Silva et al¹⁹,there was a higher prevalence among children with 10 years old or older (16.6%).

In the present study, it was observed that maxillary molars were more effected as compared to maxillary incisors, but the difference was not statistically significant (p=0.728). This could be explained by the contribution of Lunt and Law²⁰ who modified the chronology of the deciduous human dentition and concluded that maxillary teeth are generally ahead of the mandibular teeth in development.

**Conclusion**

Recent research supports the assumption that MIH is a widespread problem all over the world. Findings from the present study show the following:

- The prevalence of MIH in 9–12-year-old children is 13.12 % with no gender predilection.
- 10 year old children showed the highest prevalence (15%) among all the age group.
- Majority of children with MIH (70.2%) have lesions in both molars and incisors with demarcated opacities and atypical restorations being the most frequent defect type.

Hence, it appears that this condition is more prevalent than was recognized until recently. Assuming the low awareness of this condition among the dentists and general population of India, the demanding nature and the costs involved, the urgent need for further investigations into this problem becomes clearly evident. A diligent follow up and recall program for children who are affected is essential for developing preventive and therapeutic measures. There is also a need for formulating public awareness and prevention programs. A nationwide survey to find the prevalence of MIH is recommended.

Self Reported Oral Pain and Dysfunctions Associated with Radiation Induced Oral Mucositis among Head and Neck Cancer Patients: A Prospective Observational Study

Prabha Lis Thomas¹, Harmeet Kaur², Karthik S. Rishi³

¹Research Scholar, Vice Principal Krupanidhi College of Nursing, Chikkabellandur, Carmelaram, Bangalore, ²Principal, Chitkara School of Health Sciences, Chitkara University, Punjab, ³MBBS, MD, DNB Radiotherapy, Consultant, Radiation Oncology, Sri Shankara Cancer Hospital and Research Centre, Bangalore

Abstract

Objectives: This study aimed at identifying and describing self reported oral pain and dysfunctions associated with oral mucositis among patients with head and neck cancer treated with radiation.

Method: A prospective observational study was conducted on 30 head and neck cancer patients who were undergoing radiation therapy and consented to participate. Data was collected by using a baseline proforma, WHO Oral Toxicity scale and Patient reported oral mucositis symptom scale. The patients were followed up during the entire course of radiation therapy and were monitored for the development of oral mucositis and were asked to rate their pain and associated dysfunctions on 100 mm scale.

Result: The present study findings revealed that all the subjects developed oral mucositis at the end of third week which was progressed to grade 3 or 4 mucositis by the end of therapy. The scores of oral pain and oral dysfunctions were progressively increased during the course of treatment with its peak at the end of treatment. Cumulative dose of radiation therapy and receipt of concurrent chemotherapy were found to have a significant association with oral dysfunction. The study also noted a significant positive correlation with severity of mucositis and oral dysfunctions.

Conclusion: Severe and painful oral mucositis is a dose limiting adverse effect of radiation therapy and its detrimental effect on oral functions is significant. Hence adequate preventive measures of mucositis to be identified to enhance the quality of life of head and neck cancer patients receiving radiation therapy.

Keywords: Oral pain, oral dysfunctions, head and neck cancer patients.
often progresses to skin loss and ulceration. Ulcers are typically covered by a white pseudo membrane\textsuperscript{2, 3}.

Mucositis is a clinical challenge with an incidence of 36-100\% among head and neck cancer patients receiving radiation therapy\textsuperscript{4} and is a major burden on head and neck cancer patients as it adversely affects the oral functions. Oral pain associated with radiation therapy induced mucositis is a significant contributor to emotional distress and often leads to lower food intake potentially resulting in undernourishment and weight loss\textsuperscript{5}. In radiotherapy-induced mucositis, the pain intensity escalates at week 3, peaking at week 5 and persists for weeks. Pain is intense and interferes with oral functions\textsuperscript{6} and results in dry mouth, dysgeusia, dysphagia, altered speech, and chewing or eating difficulties\textsuperscript{7}.

Oral mucositis, pain, dysphagia, and altered taste perception may lead to loss of appetite, malnutrition, reduced treatment compliance and radiation treatment breaks with a possible interference on tumour control. A systematic review conducted on literature on pain in chemoradiotherapy treated head and neck cancer patients reported that mucositis pain is frequent (80\%), and interfere with daily activities (40\%) and social activities (60\%)\textsuperscript{8}. These consequences greatly affect the patient’s total quality of life\textsuperscript{9} and may lead to severe disability which can increase the costs of care, tube feeding, extended hospitalization, or unanticipated re-hospitalization, and can cause modification to or interruption of the cancer therapy itself\textsuperscript{10}.

Hence an investigation of self reported oral pain and oral dysfunctions associated with radiation induced oral mucositis could help to reduce the patients anxiety by explaining them how the oral pain will affect their oral function. Addressing the patient reported clinical outcomes during cancer therapy helps the care givers to identify and institute possible novel protocols for reducing and managing the complications during head and neck irradiation.

**Method**

**Population and sampling of study:** The study employed a descriptive approach and 30 histopathologically confirmed patients of head and neck cancer scheduled to receive radiotherapy at Sri Shankara Cancer and research institute, Bangalore were selected randomly as per the inclusion criteria. Exclusion criteria included patients younger than 18 years, patients who had oral surgery within the previous 6 weeks, and patients with co morbid conditions. The study was approved by the hospital ethical committee. Informed written consent was obtained from the subjects and the subjects were followed up during the entire course of radiation therapy.

**Data collection method:** Base line Performa was used to collect demographic data and the clinical data regarding the site of cancer, daily and cumulative dose of radiation therapy, type of chemotherapy medications were obtained from the subjects’ medical records. The clinical manifestations of oral mucositis was evaluated by WHO toxicity criteria every week till the end of radiation therapy and was graded in to 4 categories ranging from 0-4 based on soreness, erythema, presence of ulcerations, ability to swallow solid food and the extent to which alimentation is not possible. At each clinical examination the participants completed a Patient reported oral mucositis symptom scale (PROMS) to appraise how oral mucositis affected common oral functions. The PROMS scale consists of 10 questions that are answered on a visual analogue scale (VAS), by setting a mark on each horizontal line measuring 100 mm. Two questions focused on mouth pain and change in taste and the other 8 questions focused on how much their mouth sores affected different oral functions on the day of the clinical examination.

**Data analysis:** The data were typed into spreadsheet and SPSS (Statistical package for Social Science, IBM Corporation) version 23 was used for statistical analysis. Descriptive statistics using frequency, mean and standard deviation were employed to summarize the demographic and clinical characteristics of the participants and severity of oral pain and dysfunctions. Chi square test was computed to determine the association between oral dysfunctions and clinical characteristics. Spearman rank correlation was computed to identify the correlation between oral mucositis and oral dysfunctions.

**Results**

**Description of characteristics of the subjects:** A total of 30 patients who fulfilled the eligibility criteria were included in the study and the study comprised of 77\% males. The mean age was 60.9 years and 23\% of them were educated up to higher secondary. The participants were diagnosed with carcinoma of oral cavity (63\%), Laryngeal cavity (23\%) and pharyngeal cavity (13\%). A high proportion of tumours were classified as T2 (44\%), followed by T3 (30\%); T4 (23\%) and T1...
(3%) and 92% of the subjects had undergone surgical resection of the primary tumours site. Majority (47%) of the patients received a cumulative dose of 70 Gy and a fractionated dose of 2Gy per day (73%). 46.66% of the subjects received concurrent chemotherapy during radiation therapy and all of them received Cisplatin and 5 Fluorouracil.

**Onset and severity of oral mucositis:** The analysis revealed that the early manifestations of oral mucositis (grade 1 or grade 2) appeared in 43% of the patients by the end of first week and all the subjects developed Radiation induced oral Mucositis at the end of third week. Grade 3 or 4 mucositis was present in all the subjects by seven weeks and Ryles tube feeding was initiated for 4 subjects who developed grade 4 mucositis. (Fig 1). The cheeks, lower lip and ventral and lateral tongue were the predominant sites of ulceration. Mean mucositis score was increased from 0 at baseline to 3.4 ± 0.31 at the end of the treatment. (Fig 2).

![Percentage of radiation induced oral mucositis](image1)

**Fig 1:** Onset and severity of radiation induced mucositis

![Percentage of radiation induced oral mucositis](image2)

**Fig 2:** Mean mucositis scores during the course of radiation therapy
Oral pain and oral dysfunctions associated with radiation induced oral mucositis: The scores of all the ten components of PROMS increased gradually during the cancer treatment period. Oral pain scores associated with mucositis were progressively increased from 17.3± 1.53 at the end of first week to 75.45 ± 1.95 at the end of seven weeks. Ninety percent of the subjects (n=27) were taking analgesic medication more or less constantly during the course of radiation therapy and despite this medication the participants reported consistently increasing pain score throughout the entire period of radiation therapy. Difficulty eating hard foods, Change of taste and difficulty in swallowing were considerably more affected by oral mucositis than the other components of the Patient reported oral mucositis symptoms scale (Table.1)

Discussion

Head and neck irradiation is often accompanied by significant and profound acute oral mucositis which adversely affects many of the oral functions. Clinical significance of oral mucositis is attributed to a complex interaction of the patient’s perception of the altered oral function\textsuperscript{11}. The present study observed that all the subjects developed oral mucositis by the end of 3rd week and intensified in severity by sixth or seventh week of radiation therapy. This finding supports the previous findings that oral mucositis is a distressing condition which is observed at the first week of head and neck irradiation and reaches its maximum intensity at the end of the treatment\textsuperscript{12}.

The suffering caused by oral mucositis is multifaceted. Pain due to oral mucositis is the most frequently reported patient related complaint affecting quality of life\textsuperscript{9}. In the present study the subjects reported a consistently increasing pain score during the course of radiation therapy despite the intake of analgesics. These findings corroborates the observations made by a previous prospective observational study conducted on head and neck cancer patients which reported a poor pain control and high intake of analgesics during radiation therapy indicating neuropathic nature of pain which adversely affect activities of daily living and require a greater dose of analgesics\textsuperscript{13}.

Severe and painful oral mucositis is associated with a high level of oral dysfunctions and in general, the most common presentations of oral mucositis-related dysfunction are dysphagia, changes in food tastes, dry mouth, eating and drinking difficulties and inability to speak\textsuperscript{12,14}. It is observed in the current study that the oral functions eating, drinking, swallowing, speaking and sense of taste were affected and change of taste, difficulty eating hard foods and difficulty in swallowing were the most affected dysfunctions. Previous studies have reported similar findings that dysphagia (88%), change of taste (92%)\textsuperscript{12}, and difficulty in eating solids (90%)\textsuperscript{13,15} were the most prevalent oral dysfunctions among patients during head and neck irradiation. A cumulative dose of more than 30 Gy can cause damage to the taste buds and salivary glands and impairs the individual’s ability to detect basic tastes (sweetness, sourness, saltiness, and bitterness)\textsuperscript{16}. Dysphagia combined with loss of taste can interfere with the patients’ food and fluid intake with significant weight loss and malnutrition\textsuperscript{12}.

Cumulative radiation dose and receipt of concurrent chemotherapy were found to have a significant association with the severity of oral dysfunctions (p =0.01) and the study also observed a significant positive correlation between mucositis and oral dysfunctions. Similar findings have been reported in a cross sectional study on eighty eight head and neck cancer patients with oral mucositis receiving cancer therapy in which intensity of oral mucositis were significantly correlated with distress score of oral dysfunction (r = .791, P < 001), dysphagia (r = .513, P < 001) and loss of taste (r = .578, P < 01)\textsuperscript{12}. The findings indicate that oral mucositis adversely affects oral functions and an altered oral function is common sequelae of oral mucositis.

The current study is limited to a small sample size of 30 and to a single setting. The study was aimed to quantify the severity of oral dysfunctions perceived by head and neck cancer patients during radiation therapy and hence did not involve any objective measurement of these dysfunctions.

Conclusion

The findings have demonstrated that the intensity of oral dysfunction during head and neck irradiation were moderately high from the patients’ point of view and hence increased attention and treatment of oral dysfunctions are essential to achieve the best outcomes of cancer therapies.

Conflict of Interest: The authors declare no conflict of interest.

Ethical Clearance: The study was approved by the hospital ethical committee. Patients and their caregivers indicated their willingness to participate in the study after the details of the study had been explained to them. The subjects were also informed that they had the right to withdraw from the study at any time during the course of the study and written informed consent was obtained from them.

Asituational Analysis of Oral Health Programs in the Primary Schools of Pune City (India)

Saurabh P. Kakade¹, Sahana Hegde-Shetiya², Ravi V. Shirahatti³, Deepti Agrawal³, Pradnya Kakodkar⁴

¹Senior Lecturer, Bhartiya Vidyapeeth, Dental College and Hospital, Pune, ²Prof & Head, ³Ex-Lecturer, ⁴Professor, Department of Public Health Dentistry, Dr. D.Y. Patil Vidyapeeth, Dr. D.Y. Patil Dental College, Pimpri, Pune

Abstract

Objective: To evaluate (situational analysis) the status of oral health programs in the primary schools of Pune city.

Method: A cross sectional questionnaire study was conducted among the principals of the primary schools. A structured set of 16 questions were designed for the three domains of school oral health program. The choices of the questions were based on the 5 point Likert scale. 85 schools from Pune were selected for the study.

Results: 65 schools responded for the study, yielding a response rate of 76.4%. Majority of the school health care provided was in the form of health and oral health check up. The teacher (47.7%) and physical education teacher (12.3%) were mostly involved in coordinating school oral health care program. 93.9% of the schools have reported that their school have guidelines regarding oral health services for school children. Almost 89.2% schools have banned tobacco use among their teaching and non-teaching staff. Teachers (72.3%) and government (73.8%) are reported to play a key role in oral health program/policies to be implemented in the school. The principals reported positively to all the healthful school living statements.

Conclusion: The school health programs are being functionally conducted in majority of schools but hardly there are any services being provided for oral health.

Keywords: School oral health program, children, oral health, school services.

Introduction

Though there has been considerable improvement in the oral health of children in the last few decades, dental caries remains one of the most commonly occurring oral health problems in the children all over the globe.¹ There is no single country that claims to have caries free children.² Adverse dental experience during childhood can lead to phobia and further impact their attitude towards oral health in the adult life.

According to the literature, the services of special oral health workers, dental hygienists, school teachers and parents for oral health education of the school children have proven to be an effective method for prevention of various oro-dental problems.³-⁶ School-based oral health programs are one way to ensure equal access to oral health services for all children. However these services have not developed and remain a neglected area⁷. In India, over the years umpteen number of health check-ups and dental check-ups in the schools have been carried out and voluminous data is collected, conversely without any action resulting in oro-dental problems to be the leading cause of morbidity in primary school children⁸. School oral health programs include three important elements: school oral services, school health education and healthful school living.

Pune (Maharashtra, India) is referred as “The Oxford of the East” due to the well-known academic and
research institution. Owing to this background, a need was felt to understand whether such upright scenario is also seen with regards school oral health programs. Hence, this present study is conducted to evaluate (situational analysis) the oral health program in the primary schools of Pune city.

**Material and Method**

A total of 192 primary schools under the Education Department of Pune Municipal Corporation Jurisdiction and 391 private primary schools in Pune city were considered. Out of the 583 schools, 85 schools were recruited for the study using convenience sampling.

The situational analysis was conducted by interviewing the school principal to evaluate their perception about school oral health programs. A structured set of questions were designed for the three domains of school oral health program. 9 questions were designed for the combined domain of school oral health services and school oral health education. Each question had a fixed set of choices which the principals had to choose except for question no 1b which was open ended. 7 questions were separately designed for the domain of healthful school living. The choices of the questions were based on the 5 point Likert scale.

The participants were included in the study on giving written consent. Their participation was voluntary and assurance of confidentiality of the collected information was given.

**Results**

85 primary schools of Pune city were contacted, but only 65 schools were willing to participate, 12 schools were not willing and 8 schools did not respond. The response rate was 76.4%. The results are presented in Table 1 and 2.

**Table:1 Perceptions of school Principals regarding “School oral health services” and “School oral health education”.

Discussion

In India, there is no school oral health policy. Major part of the work in this area is because of the Department of Public Health Dentistry and Pedodontics which conduct dental screening and treatment camp or undertake school projects as part of postgraduate student dissertation. While some NGO’s work in this area and meagre number of schools take interest and arrange for school dental program. Bright Smile Bright future program organized by the IDA and Colgate Palmolive Pvt Ltd under the aegis of NOHCP is mounted since July 2003 targeting 45 lakh school children across India. In this program it has been ritual to distribute colgate toothpaste and brush to children and conduct teacher training program using imported charts and visuals and alien films. The program does not ensure any follow up or maintenance of data. It is criticized and called an advertisement gimmick of the colgate product rather than actual oral health benefitting program. Since, 2014 IAPHD has initiated national toothbrushing program to be conducted on 7th November of every year and appealed to all the dental colleges to promote this activity. In a nutshell, this is the reality prevailing regarding school oral health services.

The schools actually provide a valuable site for community based education. School oral health service is totally a virgin soil; anything invested would certainly bear the fruits. But in Pune also, the situation is discouraging. Out of the 65 schools, analyzed in the study, 42 schools do not have any provision, while 23 schools have tried to provide oral health services and they have taken help of different organization, while five schools have appointed a dentist. The sample of the study is a mix of private and government school principals. The majority are from the government school where no school program exists. It is because they have no policy and directive to start school oral health program, there is lack of funds and neither the health nor education department has taken any initiative for implementing school oral health programs. Some of the private schools do not have school oral health program. This is because, they give more stress on the academic activities and do not have any stipulated time in their calendar to conduct oral health activities. The school programs conducted are majorly for general health screening followed by oral health. None of the schools conduct any primary preventive school programs like the pit and fissure sealant, topical fluoride application and mouth washing program.

School teachers may be utilized as good medium for oral health promotion among school children in India and other developing countries. In the present study teachers were majorly responsible for co-ordinating the oral health programs. A Primary Preventive Dental Health Education Programme implemented through school teachers for primary school children resulted in bringing about an enhancement in the KAP towards oral health and also an improvement in dental caries, oral hygiene, and gingival health status of the school children. As the teachers are in constant, contact with the children, they are in a position to notice any deviation of the children from their normal health and behaviour. Further, teachers words are highly valued by the school children. Byalakere R et al recommends training the teachers on short term basis which is to be included.
in their curriculum regarding how to provide dental health education to students and perform screening for any gross deposits of food and calculus. This can bring about a change in oral hygiene behavior which in turn can bring about a change in lifestyle practices.

It has been found that, there is involvement of health care providers in school health services in Kendriya Vidyalaya, while in other schools the health services are provided by the NGO’s who are contracted for a short time, but carry out only medical examination of students.

Only, 59.60% arrange for school oral health education program. Health education is an essential aspect of oral health promotion. It is one of the cost-effective oral health programs aimed at prevention of oral diseases and promotion of good oral health. Gambhir RS et al conducted a systematic review on the impact of school based oral health education programs in India and concluded that the most favorable environment to impart oral health education to children is schools and that there is a positive outcome of the school dental health education programs with respect to plaque, gingival health and dental caries. Studies recommend utilizing teachers to improve the oral health of the children.

The present study results indicate that the government (73.8%) and teachers (72.3%) should play a key role in oral health programs and the policies being implemented in the schools. Unfortunately, oral health is given last priority by policy makers in India. The relevant authorities are inadequately informed about the burden of dental problems and its association with systemic health.

Though majority of principals responded that the law is being implemented regarding ban of sale of tobacco products in and around the school premises (64.6%). Majority of the principals responded that ban on use of tobacco use by the teaching and non-teaching staff is not implemented 100%; school authorities should be held responsible for the above as, Ministry of Health and Family welfare, Government of India says that school authorities should be held responsible if not implemented and it has provided anti-tobacco cell with a toll free number across India to report about violation of this law. Secondly, it is the prime duty of teachers and non-teaching staff of being a good role model and students would like to emulate them.

The principals have positively responded for all the seven questions under the Healthful school living. Majority of the principals felt that it is important to have control over unhealthy food served in the school canteens but again the percentage of responses is low; teachers and principals may feel that it is not their responsibility of what the schoolchildren should eat, as it is totally dependent on parents. Secondly, there are no such regulations from the government on what is to be served and kept for sale in school canteens. Sale of healthy and nutritious food should be promoted in schools, as it is being laid down in the pilot project. Pictorial statutory warnings stating that “sweets can cause tooth decay” to be made compulsory on the confectionary wrappers and promotion of tooth friendly sweets.

Overall, the survey indicates that very little is been done in the area of school oral health programs. There is a need to create awareness regarding the importance of school oral health activities so that the dental burden can be addressed at the very initial stages. Schools are the ideal places for such activities and the school authorities and the government can take steps to strengthen this area.

Conclusion

This questionnaire based study concluded that oral health programs are functionally conducted in majority of schools but hardly there are any services being provided for oral health. There are no guidelines and the principal feel that it is the responsibility of the teachers and government majorly. It will be very beneficial to the children and their parents, if school based oral health programs are started.

Abstract

Human growth is very complex in nature characterised by considerable variation in an individual’s rate of physiologic and skeletal maturity. Variability is the law of nature because of infinite number of genetic possibilities present. No individuals are ever exactly alike. The growth factor is a critical variable in orthodontic diagnosis and treatment planning. Predicting the outcome of treatment results in a growing patient is often more difficult than in a non growing patient. Prior knowledge of the amount along with rate, timing and direction of maxilla–mandibular growth in any given patient would be extremely useful for forecasting treatment outcome.

Skillful evaluation of growth left in a patient makes a difference in such growth modulations. Having an intrinsic indicator could be a boon for the clinician. Hence the search for such an intrinsic indicator was initiated in this study.

Keywords: Mandibular Corpus Index; Cervical Vertbral Maturation stage; CBCT; Skeletal Maturity of the mandible.

Introduction

Human growth is very complex in nature characterised by considerable variation in an individual’s rate of physiologic and skeletal maturity. Variability is the law of nature because of infinite number of genetic possibilities present. No individuals are ever exactly alike.

The growth factor is a critical variable in orthodontic diagnosis and treatment planning. Predicting the outcome of treatment results in a growing patient is often more difficult than in a non growing patient. Prior knowledge of the amount along with rate, timing and direction of maxilla–mandibular growth in any given patient would be extremely useful for forecasting treatment outcome.

As Scammon has shown in his growth curves that the brain and the central nervous system grows faster than the muscular and skeletal elements. The overall pattern of growth is the reflection of the growth of various tissues making up the whole organism. This phenomenon is seen not only with different tissue systems but also with in each system too. The skeletal system undergoes similar spurts of growth rate, amount direction and timing of growth which differ from one bone to another.

A number of methods have been developed for the estimation of skeletal maturity. Nanda⁶, Hunter¹³, Bjork², Brown and Bishara all used body height as a measure of general skeletal maturation when discussing the timing of mandibular growth. Johnston, Bergersen¹, Grave¹⁰, Piteski and Fishman⁸ related facial growth to hand wrist growth. Hagg¹¹, Lewis and Derinjian all used sexual maturity as their scale to evaluate craniofacial growth.

Chertkow, Engstrom and Coutinho used the teeth such as the canine, lower premolars and third molars as dental indicators of skeletal maturity. Lamparski used the cervical vertebrae to assess skeletal age and O’Reilly studied growth of the cervical vertebrae as it relates to the mandibular growth. The mandible is the longest and strongest bone in the face. Variations in the mandibular morphology, which is prone to ontogenic and phylogenetic changes contribute significantly to most of the mal occlusions.

The mandible is an intra membranous bone which also has a cartilaginous head. Mandibular growth has shown to be controllable by various growth modulation procedures. Various parameters have been used to predict mandibular growth. Bjork used implants to describe multiple structural signs seen in extreme types of mandibular rotations. Jarabak used cephalometric analyses to predict direction of mandibular growth rotation. Skieller predicted the direction of mandibular growth using four variables (mandibular inclination, intermolar angle, shape of lower border and inclination of symphysis).

Ricketts used the mandibular symphysis to predict mandibular growth .Aki et al predicted the direction of mandibular growth using the morphological characteristics of the symphysis. The growth of the mandible occurs in several principle directions. Increase in width, height and depth occurs simultaneously .

The terminal growth of the mandible can be utilised in various growth modulation procedures. Having an intrinsic indicator could be a boon for the clinician. Hence the search for such an intrinsic indicator was initiated in this study.

**Materials and Method**

This cross sectional study was based on 60 individuals, who consisted of Group A 30 males and Group B 30 females who were of good health, physically and mentally. None of them had any developmental disorders. The subjects were within age group of 8-16 years. Standardised lateral cephalometric radiographs were taken from the left side of all the individuals by a PM 2002 Cephalostat on a 8” by 10” Kodak X–Omat K X K-5 dental film.. The transverse slicing section were obtained in the pre molar region of all the individuals using CBCT (Figure 4).

**Measurements:** Various measurements recorded were a) The Ascending Ramus Length (Ar-Go) b) The Mandibular Corpus length (go-gn) c) Total mandibular length (Co-Gn) (figure 1) The dimensions of the transverse slicing section of the mandible were measured in the following method. The outline of the mandibular corpus was traced, the buccal cortex, lingual cortex and lower border were measured and recorded. Then a line joining the buccal and lingual alveolar crest line was made, a grid was formed with lines of the grid parallel and perpendicular to the constructed alveolar crest line.

The superior line was taken as the alveolar crest line and inferior anterior and posterior limits were taken at the most inferior, anterior and posterior borders of the transverse section of the mandibular corpus. The measurement taken were a) Buccal cortical thickness (BCC) b) Lingual cortical thickness (LCC) c) Lower border thickness (LBC) d) Mandibular corpus height (HC) the linear distance between the superior and inferior limit of the grid e) Mandibular corpus depth (DC)the linear distance between the anterior and posterior limit of the grid f) Corpus ratio–(H/D) corpus height divided by corpus depth(figure 2)

**Cervical Vertebrae Assessment:** Cervical vertebrae development of the sample was evaluated by Hassel and Farman modifications of Lamparskis criteria which assess maturation changes of the second, third and fourth cervical vertebrae. The sample was divided into distinct stages according to this.

**Findings:** The results include the values of Thickness of buccal cortex, lingual cortex and lower border and the height and width of the symphysis.

The height, width and height width ratio of the mandibular corpus were compared with the lengths of the ramus, mandibular corpus and the effective length of the mandible.

**Intrinsic Indicator Scoring:** Group A The mean height–width ratio for the stage of acceleration was 1.81+0.08 The mean height–width ratio for the stage of transition was 2.05+0.02 The mean height–width ratio for the stage of deceleration was 2.15+0.01 The mean height–width ratio for the stage of maturation was 2.35+ 0.01 The mean height–width ratio for the stage of completion was 2.56+ 0.02.
GROUP B The mean height–width ratio for the stage of acceleration was 1.81 + 0.03 The mean height–width ratio for the stage of transition was 2.06 + 0.03 The mean height–width ratio for the stage of deceleration was 2.15 + 0.03 The mean height–width ratio for the stage of maturation was 2.36 + 0.02 The mean height–width ratio for the stage of completion was 2.53 + 0.01

Discussion

In the growing years skeletal indicators of the level of maturational development of an individual provide the best means of evaluating biologic age. The skeletal maturity was found to have a definite correlation with craniofacial skeletal growth and is a critical factor in orthodontics.

Numerous method have been employed for the study of skeletal maturation over the years. The simplest of them is the use of standing body height as a measure of general skeletal maturation. Even though correlation between craniofacial growth and standing height have also been studied and positive correlation found at most levels of maturation, the use of standing height to assess skeletal maturity how ever has been inadequate.

Lamparski\textsuperscript{15} in 1972 was the first person to study cervical vertebrae and he found them to be as reliable as a hand wrist film. He developed a series of standard for assessing skeletal age in both females and males based on cervical vertebrae. It was O’Reilly\textsuperscript{17} in 1988 who related mandibular growth changes to maturation of cervical vertebrae maturation.

The area used to calculate the corpus index was the premolar region. Only the left side was taken to standardize the study. The premolar region was taken because in various studies\textsuperscript{21,14} under it was observed that its proportion of cortical bone and trabecular bone corresponds well with bone mass in the cortical bones of the skeleton.

The intrinsic indicator (corpus index) was calculated by dividing the height by width of the corpus. To determine the height and width of the corpus firstly, a line was drawn joining the buccal and lingual alveolar crest. A grid was constructed with lines parallel and perpendicular to alveolar crest line.

The linear distance between the superior and inferior limit of the grid was taken as the corpus height and the linear distance between the anterior and posterior limit of the grid was taken as the corpus width. A definite curvi linear increase was observed between the values of mandibular corpus index and the effective mandibular length.

A similar increase of corpus index was observed corresponding with each stage of cervical vertebrae maturation. A definite intrinsic indicator scoring (corpus index) was observed with each stage. According to Hassel and Farman’s\textsuperscript{12} description of the cervical vertebrae maturation stages, 65% to 85% of remaining pubertal growth is estimated at the acceleration stage(Figure 3). Hence it was observed that a corpus index scoring of 1.81 (average effective mandibular length of 101 mm) represent a remaining pubertal growth potential of 65% to 85% present, like wise a scoring of 2.05 (corresponding to transition), (2.15 corresponding to deceleration), (2.35 corresponding to maturation) represents a remaining growth potential of respectively of each stage. Similarly a corpus index scoring of 2.56 (average effective mandibular length of 121 mm) represents completion of the pubertal growth. The mandible where the greatest growth occurs in the craniofacial region is also the strongest and largest bone in the face.

As the cephalo caudal gradient of growth shows the mandible being further away from the brain grows for a longer time and more than the maxilla. This growth can be utilised for various growth modulation procedures to successfully correct jaw discrepancies in an early age of itself. Unfortunately untimely treatment may lead to relapse due to continual growth of the mandible. Hence a reliable indicator for estimation of the skeletal maturation is essential for successful treatment.

Orthopaedic treatment can be accomplished when the patients shows a corpus index score of 1.81 (corresponds to acceleration phase of cervical vertebrae maturation) as there is good amount of adolescent growth potential still left. The same is difficult to accomplish during the stage of transition which shows a corpus score of 2.05 where in probably fixed functional orthopaedic treatment can be accomplished successfully.

Once the patient reaches a score 2.15 the end of transition stage and start of deceleration stage orthopaedic appliances can bring only minimal skeletal changes and more of dental changes. The same becomes unrealistic when the score reaches 2.35 corresponding to the stage of maturation where the bone is completely matured.
Carrying out dentofacial orthopaedic treatment when the score is 2.5 is not possible as growth phase is completed and orthopaedic remodelling cannot be attained.

Hence it is advisable to treat with dentofacial orthopaedic appliances till a score of after which the patient should undergo orthodontic treatment alone or surgical orthodontic intervention depending on the magnitude of discrepancy. There is definitely a need for further study with a larger sample as it can show much higher correlation than the reading we have seen in this study and hence can confirm to say it is a better method of skeletal maturation indication.

The need for longitudinal study is necessary and if done will be useful and appreciated. This is because it is more reliable than a cross-sectional study. In a cross-sectional study the amount of variation is too much such as the socio-economic status, nutritional status can vary very much in individuals. But whereas in a longitudinal study the samples being the same the degree of variation is much less or negotiable.

![Figure 1: Mandibular Corpus Length](image1)

![Figure 2: Mandibular Corpus Height/Width](image2)
Figure 3: Cervical Vertbral Maturational Stages (CVM)

Figure 4: CBCT Slice of the Mandible

Conclusion

This study presents some of the basic relationships associated with skeletal maturation during the growing phase, with a new technique of skeletal maturation assessment. We have utilized the transverse slicing sections of the mandible taken with CBCT to facilitate the evaluation of maturational developmental.

The results of this study provide evidence that there is a significant and relatively simple relationship between structures of the mandibular body and its maturity. These findings demonstrated the validity of the method of use of an intrinsic indicator such as the corpus index for the evaluation of skeletal maturity.

Further observations showed that with increase in mandibular growth there was a subsequent increase in the mandibular corpus index. Mandibular corpus index value showed a definite score for each stage of cervical vertebrae maturation showing a gradual increase with each stage. No significant differences were observed between group A (males) and group B (females) values of the corpus measurements.

Intrinsic Indicator (Corpus Index) Scores Were

Group A (Boys) The mean height–width ratio for the stage of acceleration was 1.81+ 0.08 The mean height–width ratio for the stage of transition was 2.05+ 0.02 The mean height–width ratio for the stage of deceleration was 2.15+ 0.01 The mean height–width ratio for the stage of maturation was 2.35+ 0.01 The mean height–width ratio for the stage of completion was 2.56+ 0.02.

Group B (GIRLS) The mean height–width ratio for the stage of acceleration was 1.81+0.03 The mean height–width ratio for the stage of transition was 2.06+0.03 The mean height–width ratio for the stage of deceleration was 2.15+0.03 The mean height–width ratio for the stage of maturation was 2.36+0.02 The mean height–width ratio for the stage of completion was 2.53+0.01.

Status and Effectiveness of Implementation of Weekly Iron and Folic Acid Supplementation Scheme in Schools in Central India

Prasoon Shrivastava¹, Chetna Maliye²

¹Assistant Professor, Department of Community Medicine, Sukh sagar Medical Collage and Hospitals, Jabalpur M.P., ²Professor, Department of Community Medicine, Sushila Nayar School of Public Health, Mahatma Gandhi Institute of Medical Sciences, Sevagram, Wardha, Maharashtra, India

Abstract

Objective:
1. To study the coverage of weekly iron folic acid supplementation scheme in schools of Wardha block.
2. To know about prevalence of anaemia among students benefitting with WIFS (WIFS group) and those who are not getting benefit from WIFS (Non WIFS group)
3. To study the factors affecting the implementation of the scheme.

Study design: Study was conducted in adolescents of rural schools of Wardha Block. Mixed method was used for the study. During the first stage both Quantitative and Qualitative technique (In-depth interview) was used to collect information about implementation of the Weekly IFA supplementation scheme in various schools. Second stage study was a cross-sectional study to assess the prevalence of anemia among WIFS group and Non WIFS group. In-depth interviews of key holders like medical officers of concerned schools, district drug distribution incharge and principal of concerned schools were taken to know about the factors affecting scheme implementation.

Results: Coverage of WIFS scheme was found to be 11.54%. The mean haemoglobin level was 11.84 +1.82 mg/dl among WIFS group while the mean haemoglobin levels among Non-WIFS group was 11.8±1.56 mg/dl. These values are not found to be statistically significant. The in-depth interviews led to conclusions regarding lack of monitoring and supervision of the programme, poor supply of WIFS tablets in the district drug store, which leads to further reduction in distribution of tablets to the ANM, lack of training of school teachers regarding drug administration and management of any side-effects, lack of IEC material in the school which may be used to increase compliance and adherence of students towards WIFS.

Conclusion: To gain maximum benefit for such an important and Highly demanding scheme, proper information regarding Weekly Iron Folic acid Supplementation (WIFS) should be communicated by appropriate channels so that awareness about the modus operendi and benefits of the program can reach to beneficiaries. Periodic trainings of teachers and health workers should be held jointly regarding the programme. Supply of medicine should be uninterrupted.

Keywords: WIFS, Anaemia, Adolescents.

Introduction

Around 1.6 billion people, almost a quarter of the world’s population, are anemic¹. Despite considerable economic and scientific advancement during recent decades, only marginal reduction in the global prevalence of anaemia occurs.² The World Health Organization (WHO) estimates that worldwide, 42% of pregnant
women, 30% of non-pregnant women (aged 15 to 50 years), 47% of preschool children (aged 0 to 5 years), and 12.7% of men older than 15 years are anemic.\textsuperscript{2} WHO has also estimated that half of these anaemia cases are due to iron deficiency.\textsuperscript{3,4} Iron deficiency is the most prevalent and also the most neglected nutrient deficiency in the world.\textsuperscript{5}

According to NFHS-III data, over 55% of adolescent boys and girls in the age group of 15-19 years are anaemic. Adolescent girls in particular are more vulnerable to anaemia. To address this problem Ministry of Health & Family Welfare launched Weekly Iron Folic Acid Supplementation Program for Adolescents on 2013, under this supervised IFA supplementation is being given weekly to adolescents. Sessions on Nutrition and Health Education are planned at the schools and Anganwadi centres to inform and counsel adolescents and their care givers on nutrition and related health issues. The program is implemented across the country, covering 13 crore adolescents. The key feature of WIFS is administration of supervised Weekly Iron Folic Acid Supplements of 100mg elemental iron and 500mg Folic acid. Since there are many research studies on prevalence of Irondeficiency anemia among adolescents but very few studies are on program implementation. So this study is to assess the implementation of WIFS programme in Schools in central India.

**Objectives**

1. To study the coverage of weekly iron folic acid supplementation scheme in schools of Wardha block.
2. To know about prevalence of anaemia among students benefitting with WIFS (WIFS group) and those who are not getting benefit from WIFS (Non WIFS group)
3. To study the factors affecting the implementation of the scheme.

**Material and Method**

**Study setting:** Study was conducted in the schools of Wardha block. In first stage List of all schools in rural area of Wardha block was prepared. In all schools a predesigned pretested questionnaire was used to assess the coverage of Weekly IFA supplementation among adolescents. On the basis of coverage of Weekly IFA supplementation, high coverage and low coverage schools was selected for the study to assess the prevalence of anemia among school-going adolescents.

**Study design:** Mixed method was used for the study. During the first stage both Quantitative and Qualitative technique (In-depth interview) was used to collect information about implementation of the Weekly IFA supplementation scheme.

Second stage study was a cross-sectional study to assess the prevalence of anemia among school-going adolescents.

**Study period:** This study was carried out over a period of 1 and half year (2014-16).

**Study subjects:** School going adolescents (10-19 years).

**Sample size:** Considering 50% prevalence of anemia, the sample size required at 5% precision, alpha error of 5% with design effect of 1, was calculated using the Open Epi-software (version 3.01), sample size is 384. A total of 768 students was studied (384 students from schools with high coverage of Weekly IFA supplementation and 384 students with low coverage of IFA supplementation).

**Data Collection:** Coverage of Weekly Iron and Folic acid supplementation was studied using a pre-designed, pre-tested self administered questionnaire. On the basis of coverage, high coverage schools and low coverage schools was selected for the study. Data was collected by interview method using a predesigned and pretested questionnaire. The data collection tool includes socio-demographic profile, dietary history, information on Weekly IFA supplementation, anthropometric measurements, medical history, menstrual history (adolescent girls) and hemoglobin estimation using cyanmethemoglobin method using filter paper technique.

**In-depth Interview of Health-care providers/ School Principal/School teachers:** In-depth interview was conducted to collect information about implementation of the Weekly Iron and Folic Acid supplementation scheme from Health care providers (District RCH officer, Medical officer of Primary Health Centre), Nodal teachers and District level supply officer to study the mechanism of procurement and supply of IFA tablets to the schools using a structured In-depth interview guideline.

The data entry and analysis was done in Epi_Info software (version 6.04d).
Results

1. Coverage of WIFS Supplementation: Coverage of WIFS scheme was found to be 11.54%. Out of 52 rural schools in Wardha block, only 6 schools were found to implement WIFS and in 46 it was not implemented at all. Thus it was found that the coverage of WIFS is very poor in the block.

2. Prevalence of anaemia among the students receiving WIFS and Not receiving WIFS

3. Findings of In-depth interview for studying the factors affecting the implementation of WIFS

In-depth interview was conducted to study the factors affecting the implementation of WIFS. A total of 8 In-depth interviews were conducted using an In-depth interview guide.

The following personnel’s were interviewed:

1. Principal of Schools (4)
2. Medical officer of Primary Health Centre (2)
3. District RCH Officer (1)
4. District Drug store In charge (1)

Findings of In-depth interview with School Principals: In most of the school’s Principal was aware of other programs which were implemented in their school. They also shared that they are notified periodically by their Block Education Officer and ANM regarding any new programme. While in case of WIFS, most of them requires help of other teacher whenever questions regarding WIFS were asked to them. Some were confused between deforming and Iron folic acid tablets. Some Principals were inquisitive to know about WIFS.

Almost all of the schools did not assign any teacher as nodal teacher to manage WIFS. In few of the schools register is maintained by the class teachers for WIFS. In almost all the schools no teacher had participated in any training held for WIFS program in health department, education department or in ICDS. In only one school a teacher was assigned to administer IFA WIFS tablets to adolescents. No committee has been formed for the program separately at school level. Similarly student wise register that meant to be formed for information regarding WIFS is available only in one school.

Almost all the principals responded that they have not received IFA WIFS tablets in the year 2015; they got supply of IFA WIFS only a single time during 2014. Even most of them did not know, from where they receive the supply and where they have to put forth the demand. Principals received a letter from Block Education officer in 2014 to stop administration of WIFS after a few cases of nausea; vomiting and diarrhea which lead to hospitalization in students of one of the block was reported. After that incident IFA WIFS tablets were checked in laboratory and found to be safe for adolescents, but no Principal received any letter to restart the WIFS. No significant health related complaint was noticed by the school teachers in WIFS received adolescents.

On asking for suggestions to improve the programme, most of the Principals told that they are not thoroughly informed regarding newly implemented programmes. One of the Principal told that there teachers are anxious while giving tablets to adolescents because if anything happens to students due to any cause, parents will blame them. Principals also suggested that teachers should be trained to treat minor side effects of IFA tablets. Health education sessions should be organized periodically for students regarding usefulness of WIFS. One of the Principal told that most of the sessions conducted in their schools are focused on hygiene and sanitation, students are not informed or motivated to take WIFS by their own. In one of the school where they administer all the supplied IFA tablets to students, they were unaware about how they indent for more tablets and what the
According to drug store In-charge, they indent IFA got all distributed by 17/06/2014 to all the 27 PHC’s. received on 28/02/2014 of 37,62,000 tablets which this year. The first and only supply of WIFS tablets was no supply of IFA WIFS has been received in the district stock of IFA in district drug store, it was found out that Store In-charge: consumption of IFA tablets by adolescents. they have not observed any serious complication by IFA tablets. Medical Officers of the PHCs also said that there should be demand from the school side for instead of providing in schools. They also suggested that ANM will distribute tablets to pregnant mothers of IFA tablets should be adequate otherwise it’s obvious WIFS, Medical Officer suggested that the regular supply ANM collects IFA tablets from the pharmacist of the PHC. On observing registers from pharmacist, it was found that they did not make a separate entry sheet for WIFS till 2015. They are confused regarding use of WIFS and regular Iron folic acid tablets, since both have same content and also they have not received appropriate information regarding their use. Thus they might supply IFA-WIFS tablets to pregnant women in case of shortage of regular IFA tablets. Meanwhile PHC’s drug registers shows that PHC has not received IFA tablets in 2015. Only IFA tablets for pregnant women are present in the PHCs and pharmacist distributed all the WIFS to the ANM previously. Regarding suggestions to improve WIFS, Medical Officer suggested that the regular supply of IFA tablets should be adequate otherwise it’s obvious that ANM will distribute tablets to pregnant mothers instead of providing in schools. They also suggested that there should be demand from the school side for IFA tablets. Medical Officers of the PHCs also said that they have not observed any serious complication by consumption of IFA tablets by adolescents.

Findings of In-depth interview with District Drug Store In-charge: On collecting information about the stock of IFA in district drug store, it was found out that no supply of IFA WIFS has been received in the district this year. The first and only supply of WIFS tablets was received on 28/02/2014 of 37, 62,000 tablets which got all distributed by 17/06/2014 to all the 27 PHC’s. According to drug store In-charge, they indent IFA tablets with priority every time. They have not received the demands from PHC’s or Education Department. He also narrated similar incident of gastric trouble noticed in schools of one of the block which led to panic among school teachers regarding distribution of IFA tablets to adolescents. According to him it is also one of the reasons for the decrease in demand of IFA WIFS tablets.

Findings of In-depth interview with RCH Officer: RCH officer told that ARSH, WIFS and Menstrual hygiene programme are run by government for adolescents. Except menstrual hygiene programme others programs are running satisfactorily in the district. He was surprised of the fact that WIFS tablets do not reach to schools properly, as they are receiving reports of program running regularly by their field workers as ANM, MPW and HS (health assistants). Also he shared that they cross check the ANM’s information during monthly meetings. On asking for their awareness regarding the stock status in district drug store for WIFS, he confidently told that as far as his information, it is sufficient. Regarding the mechanism through which Principal demands IFA, he replied that school should demand to their respective MO’s of PHC and then from there the demand will reach the drug store. On asking about collaboration between Education Department, ICDS and Health department, he said that there was no meeting conducted. He also told that Education Officer should contact them to get uninterrupted supply of WIFS, but they do not communicate but said that it is essential that the two departments must play an important role for making the program effective. Health department should come forward to create awareness in the schools about complications of IFA supplementation and how to handle if they arose. He also suggested that Education department should consult Health department regarding stocks and any obstructions that they are facing for implementing the program.

Proper information regarding health programs should be communicated by appropriate channels so that awareness about the modus operendi and benefits of the program can reach to beneficiaries. Periodic trainings of teachers and health workers should be held jointly regarding the programme.

Summary and Conclusion

Since it is the evaluation of an ongoing programme, so to keep it in proper pace and the scheme is not being implemented in so many schools the major factors are
firstly their is lack of communication between health and education department. Even after completion of 2 years of the programme, no meeting has been organised between them. So without any coordination, there is improper monitoring and supervision of programme. Training of drugs provider also needed to make the primary provider of the scheme more efficient. There is also lack of IEC material in the school which may be used to increase compliance and adherence of students towards WIFS. Lastly inadequate supply of WIFS-IFA tablets in the block. These challenges make the programme difficult to run till now. There are certain limitations of the study like it was school based study and healthy worker effects can’t be taken in consideration.

**Conflict of Interest:** None

**Source of Funding:** Self

**Ethical Clearance:** Informed consent was taken from the adolescents and School teachers. Confidentiality of information was maintained. Adolescents suffering from severe anemia referred to appropriate health care facility for treatment. The study is done after article acceptance from the ethical committee members of MGI SMS Sewagram.

IoT Based Ketoacidosis Detection

R. Chandrasekaran¹, S. Sharika², Josephin Arockiya Dhiyva¹, T.R. Thamizhvani¹

¹Assistant Professor, ²Student, Department of Biomedical Engineering, Vels Institute of Science, Technology and Advanced Studies, Chennai

Abstract

Ketoacidosis also known as DKA (diabetic ketoacidosis) is a serious condition which occurs in patients who suffers from diabetes. It affects people above 25 years of age. It occurs due to insufficiency of insulin. Detection of ketone is done by the nitroprusside-based urinary dipstick ketone test and plasma/serum ketone analyses. Non-invasive detection of ketoacidosis is done by breath analyzer. In this paper we are using breath acetone as a biomarker for ketoacidosis. The resultant ketoacidosis values are transmitted through ESP8266. The ESP8266 sends the sensor values to think speak (private cloud). The new channel is created in Think Speak private clouding and Channel API keys are generated to read and write the sensor data from ESP8266. Through this simple IoT device the physician is always connected to the patient and can be able to monitor the ketoacidosis condition of the subject

Keywords: Ketoacidosis, think speak, IoT, API keys.

Introduction

Ketoacidosis is related to concentration of ketone bodies which are high. The human produced ketones are of two types such as acetoacetic acid and β-hydroxybutyrate. It causes accumulation of ketacids and pH change in blood. It mainly occurs in type 1 diabetes mellitus patients but also seen in type 2 diabetes mellitus. No proper treatment of ketoacidosis can lead to coma or fatal. In this paper ketoacidosis data is acquired and transmitted to doctor via internet.

The condition called as Diabetes Mellites which is a great threat to the healthcare and its detection in noninvasive is rare methodology [1]. The Diabetic patients does not produce enough insulin, the fat molecules stored in the body is converted as energy. If the fat is converted as ketones, then it produces the acetone. Hence the acetone can be used as biomarker for the detection of Ketoacidosis condition [2][3] and the hydrogen Sulphide can be used as biomarker for detection of Halitosis [4] condition. The diabetic patients have sweet odor in the breath because of acetone mixed with the exhalation of the patients.

Diabetic ketoacidosis (DKA) is a buildup of acids in your blood. [5] It can happen when your blood sugar is too high for too long. It could be life-threatening, but it usually takes many hours to become that serious. You can treat it and prevent it, too. It occurs when the body doesn’t have enough insulin. The cells can’t use the sugar in their blood for energy, so they use fat for fuel instead. Burning fat makes acids called ketones and, if the process goes on for a while, they could build up in the blood. That excess can change the chemical balance of blood and throw off the entire system. People with type 1 diabetes are at risk for ketoacidosis, since their bodies don’t make any insulin. DKA can happen to people with type 2 diabetes, especially in older people.

In human breath, diverse components are found including water vapor, hydrogen, acetone, toluene, ammonia, hydrogen sulfide, and carbon monoxide, which are more excessively exhaled from patients [6]. Some of these components are closely related to diseases such as asthma, lung cancer, type 1 diabetes mellitus, and halitosis. Breathe analysis for disease diagnosis started from capturing exhaled breaths in a Tedlar bag [7] and subsequently the captured breath gases were injected into a miniaturized sensor system, like an alcohol detector. It is possible to analyze exhaled breath very rapidly with a simple analyzing process. The breath analysis can detect trace changes in exhaled breath components [8], which contribute to early diagnosis of diseases [10], a system for detecting halitosis that comprises a gas sensor for generating a sensor signal signaling the detection of compounds indicative of halitosis exhaled through

DOI Number: 10.37506/v10/i12/2019/ijphrd/191978
an oral cavity, an image sensor for capturing an image of a dental condition and/or tongue condition in said oral cavity and a processor communicatively coupled to the gas sensor and the image sensor and adapted to process the sensor signal and the image in order to determine if in case of the sensor signal signaling the presence of a compound indicative of halitosis, said halitosis originates from said oral cavity by determining the dental condition and tongue condition in said image. Thus, the result states it 85% accurate to the gas chromatography.\cite{11} A non-invasive breath test to monitor the condition of diabetic patients where it is identified as an easier technique and quick diagnoses of diabetic ketoacidosis that prevent acute complication of type 1 diabetes mellitus. A method of monitoring ketone level by using breath measurement is done. An easy handheld health care on monitoring diabetic level with breath is presented. Method presented a development of hardware connection with Internet of Things (IoT) system to facilitate the process of patients’ diagnosis and personal monitoring. An Arduino board is used to read the sensor with sense the breath. Breath value level is log to system using wireless communication. Data collection is interfaced to web page. Ketone level is measured as the amount of breath acetone is collected when patients exhale into a mouthpiece that consists of gas sensor. This research is identified as a significant research where patients can independently monitor their diabetic health and the IoT system can be alerted directly to medial officers in the hospitals. The analysis of ketone level from the breath is based from the resistance of the gas sensor. FIGARO TGS 822 gas sensor is used to detect the amount of gas acetone in a person’s breath. When the concentration of the acetone gas increases, the resistance of the sensor is decreased. The decrease of resistance is depending on the three factors; gas concentration, humidity and temperature. To get an accurate concentration of acetone gas in a person’s breath, humidity and temperature sensor (DHT11) is added. This is due to the sensitivity of the electrochemical gas sensor towards other gasses other than acetone. As the reading from sensor is sent to Arduino, the data is shared to the database via Wi-Fi module ESP8266. ESP8266 gives Wi-Fi networking with TCP/IP protocol stack which can give Wi-Fi connection to Arduino board so that the data can be processed and shared to the web database. Thus the result shows that the amount of breath acetone method to determine the ketone level of diabetic patients is applicable as there is a good correlation between breath acetone levels and blood ketone levels developed a new generation of diagnostics for halitosis, replacing the subjective organoleptic assessment, a series of exhaled breath analyzers has been developed and assessed. All three devices rely on the assessment of exhaled Volatile Sulfuric Compounds (VSCs), which are mainly generated in and emitted from the oral cavity, contributing to the malodor. Portable, on-site and easy to use, these devices have potential for non-invasive diagnosis of halitosis. However, global assessment of exhaled VSCs alone has two main drawbacks: (1) the absence of VCSs does not rule out halitosis; (2) non-sulfuric volatile compounds that could be biomarkers of systemic diseases, found in up to 15% of halitosis cases, are neglected. The field of oral/exhaled volatile compounds as potential noninvasive diagnostics for halitosis. Thus, cross-reactive (semi-selective) sensors are used to analyze patterns qualitatively. the system is not capable of quantitative analysis or identifying the exact VOCs/VSCs in a given sample. Therefore, prior to the clinical phase, it is critical to study the identity of the targeted compounds in vitro and in vivo, by chromatography and spectrometry. In addition to this, a wide database of breath samples from oral and extra-oral halitosis patients should be used for clinical validation of the sensors for use as a database of pattern references that the software would use to match the pattern and classification of each newly obtained breath sample.

Proposed an apparatus for detecting and separating specific compounds in breath gas mixtures for halitosis analysis consisting of a line for delivering a pressure-controlled neutral gas; a removable connected sample chamber of specific volume for receiving the gas mixture to be evaluated; an electronically controlled valve for injecting the gas sample into the line a temperature-controlled micro-fabricated separation capillary column arranged to receive the gas sample injected into the line a gas sensor at the outlet of the capillary column and a control interface for managing the measurement and evaluating the obtained data stated Sensitive detection of acetone and hydrogen sulfide levels in exhaled human breath, serving as breath markers for some diseases such as diabetes and halitosis, may offer useful information for early diagnosis of these diseases. Exhaled breath analyzers using semiconductor metal oxide (SMO) gas sensors have attracted much attention because they offer low cost fabrication, miniaturization, and integration into portable devices for noninvasive medical diagnosis. However, SMO gas sensors often display cross sensitivity to interfering species. This
work reports on highly sensitive and selective acetone and hydrogen sulfide detection achieved by sensitizing electrospin SnO\textsubscript{2} nanofibers with reduced graphene oxide (RGO) nanosheets. SnO\textsubscript{2} nanofibers mixed with a small amount (0.01 wt %) of RGO nanosheets exhibited sensitive response to hydrogen sulfide (R\text{air}/R\text{gas} = 34 at 5 ppm) at 200 °C, whereas sensitive acetone detection (R\text{air}/R\text{gas} = 10 at 5 ppm) was achieved by increasing the RGO loading to 5 wt % and raising the operation temperature to 350 °C. The detection limit of these sensors is predicted to be as low as 1 ppm for hydrogen sulfide and 100 ppb for acetone, respectively. These concentrations are much lower than in the exhaled breath of healthy people. This demonstrates that optimization of the RGO loading and the operation temperature of RGO–SnO\textsubscript{2} nanocomposite gas sensors enables highly sensitive and selective detection of breath markers for the diagnosis of diabetes and halitosis. The result was highly selective and remarkably sensitive sensors to H\textsubscript{2}S and acetone were produced by mixing SnO\textsubscript{2} NFs with RGO NSs. The SnO\textsubscript{2} NFs were produced by electrospinning, a simple and versatile method for the fabrication of NFs of different materials. Subsequently the SnO\textsubscript{2} NFs were mixed with GO NSs at loading levels of 0.01 or 5 wt % GO, and eventually the GO NSs were reduced to RGO by annealing in forming gas. This resulted in porous nanocomposite layers of SnO\textsubscript{2} NFs mixed with RGO NSs. The SnO\textsubscript{2} NFs were produced by electrospinning, a simple and versatile method for the fabrication of NFs of different materials. Subsequently the SnO\textsubscript{2} NFs were mixed with GO NSs at loading levels of 0.01 or 5 wt % GO, and eventually the GO NSs were reduced to RGO by annealing in forming gas. This resulted in porous nanocomposite layers of SnO\textsubscript{2} NFs mixed with RGO NSs. At the small RGO loading level (0.01 wt %) the electrical transport and gas sensing properties of the nanocomposite layer were dominated by the SnO\textsubscript{2} NFs, but at the high loading level (5 wt % RGO) the RGO NSs formed continuous percolation pathways and they became the dominant component controlling the electrical transport through the nanocomposite layer. This enabled tuning the gas sensing characteristics of the RGO NS–SnO\textsubscript{2} nanocomposite sensors to achieve enhanced sensitivity and selectivity to traces of H\textsubscript{2}S or acetone in humid air for sensors with low or high levels of RGO loading, respectively. Besides changing the RGO/SnO\textsubscript{2} ratio we also found that tuning the operation temperature of the sensors enabled achieving high selectivity between H\textsubscript{2}S and acetone.

**Methodology**

The subject blows into the gas chamber which contains temperature and humidity sensor (DHT-11) and gas sensor (MQ-138). The gas sensor measures the concentration of acetone gas in the chamber and the temperature and humidity sensor measures the temperature and humidity of the chamber. The sensed data is sent to the Arduino uno. The microcontroller processes the output and displays it in the LCD. The microcontroller sends the output to the ESP8266 and is uploaded in the internet in real-time.

**MQ-138 Formaldehyde sensor:** The MQ-138 sensor is used to detect the acetone from the forceful blow of patient breath. The sensor is placed in a gas chamber where based on the gas concentration the acetone range is detected and displayed in serial monitor and LCD. This sensor can also detects Aldehydes, alcohols, ketones, aromatic compounds which are volatile compounds.

**DHT-11 Temperature and Humidity sensor:** The DHT-11 is a digital temperature and humidity sensor from micropik. A capacitive humidity sensor and a thermistor to measure the surrounding air is used which ranges from 20-90% with a resolution of 1 temperature from 0-50°C with a resolution of 1 at accuracy of 2°C.

**ESP 8266 WIFI module:** The ESP8266 microcontroller is integrated with a Tensilica 32-bit processor, which reaches a maximum clock speed of 160 MHz. The RTOS and Wi-Fi stack allow about 80% of the processing power to be available for user application programming and development.

**Thing Speak:** Thing speak is an open source Internet of Things (IoT) application and API to store and retrieve data from things using the HTTP protocol over the Internet or via a Local Area Network. Thing Speak enables the creation of sensor logging applications, location tracking applications, and a social network of things with status updates.

**Gas chamber:** The gas chamber contains two sensors. One is gas sensor and another one is temperature sensor. The gas sensor is designed similar to gas chamber. The dimension of the gas chamber is 255cm³. The gas chamber in this project can hold up to ppm of acetone gas.

**Results and discussion:** The Ketoacidosis condition is a pathological Condition in which it is important to monitor regularly for the diabetic patients. In this paper the noninvasive method of monitoring the ketoacidosis is designed using the gas sensor. The gas sensor is placed in the gas chamber with that of Digital temperature and humidity sensor. The subject is guided to blow into the gas chamber, based on the gas concentration of acetone inside the chamber the acetone ppm values are displayed in the LCD as well as serial monitor and
the acetone values are transmitted to the Thing Speak cloud individual private channel using ESP8266 (via API key). The ketone, temperature, humidity values are plotted in Thing speak web channel in real time. The real time plotted values are monitored by the physician and it is easy to get connected with the patients online. The recent trends in IoT development makes the patient get connected with the physician. The subject used to test for ketoacidosis conditions are diabetic as well as non-diabetic. The subject 1, 2, 3 are healthy individual and subject 4 and 5 are diabetic individuals. The subject 4 and 5 exhibit abnormal acetone values because all the subject has undergone two hours of fasting and acetone values are measured. For diabetic subjects the stored fats are converted into ketone bodies and that ketone bodies produces acetone, if food is not taken at proper intervals, that’s why the diabetic subjects always have fruity odor in their breath. This methodology is very helpful for noninvasive monitoring of ketoacidosis than measuring invasively by blood and urine. The work is then extended in future by making it very compact and mobile application-based monitoring and guiding the diabetic subjects for proper ketogenic di

Smart Aid for the Blind

R. Chandrasekaran¹, Josephin Arockia Dhivya¹, T.R. Thamizhvan¹, R.J. Hemalatha¹

¹Department of Biomedical Engineering, Vels Institute of Science Technology and Advanced Studies, Chennai, India

Abstract

The assist device for blind people is much needed in recent days. The gadgets in recent trends are digitized that the blind people are not capable of handling digitized applications hence in our project we design text to voice converter, that converts the eBooks, audiobooks to voice format. In this project the audiobook eBooks are fed into SD card reader after that the sd card reader is interfaced and the Arduino UNO converts the text file to Audio output. The audio books can be heard in headphone/speaker using Arduino UNO. This project is low cost it will be more useful for blind people.

Keywords: Braille; Arduino Uno; SD card module, jump wire.

Introduction

The Braille Displays, Books, Gadgets are the best companion for the Blind people. In order to make them ease in reading any text, the Braille pattern books are developed. In recent days the Braille Electronic Keyboards, Braille Display Electronic Gadgets are available for the Blind people. In this project we propose an idea of making a smart Braille device in which it can able to read any e-books and convert the text to voice format. This smart Braille device will be a best companion for the blind people. The objective our study is to assist the visually impaired people with reading text and converting text into audio format using micro controller at low cost and more reliable

Literature survey: Text to braille interpreted printed document through (OIP)optical text to braille converter device for aiding visually impaired individuals to read printed materials-this system will give visually impaired people chance to read any printed reading paraphernalia-components-camera, optical image processing, USB to UART device, microcontroller, braille cells

Teaching interface of finger braille teaching system using smartphones finger braille teaching system between non-disabled senders’ deaf blind receiver has been developed single column teaching interface for more easily viewable double column teaching interface promoted better performance (response time dotting speed and accuracy) using smartphone component-deafblind, finger braille, teaching interface, smartphone

Braille based mobile communications translations glove for deaf blind people the literate deaf blind population, into text and vice versa, and communicates message via SMS to remote contact it enables to convey simple message by capacitive touch sensor input sensor placed on palmer side of glove and converted to text by PC/smartphone added min vibrational motor-assistive technology; braille; deafblind; haptic; human computer interaction; mobile communications; sensory impairments; wearable device

Smart reader for visually impaired-OCR-the optical character recognition functions of MATLAB for converting image to text this paper proposes smart reader system for visually impaired here proposed novel audio tactile user interface that supports user to read information, component-MATLAB, OCR, text to speech, Web cam

Methodology

The usage of electronic gadgets by the blind people when compared to the normal people is low because of its in-accessibility. Most of the electronic gadgets are created for the use and easy access of the normal & healthy people whereas the blind people cannot be able to access the electronic gadgets easily, voice recognition in mobile based application will be more helpful to the blind people. The blind people cannot be able to read an e-book or any e material It is very important to develop electronic gadgets for blind people with universal design. Voice recognition will be
more helpful for blind \cite{5,11}. The universal design plays an important role in day to day life of the blind people. It is the primary responsibility for the society to create an easy and comfortable environment that are usable by all kind of people braille will be much more helpful in reading books for the blind \cite{7,12}. The people with low vision or poor vision should also be considered as a user of electronic gadgets and the devices should strictly follow the universal design protocol for the easy access by the blind and low vision people. IOT are the recent in connecting blind people with technologies \cite{12}.

**Hardware Required:** The Arduino Uno is an open source microcontroller board based on the microchip ATMEGA328P microcontroller and developed by Arduino Uno the board is equipped with sets of digital and analogue input/output pins that may be interfaced to various expansion board and other circuit the Arduino guanine board, or other microcontroller. The ATMEGA328 provide UART TTL (5v) serial communication, which is available on the digital pin 0(RX) and (TX) an ATMEGA16 U on the board channel this serial communication over USB and appears as virtual com port to the computer software.

SD card module mostly useful for projects that require data logging the Arduino can create file in an SD card to write and save data using SD library there are different models from different supplier but they all work in similar way, using SPI communication protocol the module used in the tutorial The module comes with voltage regulator therefore the Arduino 5V and 3.3v pin can be used for voltage supply the modules communicates via SPI (serial peripheral interface) to the Arduino Uno.

**Software Required:** The open-source Arduino Software (IDE) makes it easy to write code and upload it to the board. It runs on Windows, Mac OS and Linux. The environment is written in Java and based on Processing.

**Result and Discussion**

In this study the SD card reader is interfaced with the Arduino Uno. The Pdf file is fed into the SD card reader and the Arduino converts the text file to audio format. Pulse Width Modulation, or PWM, is a technique for getting analog results with digital means. The speaker wire or headphones are connected to the 9th pin of Arduino which is PWM pin of the Arduino. However, the output should be amplified using external audio amplifier. This study can also read the audio books and plays via speaker/headphones. In this study the SD–Card is interfaced with the Arduino Uno controller. The SD-Card reader can be expanded up to 120 GB. In this prototype we have used 8 GB memory card, that is loaded with audio books, readable pdf and word documents. Arduino Uno reads the all the text files in the SD card reader and displays in the serial monitor and converts the text in to speech using PWM technique and plays the audio file via head phone and speakers. The voice output is not clearly audible hence an external audio amplifier is required to amplify and filter out the noises. In future the project can be extended by adding suitable braille keys, so that the voice synchronous with the braille texts.

**Future Scope:** The project can be extended in future by converting text to Braille keys. The rotatable Braille keys from A to Z or raised Braille dots (keys) can be used to design a Braille keypad. The fully refreshable Braille keypad can be developed in future for easy text to Braille converter.

**Ethical Clearance:** The Study is based on the Digital Processing of the sensor and its connectivity via IoT (Internet of Things). The Study is been conducted by the guidance of Head of the Department, Ms. R.J. Hemalatha.

This Study does not require Ethical Clearance. This Study is conducted in the Biomedical Instrumentation Lab of Vels Institute of Science Technology and Advanced Studies–Department of Biomedical Engineering, Chennai-117.

**Source of Funding:** It is one of the Self-funding projects of Department of Biomedical Engineering.

**Conflict of Interest:** Nil

A Novel Design of Wearable Automatic Stress Detecting Device for Women Safety Using Heart Rate Variability

R. Mercy Kingsta\textsuperscript{1}, R. Aashifa\textsuperscript{2}, S. Bala Meenakshi\textsuperscript{2}

\textsuperscript{1}Assistant Professor, \textsuperscript{2}Student, Department of ECE, Mepco Schlenk Engineering College, Sivakasi, India

Abstract
This paper presents the design of novel device to identify abnormal heart rate variability (HRV) due to anxiety in threatening circumstances, and to automatically relay alert along with location coordinates to the pre-saved phone numbers through global system for mobile communication (GSM), in order to acquire help. Physical activities change heart rate but not HRV whereas fight-or-flight response causes change in both. It is found that, with the help of HRV measurement it is possible to distinguish the changes in electrical activity of the heart due to physical activities and acute stress. The proposed design can also be used to know the abnormal conditions of heart patients and to provide timely help.

Keywords: Heart rate, Heart rate variability, HRV abnormality, GSM and GPS module, Pulse sensor.

Introduction
Marching towards technological augmentation, restless toil is to confer the capital that makes our living. In such an eventful life women face a lot of disquieting situation. Counting from a teenage girl to a married woman, women from all walks of life are being assaulted, molested and violated every single day. The streets, public transport, public spaces in particular have become the territory of the molesters. Millions of crimes against women were reported over the past decade \textsuperscript{(1)}. Women are more at risk from gender based violence than war, malaria or cancer. There are a lot of legal solutions to the issue but it becomes difficult to provide a timely help. With our proposal “The Guard Watch” we aspire to develop an embedded device that can afford well-timed help rather than abandoning the women in crisis. There is no system to absolutely stop the crimes against women but at least we can ensure the safety of our loved ones instantly when there is a jeopardy waiting. The entire hardware for the detection of anxiety contributes to the innovation of this solution.

The existing devices designed for women safety embraces a manual alert system which entails a person to physically operate the device to acquire help. Many devices in the form of hair clip, smart dresses, and smart jewelry have this facility. Other smart watches existing in the market, which are generally designed for sports persons, compute heart rate, blood pressure and other related parameters to estimate the health condition of the person wearing the device \textsuperscript{(2)}. Thus, such devices focus only on health and fitness alert. Some system available in market propose to identify stress which either involves techniques like salivary test, adrenaline measurement etc., or involves the prolonged measurement of heart rate to compute stress\textsuperscript{(3,4)}. None of these tests can be done instantaneously and noticeably differentiate the diversity between flight/flight stress and the habitual stress.

For example, the heart rate increases during extreme anxiety and also due to exercise. It is impossible to categorize this systematic activity from the atypical fear. Heart rate focuses on the average beats per minute while heart rate variability (HRV) measures the specific change in time between successive heart beats. HRV is non–invasive and provides more accurate stress measurements by measuring the timely variation when a person is undergoing fear \textsuperscript{(5-9)}.

The projected design uses Heart Rate Variability as a factor to measure the fretfulness of the women in danger by continuously monitoring the HRV. The Guard Watch involves the unification of technologies like a pulse sensor to record the electrical activity of the heart through the reflection of light from blood vessels and compute HRV, Global System for Mobile communication (GSM) and Global Positioning System.
(GPS) modules to send the alert message, in case of menacing situations, along with the location coordinates to the pre saved phone numbers. methodology

In this section heart rate variability, the main parameter that is going to be used in the proposed device, its features, measurement procedure and the use of Photo Plethsmo Graph sensor to measure heart rate are discussed.

**Heart rate Variability:** An ECG graph consists of five regions (PQRST) with respect to the functionality of the chambers of the heart. HRV is the time difference between the R-R peaks in an ECG waveform. Fig. 1a and Fig. 1b show respectively the ECG waveform with equal and unequal R-R intervals. Under normal body conditions, the time difference between the successive R-R peaks (HRV) remains almost constant. However, when a person is in fear the heart beat occurrence varies and hence the time difference between the adjacent R-R peaks (consecutive HRV measured) varies abruptly. This occurs because the heart may skip a beat (due to extreme anxiety). The interesting feature of HRV is, it can reflect changes in mental stress while other physiological parameters, like blood pressure, are still in normal or accepted ranges. HRV changes are different for fight/flight response compared to customary physical activities like exercise.

**Photo Plethsmo Graph Sensor:** Optical heart rate sensors use a methodology called Photo Plethsmo Graph (PPG) to measure heart rate. PPG is an optical sensor that measures the electrical activity of the heart based on the fact that light entering the body will scatter in a predictable manner as the blood flow dynamics change, such as with changes in blood pulse rates (heart rate) or with changes in blood volume (cardiac output). PPG provides accurate inter pulse intervals from which HRV measures can be accurately derived\(^\text{(10)}\).

**HRV measurement:** A threshold is set to detect the R peaks from PPG sensor output. Since the optical reflectivity from PPG sensor varies for persons with
different muscle densities, color tones, age groups and
gender, the R peak amplitude also varies from person
to person. So it has to be manually determined for a
particular person under complete physical and mental
rest and set in the device. Since HRV is the time
difference between successive R peaks, the interval
between successive R peaks is of much important for
further calculation than the amplitude.

The normal values of R peak to peak interval also
depends on various criteria like age and gender, but this
does not influence the abnormality in HRV the heart
shows during stress.

**Change in HRV due to flight/fight response:**
Habitual stress is a response to daily pressure. During
such circumstances also the heart may skip a beat and
alert may be generated in a vibrator but it can be rejected
by the user. Stress due to fear (fight/flight stress) is the
process during which a person becomes scares awaiting
what lays ahead and the changes in HRV due to this
kind of circumstances entails help from another person.
Exercise is another physical condition which also alters
the heart functioning. When a person is under physical
training the parameters like heart rate, respiratory rate
and blood pressure varies whereas HRV remains nearly
unchanged, thus featuring HRV as the stress identifying
parameter which could acutely differentiate the anxiety
and agony from the other physical trainings and exercises.

The proposed system works as follows: The time
difference between consecutive R-R peaks is calculated.
Variation in the successive time differences means an
abnormality. Prolonged abnormality will increment a
counter. If the abnormal count crosses a particular value
(say n) the alert is given to the person through a vibrator.
A person wearing the watch can feel the vibration and
can respond to the alert. If the threat is a prank or due to
any work stress (habitual stress), the person can reject
the alarm and the entire process will be reset, instigating
the calculations again. If there is no response from the
user, in case of a real threat, for some elapsed time period
(say n), GPS coordinates of the person is automatically
sent using GSM along with the alert message to the pre-
saved numbers, so that the person could receive timely
help. The following flow chart explains the working of
the proposed system.

**Results and Discussion**

**Observed HRV during physical activity:** The
PQRST waveform is recorded for various persons
under various conditions to study the variations in R
peak amplitude and HRV. Fig. 2 (a) and 2 (c) show
the waveforms recorded using pulse sensor for persons
under complete rest. We can observe the different peak
amplitude for both persons which are due to change in
color tone and muscle density. The pulse waveforms
are recorded for the same persons after mild exercise
as shown in fig. 2 (b) and 2 (d), (the subjects (21-25
age group) were made to go up and down a series of
20 staircases continuously for 5 minutes). From fig 2
we can infer that, the heart rate (number of R peaks per
second) increases for a person under exercise, but the
HRV (consecutive R peak to peak time interval) remains
almost constant as that of normal body condition which
means the HRV is normal. When the person is under
rest the HRV is ‘x’ (say) seconds and after exercise
it has decreased to ‘y’ (say) seconds, but the HRV in
consecutive interval remains nearly same. This robustly
proves the fact that HRV does not vary during physical
activity.
Observed HRV for persons by inducing anxiety: As real-time stress measurements cannot be demonstrated, various readings are recorded for different person by inducing stress. To prove that HRV varies when a person is under stress, the pulse waveform is recorded when a person is watching a horror movie. Sample waveforms are taken for persons who undergo extreme fear while watching a horror movie. The samples at the start of the movie and the samples taken as movie proceeds are compared as shown in fig. 3. Fig. 3 (a) and 3 (b) shows the setup for recording the PPG waveform and sending alert message.

As shown in fig. 3 (c) and 3 (e), at the start of the movie both persons were normal. But when the movie proceeds, as they undergo fretfulness, the waveform varies abnormally, as shown in fig. 3 (d) and 3 (f), in contrast to physical activities and some of the peaks are skipped thus making adjacent HRV to vary. Depending on the tolerable anxiety level of the persons the abnormality in HRV differs for both persons. However, as the change in HRV increments counter, the prolonged abnormality automatically will trigger GPS and GSM modules and will send the alert.

A code is developed to calculate the abnormality in HRV. When the threshold for peak detection is set, the time where the first peak occurs is noted. Then the time of occurrence of second peak is detected and the time difference between successive peaks (HRV) is calculated. This time difference is compared with the consecutive HRV values to identify the variation in HRV and if it is varying an abnormal count is initiated.
When the abnormal count is under acceptable range, no alert is triggered and when it is increasing continuously alert message is sent. For demonstration purpose the maximum abnormal count range is set as 6 and when the count crosses the value 6, an SMS is sent as shown in Fig. 4.

When a person suffers from heart ailments (like mitral valve replacement, AV block etc.) electrical activity of the heart varies and the heart may produce irregular beats. In some cases, the heart may skip a beat or may produce faint beats due to the blocks resulting in abnormal HRV changes. Hence the proposed design can also be used to know the abnormal conditions of heart patients in order to take immediate measures.

**Fig. 3 (d) Waveform recorded when the person 1 undergoes fretfulness**

**Fig. 3 (e) Waveform recorded at the start of the movie for person 2**

**Fig. 3 (f) Waveform recorded when the person 2 undergoes fretfulness**

![Arduino serial monitor output](image)

**Fig. 4 Arduino serial monitor output**

**Conclusion**

The prime concern of this paper is the safety for women. From the results, it is inferred that anxiety in emergency situations can be differentiated from physical activities as the later produces heart rate variation but not HRV. The interesting feature of this design is that the offender cannot know that information was sent from the victim. Also, it is easy to handle and suitable for people of all age as it is like an enhanced smart watch. If petite components could make the smart watches compact, the equivalent and superior miniature progression can be employed for the Guard Watch to be time-honored as the paramount security aid in the near future. Physical
protection cannot be the finest solution all the times but this kind of technological advancements can turn out to be the paramount choice for women safety.

Mobile Phone Usage and Willingness to Receive Health Care Tips among Patients Attending NCD Clinic in a Tertiary Carecentre, Pondicherry

A. Vishnpriya¹, R. Niranjjan², S. Arul Vijaya Vani³

¹MBBS Graduate, Aarupadai Veedu Medical College, ²Assistant Professor, Dept. of Community Medicine, AVMC, Puducherry, ³Assistant Professor, Department of Biochemistry, Mahatma Gandhi Medical College and Research Institute, Pillayarkuppam, Puducherry

Abstract

Background: To implement mHealth interventions for control of non-communicable diseases, it is essential to know the readiness among the target population. Among diabetes and hypertension patients attending NCD clinic, tertiary care centre, Puducherry, to describe mobile phone availability and knowledge regarding operation of mobile phones and to study the willingness to receive health related information

Methodology: A facility based cross-sectional study was conducted among diabetes and hypertension patients attending NCD clinic at a tertiary care centre, Puducherry during July and August 2018. The patients were interviewed using a semi structured, pre-tested questionnaire after obtaining informed consent. Information on demography, mobile phone availability, knowledge on mobile phone usage and willingness to receive health related information was collected. Data were entered in Epi Data 3.1 and analysed using SPSS 17

Results: Of total 300 participants, mean (SD) age was 53 ± (7.6) years. Nearly 60% were females. Almost more than half of the patients had diabetes. Personal mobile phone was with 253 (84.3%) patients. Of total 300 patients, all knew to receive a call, 95% knew to make a call. Regarding SMS, 30.8% and 28% know to read SMS and text SMS respectively. Willingness to receive health information was reported by 269 (89.6) patients; 81% preferring voice calls.

Conclusion: Four out of five NCD patients attending tertiary care have personal mobile phone. Willingness to receive health information was also very high. Hence the effective use of mobile phone technology in health care delivery may play a vital role in the management of non-communicable disease.

Keywords: Mobile phone, willingness, health tip, Non-communicable disease, tertiary care.

Introduction

Access to mobile phone has increased which includes nearly two third of the adult population worldwide.¹ The usage of mobile phone has found a rapid increase, which corresponds to the faster diffusion in the field of communication technology than any other communication tool.¹² Among the world nations India stands to be the second largest nation with wireless communication subscriber base and on comparing with urban and rural area, the urban area takes four fold increase contribution in wireless tele density.³ Mobile phone has led to various improvements among people of various sectors and one such important application of this lies in the field of self–care and health care delivery system among patients, a field which has found its way on and is termed as mobile health (mHealth).⁴

mHealth comprises of various modalities which include sending messages through text or video,
The usage of mobile phone in health care has found its attention and is found to be more attractive because of its functional modalities which helps to save people on time in situations which are found difficult for hospital care and management which includes identifying the risk population for developing acute health problems, providing health education among people, and in assisting patients on various administrative works such as assessment of health care records and scheduling appointments. As management of non-communicable disease is a major challenge in the present world, due to the limited capacity of health system in self-management due to changes in lifestyle of people.

Mobile health services can provide various information to patient whenever and wherever they require it and thereby provides an extended form of health care. The use of mobile phones and health services provided by it especially in resource poor setting play a major role in addressing the burden of NCDs. Globally the potential of mHealth is found to be more important in low and middle income countries than developed ones. NCDs are a leading contributor to morbidity and mortality worldwide. The increase in usage of mobile phone across world has provided an opportunity in transforming health care delivery for improving the management of non-communicable diseases (NCDs). The willingness of the target population and knowing their capacity before planning on mHealth is of much importance. Hence this study is planned to assess the mobile phone usage and willingness to receive health related information among patients attending NCD clinic in a tertiary care setup.

**Aims and Objectives:** Among patients attending NCD clinic in tertiary care Pondicherry.

1. To assess mobile phone availability and knowledge regarding operation of mobile phones (Smart phone/Ordinary)
2. To assess their willingness to receive health-related information through mobile phone.
3. To study the factors associated with willingness to receive health related information

**Material and Methodology**

**Study setting & Study population:** It was a facility based cross-sectional study conducted during July to August 2018. Approval from Institute research committee and Institute ethics committee were obtained. The study was conducted in Non-communicable disease clinic under control of department of General medicine, Aarupadai Veedu Medical College, Pondicherry. NCD clinic is regularly conducted by department of General Medicine twice weekly. On average 30-40 patients are attending the NCD clinic on each day. All new and previously diagnosed cases of hypertension, diabetes patients attending NCD clinic were included in the study.

**Inclusion criteria:** New and old cases of hypertension, diabetes attending NCD clinic in Aarupadai Veedu Medical college, Pondicherry.

**Exclusion criteria:** NCD patients other than diabetes and hypertension, patients who were extremely ill & not willing to give informed consent.

**Procedure:** After obtaining informed consent, a pretested semistructured questionnaire was administered to all study participants who will satisfy the inclusion criteria. Details regarding socio-demographic details, access to mobile phone, knowledge on mobile usage (both smartphone and ordinary) and willingness to receive health related information were obtained. Data was entered in EpiData version 3.1 and analysed using SPSS 20.

**Operational Definitions:** Following operational definitions were followed in this study:

**Personal mobile phone:** a mobile phone (Smart phone/ordinary) owned by the individual. It does not include access to a mobile phone through a family member.

**Smart phone:** a mobile phone which have 3G/4G internet connectivity with touch screen with whatsapp application

**Ordinary phone:** a mobile phone which does not have 3G/4G internet connectivity with touch screen with whatsapp application

**Receive and answer a call:** knowledge on attending an incoming phone call irrespective of ownership or present access to a mobile phone.

**Make a call:** knowledge on making an outgoing call irrespective of ownership or present access to a mobile phone.

**Read SMS:** knowledge on opening and ability
to read an incoming whatsapp message or SMS text irrespective of ownership or present access to a mobile phone.

**Send SMS:** knowledge on typing and sending whatsapp message or SMS irrespective of ownership or present access to a mobile phone.

**Health tip:** Any information concerning the specific disease of the patient is suffering from aimed at improving the outcomes of disease management.

**Results**

Of total 300 participants, 174 (58%) were females and mean (SD) age was 53 ± (7.6) years. Majority (43.7%) of participants had no formal education, and 83(27.7%) participants were unemployed. In all, 154(51.4%) patients had diabetes alone, 147 (51.6%) patients had hypertension alone, and 34(11.3%) had both diabetes and hypertension.

Access to mobile phone and knowledge about its use are described in Table2. Personal mobile phone was with 253 (84.3%) patients, among them 26% were smartphone users. Off the 300 study participants 276 (92%) knew to receive & answering calls, 241 (80.3%) knew to make a call, 107(35.6%) knew to open & read SMS and 99(33%) knew to type & send SMS.
Almost 68% of mobile phone owners currently using Tamil (local) language. Willingness to receive health information was reported by 269 (89.6%) patients (Table 2), 81% preferring voice calls. Almost 98% of the mobile phone users prefer to receive health tips in Tamil. Off the 269 willing participants, 116(43%) prefer evening time for receiving health tips followed by 62(23%) prefer morning time. Almost half of the participants who shows willingness to receive health tip prefer once a week followed by 102(37.9%) prefer daily health information.

Date of next visit (29.7%), medication usage (27.1%) and diet (7%) were the 3 most common bits of information that participants were willing to receive.

In bivariate regression analysis, higher age group (OR=4.8[1.4-16.3]), having no formal education (OR=10.7 [3.6-31.4]), unemployment (OR=2.5 [0.5-13.0]), were associated with willingness. In multivariate analysis, having no formal education (OR = 9.6 [2.7-34.0]) independently associated with willingness to receive health tip.

Discussion

mHealth is emerging field in health care delivery system, especially in control of chronic non-communicable disease. To address irregular drug intake, physical activity, wide gap in follow up visits, mobile phones are valuable tool to access the patients at regular intervals and make them touch with health care delivery system. Personal mobile phone is easy to access either through voice call or text messages for health care information. Hence the present study was planned to assess the proportion of mobile phone usage and willingness to receive health related information among non-communicable disease patients attending tertiary care institute.

In this present study, it was found that 84.3% of the study participants had personal mobile phone, among them 26% were smartphone users. Nearly 90% of the study participants willing to receive health tips to control their disease irrespective of having personal mobile phone. More than 80% preferring voice calls. A Similar study was conducted by Niranjan et al in rural Pondicherry and reported that only 38% had personal mobile phones and 60 % of the patients willing to receive health tips and more than half of them preferred voice calls. Okoro EO et al conducted a study in 2009 about Mobile phone ownership among Nigerians with diabetes reported that Eighty nine 68.5% patients had active Mobile phone. These results are very much lower when compared to the present study. The difference could be due to rural and urban difference in study setting. Another community based cross-sectional study from rural area of Bangalore reported that 99% were willing to receive health-related information on mobile phone, and 89% prefer voice calls which is little higher than the present study.

About knowledge of operating mobile phone, 100% of study participants knew to answer the calls, 95% knew to make a call, 30.8% knew to read SMS and 28% knew to text SMS whereas study from rural area of Puducherry reported only half of the patients knew to receive & answering calls, 40.7% knew to make a call, 15.4% knew to open & read SMS but only 8.8% knew to type & send SMS. These results make the difference between urban and rural setting.

In the present study more than half of patients had diabetes alone the remaining half patients had hypertension alone, and 11.3% had both diabetes and hypertension whereas study from rural area of Puducherry reported that 12.3% patients had diabetes alone, 51.6% patients had hypertension alone, and 64 22.5% had both diabetes and hypertension.

In the present study, Date of next visit (29.7%), medication usage (27.1%) and diet (7%) were the 3 most common bits of information that participants were willing to receive whereas study from rural area of Puducherry showed Diet (38.6%), medication usage, (21.6%), and lifestyle modification (25.2%) were the 3 most common bits of information that participants were willing to receive.

In the present study, higher age group, having no formal education, unemployment, were associated with willingness whereas study from rural area of Puducherry showed lower age group, male gender, having formal education, employment, and access to mobile phone were associated with willingness.

This is one of the few studies assessing the knowledge and willingness related to mHealth interventions among patients with non-communicable diseases. This study has a few implications. This comprehensive assessment on receiver level

Knowledge and willingness will help in effective planning of mHealth interventions for chronic non-communicable disease patients. mHealth interventions
have shown favorable results in blood glucose control in diabetic patients, an increased rate of HbA1c testing among previously nonadherent patients, and improved outpatient attendance.\textsuperscript{10,17-20}

The study was conducted among patients attending a tertiary care centre, which caters mixing of urban and rural population. This study findings can be generalised to all tertiary care centres in Puducherry

**Conclusion**

Non-communicable diseases become one of the leading cause for morbidity & mortality. Regular physical activity, follow up visits & regular adherence to medication are at most priority in management of Diabetes & Hypertension. Four out of five chronic disease patients in this tertiary care setting have personal mobile phone. Willingness to receive health information was also very high. Hence the effective use of mobile phone technology in health care delivery may play a vital role in the management of non-communicable disease.

Abstract

Resorption of the root can be either internal or external and may manifest in the form of perforations on the middle third of the root surface. These resorptions may have undesirable sequelae such as gingival inflammation, periodontal destruction and bone resorption. Numerous materials have been tested to treat such lesions in the past. The present case makes use of mineral trioxide aggregate (MTA) and a periodontal flap for the management of external root resorption. With the success of treatment and desirable outcomes at follow-up appointments, MTA proved to be an effective and viable material of choice.

Keywords: Root resorption, periodontal flap, mineral trioxide aggregate.

Introduction

Resorption is a condition associated with either a physiologic or pathologic process resulting in the loss of dentin, cementum or bone, as defined by the Glossary of American Association of Endodontists.¹ Primary teeth undergo physiologic resorption, allowing the permanent dentition to take their place. Pathologic resorption may follow trauma, orthodontic forces or pulpal or periodontal infections.²

Resorption may also be of the internal or the external type. External resorption is further classified into external surface resorption, external inflammatory resorption, external replacement resorption, external cervical resorption and transient apical breakdown. If permitted to progress, external root resorption may lead to rapid tooth loss.³,⁴

A recently emerged material being increasingly used for management of cases of external root resorption is mineral trioxide aggregate (MTA). MTA is a reliable material owing to its advantage of being biocompatible, with good sealing properties. It also encourages the regeneration of peri-radicular tissues including the periodontal ligament, cementum and bone. MTA finds a wide application as an ideal material for root-end filling, perforation repair and pulp capping.⁵

The following case report demonstrated the use of MTA in the treatment of external root resorption.

Case Report: A 53-year-old female patient reported to the Department of Periodontology and Oral Implantology, with the chief complaint of food lodgement in the upper and lower back tooth region. Her medical history was non-contributory. On clinical examination, grade 2 mobility with 21, and a grade 1 mobility with 22 was detected. Generalized gingival recession along with generalized deep periodontal pockets was noted. Radiographic examination revealed round-shaped regions of radiolucency in the maxillary left central and lateral incisor, indicative of areas of external resorption (Figure 1). Palpation and percussion tests on the tooth revealed no pain, tenderness or discomfort. A combination of the clinical and radiographic examination led to the diagnosis of chronic generalized periodontitis, with external root resorption in 21,22. A complete scaling and root planing were carried out. After 15 days, the patient returned, having fractured her upper left central incisor (21) while brushing.

The two teeth (22, 23) were isolated, an access cavity was made, following which the working length was determined (Figure 2). Copious irrigation of the canal was done using sodium hypochlorite followed by...
normal saline. Calcium hydroxide dressing was placed as an intracanal medicament followed by a temporary restoration.

To deal with the sites of external resorption, probing depth to the lesion was determined using a calibrated probe (Figure 3). Once the depth was determined both clinically and radiographically, a conventional flap elevation was made on the site of interest. A periosteal elevator was used to elevate the flap and clinically expose the site of external root resorption (Figure 4). Once adequate access was gained to the site, the granulation tissue was removed (Figure 5). MTA was mixed on a glass slab as per the manufacturer’s instructions and then placed on the site of external resorption with a plastic instrument. It was allowed to set for 10 minutes. Placement of MTA was coupled along with the obturation of the prepared canals (Figure 6,7). Flap was repositioned and sutured in place, achieving a total coverage of the MTA and the root surface (Figure 8).

A follow up was done after a period of 3 months. No signs or symptoms were noted. The radiograph showed that external resorption had been arrested. Adequate healing was noted (Figure 9).

Figure 1. Radiograph showing areas of root resorption
Figure 2. Working length determination
Figure 3. Probing depth to the lesion
Figure 4: Elevation of periodontal flap
Figure 5: Removal of granulation tissue
Discussion

External root resorption is not an uncommon phenomenon. It is found on isolated teeth rather than in the generalized form. External resorptions can be external surface resorption, external inflammatory root resorption, ankylosis and replacement resorption, with inflammatory resorption being the most common type.

External root resorption remains to be one of the most difficult to treat conditions. Thus, the solution lies in something beyond endodontic therapy, as a communication pathway opens between the root canal and the periodontium. It is ideal to make use of a material that is biocompatible and preserves bacterial leakage.

In the present case, MTA was the choice of material for sealing the subgingival area denuded by external resorption. To date, resin-modified glass ionomer cements have been demonstrated to have histologic and clinical biocompatibility to both epithelial and connective tissue adhesion, when placed subgingivally. MTA, by virtue of being a bioactive material, has the ability to form an apatite-like layer on its surface on coming in contact with physiologic fluids in the oral cavity. MTA is composed of tricalcium and silicate. Studies have demonstrated that MTA can conduct and induct hard tissue formation, in addition to the fact that several ions are released from MTA in a sustained manner, when placed in the oral cavity.

The use of MTA in combination with flap surgery have had favourable outcomes in recent studies. This
procedure has demonstrated an increase in clinical attachment level, reduction in probing depth, and MTA can be maintained adequately over teeth with resorptive lesions for over a period of 6 years, despite the subgingival location.\textsuperscript{11}

The use of MTA in such a case of external resorption leads to avoidance of surgical treatment with similar prognostic outcome. Further long-term clinical studies using MTA in different scenarios should be encouraged.\textsuperscript{12}

\textbf{Conclusion}

The present case supports the use of MTA as an effective material to treat external root resorption. When combined with a surgical flap, it can be an ideal replacement to other materials to treat subgingival lesions successfully.

Abstract

High energy x-rays from a medical linear accelerator (LINAC) is used to treat cancer patients in radiotherapy department. The medical linac can produce bremsstrahlung x-rays from 4MV to 18MV and the commonly used linac produces 6MV, 10 MV and 15MV photons for treating major parts of the cancer patients. The photo neutron production during the radiation treatment is one of the major issues which have to be addressed with high impact because of the high LET nature associated with it. Photo neutrons are produced from several high atomic number (Z) elements present in the linac head mostly by the (γ,n) reaction. The flattening filter used in medical linac to produce uniform intensity distribution (made up of either tungsten, steel, lead, uranium, aluminum or a combination) is one of the photo neutron sources in the linac head. Advanced radiotherapy treatments like Intensity Modulated Radiotherapy (IMRT) and Volumetric Arc Therapy (VMAT) doesn’t require a flat radiation field, and hence the flattening filter could be removed. This is called flattening filter free beam (FFF beam) 1,2. The removal of the filter will result in a forward peaked photon beam, which is very advantageous for these kinds of treatments 3,4. The purpose of this work was to find out the difference in the percentage of photo neutron production in a flattening filter free (FFF) and flattening filter (FF) mode of operation than the FF mode. The neutron fluence was measured at different positions with FFF and FF mode and the results were tabulated. The neutron fluence was lower for the FFF mode of operation than the FF mode. The reduction ranges from 2.27% to 44.22%.

Keywords: CR 39 SSNTD, Medical Linac, flattening filter.

Introduction

The high energy x-ray from a Medical linear accelerator is used to treat cancer patients with modern treatment techniques in order to get maximum therapeutic ratio. The high energy electrons accelerated by microwaves when collide with a heavy metal target x-rays (photons) are produced. These high energy photons will be directed to the patient by shaping the beam to confirm the shape of the tumor. The treatment head contains different components designed to shape and monitor the treatment beam.

The beam flattening filter is a conical shaped metal absorber which absorbs more photons in the central part than the ones in the periphery. It makes the intensity almost uniform. A flattened beam is essential to create uniform dose distribution during the treatment 5. It is usually made of either tungsten, steel, lead, uranium, aluminum or a combination. In dual energy photon linacs, separate flattening filters are used for the low and the high energy photon modes. Removal of the flattening filter 6 results in increasing dose rate (2-4 times higher) reduces head scatter, non-uniform beam profile etc 7.

The photo neutron production is one of the major problems associated with high energy bremsstrahlung x-rays 8. The various components in the treatment head (shielding blocks, collimators, flattening filters, scattering foil, vacuum windows, water cooling etc)
are continuously exposed during radiation treatment and become sources for photo neutrons by the (gamma, n) reaction. Also high energy photons interacting with treatment volume and surrounding tissues produces photo-neutrons. So the patient itself becomes source of photo neutrons. The total reaction yield dependent upon the isotopes present, photon flux as well as energy and resonances in cross section. Nuclei with loosely bounded neutrons contribute significantly to this process even at relatively low energies.

The photo neutrons have a continuous energy spectrum with respect to the incident bremsstrahlung photon energy and the threshold energy required for the particular target element. The high LET associated with photo neutrons makes it radio biologically more hazard than the photons. The neutron induced activity is another problem due to the (n, gamma) reaction. The out of field dose and induction of cancer in late period are the outcome of these problems.

Previously neutron fluence and dose measurements were done with different method like foil activation method, CR39 etched track method and using TLD600-TLD700 combination etc. Kry SFet al measured and compared neutron fluence around an accelerator operating at 18MV withFFF and FF mode using gold foil activation in neutron moderators. The result was that, neutron fluence per monitor unit was approximately 20% lower in the FFF mode than in the FF mode. Total neutron fluence during the entire course of prostate IMRT case was 69% lower with the FFF mode.

Hassen Ali Nedaiein their work measured the photo-neutron contamination arising from the 18MV varian clinac 2100CD and Elekta Precise machine using TLD600 and TLD700 pairs and the MCNPX code. They concluded that the larger photo-neutron production in Varian linac compared to Elekta due to differences in the linac head configuration as well as accelerating potential of the incident electron impinging the target.

V et al examined the chemical etching parameters of CR39 as a neutron dosimeter. The CR 39 film placed in polyethylene radiator were exposed to neutron source for different time intervals and the neutron fluence were varied from 4.68x to 2.7x/n. Etched tracks were analyzed and counted at 40X with microscope and neutron recoil track density was calculated after every hour of etching. This study shows that there was a correlation between the total number of tracks per unit area with dose and neutron fluence, and it shows a linear relation. Their experimental results suggested that the potentiality of CR39 as neutron dosimeters in future for high energy linear accelerators and radioactive ion beam facilities.

The present work was carried out with CR39 SSNTD. Different neutron detectors have different characteristics, and they have to be chosen based on the situation. CR39 SSNTD is an ideal detector for neutron dosimetry since it is insensitive to photons of all energies and unlike active detector, no power is required for CR 39 SSNTD operation and the analysis can be done off site. It is also not bulky and can be placed easily anywhere to measure the neutron dose.

The present work focuses on the change in neutron spectrum due to FF and FFF beams. We have recorded photo neutron spectrum due to 10MV X rays from a medical linac (Elekta Versa HD) in FF and FFF modes. The neutrons so produced are detected in a CR39 SSNTD and analyzed using image processing software. The spectral behavior in both FF and FFF mode are analyzed accordingly.

### Materials and Method

The CR39 SSNTD used in this work is a 250 µm thick film and density 1.3 g/cc. The film was cut into eight pieces each of having a dimension of 1cm*1cm using a diamond cutter. Each of eight films was given an identification tag for future reference.

The measurements were done in Elekta Versa HD Linear Accelerator. 10 MV X-rays with FF and FFF mode were used. 1000 MU was delivered to each mode with collimators fully closed. Four positions were selected for measurements, first position is close to the MLC, second position is at isocentre, third position is 30 cm left to isocentre and fourth position is 30 cm right to isocentre (Figure(1)).

In the FF mode, four CR 39 SSNTDs were placed at positions 1 to 4 and irradiated with 10MV X-rays with 1000 MU and jaws fully closed. Then another set of four CR39 SSNTDs were placed at positions 1 to 4 and irradiated with 10 MV X-rays in the FFF mode with 1000 MU with jaws fully closed. The CR 39 SSNTDs were taken out and properly tagged for future reference.

The measurements were done in Elekta Versa HD Linear Accelerator. 10 MV X-rays with FF and FFF mode were used. 1000 MU was delivered to each mode with collimators fully closed. Four positions were selected for measurements, first position is close to the MLC, second position is at isocentre, third position is 30 cm left to isocentre and fourth position is 30 cm right to isocentre (Figure(1)).

In the FF mode, four CR 39 SSNTDs were placed at positions 1 to 4 and irradiated with 10MV X-rays with 1000 MU and jaws fully closed. Then another set of four CR39 SSNTDs were placed at positions 1 to 4 and irradiated with 10 MV X-rays in the FFF mode with 1000 MU with jaws fully closed. The CR 39 SSNTDs were taken out and properly tagged for future reference.

The irradiated CR39 SSNTDs were chemically etched in an in house chemical etching setup made at University of Calicut. Two CR 39 SSNTDs can etch
simultaneously. The chemical etching was done at standard etching conditions such as 6N NaOH at 60°C for 6 hours with 30 rotations per minute.

The chemically etched CR 39 SSNTDs were then imaged with an optical microscope with 40X Magnification. The images of the tracks obtained at different positions are as shown in figure(2) for both FF and FFF modes.

Each CR39 SSNTD was read out using Triac II automatic track counting software\textsuperscript{18, 19}. The Triac II is a programming software written in matlab and is based on Hough transform method. This software is used to measure the length of Major axis, minor axis, Orientation and brightness of the elliptical tracks formed in the detector. During analysis of the CR39 detectors, the Triac II programme fits ellipses to the openings of the nuclear tracks in the image. Once an image is analyzed and all tracks within the image were measured and the programme gives the output in excel format.

The recoil proton energy can be calculated from the track diameter by using a calibration graph\textsuperscript{20,21}. The calibration graph is obtained by plotting track diameter and known proton energy (See figure (3)). The equation to best fit the data is calculated and is given by

\[ E_p = (0.0295956 \times d^2) + (-1.16821 \times d) + 12.674 \]  

where \( d \) is the track diameter.

Then the corresponding neutron energy is calculated using the equation

\[ E_n = E_p \cos^2 \Theta \]  

Where \( E_p \) is the energy of proton, evaluated in the previous step, \( E_n \) is the neutron energy and \( \Theta \) will be the recoil angle.

Thus the neutron energy corresponding to each track can be calculated.

The neutron energy is binned with 200 KeV and the average energy for each bin is calculated. The number of photo-neutrons for each average energy was counted. This is then corrected with the efficiency as

\[ Y = n \sigma \phi \]

Here \( n \) is the number of hydrogen atoms present in 1cm\(^2\) unit of CR39 film, \( \sigma \) is the cross section for \((\gamma,n)\) reaction obtained from EXFOR ENDS, \( \phi \) is the efficiency corrected number of photo-neutrons and \( Y \) is the number of tracks formed in the CR39 film in 1 cm\(^2\) area. The spectrum is then plotted with energy along X axis and corrected counts along Y axis (See Figure (4)).

### Results and Discussion

The photo neutron fluence was measured at the four specified positions using CR 39 SSNTD with the accelerator operated in both FF and FFF mode. For all measurements the gantry was kept at zero degree and collimator fully closed. 1000 MU was delivered for each mode. The images of the tracks obtained for FF and FFF mode using CR 39 SSNTD is as shown in figure(2). The result shows a considerable reduction in neutron fluence for the FFF mode when compared to the FF mode. This reduction ranges from 2.27\% to 44.22\%. On average the reduction in neutron fluence was 19.87\% for the FFF mode of operation.

In the first position, the number of neutron production was 2.27\% more in the FF mode. Similarly which is 44.22\% more at isocenter, 26.06\% more at 30 cm right of the isocenter and 6.94\% more at 30 cm left of the isocenter. It shows there was no discernable trend in the reduction of neutron production as a function of position. On average neutron production was 19.87\% lower in the FFF mode of operation compared to the FF mode. Total number of tracks and percentage of difference is as shown in the table (1).

The plot between number of counts and neutron fluence is presented in figure (4). It provides information about the Q value of the materials involved in the \((\gamma,n)\) reaction. The highest peaks in the spectrum is near to the Q value of lead (Pb) which shows that the majority of the photo neutron production from the linac head is due to Pb which is present in flattening filter, shielding materials, collimators etc. The presence of flattening filter increases the photo neutron production in FF mode compared to the FFF mode.

**Conclusion**

In the present work the photo neutronfluence was measured for FF and FFF mode in an Elekta Versa HD medical linear accelerator. The neutron fluence was measured at four preselected positions around the gantry with FF and FFF mode. The result shows that the removal of the flattening filter led to a reduction in the number of photo neutrons produced during treatment session. This reduction ranges from 2.27% to 44.22% with an average of 19.87%. No discernable trend was found in the measurement as a function of measurement position.

The result of this study reveals that the photo neutron production associated with high energy radiotherapy can be reduced by a considerable amount by operating the medical linac in the FFF mode. FFF mode removes one of the components responsible for the photo-neutron production. Also the machine requires only less beam on time in the FFF mode to deliver the treatment which reduces the photo neutron production associated with other components in the linac head such as shielding blocks, collimators etc. This considerable reduction in the photo neutron production reduces the severe biological effects caused by the high LET nature. It also reduces the induced activity due to the interaction of neutrons with various components in the linac head. The out of field neutron dose also decreases which may induce fatal secondary malignancies in the patient. The risk of fatal secondary malignancy from 18 MV IMRT to the prostate cancer has been previously studied by Kry SF et al for an accelerator equipped with flattening filter. The present day treatment planning systems doesn’t include the neutron dose associated with the high energy radiotherapy treatment. The algorithm should include the photo neutrons produced from the treatment head, air and from the patient itself. The montecarlo simulation studies can be used for the complex neutron transport and hence the dose. The present study gives an insight in to the photo neutron production percentage in FF and FFF modes and it gives an added advantage for the FFF mode treatment in addition to the less beam on time.

Effectiveness of Mobilization to Sitting in Improving Arousal at Various Durations in Traumatic Brain Injury Patients

Venkatesh Nagarathinam¹, Rajeswari Muthusamy², Sivakumar Ramachandran³

¹Postgraduate Student, ²Associate Professor, ³Professor, Faculty of Physiotherapy, Srinagar-116

Abstract

Background: Rehabilitation of motor function in Traumatic brain injury patients in the acute phase depends on their state of consciousness and arousal level. Upright positioning stimulates the ascending reticular activating system and is proved to have improvement in arousal level. Verticalization in the acute phase is not well tolerated due to orthostatic intolerance. Mobilization to sitting in the acute phase could reduce the negative effects and improve arousal but the effective duration of mobilization is not well studied which demands the need of the study.

Methodology: This interventional study was conducted in the Neurosurgery ICU with 24 patients in each group. Brain abnormalities were classified using Marshalls CT TBI classification and patients with Coma Recovery scale (CRS-R) of ≤ 7 were included and allocated to either ½ hour or 1 hour mobilization for 15 days. Changes in the arousal level were assessed with CRS-R after 15 days to measure their improvement.

Results: Both the groups showed statistically significant improvement in arousal with p value ≤0.01 in paired test and unpaired t test showed increased arousal in group 2 than group 1 with p value ≤ 0.01. Negative correlation was observed between onset of mobilisation and improvement in CRS-R in both the groups with Pearson correlation (p ≤ 0.01)

Conclusion: The study concludes that arousal in TBI patients is significantly improved by early onset of mobilization to sitting both for ½ and 1 hour duration without much orthostatic intolerance in the acute period which could be included into the standard care of rehabilitation of TBI patients.

Keywords: Arousal, Traumatic Brain injury, Verticalization, Mobilisation to sitting.

Introduction

Traumatic brain injury (TBI) is a non degenerative, non congenital insult to the brain from an external mechanical force, possibly leading to permanent or temporary impairment of cognitive, physical, and psychosocial functions, with an associated diminished or altered state of consciousness.¹,² 1.5 to 2 million persons are injured and 1 million die in India with Road traffic accident (RTA) accounting for 60%, falls around 20-25% and violence of 10% with alcohol involvement in 20% of TBI patients at the time of injury.³

The mortality rate of severe brain injury was around 33%, and for moderate brain injury was 2.5% as per Traumatic Coma Bank.⁴ TBI results in chronic disability and long term complications of TBI include physical disability, cognitive, psychological, behavioural and emotional deficits leading to psychosocial and economic burden.⁵ Open TBI results when the scalp or skull is fractured and closed TBI results when an outside force impacts the head without any external injury.⁶ Primary damage that occurs at the time of actual impact includes skull fracture, contusion, hematoma, laceration, nerve damage. Secondary damage occurs over time after the actual injury which is aggravated by obliteration.
of microvasculature, release of proinflammatory cytokines leading to reduced tissue perfusion and oedema\(^6\).

Diffuse bilateral hemisphere damage and failure of the ascending reticular activating system (RAS) cause coma or vegetative state. Coma is defined as an unarousable state without eye opening, verbalization, or the ability to follow commands\(^7\). Vegetative state is a condition characterized by complete unawareness of the self and the environment but accompanied by sleep–wake cycles which continues for at least six months\(^8\). Arousal is the physiological readiness of the human system for activity. RAS plays an important role in arousal\(^9\). Neurotransmitters of RAS include serotonin, acetylcholine, noradrenaline, adrenaline, dopamine and GABA which are activated by collaterals from somatic sensory pathway, olfactory, visual, auditory, visceral, descending motor pathway and circulating catecholamines. All stressful activities activate ascending RAS which in turn activates hypothalamus\(^10\). Physiological arousal can be increased by stressors which affects the physical or psychological health that stimulates the nervous and cardiovascular systems\(^11\). A change within the autonomic system affects the cardiac muscle, smooth muscle and endocrine glands and in response to arousal there is an increase in blood pressure\(^12\).

Rehabilitation of a TBI patient in the acute phase depends on the level of arousal of a patient. Various strategies like Tactile, Auditory, Visual stimulation as well as multisensory stimulation have been used to improve arousal in TBI patients. Electrical stimulation of peripheral nerves activates the Neuro-endocrine system and it is proposed to stimulate ascending RAS which enhances arousal following TBI\(^13\).

Changes in body position play an important role in arousal, improvement of alertness. Positional changes like sitting upright or lying down in a relaxing chair, standing in tilt table with and without stepping and Locomotion therapy in robotic tilt table improves arousal in vegetative or minimally conscious patients\(^14\). Many studies have showed positive effects of verticalization on tilt table but upright positioning in early phases of TBI is not completed as it results in the occurrence of postural hypotension, syncopal or pre syncopal symptoms due to central sympathetic dysfunction, absence of venous pump and effects of gravity which leads to increased blood pressure and heart rate\(^15\). Randomized crossover pilot trial,” “type”: “article-journal”, “volume”: “22” }, “uri”: [ “http://www.mendeley.com/documents/?uuid=5f8ee86f-4595-4a46-876f-3e618401ac5b” ] }, { “id”: “ITEM-2”, “item Data”: { “ISBN”: “0269-9052”, “ISSN”: “02699052 (ISSN These effects would be reduced in sitting which could be advantageous to start in the acute period earlier than standing but not many studies have been done in analyzing the effect and the ideal duration for sitting which could improve arousal is also not well studied which demands the need of this study.\(^16\)

**Materials and Method**

This intervention study was approved by the Ethics Committee (CSP/16/AUG/50/230) Sri Ramachandra Institute of Higher Education and Research. Subjects were recruited from Neurosurgery Intensive care unit and wards. 48 patients in the age group of 20-75 years diagnosed as TBI with both open and closed head injuries who were haemodynamically stable and out of sedation with a CRS-R score of <7 were included in the study. Subjects who were associated with severe cardiac arrhythmias, uncontrolled seizures and pelvic bone fractures were excluded from the study.

**Procedure:** Operational definition for Mobilization to sitting is bringing the patient to an upright sitting position from supine lying passively on to the chair. Subjects were screened for their inclusion criteria after receiving the referral from Neurosurgeon and informed consent was obtained from their Caretakers. Study subjects were allocated to enter into Group1 or Group 2 based on sequential sampling technique. Marshalls CT classification was used to classify brain abnormalities of TBI patients. Their arousal level was assessed by CRS-R. After receiving routine Physiotherapy, subjects were mobilized passively to sitting in a chair with safety precautions by positioning with pillows and straps in comfortable position.

Group 1 subjects were made to sit for 30 minutes and Group 2 were made to sit for one hour for seven days a week and continued for 15 days. Blood pressure and heart rate were monitored in supine lying and in sitting after 15 minutes of mobilization. Patients were reshifted back to bed safely when they showed syncope or presyncope symptoms such as tachypnoea, tachycardia, pallor or increase in sweating. After 15 days of intervention subjects were again assessed with CRS-R to assess the improvement in arousal level.
Mobilization to Sitting

Results

Data was analysed with SPSS version 17.0. Table 1 shows the mean and standard deviation of improvement in CRS–R between day 1 and day 15 within and between the Groups. Both showed statistically significant improvement in arousal with p value of < 0.01 in paired t test and p value < 0.01 in group 2 in unpaired t test. Correlation between onset of mobilisation with improvement in CRS-R was found with Pearson correlation which showed a negative correlation with statistically significant p value of < 0.01 in both Groups (Table 2). Table 3 shows the changes in CRS-R scores in different grades of Marshall CT scan classification and Table 4 shows the mean blood pressure of lying and sitting in Group 1 and Group 2 at day 1 and day 15.

Discussion

Arousal impairment is the major problem following TBI which plays an important role in recovery of motor function. Coma indicates dysfunction of the ascending RAS resulting in environmental deprivation which can retard recovery and further depress impaired brain functioning. Enhancing the recovery from coma is important in setting realistic goals and attaining...
maximum functional outcome. Strategies to stimulate ascending RAS to improve arousal are required to perceive the incoming stimuli which could lead to meaningful activity.

Four patients who underwent mobilisation were not able to continue sitting due to orthostatic intolerance which was minimal in number compared to studies on tilt table verticalization to upright standing. Riberholt et al (2013)\(^{22}\) investigated mobilization in tilt tables to improve arousal but fifteen of sixteen patients did not complete 20 minute session of tilt table training which conveys that mobilization to passive sitting is well tolerated than standing.

Patients who were mobilized to one hour sitting showed better improvement in CRS-R score compared to half an hour mobilization which is evident from the higher mean difference score in Group 2. Comparison of CRS-R scores between day 1 and day 15 showed significant improvement in both the groups conveying that mobilization to sitting from lying as well as both duration had a strong influence in improving arousal (Table 1). This finding is consistent with the study done by Megha M et al\(^{23}\) where multimodal coma stimulation was given for 3 groups of TBI patients and the two interventional groups received 20 minutes and 50 minutes of stimulation and third group received conventional therapy. Results convey that short duration of high frequency stimulation at regular intervals will adequately stimulate ascending RAS thereby improving arousal.

Many studies on verticalization in TBI patients are done after 3-4 weeks post injury but mobilization in this study has been initiated at an early period after the patients were out of the drugs inducing sedation in the acute period in the Intensive Care Unit. The mean day of onset of mobilization was 6.08 in Group 1 and 6 in Group 2 respectively. Table 2 shows the correlation between onset of mobilization post injury to the improvement in CRS-R which had a significant negative correlation conveying that early mobilization will result in significant improvement of arousal from coma. A very Early Rehabilitation Trial for Stroke patients (AVERT) done by Bernhardt et al\(^{24}\) showed that very early mobilization was safe, feasible and patients were able to tolerate longer period of upright positioning. This conveys that higher centres could be stimulated without ill effects when mobilized at an early period which could have an additional benefit of improving arousal.

Oedema is the cause of death in large number of TBI patients where ICP persistently remains high leading to widespread damage and deterioration of higher functions. Medical management with Diuretics in the acute period extract water from intracellular compartments and thereby causing a reduction in oedema and intra cranial pressure\(^{25}\). As this study is done in the acute period, reduction in oedema could also have enhanced the improvement of arousal.

Comparison of Grades of Marshall CT scan with improvement changes of CRS-R score (Table 3) shows that subjects having Grade II in Group 1 and Grade VI in Group 2 showed good recovery but result cannot be taken up as there were unequal numbers of subjects in all grades. Maximum number of subjects were in Grade II which conveys that majority of patients with TBI following RTA have similar intensity of injury with the midline shift of 0–5 mm in this study group. The mean decrease in blood pressure from lying to sitting in day 1 was 4.87/3.04 mmHg in Group 1 and 4.29/3.12 mmHg in Group 2 which was within physiological limits as the subjects did not show any orthostatic intolerance(Table 4). The mean Blood pressure in day 15 in both groups did not show much difference in lying to sitting which could be attributed to the fact that subjects would have got accommodated to the sitting position on the 15th day. Intra cranial pressure monitoring could have been done as this study was done in the acute period which is considered as limitation of the study.

**Conclusion**

The study concludes that both mobilizations to sitting at both ½ and 1 hour duration has a beneficial effect in improving arousal in the acute period without much orthostatic intolerance which could be included into the standard care of rehabilitation of TBI patients.

Vegetation and Pollution in Delhi-Frequency, Abundance and Density of Plants and Pollutant Levels: An Analysis

Rudraksh Gupta¹, Manju Rawat Ranjan², Usha Mina³, Rajul Kumar Gupta⁴

¹Post Graduate, Amity Institute of Environmental Sciences, Amity University, Noida, ²Associate Professor, Amity Institute of Environmental Sciences, Amity University, Noida, ³Associate Professor, School of Environmental Sciences, Jawaharlal Nehru University, New Mehrauli Road, Delhi, ⁴Professor, Army College of Medical Sciences, New Delhi

Abstract

The present study endeavours to explore the role of vegetation in air quality improvement at selected sites of Delhi. The study was conducted at four sites of Delhi-Pusa in Central Delhi, ITO in East Delhi, Dwarka in South West Delhi and Rohini in North West Delhi. To monitor and quantify the abundance, frequency and density of vegetation of the sites, belt transect method (with 500m transect and 30 quadrats of 0.5 x 0.5m) was used. Results of the study indicate that Pusa had highest abundance (6.7), frequency (86%) and density (6.2) of vegetation as compared to Dwarka, Rohini and ITO. ITO site has minimum abundance (2.0), frequency (50%) and density (1.9) of vegetation. There was a statistically negative correlation between the abundance, frequency and density of vegetation and ambient levels of chemical air pollutants. Physical pollutant (PM₂.₅), doesn’t seem to get affected by vegetation. The study indicates that the contribution of vegetation is significant in improving air quality of urban areas.

Keywords: Air quality, Vegetation, Pollution reduction, Abundance, Frequency, Density, Belt transect method, Delhi.

Introduction

Being the capital of India and a metropolitan city with ahuge population of 1.25 crore, Delhi has experienced a phenomenal growth in recent years. Delhi is adversely affected by problems of urbanization. There is rapid growth of vehicles, construction, and energy consumption resulting in serious environmental concerns.

Delhi has a relatively rich tree and forest cover which facilitates pollution control. But the tree cover varies from location to location. It is therefore important to assess the vegetation cover and to correlate it with pollutant levels at specific places. So far as the role of vegetation is concerned, pollution reduction is a function of the quantity and quality of vegetation. While the quantity of plants (number, frequency and density) present at a location would determine the level of pollution reduced by them, it is also the type of vegetation (shrubs/tress and species) which is important. In the present study, the vegetation cover and pollution level at various regions was assessed to ascertain the relationship between vegetation and pollution levels.

Methodology

This analytical study was undertaken at New Delhi, with an area of 1484 sq km. The study was undertaken over five months and pollution levels measured during January to March 2018, at four selected sites catering to all directions-North, East, Central and South-West, located far away from each other:

1. Dwarka (DAV School)-South West Delhi
2. ITO (Near Metro Station)-East Delhi
3. DTEA Senior Secondary School, Pusa Road-Central Delhi

4. Rohini (Delhi Technical University)-North West Delhi

Data of PM$_{2.5}$, NO$_2$ and NO levels, on daily basis was downloaded from Central Pollution Control Board (CPCB) nearbymonitoring sites displayed on website (https://app.cpcbccr.com/ccr/#/caaqm-dashboard-all/caaqm-landing/data) for the entire study period.¹

**Studying Vegetation:** Belt transect methodology was used to monitor and quantify vegetation.² The belt transects were marked between two points of 500 m area. The length of the belt transect was taken as 500 m at each selected site, where 30 quadrats were laid down, each of size 0.5m x 0.5m. The vegetation in each quadrat was identified, counted and tabulated. The abundance, frequency, density of vegetation was quantified using following formulas³

- **Abundance** = Total no of individuals
- No of quadrats of occurrence

- **Frequency (%)** = No of quadrats in which species occurred x100
- Total no of quadrats studied

- **Density** = Total no of individuals
- Total no of quadrats studied

**Equipment Used for Monitoring Vegetation:**
0.5 X0.5 m Quadrat, 30m measuring tape, nails, thread, camera

**Results**

**Average Pollutant Concentration:** Average Pollutant concentration for PM$_{2.5}$, NO$_2$ and NO was ascertained from 3 January to 9 March 2018 which is summarized in **Table 1**.

As abundance, frequency and density of plants increases pollutant level decrease. ITO is one of the most polluted areas in Delhi. Pollution is caused by high vehicular density; Pusa on the other hand has lots of green areas, and less vehicular pollution resulting in lower levels of PM$_{2.5}$, NO$_2$ and NO.
Correlation of Pollutants Versus Abundance, Density and Frequency of Plants: Correlation of pollutants (PM$_{2.5}$, NO$_2$ and NO levels) versus the abundance, density and frequency of the three plant species (*E. hirta*, *Cynodon*, *Amaranthus*) were calculated. (Table 4). An inverse correlation was seen between frequency of various plant species and levels of NO and NO$_2$. (statistically significant for frequency of *Euphorbia* and *Cynodon* with NO$_2$ and NO) and *Amaranthus* with only NO.

</tbody>
</table>

Figure 3: Correlation between frequency of Euphorbia with NO (R=-0.98, p=0.02) & NO2 (R= 0.96, p =0.04)
An inverse statistically significant correlation was also seen between abundance of two plant species (Amaranthus and Cynodon) and levels of NO. Abundance of Amaranthus also exhibited a statistically significant inverse correlation with NO level.

An inverse correlation was seen between abundance of Euphorbia and Amaranthus and levels of NO and NO\textsubscript{2}. It is seen that there was a statistically significant inverse correlation between density of Amaranthus with NO Levels and Euphorbia with NO and NO\textsubscript{2} levels. Density of Amaranthus also exhibited a statistically significant inverse correlation with NO level.

However there was no correlation between frequency, abundance and density of all three plant species and PM\textsubscript{2.5}.

**Discussion**

PM\textsubscript{2.5}, NO\textsubscript{2} and NO are dangerous pollutants which adversely affect human health and environment. The present study was undertaken to correlate levels of these pollutants with abundance, frequency and density of plants at various urban sites in Delhi.

**Health Effects:** Particles in the PM\textsubscript{2.5} size range travel deeply into respiratory tract, reaching the lungs. Exposure to fine particles causes short-term health effects such as eye, nose, throat and lung irritation, coughing, sneezing, runny nose and shortness of breath. Exposure to fine particles also affects lung function and worsens medical conditions such as asthma, chronic bronchitis, reduced lung function and increased mortality from lung cancer and heart disease.

When nitrogen is released during fuel combustion, it combines with oxygen atoms to form nitric oxide (NO). This further combines with oxygen to create nitrogen dioxide (NO\textsubscript{2}). Oxides are together referred to as (NOx). NOx gases react to form smog and acid rain besides being central to the formation of fine particles (PM) and ground level ozone, both of which compromise health.
High NOx levels have a negative effect on vegetation, including leaf damage, reduced growth, making vegetation more susceptible to disease and frost damage. A study of the effect of nitrogen dioxide and ammonia on the habitat of Epping Forest revealed that pollution is likely to significantly influence forest-ecosystems.4,5

**Pollution Levels:** The site at ITO had the highest level of pollutants followed by Rohini, Dwarka and Pusa. In January 2017, the pollution levels at ITO were maximum. According to Times of India, PM$_{2.5}$ average at ITO between December 18, 2016 to January 2, 2017 was 309 µg/m$^3$, more than five times the 24 hour standard and more than 12 times the WHO guidelines.6

Levels are highest at ITO being a traffic intersection and most of the land is concretized. According to a study by IIT, it was found that Pusa was one of the least polluted areas in Delhi followed by Dwarka and Rohini7. Present study also depicts similar results. Pusa and Dwarka have lower pollution levels due to high abundance of trees, lesser construction activities and lower traffic. Rohini is an industrial area with lots of construction work and smoke being emitted from industries.

**The Role of Plants in Reducing Pollution:** The present study shows that with rising vegetation (i.e. increasing abundance, density, frequency of plants) there is an increased reduction in pollution at that particular site. From the present study it was also clear that Pusa had the highest quantity of the three common plant species followed by Dwarka and Rohini. ITO had the lowest abundance, frequency and density of the three plant species, which reflected on its high pollution levels.

However, there was no correlation between plants and PM$_{2.5}$. It is owing to the fact that being a physical particulate matter PM$_{2.5}$ is seen to be unaffected by the level of vegetation.8 From these results, it can be inferred that the plants exhibited a statistically significant inverse correlation with chemical pollutants.

**Conclusion**

According to a Times of India, Delhi is one of the most polluted cities in India and ITO the most polluted site.6

To take a case in point, ITO also has lowest abundance, frequency and density of plants resulting in highest pollution levels. Plants are most effective in reducing the levels of chemical pollutants like NO$_3$ and NO. The physical pollutant, i.e. PM$_{2.5}$ is not seen to be affected by the plants.

The study re-emphasises the importance of acute and urgent requirement of planting more tress, besides taking other pollution control measures. These are needed most at ‘high-pollution/low-vegetation’ sites, like the ITO. The plantation drives by the Delhi Government are commendable. There is a requirement of indulging in similar plantation drives by schools, NGOs, other government organizations, industries, corporate houses, and the general public. As brought out by the study, if intensive plantation drives are implemented, the pollution level in Delhi will reduce significantly, contributing to health for the community and the environment.

Prevalence and Factors Influencing Chronic Kidney Disease in Urban Slum Area of Mysuru City

M.R. Narayana Murthy\textsuperscript{1}, Rashmi S\textsuperscript{2}, Praveen Kulkarni\textsuperscript{3}, Manjunatha S. Shetty\textsuperscript{3}

\textsuperscript{1}Professor and Head of Department, Department of Community Medicine, JSS Medical College, Mysuru, \textsuperscript{2}Post Graduate, Department of Community Medicine, JSS Medical College, Mysuru, \textsuperscript{3}Assistant Professor, Department of Community Medicine, JSS Medical College, Mysuru, \textsuperscript{3}Professor and Head of Department, Department of Nephrology, JSS Medical College and Hospital, Mysuru

Abstract

Introduction: Chronic Kidney Disease (CKD) leads to high morbidity and mortality in both developing and developed countries. CKD as a complication of non-communicable diseases and as itself leads to huge economic burden to the individual and nation. Screening is the only measure to prevent or delay in progress of early CKD. Hence this study was undertaken in urban slum area of Mysuru with the objectives to estimate the prevalence of Chronic Kidney Disease (CKD) using estimated-Glomerular filtration rate and Urinary abnormalities in people residing in urban slum area of Mysuru and to find out the factors influencing Chronic Kidney Disease

Method: This cross-sectional study was conducted in the urban slum, Mysuru. A total of 828 adults above 18yrs, consenting to participate were included in the study. A semi-structured proforma was used to collect data by interview technique. Serum creatinine was used to calculate eGFR. Urine analysis was done using dipsticks.

Results: The prevalence of CKD of Stage 3 and above (using CKDEPI equation) was found to be 6.8% and proteinuria of 3.5%. Risk factors identified were age, gender, obesity, hypertension, smoking, alcohol and indigenous medicine usage.

Conclusion: Screening for CKD at PHC level with tests like S. Creatinine estimation (hence eGFR calculation) and urine dipstick analysis along with information on age, gender, blood pressure, smoking status and presence or absence of diabetes mellitus can help in implementing preventive measures at grass-root level.

Keywords: Adults, Chronic Kidney Disease, Urinary abnormalities, Risk factors, urban slum, Mysuru.
the Indian CKD Registry of 52,273 adult CKD patients who registered till 2010, 35.5%, 27.9%, 25.6% and 11% patients were from South, North, West and East zones respectively. Important risk factors for kidney disease recognized globally include diarrheal diseases, HIV infection, low birth weight, malaria and preterm birth, all of which are also leading global causes of DALYs. Modifiable risk factors like tobacco use, physical inactivity, harmful use of alcohol and unhealthy diets all are known to increase risk of developing CKD. In India, aetiology of CKD varies considerably with Diabetic nephropathy being the commonest cause (31%), followed by CKD of undetermined aetiology (16%), chronic glomerulonephritis (14%) and hypertensive nephrosclerosis (13%). Few parts in the states of Andhra Pradesh, Odisha, and Goa have high levels of CKD of unknown aetiology (CKDu), which is a chronic interstitial nephropathy with insidious onset and slow progression.

People with CKD may not feel ill or notice any symptoms. Only way to find out for sure is screening through specific blood and urine tests which includes measurement of both creatinine level in blood and protein in urine and decreased renal function (below thresholds of GFR estimated from serum creatinine concentration). There are very few data available about prevalence of CKD in Urban areas of Karnataka and in Mysuru. Hence this study was done to know the prevalence of CKD and risk factors influencing CKD in adults residing in urban slum area of Mysuru.

Method

This community based cross-sectional study was done in Urban field practice area (Urban health centre-UHC) of JSS Medical College, Mysuru for a period of 18 months (January 2017 to June 2018). Sample size of 828 was derived from prevalence of 17.2% from the SEEK study. This was divided among 6 blocks of UHC area using Population Proportion to size. After taking informed consent, data was collected by house-to-house survey by interview technique, random blood sample for serum creatinine estimation and random midstream urine sample for dipstick analysis were collected. Serum creatinine thus estimated was used to calculate estimated glomerular filtration rate by CKD-EPI equation and stages of CKD was categorized according to KDOQI guidelines. Data thus collected was coded and entered in Microsoft excel spreadsheet and analyzed in SPSS version 22. Descriptive statistics like percentages, mean and standard deviation were calculated and inferential statistics like Chi-square test was applied and p-value less than 0.05 was taken as statistically significant.

Inclusion criteria: Individuals aged 18 yrs and above residing in study area.

Exclusion criteria:
- Severely ill and bed ridden patients
- Pregnant women and women who had just delivered (up to 40 days after delivery) were excluded.

Results

Among the study participants, 378(45.7%) belong to age groups 30-39 and 40-49 years with nearly equal representation from both groups. 223(27%) of study participants were males and 605(73%) were females. Most of them, 260(31.4%) were non-literates, majority were unemployed 409(49.4%) and majority 364(44%) belonged to Lower Middle Class and Middle class according to Modified B.G. Prasad’s Socio Economic Status Classification.

With S. Creatinine, eGFR was calculated according to CKD-EPI equation and stages of CKD were categorised according to KDOQI guidelines based on eGFR value and presence of either proteinuria or hematuria. Mean eGFR was noted to be 90.37 ml/kg/m² and 391(47%) had CKD (Figure 1). Among them 7(0.84%) belonged to Stage 1, 328 (39.6%) were in Stage 2, 44 (5.31%) were in Stage 3A, 8 (0.96%) were in Stage 3B of CKD classification. 3 (0.36%) had Stage 4 and 1 (0.12%) had Stage 5 which are severe to very severe CKD among study participants (Figure 2). 37(3.5%) had hematuria of 37(3.5%) and 9(1%) had proteinuria.

Obesity was noted in 413(50%), 348 (42.1%) were found to be hypertensive with 258 (31.2%) having Stage 1 Hypertension and 90 (10.9%) having Stage 2 Hypertension and 216(26.1%) had pre-existing Diabetes Mellitus. Smoking was noted in 190 (22.9%), 190(23%) were consuming alcohol and 86 (23%) were using smokeless tobacco. Indigenous medicine use was noted in 327(39.5%), analgesics (NSAIDs) use without prescription was noted in 436(42.7%) of the individuals.

Among socio-demographic variables tested for association with CKD, a statistically significant association was found with age (p<0.001), gender...
(p=0.01), education (p<0.001), occupation (p<0.001) and socioeconomic status (p=0.002).

Among modifiable risk factors tested for association with moderate to severe CKD, a statistically significant association was found with BMI (p=0.048), hypertension (p<0.01), smoking (p=0.003), alcohol (p=0.001) and use of indigenous medicine (p=0.014). (Table-1).

Figure 1: Distribution of CKD among the study participants based on CKD-EPI equation
Discussion

In the present study comprising of 828 study participants, majority (45.7%) belonged to age group 30-39 and 40-49 years, 73.1% were females, 31.4% were non-literate and 49.4% were unemployed. This can be explained by the study being conducted in urban slum area and majority were females. Majority (44%) belong to lower middle socio-economic status according to modified BG Prasad Scale of Socio-economic status.
Present study documented prevalence of CKD based on CKD-EPI equation (according to KDOQI classification) to be 47% and moderate to severe CKD (Stage 3A and above) was found to be 6.8%. This is more than that in SEEK multi-centric study, where overall prevalence of CKD in India was 17.2% and that in Mysuru was 4.2% (CKD-EPI equation). In a study done in South rural Karnataka by Anupama et al., noted prevalence of CKD to be 6.3% (MDRD equation). In present study, association between age and CKD was found to be statistically significant at p value of 0.01. Studies have already proved age to be an independent risk factor for CKD and advancing age is the most powerful independent risk factor for CKD. In our study, with respect to gender, CKD stage 3A and above was noted to be 7.2% of males and 6.6% of females. The association between gender and CKD was found to be statistically significant at p-value of 0.01. In SEEK multi-centric study, prevalence of CKD was more in males than females and in a study conducted in South Karnataka, CKD prevalence was noted to be high among males than females. Our study is in concordance with both the studies with CKD seen more in males than females. In our study, there was statistically significant association between educational status and CKD with p-value of <0.001. In the SEEK study, it was noted that individuals with education level more than the High School had higher prevalence of CKD and association was noted to be statistically significant. This was in contrast to our study where CKD prevalence was noted more in non-literate individuals. This can be explained by composition of study participants which had more of non-literate. Our study result was in concordance with that in the KIDS project in South interior Karnataka, where prevalence of CKD was more among those who had education level lesser than High school.

Prevalence of hypertension in Urban India was noted to be 33.8% and in South India was 31.8% from a meta-analysis study done in 2014. Our study had higher prevalence than this with 42.1% were hypertensive and was associated with statistical significant at p value of <0.001 with CKD. Our study finding was similar to that of KIDS project where there was statistical significant association between hypertension and CKD. Prevalence of pre-existing diabetes mellitus in the present study was 26.1% which is more than prevalence of DM in India which was 8.5% in 2016. Even though diabetic nephropathy is the most common cause of CKD, there was no statistically significant association between DM and CKD and this may be due to inclusion of only individuals with history of DM and no screening was done for the same. Present study documented tobacco consumption in 33.3% of study population. Tobacco use as smoke tobacco was 22.9% and smokeless tobacco was 10.4% in contrary with the Global Adult Tobacco Survey (GATS-2) done in India in 2016-17 which reported 28.6% of tobacco use in any form with 10.7% using smoke tobacco and 21.4% using smokeless tobacco and tobacco use in any form in Karnataka was noted to be 22.8%, which is lesser than our study. Prevalence of alcohol consumption was found to be 23% in the present study similar to National Household Survey of Drug Use in India in 2015 which recorded alcohol use in India was 21.4%. In the present study, indigenous medicine usage was noted in 39.5% which is more than the WHO-Sage study in 2016 in which 11.9% were using traditional medicine. In the present study, analgesics (NSAIDs) usage without prescription was noted in nearly 52.7% was more than that in a study done in Bangalore, which was noted as 35.8%. Generalised obesity was noted in 49.9%, similar to a study conducted in urban north India, in which the prevalence of generalized obesity was 50.1% and the Chennai Urban Rural Epidemiology Study (CURES) conducted in Chennai city in Tamil Nadu which reported age standardized prevalence of generalized obesity to be 45.9 per cent and association was found to be statistically significant with p value of 0.023. Our study result was similar to that of results in SEEK study where there was statistically significant association between BMI and CKD.

Conclusion

CKD and risk factors for CKD are prevalent in urban slum population. Among study population, majority had normal eGFR, but 7 individuals were noted to have urinary abnormality as proteinuria/hematuria with normal eGFR. Nearly 6.8% had eGFR suggestive of CKD (stage 3A and above). This proportion of CKD calls for preventive measures. Risk factors are gradually increasing in Indian population and represent a public health concern which indicates that there is need of intervention to reduce these are necessary. Use of simple tests like S. Creatinine estimation (hence eGFR calculation) and urine dipstick analysis can be recommended in PHC level and preventive measures can be implemented in individuals who are at risk of CKD (stage 2) can be identified and can be made aware of measures to be taken to prevent or delay progression into further stages of CKD.

An Epidemiological Study on Barriers of Utilization of Contraception among Married Women of Reproductive Age Group in Rural Population of Meerut

Ravi Shastri¹, Pawan Parashar², Varsha Chaudhary³

¹PG 3rd Year, ²Professor, ³Associate Professor, Department of Community Medicine, Subharti Medical College, Swami Vivekanand Subharti University, Meerut, Uttar Pradesh

Abstract

Background: Family planning promotion has the potential to reduce poverty, maternal and child mortality, high risk pregnancy, and abortion.

Objectives: To assess the barriers in acceptance of contraception among the women of reproductive age group in the rural population.

Materials and Method: A community based cross-sectional study was conducted in the rural setting of Parikshitgarh block of Meerut in Uttar Pradesh. 285 women of reproductive age group (15-49 years) were selected by multistage random sampling. Information regarding the various barriers was obtained from the participants by interview by door to door survey.

Results: Out of the 285 women, contraceptive use was seen in 150(52.6%) whereas 135(47.4%) women were not using any contraceptives. The reasons of non use of contraceptives seen in this study were wanted child/pregnant 74(54.8%), don’t feel necessary/not interested 33(24.4%), Menorrhagia/abnormal or excessive bleeding 8(5.9%), husband not ready/not allowed 3(2.2%), diminution of vision 2(1.5%), menopause started early 1(0.7%), uncomfortable/don’t like 1(0.7%), weight loss 1(0.7%).

Conclusions: This study found that desire for child was the main reason for non utilization of contraception followed by not understanding the necessity of contraception. Side effects and opposition from husband were also important reasons but were reported by considerably less women compared to the two major reasons.

Keywords: Contraceptive, Barriers, Non utilization.

Introduction

The family welfare programme has travelled a long way, but still total fertility rate has not reached the desired target of 2.1%. In spite of availability of a wide range of contraceptives, mass media campaign and Information Education and Communication programme, the population control seems a distant dream to achieve.[¹]

The factors responsible operate at the individual, family and community level with their roots in the socio-economic and cultural base of society. Most of the married women want to use the contraceptive method but are unable to use because of illiteracy, lack of knowledge, economical problem, fear of side effects, social customs, religious cause, superstitions, insufficiency of family planning worker, uncooperative husband and limited supply and high cost.[²]

Cultural barriers inhibit from postponing childbearing, parents, in-laws and relatives influence
couples to give births soon after marriage. Moreover, persistent misconceptions about modern contraceptive method act as barrier to use. Reasons for not using oral contraceptive pills were reported as perceived or experienced side effects/health concern, dizziness, loss of appetite, weight gain, nausea/vomiting, breast tenderness, mild headache, fatigue, and depression or mood change. With regard to use of condom, inconvenience or lack of privacy was reported as barrier to use. Lack of correct knowledge about contraceptive method was also found as barrier to use contraception.\(^3\)

**Objective:** To assess the barriers in contraception acceptance among married women of reproductive age group in rural population of Meerut.

**Materials and Method**

A community based cross-sectional study was conducted in the rural setting of Parikshitgarh block of Meerut, Uttar Pradesh in India, from March 2017 to February 2018. The present study was conducted in the area of rural health & training centre Khajoori in Kila Parikshitgarh block which is rural field practice area of Department of Community Medicine, Subharti Medical College, Meerut. There are 12 blocks in Meerut district and Kila Parikshitgarh is one of them. From the List of Villages in the block, 3 villages (Khajoori, Alipur and Badhla) were selected by Simple Random Sampling. Using the Simple Random Sampling first village to start was chosen (Khajoori).

For selecting the first house for the study the researcher with one female health worker reached the centre of the village and rotated the pencil and the house towards which the tip of the pencil pointed was chosen as our house no. 1 and then every 5th house by Systematic Random Sampling was covered by using left hand rule. After first village Khajoori next village Alipur was chosen by left hand rule and then the last village selected was Badhla till we got the desired sample size \((285)\) calculated by taking the prevalence of unmet need of contraception (rural) 23.1% on the basis of National Family Health Survey 2005-06 (NFHS-3).\(^4\)

If there were no eligible woman in the house according to sampling technique then we moved on to the next house.

Informed consent was taken from the woman prior to the interview. The purpose and objectives of the study was explained to the married females prior to data collection and they were assured about the confidentiality.

Only one eligible woman in one house was included in study. The data was collected by using prestructured, pretested, pre validated schedule. Interview method used was using validated Hindi translation of the schedule.

A pilot study was done on 30 married females for validating the schedule and necessary modifications and rectifications were done. After the necessary modifications survey was started in compliance with basic ethical issues. These 30 families were not included in the final sample of 285 households used for analyzing.

Data was analysed using SPSS version 19.0. Frequency tables were made for proportion and Pearson’s Chi square test was applied to find out significant association between independent and dependent variables. A p-value of less than 0.05 was considered significant.

**Results**

In the present study a total of 285 married women of reproductive age group (15-19 years) were interviewed, out of which 59.4% women in our study group belonged to nuclear families while 40.6% women were living in joint families. Majority of women 162(56.8%) belonged to Muslim religion, whereas 120(42.1%) women belonged to Hindu population and only 3(1.1%) were from Sikh community. Among all the families 85(29.8%) were of lower middle class, followed by 72(25.3%) middle class, 71(24.9%) upper middle class, 38(13.3%) upper class and only 19(6.7%) belonged to lower socio-economic class.

In our study group 80(28.1%) women belonged to age group of 25-29 years, followed by 72(25.3%) in 30-34 years age group, 54(18.9%) in 35-39 years age group, 46(16.1%) in 20-24 years age group, 27(9.5%) in 40-44 years age group. Only 5(1.8%) women were in 45-49 years age group and 1(0.4%) women was in 15-19 years age group(as also depicted in figure 2).

Majority women (61.1%) in our study were literate (as also shown in figure 3).In the present study majority women were housewives 255(89.5%).

Table No.1 shows that the current level of contraceptive use as reported in this study was 52.6%. The method of contraception being used are depicted in figure 1 in which condom usage was by 57% followed by female sterilization by 20%.
Table No.2 depicts that the reasons of non use of contraceptives seen in this study were wanted child/pregnant 74(54.8%), don’t feel necessary/not interested 33(24.4%), Menorrhagia/abnormal or excessive bleeding 8(5.9%), husband not ready/not allowed 3(2.2%), diminution of vision 2(1.5%), menopause started early 1(0.7%), uncomfortable/don’t like 1(0.7%), weight loss 1(0.7%).

Discussion

In the present study, out of 285 women, nearly half (46.3%) of the women were in 35-49 years age group, followed by 28.5% in 15-29 years age group, and 25.3% women in 30-34 years age group, while in Shukla et.al (2015) [4] in Lucknow slums majority of the women(63%) were in 15-29 years age group, followed by 21.1% women in 30-34 years age group and 15.9% women in 35-49 years age group.

In the present study, majority of the women(57.9%) were Non-Hindu (162 Muslim, 3 Sikhs), followed by 42.1% women of Hindu religion, whereas in Setu Y et.al (2018) [5] study in urban slums of Allahabad, most of women (94.4%) were of Hindu religion.
In the present study, 59.4% women were living in nuclear families and 40.6% women were living in joint families, whereas according to Vohra et al. (2014) [6] in their study done in rural and urban area of Jaipur, 93.2% women lived in nuclear families and only 6.8% women lived in joint families.

Majority of the women (89.5%) in our study were housewives; similar findings were reported by Rizvi A et al. (2013) [7] in their study in urban Lucknow (94%) were.

In our study 38.9% women were illiterate, similar findings were reported by Choudhary S et al. (2011) [8] in their study in rural area of Hisar, Haryana in which 43.3% were illiterate.

In the present study we found that majority women belonged to lower middle class (29.8%), followed by middle class (25.3%), and upper middle class (24.9%) according to BG Prasad socio-economic Classification (2017) [9], whereas Chakraborty et al. (2016) [10] in their study in rural area of North 24 Parganas of West Bengal reported slightly lower number of women in lower class (19.5%), middle class (20.7%), but slightly higher number of women in upper middle class (28.9%).

Table no.1 shows that in the present study out of 285 women current users of family planning in our study were 52.6% which was much higher than the prevalence of contraception in rural UP as reported in the NFHS 3 (2005-06) [4] (39.7%) and NFHS 4 (2015-16) [11] (42.1%). Similar findings were reported by Afzal Hakim et al. (2017) [12] in their study done in Jodhpur (57.2%) and Jesha MM et al. (2016) [13] in their study in North Kerala, in which current users were 49% whereas Rizvi A et al. (2013) [7] in their study in urban Lucknow reported almost half (26.2%) current users in comparison to our study.

Table no.2 depicts that in the present study out of 135 women who were not using any family planning method currently the most common reason given was pregnancy/desire for pregnancy (54.8%), followed by who did not feel necessary/were not interested in using any method (24.4%), reason of abnormal or excessive bleeding during previous use (5.9%), opposition from their husband (2.2%), non use due to dimunition of vision due to prior use of any method (1.5%), menopause started early/uncomfortable with any method/weight loss (0.7%). Similar to our result the most common reason for not using any method of contraception in Hajira Saba et al. (2014) [14] study in urban areas of Bangalore, Hemavarneshwari et al. (2015) [11] study in rural areas of Bangalore and Murarkar et al. (2011) [15] study in rural area of Ambajogai, Maharashtra was desire for pregnancy (56%, 46.3% and 39.8% respectively), the second reason was need not felt in 20.1% in Hajira Saba et al., whereas in Hemavarneshwari et al. and Murarkar et al. the second reason were fear of side effects in 14% and 16.3% respectively. Opposition of partner/relative was given as reason by 12% in Hemavarneshwari et al. and 14% in Murarkar et al which was higher than our study whereas it was only 0.8% in Hajira Saba et al. which was less compared to our study. Other reasons in these studies different from our studies were misconception and against religion in 10.5% each in Hajira Saba et al; fear of surgery in 10.6%, religious reason in 5.1% and lack of knowledge in 2.6% in Hemavarneshwari et al.; early menopause by 14%, breastfeeding by 8%, reason of no knowledge of source of obtaining any method by 5.7%, ignorance about use and anti religion by 4.5% each, infrequent sex by 3.8% and undergone hysterectomy by 3% in Murarkar et al. In contrast to our findings Lakkarwar et al. (2014) [16] in their study done in sub-urban Pondicherry reported that the most common reason for not using contraception was lack of knowledge (54.3%), followed by against the religion (49.3%), worry of side effects (48.9%), opposition to family planning (44.3%), cost factor and health does not permit (24%), afraid of sterilization (15.8%) and do not like any method (6.3%).

**Conclusion**

The present study also conclude that the barriers identified in the study were, desire for child, fear of side effects, opposition from husband/family members, need not felt, no proper explanation by health worker regarding family planning, contraception causes weight loss, diminution of vision and uncomfortable to use in previous episode.

**Limitations of the Study:** It was a cross sectional study. No follow-up was done. Data was collected by interview method so there may be recall bias, response bias although our questionnaire was pretested and validated.

Transcranial Direct Current Stimulation in Combination with TENS: Effectiveness on Pain and Functional Outcomes in Knee OA Patients: A Study Protocol

Rekha Chaturvedi1, Sivachidambaram Kulandaivelan1, Manoj Malik1, Shabnam Joshi1

1Assistant Professor, Guru Jambheshwar University of Science and Technology Hisar, Haryana

Abstract

The goal of the study is to investigate the effectiveness of combination of Transcranial direct current stimulation (tDCS) and TENS on pain and functional outcomes in patients with knee osteoarthritis. Patients following ACR criteria for knee osteoarthritis, aged more than 45 years will be selected for the study. 80 patients will be selected and will be randomized into following four groups: Active tDCS/active TENS (group 1), Sham tDCS/active TENS(group 2), Active tDCS/sham TENS(group 3), Sham tDCS/sham TENS(group 4). The study will be participant blinded randomized controlled trial. The outcome variables are pain and functional assessment using six minute walk test and self-reported questionnaire KOOS. Trial Registration: CTRI/2018/02/012027.

Keywords: Combination, Transcranial direct current stimulation, TENS, Pain, Osteoarthritis, Knee.

Introduction

Knee osteoarthritis (OA) is one of the common cause of musculoskeletal pain and disability. It is estimated that 20% of people aged over 30 years experience knee symptoms in India1, resulting in substantial pain and physical dysfunction2. Various therapeutic exercises are recommended for patients of knee osteoarthritis with the prime aim of improving muscular strength, as weakness is common in knee OA. Strength training can conquer the muscle weakness in such patients by improving the muscle mass. However, pain becomes a hurdle in exercising that causes individuals to under perform the exercises. Therefore, strengthening the musculature of lower limb can overcome this problem. Many pharmacologic treatments are available however; there is growing interest in non-pharmacologic intervention targeting the central nervous pain processing system.

Transcranial direct current stimulation (tDCS) is used in chronic pain conditions because of its neuromodulatory effect3-6. The application of TENS in knee OA has been demonstrated to be effective in managing arthritic pain7-12. Thus, by combining the two interventions can generate both the neuromodulatory effect (cortical effect) as well as segmental inhibition in the pain gate13 and descending pain suppression via δ-opioid mechanisms (spinal and peripheral effect). Various studies have suggested tDCS combined with TENS resulted in greater pain reduction than their isolated application in low-back pain (LBP) by the priming effect14,15. Therefore, taking in account of these encouraging results, we hypothesize that the combined application of tDCS, TENS and exercise will reduce pain to greater extent and may enhance mechanistic and clinical outcomes in knee OA. Moreover, RCTs from Asian countries, particularly India where knee pain is common1, is still lacking and our protocol is aimed to reduce this knowledge gap.

Objectives: The primary objective of the study is to find out the effectiveness of combined tDCS and TENS on pain. The secondary objective of the study is to find out the effectiveness this combination on quality of life in patients with knee osteoarthritis.

Hypothesis: Transcranial stimulation (tDCS) in combination with TENS will reduce pain and bolster the
effect of exercise by priming effect thereby improving function in knee osteoarthritis patients and may regulate pain by the “top down and bottom up” mechanism.

Method

Target population and sample: The subjects will be recruited from public announcements, flyers and referral cases of knee OA from various hospitals. The study will be conducted at 3 centers in XXX. The participants fulfilling the American college of Rheumatology (ACR) criteria for clinical classification for idiopathic knee OA will be recruited for the study.

The sample size was calculated by pilot study on 8 subjects with 80% power at 95% confidence interval of effect size 0.54. Sample size of 16 subjects in each group was calculated. The sample size was increased to 20 subjects expecting 20% dropout rate.

Inclusion criteria: The subjects will be selected on the basis of criteria defined by the ACR Criteria: Presence of knee pain and any three of following: age over 45 years; morning stiffness lasting less than 30 min; crepitus; bony tenderness; bony enlargement; no palpable warmth.

Exclusion criteria: The subjects will be excluded if they have the following: Any knee surgery in the past 6 months; Knee joint replacement or high tibial osteotomy on the affected side; other muscular, joint or neurological conditions affecting the functions of lower limb;unable to walk unaided; currently undertaking any exercise programme for knee OA; contraindications to tDCS (eg, epilepsy).

Discontinuity criteria: The subjects will be discontinued if: They miss 3 consecutive session of exercise even after repeated reminders made through phone call; any moderate to severe adverse events are presented by the subjects that are related to application of therapeutic intervention or exercises; subjects who involves in other medical treatment for knee OA that may interfere with the results;any other health program like weight reduction or aerobic exercises or Pilates or any other fitness training program.

Research group and study design:

Study design: Present study is 4-arm parallel group, participant blinded; sham (placebo) controlled randomized trial. After taking the informed consent at the baseline visit the subjects will be assessed by the researcher thoroughly at the baseline visit and will be randomly allocated to one of the four groups by corresponding author through lottery method done by independent person not participating in the study. All the subjects will receive hot packs followed by the interventions and exercise protocol thrice weekly. All the participants will be assessed four times a) at the baseline visit b) week 1 (after 5 days of intervention) c) end of 2nd week d) end of 6th week. All the subjects will undergo weekly thrice supervised exercise training for 5 weeks and advised to do exercises taught at home on the days not coming for the treatment. Home exercises and supervised exercise will be taught by experienced physiotherapist (First author). The study participants were allowed to continue their medications if any, throughout their participation in the trial. At the baseline visit, type of medication, dosage and frequency of medication will be recorded. Total duration of study is 6-weeks including 1st week 5 treatment sessions followed by weekly thrice supervised exercise for 5 weeks.

Research group: The study participants selected following the inclusion and exclusion criteria for the study will be randomly assigned to one of the four groups.

Group 1: Active tDCS/Active TENS (n=20)
Group 2: Active tDCS/Sham TENS (n=20)
Group 3: Sham tDCS/Active TENS (n=20)
Group 4: Sham tDCS/Sham TENS (n=20)

Intervention description:

Transcranial direct current stimulation (tDCS): A constant current of 2 mA for 20 min once a day for 5 consecutive days will be by a pair of circular sponge electrode saturated with normal saline. The anode will be placed on primary motor cortex (M1, C3 or C4) as per 10/20 International electroencephalogram EEG system) contralateral to the most painful knee and the cathode will be placed on opposite supraorbital region ipsilateral to the affected knee. For sham stimulation same electrode placement will be used. The equipment will be turned on for 30 sec, and then turned off. A Customized model, Medicaid, Chandigarh (Mohali), India will be used for transcranial stimulation.

Transcutaneous electrical nerve stimulation (TENS): A pair of surface electrodes 5cm × 5 cm, placed on the skin at medial and lateral side of the knee joint
fastened by velcro will be used. High frequency TENS at 100 Hz for 20 min duration will be given to the patient for five consecutive days. Only the most painful side will be stimulated. For sham stimulation the same placement of electrode will be used, with stimulator turned on for 30 sec and then turned off. TENS Enraf Nonius, USA will be used for stimulation. Both the stimulators (tDCS and TENS) will be turned on and off simultaneously during each session of treatment.

**Exercises:** The subjects will perform a supervised exercise protocol following the interventions. Each exercise will be done for 3 sets of 10 repetitions with a break of 30 sec in between the sets. The exercise program will progress as mentioned in the prescribed protocol. The study physiotherapist will decide the initial level of exercise depending upon the ability of the subject and the time when to progress the exercise based on the participant’s performance and therapist’s clinical judgment. The subjects will undergo initial 5 sessions of exercise on 5 consecutive days post intervention (1st week). Subjects will undergo thrice a week supervised exercise sessions for next 5 weeks (2nd-6th week) by study therapist. The participants will also be taught home exercises to be performed on days not coming for treatment. The subjects must undergo at least 12 sessions (including 1st week 5 sessions) of supervised exercise session for estimating the desired benefits of the exercise regime.

**Outcomes:** The outcome variables of all the participants will be assessed four times: at the baseline visit, week 1 (post intervention), 2 week and at week 6.

- **Pain:** The intensity of pain will be measured by VAS (0-10 cm) by asking pain on walking during previous day, self-assessed pain describing ‘no pain’ (score 0) and ‘extreme pain’ (score 10) will be reported.

- **Function:** Six minute walk test is reliable tool in Indian population will be used for functional assessment. Subject was asked to walk on a 20-m corridor for six continuous minutes as per Ateef et al 2016. The distance covered in meter by the participant will be recorded in the assessment form.

- **Quality of Life:** It will be assessed through self-reported Knee injury and Osteoarthritis Outcome Score (KOOS) questionnaire containing 42 questions in five subscales namely pain, symptoms, activities of daily living (ADL), sports/recreation and quality of life. Score ranges from 0 to 100 where 100 means maximum problem. KOOS is a reliable assessment tool in Indian knee OA patients.

**Safety:** For ensuring safety of the participants questions like any symptoms of itching or burning sensation, tingling, any kind of pain at the stimulation site, headache, mood changes, anxiety, nervousness, or any kind of changes in visual perception during or after the treatment or any other potential risk described by Rossi et al 2009 will be asked.

**Ethical aspects:** The trial will be conducted according to the ICMR (Indian council of medical research) 2017 guidelines which are in accordance with Helsinki declaration 2013 (7th revision). All the participants will sign the informed consent prior to participation in the study.

The trial has been prospectively registered with the Clinical Trail Registry of India number CTRI/2018/02/012027 registered on 21/02/2018. Ethical approval was obtained from Institutional ethical committee vide letter no. PTY/2017/484 dated 9th October 2017. The findings of the study will be shared with the participants in simple language. Confidentiality of the participants will not be breached at any point of the study. The raw original data will be archived for 5 years by the investigator of the study. Consolidated data without participant’s personal details will be permanently archived in Mendeley data repository.

**Consent to publish:** A written permission from the participant will be obtained for the data and images to be published.

**Data analysis:** The data will be analyzed as per principle of intention to treat. To find out the effectiveness of interventions, analysis of pain and functional outcomes per protocol analysis of variance (ANOVA) will be used. Repeated measure ANOVA will be used to estimate the effectiveness of interventions within the group for all the four groups. Effect size will be calculated.

**Discussion**

The paper is in accordance with the recommendations of SPIRIT guidelines (Standard Protocol: Recommendations for Interventional Testing) in evolution and recording of protocol for the study. Considering OA as a debilitating health problem, requires better management of pain and function thus making the population less disabled. Supervised exercise
program shows better results as the treatment is given on one to one basis. In a study on knee osteoarthritis, the application of tDCS demonstrates substantial pain reduction and improved mobility performance and the effect of stimulation lasts for 3 weeks. In another study, tDCS combined with TENS demonstrates promising results in chronic LBP patients. Present protocol is similar to Luz-Santos et al. and marginally different from it by outcome measures. We believe 6-minute walk test is more functional hence meaningful to patients; would help the therapists to monitor rehabilitation outcome. Considering the results obtained from these studies, the effectiveness of tDCS used alone as well as in combination with TENS must be explored for treating musculoskeletal conditions like knee OA. tDCS, either alone or combination, may be a potential intervention for better management of pain and functional activities in knee OA.

Benefits: The subjects will be asked to continue the exercises even after the completion of trial at home to sustain the benefits of exercises. The results of the study if comes out to be effective, the leading treatment will be offered to the people not received the treatment.

Trial status: The study is enrolling participants from April 2018 onwards and estimated to be completed by March 2020.

Compliance with Ethical Standards: This article does not contain any studies with human participants performed by any of the authors.

Funding: There is no external funding to write this paper.

Conflict of Interest: The author of the study declares no conflict of interest.

Are Teachers/Motivators in Schools Aware of MR Vaccination?: A Study in a City of South India

Rock Britto¹, S. Priyadarshini², P. Priyanka²

¹Assistant Professor, Department of Community Medicine, ²MBBS, Medical Interns, Department of Community Medicine, Chennai Medical College Hospital and Research Centre, Trichy, Tamil Nadu

Abstract

Introduction: Measles is a major killer disease and Rubella leads to lifelong birth defects. In India, every year nearly 2.7 million children get measles and over 4000 children are born in India with such birth defects (Congenital Rubella Syndrome). The mortality and morbidity of measles and rubella is not declining a significant level in recent years. To bring it down, government of India has planned a massive vaccination campaign on measles and rubella among children (9 months to 15 years). School based immunization was a part of the strategy.

Method: This study aimed at assessing the awareness of MR vaccination among principals and teachers in 90 schools in Trichy, using a self-administered questionnaire and the results were compiled and analyzed.

Result: The results showed that 94.4% of the study group was aware of the disease with the main source of awareness being media and social workers which accounted for 38.9%. The results showed that 78.9% people were convinced that measles and rubella is a big burden to our country. Respondents strongly felt that health education regarding MR vaccine was necessary in order to eradicate measles and rubella. IEC activities, Training Programs can be aimed at improving the knowledge about MR Vaccination to the school teachers. Teachers can be trained to conduct Counseling sessions to increase the acceptance rate

Keywords: Measles, Rubella, MR Vaccine.

Introduction

Measles is a deadly disease and one of the main causes of children mortality in the country. It is highly contagious and spreads through coughing and sneezing. Rubella is generally a mild infection, but has serious consequences, if infection occurs in pregnant women, causing congenital rubella syndrome, which is a cause of public health concern. (¹) High level of herd immunity is required for its elimination. (²) Sero-prevalence studies suggest that coverage in the range of 90–95 % is needed. (³) India along with ten other WHO South East Asian region member countries, have resolved to eliminate measles and control rubella and congenital rubella syndrome by 2020. (⁴) With an aim to eradicate rubella and measles from India, the union health ministry launched the measles-rubella campaign, targeting 41 crore children from 9 months to 15 years across the country. The first phase of MR vaccination campaign was held in February 2017. The campaign was first launched in Karnataka, Tamil Nadu, Puducherry, Goa and Lakshadweep covering nearly 3.6 crore target children. However, it will later be extended to cover the entire country. According to the ministry, after the campaign, MR vaccine will be introduced in routine immunization, replacing the two doses of measles vaccine given to children at 9 to 12 months and 16 to 24 months of age. The government is committed to eradicate Measles and Rubella from the country and have taken this as an achievable target. This shall be taken up in a mission mode and rolled out in a partnership with state government and NGO’S.

All children aged between nine months and less than 15 years was be given a single shot of MR vaccination irrespective of their previous measles/rubella vaccination
status or measles/rubella disease status. MR vaccine was provided free of cost across the states from session sites at schools as well as health facilities and outreach session sites. All eligible children were vaccinated in schools for first 1-2 weeks of campaign. Next 2 weeks, health sub-centres, antidepressants, fixed outreach sessions and mobile/special posts in villages and urban area conducted vaccination for the missed and school absentees. Government health facilities vaccinated on all days of campaign.

This study had teachers and principals as respondents, considering them as point of contact in the society who can establish contact and extend their knowledge to others in the population. The study aimed at assessing the knowledge about the vaccine and henceforth reinforcing the importance, awareness and acceptance of the vaccine which will aid in elimination in the near future.

**Objectives:** To assess the level of awareness about MR vaccination campaign among the teachers/motivators in schools in Trichy city.

**Materials and Method**

Cross sectional study was done in Feb-March 2017 among 90 schools in Trichy district. From each School a single participant was selected either a principal or a teacher. A self-administered questionnaire was used to collect relevant information from the teachers and other staffs considering them as the point of first contact for this campaign. The study was done with their informed consent and after proper explanation. The Questionnaire included basic details about the school, awareness about the measles and rubella disease, vaccines and source of information. The data was entered in MICROSOFT EXCEL and analyzed using EPI INFO software. Descriptive statistics were done using frequency and percentage.

**Results**

**A. Awareness about MR Vaccination:** Out of 90 participants in this study, Most of the respondents, 47 (53%) were Principals and remaining 43 (47%) were teachers. In this study, 85(94%) were aware of the vaccination program and the remaining 5(6%) were unaware of the vaccination campaign as represented in Figure 1.

**Figure 1: Awareness about vaccination campaign (n=90)**

Among the study population, 72(80%) of respondents answered correctly as MR vaccine, 13(14%) answered as rubella and 5(6%) answered as MMR. This is represented in the following Figure 2.

**Name the vaccine correctly**

**B. Information related to MR Vaccination:** Out of the study participants, 71 (79%) of participants considered measles and rubella as a burden to our country hindering our country’s growth and 50(56%) have answered the exact age group for MR vaccination as 9 months to 15 years. Also 76(84%) have answered that health education regarding MR vaccination was adequate and 85(94%) feel that MR vaccine is necessary for eradication of the two diseases which aids nation’s growth. This is represented in the following Figure 3.

**Figure 2: Awareness about name of the vaccine given during campaigns (n=90)**

**Figure 3: Awareness about age group for MR vaccination (n=90)**
C. Source of Information: Media and social workers contribute to source of awareness of equal percentage 35(39%). The other sources include Pamphlets, Posters and Demonstrations. This is represented in the following Figure 4.

Nearly 50 to 75 respondents are aware about the importance and need for the vaccine and the exact age group for the vaccine. As media can have a huge impact on the general population as it can reach people easily in an effective manner and can break all the myths regarding the vaccine and their adverse effects. Advertisements may be provided in newspapers and other radio channels so that it can enhance the acceptability and the need for the vaccine. Training programs can be organized for the teachers and other social workers who can improve the knowledge about the vaccination campaign thereby increasing the success rate of the vaccination.

In our study 85(94%) were aware of the vaccination program where as in a study done among parents about rota virus and pneumococcal vaccine 120(34.2%) of mothers were aware about Rota virus and 148(39%) about Pneumococcal vaccine. Awareness of these vaccines was seen among the middle and upper socio economic group with the major source of awareness being doctors and health workers. Similarly another study done among parents about knowledge and attitude about immunization calendar showed 80% of unawareness. This increase knowledge among the study population in the current study may be due to the recentness in the campaign and training programmes for the school authorities about these particular campaigns.

Studies done about similar campaigns in Tehran showed that one day before the beginning of the
campaign, over 80% of the people under study were aware of it. This increased and at the end of the 2nd week the coverage reached more than 96%. By the end of the program, all of the people sampled were aware of it.(7) Our Study results shows good knowledge level among the teachers compared to the general population of other studies. However, a teacher is expected to fit in to the role of motivator, counselor for promoting the vaccination campaign. For that role the knowledge related to MR vaccination is not complete.

Regarding the source of information, Media contributes equal to source of information spread by social workers (39% each). The effective use of spread of information through both media and social workers is needed.

**Conclusion**

Mass vaccination campaigns are considered an important strategy to increase vaccine coverage. Teachers in this case, act as bridge between health care providers and the community. They are not completely aware of the MR Vaccination and its related information. IEC activities, Training Programs can be aimed at improving the knowledge about MR Vaccination among the school teachers. Teachers can be trained to conduct Counseling sessions to increase the acceptance rate.

**Recommendation:** Health care providers and other social workers being persons with good understanding about vaccines can be used to create awareness. Training programs can be conducted to the teachers to create awareness about the disease and vaccination as they can motivate students and their parents. Small advertisements in mass media regarding vaccine and its usefulness may be done to reach people in all levels.

**Ethical Clearance:** Obtained ethical clearance from our Institutional ethical committee, Chennai Medical College Hospital and Research Centre, Trichy, Irungalur-621105

**Funding:** Self

**Conflict of Interest:** None

Causes of Occupational Stress among Women Healthcare Professionals (Nurses) in Private Hospitals

S. Bulomine Regi¹, S. Anthony Rahul Golden²

¹Assistant Professor of Commerce, St. Mary’s College (Autonomous), Thoothudi Affiliated to Manonmaniam Sundaranar University, Tirunelveli; ²Assistant Professor of Commerce, St. Xavier’s College (Autonomous), Palayamkottai Affiliated to Manonmaniam Sundaranar University, Tirunelveli

Abstract

Occupational stress has become an issue of great concern over the last decade. It represents an important concern among healthcare workers due to its crucial contribution in attaining maximum job output and optimal quality of working life. The study aims at identify the factor causing occupational stress among women health care professionals and to compare the occupational stress among women health care professionals based on category of employees. Both primary and secondary data were collected for the study. Primary data were collected using questionnaire method and secondary data were collected from reports, books, magazines and websites. The research study was based on primary data. The sample respondents were selected using purposive random sampling i.e. purposively nurses working in private hospitals of Palayamkottai in Tirunelveli city. The data collected were analysed using various statistical tools like percentage analysis, ANOVA, t-Test, Weighted Average Score and Ranking. The major findings of the study are selected sample respondents are under the age group of 20-30 years. Majority of the respondents have completed diploma in nursing. The nurses working in private hospitals are satisfied about their job but not satisfied about the shift working time. The researcher found that there is significant difference among marital status and causes of occupational stress also there is no significant association between age and occupational stress and there is a significant association between working hours and occupational stress. The researchers conclude that women health care professionals are more stressful.

Keywords: Occupational Stress, Health Care, Causes, Nurses, Women, Work Stress.

Introduction

Occupational stress is a stress related to one’s job. Occupational stress often stems from unexpected responsibilities and pressures that do not align with a person’s knowledge, skills, or expectations, inhibiting one’s ability to cope.¹ Occupational stress can increase when workers do not feel supported by supervisors or colleagues, or feel as if they have little control over work processes. Occupational stress focuses on important aspects of job characteristics, such as skill variety, task identity, task significance, autonomy, and feedback.² These characteristics are proposed to lead to ‘critical psychological states’ of experienced meaningfulness, and experienced responsibility and knowledge of outcomes. It is proposed that positive or negative work characteristics give rise to mental states which lead to corresponding cognitive and behavioural outcomes, e.g. motivation, satisfaction, absenteeism, etc.³ In conjunction with the model, Hackman and Oldham (1980) developed the Job Diagnostic Survey, a questionnaire for job analysis, which implies key types of job-redesign including combining tasks, creating feedback method, job enrichment, etc⁴.

Stress in nurses is an endemic problem. It contributes to health problems in nurses and decreases their efficiency. The nursing profession is known to be stressful throughout the world and has detrimental effects on the physical and psychological well-being of an individual’s health.⁵ Occupational stress is of key interest to employers because of the known adverse effects on employee performance, productivity, job satisfaction and health as a whole. Stress basically involves the relationships between individuals and their environment that are considered as challenging or exceeding their resources and jeopardizing their well-being.⁶ Stressors are objects and events; stress reactions
are responses in the form of physiological (such as rapid heart rate, increased blood pressure) and psychological (e.g. anger, fear), that occur when confronted with a stressor. World Health Organization has observed that stress is a worldwide epidemic because stress has recently been noted to be associated with 90% of visits to physicians.

Statement of the Problem: Stress makes one depressed and makes them to fail in their life. Women are a backbone of a family. At present, along with family pressure, women are forced to go for job. Then only it is easy and manageable to the family economically. So, women are going for job. Now-a-days women preferred to go for hospital service jobs like doctors, nurses and administrative support staff. Even trying to manage family, women are facing problems in their work place too i.e gender inequality between co-worker, sexual harassment and so on. So it creates job stress to the workers. As a nurse, woman faces many situations like personal life and the career. Women balance both responsibilities equally and sincerely.

Objectives of the Study: The following are the objectives focused in this study:

1. To study about the concept of occupational stress among nurses.
2. To find out the causes of occupational stress among nurses working in select private hospital of Palayamkottai city.
3. To give suggestions to cope up with occupational stress among nurses.

Methodology

The researcher select Palayamkottai city for conducting the research. Palayamkottai is the heart of Tirunelveli district. There are so many hospitals in and around Palayamkottai city with ample facilities and various speciality hospitals. So, the researcher select palayamkottai city as the study area. The period of the study is six month s from November-2017 to April-2018. The study was confined with both primary and secondary data. The primary data were collected using questionnaire. The questionnaire was issued to the nurses working in private hospitals and the data were collected for analysing. The secondary data were collected from websites, magazines, articles and so on.

Four hospitals were selected for the study. The nurses working in the select hospital were selected as sample respondents. The nurses working in private hospital were selected for the study using purposive stratified random sampling. The respondents were selected for the study randomly based on the availability and willingness of the respondents to fill the questionnaire. The sample of seventy respondents was selected for the study. The study was analysed using percentage analysis, ANOVA, t-Test, weighted mean score and rank.

Analysis and Interpretation: The followings are the findings observed based on the objectives of the study.

- Most of the respondents (70 per cent) are belong to the age group between 20-30 years.
- Majority (74 per cent) of the respondents have completed diploma in nursing.
- Majority (69 per cent) of the respondents are unmarried.
- Majority (87 per cent) of the respondents are staff nurse.
- Majority (59 per cent) of the respondents are earning Rs.5000–8000 per month.
- Majority (67 per cent) of the respondents not have enough salary.
- Most (26 per cent) of the respondents are in paediatric department.
- Majority (56 per cent) of the respondents are satisfied with their job.
- Majority (56 per cent) of the respondents are having heavy stress due to Shift working hours.
- Majority (33 per cent) of the respondents are having break time for 30 minutes to one hour.
- Majority (61 percent) of the respondents are working for 11-12 hours in a day.
- Majority (54 per cent) of the respondents can avail casual leave up to above 12 days in a year.
Table 1: Association between Age and Causes of Occupational Stress

<table>
<thead>
<tr>
<th>Variable</th>
<th>Age (in years)</th>
<th>F-Value</th>

<td>S.D</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Source: Computed Data

The above table shows that there is no significant association between age and causes of occupational stress. The null hypothesis was accepted at 5 per cent significant level. It describes that age does not associate with the causes of occupational stress. All type of age group of the healthcare professionals especially nurses is having similar stress over their job.

Table 2: Significant Difference between Marital Status and Causes of Occupational Stress

<table>
<thead>
<tr>

<td>Unmarried</td>
<td>4.75</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>2.869</td>
<td>0.005**</td>
</tr>
</tbody>
</table>

Source: Computed Data

The above table shows that there is a significant difference between marital status and causes of occupational stress. The null hypothesis was rejected at 5 per cent significant level. It describes that marital status also paves a way for stress on job. Because married family women are having more responsibilities to balance their work and family. It creates a conflict which is first family or job that leads to a server stress over their job.

Table 3: Association between Working Hours and Causes of Occupational Stress

<td>&lt;0.001**</td>
</tr>
<tr>
<td></td>
<td>S.D</td>
<td>3.18</td>
<td>5.09</td>
</tr>
</tbody>
</table>

Source: Computed Data

The above table shows that there is a significant association between working hours and causes of occupational stress. The null hypothesis was rejected at 1 per cent significant level. It describes that working hours plays a significant association with the causes of occupational stress. Increase in working hours leads to have depression and which leads to get stress over job.

Suggestions:

- There are many ways to overcome stress, by doing some exercise and meditation can give some peace to our mind and help us to get relief from stress.
- Due to overcrowding the stress level increases can be controlled by division of the work load equally to all nurses.
- Lack of concentration and Forgetfulness create stress can be overcome by doing meditation.
- Each organization should appoint one person as a counsellor/mentor who will look after worries, tensions, and stress of employees.
• Work should be properly delegated to the employees to avoid overload of work, which could cause stress.
• Good relationship should be maintained within the employees to feel better environment.
• Employees can be motivated by giving rewards for their excellent performance.
• Proper grievance handling system can be practiced to help the employees to overcome their problems.
• Work life balance and stress relief techniques should be demonstrated to the employees to avoid stress over their job.

Conclusion

The level of occupational stress among a group of staff nurses was measured using a questionnaire survey. In addition, factors contributing to occupational stress were examined. Stress will leads to decreases in attention, concentration, productivity and decision making, and judgment skills. Occupational stress is also negatively related to quality of care due to loss of compassion for patients and increased incidences of mistakes and practice errors. Thus, hospital managers should initiate strategies to reduce the amount of occupational stress among the nurses. They should provide more support to the nurses to cope up with the stress.

Conflict of Interest: Nil

Source of Funding: Self

Ethical Clearance: The Data were collected from outside of the working premises. The hospital names were not mentioned anywhere in the research work for ethical conduct.

Financial Performance of Gold Jewellery Merchants of Cuddalore District, Tamilnadu

S. Gunaseelan¹, M. Chandran²

¹Assistant Professor, ²Professor and Head Department of Commerce, VELS Institute of Science, Technology and Advanced Studies, Pallavaram, Chennai

Abstract

The present research paper envisaged the financial performance persisted in the small jewellery merchants in the Cuddalore district has been identified in certain factors. Such as present net worth asset and liabilities present worth of the asset fixed cost per annum variable cost per annum financial assistant in the business start financial bank loan and relative problems by purchase, cost of production, and competition, fashion problems by changing fashion and traditional way of grafting, labour problems by lack of training facilities to unsatisfied working conditions, financial problem, and pricing problem. The primary data have been collected from the identified SJM and analyzed. The results and findings of the study will implicate the SJM and the general public.

Keywords: Jewellery Merchants, Ornamental Usage, Retail Merchants.

Introduction

In today socio-economic empowerment of the people is processing precious metals like platinum, gold and silver. Among the metals, gold has first place as an Ornamental usage. It has possessed by lower class people to upper class of people. As per the religious concepts wearing ornament is parable and Vedic conceptually accepted. The execution of fashion and style of human expression by means of wearing Jewellers is habitually or socially attributed for goodness. In India people are accustom with doing their saving and investment on „Gold”. In south India “Atchayathiruthiyai” is a good sign for investing money on gold. Particularly in Tamilnadu, the people are practicing Gift for others at memorable occasions they prefer only gold coin or ornamental object. Basically the Hindu and the Islamic religious people are practicing the „marriage gift” of offering gift and initial life sources, they are giving Gold ornament. In this juncture, the role of small Jewellery merchants is inevitable.¹ In Tamilnadu, past Ten years back, there is no much of corporate Jewelers, but now (2014) most of the cities in Tamilnadu, the corporate business people having their branch show rooms. They are selling the Gold and other precious metals with a lesser of wastage rates, making cost and VATT (Value Added Tax and Tariff). Thus, this study aims to study the problem of small Jewellery merchants.²

Present Worth of the Assets/Liabilities: To know their financial problems and business growth present worth of the assets and liabilities is to be analyzed. Due to that the researcher has collected the worth of Assets/Liabilities as Up to 20 Lakhs, 20 Lakhs to 50 Lakhs and Above 50 Lakhs.³

Table No. 1: Present Worth of the Assets/Liabilities (Amount in Lakhs)

<table>
<thead>
<tr>
<th>Present worth of the Assets/Liabilities (Amount in Lakhs)</th>
<th>Small Jewellery Shop located in the talks of Cuddalore district</th>

</tbody>
</table>

Source: Primary Data
From the above table the researcher has inferred that most of them (40.8%) developed their business worthiness above 50 lakhs. 33.9 per cent of them are developed 20 lakhs to 50 lakhs. Only 25.3 per cent of the SJM are developed their business worthiness up to 20 lakhs. Thus, the researcher inferred that 74.1 per cent of the SJMs are developed their business above 20 lakhs due to various factors such as rupee net present value, building and land value appreciation, further establishment, extension and increase of stakeholders, interior decoration, capitalization, and utilization of other resources.

**Present Worth of the Net Assets:** Continuations of the above table, researcher has extended that the present worth of net asset value to determine the real growth of their business.

**Table No. 2: Present Worth of the Net Assets (Amount in Lakhs)**

Source: Primary Data

From the above table the researcher has inferred that most of them (40%) are spending fixed costs around up to 2 lakhs per annum. 35.5 per cent of them are spend fixed cost 2 to 5 lakhs. Only 24.5 per cent of the SJM are spending above 5 lakhs. Thus, the researcher inferred that 60 per cent of the SJMs are spend 2 lakhs and above per annum.
**Variable Cost Per Annum:** Continuations of the above table, researcher has extended that the variable costs spent by the SJMs in Cuddalore district.

<td>26 (28.3)</td>
</tr>
<tr>
<td>Total</td>
<td>76 (100)</td>
<td>92 (100)</td>
</tr>
</tbody>
</table>

Source: Primary Data

From the above table the researcher has inferred that most of the respondents (39.6%) are spending variable costs around 1 lakhs to 2 lakhs per annum. 34.7 per cent of them are spend variable cost above 2 lakhs. Only 25.7 per cent of the SJM are spending up to 0.5 lakhs. Thus, the researcher inferred that 74.3 per cent of the SJMs are spend variable costs 1 lakhs and above per annum.

**Sources of Financial Assistance:** During the business operation, the SJMs are availed financial assistances from different sources such as family support, relatives, friends, commercial banks and financial institutions.

<table>
<thead>
<tr>

</tr>
<tr>
<td>Financial institutions</td>
<td>12 (15.8)</td>
<td>25 (27.2)</td>
</tr>
<tr>
<td>Total</td>
<td>76 (100)</td>
<td>92 (100)</td>
</tr>
</tbody>
</table>

Source: Primary Data

From the above table, the researcher infers that most (24.5%) of the respondents are availed the financial assistances from the commercial banks; 20.4 percent of them got financial assistances from financial institutions; 20 per cent of them assisted by their friends; 18.8 per cent of them are got from their relatives and only 16.3 per cent of the SJMs are having the family support for the financial assistances during the business.

**Suggestions**

1. Most of them (34.7%) have taken the investment decision by their relatives
2. Most of them (40%) are spending fixed costs around up to 2 lakhs per annum.
3. Most of them (39.6%) are spending variable costs around 1 lakhs to 2 lakhs per annum.
4. Most (24.5%) of the respondents are availed the financial assistances from the commercial banks.
5. Most of them (39.6%) are held with their business about 10 to 20 lakhs of net asset worthiness.

**Conclusion**

From the above findings and suggestions the researcher has concluded as per the respondents’ opinion that the SJMs are affected at the financial performance of net asset and financial assistant time of purchasing the raw materials for the production of gold and silver ornaments. SJMs are exaggerated on cost of production of gold and silver ornaments. SJMs are embellished by competition on gold and silver ornaments sales. Changing fashion is a hectic problem and it will increase the cost of production and wastages. Traditional way
of grafting will create the replacement of the modern technology in to the old one but it is highly impossible once installed the machines and electrified technology in ornamentation of gold and silver will not revoke into the traditional. The labour oriented gold industry needs the appropriate training facilities. It can be rectified through conducting workshops for fresher’s and the new entrepreneurs. The unsatisfied working conditions have been existed much in the gold jewellery industry and it cannot be rectified by the small jewellery merchants. The financial problems have not stay alive in the small jewels merchants and the financial supports and commercial banks financial assistances are not satisfied. The pricing problems have been continued and it is inherent in nature of small jewellery merchants in Tamilnadu and the price fluctuations and variations are depended with the economy of the nation and the bargaining activities of the customer are everywhere in the competitive marketing environment.

A Study on Changing Family Structure in Tamilnadu

R. Premalatha¹, S. Thangamayan¹, S. Sudha¹

¹Assistant Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, Chennai

Abstract

The traditional values were losing importance and new thinking new values were adding in society. Men and women will be treating equal in modern era. The new health treatment and facilities were opened to serve village people’s health sector. All individuals were given equal opportunity in society. The village people’s way of life, structure of the family has been changed because of impact of liberalization privatization and globalization in our country. The family has also been influenced by the effects of Globalization. Though it is the fact that processes like-Industrialization and Modernization have influences the traditional structure of family in the early years, but the changes have been rapid in the recent years on the Indian rural society, which has also passed through Globalization and Information. The data for this paper is obtained from the Household questionnaire, which contains information, related to age, sex, marital status, education, occupation and relationship to the head of the household for all usual residents as well as for the visitors who slept last night in the house. The family has been and continues to be one of the most important elements in the fabric of Indian society. The bond that ties the individual to his family, the range of the influence and authority that the family exercises make the family in India not merely an institutional structure of our society, but accord give it a deep value. The Indian family is subjected to the effects of changes that have been taking place in the economic, political, social and cultural spheres of the society.

Keywords: Family Structure, Change in Culture, Impact of Society.

Introduction

The term family is derived from the Latin word ‘familia’ denoting a household establishment and refers to a “group of individuals living together during important phases of their lifetime and bound to each other by biological and/or social and psychological relationship”. The Indian society is “collectivistic” in that it promotes interdependence and co-operation, with the family forming the focal point of this social structure. In a situation where the mental health resource is a scarcity, families form a valuable support system, which could be helpful in management of various stressful situations. Ever since the growth of human civilization, change has remained a consistent part of every society though there have been variations in its state and directions. At different phases of growth the processes of change have affected the various aspects of society. The processes of social change like: Modernization, Westernization, Urbanization and Sanskritization have contributed a lot in changing the Society. In the decade of 90’s, the policy of Liberalization in the economic field, has resulted in frequent exchanges and a huge increase in the import-export between nations, and the development of various modes of communication has made the social exchanges between nations possible and easy.¹ These social contacts have been defined in the form of globalization have also influenced the different aspects of Indian society. The primary unit of society and also primary source of socialization is family. The family has also been influenced by the effects of Globalization. Though it is the fact that processes like-Industrialization and Modernization have influences the traditional structure of family in the early years, but the changes have been rapid in the recent years on the Indian rural society, which has also passed through Globalization and Information. The revolution along with other social changes. Globalization is a concept of the emergence of a society that is based on the global outlook. Globalization is outcome of various social and cultural interactions between the masses.²

Objectives of the Study:

1. To understand the change in family structure of the study area.
2. To study the differentials in family structure by different socio-economic characteristics of the head of the family at the state level.

**Sources of Data:** The data for this paper is obtained from National Family Health Survey. The primary objective of the survey is to provide national and state-level data on different demographic and socio-economic determinants in respect of family planning, maternal and child health indicators. The survey also collected the information at three levels-Village, Household and Individual levels. The data for this paper is obtained from the Household questionnaire, which contains information, related to age, sex, marital status, education, occupation and relationship to the head of the household for all usual residents as well as for the visitors who slept last night in the house. In addition, the household questionnaire also included information on housing conditions, such as the source of water supply, type of toilet facility, land owning, type of house and various consumer durable goods and characteristics of the head of the household such as religion, caste and place of residence. This paper the above mentioned particulars are analyzed only for the usual residents in the family.³

**Family Orientation:** The family is the basic unit of society. Families exist in all sizes and configurations and are essential to the health and survival of the individual members and to society as a whole. As the primary group for the individual, the family serves as a buffer between the needs of the individual and the demands and expectations of society. The family is a unity of interacting persons related by ties of marriage, birth or adoption, whose central purpose is to create and maintain a common culture which promotes the physical, mental, emotional and social development of each of its members.⁴

**Extended Family:** A Hindu Joint Family or Joint Family is an extended family arrangement prevalent among Hindus of the Indian subcontinent, consisting of many generations living under the same roof. The joint family status being the result of birth, possession of joint cord that knits the members of the family together is not property but the relationship. The family is headed by a patriarch, usually the oldest male called “Karta”, who makes decisions on economic and social matters on behalf of the entire family. The patriarch’s wife generally exerts control over the kitchen, child rearing and minor religious practices.⁵

**Results Discussion**

To know the distribution of family structure in India, following classifications are considered:

**Table 1. Nature And Size of Family in the Village Community**

<table>
<thead>
<tr>
<th>Sl. No.</th>
<th>Nature of Family</th>
<th>Size of Family</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Nuclear</td>
<td>Small (01-07 Members)</td>
<td>73</td>
</tr>
<tr>
<td>2</td>
<td>Joint</td>
<td>Large (Above 7 Members)</td>
<td>27</td>
</tr>
<tr>
<td>3</td>
<td>Total</td>
<td></td>
<td>100</td>
</tr>
</tbody>
</table>

Table 1 shows that the above mentioned table deals with the about 73 percent families belong to small family’s below7 member’s that is nuclear family and 27 percent families belongs to large-size and come under the category of joint family systems. The tendency of respondents in regard to family authority and decision-making in the changing scenario is demonstrates in the table given below:

**Table 2. The Tendency in Regards to Family-Authority and Decision-Making in the Changing Scenario**

<table>
<thead>
<tr>
<th>Sl. No.</th>
<th>Nature of Decision</th>
<th>Only Husband</th>
<th>Only Wife</th>
<th>Husband</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Education related decision of children</td>
<td>(27)</td>
<td>(11)</td>
<td>(62)</td>
<td>100</td>
</tr>
<tr>
<td>2</td>
<td>Family expenditure related decisions</td>
<td>(26)</td>
<td>(17)</td>
<td>(57)</td>
<td>100</td>
</tr>
<tr>
<td>3</td>
<td>Decision about Professional future of young members of the family</td>
<td>(33)</td>
<td>(09)</td>
<td>(58)</td>
<td>100</td>
</tr>
<tr>
<td>4</td>
<td>Decision regarding agricultural–work</td>
<td>(31)</td>
<td>(14)</td>
<td>(55)</td>
<td>100</td>
</tr>
<tr>
<td>5</td>
<td>Decision regarding marriage</td>
<td>(29)</td>
<td>(21)</td>
<td>(50)</td>
<td>100</td>
</tr>
<tr>
<td>6</td>
<td>Decision regarding the arrival of Guests</td>
<td>(34)</td>
<td>(15)</td>
<td>(51)</td>
<td>100</td>
</tr>
<tr>
<td>7</td>
<td>Decision regarding property–buying/house building etc.</td>
<td>(36)</td>
<td>(14)</td>
<td>(50)</td>
<td>100</td>
</tr>
</tbody>
</table>

The table 2 reveals that the tendency of in regards to family decision making education related decision of children. The 27 percent only husbands will be taking decisions, 11 percent only wives will be taking decisions and 62 percent husband and wife both will be taking decisions. The family expenditure related decisions 26 percent only husbands, 17 percent only wives and 57 percent both husband and wife will be taking decisions. The decision about professional future of young members of the family respondents. The 33 percent only husbands, 09 percent only wives and 58 percent both husband and wife’s are taking the decisions. The Decision regarding agricultural work 31 percent only husbands 14 percent only wives and 55 percent both husband and wife’s will be taking decisions. The Decision regarding marriage the 29 percent only husbands, 21 percent only wives and 55 percent both husbands wives will be taking decisions. The Decision regarding the arrival of Guests 34 percent husbands, 15 percent wives and 51 percent both husband and wives will be taking decisions. The Decision regarding property buying/ house building etc 36 percent only husbands, 14 percent only wives and 50 percent husband and wife both will be taking decisions.

Table 3. The Tendency in Regard to Decrease in the Mutual Relations among of Family

<table>
<thead>
<tr>
<th>Sl. No</th>
<th>Nature of Relations</th>
<th>No. of Respondents</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>

<th>No of Respondents</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>New means of treatment</td>
<td>177</td>
<td>59</td>
</tr>
<tr>
<td>2</td>
<td>Traditional means of treatment</td>
<td>123</td>
<td>41</td>
</tr>
<tr>
<td></td>
<td>Total</td>
<td>300</td>
<td>100</td>
</tr>
</tbody>
</table>

Table 3 and 4 shows that about 07 percent respondents have more intimate relations, 44 percent respondents have close relationships, 40 percent respondents have formal relations,09 respondents have sour relations. The Tendency in Regards to Means of Treatment above table reveals that 59 percent respondents agree to the practice of modern means of treatment. They have viewed that because of the process of change and modernization, new means of treatment have come in use and they have replaced traditional means of treatments. Most of the respondents who approve of these modern means are educated and have modern ideas while the other 41 percent respondents accept that they prefer and approve of the traditional means of treatment these respondents feel that the traditional means do not give any adverse effect on health. The respondents who have expressed these views are traditional, illiterate and also have conventional attitude.

Family: Family, a basic unit of social structure, the exact definition of which can vary greatly from time to time and from culture to culture. How a society defines family as a primary group, and the functions it asks families to perform, are by no means constant. There has been much recent discussion of the nuclear family, which consists only of parents and children, but the nuclear family is by no means universal. In the United States, the percentage of households consisting of a nuclear family declined from 45% in 1960 to 23.5% in 2000.19 In preindustrial societies, the ties of kinship bind the individual both to the family of orientation, into which one is born, and to the family of procreation, which one founds at marriage and which often includes one’s spouse’s relatives. The nuclear family also may be extended through the acquisition of more than one spouse, or through the common residence of two or more married couples and their children or of several generations connected in the male or female line. This is called the extended family; it is widespread in many parts of the world, by no means exclusively in pastoral and agricultural economies. The primary functions of the family are reproductive, economic, social, and educational; it is through kin itself variously defined that the child first absorbs the culture of his group.6

Problems of Changing Family: The family has been and continues to be one of the most important elements in the fabric of Indian society. The bond that ties the individual to his family, the range of the influence and authority that the family exercises make the family in India not merely an institutional structure of our society, but accord give it a deep value. The family has indeed contributed to the stability to Indian society and culture today, the Indian family is subjected to the effects of
changes that have been taking place in the economic, political, social and cultural spheres of the society. In the economic sphere, the patterns of production, distribution and consumption have changed greatly. The process of industrialisation and the consequent urbanisation and commercialisation have had drastic impacts on the family. Migration to urban areas, growth of slums, change from caste oriented and hereditary occupations to new patterns of employment offered by a technological revolution, the cut-throat competition for economic survival and many other economic changes have left their impact on the family.7

Social Processes Affecting Family Structure: A host of inter-related factors, viz., economic, educational, legal and demographic like population growth, migration and urbanization, etc., have been affecting the structure of the family in India. We shall take care of these factors while discussing the changes, in the following sections. Here, let us discuss the broad processes of industrialization, urbanization and modernization as factors affecting the family structure. The changing structure of the family due to industrialization, it is not yet possible to establish any one-to-one relationship. Various accounts demonstrate how both nuclear and joint structures have evolved innumerable varieties due to the influence of urbanization.8

Conclusion

The present paper concludes that there have been many changes found in the village community and this has been because of the impact of globalization. But this change mainly happens in the form of limited changes that have been occurred in their family structure. This change is related mainly to the both aspects of family structure but the functional aspect of change has been demonstrated in a limited way. This community has it neither altogether given up its traditional practices nor has it totally accepted modernization in regard to family structure. The social functioning is operational in between the background of globalization and family values. Due to the continuous and growing impact of urbanization and westernization, nuclear family has now become the characteristic feature of the Indian society.9 The phenomenon of male-headed households has now been transforming into female-headed ones. Another noticeable change in the Indian family system is dissolution of marriages and the number of divorce cases is slowly mounting day by day.

Meat Merchandising in Single Look Produce the Chance of Foodborne Illness: Shoppers Alert!

R. Bhuvaneswari¹, S. Senith², A. Alfred Kirubaraj², S.R. Jino Ramson³

¹Bharathiar University, Coimbatore, Tamil Nadu, India, ²Assistant Professor, Karunya Institute of Technology and Sciences (Deemed to be University), ³School of Engineering Technology, Purdue University, Indiana-47907, USA

Abstract

Purpose: The aim of the study is to produce information of food safety relates to meat consumption to guage the knowledge and angle of shoppers to make the notice publically to avoid the chance of foodborne ill health. Here the investigation belongs to however the shoppers square measure influenced by getting at totally different levels of meat below the chance perception.

Design/methodology/approach-Structural equation modeling (SEM) was engineered to grasp the chance perception of urban and rural shoppers in Coimbatore, Erode and Nilgris by scale back with the perceived risk of their probability of goat meat, chicken, fish, beef and pork.

Findings–The intentions of shoppers in these 3 districts is to facilitate with the acquisition behavior, attitude, knowledge, food safety awareness square measure involved with the microbiological risk of food contamination.

Social implications-The retail search oversubscribed their meat and poultry in single buy their convenience of shopper to avoid wasting time period and cash by mistreatment constant knife and board. It’ll produce the microbiological risk and facilitate to grasp the food handling behavior conjointly to guage the effectiveness of food safety to avoid the chance.

Practical implication-The merchant and shopper prefers these quite consumption for saving the time and cash to urge all meat in one place however they’re not knowing the chance of pathogens they use same knife and cutting all meat and poultry this produce the chance of food borne sickness and also the snacks search, tea shop, fruit stall square measure closely around the meat search and also the meat search marketing in Associate in Nursing open show there’s a necessity of closed glass box that stop mud, and bug will unfold the sickness.

Research implications–The result offer with the data of food safety steerage from producer to shopper to avoid the chance of foodborne ill health and create safe consumption to the buyer with clean and clear setting.

Originality worth–The risks are unknown by the retailers and shoppers it provides the data of meat consumption that relates to food safety with detail understanding of risk perception.

Keywords: Food safety, shopper risk, Hazards, interference of cross-contamination, correct cleanup and sanitizing, shopper education.

Introduction

The preference and selection square measure take issue from person to person one provide preference for style, the opposite one like for texture and somebody like for nutrition diet likewise each person’s shopping for thoughts and angle and emotions square measure totally different it’s necessary to grasp the data and angle of the buyer, it’ll facilitate North American country to avoid the perception of risk relates to meat consumption the essential of food safety square measure involved with the perception of risk in 3 varieties like microbiological
risk, physical risk and chemical risk here the scientist concentrates with the challenges of microbiological risk (Ruth yeung, 2010). Risk might cause at any time the causes of contamination might happen at stage from producer to shopper it’ll happen throughout the assembly stage (or) throughout the process stage square measure within the stage if transformation of product from one place to a different place the HACCP hazard analysis important management purpose explains the hygiene attempt to avoid the chance of food contamination (E. Hoornstra, 2001). General dimension of risk square measure mentioned in four ways that the primary one is risk perception the other is communication of risk third one is lay handling risk and also the fourth one is trust in establishments and specialists. because of the rise of increase the necessity and need demand of product conjointly increase with risk these days the worldwide trade modified the ingestion habits of shoppers with their promoting food stuff IOM (institute of medicine) known the chance into six teams with the emergence of influencing parasitic zoonoses they’re “changes in demographic, changes in technology and business, the increasing international travel and commerce, environmental changes and land use” (Broglia A, 2011).

This study examine the food safety relates to meat consumption with perception of hazards by creating choices of buying time with the priority to create interference of cross contamination with clean condition of healthful setting and insight with the highlight to boost the data of shopper education in future.

**Research Methodology**

**Measurements:** The form was created to access the food handling behavior of the shopper’s angle, data the perception of shopper risk in meat and poultry retail search the form were tested with pilot study and also the correction square measure done and SEM Model won’t to reduce the chance of foodborne sickness. Structural equation modeling may be a applied math technique that mixes parts of ancient variable models, like multivariate analysis, correlational analysis and synchronous equation modeling. The Structural equation modeling approach is usually conjointly referred to as caused modeling as a result of competitive models may be assumed regarding the info and tested against one another several applications of Structural equation modeling may be found within the social sciences, wherever mensuration error and unsure casual conditions square measure ordinarily encountered.

**Data assortment and analysis:** The scientist collect information within the 3 districts kind Tamil Nadu from Bharat specifically Coimbatore, Erode and Nilgiris from 1105 respondents these space the retailers oversubscribed their meat mix for the convenience of shopper for saving their cash and time however the chance is unknown by the retailers. The model explains with food handling behavior to avoid the chance of foodborne sickness.

**Results**

Here the co-efficient of information of the buyer relates to food safety is zero. 193 represents the partial result of information of the buyer relates to food safety on shopper food handling behavior holding alternative factors ‘Perception of risk relates to purchasing chicken, lamp meat, fish, beef, and pork, General nutrition data of consumption, shopper awareness of food safety, Awareness on Standards and regulation of food safety, Awareness on Food contamination’ as constant. The calculable positive sign implies that such result is positive that shopper food handling behavior would increase by zero.193 for each unit increase in data of the buyer relates to food safety and this co-efficient worth is critical at Chronicles level.

The co-efficient of Perception of risk relates to purchasing chicken, mutton, fish, beef, and pork is zero.15 represents the partial result of Perception of risk relates to purchasing chicken, mutton, fish, beef, and pork on shopper food handling behavior holding alternative factors ‘Knowledge of the buyer relates to food safety, General nutrition data of consumption, shopper awareness of food safety, Awareness on Standards and regulation of food safety, Awareness on Food contamination’ as constant. The calculable positive sign implies that such result is positive that shopper food handling behavior would increase by zero.15 for each unit increase in Perception of risk relates to purchasing chicken, mutton, fish, beef, and pork and this co-efficient worth is critical at I Chronicles level.

The co-efficient of General nutrition data of consumption is zero.045 represents the partial result of General nutrition data of consumption on shopper food handling behavior holding alternative factors ‘Knowledge of the buyer relates to food safety, Perception of risk relates to purchasing chicken, mutton, fish, beef, and pork, shopper awareness of food safety, Awareness on Standards and regulation of food safety, Awareness on Food contamination’ as constant. The calculable positive sign implies that such result is positive that shopper food handling behavior would increase by zero.045 for each unit increase in General nutrition data of consumption and this constant worth is square measure important at five-hitter level.

The co-efficient of shopper awareness of food safety is zero.041 represents the partial result of shopper awareness of food safety of shopper food handling behavior holding alternative factors ‘Knowledge of the buyer relates to food safety, Perception of risk relates to purchasing chicken, lamp meat, fish, beef, and pork, General nutrition data of consumption, Awareness on Standards and regulation of food safety, Awareness on Food contamination’ as constant. The calculable positive sign implies that such result is positive that shopper food handling behavior would increase by zero.041 for each unit increase in shopper awareness of food safety and this co-efficient worth is critical at the five hundred levels.

The constant of Awareness on Standards and regulation of food safety is zero. 086 represents the partial result of Awareness on Standards and regulation of food safety in shopper food handling behavior holding alternative factors ‘Knowledge of the buyer relates to food safety, Perception of risk relates to purchasing chicken, mutton, fish, beef, and pork, General nutrition data of consumption, shopper awareness of food safety, Awareness on Food contamination’ as constant. The calculable positive sign implies that such result is positive that shopper food handling behavior would increase by zero.086 for each unit increase in Awareness on Standards and regulation of food safety and this constant worth is critical at the half of level.

The co-efficient of Awareness of Food contamination in zero.14 represents the partial result of Awareness of Food contamination on shopper food handling behavior holding alternative factors ‘Knowledge of the buyer relates to food safety, Perception of risk relates to purchasing chicken, mutton, fish, beef, and pork, General nutrition data of consumption, shopper awareness of food safety, Awareness on Standards and regulation of food safety’ as constant. The calculable positive sign implies that such result is positive that shopper food handling behavior would increase by zero.14 for each unit increase in Awareness of Food contamination and this co-efficient worth is critical at the half of level.

more the co-efficient of shopper food handling behavior is one.813 represents the partial result of shopper food handling behavior on angle influence the buyer to buy Chicken, lam meat, Fish, Beef and Pork is holding alternative factors 'Knowledge of the buyer relates to food safety, Perception of risk relates to purchasing chicken, mutton, fish, beef, and pork, General nutrition data of consumption, shopper awareness of food safety, Awareness on Standards and regulation of food safety, Awareness on Food contamination’ as constant. The calculable positive sign implies that such result is positive that shopper food handling behavior would increase by one.813 for each unit increase in shopper
food handling behavior and this constant worth is critical at the half of level.

From the on top of model work outline table it’s found that the calculated p worth is zero.062 that is larger than zero. 05 that indicates absolutely work. Here GFI (goodness of work index) worth and AGFI (Adjusted goodness of work index) worth is larger than zero.9 that represents it’s a decent work. The calculated CFI (Comparative work index) worth is zero.937 which it’s found that RMR (Root mean sq. residuals) is zero.064 and RMSEA (Root mean sq. error of approximation) worth is zero.055 that is a smaller amount than zero.10 that indicated it’s absolutely work.

**Discussion and Conclusion**

The study is vital to grasp the quantity and speed of trade increase the chance of foodborne ill health, it conjointly will increase the world level downside within the facet of the buyer to guard their health and conjointly make sure they want of trade follow in global level resolution. within the facet of Scio-demographic info supported the interviews across with the 3 elite districts of Tamil Nadu is chosen in their aspects of angle, behavior, data and with their food handling behavior with their perception of food risk within the meat and poultry with fourteen dimensions. these days it’s terribly essential to grasp the data, angle with the demographic info regarding food safety relates meat and poultry consumption the folks from this space should take into account realizing the chance of combined marketing of meat and poultry in one place it’s necessary to contemplate the hazards that happened within the contamination of microorganism, viruses and parasite because of the poor food handling behavior {of retailers of searches|of outlets} in meat and poultry shop.

The place of distribution for food ought to be clean and clear it’ll shield the market setting for safe consumption to the shoppers it’ll helps to avoid the chance of food borne ill health and conjointly it becomes the responsibilities of every and each individual it makes a secure consumption with smart quality of product to {the customers the purchasers these archers} within the retail shop of meat and poultry the employees ought to recognize the foundations and regulation and policy and procedures thus there’s a necessity of coaching to coach them regarding the hygiene and expanse of operating place clean and clear.

“To any work there’s a necessity for safety, particularly within the food business hygiene and safety is important to guard the buyer for safe consumption” Food is an important part of our life for all to measure thus producer ought to take into account it to offer the merchandise safe with quality.

**Direction for future analysis implications:** The angle and data of meat consumption relates to food safety target 5 things meat, chicken, fish, beef and pork these food things purchased for the daily use of shoppers. It might be preferred for the separate study of pork and meat. Pork includes poultry and food. Meat includes goat, pork, and beef. Current study centered on (raw) recent meat solely more study advocate in processed Meat. As a result of the state of Tamil Nadu folks get solely recent meat. The study concentrates on the microbiological risk of food safety future analysis might consider physical risk, chemical risk, technology risk and mode of the folks.

A Study to Find Barriers for Physical Activity among Chronic Kidney Disease Patients

Anupama Das¹, S. Sridevi², N. Venkatesh³, T. Senthil Kumar⁴

¹Postgraduate, ²Assistant Professor, ³Course Chairman & Professor, ⁴Assistant Professor, Faculty of Physiotherapy, Sri Ramachandra Institute of Higher Education and Research (Deemed to be University)

Abstract

Introduction: Physical inactivity has various harmful effects but in case of chronic diseases patients perceive various barriers for physical activity. This study aims to find such barriers in Chronic Kidney Disease patients.

Methodology: This is an observational study conducted in dialysis unit of a tertiary care hospital with 104 both female & male patients of age group 40–60 years undergoing hemodialysis (HD) at least for past 6 months. Patients with recent MI, stroke & with physical impairment were excluded. Consented patients participated. Human Activity Profile Questionnaire (HAP) was used to assess the patient’s physical activity level and patient related perceived barriers for physical activity.

Result: Among 104 patients, male-female ratio was 62:42, mean age was 54.56 years, mean dialysis vintage was 27.85 months (range 6-120 months). Hypertension (91.3%), Diabetes (53.8%) were most frequent chronic co-morbidities. According to MAS and AAS of HAP, 55.8%, 43.3%, 1% patients were impaired, moderately active & active.

The most frequently reported barriers were fatigue or tiredness (54.8%), shortness of breath (51.9%) (p 0.03), fear of getting hurt (22.1%), body pain (21.2%). Other reported barriers are joint pain, family protection, lower limb swelling, foot ulcer, chest pain, less self confidence, anxiety, overstressed, depression. Shortness of breath is the most influential barrier and statistically significant (p0.04).

Conclusion: There were a number of patient related perceived barriers for physical activity were identified and among that fatigue & SOB were found to be influential factors.

Keywords: Chronic Kidney Disease, End Stage Renal Disease, Physical Activity, Barriers, Fatigue, Shortness of breath, Hemodialysis.

Introduction

Worldwide Chronic Kidney Disease (CKD) has become a serious health issue and has drawn much attention due to its increasing prevalence. End Stage Renal Disease (ESRD) is one of the chronic diseases resulting a high level of disability in different domains of the patients’ lives regardless of age. A cross-sectional cohort study has stated that prevalence of CKD is 17.2% in India & as per stages 1, 2, 3, 4 and 5 was 7%, 4.3%, 4.3%, 0.8% and 0.8%, respectively.¹ Hypertension, anemia, diabetes were seems to be the most common risk factors associated with CKD.¹ The most common cause for kidney disease is diabetic nephropathy. Nearly 48% cases presented in Stage V; they were younger than those in Stages III-IV. Patients belongs from lower income groups had more advanced CKD at presentation.²

Patients with advanced CKD and ESRD experience profound greater fatigue, increased risk of Cardio

Vascular Disease (CVD), muscle weakness, wasting of muscle, depressive symptoms, restless leg syndrome, excessive daytime sleepiness, and decrease physical and sexual functioning.\(^3\)

Physical inactivity is a strong predictor of mortality in patients with end-stage renal disease. The younger patient who are undergoing hemodialysis, physical activity level was within the 50th percentile for healthy individuals >70 years of age, where female are lesser active than male.\(^4\) The dialysis patients has impaired exercise capacity, but 90 minutes of sub-maximal exercise twice a week for 12 months, may improve physical function, aerobic capacity and quality of life. As the important aspect of the care of selected dialysis patients mild & regular physical activity should be recommended and encouraged.\(^5\)

Few data are currently available for factors contributing inactive on CKD patients in Western population. It is likely that Co-morbid conditions (CVD; hypertension, respiratory disease; diabetes mellitus; musculoskeletal and mental health illnesses) and symptom burden (fatigue, pain in joints and back, shortness of breath, lack of motivation).\(^6\) Other associated factors were expressed as injury concerns and aggravation of the physical condition through exercise perception, too many medical problems, sadness, lack of time on dialysis days.\(^7\) Other barriers were lack of time, lack of company, lack of money, fear of injury, disliking exercise, feel too old & having an injury/disease, but only the disliking exercise is statistically significant.\(^8\)

The purpose of the study is to carefully identify patient’s perceived barriers to physical activity among HD population according to their physical activity level and find out more influential barrier for physical activity in Indian population as there is dearth of knowledge in this area.

### Materials and Method

This is an observational study which was conducted in dialysis unit of tertiary care hospital. The sample size were estimated from the previous study where Expected proposal: 48%, Relative precision: 20%, Confident level: 95%, Sample size: 104. After obtaining the study approval by The Institutional Ethics Committee of Sri Ramachandra Medical College and Research Institute (REF: CSP/17/AUG/60/244), the subject has been recruited. To meet the criteria, both male & female patients were included within the age group of 40–60 years who were undergoing hemodialysis at least for past 6 months. Patients with recent MI, stroke & with physical impairment were excluded. After screening and consented the patient’s physical activity level was assessed by using Human Activity Profile Questionnaire (HAP) and is administered during hemodialysis session and then the patient related perceived barriers for physical activity was enquired through a mixed type interview session.

The physical activity level is assessed by using Human Activity Profile Questionnaire (HAP).

**Statistical Analysis and Results:** In this study data were collected from 104 Chronic Kidney Disease patients who are undergoing hemodialysis. The collected data were tabulated and analyzed with SPSS version 23.00, the variables such as Age, Gender, Stage of CKD, Duration of Dialysis, No of Dialysis in a Week, Co-morbidities (Hypertension, Diabetes, Coronary artery disease), Maximal Activity Score, Adjusted Activity Score, Pre Dialysis Weight, Post Dialysis Weight, Intra Dialysis Weight Loss, Inter Dialysis Weight Gain were calculated and their mean and standard deviation were computed. The physical activity level was segregated according to the AAS (< 53 sedentary, 53-74 moderately active, >74 active). The association between physical activity level with age, gender and each perceived barriers chi-square test has done. Six commoner barriers like fatigue or tiredness, shortness of breath, pain, disturbed sleep, fear of get hurt, family over protection have been taken for the further analysis for identifying the most influential barrier to the physical activity by logistical regression analysis was done.

Among 104 CKD patients in this study 91% are having hypertension, 54% are reported as diabetic, 3% are having hypothyroidism & coronary artery disease and only 2% are reported as anemic. In this study Physical Activity Level distribution shows that as per AAS value of HAP most of the CKD patients are impaired 56%, 43% were moderately active & only 1% was active. There is an inverse relationship between age & physical activity level and is statistically significant (p=0.06) There is no statistical difference in Physical activity level among Gender.(Table:2). The barriers frequency distribution showing that 30 (29.1%) patients having 3 barriers, where 11 (10.7%) patients reported as no barriers & only 1 (1%) patients stated that having highest 8 barriers in this study population. Barriers of physical activity distribution shows fatigue/tiredness and shortness of breath were the commonest barriers among CKD patients. The Other reported barriers are lower limb pain/discomfort, back pain, family over protection, lower limb swelling or pedal edema, foot ulcer, weakness, knee pain, shoulder pain, chest pain, less self confidence, giddiness, unable to do activity or feeling too old to do activity, anxiety, not willing or avoid to do any activity, chest discomfort, numbness, overstressed, depression, balance disturbance, sole pain. The commonest barriers are fatigue/tiredness (54.8%), shortness of breath (51.9%) & disturbed sleeping (38.7%). Though most of the impaired physical activity leveled patients reported fatigue & shortness of breath as their commonest barrier, but only shortness of breath & lower limb pain were statistically significant barriers for the physical activity.(Table:3) Beta value of SOB is highest (0.861), means it is the most influential barrier & statistically significant (p=0.04**) (Table: 4).

Discussion

Chronic kidney disease is a complex & progressive condition and now it is one among the major worldwide health crisis. As CKD is highly associated with HTN & DM, it could be termed as Diabetic Hypertension-Kidney Disease (DHKD) Syndrome. India, with the highest incidences of DM and HTN in the world, is likely to face a high CKD/ESRD burden, with more than 50% of its population at risk.

Among 104 patients, (62 patients, 59.6%) were male and (42 patient, 40.4%) were female, mean age was 54.56 years. Mean dialysis vintage was 27.85 (range 6-120 months); dialysis was done for most of the patients through an arterovenous fistula, twice weekly (3 patients, 2.9% once weekly; 77 patients, 74% twice weekly; 24 patients, 23.1% thrice weekly).

In present study Hypertension (91.3%), diabetes mellitus (53.8%) were the most frequent chronic co-morbidities. A study done by Pani et al, states Diabetes, hypertension, hyperuricemia were associated with a decline of GFR and associated with CKD which is similar to our study.

Several studies documented that dialysis patients are having very less physical activity level regardless of age. A study on Italian dialysis population which has presented more than half of the CKD patients had been defined totally inactive. In our present study according to Maximum activity score (MAS) and Adjusted activity score (AAS) of Human Activity profile (HAP), most of the CKD patients in this group were having impaired physical activity level as per as AAS values (impaired–58 patients, 55.8%; moderately active-45 patients, 43.3%; active-1 patient, 1%). Most of the patients are inactive which is similar to previous study.

In present study the association between age & physical activity level is statistically significant (p value 0.06**), which means if age increase the physical activity level will decrease which is similar to a earlier study which reported that Age and BMI were associated with physical activity at an inverse relation.

Out of 104 patients, 11(10.7%) patients have reported that there is no barriers for physical activity (5 patients are having impaired physical activity level), and only 1 patient has reported of having maximum 8 barriers .14(13.6%) patients had 1 barrier, 20(19.4%) patients had 2 barriers, 30 (29.1%) patients had 3 barriers,18(17.5%) patients had 4 barriers, 7(6.8%) patients had 5 barriers, 2 (1.9%) patients had 6 barriers.

The most frequently reported barriers stated in a previous study were fatigue in dialysis days (56.7%), perception of too many medical problems (54.8%), sadness (50%), lack of motivation (42.3%) and lack of time on dialysis days (32.7). In present study the most frequently reported barriers were fatigue or tiredness (54.8%) and shortness of breath (51.9%). Though fatigue was a commonest barrier for physical activity which is reported by all groups of physical activity leveled patients but it is not statistically significant. Whereas only shortness of breath (p 0.03**) and lower limb pain (p 0.03**) were statistically significant barriers for physical activity.

Our study result in Indian population was similar to other countries where most common seen barriers were fatigue on dialysis days, shortness of breath, lack of motivation and Co-morbidity and symptom burden (fatigue, joints and back pain and shortness of breath) were the most prevalent barriers. There are a number of factors that can cause clinically significant fatigue in CKD patients, including sleep disorders, depression, sedentary lifestyle, anemia, and chronic inflammation. Low physical activity subjects showed more number of barriers than moderately active patients.

Among 26 barriers only 6 commonest barriers like fatigue, shortness of breath, pain (included all various types of pain), disturbed sleep, fear of getting hurt, family over protection were selected for logistic regression analysis to find out the most influential barrier. The result revealed that beta score (B 0.861) of shortness of breath is highest & statistically significant (p 0.04 and thus concludes the shortness of breath as most influential barrier for physical activity for these patients.

In all the previous studies done, fatigue was the major barrier whereas in present study SOB was the most influential factor. Dyspnea is one of the most common symptoms related with CKD. It has an intense influence on the quality of life of CKD patients, and its underlying causes are often associated with a negative prognosis. Underlying physiological changes in cardiovascular and pulmonary system can lead to SOB and Early recognition may reduce mortality in CKD patients.

Early recognition of SOB to be addressed for improving physical activity level and QOL. There is need of proper education about disease condition & the...
importance of physical activity to the CKD patients as well as the family members & care givers.

Economic Development and Employment Creation in India

S. Thangamayan¹, R. Premalatha¹, S.N. Sugumar³, S. Chandrachud⁴

¹Assistant Professor, ²Professor and Head, ³Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, (Deemed to be University) Chennai

Abstract

Employment has featured as an important item in the development agenda in India. Approaches to the subject have, however, varied in different periods during the last over 50 years. In the initial years of development planning, unemployment was not expected to emerge as a major problem. Yet care was taken to see that employment of a reasonable magnitude is generated in the development process to productively employ the growing labour force. A reasonably high rate of economic growth combined with an emphasis on labour intensive sectors like the small scale industry was envisaged to achieve this goal.

To analyze the trend and to estimate the growth rates of the employment in different organized sectors of India, simple linear regression model and semi-log linear regression model have been fitted respectively to the data on the organized sector for the periods 1990-91 to 2009-10. The estimated value of the regression co-efficient, their standard error and other important results are given. Employment in mining and quarrying sector increased by 0.072 lakh persons per year. The manufacturing sector’s employment increased by 0.389 lakh persons annually.

Keywords: Employment, Economic Development, Manufacturing Sector.

Introduction

Employment has featured as an important item in the development agenda in India. Approaches to the subject have, however, varied in different periods during the last over 50 years. In the initial years of development planning, unemployment was not expected to emerge as a major problem. Yet care was taken to see that employment of a reasonable magnitude is generated in the development process to productively employ the growing labour force.¹ A reasonably high rate of economic growth combined with an emphasis on labour intensive sectors like the small scale industry was envisaged to achieve this goal. The rate and structure of growth rather than technology were seen as the instruments of employment generation. If the Employment GDP is taken one of the indicators to measure the growth of employment in organized sector in general, employment in different organized sector GDP ratio may be taken as a measure to indicate the economic growth in the organized sector employment.²

Main Objectives of the Study:

1. To find out the growth of employment in different organized sectors of India during 1997-98 to 2016-17.
2. To investigate the relationship between the GDP and employment in different organized sectors of India.
3. To give some policy suggestions from the analysis of data.

Data and Methodology

To study the employment in different organized sectors and the contribution of economic growth, macro economic data on GDP, various sectors employments have been used. To analyze the present position of economic growth, time series data for a period of 20 years, from 1997-98 to 2016-17 have been used.

Employment in Different Organized Sectors of India: Employment in different organized sectors of India may be classified either on the basis of time period maturity or on the basis of the sectors in India. In this paper, an attempt is made to study the employment generation in different components of organized sector, during the period 1997-98 to 2016-17. For this purpose
the employment in organized sectors of India is classified into agriculture & hunting, mining and quarrying, manufacturing, Electricity, gas and water, construction, trade, Transport, storage and communications, Finance, Insurance Real estates and community, Social and personal Services. This type of classification is followed by the Reserve Bank of India, Economic survey and the data on employment in different organized sectors are available in this type of classification.3

Trend Analysis of the Employment Organized Sectors of India: To analyze the trend and to estimate the growth rates of the employment in different organized sectors of India, simple linear regression model and semi-log linear regression model have been fitted respectively to the data on the organized sector for the periods 1997-98 to 2016-17. The estimated value of the regression co-efficient, their standard error and other important results are given in Table 2.

For the Period from 1997-98 to 2016-17: The regression co-efficient of the regression model for the period 1997-98 to 2016-17 revealed that employment in agriculture, employment in hunting sector employment decreased by -0.020 lakh persons per year. Employment in electricity, gas and water sector increased by 0.053 lakh persons annually and that of construction increased by 0.200 lakh persons per year, followed by employment in trade sector increased by 0.085 lakh of persons per year. Employment in transport storage and communications sector increased by 0.260 lakh persons, Finance, insurance, real estate’s sector employment increased by 0.620 lakh persons and community, social and personal service increased by 0.175 lakh persons per year.

The compound growth rates worked out from the regression co-efficient of the semi-log linear reveal that the growth rate of agriculture, hunting sector was 2.32 per cent, mining and quarrying, manufacturing and trade grew at the compound growth rate of 1.61 per cent. The Electricity, gas and water sector employment grew by 1.40 per cent. For the Transport, storage and communications sector the growth rate of employment was 0.90 per cent. The compound growth rate of employment in Finance, insurance and real estate’s sector was 3.14 per cent. The community, social and personal services sector employment has grown by 1.11 percent. In terms of growth rate, Finance, insurance and real estate’s sector employment were placed first, and agriculture, hunting sector employment was in the second place. The construction sector employment stood in the third place, followed by mining & quarrying, manufacturing and trade sectors in the fourth place. The electricity, gas and water sector employment come in the fifth place.

Contribution of Organized Sector Employment To The GDP: Employment in different organized sectors of India may contribute, on the basis of the sectors in India. For this reason the employment in organized sectors of India is classified into the following nine sectors. Agriculture & hunting, mining and quarrying, manufacturing, Electricity, gas and water, construction, trade, Transport, storage and communications, Finance, Insurance Real estates and community, Social and personal Services.

Table 3: Gross Domestic Product in Different Sectors of India (Rs. in crores)

### Economic Growth and Employment in the Organized Sector:

In terms of Economic growth, the transport, storage and communications sector is 10.96 per cent, but the employment growth was 0.90 per cent only. The finance, insurance, real estate’s sector’s growth was 8.76 per cent, but the contribution of same sector in the growth of employment was 3.14 per cent. The growth in construction and trade sector was at the same level i.e., 8.65 per cent. But the employment growth level was 1.91 per cent and 1.61 per cent respectively. For the manufacturing sector growth was 7.03 per cent, the contribution of employment level was 1.61 per cent only. The community, social and personal service sector’s growth was 6.92 per cent, at same time the employment level was 1.11 per cent. The electricity, gas and water sector’s growth was 5.97 per cent; the share of employment growth was 1.40 per cent. The agriculture, hunting sector growth was 3.12 per cent; employment growth in this sector level is 2.62 per cent.

For the whole period, GDP growth rate, for different sectors in India ranges from 2 to 10 per cent level, but the employment growth rate of different organized sector ranges between 0.90 and 3 per cent only.¹

### Conclusion

The above results indicate that the aggregate employment in the organized sector has fallen in absolute terms since 1997. Organized employment had been falling since the early 1990s. There are reasons to believe that the pattern of economic growth under an open economic regime tends to be such that the responsiveness of employment growth to the growth in output declines. It is worth noting that the combination of high output growth and low employment growth is a feature that has characterized in India during the years when the economy underwent a change in the global policy. This new trend therefore suggests that greater employment generation is not a necessary result of more growth in organized sector—indeed, it could even be associated with falling employment in future as well. This is an extremely important fact that policy makers must take on board, if there is to be an even pretence of “more inclusive” economic growth in the country.²

Effectiveness of TMJ Mulligan Mobilization in Individuals with Trismus

Sameer Sudhir Karpe¹, Poonam Patil²

¹Intern, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India, ²Assistant Professor, Department of Cardio Pulmonary, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Objectives: To find out the effect of mulligan mobilization in individuals with trismus.

Method: Ethical Clearance was obtained from institutional ethical committee. A total 30 subjects with trismus were selected and mulligan mobilization were given for 1 hour/day and 5 days/week. The preassessment of ROM was measured by vernier caliper and pain was measured on VAS and post interventional assessment was taken for the same after 10 days.

Result: This study showed significant improvement in the outcome variables concluding that it increases ROM and decreases PAIN. This was confirmed using statistical analysis by using paired t test for within group comparison. ROM Post training there was extremely significant improvement noted with individuals with trismus. p value =<0.0001, VAS post training there was extremely significant improvement noted with trismus p value= <0.0001

Conclusion: Hence Mulligan mobilization is effective in improving ROM and it is also effective in decreasing pain in TRISMUS condition.

Keywords: Trismus, physiotherapy, mulligan mobilization.

Introduction

- Temporomandibular joint is a synovial, condylar, modified ovoid, and hinge type joint with fibro cartilaginous surfaces rather than hyaline cartilage and an articular disc, this disc divides each joint into two categories.
- Gliding, translation or sliding movements occur in upper cavity of the temporomandibular joint, whereas rotation or hinge movement occur in lower cavity.¹⁰
- Trismus, whenever there is restriction of normal opening or inability to open the mouth fully, the term trismus is used.
- It is the condition in which muscle spasm or contracture prevents the opening of mouth.¹
- It is known to interfere with eating, speaking and maintaining proper oral hygiene. This interference, specifically with the individual’s ability to swallow properly, results in an increased risk of aspiration. The conditions may be distressing and painful for the individuals.
- Trismus also called lock jaw, is reduced opening of jaw is most common problem encountered by dental practitioner which has number of cause.²
- Trismus has number of causes, which may be simple and non-progressive or may be potentially life threatening.
- Cause of trismus includes infection, trauma, dental treatment, temporomandibular joint disorders, tumours, and oral care, drugs, radiotherapy and chemotherapy, ankylosis, prolonged dental treatment (eg root canal), tetanus, sub mucous fibrosis, myositis ossificans.³
- Mobilization is the treatment option used in treating the temporomandibular joint. Mulligan mobilization with movement (MWM) is the concurrent application of sustained accessory mobilization
applied by the therapist and an active physiological
movement to end range applied by the individuals(4)

Materials and Methodology

Study design: experimental study, sample size-30
subjects, study place-KIMS hospital, Karad, duration-10
days, sampling method-simple random sampling,
treatment duration: 1 hour per day.

Inclusion criteria: 1) Age group between 30-50
years 2) Both sex 3) Individuals with trismus 4) Subjects
willing to participate in the study on voluntary basis

Exclusion criteria: 1) Subjects with congenital
problems of tmj 2) Subjects with neoplastic disease.

Outcome Measures: 1) Vernier caliper
2) Measuring scale 3) Visual analog scale

Ethical clearance was obtained from the institutional
Ethical Committee, KIMSDU, Karad. 30 subjects were
assessed and diagnosed with trismus for eligibility
of the study. 30 trismus individuals were enrolled. 30
individuals were included in the study. Prior to the
treatment pre assessment was done which includes
range of motion assessment of temporomandibular
joint and visual analogue scale assessment for jaw pain
was done. After finding restricted range of motion of
TMJ patients were given Mulligan’s mobilization for
temporomandibular joint for 10 days 1 hour per day
and 5 times per week. Range of motion was measured
after every session and noted in data collection sheet.
Then after 10 days of session range of motion and VAS
compared with the pre-treatment range.

During the study in 2 individuals dropped out due
to migration ,1 individual due to irregular follow up and
1 because of some other personal reason. Totally 30
individuals were taken for analysis in the study.

Treatment protocol was as follows: Before
treatment, visual analogue scale and range of motion of
TMJ was assessed. 4 glides of Mulligan’s mobilization
for temporomandibular joint were given which are as
follows:
1. Anterior glide
2. Posterior glide
3. Medial glide
4. Lateral glide

Dosage was 6 repetitions and 3 sets of each glide.

After treatment session range of motion and VAS
were reassessed.

Self-mobilization was taught to the patient and
asked to perform at home once in a day.

Data Analysis:

1. Gender Distribution

<table>
<thead>
<tr>
<th>Sr. No</th>
<th>Gender</th>

</table>

Interpretation: This table shows that the age
distribution in this study included is more in the age
group of 41–45 yrs.

Rom Graph:

Figure 1: Interpretation-In this graph post
treatment shows increase in range of motion
Result and Statistical Analysis

Data of all outcome measures were measured as pre training and post training values: Arithmetic mean and standard deviation was calculated for each outcome measure. Arithmetic mean was derived from adding all the values together and dividing the total number of values. Standard deviation (SD) was calculated according to the following formula. Post training there was extremely significant improvement in ROM noted according to the p values <0.0001, and in post training there was extremely significant improvement in Visual analogue scale was noted according to the p values <0.0001.

Discussion

Trismus also called locked jaw, is reduced opening of jaw is most common problem encountered by dental practitioner which has number of causes. It is known to interfere with eating, speaking and maintaining proper oral hygiene. This interference, specifically with the individual’s ability to swallow properly, results in an increased risk of aspiration. The condition may be distressing painful for the individuals. The objectives of the study were to find the effect of mulligan mobilization in individuals with trismus. The study was conducted in 30 subjects. Both males and females were taken in the groups. Prior consent was taken from them. The interventions were carried out for 10 days. The outcome measures of the study were VAS and ROM. ROM was measured by verniere'scaliper.

The subjects receive MULLIGAN mobilization in individuals with trismus, four glides were given to each individual. The study showed significant improvement in outcome variables concluding that it increases ROM and decreases pain.

This was confirmed using statistical analysis by using Paired t test for within group comparison.

1. Range of Motion: Post training there was extremely significant improvement noted with individuals with trismus. p value = <0.0001

2. Visual Analogue Scale: Post training there was extremely significant improvement noted with individuals with trismus. p value=<0.0001

This suggests that Mulligans mobilization is effective in individuals with trismus individuals and for rehabilitation the interventions should be continued for 10 days.

Conclusion

On the basis of the results of our study, it was concluded that Mulligans mobilization was significantly effective in improving range of motion and decreasing pain more than conventional physiotherapy.
Conflict of Interests: The authors declare that there is no conflict of interest concerning the content of the present study.

Efficacy of Occlusal Splints in Managing Temporomandibular Disorders

Saranya S.K.1, Chandrashekar Janakiram2, Anil Mathew3, Pramod Subash4, Priya K. Nair5

1Assistant Professor, Prosthodontics and Crown and Bridge, Oral Medicine and Radiology, 2Professor and Head, Department of Public Health Dentistry, 3Professor and Head, Prosthodontics and Crown and Bridge, 4Professor, Oral & Maxillofacial Surgery, 5Assistant Professor, Amrita School of Dentistry Amrita Vishwa Vidyapeetham AIMS, Kochi, India

Abstract

Objective: To compare the efficiency of Occlusal Splints, with placebo treatment with Stabilization splints (SS) or no treatment, for reduction in pain, in adults with TMD.

Method: This systematic review was conducted following the preferred reporting items for systematic reviews and meta-analyses (PRISMA) statement and the patient, intervention, comparison, outcomes (PICO). It was limited to randomized controlled trials (RCTs) with randomization at individual level. Included studies were those with participants who were adults >18 years. The intervention group consisted of subjects using stabilization splints or, a modified stabilization splint or, a combination of splint. The control group may be using the non-stabilization splints or placebos. We performed an evaluation of the heterogeneity of the data using Cochran’s Q statistic, a chi-square test, with a threshold p-value of less than 0.10 (Huedo-Medina et al. 2006 Jun 1). The consistency of the results was assessed visually using forest plots and by the I² statistic. The I² statistic describes the proportion of variation in point estimates attributable to heterogeneity as compared to sampling error.

Results: The 23 RCTs comprised of 1,512 patients. Overall in 5 pooled studies involving 381 adults participants in control group were more likely to experience a reduction in TMD signs and symptoms compared to those using stabilization splints [SMD 16.16, 95% CI (16.08 to 16.23)], but there was heterogeneity among studies (100%). The results did not favor stabilization splints when compared to control group.

Conclusion: All trials individually reported positive results on reducing TMD signs and symptoms for both stabilisation splints and control groups, with stabilisation splint being more effective. But there was no significant difference in the meta-analysis of pooled estimates.

Keywords: Temporomandibular Disorders, Pain, Splints.

Introduction

Temporomandibular disorders are a collective term embracing several clinical problems that involve the masticatory musculature, Temporomandibular joint (TMJ) and associated structures, or both1. Dentists are the primary healthcare specialists in managing temporomandibular disorders2. The most of common conservative management of TMD is with occlusal splints3 stabilization appliances being the most commonly used4.

There are conflicts of reports regarding the efficacy of stabilization splints (SS) over other splints. Studies which compared the efficacy of stabilization splints over soft splints showed that SS did not yield a better clinical outcome than the latter5, 6. There exist inconsistencies about choosing a splint for a TMD disorder, fabrication
Objective: To compare the efficiency of Occlusal Splints, or a combination of occlusal splints with any other treatment modality, or placebo treatment with Stabilization splints (SS) or no treatment, for reduction in pain, in people diagnosed with TMD.

Materials and Method

This systematic review was conducted following the preferred reporting items for systematic reviews and meta-analyses (PRISMA) statement and the patient, intervention, comparison, outcomes (PICO) method as applicable in relation to the topic of the review.

Patient: Adults > 18 years

Intervention: Stabilization splints (SS)

Comparison: placebo or no treatment or a modified stabilization splint or a combination of splint with adjunct therapy or other occlusal splints

Outcomes: Reduction in Pain

Information sources and search: The electronic search was performed with the databases MEDLINE Ovid, EMBASE Ovid, WHO clinical trial register, ClinicalTrials.gov and Cochrane Library, with a platform-specific search strategy consisting of combinations of controlled terms (MeSH) and text words. This systematic review was limited to randomized controlled trials (RCTs) where randomization occurred at the level of the individual. Quasi-randomized trials were excluded.

Data Collection Process: Two authors (SK and PT) independently eliminated any duplicate from the gathered results and examined the remaining articles by title and abstract. Subsequently, the full texts were obtained and analysed for further inclusion/exclusion. Studies that did not meet the inclusion criteria were excluded. The search was performed on June 2018 for all mentioned databases with no lower limit for the analysed time frame. Random-effects models (Higgins and Green 2011) were used to calculate a pooled estimate of effect and its 95% confidence intervals (CIs). Data were analysed with RevMan 5.3.

Assessment of Risk of Bias: The risk of bias assessment of the included studies used the approach recommended by with the Cochrane Collaboration’s tool (Higgins et al. 2011). A score of 3, 1, and 0 were considered as low, unclear, and high risk of bias respectively for each of the seven categories of biases. The scores were averaged for each included study and results are provided in the Figure 1 and 2.

Synthesis of Results: The decision to pool studies was based on the absence of significant clinical heterogeneity which was based on patient demographics, clinical circumstances, and the comparability of the interventions applied. We performed an evaluation of the heterogeneity of the data using Cochran’s Q statistic, a chi-square test, with a threshold p-value of less than 0.10 (Huedo-Medina et al. 2006 Jun 1). The consistency of the results was assessed visually using forest plots and by the I^2 statistic (Higgins and Thompson 2002). The I^2 statistic describes the proportion of variation in point estimates attributable to heterogeneity as compared to sampling error. Subgroup analyses were performed to assess the impact of the treatment. Forest plot was used for graphic presentation (Figure 3). A ‘Summary of Findings’ table (table 1) used the GRADE Profiler software (version 3.6) for the primary outcomes (2004).

Results

Electronic searches from all sources retrieved 189 citations. 129 articles were excluded due to non-clinical studies in humans or were reviews or opinion papers. Out of 60 clinical trials, 37 did not meet the inclusion criteria. The 23 RCTs comprised of 1,512 patients. The diagnostic aid used by 13 studies was Research Diagnostic Criteria for TMDs (RDC/TMD). Special screening forms, modified from Nassif and Hilsen for diagnosis of TMD were used by Al Saadet et al. While Al Quran et al used basic chair side examination procedure; Kuttila et al used clinical examination and interview. The criteria for inclusion of patients for Lundh et al were (1) pain on chewing assessed by the patient as more than 50 on a 100 mm visual analogue scale; (2) arthrographic evidence of disk displacement without reduction in one or both TMJs. Schmitter et al used Bilateral magnetic resonance
images, clinical Temporomandibular joint disorder examination protocol, including muscle palpation, mandibular range-of-motion measurement, and joint sound detection, according to the recommendations of the German Dental Association. Stieschscholez et al.\textsuperscript{25} depended on clinical examination and MRI and Tatli et al.\textsuperscript{26}, used Clinical examination with RDC/TMD and MRI. Wassell et al. 2004\textsuperscript{27} and Wassell et al. 2006\textsuperscript{28} used the International Headache Society Criteria for the diagnosis of the disease. One study\textsuperscript{29} failed to report the diagnostic aid used.

10 studies\textsuperscript{12,13,15,16,19,20,22,25,27,29}, assessed the short term effects of stabilization splints and 5\textsuperscript{7,11,17,18,23} studies assessed the long term effects of it. Both the short term and long-term effects were assessed by 8 studies\textsuperscript{8, 9,10,14,21,24,26,28}. Different scales and pain evaluation tools were used by different studies.

**Risk of Bias Assessments:** A synthesis of the assessment of the methodological quality items (authors’ judgement of risk of bias for each included study) is presented in Figure 1. There were no studies with low risk of bias. 3 studies\textsuperscript{8, 11, 13} were identified with unclear risk of bias and all the others were of moderate risk of bias. Al Saadet al.\textsuperscript{20} had the highest risk of bias among the studies. The bias present in majority (11 of the studies) was allocation concealment (selection bias) followed by blinding of participants and personnel (performance bias) in 8 studies. Figure 2 depicts a risk of bias graph, illustrating the author’s judgements about each risk of bias item presented as percentages across all included studies.

**Synthesis of results-Effect of Interventions:** Overall in 5 pooled studies involving 381 adults participants in control group were more likely to experience a reduction in TMD signs and symptoms compared to those using stabilization splints [SMD 16.16, 95% CI(16.08 to 16.23)], but there was heterogeneity among studies (100%). The results did not favor the stabilization splints when compared to the control group.

Discussion

Currently there is lack of definitive universal diagnostic criterion for diagnosis of TMD. Even though the Research Diagnostic Criteria for TMD (RDC/TMD) is the most accepted, out of the 23 studies only 12 depended on the RDC/TMD. The outcome assessment of TMD signs and symptoms were not standard and heterogeneous in nature. The studies used various method in assessing pain such as VAS, CPI and GCPS. Usage of uniform scale is highly recommended. Again, we could observe the heterogeneity in duration of follow-up following intervention in studies which is difficult to conclude or pool with the effect of the splint on reduction of the pain symptoms. The post insertion instruction that was given following the insertion of the splints was also different for different studies. There is substantial clinical heterogeneity of outcome assessment suggests low evidence of splints on the reduction of TMD. This suggest the need of development of the standard protocol for the assessment effectiveness of splints of TMD

23 studies were included for qualitative assessment, while 10 were selected for the quantitative evaluation as there was substantial clinical and methodological variation in the rest of studies. Included 10 studies for quantitative assessment had less clinical and outcome assessment variation which assessed the stabilisation appliance as one of the intervention against control appliance or like counselling or exercise or both. Due to missing information of individual estimates the data from the five studies were not analysed.

Future research would benefit from a uniform method of assessment for clinical effectiveness of these appliances and treatment method. Heterogeneity in diagnosis, patient inclusion criteria, appliance design, methodology and evaluation including the duration of follow-up and assessment is hindering the development of synthesized evidence to determine the appliance effectiveness.

Conclusion

Almost all trials included in this systematic review individually reported positive results on reducing the TMD signs and symptoms for both stabilisation splints and control groups, with stabilisation splint being better and more effective. Even then, the results of our meta-analyses did not produce significant differences of the pooled estimates, suggesting that that the evidence remains insufficient.

Abstract

The purpose of this randomized control trial was to compare the efficacy of splints fabricated in maximum intercuspation position and bite plane induced occlusal position with splints fabricated in centric relation (control group) in the treatment of temporomandibular disorders. 30 patients with Temporomandibular disorder (TMD), were randomized into three groups by computer generated random sequence. Thus, 10 patients were allocated to any of the three groups–Splints fabricated in biteplate induced occlusal position, splints fabricated in maximum intercuspation and splints fabricated in centric relation. The variables—pain, head position and amplitude of mandibular movements were measured before insertion of splints and later after one week, one month and three months of treatment. There was statistically significant reduction in pain (p<0.05) after three months of treatment, statistically significant improvement in maximum mouth opening and head position within the three splint groups. The splints fabricated in three different mandibular positions were equally effective in reducing the symptoms in temporomandibular disorder patients.

Keywords: Temporomandibular disorder, occlusal splints, centric relation, maximum intercuspation.

Introduction

Temporomandibular disorders include a cluster of related disorders like masticatory muscle disorders, disc displacement disorders and inflammatory disorders of the temporomandibular joint. 75% of the populations have at least one sign of dysfunction and approximately 33% have at least one temporomandibular disorder symptom.¹,²

Dental management of temporomandibular disorder often involves occlusal splints and occlusal adjustment.³ Occlusal splints are conservative and reversible⁴-⁶ and have been reported as effective mode of treatment in managing temporomandibular disorder patients.⁴,⁷,⁸ Occlusal splints bring about temporary alteration in previous dental contacts, liberate masticatory system from occlusal disharmony, reduce hyperactivity of the mandibular muscles, reposition the mandible and alter the neuromuscular position of mandible there by reducing the symptom.⁹ Stabilization splint is considered as the gold standard in the treatment of temporomandibular disorders.¹⁰ Centric relation has been advocated as a reference position for fabrication of stabilization splints because they are effective only if the condyles are located in the most musculoskeletally stable position on wearing the splint. Mandibular condyles are located in their most musculoskeletally stable position in centric relation.¹¹,¹²

However the use of centric relation is arguable in
many conditions; for example, in temporomandibular disorder patients with pain. This is because centric relation has been defined in asymptomatic patients. The presence of pain, emotional or physical distress, inability of the operator and lack of neuromuscular conditioning may influence the recording of centric relation.\textsuperscript{11,13,14} Studies have utilized other mandibular positions like maximum intercuspation and muscular position like bite plate induced occlusal position (BPOP) as reference position for providing optimum occlusion in rehabilitation and temporomandibular disorders.\textsuperscript{11, 15-17} These alternative positions have the potential to reduce the complexity and treatment cost, chair time of treatment because recording them is not as technique sensitive as centric relation. However, it is not known whether any or both of the alternative positions can produce results comparable with results obtained using centric relation as the treatment position. The present study was undertaken to address this gap in knowledge. It is expected that the results of the present study might add to the emerging body of knowledge aimed at choice of treatment position of occlusal splints in management of TMDs.

**Materials and Method**

Consecutive patients attending the outpatient department of Prosthodontics were screened for TMD. 30 patients who satisfied these predefined inclusion criteria were selected: (a) Pain in the masticatory muscle; (b) pain in the temporomandibular joint area; (c) pain on mandibular movement; (d) articular sounds on mandibular movement (e) head ache (f) bruxism and clenching (g) Angle’s class 1 molar relation (h) signs and symptoms present for a minimum of six months (i) minimum twenty functional teeth. The following exclusion criteria were adopted;(a) Angle’s class 3 molar teeth; (b) indication for or ongoing orthodontic treatment; (c) history of temporomandibular dislodgment; (d) extensive treatment for prosthetic rehabilitation. The selected subjects were informed about the study and an informed consent was sought.

**Randomization:** The selected subjects were randomized in to three groups by computer generated random sequence. Thus 10 patients were allocated to any of the three groups– Splints fabricated in biteplate induced occlusal position, splints fabricated in maximum intercuspation and splints fabricated in centric relation (control group). All the measurements were recorded by the same operator. Each measurement was performed thrice and the average selected as the entry to reduce operator bias.

Variables measured in the study were pain, head position and amplitude of mandibular movements. Amplitude of mandibular movements included right and left lateral movement of mandible, maximum mouth opening and protrusion. The variables were measured before the insertion of splints and later after one week, one month and three months of the treatment.

**Pain:** The intensity of painful symptoms and pain on palpation was evaluated using Visual Analog Scale, calibration from 0 to 10mm. The score 0 represented no pain and 10 represented the worst pain ever felt by the patient.

**Head Position:** The assessment of posture was held with the patient standing bare footed on a smooth surface with his/her feet in the same width of shoulders, in a frontal and natural head position. The head position was measured by placing a millimetre ruler vertically from the rear portion of the skull to the thoracic spine. The horizontal distance of the cervical spine by that line of the vertical bob was measured using a ruler. This measurement gave the head position. The normal head position ranges from 6-8 cm.

**Amplitude of Mandibular Movements:** Maximum opening of the mouth was measured with the millimetre ruler between the edges of maxillary and mandibular incisors. The midline of the mandibular incisors and incisal margin of the maxillary incisors were marked to evaluate the right and left lateral movements. The protrusion was also measured using the millimetre ruler. The normal maximum opening varies between 40 and 50 mm. The protrusion of the mandible in a normal individual ranges between 6 and 9 mm and lateral movement varies between 9 and 14 mm.

**Fabrication of Splints:** The upper and lower impressions were recorded using irreversible hydrocolloid and cast models fabricated. The dental casts were mounted in an articulator with aid of face
The difference between the three splints was the intermaxillary positioning of mounting of mandibular cast in the articulator.

Occlusal splints were fabricated in self-cure acrylic. Anterior deprogramming jig was used for fabricating the occlusal splints in centric relation. Anterior jig created a space of around 2-3mm in the posterior teeth. The patient was then guided to centric relation with the jig in position using Dawson’s bimanual technique. The record was registered using polyvinyl siloxane bite registration paste.

Base plate wax was also used as an interocclusal record in the study. Mandibular cast was then mounted on the articulator using the centric relation record. Splint thickness was established by the wax record thickness.

The splint in maximum intercuspation was fabricated by mounting the mandibular cast in the articulator by tactile and visual intercuspation. After mounting, the upper member of the semi-adjustable articulator was raised by 3mm to allow enough interocclusal space for the fabrication of the splint.

Splint in bite plate induced occlusal position was fabricated after asking the patient to wear a bite plate for five minutes. Anterior bite plate was fabricated using self-cure acrylic resin for each patient. The bite plate extended from first premolar on one side to the first premolar on the other side in the upper arch. The bite plate was flat and perpendicular to the mandibular incisors. This helped to condition the patient at a new neuromuscular position. This allowed free movement of the incisors in all directions. To condition the patient at the new neuromuscular position, patient was asked to tap or slide their anterior teeth against the bite plate. After conditioning, the bite plate was removed and the patient was allowed to close the mouth until the point at which patient’s teeth came into contact. This position was recorded using an interocclusal record and was then transferred into articulator. The space for the splint was created by lifting the upper member of the articulator.

The patients were instructed to wear the occlusal splint at night time. They were informed of the cyclic nature of TMD and the relationship between parafunction, muscle fatigue, muscle pain and psychological factors. The variables are measured at first week, first month and third month after insertion of splints. The patients were asked to report if the symptoms aggravated on usage of the splints. In the follow up visits, the occlusal contacts on the splints were checked and adjustments were performed in the absence of one or more teeth in contact during closure due to the change in mandibular position on usage of splint to a more musculoskeletally stable position of the condyle.

Analysis: The variables were recorded and the data was evaluated using SPSS software to find the statistical significance of the comparative efficacy between the splints fabricated in the three different mandibular positions in the management of temporomandibular disorder patients. Kolmogrov Smirnov test was used to check the normality of the data. All the variables were compared using ANOVA between the three groups. Pair wise comparison was done to evaluate the improvement in variables within the groups.

Results

There was statistically significant reduction in pain within the three splint groups (p<0.05) after three months of treatment. Splints fabricated in three groups did not show any statistically significant difference between the groups in reducing the intensity of pain during the course of treatment (Table 1 and Figure 1). Right and lateral movement showed statistically significant improvement within the three groups and between the groups (p <0.05). Patients in bite plate induced occlusal position group showed statistically significant difference (p <0.05) in right lateral movement and left lateral movement when compared to patients in other two groups before the treatment. (Table 1). There was statistically significant improvement in maximum mouth opening within the group and no significant difference between the groups in maximum mouth opening (Table 1 and Figure 2). Patients in centric relation splint group showed better improvement in protrusion after one month when compared to the maximum intercuspation splint group (Table 1 and Figure 3). There was statistically significant improvement in head position within the groups (p<0.05). But there was no statistically significant difference between the groups in improvement in head position (Table 1 and Figure 4).

Fig. 1. Evaluation of pain using descriptive statistics in the three splint groups

Fig. 2. Evaluation of maximum mouth opening using descriptive statistics in the three splint groups
Discussion

Within the confines of the clinical study, splints fabricated in the three different neuromuscular position, centric relation, maximum intercuspation and bite plate induced occlusal position did not differ over three months in reducing the signs and symptoms in temporomandibular disorder patients. In the present study we compared the efficacy of occlusal splints fabricated in maximum intercuspation and bite plate induced occlusal position with splints fabricated in centric relation in the treatment of temporomandibular disorder patients, as these were the three most probable reproducible mandibular positions in relation to body posture and muscle function.16,17

In our study splints fabricated in centric relation required less occlusal adjustment to reach occlusal stability compared to splints fabricated in other position. Some patients in the present study showed fluctuation of stability of contacts on the splint even after achievement of occlusal stability earlier. The fluctuation of occlusal
stability was associated with increase in pain. On evaluation some form of mental stress was the most common reason for increase in pain. This association of increase in pain and mental stress was earlier reported by Turk et al in his study.\textsuperscript{18}

Three patients in our study did not achieve occlusal stability in the course of the treatment. Studies have shown this could be of two reasons--(a) due to the variation in arc of closure, which occurs during the day, (b) the presence of pain on palpation, which was not completely reduced in these patients. This result in some changes in the physical status of the muscles could lead to instability in the arc of mandibular closure.\textsuperscript{19} Patients with severe dysfunction showed better improvement than those with moderate and mild dysfunction. The result was similar to the study conducted by Ekberg.\textsuperscript{20} Amplitude of mandibular motion improved considerably on reduction of pain. Head position also showed improvement on reduction of pain. Studies have shown the association between temporomandibular dysfunction and head and cervical posture.\textsuperscript{21}

**Conclusion**

Based on the methodology, study sample and results obtained in the present study, it was concluded that splints fabricated in three different mandibular positions were equally effective in reducing the symptoms in temporomandibular disorder patients.

Effect of Gaze Stability Exercises on Balance Confidence and Mobility in Elderly Population

Peteti Sairam¹, Latika Gulyani¹, Saravana Hari Ganesh M.²

¹Post-Graduate Student, ²Associate Professor, SRM College of Physiotherapy, SRMIST, Chennai, India

Abstract

Background: To determine whether gaze stability exercises are effective in improving the balance confidence and mobility in elderly population. Design: Randomized controlled. Study Setting: Physiotherapy Out Patient Department, SRM Medical College Hospital and Research Center. Participants: 40 subjects both male and female without any definite balance disorder but with history of subjective apprehension to do activities, who attend the outpatient physiotherapy department of SRM Medical College Hospital and Research Center, were selected for the study.

Intervention: Subjects are divided into 2 groups, the experimental group (n=20) performed gaze stability exercises and conventional exercises for balance, and the control group (n=20) performed conventional physiotherapy exercises for balance. Weekly progression of exercise was done as per the designed exercise protocol. The participants of both the groups performed the exercises 3 times daily over a 2-week period.

Outcome Measures: Berg Balance Scale (BBS), The Activities-specific Balance Confidence scale (ABC) was take before and after 2-weeks of intervention. Result: There were no baseline differences (P d” .05) between the Experimental and Control groups in any outcome measures. Experimental group improved significantly in both the outcome measures compared with the control group.

Conclusion: The results of this study suggest that gaze stability exercises leads to improvement of balance and subjective confidence to carry out the activities of daily life due to adaptation of age related degeneration found in elderly population.

Keywords: Gaze Stability Exercises, Elderly Population, Balance confidence.

Introduction

Good balance is an imperative skill for daily life that requires the complex integration of sensory information regarding the position of the body relative to the surroundings and the ability to generate appropriate motor responses to control body movement. Vestibular system is one of the main structures to maintain balance, given that it is considered as an absolute reference in relation to the others that also participate in this function, such as visual and somato–sensorial systems.¹,² With increased age, there is a progressive loss of functioning of these systems which can contribute to balance deficits. The healthy elderly individuals are found to have significant impairments in static as well as dynamic balance as compared to healthy young adults³ as the risk of falls increases beyond 60 years of age.⁴ The literature affirms that the vestibule-ocular reflex degeneration is the main consequence of natural aging of the vestibular system.⁵ The classical manifestation of its failure is unbalance towards body rotation by affecting the act of walking. The intensive training of this reflex, associated to other stimuli, has become efficient to balance recovery and prevention of falls.⁶,⁷

Gaze stability exercises are the adaptation exercises which are based on the demonstrated ability of the vestibular system to modify the magnitude of the vestibule-ocular reflex in response to a given input (head movement).

The adaptation of the vestibule-ocular reflex has been demonstrated in individuals with normal vestibular function and those with unilateral vestibular hypofunction.⁸,⁹ One of the signals that induce adaptation of the vestibule-ocular reflex is retinal slip combined...
with head movement.\textsuperscript{10} This is the basis for what have traditionally been considered adaptation exercises. These exercises require the individual to perform rapid, active head rotations while watching a visual target, with the stipulation that the target remains in focus during the head movements.\textsuperscript{11}

Oculo-motor exercises and gaze stability exercises are found to be effective for postural stability and dynamic visual acuity in healthy young adults.\textsuperscript{12} Previous studies have compared subjects who performed vestibular adaptation exercises plus balance and gait exercises to subjects who were simply encouraged to perform their daily activities.

**Methodology**

This study was a randomized pre-test and post-test experimental design. Physiotherapy Out Patient Department, SRM Medical College Hospital and Research Center, Kattankulathur, this study received institutional ethical approval from SRM college of physiotherapy, srm INSTUIITE OF SCIENCE AND TECHNOLOGY. permission to recruit subjects and access to medical records were granted by the participating hospital and all participants provided informed written consent.

Inclusion criteria included both male and female in the age group of 60 to 70 years with documented balance or mobility problems, with history of subjective apprehension to do activities, Exclusion criteria included Mini-Mental State Examination (MMSE) score <24/30, subjective history of dizziness, progressive medical issues that would affect mobility, presence of neurological, or ENT disorder and any other vascular, metabolic, degenerative or neoplastic disorders, which are confirmedly known to cause balance disorders. All participants gave informed consent. Control group received conventional physiotherapy exercises for balance, whereas Experimental Group received conventional physiotherapy exercises for balance, and Gaze stability exercises. Both the exercise protocols were modified in such a way that the total time duration would not exceed more than 30 minutes a day in progression by the 2\textsuperscript{nd} week onwards.

The baseline data (Pre test) were measured using BBS\textsuperscript{16} and ABC\textsuperscript{17} datasheets before the starting of treatment session. These scales have found been found to have good test-retest reliability and validity for balance and reflecting fear of falling and confidence in balance respectively.

**Gaze Stability Exercises:** These exercises require the individual to perform rapid, active head rotations while watching a visual target, with the stipulation that the target remains in focus during the head movements. If the target is stationary, then the exercises are referred to as viewing exercises. If the target is moving in the opposite direction of the head movement, then these exercises are referred to as viewing exercises. The control group performed conventional physiotherapy exercises for balance. Weekly progression of exercises for both the groups was done as per the Table 1. The participants were instructed to perform the exercises 3 times daily over a 2-week period. After 2\textsuperscript{nd} week, post intervention data was collected again to analyze the statistical differences.

**Data Analysis:** Comparing score between the pre and post treatment balance outcome measures (i.e BBS & ABC) of two groups were compared by independent t test. The pre post difference within the group was analyzed using paired t test. A two tailed (\(\alpha=2\)) probability (p) value p<0.05 was considered to be statistically significant.

P value a indicates the pre post difference within the group whereas P value indicates comparison between the groups at pre test as well as post test levels. A two tailed (\(\alpha=2\)) probability (p) value p<0.05 was considered to be statistically significant.
Graph 1: The pre and post treatment measuring outcomes The Activities-specific Balance Confidence scale of two groups. Experimental group showed significant increase in mean scores at post test as compared to pre test whereas mean change of these scores in control group was found to be insignificant. On comparing these scores between the groups, the mean change differed significantly (p<0.05).

Graph 2: The pre and post treatment measuring outcomes Berg Balance Scale of two groups. Experimental group showed significant increase in mean scores at post test as compared to pre test whereas mean change of these scores in control group was found to be insignificant. On comparing these scores between the groups, the mean change differed significantly (p<0.05).

Discussions

The results of this study indicate that experimental group improved significantly in balance measured with BBS and ABC outcomes measures whereas no significant differences were found in balance scores of the control group. Though the participants in this study were found to have the less risk of fall based on the BBS baseline scores but were found to have marked loss of confidence in balance in carrying out the activities of daily life.

This suggest that even the statistical meaningless baseline BBS scoring and small magnitude change at post intervention is capable of reducing the psychological impact of balance impairment in elderly individuals. The recommended protocols for Vestibular Rehabilitation of elderly patients consist of global stimulation of the balance which is based on exercises of substitution, adaptation and habituation.

These exercises are based on the physiopathology of unbalance that affects the elderly caused by the aging process of the sensory systems and muscle-skeletal effectors. However, these alterations begin by the aging process of the vestibular system, whose main consequence is the vestibule-ocular reflex degeneration (VOR) which leads to the unbalance towards body rotation and a deviation on the walking act. Based on all this information, the efficiency of use of specific exercises for the VOR adaptation was verified and it was observed that it had been equally effective as the long protocols of global stimulation, in elderly population.

It was reported that decreased angular head velocities improve target stabilization on the retina. Further, it was also suggested that this may begin to explain the head-trunk segmental stiffening observed in the elderly, since it may act to decrease head angular velocity during fall and subsequent balance recovery. Based on this information it may be assumed that significant improvement in experimental group might be because of another probability that participants in the GSE group do have an element of head movements to make them more accustomed to head movements with better control and stability of head-trunk segment.

The study by Courtney D. Hall et al provides evidence that in older adults with symptoms of dizziness and no documented vestibular deficits, the addition of vestibular-specific gaze stability exercises to standard balance rehabilitation results in greater reduction in fall risk.

Altogether, the intensive training of this reflex, together with other stimuli, has been presenting efficiency for both balance recovery and fall prevention. Further, results of this study fall in accordance with the suggested efficacy of specific type of vestibular (gaze stability exercises) and ocular system exercises (oculo-motor exercises) in improving postural stability for healthy young adults too. One possible mechanism leading to differential improvement is the adaptation of the vestibule-ocular reflex through performance of specific vestibular exercises. These improvements may be largely due to the learning and practice effects associated with the intervention in the GSE group.

Conclusion

Gaze stability exercises are effective in improving balance confidence and reducing the psychological impact of balance impairment in elderly adult population.

Limitations: A follow-up study to find out the long-term effects of gaze stability exercises in healthy older adult subjects may be beneficial in promoting the restoration of mobility and independence of subjects.

Conflict of Interest Declaration: The authors declare that there was no conflict of interest and no funding was received during this current project.

Manifestation of Clinical Symptoms and Associated Complications in Varicose Veins: An Institutional Study

Shiksha Sharma¹, Minakshi Vashist², Madan Gopal Vashist³

¹Research Fellow, M.D. University; ²Professor, Department of Genetics, M.D. University,
³Senior Professor & Head, Department of Surgery, Pandit Bhagwat Dayal Sharma,
University of Health Sciences, Rohtak, Haryana, India

Abstract

Introduction: Varicose veins have been recognized as chronic disorder since ancient times. Untreated varicose veins tend to worsen over time and can lead to many associated complications. Varicose veins have become a serious threat to the lives of millions of people across the globe.

Aim: Present study has been conducted with aim to make an effective self instructional module on knowledge of clinical associated complication of varicose vein.

Methodology: Information has been collected from varicose veins patients visited the out-patient unit of surgery department of Pandit Bhagwat Dayal Sharma University of Health Sciences, Rohtak. These patients were morphologically and clinically examined by a surgeon. Detailed analysis regarding age of diagnosis, sex ratio, clinical symptoms and associated complications was done. Fisher’s exact analysis and Chi-square test was used to calculate statistical significance.

Results: Present study showed Saphenous vein as most frequent among all veins. Prominent veins and aching were most frequent symptoms in varicose veins. Chi square analysis revealed significant difference between frequency of symptoms among male and female patients ($\chi^2 = 16.221^*$, df= 6, p value= 0.01). Forty two percent patients showed variable complications associated with varicose veins symptoms.

Conclusion: Symptoms in early varicose veins were minimal and they became severe with time. One must know early symptoms of this disease to avoid complications in the later stage. More importantly, varicose risk factors should be taken care of before appearance of symptoms.

Keywords: Complication, Risk factor, Symptom, Varicose veins and Veins.

Introduction

Varicose veins are swollen veins, and appear anywhere in the body, but most commonly occur in the legs. These veins may also be twisted in appearance. It is most common vascular disease in which blood escapes from a normal path and circulates in a reverse flow in already overfilled veins with blood. Vein size can vary from small (2-3mm across) to large (2-3 cm across) [1]. These veins may be superficial or deep, and generally bilateral affecting both legs (75-76%) [2] and when unilateral they are detected with the same frequency on each leg [2,3]. Many studies found that 20% population suffer from varicosity out of which 2% cases have complication of skin changes finally proceeding to venous ulceration [4].

Varicose veins patients have swelling of the feet and ankles due to fluid from stagnant blood leaking through the walls of the veins into surrounding tissues. Feelings of heaviness, tiredness and aching, especially after
periods of prolonged standing may occur. There may be change in skin color; the affected skin may turn into brownish grey color, especially around the ankles. Minor injuries to the area may bleed more than normal and/or take a long time to heal. In some people abnormally high pressure in the leg veins can damage the skin, and eventually lead to ulcer. Development of carcinoma in varicose patients can occur due to long standing venous ulcers. There have been over 100 reported cases of malignant transformation and the rate is reported as 0.4% to 1%[5]. Restless legs syndrome appears to be a common overlapping clinical syndrome in patients with varicose veins and other chronic venous insufficiency. The “more severe” are the ones that result in serious problems, as bleeding, ulcers (wounds), eczema, infections, redness, stains, thickness of the skin, pain, phlebitis and even the lung clot, that although rare in primary varicose veins, may put in risk the patient’s life.

Although there is lack of epidemiological data or studies on incidence of varicose veins from developing countries but the frequency of disease is increasing day by day. Many people in India suffer from it, but most tend to ignore it. Researcher personally has observed that most of the people were unaware of varicose veins, and also of their preventive measures. In the present study clinical symptoms and associated complications of varicose veins have been analysed in both male and female patients of varicose veins.

Methodology

Sample collection: The study has been conducted on two hundred sixteen patients of varicose veins admitted to surgery ward of PGIMS, Pandit Bhagwat Dayal Sharma University of Health Sciences, Rohtak.

Inclusion criteria: The inclusion criteria, being, patients presenting with symptomatic varicose veins, those patients presenting with complications of the disease such as pigmentation, eczema, ulceration, superficial thrombophlebitis, etc. and patients with cosmetic concern. The most specific criteria included patients with primary varicose veins of lower limb.

Study design: General assessment of patients including age of diagnosis, sex ratio, symptoms, types of varicose veins, limb involvement as well as associated complications were recorded to know the impairment in the patients of varicose veins. The overall participation rate in the questionnaire survey was 96%. The status of the superficial veins in lower limb was examined with the help of clinicians. The questionnaire data and clinically examined data were cross-tabulated. In all patients the legs were clinically examined by clinician with the help of Doppler Ultrasound and clinical tests to detect reflux in the veins.

All the patients presenting with varicose veins of lower limb, which met the inclusion and exclusion criteria were selected for the present study. Consent from the parents/guardian was taken. Institutional human ethical committee permission was taken to conduct the present research.

Results

Clinical Presentation of Varicose Veins: Varicose veins are dilated, tortuous and elongated veins of the lower extremities and classified into four types i.e. saphenous veins, segmented veins, reticular veins and web type veins. Data of two hundred sixteen cases of varicose veins was analysed in the present study. Saphenous type of vein is longest vein in body running along the length of leg and was present in 82% (177) of cases. Thirty eight point two percent patients were having segment type of veins. These veins are the small dilated blue and green veins beneath the skin surface. Reticular veins do not protrude above the skin as varicose veins do. Percentage frequency of reticular type vein was 28.16%. Webbed types of veins were present only in 14% of patients (Fig 1).

![Figure 1: Percentage frequency of different types of varicose veins (N-216).](image)
The distribution pattern of saphenous varicose veins in women and men showed more percentage frequency in the right limb. The prevalence of saphenous varicose veins was higher in males than in females.

Frequency of bilateral leg was very low in case of women as compared to men. Fisher’s exact analysis showed statistically significant association between female sex and limb involvement in different types of veins (two tailed p < 0.12), whereas, it was non-significant in males (p < .003).

**Clinical Symptoms of Varicose Veins:** Major symptoms in patients of varicose veins were prominent veins, aching, swollen ankles, itching, night cramps and ulcer. There were 95.08% of the patients with prominent veins. The next most common symptom was aching in leg (85.24%) with prominent veins which occurred alone or in combination with swollen ankle or edemas (37.70%). There were 31.53% patients with ulcer in one or both limbs. 68.70% of varicose patients complained of night cramps in affected veins (Fig 2). Frequency distribution of varicose symptoms among male and females showed that, male patients were more affected with all these symptoms. Chi square analysis revealed significant difference between frequency of symptoms among male and female patients ($\chi^2 = 16.221^*$, df = 6, p value = 0.01).

**Associated Complications of Varicose Veins:** Majority of the patients considered in the present study came to the hospital for some complications of the disease rather than for the treatment of the visible veins itself. Total complication rate observed during the study period was 42%. Leg ulceration, hematoma and deep vein thrombosis (DVT) were commonest associated complications with 31.53%, 29.30% and 27.77% of cases respectively. Hematoma along with DVT was found in 24.46% of cases. There were 16% of patients that showed recurrence of varicosity after surgery. Bleeding from superficial veins was noticed in 10.3% of varicose patients. Only 2.60% of patients were seen with femoral vein injury as associated complication of varicose veins (Fig 3).
Discussion

Varicose veins of the lower extremities are the most common vascular disease. It is common, and present in 10–30% of the general population. Once developed, there is no spontaneous recovery, and symptoms get worse with the time of disease duration\(^6\). Therefore, it should be treated in early phases.

The present study showed increased incidence of varicosity on the left limb (63.93%) than right limb (53.11%) as compared to existing literature (Table 1). The cause of increased incidence of left side is not known. The probable reason for increased incidence on left side is that the venous drainage of the left leg follows a more tortuous course through the pelvis\(^7\). The bilateral varicose veins in present study were seen in 32% of patients which is approximately in consistent to 26.67% and 26% bilateral cases of Malik and Mofidi respectively\(^8\). However in some cases no difference was observed between left and right limb involvement\(^9\).

Varicose veins of the lower extremities were classified into four types i.e. saphenous veins, segmented veins, reticular veins and web type veins. In present study saphenous type varices were observed in 82%, segment type in 32%, reticular type in 28.16% and web type in 14% of varicose veins patients. Komsuoglu, found the high frequency of segment type of varicose veins followed by saphenous veins reticular and web type varices\(^2\). The saphenous vein is the largest vein in legs so the prevalence is high in this vein. In the present study the prevalence of saphenous vein was high in men whereas frequency of non-saphenous varices was higher in women. In a study prevalence of saphenous varicose veins was equal in men and women and frequency of non-saphenous was high in women\(^9\). Varices of smaller veins, were present more frequently in women\(^9, 14\). The present study reported long or great saphenous system involvement in 53% as compared to literature(Table 2). The varicose veins are treated differently in the clinical classification of dilated veins by clinicians. It is therefore difficult to compare results of different studies.

In present study it was found that males were more affected with all symptoms than females as compared to previous studies [16]. In all studies including the present study, dilated and prominent veins were the commonest presenting symptom while other symptoms were present in variable percentage depending on the stage of disease (Table 3).

Recurrence of varicose veins is also a serious condition affecting varicose patients even after varicose surgery or after surgical removal of varicose veins [19]. Studies have reported 20% chance of recurrence at 5 years and 60% by 10 years [20, 21]. In present study 16% of patients had varicose veins after surgery for varicose veins. Untreated varicose veins tend to worsen over time and can lead to many associated complications like, hemorrhage (Bleeding) and swelling with in vein tissue, deep vein thrombosis and venous ulcers [22]. In present study 10.30% of patients were having the hemorrhage problem with varicose veins. Approximately 500,000 patients in the United States have venous ulcers with varicose veins, and physical impairment seen with venous ulcers was comparable with that of congestive heart disease and chronic lung disease [23]. Thirty one point five percent of varicose veins patients had the ulceration in present study. Deep vein thrombosis (DVT) is a serious complication of varicose veins. Superficial thrombosis or varicose vein is frequently associated with DVT which may be clinically silent [24, 25]. Three different studies in which ultra sonography used for diagnosis showed 20% to 40% prevalence of DVT with superficial vein disease [25]. In the present study 31.50% of patients were noted with DVT concurrent to varicose veins disease. So, varicose veins should be carefully followed clinically and repeat duplex ultrasound should be performed if patient symptoms get worsen.

Conclusion

Saphenous type of vein was most frequent in present study. Prominent veins and aching were observed as most frequent symptoms in varicose veins. Forty two percent patients showed variable complications associated with varicose veins symptoms. Present study revealed that males were more affected with all symptoms than females. Despite successful surgical removal of the sites of reflux varicose veins may recur again. A number of risk factors may contribute to occurrence of varicose veins i.e. underlying degenerative process of varicose veins, the disturbed venous physiology, lifestyle and genetic mutation. Symptoms in early varicose veins are minimal and they become severe with time. One must know early symptoms of this disease so as to avoid complications which can be dangerous. More importantly, varicose risk factors should be taken care of before appearance of symptoms.

Abstract

Background: Though there are several studies available on effects of obesity on cardiac autonomic dysfunction and effects of COPD on cardiac autonomic dysfunction separately but search on combined effect of obesity and COPD on cardiac autonomic dysfunction fails to produce results. Therefore there was a need to evaluate the changes in autonomic dysfunction with increasing BMI in patients with COPD.

Objective: The aims of this study were 1) to compare autonomic dysfunction in patients with COPD with increasing BMI, 2) to correlate autonomic dysfunction in patients with COPD with increasing BMI.

Methodology: In the present study, 42 subjects were categorized into underweight, normal weight, overweight and obese category. Non invasive cardiac autonomic function tests were carried out in these subjects.

Results: The mean ± SD age of underweight, normal weight, overweight, and obese patients with COPD were 57.667 ± 5.1640, 61.007 ±8.8991, 55.800±6.6106 and 56.200±7.1204 respectively. It was found that there was no correlation between BMI and autonomic dysfunction responses in patients with COPD. All four cardiac autonomic function test came out to be non significant statistically [Karl Pearson correlation (r), ns-p >0.05]. Multiple comparisons between underweight, normal weight, overweight, and obese patients with COPD for cardiac autonomic responses, FEV₁, PEF were statistically non significant.

Conclusion: In present study, although the results have shown that there was definite autonomic neuropathy in patients with COPD with increasing BMI, there was no significant difference in autonomic dysfunction with increasing BMI in patients with COPD.

Keywords: Forced expiratory volume (FEV₁), Peak expiratory flow rate (PEF), Obesity, Chronic Obstructive Pulmonary Disease.

Introduction

The chronic obstructive pulmonary disease (COPD) is characterized by persistent airflow limitation that is usually progressive and associated with an enhanced chronic inflammation response of the airways. It has been estimated that in 2030, COPD will become the third biggest cause of death.¹,²

Previous studies show that in COPD patients, cardiovascular autonomic neuropathy (CAN) is a common consequence and has been shown to negatively affect the cardiovascular and autonomic nervous system.³,⁴ Previous studies have demonstrated that COPD patients have depressed heart rate variability (HRV), indicating increased sympathetic activity at rest⁵,⁶ and Bronchoconstriction, hypoxia, hypercapnia, weight loss and systemic inflammation are other associated features.⁷,⁸ Studies on adults show that the HRV is decreased in overweight young adults especially men indicating sympathovagal imbalance. No changes were observed in HRV in underweight group. Changes in the autonomic nervous activity begin in the overweight and
may become more prominent in the obese thus indicating increased cardiovascular risk. But the number of studies that analysed the autonomic functions in obese adult population is still limited.

Available data suggests that obesity is more prevalent in patients with COPD than in the general population, depending on the severity of chronic airflow limitation. Obesity is an independent risk factor for cardiovascular disease and mortality. Autonomic neuropathy is another complication in obese patients. But limited literature is available to examine the relation between increasing body mass index (BMI) and cardiac autonomic function tests in patients with COPD. Hence, this study on the evaluation and correlation of autonomic function in the underweight, normal weight, overweight and obese patients with COPD was undertaken.

**Materials and Method**

**Subjects:** 42 COPD subjects on the basis of BMI were categorized into 6 underweight, 26 normal weight, 5 overweight and 5 obese category. Written informed consent was taken from the subjects and approval was obtained from the Institutional ethical committee. Procedures followed were in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national).

**Parameters measured:** Autonomic function tests were employed to evaluate the integrity of both parasympathetic and sympathetic innervations of the heart in all the groups.

**A. Parasympathetic Function Tests:** Blood pressure was recorded from OMERON digital sphygmomanometer and heart rate beat to beat changes can be measured from a continuous running ECG record (lead II).

1. **Valsalva maneuver:** The heart rate response to valsalva maneuver i.e forced expiration against resistance to assess baroreceptor integrity was assessed. The valsalva ratio was calculated as the ratio of longest R-R interval after maneuver to shortest R-R interval during maneuver.

2. Heart rate variation (HRV) with respiration was measured in supine position. Resting ECG was recorded and baseline heart rate was measured. The subject was asked to breathe in deeply at a rate of 6 breaths per minute allowing 5 seconds each of inspiration and expiration. The expiratory (E) to inspiratory (I) ratio was calculated as the sum of 6 longest R-R interval, divided by 6 shortest R-R intervals.

**B. Sympathetic function tests:**

1. **Cold pressor test (CPT):** Subject was asked to immerse his hand in cold water maintained at 4-6 degree Celsius and blood pressure measurement was made from other arm. Failure of systolic BP to rise by 16-20 mm Hg and diastolic BP by 12-15 mmHg was indication of autonomic neuropathy.

2. **Blood pressure response to standing:** After blood pressure measurement in supine position the subject was made to stand. Blood pressure was recorded in 30 second interval. Difference between readings of blood pressure in lying position and then after standing was calculated.

**Statistical Analysis:** SPSS 21.0 software and graph pad prism 3.0 for windows were used. Co-efficient of correlation in bivariate relationship was obtained using the Karl Pearson correlation test. The autonomic responses were compared between underweight, normal weight, overweight and obese COPD using the multiple analysis of variance (MANOVA Tukey). A “p” value of <0.005 was considered as statistically significant.

SBP-Systolic blood pressure, DBP-Diastolic blood pressure, FEV$_1$ Forced expiratory volume in 1 second, PEF-Peak expiratory flow rate. There were no correlation between BMI and autonomic dysfunction responses in patients with COPD. [Karl Pearson correlation (r), ns-p >0.05] given in Table-2.
Multiple comparisons between underweight, normal weight, overweight, and obese patients with COPD for cardiac autonomic responses. FEV₁, PEF were statistically non-significant (MANOVA Tukey, P>0.05) given in table-3.

### Discussion

The role of BMI in the pathogenesis of COPD is not clear. In previous researches it has been found that both, parasympathetic as well as sympathetic divisions have been found to be affected in the adult obese population as compared to the non-obese adult population. 16, 17 Whereas Chabra S K et al reported a reduction in both parasympathetic and sympathetic function in subjects with normal BMI with or without hypoxemia. 4 Among patients 21.4% had no evidence of autonomic neuropathy while 28.6% had early neuropathy and 28% had definite neuropathy. The relationship between autonomic neuropathy and BMI was not given by Chabra S K et al. The results of the present study found that there was definite autonomic neuropathy in normal weight COPD population similar to Chhabra S K et al. The results of the present study found that there was definite autonomic neuropathy in normal weight COPD population similar to Chhabra S K et al. Amongst all the groups of COPD population in our study 90% have definite or early autonomic neuropathy and 10% have no evidence of autonomic neuropathy (Table-1).

Wu J et al compared autonomic dysfunction in underweight, normal weight, overweight and obese adults. The study compared HRV (heart rate variation during forced breathing) and HF (high frequency spectrum) power and correlated SDNN (the standard deviation of the average NN intervals) autonomic dysfunction in underweight, normal weight, overweight and obese adults. HRV and HF power were statistically significant for obese (p<0.01) but there were non-significant results for underweight and overweight (P= 0.86, 0.15 respectively). There was no significant independent correlation of SDNN with underweight (p=0.41), overweight (p =0.80) and obesity (p= 0.43) group. It was concluded that underweight was not a correlate of any indices of Cardiac autonomic function (CAF) but over weight and obesity were independently associated factors of altered CAF. 18

In our present study, we compared autonomic dysfunction in underweight, normal weight, overweight and obese COPD population. Parasympathetic function tests were statistically non-significant between underweight, normal weight, overweight, and obese COPD patients (P<0.64, P<0.24 respectively, table-3). Sympathetic function tests i.e BP response to postural change and BP response to cold pressor tests also were statistically non-significant between underweight, normal weight, overweight and obese COPD patients. (P<0.8, P<0.84, table-4). We also found non-significant correlation between BMI and autonomic function tests (table-2)

In present study most of the underweight COPD population have definite or borderline autonomic neuropathy (table-1) which was different from the results of study of Wu J et al. 18 This may be the reason that COPD patients have enhanced sympathetic tone at rest and are
less able to respond to sympathetic and parasympathetic stimuli in comparison to healthy persons. Previous study show that resting muscle sympathetic nerve activity is significantly higher in patients with COPD as compared to age and sex matched healthy control subjects.  

Studies show that plasma nor-epinephrine was elevated in patients with emphysema compared with healthy controls. Altered lung inflation reflexes may also mediate sympathetic activation in COPD.\textsuperscript{11,20} Sympathetic activation with its chronotropic effects may be responsible for elevated heart rate response seen in COPD patients.\textsuperscript{20}

In underweight COPD patients, neuro-humoral activation caused by sympathetic activation may be a cause of skeletal muscle dysfunction. This seems to involve the diaphragm and accessory respiratory muscles, with aggravation of ventilation disturbances characteristic for COPD. Chronic hypoxemia seems to play a role in sympathetic activation, even in healthy subjects.\textsuperscript{21}

The results of this study show that there was non-significant (weak positive, r-0.006) correlation for FEV\textsubscript{1} and PEF with increasing BMI [ FEV\textsubscript{1}(P-0.62, P-0.97), PEF(P-0.39,P-0.23) respectively, table-2]. Lad U et al found in their study that there was positive correlation in underweight male and female with FEV\textsubscript{1} and overweight male, and female had negative correlation with FEV\textsubscript{1}.\textsuperscript{21}

**Conclusion**

There were several studies available on effects of obesity on cardiac autonomic dysfunction and effects of COPD on cardiac autonomic dysfunction. But till date no study is available on combined effects of obesity and COPD on cardiac autonomic dysfunction. Therefore present study was done on evaluation of autonomic dysfunction with increasing BMI in patients with COPD. In present study, although the results have shown that there was definite autonomic neuropathy in patients with COPD with increasing BMI, there was no significant difference in autonomic dysfunction with increasing BMI in patients with COPD. Furthermore, in several studies we found that irrespective of the stages of the disease, underweight was an independent risk factor for cardiovascular complication and mortality. In mild and moderate COPD the best prognosis is found in normal weight or over weight subjects. In severe COPD, over weight, and obesity, is associated with better survival (obesity paradox, prognostic). Therefore we suggest that patients with COPD in the normal to overweight range have better prognosis.

**Limitations of the Study:** Our study was constrained by the small size of the sample available. The morbidly obese were not included in our study.

Health Concerns in Elderly:  
A Survey and Public Education in Bhubaneswar, India

Shreyan Kar¹, Tushar Kanti Das², Prasanta Kumar Mohapatra³, Brajaballav Kar⁴, Anupama Senapati⁵, Nilamadhab Kar⁶

¹MBChB Student, University of Birmingham, UK, ²MD, Director of Medical Services at J. G. Hospital, TRL Krosaki Refractories Limited, Jharsuguda, India, ³MD, Consultant Psychiatrist, Odisha Medical and Health Services, Government of Odisha, ⁴PhD, Associate Professor, KIIT Deemed to be University, Bhubaneswar, India, ⁵PhD, Assistant Professor, KIIT Deemed to be University, Bhubaneswar, India, ⁶MD, MRCPsych, Consultant Psychiatrist, Black Country Partnership NHS Foundation Trust, Wolverhampton, UK

Abstract

Background: While it is apparent that old age is associated with multiple health concerns the extent of its multiplicity suggestive of the burden is often not clear. It was intended to find out self-reported health concerns for the duration of one month and cardiovascular risk factors in older adults.

Method: In a cross-sectional survey attendees of a Healthy Ageing Conference were approached with a semi-structured questionnaire about their health concerns and cardiovascular risks. Risk of cardiovascular event in 10 years based on QRISK3 was calculated.

Results: A considerable proportion of elderly had range of physical symptoms, depressive mood state and memory problems. Mean number of health problems reported were 4.8±3.3 (male 4.4±3.1 and female 5.0±4.3). Cardiovascular risk was high, mean QRISK3 score for males were 22.2% (±14.4) and for females 10.3% (±6.6) (p<0.05). On an average the heart age was increased by 7.9±6.2 years (8.6±6.6 years for males and 5.0±3.3 for females). The relative risk was 2.1 for males and 1.5 for females. The symptoms and risk factors were elicited easily and the process probably facilitated improving the awareness about the health concerns holistically.

Conclusions: The results suggested the extent of health concerns in general and cardiovascular risks in particular and may help to reflect about required range of appropriate public health awareness and intervention programmes in the community.

Keywords: Ageing, awareness, cardiovascular diseases, education, illness, prevention, public health.

Introduction

It is well known that the disease burden increases with the age suggesting that older persons have more number of illnesses that the younger adults. Most of these are chronic non-communicable diseases. Amongst these cardiovascular diseases (CVD) are leading cause of mortality and morbidity worldwide and these are a specific concern for India.1,2 The burden of CVD is increasing in India over the years along with the prevalence of major risk factors.1 While this has reflected in increased number of people being investigated and treated for the CVD these days; however the efforts on preventing these illnesses do not seem to be in the forefront. Public awareness has risen over the years, although it is still rather low;3

The risk of cardiovascular disorders is high among the Indian population; however, the awareness about it seems to be a concern. It was intended to study the feasibility of assessing the awareness of cardiovascular risk at a community level and providing the related information about remedial measures through a Health Passport approach.

Consecutive 38 individuals attending health camp were assessed for specific personal and family history of obesity, hypertension, diabetes, and heart disease. Current risk factors such as exercise, smoking, drug use, stress, and depression were ascertained, and body mass index (BMI especially considering that the risk factors are also rising. Alarmingly it has been reported that there is a growing vulnerability of lower socioeconomic groups to CVD, the section of population which may be less likely to be able to afford the cost of interventions. All these highlight the importance of prevention of CVD and the role of increasing public awareness and motivations to take health actions.

Besides CVD, many other age-related health concerns are prevalent and there is not much information about these, regarding their awareness, prevention potential, facilities for assessment and intervention. The prevalence of metabolic disorders is increasing along with many other non-communicable diseases. Information regarding diabetes, hypercholesterolemia, and other illnesses are certainly going to help in early detection and adequate management of these, ultimately decreasing the morbidity level.

There is a growing concern that the public awareness especially about the preventive measures, health actions and lifestyle issues is very low and these are not adequately addressed. We intended to find out self-reported health concerns for the duration of one month and cardiovascular risk factors in older adults through a survey. It may help to indicate the illness burden on the elderly.

**Method**

The survey was conducted during a Healthy Ageing conference in Bhubaneswar, India, in August 2018. It was a public health event where elderly people were invited to attend. The sample included all consenting older adults who attended the conference. The questionnaire of the survey were given to the elderly during registration and explained about it. Anonymity of the survey, option of non-participation or opting out at any point was conveyed. Support from a research assistant or a large print questionnaire were available for elderly who had difficulty in reading. Older adults were requested to complete the form in their own time and return at desk by the end of the day.

We used a semi-structured GeriCaRe Health Screening Questionnaire (GHSQ) which has 20 items covering various common ailments of old age, such as difficulty in vision and hearing, breathlessness, joint pain, weakness, appetite changes, tremors or slowness, lumps, bleeding, sleep problems, memory loss, depression, etc. with a ‘yes’ or ‘no’ response. These questions identify specific areas of concern and provide scope for further exploration. These were worded in a way general public can understand. Internal consistency for GHSQ in this sample was acceptable (Cronbach’s Alpha = 0.73).

We collected their demographic details of age and gender along with health related variables such as height, weight, waist circumference, smoking, diabetes, blood pressure treatment, family history of angina or heart attack in a first degree relative before age 60.

We also checked for presence of chronic kidney disease, migraine, rheumatoid arthritis, mental illness, systemic lupus erythematosus, erectile dysfunction and use of antipsychotic medication, steroids, based on the QRISK (qrisk.org). In addition there were options to provide any other health related information or investigation results.

All the elderly were provided with printed health related information on Healthy Ageing. There was a scope to discuss the health related problems and interact with the experts about the preventive measures during the course of the conference.

All the data were transferred to an excel database. We calculated individual 10-year risk for developing a heart attack or stroke using the QRISK3-2018 Web Calculator; selecting the ethnicity as Indian. The data were analysed in SPSS version 24.

**Results**

The response rate for the survey was 51.1%. The final sample consisted of 45 respondents. There were 34 males and 9 females and 2 did not provide their gender. Table 1 gives the details of health problems reported by both genders. Mean number of health problems reported
were 4.8±3.3 (male 4.4±3.1 and female 5.0±4.3, not significant) with a range of 0 to 12.

Body mass index (BMI) range was 17.7 to 30.5 with a mean of 25.2±2.8. Based on Asian cut off scores, we categorised BMI as low (18.4 or less), normal (18.5 thru 23), overweight requiring health action (23.1 thru 27.5) and obese (27.6 and above). The proportions of attendees with various categories of BMI were: low: 2.9%, normal: 17.6%, overweight 55.9%, and obese: 23.5%.

Variables suggestive of cardiovascular risk are given in table 2. There was no significant difference among the genders except for migraine, which was reported by only the females. With the available information about 5.6% had normal blood pressure, 44.4% had prehypertension and 50.0% had hypertension.

Analysis for QRISK3 score suggested that the mean score for males were 22.2% (±14.4) and for females 10.3% (±6.6) (p=0.05), compared with 12.5% (±7.9) and 6.7% (±4.0) respectively for a healthy person with the same age, sex, and ethnicity. On an average the heart age was increased by 7.9±6.2 years (8.6±6.6 years for males and 5.0±3.3 for females, not significant). The relative risk (RR) for males was 2.1 and that for female was 1.5.

Although it was evident that many people were aware of the ailments, however they were not aware about the exact nature of the risks and possible outcomes. There was inadequate engagement with health services or personal effort to deal with these. Most people were aware of the benefits of life style changes and other preventive actions, but their adherence was perceived as not optimum. Majority of the respondents (92.7%) found the public education information about different illnesses, preventive measures, lifestyle changes useful.

Discussion

The survey results conveyed the health concerns in general and CVD risks in particular in the attendees. Keeping in mind the limitation of a small sample size, few reflections can be made from the findings.

The survey process enquiring about a range of common health conditions in old age may increase the awareness about the current health status of the elderly holistically and help them to appreciate the ways and method to address those health issues through appropriate preventive or health management actions.

Health Concerns: A considerable proportion of older adults reported ill health; which is rather obvious. The results could suggest holistically what the major concerns were. While appropriate clinical assessment and investigations would suggest exact nature of the illnesses associated, the degree of health related concerns could be reflected from the average number of around 5 concerns.

It can also be gleaned that based on this screening and bringing to the fore all the health concerns, it was easier for the older population to be aware and reflect about the diagnoses possibly associated. So a screening questionnaire may help increasing awareness and communicating the health issues to the clinicians. This will help addressing the issues holistically rather than specifically which usually happens in highly specialised medical systems these days.

Specific Nature of Problems: Presence of multiple physical problems in the elderly as observed in this study have been reported elsewhere from India, and also to explore any gender and urban–rural difference morbidity.

Subject and Method:
A community-based cross-sectional study was carried out by house to house survey of all people aged over 60 years in an urban slum and a village in the field practice area of a teaching hospital. The total elderly population in these two areas was 407, with an almost equal representation from urban slum and rural area. Information (most of them self-reported with few variations. The tobacco and alcohol use in this studied population was considerably low. Our findings were in line with those from Chandigarh, where females reported higher morbidity in many areas; and more frequent health-related problems were cardiovascular, muscle and joint related problems.

A considerable portion had vision difficulties, weakness and easily getting physical exertion, joint pain and restriction were too common. These are suggestive of chronic non-communicable diseases which are becoming more common. It was surprising to note that half of the attendees had dental problem, similar to another report. It is probable that most people do not attend dentists and the services may not be adequately available.
Almost one in four had depressive or irritable mood state. In elderly, depression has been reported to be common in India, and is often associated with physical ill health. if any, was seen between depression and physical problems. The ‘patient group’ comprised of 40 drawn from MHI, Cuttack, having a depressive disorder (ICD-10). Similarly memory disturbances were reported too in around one in four. This suggested the need for detailed evaluation and monitoring to rule out cognitive impairments or early diagnoses of dementias. This is especially important as elderly population in India is increasing fast, and the dementia prevalence is considerable. Aging population is increasing in developing countries and dementia is going to become epidemic among elderly in the coming decades. This demands early action to prevent the disease and treatment of the affected persons, which is poorly existent in middle-and low-income countries. The need of the hour to tackle dementia in India is to estimate disease burden in the community, search for risk and protective factors of dementia, and undertake measures to provide social benefits to the sufferers and those who are at risk. Raising awareness among the public and general physicians is an important task ahead. In India, there is lack of good longitudinal studies which can provide true trend of the disease and determine risk factors, paucity of basic and clinical researches on dementia, poor awareness, and inadequate availability of social benefit. India, being a country of diverse ethnicity and cultures, has great advantages to carry out genetic epidemiological study. The information may be useful for undertaking remedial measure. This article will highlight the existing state of the above medical and social issues and deficiencies, so that the stakeholders can make adequate preparation to provide relief to the dementia patients and those who are at risk. It is expected that the medical and scientific community will draw attention to the medical problem with the help of governmental and non-governmental agencies, and the political leadership will be motivated to undertake the issue of providing socioeconomic benefit to families of the victims.

**Factors for inadequate non-engagement with health services:** Although it was not particularly assessed in this survey whether they have visited a doctor for their health reported problems, many themes emerged during the discussion. It is pertinent to discuss the reasons behind these. It was observed that in most cases older adults do not prefer going to clinics or hospitals. Often older people and their carers take the symptoms granted as a part of old age and neglect to address these. Some people may have financial problems, depression leading to hopelessness and inaction, even iatrophobia. However sometimes just the practicalities of travelling, long waiting, prolonged and repetitive investigations lead to disinterest; and they do not find the worth of taking the effort. Inadequate communications by the clinicians do not help as well. Often instead of feeling reassured following a visit, patients and their carers often perceive the message of dread and negative outcomes instead of possibilities and options, which leads to anxiety and avoidance of the interventions. Many times even suggestions from quacks and what someone else has found helpful are tried, rather than going for medical treatment.

**Cardiovascular risk:** Cardiovascular risk was prominent in the attendees, with 34.9% with diabetes, 44.2% with hypertensive treatment, and 23.3% having a family history of cardiac event in first degree relative before age of 60. Diabetes and hypertension are growing concerns in India, and there is an urgent need about controlling these risk factors adequately.

Males where at a higher risk (p<0.05) with around 1 in 5 chance of having a heart attack in 10 years, compared with 1 in 10 in female. This was evident by a relatively simple screening in community, and an appropriate explanation of the findings is expected to increase the awareness about it. This may help them to take appropriate preventive health actions along with the treatment.

Sleep problems were common too. One of the worrying issues associated with sleep problem is the use of over the counter sleep medications which are mostly benzodiazepines. These are known to be associated with side effects of cognitive impairment and risk of falls, besides the addiction problems.
regard individualised Health Passport can motivate, track and support to achieve long-term health action objectives.

**Background:** The risk of cardiovascular disorders is high among the Indian population; however, the awareness about it seems to be a concern.

**Aim:** It was intended to study the feasibility of assessing the awareness of cardiovascular risk at a community level and providing the related information about remedial measures through a Health Passport approach.

**Method:** Consecutive 38 individuals attending health camp were assessed for specific personal and family history of obesity, hypertension, diabetes, and heart disease. Current risk factors such as exercise, smoking, drug use, stress, and depression were ascertained, and body mass index (BMI).

While these findings are expected in the elderly, it appears that the existing systems of health care catering primarily to acute illnesses may not be geared to deal with these old age related issues. Specific geriatric assessment and treatment units may be better options which would provide holistic care.

**Conclusion**

The survey highlighted the huge prevalence of health concerns of elderly in the community. Most of these can be easily managed and many health actions can decrease the burden of these illnesses from prevention to effective management. Besides public education which is becoming common; evaluation of health concerns and risks and setting up individualised specific guidance on lifestyle changes, health promotion in a structured way may help the process of dealing with many preventable illnesses. Similarly, periodic, proactive basic health check-ups and focused attention to any emerging symptoms, clarity of communication from doctors and evidence based treatment approaches may help not only in early detection and management of illnesses but restore the confidence of elderly in the process, improving their engagement.

Biomimics: Skeletal System to Structural System

Sindhu Nachiar S., Satyanarayanan K.S., Lakshmipathy M.

1Research Scholar, 2Professor and Head, 3Professor, Department of Civil Engineering, SRMIST, Kattankulathur, Kanchipuram Dt, TN

Abstract

Biomimicry is the concept of mimicking nature and is efficient in terms of its performance, sustainable and innovative in terms of solving a problem in a unique way rather than the conventional method and has future scope. In the field of architecture, the concept can be used to improve the design of the structure, its construction techniques and to reduce its impact on the environment. This knowledge makes us think in an innovative way for creating improved civil engineering and architectural structures. Human Skeleton is the highest evolving species. The human leg bone (Femur) carries the total weight of the body and the human hand bone (Humerus) acts as a tension member. Similar to the natural human skeletal elements, the column which is a structural element plays the major role in the building by transferring the total weight of the body to the earth surface. This key idea of nature is mimicking to the composite columns of the framed structures, which should withstand both vertical and horizontal loading of structure. Research is carried out to model a column similar to the stress pattern of the human leg bone and a tie member similar to the stress pattern of human hand bone. By which the human skeletal system is being mimicked to form a structural system for building construction. In this paper some of the bio inspired structures and the literatures related to biomimics and the femur and humerus bone analysis were discussed.

Keywords: Biomimics, Skeletal System, Structural Systems, Literature, Femur, Humerus.

Introduction

Biomimicry is a concept of innovative design that utilises information from nature and imitates it to arrive at a solution for the complex human problems. Nature is a wide region that educates us about systems, materials, processes, structures and aesthetics. Many problems are already been solved by nature. By digging deep into how nature solves its problems, we could attain an easy solution. The biomimicry concept is used to find innovative solutions in many field like engineering, architecture, product design and technology. Their usage may vary but the ultimate aim is to make products that are adaptive to life in long run. It reduces the destruction of natural resources and inspires the engineers to build more efficient structures.

The idea of imitation of birds to build a human flight was one of the earliest biomimicry example. Otto Schmitt, an American biophysicist illustrates the term Biomimetics as “the engineering and construction of materials and machines are arrived from the models created from the study of biological system”. His research was to design a device that reflects the biological system of nerve in squid. The notion of biomimicry is not only to give a sustainable solution but also to produce an eco friendly environment. Biomimicry is generally a study of an element or an organism in the environment and implementing those ideas in design by mimicking shapes, properties, process, method, which finally results in a safe structure.

Some of the important parameters involved in biomimicry are form, material, function, process and construction. Form refers to the shape and size of the element, material refers to the type of material of the element, its mechanical properties, function refers to the purpose and usage of the element, process refers to the working order of the element and construction refers to the building of the structure.

BIO Inspired Structures: Canopy structure in Brisbane shown in Figure 1 mimics the concept of expansive subtropical shade trees. The design is such that the metal louvers filters the sunlight entering inside the structure similar to the trees. The metallic panels which form the truss has been cut individually and fixed to match the complex shape.
The Beijing National Stadium in China shown in Figure 2 resembles the pattern of a bird’s nest. The stadium is made of web of steel sections in a twisting pattern like a bird’s nest. This structure has grand curving beams that criss-cross in an intercut pattern of woven steel.

In USA, Denver Airport shown in Figure 3 is one other example of this kind of architecture. Naturally occurring Rocky Mountains are the inspiration for this kind of structure. It has a tensile fabric roof like the shape of rocky mountains.

Nesenbach valley bridge shown in Figure 4 was inspired from the pattern of oak tree. The steel columns of the bridge were similar to the branches of the trees.

During Greek and Roman ages, trees and plants were a source for the structural columns. Corinthian column head in Pantheon shown in Figure 5 was constructed by studying the Acanthus plants. The leaves of the plants were considered and the column head was prepared as per the pattern.

Transbay tower in San Francisco shown in Figure 6 depicts the concept of spiral systems like hurricane, sea shell, spider web, etc. Anthony Michell in 1904 developed a mathematical derivation on the perfect cantilever, the structural system of the tower is based on his concept. This structure takes minimal raw materials and gives a very effective design.
Nature as a Structural System: Human skeletal system as shown in Figure 7 is a framework connected by bones. The skeletal system has its own shape, size and properties and behaves in a particular manner when an external force acts on it. Femur bone is a thigh bone and is one of the important part of human body. These bones are responsible for actions like sitting, standing, walking and jumping. It has a complex shape and has different compositions.

Humerus bone is the longest hand bone that connects from shoulder to elbow. The upper end has a cylindrical shaft that is fitted in a socket in shoulder and the lower end is connected to elbow. The human body has structural joints like roller, hinged and fixed and different parts of the body. Human body also undergoes both tensile and compressive forces.

Biomimicry to Increase Sustainability: Biomimicry is described as a tool to increase the sustainability of human designed products, materials and the built environment. It should be noted however that a lot of biomimetic technologies or materials are not inherently more sustainable than conventional equivalents. The built environment is increasingly held accountable for global environmental and social problems with vast proportions of waste, materials and energy use and greenhouse gas emissions attributed to the habitats humas have created for themselves. It is becoming increasingly clear that a shift must be made in such a way how built environment is created and maintained. Mimicking life including the complex interactions between living organisms that make up ecosystems is both a readily available example for humans to learn from and an exciting prospect for future human habitats that may able to be entwined with the habitats of other species in a mutually beneficial way. Architectural biomimicry in general yet to be tested in built form, design that mimics how most ecosystems are able to function in a sustainable and even regenerative way, has the potential to positively transform the environmental performance of built environmental performance of the built environment. Some of the few examples for biomimicry which increased sustainability are shown in Figure 8.
Literature Study

Anjali Prashant K shirsagar, et al., (2017) tells about some of the nature inspired building structures. Nature has always been a source of inspiration for the human beings. Biomimicry can be used in various fields like engineering, architecture, material development fields. Biological organisms that have been refined over billion year research, their technologies or design can be used for solutions of the present day problems. This paper has shown new approaches to the field of architecture by discussing various bio inspired buildings.\(^{(1)}\)

Neelesh K. Sharmaa (2017) has done analysis of humerus bone. Humerus bone is the longest bone connecting shoulder to elbow. They have two cups: shoulder cup and elbow cup. The cup radius was varied in humerus bone and biodynamic response in terms of modal frequency and mode shapes was found out. The humerus bone was designed by Solid Edge. It was observed that the difference in natural frequency is less for the four different sizes and also the cup variation were the shoulder cup radius is less and elbow cup radius is more was found to be the standard variation. ANSYS as found to be the most suitable software to analyze complex shapes.\(^{(2)}\)

Moheb Sabry Aziz and Amr Y. El sherif (2016) discusses biomimicry in structures. Biomimicry helps designers in solving human problems. Few bio inspired structures are discussed. Biomimicry approaches are Design looking to biology (Top-Down approach) and Biology influencing design (Bottom-Up approach). Using computers reduces the complexity of modeling the nature.\(^{(3)}\)

Nithin Kumar KC and Tushar Tandon (2015) have done analysis of femur bone. Femur bone is an important bone in human body. It gives support during few movements like standing, sitting and walking. The material properties of the femur bone are discussed. Modelling of Femur bone in Solid Edge V19 during normal walking, standing, running and jumping activities and the stress analysis was done by ANSYS 14.0. The stress at which the failure of bone occurs is found out and the thickness and type of material required to repair the fractured bone is found.\(^{(4)}\)

Ashwani Kumar, et al., (2014) has done analysis of femur bone by finite element method. The modelling of the bone was done in SOLIDEDGE and the finite element analysis was done in ANSYS 14.5. these software has made it easy in modelling and analyzing complex shapes. The femur bone was analyzed for free-free and fixed–fixed boundary conditions. The natural frequencies and natural vibrations were examined for these conditions. It was observed that sudden accident and continuous application of load were the reasons for failure of femur bone.\(^{(5)}\)

Sumit Kumar Majumder, S.M and Purnachandra Saha, M (2014) tells about the examples of biomimicry structures. Biomimicry includes mimic of shape, properties, method, principle and processes of the nature.
Bridge design is derived from the load carrying process of a tree. A passive cooling system could be developed by mimicking a termite mound. There is reduction in material consumption and decrease in pollution.\(^{6}\)

Neelesh Sharma, Brijesh Yadav (2014) studied the natural frequencies and mode shapes of hand bone during vibration. Finite Element Analysis is a mathematical technique used for the analysis of complex objects and geometries. Analysis is done with two boundary condition, free-free(fixed in centre) and fixed-fixed boundary condition. All degree of freedom of boundaries are subjected to variations in free-free, and constraints in boundaries in fixed-fixed.Fixed-fixed boundary condition is more appropriate and it describe biodynamic behavior.\(^{7}\)

Mohd Syahrul Hisyam Mohd Sani, et al., (2013) discusses about biomimicry in civil engineering. This idea gives an economic way of construction, it improves the efficiency and reduces environmental degradation. This paper shows us ideas regarding biomimicry in concrete section. The materials are replaced which mimics the natural coarse aggregate in concrete. They have listed some bio-inspired shapes used in structures and case studies on mimics in concrete. They have concluded by saying that bio mimicry can be introduced in the industry to produce innovative, efficient and creative solutions. They have also said that in future biomimicry can be used in cold formed steel structure that can solve many problems and reduce the cost.\(^{8}\)

S. Lokanadham, N. Khaleel, P. Arun Raj (2013) studied the statistical and morphometric analysis of humerus bone is done for the purpose of determination of sex.In this 100 adult humerus bones were taken and measured 14 different parameters by using metal sliding caliper, Osteometric board, and Tape.\(^{9}\)

Yousif. A.E. and Aziz. M.Y. (2012) has done biomechanical analysis of human femur bone during normal walking and standing conditions. The stress patterns of the bone under such conditions are observed. It is found that the stress is more at the neck region of the bone for both the conditions.\(^{10}\)

Umadevi and Geethalakshmi (2011) explains the main functions of the skeleton system which are; to support and movement. The skeletons provide the framework which supports the body and maintain its shape. The joint between bones permit movement, some allows a wider range of movement than other e.g.: the ball and socket joint allows a greater range of movement than the pivot joint at the neck. They mentioned that bone is tough and rigid form of connective tissue. It is the weight bearing organ of human body and id responsible for almost all the strength of human skeleton.\(^{11}\)

Raji Nareliya and Veerendra Kumar (2011) deals with analysis of femur bone. The accurate geometry and material properties are studied to find the mechanical behavior of bones. The femur bone is analyzed in ANSYS with physiological load conditions. The stress distribution, total deformation and fatigue failure of femur bone is detected.\(^{12}\)

Zadpoor. A.A. (2006) explains about the humerus bone which is like a cylindrical shaft with two hemispheres attached to its two ends. It is considered as homogeneous and isotropic material. The vibration study of the natural frequency and natural modes was done by finite element method. The effects of boundary conditions and geometry on natural frequencies were studied. Natural vibrations are decreased with enlargement of geometrical dimensions.\(^{13}\)

Lensfeld and Kaminsky (1998) has done comparative study on geometry–based and CT voxel–based finite element modelling and validated by strain gauge measurements i.e. experimental validation. Geometry–based meshing requires the extraction of inner and outer contours from CT scan of bones whereas voxel–based meshing usually implies that the element faces are oriented parallel to the three orthogonal axes defined by the coordinates system of CT scan.\(^{14}\)

Lensfeld and Kaminsky (1996) three dimensional finite element models of the human femur created based on post processed computed tomography data meshing with brick element. Three different material properties were modelled for sensitivity analysis which demonstrated that the strain energy density patterns of different femoral parts. They found the most sensitive to the variation of the resultant force within sagittal plane i.e. plane in the direction from dorsal to ventral.\(^{15}\)

Conclusion

Biomimicry helps to solve human problems. With the above literatures, the idea of mimicking human leg and hand bones to compression and tension member is being implemented for research. By which the skeletal system is mimicked to form the structural system. Thus an optimized model of compression member
and tie member similar to stress pattern of femur bone and humerus bone will be developed. This results in economic, effective, efficient and sustainable structure.

Assessment of Performance of Services for Three to Six Years Old Children in Urban Anganwadi’s in Kozhikode Corporation in Kerala: A Cross Sectional Study

Sivakumar D.1, Deepika2

1Assistant Professor, Department of Community Medicine, Government Thiruvannamalai Medical College, Thiruvannamalai, 2Medical Officer, Kanchipuram District Hospital, Tamilnadu

Introduction: Integrated Child Development Services is the largest national programme for the development of mothers and children in the world. The services are rendered through Anganwadi worker (AWW) at Anganwadi centre (AWC). An evaluation study is carried out to assess the services provided by the anganwadi centres to 3 to 6 year old children in Urban ICDS blocks in Kozhikode Corporation to study the shortcomings in implementation, improving the services and in decision making of the programme.

Method: A cross sectional descriptive study was carried out in 4 urban ICDS blocks in Kozhikode. Data was collected using pretested semi structured questionnaire and by observation of anganwadi centres and records at the time of visit and interviewing anganwadi workers and anganwadi helpers.

Results: Among 117 anganwadi centres, 73(62.4%) of AWC’s provided average services to 3 to 6 year old children, only 26(22.2%) of centres provided good services and 18 (15.4%) of AWC’s with poor performance needs to be targeted for improvement.

Conclusions: There is a need for effective coordination between the health functionaries and the anganwadi workers in immunisation, growth monitoring, health checkups and referral services, nutrition and health education.

Keywords: Supplementary nutrition, Preschool education, Health checkups, Referral services, Immunisation, Health education.

Introduction

“The lives of children are the important indicators for the development of communities and nations, the health of the youngest and most vulnerable are vital to nations economy, hence special programmes were launched in India for these under 6 years who constitutes 13.1 % of population in India(1). Various national programmes launched for health of children such as, mid day meal (1962-63), Balwadi–community child care centre (1970-71) and Special nutrition programme (1970-71), Integrated Child Development Services (ICDS) scheme (1975).

ICDS is the largest national programme for the development of mothers and children. The beneficiary includes children less than 6 years, pregnant and lactating mothers, women in the age group between 15-44 years. The package of services provided by ICDS scheme includes Supplementary nutrition & Growth monitoring, preschool education, Immunisation, Health checkups, referral and Nutrition and Health education services. The services are rendered through Anganwadi worker (AWW) at Anganwadi centre (AWC).

ICDS has expanded remarkably in its scope and coverage, and today it covers around 33.738 million children between three to six years of age, 39.871 million children between 6 months to three years, 18.047 million children between 3 years to 6 years, and 63.684 million children below 3 years.
million expectant and nursing mothers\(^2\)). In Kerala, it covers around 4, 6249 children between three to six years of age and 4, 21540 children between 6 months to 3 years and 1, 95927 pregnant and lactating mothers\(^2\). A number of studies on evaluation of ICDS centres are available but there is a scarcity of studies regarding the functioning of urban ICDS blocks. In Kerala there are 11 urban ICDS blocks functioning of which 5 are in Kozhikode, so an evaluation study was undertaken to improve the childcare services at urban areas in Kozhikode.

**Method**

A cross sectional descriptive study was carried out in 4 urban ICDS blocks in Kozhikode city. Using Simple random sampling method sample size of 117 anganwadi centres were selected from total 543 anganwadi centres in Urban Kozhikode Corporation. Keeping in view of prevalence of average and below average anganwadis in a study in Bangalore city by Vaijayanthi et al in 2010 noted as 54%, a confidence level of 95%, absolute precision of 9.2%, a sample size of 117 anganwadi centres was calculated\(^{14}\). Data was collected over a period of one year from July 2012 to June 2013. Ethical clearance was obtained from institutional ethics committee and relevant permission from Social welfare department in Kerala. Using various tools for data collection which included pretested semi structured questionnaire and by observation of anganwadi centres and records at the time of visit and interviewing anganwadi workers andanganwadihelpers. An ad hoc-scoring system for services was devised and the AWC’s were graded. The Anganwadi centres that have achieved more than 75% of scores were graded as Good, 50 to 75% as Average and less than 50% as poor. Data entered in MS excel and analysed using SPSS Software.

**Results**

A total of 117 anganwadi centres were selected from 543 anganwadi centres in Urban Kozhikode Corporation.

Out of 117 urban anganwadi’s, majority of the anganwadi’s 100(85.47%) covered a population of 800-1600, in 10 (8.55%) had more than 1600 population and Only 7(5.98 %) anganwadis covered a population of less than 800.

The total number of children 3 to 6 years in urban locality was 4517. Around 2325 (51.5 %) were registered in anganwadi centres out of 4517 three to six yearold children in the locality of which 1159 (49.84%) were boys and 1166(50.16%) were girls. However only 1535 (66.02%) were utilised services against the registered 2325 three to six year old children. The results are discussed based on the package of services provided by ICDS scheme includes Supplementary nutrition & Growth monitoring, preschool education, Immunisation, Health checkups, Referral and Nutrition and Health education services.

It was observed that most of the anganwadi centres, (82.1%) had more than 75% attendance of enrolled children for Supplementary Nutrition Programme. In all the anganwadi’s foodis prepared in the centre itself. Take home foodis not given to the children. The model menu supplies total calories-500 kcal and total protein-12.15 gm to children as per norms. There is no irregularity in food supply. The mean duration of feeding days in last one year was noted to be 268.85(± 3.33) days which was lesser than the ICDS norms.

About (72.6%) of anganwadi’s had more than 80% attendance of enrolled children for Preschool Education. The mean time spent in preschool activity was 2.28(±0.412) hours. In the present study, at least 3 or more types of language activities and Small activities like rhythmic movements, dramatisation was conducted in all the anganwadi’s. Lesser number of indoor play activities and outdoor play activities were noted as shown in table 1. Natural walk, outings, field trips were not conducted in any of the anganwadi’s. Language activities like storytelling, songs and rhymes were conducted in all anganwadis but writing was conducted only in (57.3%) of anganwadi centres. Similarly among anganwadi centres (117), indoor activities noted were drawing & painting (35.9%), paper cutting-folding (38.5%), threading (59.8%) respectively. About (58.9%) had outdoor activities like ball/swing.

In the present study among 1535 children, there were no Unimmunised children in anganwadi
centres, the coverage of fully immunised children was 1258(81.95%) and partially immunised children was 277(18.05%). The coverage of DPT 3 doses was 88.9%, the OPV 3 doses was 88.9 % and the measles coverage was 85.9% as shown in Table 2. Vitamin A was not given to any of the children during last 1 year in anganwadi centres as shortage of Vitamin A was reported by state administration and it was not available.

In this study out of 1535 children, 276(17.98%) of children were moderately underweight and 30(1.95%) were severely malnourished as per the WHO Growth chart. In (72.6%) of anganwadi centres, more than 80% of enrolled children were weighed monthly. The growth registers were maintained regularly for all the children in all the centres.

The average number of health checkups conducted in a year was noted to be 9.41 (± 2.934). The ranges was 4 to 12. In (86.3%) of anganwadi centres had more than 6 health checkups during last 1 year. For health checkups, in (52.1%) of anganwadi’s, health workers made monthly visits and in (47.9%) they made 3 monthly visits .In (46.15%) of anganwadi’s there were monthly or 3 monthly visits by medical officer and in (53.85%) visits were infrequent. In (69.2%) of anganwadi’s had more than 80% coverage of enrolled children for health checkups during last 3 months.

Almost all the anganwadi’s have a practice of referring children to sub centre or urban health centre or district hospitals. Among 117 anganwadi worker’s, 36(30.8%) and 56(47.9%) of workers have referred to medical college and private hospitals respectively too.

More than nine sessions were conducted only in (24.8%) of anganwadi centres and (75.2%) of the anganwadi’s conducted 5-9 health education session during last one year. The mean number of health education session was noted to be 7.68(±2.188). The average attendance of women at the health education sessions was 18.51(±7.848). Only 10.96% of women between 15-45 years in the area attended the session. The average number of sessions in which health personnel participated was noted to be 3.74(±0.675).On an average 48.18% of the session was conducted by the health personnel. Some of the topics discussed were prevention of malnutrition, common childhood disease/ARI, growth monitoring, safe drinking water, diarrhoea prevention, breast feeding, immunisation, complementary feeding, hygiene and sanitation, complementary feeding .In all the AWC’s more than 6 topics were discussed during last one year.

Based on scoring the results of provision of services to 3 to 6 years old beneficiary children, the grading of anganwadi centres is shown in figure 1. Among 117 anganwadi centres, 73(62.4%) of AWC’S provided average services to 3 to 6 year old children whereas only 26(22.2%) of centres provided good services. 18(15.4%) of anganwadi’s with poor performance needs to be targeted for improvement.

Fig. 1: Grades of Provision of Services to 3 to 6 years Old Beneficiary Children
Discussions

Similar to our study findings, the NCAER report (2001 India) showed that 60% of the children were noted to be enrolled in the anganwadis (3). The NIPCCD study (2006 India) showed that 63% of the eligible children were enrolled in AWC’s and out of these 75% were availing benefits (4). The Pratichi child report (West Bengal 2009) noted 50% attendance among eligible children (5).

Similar findings were by noted in Delhi study (Neenv in 2006) with 100% of the centres providing supplementary nutrition (6). In contrast to the present study, Arundathi dhuru et al in Uttarpradesh reported that only 23% of AWC’s had regular Supplementary Nutrition Programme (7). According to the Moribund ICDS–study on child survival issues by Vikas Samvat, Sanket et al (In Madhya Pradesh 2009), cooked meals were given only in 28% of anganwadi centres (8).

A study by Seema et al (Kerala 2001) noted that in only 53% of anganwadis story telling was conducted, and 60% of centres undertook painting (9).

Immunisation coverage is similar to DLHS-3 study (Kerala) where 79.6% were fully immunised, 19.9% were partially immunised and only 0.5% were unimmunised (10). The present study reveals a higher proportion of fully immunised children (81%) as compared to DLHS-3 data of Kozhikode (65%) (10). Our findings are similar to DLHS-3 (Kerala) where coverage of DPT 3 doses was 87.1%, the OPV 3 doses was 86.6% and the measles coverage was 87.9% (10).

DLHS-3 in Kerala noted that 35.8% among children between 0-6 years were moderately under weight and 9.3% were severely malnourished. In Kozhikode 46.6% children were moderately under weight and 18.7% were severely malnourished (10) which was higher than the present study.

In contrast to present study Health checkups in Orissa was irregular based on a study-gram sabha for social audit of ICDS programme (2007) by Adhar(11) anda study on human development in India–challenges for a society in transition in Madhya Pradesh in 2009 (WHO and UNESCO) showed that health checkups and referral services was the weakest link of ICDS (12). A Study by Dayanandh singh et al (Rajasthan 2013) noted that referral services were received from 30% of anganwadi workers (13). A study by Seemetal (Kerala 2001) showed that 63% of AWC’s were not visited by medical officer (3) as similar to our findings.

Similar to the present study low percentage of attendance of women was noted in Jammu and Kashmir study (2009 PRC)-35% (3) and ICDS study (UP)-5% (7).

Conclusion

In conclusion, the study revealed that in majority of anganwadis the performance of services provided to 3 to 6 year’s old beneficiary children in urban Integrated Child Development Services blocks in Kozhikode Corporation was noted to be average. The supplementary nutrition services provided under Anganwadi centres is noted to be as per Integrated Child Development Services norms and there is no irregularity in food supply. But low enrolment and attendance of the children for SNP is a drawback. There was not much variety in food items served in Anganwadis. Under non-formal Preschool education services more emphasis is being on language activities whereas indoor and outdoor play activities are less. Majority of the AWC’s showed average performance in relation to immunisation services. A few partially immunised beneficiaries in the AWC’s are notable finding. Health checkups were mainly conducted by the female health workers and with lesser involvement of Medical officers. Though Growth chart monitoring and maintenance were regular, presence of malnourished beneficiaries are noted which suggests lack of timely intervention. This may be linked to the fact that the attendance of women in nutrition and health education sessions were noted to be low. The practice of referral services in AWC’S was found to be satisfactory. Based on scoring and grading more attention needs to be given to Preschool education, health checkups and nutrition & health education. According to mother’s perception health checkups and health education services were poor. There is a need for effective coordination between the health functionaries and the anganwadi workers in immunisation, growth monitoring, health checkups and referral services, nutrition and health education.

Incidence and Pattern of Bear Maul Injuries in Mount Abu

Somendra Mohan Sharma1, Pratik Patel2, Nabajyoti Upadhyaya3

1Cosnsultant General & Minimal Access Surgeon, Deptt of Surgery, 2DNB Resident, Deptt of family Medicine, 3Senior Clinical Associate, Deptt of Surgery, J.W. Global Hospital & Research Centre, Mount Abu, Rajasthan, India

Abstract

Background: Bears typically compete directly with humans for space, food, security and cover. Frequent numbers of casualties with bear maul injuries observed in our hospital which is located in the Sloth Bear sanctuary of Arravali range, prompted us to undertake the study of incidence & pattern of such injuries in our department.

Materials and Method: This study was both retrospective and prospective covering a period from 2001 to 2018. The pattern of bear maul injuries in term of time, location, provocation, animal/human group behavior and the injury type/distribution were recorded and analyzed.

Results: Only a total of 27 cases were registered in 17 years. All the injuries were caused by Sloth Bears alone. Most of the patients were middle aged to elders. In our study, males were victimized more (74.1%) than females (25.9%). Most of the incidents (66.7%) occurred in early morning time. In our observation 51.9% of accidents happened in croplands and 25.9% in forest.

Bear attacks were unprovoked in 81.5% cases. The face and head were injured in 74.07% cases followed by trunk and upper limb in 70.37% cases. Abdomen and lower limbs were injured in 37% cases. In spite of devastating injuries, mortality was 0 in our study.

Conclusion: The relatively low incidence of bear attack in the region of Mount Abu may be an indication of a harmonious man-animal existence. Eliminating the need for open defecation and collection of fire wood by the tribal population can go a long way in further improving the man-animal coexistence equilibrium.

Keywords: Bear Maul, Bear attack injuries, Multiple Injuries, Man–animal conflict.

Introduction

Sloth bears (Melursus Ursinus) are distributed from the southern tip of the Western Ghats Mountains to the foothills of the Himalayas. Bear population has declined due to habitat degradation with increased human population, diminished food resources and increased poaching for the bearbody parts.1,2 Sloth bears are attracted by anthropogenic food. They rarely prey on other animals.3 Bears typically compete directly with humans for space, food, security and cover.4

Sloth bears reportedly can attack without apparent provocation and may encounter humans when they raid croplands or when people enter forests to collect forest products. Sloth bears likely view humans as potential predator.5 Bear maul injuries vary from minor scratches to major trauma involving fractured bone, joint damage, skin and deep tissue injuries. Bear maul injuries to the head & neck region can result in facial disfigurement with distressing physical and psychological consequences.6,7

Mount Abu is an old wild life sanctuary blessed with different fauna and flora. Mount Abu was declared an Eco Sensitive Zone in 2009. 359 Sloth bears found safe habitat in Arravali range according to 2016 census. Apart from Sloth bears, other wild animals causative for human attacks are Leopards, Fox and Wolves found in good numbers in Mount Abu’s forest.8

Bear attacks constitute only 0.1% of all animal attacks in India.9 The incidence is obviously high in areas where bear population is high. Our hospital is situated in one such bear sanctuary (Mount Abu Eco...
Sensitive Zone), and a frequent numbers of casualty observed in our hospital with bear maul injuries prompted us to study the pattern & incidence of bear maul injuries. This is a hospital based study conducted by the department of General Surgery, J.W. Global Hospital & Research Centre, Mount Abu, Rajasthan which is a rural multispeciality hospital located within forest covered by Arravali ranges, where sloth bears are prevalent. In addition to studying the pattern of bear maul injuries, their frequency, type of encounters and seasonal variations were studied as well.

Material and Method:

This study was both retrospective and prospective in J.W. Global Hospital & Research Centre, Mount Abu, Rajasthan. Retrospective data of bear maul cases admitted to this hospital from 2001 to 2015 were collected retrospectively from the Medical Records Department of our hospital. Prospective study was continued till March 2018. Information regarding detailed history, seasonal variation, location of bear-human encounter, circumstances under which attack occurred and nature, duration and termination of attack were collected and analysed.

Results

A total 27 cases, 0.06% of the total hospital admissions were registered in this case series. All the injuries were caused by sloth bears only. Most of cases (51.9%) encountered with single bear except in (22.2%) where bear was accompanied by cubs and in (18.5%) incidents bears were in group. Most of the patients were middle aged to elders where (51.9%) patients were from >40 years age group and (40.7%) of 25-40 years age group. In our study, males were victimized more (74.1%) than females (25.9%). Most of the incidents (66.7%) occurred in day time (6AM-8PM) where majority of incidents occurred in early morning time. In our observation most of accidents happened in croplands (51.9%) and forest (25.9%), only a few incidences occurred in villages & crowded civic places (18.5%). Most of the times the victim was alone during human bear encounters (88.9%) & bear attacks were unprovoked in (81.5%) cases. Most of cases were encountered in the month of March & September. There was no peak season observed for human–bear encounters in Mount Abu. Termination of attack was spontaneous in (22.6%) of cases while in other cases victims rescued themselves or helped by others.

All 27 cases were involved with soft tissue injuries (100%), bones were injured in 14 (51.8%) cases while visceral organs involved in 7 (29.6%) cases.

The face and head were injured in 20 (74.07%) cases followed by trunk and upper limb in 19 (70.37%) cases. Abdomen and lower limbs were injured only in 10 (37%) cases. Avulsion/loss in 19 (70.37%) of scalp were noted in half the cases i.e. 14 (51.8%) and skull fractures only in 3 (11.11%) cases among head injuries. Facial fractures were found in one third (33.33%) cases, mostly involving nasal and maxilla bones. The nose was predominantly involved structure in face with laceration, fracture and avulsion led to major disfigurement of face.

The eyes were injured in 12 (48%) cases of which 7 (28%) lost eye function and 3 (12%) lost eye globe directly or indirectly as a result of bear maul injuries. Lip laceration occurred in half the cases (51.85%) along with injuries of nose and mid face area.

The ears were involved in 2 cases with loss of part of ear in 1 case and avulsion in the other.

In the extremities most commonly upper limbs were injured with fractures in 8 (32%) cases. Most commonly involved fractures were radius and ulna in 5 (20%) cases, ribs in 2 (8%) cases and clavicle in 1 (4%) case.

All 27 cases were involved with soft tissue injuries (100%), bones were injured in 14 (51.8%) cases while visceral organs involved in 7 (29.6%) cases.

The face and head were injured in 20 (74.07%) cases followed by trunk and upper limb in 19 (70.37%) cases. Abdomen and lower limbs were injured only in 10 (37%) cases. Avulsion/loss in 19 (70.37%) of scalp were noted in half the cases i.e. 14 (51.8%) and skull fractures only in 3 (11.11%) cases among head injuries. Facial fractures were found in one third (33.33%) cases, mostly involving nasal and maxilla bones. The nose was predominantly involved structure in face with laceration, fracture and avulsion led to major disfigurement of face.

The eyes were injured in 12 (48%) cases of which 7 (28%) lost eye function and 3 (12%) lost eye globe directly or indirectly as a result of bear maul injuries. Lip laceration occurred in half the cases (51.85%) along with injuries of nose and mid face area.

The ears were involved in 2 cases with loss of part of ear in 1 case and avulsion in the other.

In the extremities most commonly upper limbs were injured with fractures in 8 (32%) cases. Most commonly involved fractures were radius and ulna in 5 (20%) cases, ribs in 2 (8%) cases and clavicle in 1 (4%) case.

Discussion:

J.W. Global Hospital & Research Centre (GHRC) is a major health care centre situated amidst the Mount Abu Eco Sensitive Zone. Almost all cases of animal attacks come to this hospital for primary and/or definitive treatment. A total number of only 27 cases of Bear Maul injuries in 17 years is a very small number of incidents of human bear conflicts in contrast to studies undertaken in Himalayan range, Central India and North Gujarat. Altaf Rasool recorded 417 cases from 1990 to 2007\(^\text{10}\), 254 cases with bear attacks studied by Shafaat Rashid TAK from 2003 to 2007\(^\text{11}\) and Ajaz Shah recorded 200 patients of bear mauling from 2005 to 2009 in Kashmir valley\(^\text{7}\). H.S. Bargali et al studied 137 case of bear attacks from1998 to 2000\(^\text{12}\) and Aniruddha H. Dhamorikar et al interviewed 166 victims of bear maul injuries from 2004 to 2016\(^\text{13}\) in Central India (Chhattisgarh & Madhya Pradesh respectively). This small number of cases in our study is probably due to harmonious existence of man and animal in this region. Mount Abu was declared an Eco Sensitive Zone in 1991 and very limited construction activities have occurred in this region since then. The village population is largely tribal which is in equilibrium with man animal coexistence. Most of the incidents of human bear encounter were due to encroachment of human in bear habitat for forest resources like water, fire wood, honey and other plant products. The habit of defecation in open field is another human activity which provokes men to venture into the forest in the wee hours.

In our study majority of bear attacks were unprovoked (81.5%) similar to other studies like Altaf Rasool et al, Ajaz Shah et al\(^\text{7,10}\) recorded (93%) and (92.8%) unprovoked attacks respectively. Single bear was involved in (51.9%) cases, bears in group were involved in (18.5%) and bears with cubs were noticed in (22.2%) incidents. In all incidents where bears were found with their cubs, attacks were unprovoked as the sow becomes protective to her cubs and finds human as a predator. These data are supporting studies conducted by KS Abdul Samad\(^\text{14}\) where (57%) attacks were by solitary bears and 33%of attacks were by mother bear with their cubs, Aniruddha H. Dhamorikar et al \(^\text{13}\)observed 60% attacks by single bear, (15%) by group of bears and (25%) attacks with sows with cubs where H.S. Bargali et al\(^\text{12}\) also recorded (56%) cases by solitary bear and (41%) cases by bears in group. In our study animal ran away after attack in (22.2%)cases, in (37%) cases victim rescued by helper and in (29.6%) cases victim rescued themselves.
In our study majority of victims were male in 74.1% accidents as mostly men are breadwinner and involved in activities like farming and wood harvesting in Mount Abu. Male predominance also observed in other studies like by Altaf Rasool et al\textsuperscript{10} and Shafaat Rashid et al\textsuperscript{11}, where (80.33\%) & (71.7\%) victims were men respectively. Majority of victims (51.9\%) were aged >40 years, (40.7\%) cases were in age group of 25-40 years. This data supports other studies where majority of victims were middle age group 25–40 years.

Most of human bear conflicts (66.7\%) occurred in early morning 6am–8pm when people venture out for access to water, working in farm fields and also for defecation activity. Most of studies conducted on bear attacks on human in India evidenced early morning incidents.

In our study, human bear encounters occurred in (51.9\%) at civic secluded places, mostly in crop fields during harvesting crop, fruits and around water sources. 25.9\% incidents noticed in forest as majority of population in Mount Abu are depended on wood as fuel and other forest products like fruits, plants and honey. 18.5\% bear attacks occurred in townside in crowded area where bears were attracted to food & music. Mount Abu being a tourist place is a hub of many hotels and food stalls. Other studies conducted in bear habitat also observed majority cases in civic secluded places like farm fields and fruit garden.

There is no obvious peak season for human bear encounter noticed in our study. Most of the cases of bear attacks, 8 cases in March and 6 cases in September were observed in this study series. As after winter, March is the month of harvesting and September is the end of monsoon when bears are attracted to termites, insects, berries and black plum (jamun) in this region. In other studies peak season of bear attacks varied according to different geographical and weather condition, but most of the studies in Himalayan range observed human bear encounters during July to November. Aniruddha H. Dhamolikar et al\textsuperscript{13} recorded 40 \% cases in summer, 35\% in monsoon & 25\% in winter.

Most victims were injured over head & face in (74.07\%) cases, found to be commonest injured part of body. Face & Head commonly injured in bear attacks evidenced by studies of Altaf Rasool et al\textsuperscript{10}, Ajaz A.Shah et al\textsuperscript{7}, N.T.Geetha et al\textsuperscript{15} and Nikhil Puri et al\textsuperscript{16}. The reason behind common involvement of the head & face region could be that the bear can easily stand on his hind legs and attacks on prominent parts of face and head region with paws/claws to become dominant in human bear encounter and weaken opponent as most of the times the bear attacks are defensive.

In most cases involving Bony fractures, Facial & skull fractures were involved mostly in our study. 33.3\% facial fracture & 11.1 \% cases with skull fracture were noticed followed by upper limb fractures in 32\% cases. Altaf Rasool et al\textsuperscript{10} Observed 31.41\% case of facial fracture and Nikhil Puri et al\textsuperscript{16}, Ajaz A.Shah et al\textsuperscript{7} observed a majority of facial fractures in their series–mostly involved zygoma & nasal bone. This observation concludes face & head easy target for bears as they are prominent areas of body fixed by bear paws & claws. In our studies all cases had soft tissue injuries and 29.6\% cases with visceral injuries. Since viscera are deeply seated, only injured when there is a major avulsions, fall injury or puncture wound occurs during bear mauling. There was no mortality occurred in our series in spite of multiple life threatening injuries, where other studies also observed less numbers of mortality in bear maul injuries. Because most attacks by bears are defensive in nature and cause superficial injuries by paws, rarely injuring deep viscera.

**Conclusion**

The relatively low incidence of bear attack in the region of Mount Abu may be an indication of a harmonious man-animal existence, thanks to a near total ban on new constructions in this area ever since it was declared an Eco Sensitive Zone in 1991.

Eliminating the need for open defecation and fire wood can go a long way in further improving the man-animal coexistence equilibrium thereby drastically decreasing animal attacks on tribal population.

Physiotherapy Following Extensor Tendon Reconstruction in Zone 5 - A Case Study

Angeline R.1, Soundararajan K.2, Syed Altaf Hussain3, Senthil Kumar T.4

1Assistant Professor, Faculty of Physiotherapy, 2Post Graduate, Faculty of Physiotherapy, 3Associate Professor, Department of Plastic Surgery, 4Assistant Professor, Faculty of Physiotherapy, SRIHER, Chennai

Abstract

Background: Extensor tendon attrition in Rheumatoid arthritis is very common and if not treated properly, can lead to substantial loss of hand function. Here we present the rehabilitation of a 45 years female patient following extensor tendon reconstruction in zone 5.

Materials and Method: The motor assessment included examination of active range of motion, grip and pinch strength and hand function was done during first visit and at the end of 3rd week, 6th week and 12th week. The patient received physiotherapy (immobilization method) and the program was divided into three phases.

Results: The test results were used to find the efficacy of immobilisation method, author’s modification of the program and home based exercises. There was 60 to 80 percentile of ROM improvement in wrist joint, 50 to 90 percentile of ROM improvement in digits .By comparing 6th week and 12th week DASH there was about 47% improvement in upper limb functional activities The results show that the management combined with a comprehensive rehabilitation programme and commitment on the part of the patient makes it possible to achieve satisfactory treatment out comes enabling a return to normal daily functioning

Conclusion: The functional recovery achieved indicates the advisability of using immobilisation method in post-operative rehabilitation of patients with extensor tendon injury.

Keywords: Rheumatoid arthritis, Extensor tendon injury and repair, Rehabilitation.

Introduction

Rheumatoid Arthritis (RA) is an autoimmune condition which primarily affects the synovium of the joints. RA is a chronic inflammatory disease caused by a T cell-driven autoimmune process, which majorly affects the diarthrodial joints. Women are involved four times more than men, between 35 and 45 years of age. It is characterized by soft tissue laxity, joint erosion, and deformities which happen as a result of inflamed synovial tissue. Approximately, 70% of patients with RA develop pathologies of the hand, especially of the metacarpophalangeal joints (MCP). Besides, tenosynovitis and tendon ruptures are also frequent. Joint damage and tendon ruptures are common in patients with RA, leading to severe deformities that hinder the ability to grip, grasp, and pinch. Patients often report a reduction of their quality of life due to inability to perform several activities of daily living. Extensor tendon ruptures are often associated with rheumatoid arthritis. Extensor tendon injuries are not as common as flexor tendon injuries in Indian scenario but if not treated properly might lead to substantial loss of hand function. This condition is best treated with surgical exploration and repair of the ruptured tendons, followed by hand therapy. Rehabilitation following an extensor tendon injury helps to improve range of motion, strength and hand function. Here, we present a case of extensor tendon repair with extensor indicis (EI) transfer to extensor digitorum communis (EDC) along with resection of distal ulna. We discuss its presentation, physiotherapy assessment and management.

Case presentation and Rehabilitation: The patient came to hospital with an inability to extend ring finger and little finger since 4 months. The patient was a
known case of Rheumatoid Arthritis for past 20 years on treatment. Patient had undergone Bilateral Total Knee Replacement in 2002 and hysterectomy in 2016.

The MRI of right hand revealed rupture of extensor tendon of Right little finger. On surgical exploration it was found that EDC of ring and little finger was completely ruptured. EIP was intact, but thinned out. Proximal and Distal cut ends of EDC was identified, EIP transected and transferred to EDC. Through the same incision distal ulnar periosteum also elevated. Subluxated ulnar excision. Ulnar styloid left intact. Periostium reapproximated. Postoperative period was uneventful and patient discharged in stable condition. Functional POP applied for three weeks.

The patient was referred for hand rehabilitation following surgical repair. The patient was evaluated for range of motion, grip strength, pinch strength and hand function at the end of 3rd, 8th and 12th week after surgery.

**Physical Therapy Treatment:** The patient received physiotherapy (immobilization method) as per Hunter’s guidelines. The Physical therapy treatment was divided into three phases.

**The first phase:** During the first three weeks wound care was performed by hand surgeon. The management of edema (elevation and compression) and exercises were performed by physiotherapist. A volar splint (POP) was applied by the surgeon with wrist in 40-45 degrees extension, 0 to 20 degrees of MP flexion, and 0 degrees of IP flexion. The POP cast extended up to the level of DIP joints. DIP joint protective ROM exercises were given. After a week POP was reapplied. Sutures were removed after 15 days and POP reapplied from below elbow up to MCP joints. Protected ROM exercises to MCP, PIP and DIP joints were started. These exercises were given to prevent tendons adhesions. At the end of 3 weeks, the POP was removed and a thermoplastic splint which maintained the wrist in 40 degrees extension, MCP in 70 degree flexion and IP in neutral position was provided. Since the extensor tendon injury was associated with DRUJ disruption following surgery the patient presented with extensor lag of 20 degrees in middle finger and it was graded as fair using dragon’s criteria.

**The second phase:** From 3-6 weeks we continued with the same exercises as phase I. For extensor lag specifically isolated EDC exercise were initiated. Active MCP exercises were added to treat extensor lag and “press and hold” were added followed by tendon gliding and grip strength exercises. In week 6, we also started with abduction and adduction of fingers; Individual finger extension, Isolated EDC extension and opposition of the pollicis to the other fingers and active exercise for radio-carpal joint, composite MCP and IP flexion with wrist extension were started.

**The third phase:** In week 8-12, the patients continued with described exercises as above and mild progressive strengthening including wrist flexion/extension, forearm pronation/supination, smile ball, putty clay exercise, pegboard exercises were performed. Moderate mechanical load exercises were initiated to promote collagen synthesis in tendon stem cells. Ultrasound therapy (Pulsed 1:1, 3MHZ, Direct contact) given over scar region for effective stretching of contracted scars and to prevent adhesion formation. Composite finger and wrist flexion was initiated (after 8th week with complete recovery from extensor lag). During phase 3 splint was used only during night, travelling time.

The patient was instructed to continue the home-based exercise programme. All exercises were performed every 2 hours a day (1 set, 10 repetitions).

**Results**

**Range of motion (ROM):** Standard goniometric measurement of fingers and wrist were performed using a standard goniometer. Total active range of motion (TAROM) of the digits (Table 2), Active Range of Motion (AROM) of wrist and radio-ulnar joint (Table 1) was measured at the beginning of 3rd and at the end of 8th and 12th week and was tabulated. There was 60 to 80 percentile of ROM improvement in wrist joint, 50 to 90 percentile of ROM improvement in digits. Range of motion was reduced at first assessment and gradually improved at subsequent assessments. During 1st assessment it was observed that the ROM of the digits was very minimal. This was due to the presence of POP for initial 3 weeks and hence ROM exercises were not possible and hence the rehab program was modified according to the medical management. An extensor lag of 20 degrees was present in middle finger, but during phase 2 and phase 3 the extensor lag improved due to splinting and isolated EDC activation exercises. Wrist ROM and radio-ulnar ROM improved steadily in phase 2 and 3.

Measurement of hand function: Measurement of hand function was assessed using Disabilities of the Arm, Shoulder and Hand (DASH) scale. There was improvement in scores denoting improved hand function (Table 4). The minimal detectable change (MCD) for DASH is 12.75%-17.23%. By comparing 8th week and 12th week DASH there was about 47% improvement in upper limb functional activities.

Discussion

Extensor tendon injuries are more common but have received relatively less attention in comparison with flexor tendon injuries. Physiotherapy management of extensor tendon injuries following repair is quite challenging, requires skill and knowledge.

When RA results in degenerative changes in tendons, the surgical management consist of tendon repair and transfer which result in tendon shortening and reducing gliding of affected tendons. The challenge in rehabilitation of repaired and transferred tendon lies in finding a balance between protection of repaired tendon and prevention of adhesions. In this case study even though, it was challenging we were able to produce better results using immobilization method. It can be used in management of extensor tendon repair following attrition in rheumatoid arthritis. There was greater increment in ROM of little and ring finger however lesser improvement in supination range.

There are various protocols in managing tendon repair namely 1) immobilization 2) early controlled mobilization 3) Early active mobilization. All these protocols are variably used for rehabilitation of flexor tendon. Recently they are gradually integrated in to the treatment of extensor tendon. Even though now a day’s early controlled mobilization and early active mobilization are frequently used we followed immobilization method as selecting the protocol depends upon experience of the Hand surgeon and Hand Therapist. Studies support that three month post operative, no difference was found between the different rehabilitation programmes. Here immobilization protocol proved to be useful in managing extensor tendon rehabilitation as there was a considerable improvement in AROM, hand function.
Conclusion

The immobilisation program used, enabled early post-operative physiotherapy which resulted in high degree of recovery of hand function. Hence the outcome achieved in this patient suggests the advisability of routine.

Ethical Clearance: Being a single case study, written informed consent was obtained from the patient and the permission for the study was obtained from the Rehabilitation centre.

Role of Colposcopy in Diagnosing Potentially Malignant Disorders and Oral Cancer: A Systematic Review

T. Jane Belinda¹, Sreedevi Dharman²

¹Graduate Student, ²Reader, Department of Oral Medicine and Radiology, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Colposcope is a non-invasive device when used it aids in Detecting the appropriate site for biopsy which saves the patients from multiple biopsies and allows in a broader range of diagnoses. For this review, the following electronic databases were searched namely PubMed (Mesh), Wiley online library, Cochrane Library using key words colposcopy, oral mucosal lesions. The total number of articles obtained are 17 with preset inclusion and exclusion criteria to select the appropriate clinical trial. The search strategy included 4 potentially relevant articles for literature review. The sensitivity and specificity of biopsy through colposcopic examination done in the studies were fairly more thus revealing the diagnosis of early dysplastic changes in the potentially malignant disorders. Therefore, the studies reviewed concluded that clinical criterion of colposcopic examination was found to be more appropriate for the selection of biopsy specimens in cases of potentially malignant disorders and carcinoma. Even though the results in the studies was positive and promising, further long term studies are to be done in large populations to determine the diagnostic changes.

Keywords: Biopsy, Mucosal Lesion, Colposcope.

Introduction

The prevalence of potentially malignant epithelial lesions and oral lesions is steadily increasing throughout the world¹. Clinical evaluation of oral carcinoma is less difficult when the lesion is obviously invasive or when the patient experiences symptoms like pain, functional limitation, or regional lymphadenopathy². The Conventional method of examination visually using incandescent light, has traditionally been the mainstay of oral malignancy screenings for decades, anyhow this method remains debatable³. Conversely, the diagnosis of lesions of the oral mucosa is not completely based on clinical findings. An early diagnosis, evaluation with prompt treatment ensures an improvement in the prognosis of malignancy. Despite of advancement in the prior detection, the rate of mortality and morbidity is increased related to oral malignancies. Hence, biopsy with a histopathologic examination of the lesion is very much essential, to establish a definitive diagnosis. Though the biopsy with histopathologic examination is considered as gold standard in the diagnosis of oral lesions and oral malignancy, but the requirement of the site for biopsy is still critical. The selection of biopsy site is of a subjective choice, and it is possible that the biopsy specimens are taken from unrepresentative areas of the lesion or before the morphologic changes could be detected in oral lesions. There are simple chair side method of histopathologic examination including staining with toluidine blue, light based detection systems, and exfoliative cytology or brush biopsy to help in the diagnosis of such changes, with related disadvantages with these method⁴. Clinical examination alone often leads to not a certain diagnosis, and thus the provisional diagnosis or final diagnosis of any carcinomatous or premalignant lesions of the oral mucosa is not mainly based on clinical findings⁵. With the aim of improving the efficacy of these diagnoses, various techniques have been developed to complement the clinical examination and to facilitate the identification of initial carcinomas. Toluidine blue staining is considered the most common

Corresponding Author:
Dr. Sreedevi Dharman
No.162, Poonamallee High Road, Vellapanchavadi, Tamil Nadu, India-6000077
e-mail id: sanjamrut@gmail.com
technique used for early detection of oral cancer in high risk patients. Questions have also been raised regarding the risks of developing malignancies associated with the use of toluidine blue because it shows an affinity for DNA. Exfoliative cytology has a false-negative rate of approximately 30%\(^6\). The use of oral exfoliative cytology in clinical practice had been declined due to the subjective nature of its interpretation and only a small number of abnormal cells identifiable in a smear\(^7\). Various other methods used for the early detection of precancerous lesions and conditions include oral brush biopsy, autofluorescence, acetic acid staining, chemiluminescence\(^8,9\).

Therefore, a technique for non-invasively detected will choose the appropriate site for biopsy that can save patients from multiple biopsies and allow a broader range of diagnoses which can aid in early detection of oral potentially malignant lesions\(^10\). With the aim of improving the efficiency of these diagnoses, techniques are being developed to complement clinical examination and to facilitate the identification of lesion. One such technique is colposcopy, also known as direct oral microscopy that offers advantages in selecting more representative sites for biopsy than routine clinical examination and other available chair side diagnostic method\(^11\). Colposcopy is defined as the study of morphology of the cervical region with the aid stereoscopic binocular magnification by the colposcope. A colposcope is helpful to find the visible clues predominantly of abnormal tissue. The colposcope resembles a pair of binoculars and is stabilised on a pedestal with a light source attached to it\(^12,13\). The aim of the study is to review the articles on Colposcopy and evaluate the potential benefits of colposcopy in diagnosing oral mucosal lesions.

**Materials and Method**

**Search Strategy:** The following electronic databases were searched namely Pub Med (Mesh), Wiley online library, Cochrane Library using key words colposcopy and oral lesions. The current review article aims in assessing the use of Colposcope has a diagnostic technique in evaluating the oral mucosal lesions, hence the following inclusion and exclusion criteria was devised to select the appropriate clinical trial. The articles were screened on the basis of title and abstract. Full text was then procured for the relevant articles which fulfilled the inclusion criteria. Only articles published in the English language were considered for this review. Potentially relevant studies identified and screened for retrieval were 17, Abstracts of studies retrieved were 9, Studies evaluated in detail to determine the relevance to inclusion criteria were 4.

**Eligibility Criteria:**

**Inclusion Criteria:** Non-Randomized study on human clinical trials.

**Exclusion Criteria:** In-vitro studies, Animal studies and experimental studies, case reports, case series, literature reviews. All irrelevant studies were excluded and the reasons for their exclusion were noted.

**Outcome Measures:** The sensitivity and specificity obtained was assessed for all the articles obtained.

**Quality Assessment:** The Criteria for the methodological quality assessment was done in all the included studies taken under review. All studies performed under valid procedures were considered.

**Results**

According to the results obtained from each study the Squamous cell carcinoma of the oral mucosa and lips, however, comprises 90–95% of all oral malignancies. [Table 1] The study done based on Schmitt\(^14\) Coppleson\(^15\), Cartier\(^16\), John\(^17\) and Creasman\(^19\), where in cases of oral submucous fibrosis, for the colposcopic examination on application of 2% acetic acid, the lesions appeared as faint pink to orange in colour. At places, it was iodine negative. On histopathological examination, it was revealed that 9 cases had mild dysplasia, 2 were with moderate, 4 were with severe dysplasia and 11 cases revealed signs of chronic nonspecific inflammatory reaction. [Table.2] Where as White raised lesions with raised, papillary borders, a feature of leukoplakia, was observed as a consistent finding by Schmitt\(^14\), Coppleson\(^15\), Cartier\(^16\), John\(^17\) and Disaia and Creasman\(^18\) was also confirmed. The lesions appeared aceto-white with 2% acetic acid and iodine negative and straw-colored with Lugol’s iodine. The directed biopsy sites revealed five cases with mild dysplasia, five with moderate, three with severe dysplasia and seven cases with signs of chronic nonspecific inflammatory reaction.

Discussion

Oral cancer is considered as one of the 10 leading cancers in the world and its prevalence is high in several countries, including India, amounting to about 40% of all malignancies. Therefore, early diagnosis is of prime importance which helps in correct diagnosis at an early enough stage when the prognosis can be improved improving the over-all 5-year survival rates in such patients\textsuperscript{19,20}. The time honoured decision on the exclusiveness of exfoliative cytology and colposcopy in the diagnosis of cervical intraepithelial neoplasia (CIN) has further given place to view as to their complementariness increasing the significance of colposcopy in the near future\textsuperscript{21}.

The intention for the colposcopic study was undertaken based on:

- Observation and recording of the surface morphology by micro-colpo-hysteroscopy of the oral tissues in different oral premalignant lesions and condition; and
- Attempting Predictability of early changes suggestive of malignant transformation.

In this study the criteria for vascular changes given in Colposcopic literature for the selection of biopsy site includes vascular pattern, inter-capillary distance, surface pattern, colour tone and opacity as well as the clarity of demarcation of the mucosal lesions\textsuperscript{22,24,25}. Different grading and scoring systems have been devised for colposcopic examination. Some of the more commonly
used criteria include the one given by Coppleson and co-workers, the Combined colposcopic index proposed by Reid and Scalz. The lesion on application of acetic acid in the case of oral squamous cell carcinoma appeared as an erythematous area with scattered, large red dots, sometimes projecting above the surface under colposcopy and with a magnification of 15–20 times, the vessel caliber of the capillaries was found to be not equal, while the newly developing blood vessels was arranged in bundles or corkscrew appearances. The vascular hypertrophy had progressively smaller blood vessels. After application of acetic acid, the vessels remain visible since the overlying epithelium was very thin. The histopathological picture was of well-differentiated squamous cell carcinoma. The findings of this well differentiated squamous cell carcinoma was reported with findings of Cartier, showing that alterations in the vascular network reflect biochemical and metabolic changes in cervical tissue. Coppleson in his study also stated that atypical vessels are corkscrew or comma-shaped in appearance which shows greatly increased vascularity and immature vessels which is better in colposcopic examination. When compared to the benign carcinoma, the vessels in invasive cancers make sharp angulations and corkscrew or hairpin turns.

Hence according to this literature, its found that the biopsy specimens selected with Colposcopic criteria appeared to be more representative of the histopathological findings at least in certain cases than those selected with routine clinical examination (COE). The altered vascular patterns, in the initial stages of lesion progression, definitely helped with the correct selection of the biopsy site, which in turn helped us reach a more definitive diagnosis, thus avoiding false-negative results. The results of Colposcopic findings are significantly based on the vascular and tissue changes. The capillary changes preceding tumour growth with the pattern of tumor angiogenesis are different from the usual neo-vascularization taking place during repair and regeneration processes. At a cellular level, various molecules such as vascular endothelial growth factor, basic fibroblast growth factor, and transforming growth factor alpha are implicated, but the clinical perceptibility of these altered vascular patterns is poor. Direct optical visualization of these patterns would be helpful in the early determination of the underlying pathology and also aid in marking out the site of biopsy.

Conclusion

With the help of colposcope, it is possible to visualize dysplastic changes in the oral tissues. Intraoral application of colposcope has a promising future. Colposcopy appeared to be more representing the histopathological findings than those selected with set clinical criteria. The altered vascular patterns definitely helped with the correct selection of the site for biopsy, which in turn helped us reach a more definitive diagnosis thus avoiding false-negative results. Further studies are to be carried out in large population and sample size for diagnosing the early diagnostic changes in potentially malignant disorders and oral cancer.

Alveolar Ridge Dimension and Morphology Measurement in Anterior Maxilla for Immediate Implant Treatment Planning: A Cone Beam Computed Tomography Study

M.A. Fazeelath Banu¹, Sreedevi Dharmann°

¹Graduate Student, ²Reader, Department of Oral Medicine and Radiology, Saveetha Dental College, Saveetha Institute of Medical and Technical Science, Saveetha University, Chennai, India

Abstract

Background: Implants have been widely used to replace missing teeth. Successful implant treatment depends on proper planning. The height, width, morphology and density of alveolar bone surrounding the implant site is very important for determination of the size of implant. Conventional radiographic techniques have image distortion and superimposition and compromise the accuracy of treatment planning. Cone beam computed tomography provides high resolution and accurate images at low dosage which can be used in implant planning.

Aim: To measure alveolar ridge and buccal undercut dimension at the anterior maxilla to develop treatment planning for immediate implant placement using Cone beam computed tomography (CBCT).

Materials and Method: 80 CBCT scans of subjects with full dentition at right maxilla were taken. Measurements were taken at the cross sectional views in the middle of the maxillary right central incisor, lateral incisor, and canine regions. The parameters measured were alveolar height, alveolar width, buccal undercut location, buccal undercut depth.

Results: There was no significant difference in the alveolar height among the teeth. The mean alveolar widths (mm) were: central incisor, 8.1; lateral incisor, 7.4; canine, 8.9. The lateral incisor had a significantly smaller alveolar width than the other anterior teeth. Among the maxillary anterior teeth 72% of central incisors, 88% of lateral incisors and 51% of canines had buccal undercut. The lateral incisor had the maximum buccal undercut. The buccal undercut depth for central incisor, lateral incisor, canine are 1, 1.61 and 0.91 respectively.

Conclusion: Thus in anterior maxilla lateral incisor has the thinnest alveolar bone and buccal undercut among the other anterior teeth.

Keywords: Alveolar ridge, Implants, Alveolar height, Alveolar width, Buccal undercut.
were used as standard method for implant treatment planning\(^7,8\). However these 2D images have image distortion and superimposition which compromise the accuracy of treatment planning\(^9\). They fail to reveal the true morphology of the ridge particularly a defect in labial cortical plate in anterior maxilla.

Cone beam computed tomography (CBCT) is a 3-dimensional technique for assessment of alveolar bone anatomy. It provides a comprehensive preoperative implant site assessment and surgical guide in dental implantology\(^6,10\). CBCT gives views and volumetric reconstructions of craniofacial structures which is similar to multi-sliceconventional computed tomography(CT). However CBCT has reduced acquisition times, lower effective radiation doses, and a decreased financial burden compared to CT\(^11,12\).

In the present study, alveolar ridge dimension and the presence of buccal undercut were evaluated using CBCT images in maxillary anterior region. This study was aimed to provide more quantitative information to help immediate implant treatment at the maxillary anterior area.

**Materials and Method:** The subjects included all CBCT scans performed at Oral Radiology department of Saveetha Dental college, Chennai according to the selection criteria. Machine used was

**Software used was Galileos viewer:** A total of 80 CBCT scans of subjects with full dentition at right maxilla. There were 33 females and 47 males were included in the sample size. The exclusion criteria included: 1) systemic/endocrine diseases that influence bone metabolism; 2)Conditions that may affect the bone quality and quantity at anterior maxilla like moderate to severe periodontal disease, cyst, neoplasm, trauma or surgery.

**Measurements (Fig. 1):** All the measurements were taken by one examiner. The measurements taken are

1. **Alveolar height:** A line was drawn from alveolar crest paralleling with the long axis of alveolar ridge. The distance from alveolar crest to the floor of nasal fossa was defined as alveolar height.
2. **Alveolar width:** Alveolar height was divided into coronal, middle, and apical third. In the middle of each third, a line was drawn perpendicular to the long axis of alveolar ridge. The distance between buccal and palatal cortical plate was defined as alveolar width.
3. **Buccal undercut location:** For a tooth identified to have buccal undercut, a line was extended from alveolar crest which was perpendicular to the long axis of the alveolar ridge. The distance from where the buccal cortical plate started dipping to the aforementioned line was defined as buccal undercut location. This value demonstrated how close the buccal undercut was to the alveolar crest.
4. **Buccal undercut depth** For a tooth identified to have buccal undercut, a line tangent to buccal cortical plate and parallel to the long axis of alveolar ridge was drawn. The distance from the deepest point of the buccal undercut to the aforementioned line was defined as the buccal undercut depth.
5. **Percent of teeth with buccal undercut** For maxillary right central incisors, lateral incisors, and canines, the formula to calculate the percent of teeth with buccal undercut was: (the number of teeth with buccal undercut)/(total number of teeth evaluated) X100.

**Statistical analysis:** The Normality tests Kolmogorov-Smirnov and Shapiro-Wilks tests results reveal that somevariables follow Normal distribution and some variables do not follow Normal distribution. Therefore, to analyse the data both parametric and non-parametric method are applied. To compare the mean values between teeth types one-way ANOVA is applied followed by Tukey’s HSD post hoc tests for multiple pairwise comparisons.

**Results**

The mean alveolar height for maxillary right central incisor, lateral incisor, canine was 21.34mm, 20.65mm and 19.87 mmrespectively (Table 1). There was no significant difference in alveolar height among the teeth. The mean alveolar width for central incisor, lateral incisor, canine was 8.1mm, 7.4mm, 8.9mm respectively (Fig: 3).The coronal, middle, and apical third alveolar width for maxillary right central incisors was 7.8mm, 7.7mm, 8.8mm, for maxillary lateral incisor was 7.1mm, 6.8mm, 8.3mm and for canine was 8.6mm, 8.3mm, 9.1mm respectively. The alveolar width was greater in apical third of the tooth. The lateral incisors had thinner alveolar width when compared to other teeth (p<0.001). Correlation between subject’s gender and alveolar
volume measurements, showed that male demonstrated significantly larger alveolar width compared to female. Male and female alveolar width for maxillary right central incisor are 8.38 and 7.7 (p=0.010), for maxillary right lateral incisor it is 7.7 and 6.9 (p=0.001) and for maxillary right canine it is 9.4 and 8.1 (p= <0.001) (Fig: 3).

Among the maxillary anterior teeth 72% of central incisors, 88% of lateral incisors and 51% of canines had buccal undercut. The lateral incisor had the maximum buccal undercut. The buccal undercut depth for central incisor, lateral incisor, canine are 1, 1.61 and 0.91 respectively. Buccal undercut depth showed statistical difference between the teeth (p<0.001). (Fig: 5).

Discussion

For implant placement, adequate bone volume at the future implant site is a prerequisite for good aesthetic outcome and sound biomechanical support of the osseointegrated implant\textsuperscript{13}. However due to trauma, alveolar deficiencies and unpredictable patterns of bone resorption occur which may prevent an ideal implant therapy for prosthodontic rehabilitation\textsuperscript{13}. It has been seen that an accurate preoperative evaluation of alveolar dimension of the future implant site is very important to develop an appropriate placement strategy and also to preserve adjacent anatomical structures, in need of immediate implant placement\textsuperscript{14}. Therefore identification of the exact anatomy of the implant site is mandatory. Alternative to conventional approach, immediate implant placement have been proposed. This was done to decrease the overall treatment time and surgical interventions\textsuperscript{15}. In the anterior maxilla, implant placement presents more challenges due to the demand for well-anchored implant, satisfactory aesthetic result and difficult preexisting anatomy\textsuperscript{16,17}. In the present study alveolar ridge dimension of anterior maxilla was measured using Cone beam computed tomography for immediate implant treatment planning.

In the study, the alveolar width was greater for canine and least for lateral incisor. The alveolar width was increased in the apical third for all the three teeth. Males had increased alveolar width compared to females. This was in consistent with a study done by Zhang et al in Houston and a study done in posterior mandible by Braut et al\textsuperscript{18,19}. There was no significant difference in the alveolar height in all the three teeth.

Among the maxillary anterior teeth 72% of central incisors, 88% of lateral incisors and 51% of canines had buccal undercut. This shows that lateral incisors have higher risk of perforation of the buccal plate compared to all the teeth. So additional grafting procedures is necessary for implant placement in this region. On the other hand, canines had increased alveolar width and least buccal undercuts. A careful preoperative evaluation of anterior maxilla, especially of the lateral incisor region, is invaluable for selection of the optimal treatment approach and reducing surgical complications.

Conclusion

This study concludes that careful preoperative evaluation with CBCT is necessary for implant placement. At anterior maxilla lateral incisor has the thinnest alveolar bone and buccal undercut among the other anterior teeth. In future, studies should be done with larger samples from diverse populations to enhance the reliability of the parameter.

A Rare Case of Multiple Osteochondromas with Short Metatarsals and Seizure

N.K. Sundaray¹, Srikant Kumar Dhar¹, P.K. Tudu², S.C. Das², Bijendra Mohanty³, Gourab Arun⁴

¹Professor, ²Assistant Professor, ³Senior Resident, ⁴Junior Resident, PG Department of Medicine, IMS and SUM Hospital, Siksha “O” Anusandhan University, K8, Kalinganagar, Bhubaneswar; Odisha, India

Abstract

Multiple Osteochondromas described first in 1786 is an autosomal dominant inherited disorder with 100% penetrance manifesting more in males (M:F =1.5:1) with a prevalence rate of 1:50000. The defect involves the tumour suppressor gene EXT 1 and EXT2. They appear in first decade of life with two or more bony outgrowths from the end of growing long bones and grow till puberty. They can arise from any bone except facial bones. They present with pain and symptoms due to pressure effects on the nerves, muscles, tendons, ligaments, brain and spinal cord and cause many type of deformities. Brachydacty l and relative shortening of metatarsals as well as possibility of seizure consequent to exostoses of skull bones have been described but has rarely been reported. Here we are presenting a case of MO with distinct shortening of metatarsals and seizure.

Keywords: Osteochondromas, Brachydactyl, seizure, exostoses.

Introduction

Exostoses are bony outgrowths usually arising from the diaphyseal end of the tubular bones containing marrow and cortex being continuous with that of the parent bone. When they are capped with a cartilage they are termed as osteochondromas.¹ It was first described by John Hunter in his lecture on the principles of surgery in 1786. Following first publication of exostoses in a family by Boyer in 1814 many such cases in families had been reported. However it was Jaffe who characterised it in detail as Hereditary multiple exostoses.² Other synonyms are Multiple hereditary exostoses(MHE), Hereditary multiple exostoses (HME), Diaphyseal aclasia, (multiple hereditary), multiple congenital osteochondromata, Chondrodysplasia, Chondromatosis, Russel-Hagen Disease. However in 2002 WHO termed it as Multiple Osteochondromas (MO)². It is genetically heterogenous affecting the tumour suppressor gene EXT1 and EXT2 which encodes the protein ‘EXOSTOSINS’. These are glycosyltransferases and are involved in the biosynthesis of heparin sulphate (HS). Thus the persons who are deficit in HS cause an error in negative feed back to prevent chondrocyte proliferation and maturation thus leading to abnormal bone growth ie the exostoses. When two or more such exostoses are noted the condition is termed as MO It is inherited as an autosomal dominant disorder with 100% penetrance with a prevalence rate of 1:50000 with a male to female ratio being 1.5:1. Although they are benign they cause multiple deformities, pain and complications due to pressure effect on nerves, vessels tendons, ligaments, muscles, brain and spinal cord. In 0.5-5% cases they may transform to malignancy.³

Case Report: A 16 years old girl born to non-consanguineous parents who had no history of anyantenatal, natal, postnatal insult, head trauma, fever with altered sensorium came under medical attention on 26 September 2014 with history of having fallen unconscious from bicycle a day before. A CT scan of brain was reported as normal while an EEG taken revealed 1-2 HZ generalised spike and wave discharges apparently arising from both frontal regions. She was diagnosed as a case of seizure disorder and was prescribed tab Dilantin ER300 mg OD. She had a recurrence of a seizure (an episode of loss of consciousness lasting for
a minute) on 27 May 2016 at 7 PM on discontinuation of drugs for about two months for which she reported to us. Her parents, a brother and a sister had no such abnormality. She was studying in class IX and was of average intelligence. She has attained menarche two years back and her periods have been regular. On enquiry she revealed of the bony swellings being noted by her 5 years back which of late has not shown any change.

Examination revealed height 146 cm, weight 44 kg BMI-20.7, multiple hard, non-tender bony projections varying from 0.3-1 cm in size were noted around both ankle and knee, without any varus/valgus deformity. However bilateral cubitus valgus deformity were noted. Third toe on right side and fourth toe on left side were markedly short (Fig-1). Otherwise general and systemic examination did not reveal any other abnormality.

**Fig-1. Photograph of the patient showing short 3rd toe on right foot and 4th toe on left foot. Osteochondomas can be noted around the ankles**

**Investigation:** Blood counts, urine, Renal Function Tests, Liver Function Tests, blood sugar, serum calcium, phosphorus were all normal. Radiological examination showed multifocal wide based cortical outgrowths seen arising from the both ends of tibia and fibula of both sides, lower end of the femoral bone on both sides with expanded cortex. All the lesions show metaphysical origin growing away from the joint space. Right 3rd and left 4th metatarsal bones are short. Ulna shows shortening with bowing of the radius on both side. No soft tissue calcification seen overlying the bony outgrowths. (Fig-2). A plain CT scan of brain (of September 2014) did not reveal any abnormality. (Fig-3) EEG (of September 2014) was abnormal. (Fig-4).

**Fig-2. Exostoses can be seen arising from both ends of tibia and fibula of both sides and lower end of femur of both sides growing away from joint space. Shortening of both ulna and bowing of radii can be noted. The 3rd metatarsal on right side and 4th metatarsal on left side are short.**

**Fig-3. CT Scan of brain did not reveal any parenchymal lesion nor any bony outgrowth.**
Fig 4: EEG-showing 1-2 Hz generalised spike and wave discharges apparently arising from both frontal regions.

She was diagnosed to be a case of MO with seizure and was counselled to continue tab Levopiracetam 500 mg twice daily uninterrupted and consult neurologist regularly.

Discussion. This short statured non-obese girl has normal biochemistry (Calcium, Phosphorus) with exostoses (total 16) and short metatarsals has presented with seizures. Diagnosis of MO is based on the patient history, family history, the radiological picture, histology of the lesions where available and germline mutation studies of EXT1 and EXT2. In our case it is based on history and radiological picture as there was no positive family history. Positive family history is detected in about 62% of cases. Mutation studies in this patient could not be carried out as the patient did not agree for any further studies.

The exostoses develop in childhood and are evident by the 1st decade (our patient noted them around 11 years). Their growth ceases at puberty. The cartilaginous cap is usually radiolucent and may show irregular calcification around that time. They can be sessile or pedunculated and usually project away from the joint space. They vary in number (2-100) but on an average 15-18 are noted (our patient had 16). They can arise from almost every bone except that of facial bones. Only one case of skull base involvement has been reported. However Sinha et al on analysing available images of skull has found out involvement of base of skull in about half of their cases.

Clinical manifestation. Usually the exostoses are benign and asymptomatic. Main and troublesome symptom is pain which in 50% of cases is general or else it could be due to pressure effect on tendon, ligament, nerve, vessel, or due to fracture of the exostoses and surgery which produces other symptoms as well. Our patient has no experience of pain. Multiple deformities have been noted like short stature (37-44%), unequal limb length (10-50%), short ulna, bowing of radius (39-60%), different deformities of hand, varus/valgus deformity of knee (8-33%) and ankle (2-54%). Relative shortening of metacarpal, metatarsal and phalanges may be noted. Our patient had short ulna and bowing of the radius, cubitas valgus and had short metatarsals.

The complications are all due to it’s pressure effects on muscles, tendons, ligaments, nerves, vessels, spinal cord, brain etc. Exostoses on skull can compress brain or entrap cranial nerves, cause focal neurological deficit. Extension of Intracranial lesions on impingement on neuro-axis by way of compression, irritation can cause a seizure focus which has happened in our case though exostoses on skull could not be demonstrated on the CT scan of Brain. An MRI could not be carried out as the patient refused to undergo any further investigation. Exostoses of foramen magnum and C1 have been described to cause vertebral artery occlusion manifesting with dizziness, headache and weakness. Other compressions of importance are that of spinal cord (0.6%) causing spastic paraparesis, rib exostoses leading to haemothorax and that of pelvis leading to obstructed labour. The vascular complications reported are pseudoaneurysm, aneurysm, vascular compression, arterial and venous thrombosis and account as high as 11.3%. The important complication is malignant transformation (0.5-5%) which is suspected if there is growth after puberty, persistent pain and the cartilaginous cap thickness is more than 1 cm. The mean age of malignant transformation is 31 years of age. It never occurs before 10 or after 50 years of age.

The clinical course of MO has been phases to phase one of lumps around joints, phase two to lumps with pain or deformity, phase three to lumps, deformity and pain. In a study of 283 children in Netherlands it was noted to restrict sports activities in 30% of cases, to have problems like difficulty in writing, using computers or being bullied in 50% of cases, to have complained...
of pain in 60% of cases.\textsuperscript{11} Our patient was in phase two (lump and deformity) and did not complain of any such psychosocial problem.

**Differential diagnoses.** Other causes of exostoses and short metatarsals like Turner’s syndrome (TS), Pseudohypoparathyroidism (PHP) and pseudopseudohypoparathyroidism (PPHP) have characteristic features. The exostoses seen in these conditions are periosteal, arise from the shaft and project straight outwards. Thus our patient fits to be a case of MO. Unlike MO the genetic pattern is 45XO in TS while DNA\textsubscript{1} gene is involved in PHP and PPHP. Foetal alcohol syndrome exhibit exostoses from tibia while in cases of Tuberous Sclerosis exostoses of long bones are noted. In Dysplasia Epiphysialis Hemimelica (DEH) epiphyseal overgrowths predominantly affecting lower limbs of one side are noted in young boys. There is no genetic transmission nor malignant transformation. Metachondromatosis (MC) exhibits osteochondromas in hands and feet pointing towards the growth plate. They do not cause deformity and have a tendency to resolve.\textsuperscript{3}

**Management:** Asymptomatic patients require no treatment. Analgesics are recommended for those having for pain. Corrective surgeries are indicated for patients presenting with pain, pressure symptoms, deformities and malignant transformation. Psychosocial support are recommended for those with pain, deformity, cosmetic problems and adjust problems in school/society. Our patient was counselled to continue anticonvulsants with periodic follow up.

**Genetic counselling** is possible as it can be diagnosed antenatally from amniotic fluid examination by 15\textsuperscript{th} week and from chorionic villi biopsy by 8-13 weeks.\textsuperscript{12} The affected patient can transmit to half of the offsprings, it being an autosomal dominant disorder. The patient had been counselled accordingly.

**Prognosis:** It is a benign disorder. But quality of life may be compromised due to pain, deformities, pressure effects and cosmetic appearance. In cases with malignant disease 10 year survival rate is 83% for grade 1 for 29% in grade 3 chondrosarcomas.\textsuperscript{13}

**Conclusion**

A case of MO in a 16 years old girl with short 3\textsuperscript{rd} and 4\textsuperscript{th} metatarsals and seizures has been presented. She has no family history of such lesions. The features to be noted in this patient are firstly distinct short metatarsals in contrast to relative shortening described in literature which can confuse with pseudopseudohypoparathyroidism (PPHP) and secondly of seizure which is a rare manifestation and we believe it to be the first report in literature. It is suggested that in all such cases of MO an all out effort by way of imaging be made to demonstrate exostoses in skull base and an EEG be taken, to delineate a seizure focus so that preventive antiepileptic drugs can be instituted.

**Conflict of Interest:** There is no conflict of interest.

A Comparative Study to Analyse the Effectiveness of PNF Versus Balance Exercises in Parkinsonism

K. Kamatchi1, S. Priya2, C.V. Senthilnathan3, G. Mohan Kumar4, G. Tharani5, G. Yuvarani6

1Assistant Professor, Faculty of Physiotherapy, 2Faculty of Physiotherapy, 3Professor, Principal, Faculty of Physiotherapy, 4Professor, Faculty of Physiotherapy, 5Assistant Professor, Faculty of Physiotherapy, 6Assistant Professor, Faculty of Physiotherapy, Dr.M.G.R. Educational and Research Institute.

Abstract

Objective: The aim of the study is to analyse the effectiveness of PNF techniques and balance exercises in Parkinsonism.

Background: Parkinson’s disease is a progressive neurodegenerative disorder that affects neurophysiologic function, movement abilities and quality of life (QOL). It commonly presents with postural instability, hypokinesia, rigidity and tremor. These symptoms decreases physical activity (PA) and increases time spent in sedentary behaviours. This in turn leads to a cycle of poor balance, muscle weakness, fear of falling and a sedentary life style. The background of the study is to find out the effectiveness of PNF techniques and balance exercises in Parkinsonism patients for the improvement of balance and improve the quality of life.

Materials and Method: Once the study is approved by institutional review board 30 patients both male and female were selected from clinically diagnosed parkinsonism. The study setting was in the Physiotherapy outpatient department of ACS Medical College and hospital, velappanchavadi, Chennai. The study includes patients with clear history of parkinsonism. Both male and female patients age group within 55-70 years. Subjects in the 1.5-3 HOEHN and YAHR stages. The study population excludes Dementia, Cardiovascular conditions, Musculoskeletal conditions, and subjects in the 4 & 5 stages of H & Y scale. The samples were fully explained about the benefits of participating in the study. They were asked to fill the consent form duly signed by the samples and therapist. Data regarding the balance were collected using berg balance scale and unified parkinsons’s disease rating scale.

Result: Result of this study shows that both the PNF techniques and balance exercises is effective in improving balance. However PNF techniques was better than balance exercises in improving the balance among parkinson’s diseased patients.

Keywords: PNF, Balance exercise, Hoehn and Yahr scale.

Introduction

In 1817, James Parkinson first described the clinical syndrome “the shaking palsy” that was previously referred as or Paralysis agitans. Later in the 19th century Charcot gave credit to Parkinson by referring to the disease as by his name Parkinson’s disease (PD) or “maladie de Parkinson”. Worldwide it is the 2nd most common neurodegenerative disease. PD is a progressive disorder of the central nervous system with both motor and non motor symptoms. Early symptoms includes anoxia, constipation, rapid eye movement (REM) sleep behavior disorder, mood disorders and orthostatic hypotension. Motor symptoms includes cardinal features of tremor, rigidity, bradykinesia and postural instability. Non motor symptoms may precede the onset of motor symptoms by years, it include altered bladder function, excessive saliva, intedumentary changes, difficulty in speaking and swallowing, cognitive problems (bradyphenia, confusion and in some cases

Corresponding Author:

Assistant Professor, Dr. M.G.R. Educational and Research Institute, Faculty of physiotherapy, Vellappanchavadi, Chennai-600077
e-mail: physiokamatchikaviraja@gmail.com
dementia). Other motor symptoms includes forward flexed posture with a typical festinating gait. Postural instability is typical in later stages of disease, leading to impaired balance and frequent falls. The other symptoms includes fatigue, masked face, and greasy skin. The first clinical sign occurs when about 60% of the dopamine producing cells in the substantianigra have degenerated. The onset is insidious with slow rate of progression. The mean age of onset of PD is in the mid fifties, with increasing incidence and prevalence as age increases. When it is seen before the age of fifty, it is called young onset PD. Males are slightly more at risk than females. About 7 to 10 million people are affected worldwide. Prevalence rises from 1% with those with 60 years age to 4% in population over 80 years. Basal ganglia (BG) nuclei play a key role in mediating motor and non motor behaviour, cognition and emotion. Basal ganglia are involved in movement initiation and preparation. Any lesion in basal ganglia produces balance impairment and hypokinesia. The most consistent pathological findings are degeneration of nigrostriated tract, depletion of dopaminergic neurons, reduction in striated dopamine, acetylcholine hyperactivity.

Most of the movement related symptoms of the parkinson’s disease are caused by the lack of dopamine due to loss of dopaminergic cells in substantianigra. When the amount of dopamine is too low, communication between substantianiagra and corpus striatum becomes ineffective. Thus, movement becomes impaired. Balance is the ability to control the body mass or centre of mass or integrated sensory and musculoskeletal system and is modified with CNS in response to changing internal and external environmental conditions. Postural instability has been noted to be one of the major causes for frequent falls among the Parkinson’s disease affected persons. The Proprioceptive Neuromuscular Facilitation (PNF) is a widely used technique as an intervention for neuromuscular dysfunction. In applying PNF a therapist can enhance movement re education and expand on existing techniques already utilized for muscle strengthening and stabilization. PNF uses nervous system reflexes to help relax a muscle. The Berg Balance Scale, Unified Parkinson’s Disease Rating Scale and Hoehn and Yahr scale were used as the outcome measures in the study. Physiotherapy is often prescribed in parkinson’s disease.

Optimal management of parkinson’s disease involves both pharmacological treatment and encouragement of physical activity according to American academy of neurology (1993). There is mounting evidence for the effects of physiotherapy in all stages of the disorder, yet few well controlled prospective studies have documented the benefits of physical activities in parkinson’s disease. The present study is intended to analyse the effectiveness of PNF versus Balance exercises to improve balance in patients with Parkinson’s disease.

Materials and Method

Once the study is approved by institutional review board 30 patients both male and female were selected from clinically diagnosed parkinsonism. The study setting was in the Physiotherapy outpatient department of ACS Medical College and hospital, velappanchavadi, Chennai. The samples were fully explained about the benefits of participating in the study. They were asked to fill the consent form duly signed by the samples and therapist. Data regarding the balance were collected using berg balance scale and unified parkinsons’s disease rating scale. Subjects were selected based on the selection criteria and divided into two groups.

Group-A: Subjects were treated with PNF techniques.

Group-B: Subjects were treated with balance exercises.

PNF Techniques: Exercises includes upper trunk rotation, lower trunk rotation and chopping to lifting.

Duration: 50 minutes per session, 3 days per week for about 7 weeks.

Balance Exercises: Exercises includes tandem stance, tandem gait stance, heel raises and toe raises, modified squats repetition, balanced stand on foam pad, mambo walking.

Duration: 50 minutes per session, 3 days per week for about 7 weeks.

Data Analysis: The collected data were tabulated and analyzed using both descriptive and inferential statistics. All the parameters were assessed using statistical package for social science (SPSS) version 24. Paired t-test was adopted to find the statistical difference within the groups & Independent t-test (Student t-Test) was adopted to find the statistical difference between the groups.

This table shows that there is no significant difference in pre test values of the Unified Parkinson’s Disease Rating Scale between Group A & Group B (*P > 0.05).

This table shows that statistically highly significant difference in post test values of the Unified Parkinson’s Disease Rating Scale between Group A & Group B (***-P ≤ 0.001) (Graph-II).

Both the Groups shows significant decrease in the post test Means but (Group-A) which has the Lower Mean value is more effective than (Group-B)

Table 3: Comparison Of Berg Balance Scale (BBS) Within Group – A & Group – B Between Pre & Post Test Values

Group A – PNF, # GROUP B – BALANCE EXERCISE, (***-P ≤ 0.001)

The above table reveals the Mean, Standard Deviation (S.D), t-value and p-value of the Unified Parkinson’s Disease Rating Scale between pre-test and post-test within Group – A & Group – B. In Unified Parkinson’s Disease Rating Scale, there is a statistically highly significant difference between the pre test and post test values within Group A and Group B (***-P ≤ 0.001). (Graph-IV)

Results

On comparing the Mean values of Group A & Group B on Berg Balance Scale Score, it shows significant increase in the post test Mean values but (Group A- Proprioceptive Neuromuscular Facilitation) shows (51.33) which has the higher Mean value is more effective than (Group B- Balance Exercise) (47.20) at P ≤ 0.001. Hence Null Hypothesis is rejected. On comparing the Mean values of Group A & Group B on Unified Parkinson’s Disease Rating Scale, it shows significant decrease in the post test Mean values but (Group A- Proprioceptive Neuromuscular Facilitation) shows (66.60) which has the higher Mean value is more effective than (Group B- Balance Exercise) (73.20) at P ≤ 0.001. Hence Null Hypothesis is rejected. On comparing Pre test and Post test within Group A & Group B on Berg Balance Scale & Unified Parkinson’s Disease Rating Scale shows highly significant difference in Mean values at P ≤ 0.001

Discussion

In this study, results shows statistical significance of PNF techniques and balance exercises within group analysis pre and post intervention of both the group shows the improvement in balance.

Between group analysis of post intervention shows there is more improvement in balance. According to the result PNF techniques improves balance in Parkinson’s disease patients after receiving PNF and balance exercises. But there was more improvement seen in PNF group.

Abu A Qutubuddin, et al, 2007 has showed that physiotherapy has improvement on selected outcome measures in Parkinson’s disease.

Smania, et al, 2013 Balance training is often studied in Parkinson’s disease patients, because of lack of motor control and balance that leads to falls. A study that evaluated balance training on Parkinson’s disease found that balance training improved postural stability, confidence level in performing daily activities and reduced the frequency of falls.

Sneha B.S, et al, 2016 has concluded that trunk based PNF training is beneficial in improving dynamic balance, mobility and quality of life in patients with Parkinsonism.

William DB, et al, 2001 PNF promotes strengthening, motor learning and restoration of motor control in older adults with neuromuscular deficits. It is a widely used technique as an intervention for neuromuscular dysfunction with particular emphasis on the trunk.

Table 1 shows that there is no significant difference in pre test values of the BBS between Group A & Group B (*P > 0.05). This table shows that statistically highly significant difference in post test values of the BBS between Group A & Group B (***-P ≤ 0.001) (Graph – I)

Table 3 shows that in BBS, there is a statistically highly significant difference between the pre test and post test values within Group A and Group B (***-P ≤ 0.001). (Graph – III)

Table 2 shows that statistically highly significant difference in post test values of the Unified Parkinson’s Disease Rating Scale between Group A & Group B (***-P ≤ 0.001) (Graph – II).
Table 4 shows that in Unified Parkinson’s Disease Rating Scale, there is a statistically highly significant difference between the pre test and post test values within Group A and Group B(***-P ≤ 0.001).(Graph-IV)

In between group analysis it was found that the group which underwent PNF techniques showed more increase in balance as compared to the group which received balance exercises.

Finally, PNF techniques can be used as effective treatment program in improving balance in Parkinson’s diseased patients.

Conclusion

The present study concludes that PNF technique as well as balance training are effective in improving balance in Parkinson’s Disease patients. But PNF technique is more beneficial in improving balance in Parkinson’s Disease. Hence the findings of this study suggest that the PNF technique, if added to conventional rehabilitation protocol in treatment is beneficial to improve balance and thereby quality of life in Parkinson’s Disease.

Life Skills: A Study on Young Girls Working in Organized Sectors in Coimbatore, Tamil Nadu

K. Umamaheswari¹, Suja M.K.²

¹PhD Scholar, ²Thesis Advisor and Chairperson, Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India

Abstract

Introduction: One in every ten Indians is a young girl. Consequently, India hosts nearly 20% of the world’s population of young girls in age of 14 to 21 years, and each and every one of them has the potential to contribute to India’s future economy¹. Yet, work participation rates for women remain dismally low¹. Denying girls the opportunity to finish their schooling and build income-generating skills, keeps them from realizing their economic potential³. Life skills development empowers learners to observe the process involving “what to do, why to do, how to do and when to do”. It encompasses the ability to build sound, harmonious relationships with self, others and the environment, the ability to act responsibly and safely, the ability to survive under a variety of conditions, and the ability to solve problems⁴.

Aim: To measure the level of life skills in young girls working in organized sectors, Coimbatore.

Results: The statistical measure of central tendency the mean age of the respondents is 17.42 years and there is no difference between the mean median and mode. Regarding the global score of life skills, the majority (40.8%) of the respondents had average level of life skills. There is significant association between education level of the respondents and their life skills levels, between experience and of problem solving skill of the respondents, association between educational qualification and of coping with stress level of the respondents.

Conclusion: Through this study it is evident that majority of the respondents had only average level of life skills. And it is understood that majority of the respondents had average level of life skills, so this is the main reason for young girls to become vulnerable in working environment. Vulnerable in the form of low wages, over work load, verbal abuse and suffering from occupational hazards. Through the promotion of life skill education to these young girls their quality of life and quality of work environment can be improved.

Keywords: Young girls, Life skills. Organized sectors, Mental health, vulnerable.

Introduction

One in every ten Indians is a young girl. Consequently, India hosts nearly 20% of the world’s population of young girls in age of 14 to 21 years, and each and every one of them has the potential to contribute to India’s future economy¹. Yet, work participation rates for women remain dismally low. Denying girls the opportunity to finish their schooling and build income-generating skills, keeps them from realizing their economic potential³.

Life skills are a set of human skills acquired via teaching or direct experience that are used to handle problems and questions commonly encountered in daily human life. The subject varies greatly depending on societal norms and community expectations².

Life skills are those abilities that enable individuals...
to deal effectively with demands and challenges of everyday life. Life Skills help individuals to convert intangible assets like knowledge and attitude into healthy behaviors.

Life skills development empowers learners to observe the process involving “what to do, why to do, how to do and when to do”. It encompasses the ability to build sound, harmonious relationships with self, others and the environment, the ability to act responsibly and safely, the ability to survive under a variety of conditions, and the ability to solve problems.

Many mental health problems emerge in late childhood and early adolescence. Enhancing social skills, problem-solving skills and self confidence can help prevent mental health problems such as conduct disorders, anxiety, depression and eating disorders as well as other risk behaviors including those that relate to sexual behavior, substance use, and violent behavior.

Coimbatore enjoys a place of significance in the industrial map of India. The textile units at Coimbatore range from small to large scale with the specialisation in spinning. The cotton textile industries still dominate the city and provide about 50 percent of registered manufacturing employment. Since independence, the engineering and metal-working industries developed rather rapidly with the initial impetus provided by the textile mills and commercial agriculture for electric motors and pumps. Now, engineering and metal-working industries came to dominate the city of Coimbatore although textile as well as trade and commerce continue to occupy a significant space in the urban economy of Coimbatore. The dynamic industrial development of the city has been due to a variety of factors, locational as well as historical, and this has probably attracted migration of people from the vast rural hinterland contributing to a rapid increase in the population of the city. Among them women workers in organized sectors are about 65% mostly unskilled workers. The age group of the workers is predominantly in the range of 14 to 21 year are in fact a minority segment among the total workforce.

Methodology

The researcher followed descriptive research design for the study. The major goal of this descriptive research is to find out the level of life skills of young girl’s working in organized sector. There are more than 25,000 small, medium, large sale organized sectors in Coimbatore. 60 to 80% of workers in the organized sectors are temporary workers. An estimated 120,000 young girl’s are currently employed. Convenient sampling was used. The researcher selected all the organized sectors in east zone of Coimbatore. The population of the working adolescent’s girls in this zone was about 40,000 out of 2500 industries approximately. Young girl’s working in these sectors, willing to participate in the study in the age group of 14-21. The first part of the structured questionnaire consists of the socio demographic profile of the respondents.

The second part of the structured questionnaire consists of the Life skills Assessment scale constructed by RGNIYD. The multi-dimensional life skill scale consists of 100 items in the form of statements in-build with 5-point scale was used.

Young girls constitute one fifth of the female population in the world. Unmarried young girls of 14 to 21 years of age are preferred in the textile and garment industry for their efficiency in work output. The influx of female workers started in the 1970s when textile and garment manufacturers from different parts of India started relocating to Tamil Nadu in search of a more pliant workforce.

Selection of the Respondents: The organized sectors had a working population of 1204 girls in the age group of 14-21. The researcher selected 10% of the total population using simple random procedure. Thus 120 respondents were selected.

Inclusion Criteria: Young girl’s working in organized sectors in the age group of 14-21.

Exclusion Criteria: Women working in organized sectors exceeding the age of 21.

Results

Socio Demographic Data: The data of the current studies was taken from 120 young girls working in organized sectors. The socio demographic data reveals the following information. The statistical measure of central tendency the mean age of the respondents is 17.42 years and there is no difference between the mean median and mode. It’s interesting to see nobody is illiterate among them. The data indicates that school drop outs were high after primary and secondary level. Majority of the respondents belonged to Hindu religion (88.3%), and adhering to Islam (6.7%) and remaining Christianity (5%).Nearly one fourth of the respondents
(24.2%) belonged to Backward Community, 55.8% belonged to Most Backward Community and rest one fifth of the respondents (20%) belonged to Scheduled Caste and Scheduled Tribe.

**Level of life skills**

**Global Score:** Life skills: The World Health Organization has defined life skills as, “the abilities for adaptive and positive behavior that enable individuals to deal effectively with the demands and challenges of everyday life”.

<table>
<thead>
<tr>
<th>Level of Life skills</th>
<th>No of respondents</th>
<th>Percentage</th>

</tr>
<tr>
<td>Very low</td>
<td>7</td>
<td>5.8</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>120</strong></td>
<td><strong>100.0</strong></td>
</tr>
</tbody>
</table>

Less than half of the respondents (40.8%) possessed average level of life skills. Only 16.7% of respondents had very high level of life skills, 35.8% of respondents with low level of life skills and 5.8% of respondents with very low level of life skills. The researcher is of the opinion that majority of the respondents need to improve their life skills level for their betterment.

Majority of respondents (64.2%) had average level of self awareness. Only 1.7% of respondents had very high level of self awareness and 4.2% of respondents had very low level of self awareness skill. 59.2% of the respondents had average level of empathy. Only .8% of respondents had very high level and 4.2% of respondents with very low level of empathy skill. Majority of respondents (60%) had average level of effective communication skill. 17.5% of respondents had very high level of effective communication skill and 3.3% of respondents with very low level of effective communication skill. 59.2% of respondents had average level of life skills and 8.3% of respondents had very low level of interpersonal relationship skill. 51.7% respondents had average level of creative thinking skill. 1.7% of respondents had very low level of creative thinking skill and 15.8% of respondents had very high level of creative thinking skill. Majority of the respondents (65%) had average level of critical thinking skill. 42.2% of respondents had average level of decision making skill. Less than half of respondents (42.5%) had average level of problem solving skill. The majority of respondents (59.2%) had average level of coping with emotions skill. Less than half the respondents (48.8) had average level of coping with stress.

Less than half of the respondents (47.6%) from primary level of education had average level of life skills level. This indicates that there is significance association between educational status and life skills level. There is no statically significant difference between income level and life skills level. The level of life skills were low among the age group 14-16, 17-19 had average level of life skills and 20 and 21 age group has low level of life skills. This result indicates that there is no significant association between age and life skills level of the respondents. There is no statistical significant association between age and problem solving skill. The problem solving skills found to be average among all the age group. Education status had average level of critical thinking skill. Hence, it can be concluded that there is no significance association between the educational status and critical thinking. All the age group had average level of decision making and statistically it is inferred that there is no significance association between age and decision making. There is significant association between experience and problem solving skill. The primary and secondary level of education had average level of coping with stress, whereas it were found to be coping with stress were very high among the higher secondary level. This result indicates that there is no association between education status and coping with stress. The respondents from rural and urban area had average level of interpersonal relationships. Hence there is no significance association between geographical area and interpersonal relationships. All the community had average life skills level. It is statistically not significant.

There is no significant association between the educational status and decision making. Both rural and urban people had average level of decision making skill. There is no statistically significant association between area and decision making.
The association between selected socio economic variables and life skills level: There is significance association between education statuses, experience with life skills level. However it is interesting to see there is highly significant association between respondents experience and self awareness. There is significant association between education status of the respondents and empathy. Whereas no such association between age, demographic area, income level and experience of the respondents with empathy. There is highly significant association between respondent’s education status and experience with effective communication. There is no significant association between age, education status, demographic area, income and experience of the respondent’s with interpersonal relationships. There is highly association between the educational level, and experience with critical thinking. There is no significant association between the age, education level, demographic area, income and experience of the respondent’s with critical thinking. There is moderate level significant relation between the education statuses of the respondent’s with decision making. It is highly significant with income level and experience of the respondent’s. It was found that there is no significant relation between the respondent’s age and demographic area. There is highly significant relation between education statuses and experience of the respondents’ with problem solving. However it is noted that there is no significant relation between age, demographic area and income of the respondent's with problem solving. There is no significant relation between respondents’ age, education, demographic area and income with coping with emotions. It is interesting to note that there is moderate significant relation between experiences of the respondents with coping with emotions. There is highly significant relation between experience of the respondents’ with coping with stress, whereas such relations is at a moderate level with regard to the age of the respondents. However, there is no significant relation between demographic area and income of the respondents with coping with stress.

**Conclusion**

Through this study it is evident that majority of the respondents had only average level of life skills. And it is understood that majority of the respondents had average level of life skills, so this is the main reason for adolescent girls to become vulnerable in working environment. Vulnerable in the form of low wages, over work load, verbal abuse and suffering from occupational hazards. Through the promotion of life skill education to these adolescent girls their quality of life and quality of work environment can be improved.

Life skills are an essential tool for understanding one’s strength and weakness and the individual is able to discern an available opportunity is able to face the possible threats. Life skills enable oneself to explore alternatives, weigh pros and cons and make rational decision in solving each problem or issue and facilitate to establish productive interpersonal relationships with others.
Life skills are a topic largely neglected rather untouched throughout any stage of education in India, and yet is an essential part of children’s overall development. In a country nearly half of the population is in the age group of adolescence. At this point of the time the much neglected life skills education has become the need of the hour for discussion, and its implementation in our Indian educational system. Life skills education can be included in the central board of workers education scheme which will improve the ability of the young adolescent girls in all the aspect of life situations.

Life skills training are the act of increasing the knowledge and skill of an employee for doing a particular job. It is required in every industry so as to cope the employees with the emerging trends. Life skills can substantially improve the quality of life and productivity among the employees. Industries imparting life skills training are more effective than other, which reduces employee turnover. Therefore life skills training and education are the only way to resolve today’s crisis of any young girl’s facing in the day to day life situations.

**Conflict of Interest:** No

**Ethical Clearance:** All procedures performed in the study involving human participants were in accordance with the ethical standards of the institution and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. The clearance for research was obtained from the Human Ethics Committee, Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India, for ethical clearance and the same was obtained.

Abstract

A descriptive study to assess knowledge and attitude towards Caesarean section among antenatal mothers in a selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India.

The objectives were to assess knowledge towards caesarean section among antenatal mothers in a selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India, to assess attitude towards Caesarean section among antenatal mothers in a selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India, to correlate between Knowledge and Attitude towards Caesarean section among antenatal mothers in a selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India, to associate between knowledge, attitude of antenatal mothers towards Caesarean section with the selected demographic variables in a selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India.

The Hypothesis were: There is no significant correlation between knowledge and attitude, there is no significant association between selected demographic variables and the knowledge level towards Caesarean section among Antenatal mothers in a selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India, There is no significant association between selected demographic variables and attitude towards caesarean section among Antenatal mothers in a selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India.

Associate between knowledge, attitude of antenatal mothers towards Caesarean section with the selected demographic variables in a selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India. The hypothesis were: There is no significant correlation between knowledge and attitude, there is no significant association between selected demographic variables and the knowledge level towards Caesarean section among Antenatal mothers in a selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India. There is no significant association between selected demographic variables and attitude towards caesarean section among Antenatal mothers in a selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India.

The convenience sampling was adopted to select 50 samples. The data collection tools were validated and reliability was established. The data was collected by self-administer questionnaire and 5 points opinionnaire attitude scale method. The collected data tabulated and analyzed. Descriptive and inferential statistics were used. The study shows that most of Antenatal mothers 28 (56%) had inadequate knowledge, 21 (42%) had moderate knowledge and only 1 (2%) mother had adequate knowledge towards Caesarean section. In terms of attitude of mothers 31 (62%) had moderately positive attitude, 17 (34%) mothers had positive attitude and 2 (4%) mothers had negative attitude towards Caesarean section. There is no significant association between knowledge, attitude towards Caesarean section with selected demographic variables and there is no correlation between knowledge and attitude of Antenatal mothers towards Caesarean section.

Keywords: Knowledge, attitude, Caesarean section.

Introduction

In developed countries, women often opt for cesarean delivery because of their improved understanding of its role and safety and increasing importance given to the right to self-decision making regarding mode of delivery. However in developing countries, women are reluctant
to accept cesarean delivery because of their traditional beliefs and socio-cultural norms. Hence they try to avoid hospital delivery and engage in the services of untrained and unskilled care providers. These women usually report to hospital with life threatening complications and in such situations most of the cesareans are performed as an emergency procedure under suboptimal circumstances. Main reason of choosing cesarean section by pregnant women is fear and lack of sufficient knowledge about normal vaginal delivery. Although in specific situations cesarean section can prevent serious morbidity and mortality of the fetus and mother, data indicates that in many cases the procedure is not indicated and vaginal delivery could have been achieved safely

The CS rate varies worldwide, from country to country and within a country. The National CS rate of Great Britain and America have been reported as 23.8% and 32.8% respectively, while 0.6% national CS rate was reported from Ethiopia. In Nigeria, CS rates ranging from 12.2% to 34.5% were reported in some tertiary health facilities and in recent times the CS rates globally have been on the rise.

Materials and Method

Research Approach: A quantitative approach was selected for the study.

Research Design: Research design is blue print for conducting a study maximizes control over factors that could interfere with the validity of the finding. Non-experimental – Descriptive design found to be the appropriate design for the study.

Research Setting: The study was conducted at OG OPD, Antenatal ward, Labour Room in Chettinad Hospital & Research Institute at Kelambakkam, Kanchipuram District, Tamilnadu, India.

Population

Target Population: The entire group of people or objects to which the researcher wishes to generalize the findings of a study.

Sample: A subset of the population that is selected to represent the entire population.

The sample of the study were Primi Antenatal mothers in second and third trimester in OG OPD, Antenatal ward, labour room in Chettinad Hospital & Research Institute at Kelambakkam, Kanchipuram District, Tamilnadu.

Sample Size: Sample size for the present study was 50 Primi Antenatal mothers who are satisfied the inclusion criteria.

Sampling Technique: Sampling is the process of selecting a representative part of the population. Convenience sampling technique was adopted for the study.

Sampling Criteria

Inclusion Criteria: Inclusion criteria are characteristics that the subjects must have if they want to be included in the study. The inclusion criteria were:

- Primi Antenatal mothers who are in 2nd and 3rd trimester from 13 to 38 weeks.
- Who visit Antenatal OPD
- Admitted in Antenatal ward
- Who were willing to participate

Exclusion Criteria: Antenatal mothers who had previous Caesarean section

- Who did not understand Tamil
- Who are in labour

Selection and Development of Study Instruments:
Self-administered questionnaire will be used to collect data regarding demographic variables and knowledge towards Cesarean section

Opinionnaire will be used to collect data regarding attitude towards Cesarean section

- Part A: Demographic variables
- Part B: Self-administered questionnaire for knowledge assessment.
- Part C: Opinionnaire

Scoring and Interpretations

- The knowledge questions were 15.
- The attitude questions were 15.
- Each correct question will be given 1 mark.
Data Collection Procedure: After getting permission questionnaire were given to the Antenatal mothers to assess the knowledge and opinionnaire scale to assess the attitude. They read the questionnaire carefully and took 15 mins time to fill the questionnaire and attitude scale.

Duration of Data Collection was 2 weeks.

Plan for Data Analysis: The descriptive statistics are the percentage, co-relation & co-efficient and the Inferential statistics is chi square test was used to analyze the data.

Results and Discussion

The Discussion is Presented as Follows

- Frequency and percentage distribution of demographic variables of Antenatal mothers.
- Frequency and percentage distribution of knowledge and attitude among Antenatal mothers towards Caesarean section.
- Association between knowledge towards Caesarean section and selected demographic variables.
- Association between attitude towards Caesarean section and selected demographic variables.
- Co-relation between knowledge and attitude towards Caesarean section.

- Regarding to occupation majority 27(54%) of Antenatal mothers were unemployed whereas minority 3 (6%) mothers were Government employees.
- Regarding to monthly family income majority 29(58%) of Antenatal mothers were under above poverty line whereas minority 21(42%) were below poverty line.

1. Frequency and percentage distribution of demographic variables of Antenatal mothers:

- Regarding to age group, majority 44 (88%) of Antenatal mothers were at the age group (20-30) whereas minority 6(12%) at the age group of (31-40).
- Regarding to Gestational age, majority 30 (60%) of Antenatal mothers were including (29-38) weeks whereas minority 20 (40%) were (20-28) weeks.
- Regarding to educational status majority 28 (56%) of Antenatal mothers were undergraduates, whereas minority 3 (6%) were illiterates.
- Regarding to occupation majority 27(54%) of Antenatal mothers were unemployed whereas minority 3(6%) mothers were Government employees.
- Regarding to monthly family income majority 29(58%) of Antenatal mothers were under above poverty line whereas minority 21(42%) were below poverty line.

2. Frequency and percentage distribution of knowledge and attitude among Antenatal mothers towards Caesarean section:

</table>

In terms of attitude of mothers 31(62%) had moderately positive attitude, 17(34%) mothers had positive attitude and 2(4%) mothers had negative attitude towards Caesarean section.

3. Association between knowledge and selected demographic variables: The chi-square value shows that there is no significant association between knowledge with selected demographic variables like age, gestational age, education, occupation and family income.

4. Association between attitude and selected demographic variables: The chi-square value shows that there is no significant association between attitude with selected demographic variables like age, gestational age, education, occupation and family income.

5. Co-relation between knowledge and attitude: The co-relation co-efficient result shows that there is no co-relation between knowledge and attitude of Antenatal mothers towards Caesarean section.

Conclusion

As our study state that antenatal mothers had inadequate knowledge on Caesarean section and had moderately positive attitude towards Caesarean section. So researchers in order to create awareness on Caesarean section, were given health talk about Caesarean section.

The Issues Affecting the Correct Practice of Healthcare Waste Management in Lae’s Angau Memorial General Hospital

Keven Gaitu, Kamalakanta Muduli, Harrison Apana, Satyabrata Aich, John Pumwa

Abstract

Healthcare Waste Management (HCWM) is a vital issue not only to hospitals, but also to the environment, law enforcement agency, and the general public. It is one of the biggest challenges of the present day times since it has a direct impact on the health of the citizens, animals and the environment. Since it is hazardous in nature, its safe and proper disposal is extremely important. In the past, healthcare waste was often mixed with municipal solid waste and disposed of in residential waste landfills or improper treatment facilities (e.g. inadequately controlled incinerators). In recent years, many efforts have been made by environmental regulatory agencies to better manage the waste from healthcare facilities. This situation requires an organized system of healthcare waste management to curb public health risks as well as occupational hazards among healthcare workers as a result of poor in waste management. This paper presents an overview of the current management practices of healthcare waste in Angau Memorial General Hospital (AMGH) in Lae city, Morobe, Papua New Guinea (PNG). Data were collected via surveys, interviews, and on-site observations. Information regarding generation, segregation, transportation, and disposal of healthcare wastes is provided and discussed. The study showed that the hospital does not have a proper policy and plan in place for managing medical waste as well as an inadequate practice of handling healthcare waste from generation to disposal.

Keywords: AMGH, HCWM, Papua New Guinea (PNG), Healthcare Facilities (HCF).

Introduction

A developing country like PNG is struggling in recent years solely to meet the medical needs of its people. Much of the country’s citizens are rurally situated with inadequate supply of medical resources. Many of the HCF in the country which are government-operated are old, run-downed and are limited in resources. Due to this fact, most of these HCFs only focus on the primary objective of delivering medical supplies and to restore good health to the sick and injured. In doing so, these HCF overlook some of the medically sensitive issues like the practice of proper Healthcare Wastes management within their facility.

Healthcare Wastes means any solid, fluid, or liquid waste including its containers and any intermediate product which is generated during the diagnosis, treatment, or immunization of human beings or animals or in research activities that are considered harmful and infectious. Healthcare waste (HCW) collection and proper disposal has become a significant concern for both the medical and general community. Inadequate and inappropriate knowledge of handling of healthcare waste in the case country may have serious health consequences and a significant impact on the public health.
environment as well. However, lack of awareness has led to the hospitals becoming a hub of spreading diseases rather than working toward eradicating them.

Despite the efforts for the management of wastes, the current system of healthcare waste management in Lae’s AMGH is seen to be inadequate and risky. There is less consideration given to the final handlers of the waste by the segregation or sanitary officers. Therefore, there is a dire need of immediate attention and improvement and to develop a national policy and implement a comprehensive action plan for HCWM providing environmentally sound technological measures to improve HCWM in PNG.

The overall aim of the research is to

- Study the healthcare waste management situation in the case hospital.
- Suggest recommendations and policy implications.

Review of Healthcare facility and HCWM in Papua New Guinea: Healthcare in PNG is mainly provided by government and church health facilities, funded by a mix of government tax revenues, out-of-pocket payments and donor funds. In 2013, according to WHO, PNG spent 4.5% of its GDP on health services with approximately 20% of this coming from donors such as Australia and in the preceding year, launched a free primary healthcare program eliminating all user fees from medical centers and clinics. PNG has minimum number of healthcare physicians, with just 1 doctor per 17,068 of the population with these doctors poorly distributed geographically. Although 85% of the population live in rural areas, majority of doctors work at the national specialist hospital or nearby regional public hospitals, with just 51 physicians working outside the capital Port Moresby.

Healthcare waste is one of the major environmental health concerns for many hospitals and clinics both in rural and urban areas in PNG. A great majority of Lae’s hospitals and clinics lack proper health care waste management practices and many have gone slack in upholding the policies and regulations from the government. The present method of healthcare waste management are potentially hazardous and pose health risk to hospital workers, hospital sanitation workers, the general public, solid waste handlers and the environment. The city of Lae serves as a hub for many neighboring provinces because of its welcoming climate and the fact that it is an industrial city. For that, there is a high chance of viral, bacterial and protozoan infections to be contracted. Hence there is a great urgency to ensure effective management of biomedical waste to contain the spreading of contagious diseases.

Methodology

Study Area: Lae is the capital of Morobe Province and is the second-largest city in Papua New Guinea. It is located near the delta of the Markham River and at the start of the Highlands Highway, which is the main land transport corridor between the Highlands region and the coast. Lae is the largest cargo port of the country and is the industrial hub of Papua New Guinea.

Selected General Hospital in Lae: AMGH: Angau Memorial General Hospital is located in the central Lae area next to the old Lae Airfield. It is biggest and the main referral hospital for the general Morobe Province, as well as the other provinces connected by road link. It contains the only Radiotherapy facility in the country and thus serves as the main referral center for cancer patients. The hospital was developed to serve the people of Lae and Morobe Province and was constructed in the early 1960s and officially opened on April 17, 1964. It was named in memory of the Australia New Guinea Administrative Unit (ANGAU) whose members distinguished themselves during the Second World War in Lae and its surrounding areas.

Survey: The survey was conducted using a prepared questionnaire and all wards with all the staff (doctors, nurses, sanitary officers, and medical administrators) were involved in providing vital information. Questionnaire and field observation check list were prepared from WHO recommendation assessment tool and were used to describe the healthcare waste management practices of HCWs in healthcare facilities.

Healthcare waste is one of the major environmental health concerns for many hospitals and clinics both in rural and urban areas in PNG. A great majority of Lae’s hospitals and clinics lack proper health care waste management practices and many have gone slack in upholding the policies and regulations from the government. The present method of healthcare waste management are potentially hazardous and pose health risk to hospital workers, hospital sanitation workers, the general public, solid waste handlers and the environment. The city of Lae serves as a hub for many neighboring provinces because of its welcoming climate and the fact that it is an industrial city. For that, there is a high chance of viral, bacterial and protozoan infections to be contracted. Hence there is a great urgency to ensure effective management of biomedical waste to contain the spreading of contagious diseases.
The questionnaire used in this research contained 113 straight-forward questions requiring Yes/No and closed-end responses. They are arranged in categories of the respondent’s knowledge, attitude and practices, the awareness and the assessment of factors affecting HCWM Practices in healthcare waste management. From the filled-out questionnaires, significant results based on issues that affect HCWM will be discussed.

**Analysis of Survey Results:** The case hospital has 33 wards that include medical, surgical, labour, paediatric, psychiatric, cancer and the rest all produce medical and general wastes. The Cancer wards produce about 2 bags/day from the 10 beds available in the cancer treatment room i.e. one bag is the average size of a garbage plastic. Medical and surgical wards with 27 beds each produced waste depending on the illness and the types of medical condition of the patients. On average, the hospital produces about 5kg-7kg of waste daily. Measurement of waste was taken with respect to time, where the very ill patients were treated 3 to 6 hours in one day whereas ill patients were treated for 2 to 3 hours. In turn, the waste generated depended upon the sickness of patient in both the medical and surgical wards. AMGH only has three color coding systems for segregation of waste where, orange is used for cytotoxic waste, yellow for all medical waste excluding cytotoxic waste and green is for general non-hazardous waste.

Identified Issues that affect the proper practice of Healthcare Waste Management in AMGH

**Lack of Proper Segregation Practice:** The hospital does not follow proper color-coding for biomedical waste that differentiates the type of waste and the proper packaging for certain waste; rather, they use brown boxes for sharps, black bags for all medical waste excluding cytotoxic waste which is put in a primary bin for temporary storage in the wards and when full they store them outside in bigger-rubbish bins ready to be taken away and yellow bags for cytotoxic waste. The third party waste handlers then bring the waste to the incineration area where segregation is done again and all medical wastes are incinerated except cytotoxic waste and the general waste including the cytotoxic waste is transported to the dump site where the cytotoxic waste is burnt there. The current incinerator is not capable to fully disintegrate the cytotoxic waste.

![Figure 1: Waste Storage Practice.](image1)

Brown boxes used to store used sharps like injections

Black plastic bag in the primary storage inside the ward that is used to house all medical wastes except cytotoxic waste

![Figure 2: General and Medical Waste Storage Practice.](image2)

Green rubbish bin for general waste

Yellow rubbish bin for medical waste
No Proper Storage for the Medical Waste and General Waste before disposal: The medical waste including general waste is stored outside the incineration area where final segregation is done before incineration or disposal at the dump yard is carried out.

![Figure 3: Current improper storage area.](image)

![Figure 4: No proper storage of Wastes.](image)

Old, Unhygienic and a Potential High Risk Incinerator & a New but Disfunctional Incinerator: The Hospital currently has two incinerators out of which the new incinerator is problematic and disfunctional; therefore, the old incinerator is used to incinerate the medical wastes. Due to the inefficiency of the old incinerator to completely and effectively destroy the contents of the cytotoxic waste, the cytotoxic waste is not incinerated on-site.

![Figure 5: The Old Incinerators.](image)
Respondents Perception towards the Knowledge, Attitude and Practices of HCWM: Survey results based on the knowledge assessment, revealed that 63% of the respondents were not aware of any legislation applicable to hospital waste management whilst 19% were aware of it and 18% were not sure. These results imply that, healthcare workers practice hospital waste management without government regulated legislations or standards in place for proper healthcare waste management. Similarly, responses to questions based on attitude assessment, indicate that 63% of respondents believe that the proper management of BM waste is the sole responsibility of the government whilst the other 31% argued that BM waste was not the sole responsibility of the government. Similar results were found whereby 50% agreed that safe management efforts by hospital increases financial burden on management and safe management of biomedical waste is an extra burden on work. These results imply a general conclusion that about half the population of healthcare workers take HCWM as a personal responsibility. Responses on questions based on practices assessment, revealed that 68.7% do not maintain a register for waste disposal implying that majority of healthcare workers are not aware of a register in place for waste disposal. Furthermore, 81.2% said that they have not undergone any training program on hospital waste management and 75% said that the hospital does not provide annual education on waste management. This implies that, most healthcare workers are on not well-educated on HCWM. The results also show that, 56.3% of respondents admit that neither all waste containers are properly labelled with type of dangerous waste nor accumulation start date whilst 31.3% admit existence of proper labelling system. This would imply that, maybe some wards or sections might have or not have properly labelling. 25% said that staff who handle hazardous waste do not receive training while 43.8% said that the staff receive training. This implies that, maybe selected or specified healthcare personnel undergo or have undergone some form of HCWM training. 56.3% said that their department do not keep record of the amounts of dangerous waste generated per month while 25% said that they kept records while the other 18.7% were not sure. This implies that the waste management plan probably does not include keeping records of dangerous wastes per month or whether 25% of respondents were part of departments that kept records of monthly generation of dangerous waste.

Recommendations: The staff and waste handlers in each hospital should be well trained at the beginning of their work at hospitals and clinics, and regularly updated with pre-employment and in-house specialized training, which should provide them with a knowledge base about the process of healthcare waste management and associated health risks.

The Authorities or the Ministry of Health should put laws and regulations related to healthcare waste management within healthcare establishments. The Ministry of Health should also coordinate with the Local Level Government (LLG) and the Environmental Quality Authority to devise a mechanism for monitoring healthcare waste management outside healthcare establishments.

It should be obligatory for each healthcare facility to ensure a safe and hygienic system of medical waste handling, segregation, collection, transportation, storage, treatment and disposal, with minimal risk to handlers, public health and the environment through coordination between the respective persons in the Waste and Infection Control management according to their responsibilities.

Improve the current colour-coding practice. If more available colour-coded bins representing different medical waste categories are available in every wards, it will speed up the process of segregation. It will be less tedious for the sanitary officers to do further separation and it will minimize the wastes’ storage time or time of exposure to the environment, animals, and human beings. This will greatly reduce the risk of contracting any infectious diseases.

Posters with labelled pictorial diagrams should be made available in wards and public grounds of hospitals and clinics to provide awareness and direction on the types of waste and how they should be disposed. This is important as most of the users of these healthcare facilities come from rural areas and many are illiterate. These pictorial depictions will assist greatly in segregation and the waste handlers will go through less problem in doing separation.

Environmentally sustainable technological options for treating waste, which can be well operated and maintained, should be considered for healthcare waste management.
Conclusion

The overall findings of this study indicated that the majority of HCWs did not apply the recommended healthcare waste management practice set by WHO. Furthermore, the current healthcare waste management practice in the studied health facility was managed improperly and can pose a risk for human health and the environment. All medical wastes in all wards are disposed into a single bin which are later separated by sanitary officers after collection. The problem with this is that the wastes may not be separated well according to their risk sensitivity and the workers could get infected easily. Although there is segregation practice in place, there is still risk involved in handling wastes especially to the workers who are at the tail-end of the waste management; those who come into direct contact with the wastes before they get disposed or incinerated. Also, inadequate supply of color coded containers, lack of guideline for healthcare waste management, and low commitment of HCWs were observed. Moreover, knowledge on healthcare waste type, knowledge on diseases transmitted with contact of infectious wastes, training and availability of guideline documents were significantly associated with healthcare waste management practices of HCWs.

Achondroplasia: A Case Report

Kavitaa Nedunchezhian¹, Nalini Aswath²

¹Consultant Oral Physician and Maxillofacial Radiologist, Private Practice, Chennai, India,
²Professor and Head of Department, Dept. of Oral Medicine & Radiology, Sree Balaji Dental College & Hospital

Abstract

Achondroplasia, most frequent form of dwarfism, is of special interest in the field of dentistry because of its craniofacial characteristics that includes relative macrocephaly, frontal prominence depressed nasal bridge, maxillary hypoplasia and dental malocclusion. The present paper reports a case of 30 years old male achondroplastic patient with review of the literature.

Keywords: Dwarfism, Cartilage, Gene mutation, FGFR3 and orofacial manifestation.

Introduction

Chondrodystrophias fetalis, known as achondroplasia, is a non-lethal form of chondrodysplasia. Most frequent form of short–limb dwarfism, transmitted as autosomal dominant trait with complete penetrance due to mutation in the fibroblast growth factor receptor-3 gene (FGFR3), mapped to band 4p16.3.¹,² Characterized by intrinsic disturbances in bone formation and modelling, causing disproportionate short stature affecting long bones of the body owing to defect in intra-cartilaginous ossification.

Estimated prevalence is one in 15000-40000 cases worldwide. Approximately, 80 % cases are de novo dominant mutations. It occurs as a result of mutation in one copy of the FGFR3. More than 97 % of patients have same point mutation. Common mutation causes gain of function of FGFR3 gene, resulting in decreased endochondral ossification, inhibited proliferation of chondrocytes in growth plate cartilage, decreased cellular hypertrophy and decreased cartilage matrix production with varied manifestations.³

Thoracic kyphosis (infants) gradually resolves and is replaced by a lordotic lumbar spine in adults, prominent buttocks, protuberant abdomen, rhizomelic shortening of limbs, trident hand and limitation of elbow extension. Hypotonia of limbs with delayed motor development in children usually improves and disappears in childhood. 10% of children show significant bowing of tibiae and 6% of affected children develop hydrocephalus. Cervicomedullary compression, a rare complication can occur with episodes of apnoea. In the adolescent and adult, compression of nerve roots in spinal canal may be present with numbness or weakness in legs. Recurrent middle ear infections is a common problem with a risk of conductive hearing loss.⁴ Radiological features include small cuboid vertebral bodies with progressive narrowing of the caudal interpedicular distance, lumbar lordosis, and thoracolumbar kyphosis with occasional anterior beaking of the 1st and 2nd lumbar vertebrae, small iliac wings with a narrow greater sciatic notch and short tubular bones with metaphyseal flare and cupping.⁵ Craniofacial features include enlarged calvarium with hydrocephaly, brachycephaly, midfacial hypoplasia, depressed nasal bridge, forehead prominence and dental malocclusions.

Case History: A 30 year male dwarf reported with chief complaint of stains and deposits in teeth. His paternal grandmother suffered from dwarfism. Other family members were healthy. Patient was 3 feet and 9 inches tall, weighed 43 kilograms, well built, nourished, calm, cooperative, conscious, well oriented to time and place with waddling gait. Vital parameters were normal. Lumbar lordosis, limitation of lumbar extension,
shortened limbs, trident hands, prominent buttocks and protuberant abdomen were observed. (Figure 1(a))

Extra oral examination revealed brachycephalic craniometric dimension, hypoplastic maxilla, mild hypertelorism, depressed nasal bridge and incompetent lips. (Figure 1(b))

Intra-oral examination of hard tissue revealed dental caries in 37, 47, partially edentulous area in 16, 26, attrition in 46, generalized grade (++), stains & calculus, anterior open bite, proclined maxillary anteriors, crowding in mandibular anteriors, posterior cross bite, high-narrow ‘V’ shaped maxillary arch and narrow mandibular arch. (Figure 1(c))

Complete blood count, serum alkaline phosphatase, serum calcium and serum phosphorous were within normal limits. Posteroanterior (PA) view of skull revealed widened calvaria, suggestive of brachycephalic skull. Lateral cephalogram showed presence of hypoplastic maxilla, mild mandibular proclination, anterior open bite, underdeveloped posterior nasal spine and nasal bone. Orthopantomogram (OPG) revealed restored 36, partially edentulous area in 16 and 26, narrow maxillary arch and increased vertical height of the body of the mandible with prominent antegonial notching. (Figure 2)
Hand Wrist Radiographs (right & left) (Figure 3a) showed evidence of trident shaped hands. Antero-posterior and lateral views of long bones revealed shortening and thickened radius and ulna in both forearms (Figure 3b). Shortening of humerus with prominent metaphysis (Figure 3c), gross shortening of both femurs with prominent metaphysis (Figure 3d) and shortening of tibia with long fibula and prominent metaphysis (Figure 3e).

Figure 3: Radiographic images of long bones

Discussion

Achondroplasia, the most prevalent form of dwarfism in humans and the prototype of human chondrodysplasias.\textsuperscript{6,7} It is a defect in the maturation of the cartilage growth plate of long bones. Achondroplasia has currently been shown to result from a Gly to Arg substitution in the transmembrane domain of the fibroblast growth factor receptor 3 (FGFR3).

Achondroplasia is non-lethal with normal life span and intelligence quotient. In heterozygous state, patients are at risk of cervicomedullary compression, spinal stenosis, obesity, obstructive sleep apnoea. Whereas homozygous state, is lethal in the early stages of life due to severe rib cage deformity causing respiratory insufficiency.\textsuperscript{3} Sobetzko et al. (2000) reported achondroplasia in a brother and sister with unaffected parents.\textsuperscript{8} The siblings shared the classic 1138G-A mutation (134934.0001) and a 4p haplotype derived from the unaffected father. In the present case, patient’s paternal grandmother suffered dwarfism and no other family member was affected. Achondroplastics are short at birth and show stunted growth; average maximum height of women is 126 cm and of men is 131 cm. The limbs are relatively shorter than trunk with upper arm and thigh shortened. Head is usually large with prominent forehead and flat nasal bridge. The hands and feet are small and wide with short fingers and toes.

Dental development can be delayed in achondroplastic children due to altered bone growth. Stafne (1950) reported oligodontia in permanent teeth of a 30 year old affected male.\textsuperscript{9} In the present case oligodontia was not observed. Orofacial manifestations including skeletal and dental class III malocclusion, narrow maxilla, macroglossia and open bite between the posterior teeth have been reported previously.\textsuperscript{10} Clinical and radiological examination of present case revealed presence of periodontal disease, posterior cross bite, high cum narrow maxillary arch, narrow mandibular arch, hypoplastic maxilla, mild mandibular proclination and crowding, anterior open bite, underdeveloped
posterior nasal spine and nasal bone. The present case did not suffer from any kind of hearing deficiency which has been commonly reported.  

To avoid respiratory complications, mandatory precautions in head control is essential during dental intervention, due to the possible presence of cranio-cervical instability, foramen magnum stenosis and limited neck extension.

Most achondroplastics cope up extraordinarily well with their physical difficulties and lead successful lives. With psychological support, specific medical and dental management they can lead a normal life in the society.

Protocol for Review of “Efficiency of Probiotics”

Kavitha Ramanathan¹, Nalini Sirala Jagadeesh², Usha Vishwanath³, Celina D.⁴

¹Ph.D. Scholar (Full-time), Sri Ramachandra Institute of Higher Education & Research, (Deemed to be University), No. 1, Ramachandra Nagar, Porur, Chennai, ²Professor & Principal, Faculty of Nursing, Sri Ramachandra Institute of Higher Education & Research, (Deemed to be University), ³Professor of Obstetrics and Gynaecology Department, Sri Ramachandra Institute of Higher Education & Research, (Deemed to be University), ⁴Professor & Vice-Principal, Omayal Achi College of Nursing, Puzhal, Thiruvallur, Chennai

Abstract

Introduction: According to World Health Organization, “Gestational Diabetes Mellitus (GDM) is defined as any degree of glucose intolerance with onset or first recognized during pregnancy”. The goal of this review is to determine the efficiency of probiotics on maternal blood glucose level among patients with gestational diabetes mellitus and to analyse its effects on glycaemic control.

Method: This review will include only randomized controlled trials that are in English, published between the year 2008 to 2018. The data will be collected from the following electronic databases: namely Google Scholar, Pubmed and Cochrane. Data will be collected using some of the following medical subheading (MeSH) terms as search string: #probiotics (mesh terms)#, #probiotics# [All Fields] OR #Lactobacillus# OR #Bifidibacterium#, #Glycaemic control#, #Effects#, # gestational diabetes mellitus#, #fasting blood glucose level#, #insulin level#.

Discussion: The studies identified will be reviewed and assessed for its relevancy and quality based on the Joanna Briggs Institute (JBI) guidelines by two independent reviewers. JBI data extraction form for experimental studies from JBI Reviewer’s Manual will be used to extract the quantitative data from the included studies. Narrative analysis, qualitative synthesis and meta-analysis will be used to report the findings of the review.

Keywords: Gestational diabetes mellitus, GDM, probiotics, lactobacillus, Bifidobacterium, fasting blood glucose level, insulin.

Introduction

According to World Health Organization, “Gestational Diabetes Mellitus (GDM) is defined as any degree of glucose intolerance with onset or first recognized during pregnancy”.(1) Its prevalence varies from 2% to 22% of all pregnancies as different criteria for diagnosis is in use. The prevalence of GDM is increasing in India, and differs from area to area and socio-economic status. There are many studies reporting higher incidences of maternal and neonatal complications due to obesity, increased maternal age and hyperglycaemia resulting from GDM.(2)

Studies conducted in southern part of India shows higher burden of gestational diabetes than in the northern states.⁽³⁽⁴⁾⁽⁵⁾ This type of regional differences with regards to prevalence of GDM correlates with type 2 diabetes mellitus. The risk for development of type 2 diabetes is higher among women with gestation diabetes mellitus.(6)

A study conducted in Kerala concluded that the foremost feto-maternal outcomes of gestational diabetes are progression to type 2 diabetes, macrosomia and higher rate of in born nursery admissions for the newborns. These findings seemed to be deemed important to the existing health environment of the state where the burden

Corresponding Author:
Mrs. Kavitha Ramanathan
Ph.D. Scholar (Full-time), Sri Ramachandra Institute of Higher Education & Research, (Deemed to be University), No. 1, Ramachandra Nagar
of gestational diabetes is increasing seamlessly and increase further in the near future. Precautious attention needs to be given to identify therapeutic measures to confront the challenges of gestational diabetes. Creating awareness to achieve good glycemic control during pregnancy must be given to these women to prevent progression to type 2 diabetes. The Government should widely take up the responsibility in improving the maternal and neonatal care facilities of the state to manage the maternal neonatal outcomes of gestational diabetes. 

Recent true experiment studies shows evidences of influence of numerous interventions in preventing the progression to Type 2 diabetes in women with a history of GDM. Few studies highlight that lifestyle modifications and pharmacological therapies have been shown to reduce diabetes development by 50% or more. (8-10) Generally, the treatment includes diet with or without medication. (11) However, due to methodological heterogeneity and smaller sample sizes, comparability was complicated in these trials. Apart from these methodological limitations there were also considerable barriers to expectant women that engaged in rigorous lifestyle intervention programs. (12)

Presently, gut microbiome function on metabolic and inflammatory process is being investigated. Thus gut microbiome is amalgamated with bacterial species present in the gut. (11) Probiotics are commonly identified as good bacteria that are generally taken as capsules or drinks to complement the gut bacteria. (12) An expert panel commissioned by FAO and WHO defined probiotics as “Live microorganisms which when administered in adequate amounts confer a health benefit on the host”. (13) For long-run these probiotics has been investigated for its role on various infectious or non-infectious conditions. The potential benefits of probiotics has been evaluated for their efficiency in prevention of gestational diabetes mellitus and its effect on type 2 diabetes mellitus. It is determined to affect the user’s metabolic health. An emerging novel theory advocates that gut microbiota have a role in the maintenance of energy homeostasis and causing metabolic diseases and insulin resistance. Though many studies are demonstrating that probiotics as encouraging in prevention of GDM, the evidence for use of probiotics among those diagnosed with GDM is largely limited. (12)

This review will help me to gather that research systematically consolidating the evidences on therapeutic use of probiotics on blood glucose control on gestational diabetes mellitus. Thus, this review of evidence synthesis will further help to understand the potential benefits of probiotics on GDM and guide to identify the evidence gap with regards to health benefits. This systematic review will help me to disseminate the evidences that is build upon to the existing health care system pertaining to role of probiotics on glycemic control.

**Review question/objective:**

The objectives of this review are to:

1. Review the efficiency of probiotics supplementation on maternal blood glucose level among patients with gestational diabetes mellitus.
2. Appraise the efficiency of probiotics supplementation on other maternal outcomes among mothers with gestational diabetes mellitus.

**Method**

Systematic reviews are usually build on a protocol that delineates the rationale, hypothesis, and planned method of the review. Only few reviews report whether a protocol exists or not. A detailed, well-described protocols will facilitate good understanding of the review method. (16) The Preferred Reporting Items for Systematic reviews and Meta-Analyses for Protocols 2015 (PRISMA-P 2015) was used for developing the protocol for the present review. This protocol is presently registered with PROSPERO International Prospective register for systematic reviews (CRD 42018110754).

**Inclusion criteria:** The studies that fulfill the following eligibility criteria will be included in this review:

1. Study design: Under Quantitative studies, only randomized controlled trials will be included.
2. Population: studies that was conducted among women with gestational diabetes mellitus will be included
3. Intervention: study that involves supplementation of probiotics in th form of capsule / health drink to the intervention group as main variable.
4. Outcomes: Studies that measure blood glucose level as a primary or secondary outcome.
5. Studies that are available in electronic databases.
6. Trials that are published in peer reviewed journals.
7. Trials that are available in English language.
8. Studies published in the period from 2008-2018

**Exclusion criteria:**
1. Studies that do not include blood glucose levels as measuring outcome will be excluded.
2. Studies in books, journals, conference proceedings, unpublished data are excluded.

**Types of participants:** This review will include those randomized controlled trials that was conducted among women who were diagnosed with gestational mellitus as study participants.

**Types of intervention(s)/phenomena of interest:**
The quantitative studies that evaluate the effects of probiotics species supplementation as capsules, or food product with a placebo as a comparator will be reviewed to determine the evidences with regards to potential benefits of probiotics species on glycaemic control among GDM mothers.

**Types of outcomes:** This review will consider studies that include the following outcome measures:
1. Fasting plasma glucose levels
2. Post prandial blood glucose level
3. Insulin levels.
4. HbA1C

**Types of studies:** This review will consider studies that focus on quantitative data, but limited to, design such as randomized controlled trial.

**Search strategy:** A search strategy will be developed and utilized to identify the relevant studies. The electronic databases namely Google Scholar, Pubmed and Cochrane will be our search database for the eligible studies that were published between the year 2011 to 2018.

**Initial keywords to be used will be:** #probiotics (mesh terms)#, #probiotics# OR #Lactobacillus# OR #Bifidobacterium#, #Glycaemic control#, #Effects#, #gestational diabetes mellitus#, #fasting blood glucose level#, #insulin level#.

**Screening:** Based on the above search strategy, the studies will be searched and analysed for its relevancy. The first step is to examine the titles of the study for its appropriateness to include into the review. All identified titles will be screened for its relevancy and uploaded into the Mendeley software to examine for the duplicates. After the removal of duplicates, abstracts of relevant titles will be retrieved. The retrieved abstracts will be screened by the two reviewers by cross checking with the pre-established criteria. Subsequent to this, full-text screening of the relevant abstracts will be done by the two reviewers. This process of screening will be done by reviewers independently. During this process of screening, if any disagreements arise will be resolved by discussion and if necessary in consultation with the third reviewer.

**Assessment of methodological quality:** The screened studies will be assessed for its quality objectively. Because the aim of this review is to consolidate evidences from studies that are possessing high quality. So, such a quality assessment will be done by two independent reviewers prior to its inclusion into the review. All studies that will be included for the review are assessed whether it fulfills characteristics of true experimental design or randomized controlled trials. The other assessment criteria that were used to assess its methodological quality are, randomization, concealment of allocation, blinding of study participants and blinding of outcome data. Any discrepancies that may arise during methodological validity will be resolved through discussion to reach a consensus or with a third reviewer.

**Data collection:** Joanna Briggs Institute (JBI) data extraction form for experimental studies from JBI Reviewer’s Manual (15) was used to extract the quantitative data from the included studies. This is a standardized data extraction tool from JBI-MAStARI. This data extraction will include those details of the screened studies for review pertaining to Author of the study or trial, year of publication, Journal, Study interventions, populations of the study, method, study setting, population size, Authors’ conclusion, Reviewers’ comments an study results that are significant to the review specific objectives.

**Data synthesis:** Narrative analysis, qualitative synthesis and meta-analysis will be used to report the findings of the review. The findings of the studies will be pooled under the review objectives as ordered in the review protocol. A narrative analysis will be carried and will be presented in a tabular form following each review questions/objectives. Since meta analysis is not our objective, this data synthesis will not be merging the statistical findings of the review studies.
Discussion

Thus, worldwide there is a provocative emerging concept in the use of probiotics supplements by supplementing the human gut microbiota to alter or prevent a range of communicable and non-communicable diseases. Thus these probiotics when given during pregnancy and breastfeeding offer a unique opportunity to impact a range of important maternal and neonatal outcomes.(16)

Mental Health Status among Patients with Breast Cancer Attending a Tertiary Care Cancer Hospital in Mysuru, Karnataka, India

Prakash B.¹, Krishnaveni Y.S.², Narayanamurthy M.R.³

¹Professor, ²Post Graduate, ³Professor and Head, Department of Community Medicine, JSS Medical College

Abstract

Introduction: Diagnosis of breast cancer by itself is a distressing event for women. The Negative emotions often makes them neglect their food intake, healthy physical and social activities. Fear of uncontrolled pain, death, family and loved ones after death leads to symptoms of anxiety. This needs to be addressed for which assessment of depression and anxiety among them is needed.

Methodology: Across-sectional study conducted among 210 women suffering from breast cancer since 6 months. Validated questionnaire Patient Health Questionnaire 9(PHQ9) and General Anxiety Disorder 7(GAD 7) questionnaires were used to assess depression and anxiety among patients respectively. Association of these symptoms with socioeconomic factors and quality of life was assessed using inferential statistics chi-square and one way ANOVAs. P value of less than 0.05 is considered as significant.

Results: Among 210 Breast cancer patients, 121(57.6%) women had depression and Anxiety was seen among 186(88.5%) of participants. Severe depression was seen more in Stage IV and women diagnosed more than 3 years back. Fatigue and Breast specific side effects were associated with depression. Nausea & vomiting, Pain, Dyspnea, Loss of Appetite and Insomnia are more in women with severe Anxiety

Conclusion: A comprehensive therapy where multi-disciplinary approaches like clinical, psychological along with physiotherapy, social support, financial support, home based nursing care.

Keywords: Depression, Anxiety, Breast Cancer, Quality of Life.

Introduction

As per GLOBACON 2018 by International agency of Research on Cancer (IARC) cancer burden has raised to 18.1 million new cases and 9.6 million cancer deaths in 2018.¹ In India 2.5 million people are living with cancer. Cancers of oral cavity and lungs in males and cervix and breast in females account for over 50% of all cancer deaths in India.² Globally among women, Age standardized rate (ASR) of breast cancer is 46.3 with cumulative risk (birth to 74 Years) 5.03% and mortality ASR 13 with cumulative risk 1.41%. Breast cancer leads to 15.1 million DALYs (Disability Adjusted Life Years) in women.³ Diagnosis of breast cancer by itself is a distressing event for women. As they pass through the lengthy treatment process, they face new problems like turmoil in personal relationships, tiredness all the time, which make them worry about symptoms, treatment and mortality. Discrimination from relatives, neighbors and employees contribute to chronic stress, anxiety and depression.⁴ It is seen that mortality is 25% higher in women with depressive symptoms and 39% higher in women with co-existing major and minor depression.⁵,⁶ The Negative emotions often makes them neglect their food intake, healthy physical and social activities. This may also lead to lack of sleep and addiction of alcohol, caffeine, sedatives. Attitude like this affect their treatment adherence and compliance. As the treatment progresses, surgery and chemotherapy leads to hair loss

and physical disfigurement which is a challenge for a woman to face the society through her changed looks. Apart from this, difficulties in explaining their condition to their children, taking decisions about their health care, managing routine household works and controlling stress and anxiety may require external psychological support to cope with situation.

During treatment and recovery patients are fearful and anxious of diseases, treatment, doctor’s visits, tests. Fear of uncontrolled pain, death, family and loved ones after death leads to symptoms of anxiety, uncontrolled worry, trouble solving problems and focusing thoughts, muscle tension, trembling or shaking, restlessness, dry mouth, irritability or angry outbursts. If these symptoms are present most of the day, nearly every day and interfering with her life, a mental health evaluation is needed. This needs to be addressed for which assessment of depression and anxiety among them is needed. In this background the present study is conducted with the objectives to assess mental health status and the factors influencing it among Breast cancer patients.

Material and Methodology

A cross-sectional study was conducted among females with breast cancer from July 2017 to December 2017. From a purposive sampling, a total of 210 women, attending tertiary cancer care centre of Mysuru, aged more than 25 years and on any allopathic treatment for more than 6 months were included. Women with co-morbid conditions like Diabetes, Hypertension and those above 80 years were excluded. Validated questionnaire Patient Health Questionnaire 9 (PHQ-9) and General Anxiety Disorder 7 (GAD 7) questionnaires were used to assess depression and anxiety among patients respectively. Quality of life was also assessed using EORTC BR23 QLQ (breast specific European organization for Research and Treatment of Cancer). After obtaining institutional ethical clearance, Informed consent was taken from participants and clinical details regarding staging, treatment were collected from hospital records. Data was entered in Microsoft excel and analyzed by SPSS 23. Descriptive statistics like percentage and inferential statistics like chi-square tests used to analyze. A p value of less than 0.05 is considered as statistically significant

Findings: Among 210 Breast cancer patients, 121 (57.6%) women had depression and Anxiety was seen among 186 (88.5%) of participants. Depression was seen among 186 (88.5%) of participants with mild anxiety in 86 (41%) women, moderate anxiety in 83 (39.5%) and severe anxiety in 17 (8.1%) women. Severe depression was seen more in Stage IV followed by stage III, stage II. Mild and moderate depression was seen more in stage II and stage IV. Moderately severe depression was more in stage IV followed by Stage I. Severe depression was observed in women diagnosed more than 3 years back. Mild depression was noticed more in women diagnosed between 1 to 3 years. Mild depression was seen more in women on Chemotherapy. Women posted for surgery and those on supportive therapy had more moderately severe depression. Mean functional scores of QOL were poor in women with Depression compared to women with no depression. Depression was seen in women with lower emotional function scores and future perception scores. Among symptom scales Depression was associated with fatigue (OR 3.75, 95% CI 1.44-9.76, P 0.007), Breast specific side effects (OR 4.32, 95% CI 1.18-15.84, P 0.02) and Breast symptoms (OR 4.56, 95% CI 1.07-19.376, P 0.039). Anxiety is significantly more in women educated up to higher primary and puc/ diploma (χ² = 21.847, P < 0.001), women diagnosed of disease for less than 1 year (χ² = 19.22, P < 0.001) and those with good compliance (χ² = 8.029, p 0.01). It was seen that Nausea & vomiting, Pain, Dyspnea, Loss of Appetite and Insomnia are more in women with severe Anxiety. Fatigue is seen more in women with Mild and moderate anxiety. On binomial logistic regression anxiety was associated with upset due to hairloss (OR 0.22, 95% CI 0.06-0.79, P 0.02). Anxiety is less in women who are upset due to hair loss.

Discussion

Among 210 Breast cancer patients, 121 (57.6%) women had depression and Anxiety was seen among 186 (88.5%) of participants.

In a cross-sectional study done in Kerala by Debasweta Purkayastha et al, Depression is seen in 21.5% of breast cancer patients among whom moderately severe to severe depression is seen in 22%. And quality of life domains were negatively associated with depression. In a mixed –method exploration of quality of life among Chinese breast cancer survivors participants has unfavorable psychological well-being and they actively reconnected with their “self” to create a positive meaning from their cancer experience.
study among 100 patients from centre of Oncology in Bydgoszcz, after conservative surgery patients have higher average values for the mental strategies to cope with the disease and lower average in the strategy to cope up with anxiety. In present study though prevalence of depression was comparatively more, a similar association of depression with QOL was found. In present study Depression was seen more in women in stage IV, women who were diagnosed for more than 3 years and those receiving both chemotherapy and radiotherapy.

In a cohort study by Ganz et al, mental health scores declined significantly in the follow-up year. In a follow up study by Parker et al, mental health including depressive symptoms and psychosocial adjustment markedly improved by 2 years. Even in study by Inbar et al, higher levels of mental distress are seen in breast cancer survivors. In present study severe depression was seen in patients diagnosed for more than 3 years whereas mild and moderately severe depression were seen more in women diagnosed between 1 to 3 years of diagnosis than those diagnosed more than 3 years Depression was also associated with poor functional scores

Among the study of records from the 1996 to 2005 Ohio Cancer Incidence Surveillance System (OCISS) and Medicaid files, women with mental illness were less likely to be diagnosed with distant-stage cancer than those without mental illness. In present study severe depression was seen more in stage IV of breast cancer followed by stage I. Whereas mild and moderate anxiety were seen in stage II. Women diagnosed with cancer are more panic and depressed initially, as the majority of participants in the study were in stage I, depression is more seen in them.

In present study, Anxiety is significantly more in women educated up to higher primary and puc/ diploma, women diagnosed of disease for less than 1 year and those with good compliance. Anxiety was seen in women with higher functional scores than with low functional scores. Among symptom scales it was seen that Nausea & vomiting, Pain, Dyspnea, Loss of Appetite and Insomnia are more in women with severe Anxiety. Fatigue is seen more in women with Mild and moderate anxiety.

In a study done among Greek women with breast cancer, depression and anxiety are more in breast cancer women than healthy controls and women with high education level has lower anxiety. In cohort study done by konstantinos tsaras et al, Depression is seen in 38.2% and anxiety in 32.2%. Depression and anxiety are significantly seen more in rural residents, non orthodox Christians and women with high symptom burden. In a cross sectional study with explanatory sequential design by A Charalambous et al, 44% reports serious anxiety and is associated with social support. Anxiety scores are negatively co-related to quality of life scores.

Similar finding was seen in present study where women with postgraduate education had less anxiety. In present study anxiety was related only to Physical functions but among symptom scales, fatigue, nausea & vomiting, pain, dyspnea, Loss of appetite and insomnia were more in severe anxiety. But anxiety in women up set due to hair loss was less than others. This may be because of their coping with the situation. Women with anxiety experience more symptoms compared to those without anxiety.

### Conclusion

Advanced stage, duration of disease and multiple therapy had impact on depression and symptoms fatigue, nausea & vomiting, insomnia, pain dyspnea, loss of appetite were associated with anxiety. This calls for a comprehensive therapy where multi-disciplinary approaches like clinical, psychological along with physiotherapy, social support, financial support, home based nursing care.

Inter Arm Difference in the Blood Pressure and Pulse Rate in Young Adults

Deepika Madhira¹, Kumar Sai Sailesh², Ravikanth Manyam³, Sudhakara Reddy R⁴, Swathi Movva⁵

¹Second Year BDS Student, ²Assistant Professor & HOD (I/C), Department of Physiology, ³Professor, Department of Oral Pathology, ⁴Professor & Head, Department of Oral Medicine and Radiology, ⁵Lecturer, Department of Physiology, Vishnu Dental College, Bhimavaram, West Godavari District, Andhra Pradesh

Abstract

Introduction: There is small difference in the blood pressure in the right and left hands. If the difference is more, it indicates presence of heart diseases like congenital heart disease, aortic dissection, peripheral vascular disease, and unilateral neuromuscular abnormalities.

Aim and objectives: The present study was undertaken to observe the variation in the blood pressure variation in right and left arm in young adults.

Materials and Method: A total of 30 young adults including both males and females studying first year BDS were recruited for the study after obtaining the written informed consent. Blood pressure and pulse rate was recorded between 9-10 am in all the participants to avoid diurnal variations. JSB health care digital BP apparatus was used in the present study. All the participants are right handed individuals.

Results: Systolic blood pressure was lower in the left arm when compared with the right arm. However, the difference was not statistically significant. Diastolic blood pressure was lower in the left arm when compared with the right arm. However, the difference was not statistically significant. Pulse rate was lower in the left arm when compared with the right arm. However, the difference was not statistically significant.

Conclusion: Systolic, diastolic pressure and pulse rate was lower in the left arm but the difference was not significant. The study recommends need for further studies in this area to understand the variations in the blood pressure and its implications which help to develop effective diagnostic and management method for hypertension.

Keywords: Blood pressure, heart diseases, young adults.

Introduction

Blood pressure is the lateral pressure exerted on the walls of the blood vessels. It is routine and mandatory to observe the blood pressure in clinical examinations. As per the regulations of American Heart Association, blood pressure should be monitored in both the arms during first visit of the patient. There after blood pressure should be monitored only one side where higher pressure was recorded.[¹] Majority of studies where blood pressure recording was included as one of the parameter has either not specified the hand they recorded.[²] Some studies have recorded from right hand.[³] The Difference in the blood pressure of arms has an important role in the diagnosis of hypertension. It may delay to take up the steps to manage the hypertension. It is recommended to measure blood pressure in the arm where higher blood pressure is recorded. This difference is very important for the individuals applying for jobs in military or any industries. Measuring the blood pressure in both the arms is ideal as it helps to elucidate the obstructions of the blood vessels in the upper extremities. If there is
any obstruction in the aorta, there will be persistently higher difference in the inter arm difference. Though the inter arm difference is common and modest, it is associated with risk of cardiovascular diseases. Hence, it is very essential to increase the awareness in the public regarding importance of measuring the blood pressure and pulse rate in both the arms. Young adults is the age group who were not subjected to the measurement of blood pressure frequently. So the present study included this age group as any of these individuals were diagnosed with hypertension or pre-hypertension, the management can start at this age group so that severe effects of the hypertension may be prevented. The present study was undertaken to observe the variation in the blood pressure in right and left arm in young adults.

Materials and Method

Study design: Cross-sectional study

Study participants: A total of 30 young adults including both males and females studying first year BDS were recruited for the study after obtaining the written informed consent. Apparently healthy, right handed and willing participants were recruited for the study.

Study setting: The present study was conducted at Department of Physiology, Vishnu dental College, Bhimavaram.

Recording of blood pressure: Blood pressure and pulse rate was recorded using JSB fully automatic upper arm style blood pressure monitor (JSBDBP05 model). After entering the research lab in the Department of Physiology, the participants were allowed to relax for ten minutes and there after the blood pressure were recorded from right and left hands. The time gap between recording right and left arm blood pressure was 5 minutes. Three readings were obtained and the average value was recorded. Blood pressure was recorded at 2pm for the convenience of the participants. All the measurements were performed in sitting posture.

Ethical considerations: The present study was approved by the institutional research committee. Informed consent was obtained from all the participants. Confidentiality of data was maintained.

Data analysis: Data was analyzed using SPSS 20.0. Data was presented as mean and SD. Student t test was used to observe the significance of difference between the variables. Probability value less than 0.05 was considered as significant.

Results: Table no 1 presents the demographic data of the participants. Systolic blood pressure was lower in the left arm when compared with the right arm. However, the difference was not statistically significant. Diastolic blood pressure was lower in the left arm when compared with the right arm. However, the difference was not statistically significant. Pulse rate was lower in the left arm when compared with the right arm. However, the difference was not statistically significant.

Discussion

The present study was undertaken to observe the variation in the blood pressure in right and left arm in young adults. Systolic blood pressure was lower in the left arm when compared with the right arm. However, the difference was not statistically significant. Diastolic blood pressure was lower in the left arm when compared with the right arm. However, the difference was not statistically significant. Pulse rate was lower in the left arm when compared with the right arm. However, the difference was not statistically significant. Earlier studies reported a variation in the blood pressure in the right and
left arm with high pressure in right arm for both systolic pressure and diastolic blood pressure.\textsuperscript{[4–8]} Una Martin et al., observed inter-arm variation in the blood pressure in 710 patients and reported that there was no significant difference in the mean values of systolic and diastolic blood pressures.\textsuperscript{[9]} It was reported that various factors influence the variation like the health status of the participants like presence or absence of hypertension, age group, and timing of recording of blood pressure like weather blood pressure recorded simultaneously in both hands and one after other.\textsuperscript{[10]} Higher differences in the inter-arm blood pressure may be due to undiagnosed diseases that affects the vascular tree.\textsuperscript{[10]} It was reported that a difference in the inter-arm blood pressure more than 10 mmHg indicates risk of peripheral vascular diseases.\textsuperscript{[11,12]} The variation in the blood pressure may be due to anatomical reasons as the right brachial artery arises from axillary artery which originates from right brachiocephalic artery whereas left brachial artery which is direct continuation from aorta. Further, it was reported that the circumference of arm has no role in the inter-arm blood pressure.\textsuperscript{[13]} Another study reported that the inter-arm blood pressure less than 10 mm Hg is common and if the inter-arm difference is more than 10 the individual must be referred to the specialist for further management.\textsuperscript{[14,15]} However, there reference values may vary for Indians as there are demographical variations. Earlier study reported that there is a significant difference in the inter-arm blood pressures in hypertensive and diabetic population.\textsuperscript{[16]} However, there is no difference among right and left handed individuals.\textsuperscript{[17]} In the present study all the individuals were right handed. There was difference between arms with higher pressure in right arm when compared with left arm. These results are consistent with earlier studies.

\textbf{Conclusion}

Systolic, diastolic pressure and pulse rate was lower in the left arm but the difference was not significant. The study recommends need for further studies in this area to understand the variations in the blood pressure and its implications which helps to develop effective diagnostic and management method for hypertension.

Knowledge and Hygiene Practices among Mothers While Infant and Young Child Feeding in Raichur, Karnataka: A Cross Sectional Study

Kusuma¹, Bheemayya Badesab²

¹Assistant Professor, Dept. Community Medicine, Shridevi Institute of Medical Sciences, Tumkur; ²Professor & HOD, Dept. Community Medicine, Navodaya Medical College, Raichur

Abstract

Introduction: With the adoption of the 2030 Agenda for Sustainable Development, improving infant and young child feeding practices has never been more urgent. While breastfeeding provides optimal nutrition to the child and prevent infections, the timely initiation and age appropriate complementary feeding can substantially reduce stunting and related burden of disease. Poor hygiene and subsequent diarrhea may also contribute to stunting through chronic gut inflammation.

Objective: To study the knowledge and hygiene practices among mothers during infant and young child feeding.

Methodology: A cross-sectional study was conducted in the urban field practice area of Navodaya Medical College. A study population of 375 mothers having children of less than two years age were selected by systematic random sampling method. Data was collected after informed consent regarding socio-demographic factors, knowledge and hygiene practices during child feeding from mothers. Data was analyzed using EPI Info 7 and expressed in terms of percentages, proportions.

Results: The study showed 50.1% of mothers had correct knowledge on duration of exclusive breastfeeding and 42.7% on appropriate time of initiating complementary feeding. 28.35% of mothers had the habit of washing hands with soap and water before feeding the child. Only 12.8% of mothers had given safe water for drinking to child.

Conclusion: In our study half of the mothers had the right knowledge on appropriate duration of exclusive breastfeeding while knowledge on initiation of complementary feeding is much less. Hygiene practices are very low and needs more attention.

Keywords: Infant and young child feeding; Exclusive breast feeding; Complementary feeding; Hygiene practices.

Introduction

Malnutrition is a national problem and child is the chief victim of interplay of nutrition, socio-economic and health factors that cause malnutrition. The steep rise in malnutrition in children during first two year of life is indicative of poor feeding practices¹.

Infant and young child feeding is a set of well-known and common recommendations for appropriate feeding of new-born and children under two years of age². It comprises breastfeeding and complementary feeding which directly affects the nutritional status of children under two years of age and ultimately has an impact on child³.

Breastfeeding is a beautiful process connecting
mother and child. Breastmilk acts as a potent medicine for disease prevention in children. Scientific evidence shows that early initiation of breastfeeding can reduce neonatal mortality significantly. It is one of the smartest investments to boost human capital, stimulate economic growth, giving every child the same opportunity to thrive and a key driver in achieving the SDGs. Continued breastfeeding up to age 2 years or longer can provide babies with nutrients that are unavailable in settings with limited access to a diverse range of complementary foods.

The timely initiation and age appropriate complementary feeding can substantially reduce stunting and related burden of disease. Appropriate complementary feeding can prevent 6% of the estimated under-five deaths and have larger impact to lessen morbidity and malnourishment rates. Children who are fed solid foods too early are putting them at risk of early cessation of breastfeeding and infection.

In India 26 million children are born each year where less than 50% of children are breastfed within one hour of birth and EBF for 6 months is 55%. Only 8.7% children at 6 to 8 months receive adequate diet which implies that 23 million children are not optimally fed during 6-23 months.

Proper hygiene and food preparation practices include hand washing with soap for both caregivers and children before preparing and consuming meals, as well as cleaning all kitchen utensils and cooking surfaces. Foods should be provided to children using clean hands and/or utensils and liquids using a glass or cup rather than bottles with teats, as these are more easily contaminated without proper cleaning.

Dirty or improperly cleaned hands can also be a source of food contamination. Interventions promoting hand washing with soap have consistently been shown to reduce childhood diseases. Inadequate access to safe water, sanitation and hygiene are well-established underlying causes of maternal and child undernutrition. Poor hygiene and subsequent diarrhea may also contribute to stunting. WHO estimates that 50 per cent of undernutrition is associated with infections caused by unsafe water, poor sanitation and unhygienic practices.

In spite of vast available resources and contact points for imparting knowledge, there exists a gap between knowledge and practice. Community based studies are essential to obtain a clear understanding of factors that are responsible for poor feeding practices and to develop measures to reduce such faulty practices. Hence there is a need to study the knowledge and prevailing practices and find suitable interventions.

Objective: To study the knowledge and hygiene practices among mothers during infant and young child feeding.

Materials and Method

A community based cross-sectional study was conducted in the urban field practice area of Navodaya Medical College and Hospital, Raichur during the period of January 2016 to December 2016. Data was collected using pre-tested, semi-structured questionnaire by house to house visit and personal interview method. Questionnaire was validated. Data was collected from the mothers of 0-23 months age children residing in the study area and who were willing to participate in the study. Mothers having children of less than two years but are pregnant during the time of study and those mothers not willing to participate in the study were excluded.

Sample size was calculated by using the formula, \( n = \frac{4pq}{L^2} \). According to National Family Health Survey III, Karnataka data, estimated prevalence of exclusive breastfeeding for infants was 54%; Children aged 6-9 months receiving solid and semi-solid with breast milk was 74%. So lesser of two values was chosen, which was 54%. So sample size of my study was 375. Systematic random sampling technique was used to collect the sample size. Data thus collected was further processed and analyzed using Epi Info-7 version and expressed in terms of proportions.

Results

In the present study the age of mothers ranged from 18 years to 35 years. The mean age of mothers was 23.88±2.92 years. Majority of mothers were illiterate (41.9%) and belonged to lower middle class (58.4%). The age of children in the present study ranged from 4 days to 23 months. The mean age of children was 12.28±7.02 months.

Table 1: Knowledge on initiation of breastfeeding to child

<table>
<thead>
<tr>
<th>Initiation of breastfeeding</th>
<th>Frequency</th>
<th>Percent</th>

<td>121</td>
<td>32.3</td>
</tr>
</tbody>
</table>

Table shows that 42% of mothers were not giving safe water for drinking to child while only 26% were giving safe water to the child.

**Discussion**

In the present study, 83.5% mothers had correct knowledge regarding initiation of breastfeeding. WHO and UNICEF recommend early initiation of breastfeeding within one hour of birth. The high level in our study may be due to high institutional delivery which is 83.2%.
The colostrum which is highly nutritious and contains anti-infective factors acts as the first immunization to the child after birth. In the present study 44.3% mothers had knowledge regarding colostrum. It means that more than half of mothers had no knowledge regarding importance of colostrum. In the study conducted by Premalatha et al\textsuperscript{16} 75.8% had knowledge and said it was good for baby; 18.7% considered it was not good and 5.5% had no knowledge regarding colostrum. The study conducted by Nigam et al\textsuperscript{17} found that 83% had no knowledge regarding colostrum.

In the current study 25.1% of mothers had perception that there is no harm in giving pre-lacteal feeds. These mothers believed that milk is secreted usually three days after delivery. They believe that honey, jiggery water, castor oil and pasteurized milk can be given as pre-lacteal feeds to the newborn. Caesarian delivery, local customs and inadequate lactation were the other reasons further contributing their perception on pre-lacteal feeds. In a study by Rani Jet al\textsuperscript{18} 24.7% of respondents had fed their children with pre-lacteal feeds. Study done by Das N et al\textsuperscript{19} in west Bengal showed 42.1% and study done by KhanS et al\textsuperscript{20} showed as high as 90% because of ignorance or due to belief that pre-lacteal feeds act as laxatives. An appropriate health education during peri-natal period regarding danger of pre-lacteal feeds is essential.

Knowledge of mothers on exclusive breastfeeding depends on guidelines from delivery institutions, pediatricians’ advice and moderate literacy levels of mothers which attribute to EBF practices. In our study 50.1% of mothers had a knowledge on exclusive breastfeeding. In the study conducted by Maiti A et al\textsuperscript{21}, PremalataM et al\textsuperscript{16}, Ilyasu et al\textsuperscript{22} 34.97%, 33.9%, 31% of mothers had knowledge on EBF respectively which is less than the results of our study. In contrary to it the study conducted by Aidam et al\textsuperscript{23} in Aura Ghana 98% of mothers had knowledge on EBF.

Improper complementary feeding practice is one of the main reasons for malnutrition. The current study showed that 42.7% of mothers knew that complementary feeding should be initiated at 6 months of age. The study done by Das N et al\textsuperscript{19} had shown much lower knowledge on initiation of complementary feeding i.e 28%. Our study is similar to study done by Kulkarni RN et al\textsuperscript{24} and Agarwal et al\textsuperscript{25}.

Hygiene practices are essential while feeding to children to break the vicious cycle of infection and malnutrition. In the present study only 28.3% of mothers fed the child with freshly prepared food. 19.2% of mothers had the habit of washing hands with soap and water before feeding the child and 15.2% of mothers wash child’s hand with soap and water. Majority (40.1%) of mothers did not have the habit of washing hands of their children before feeding and 20% of mothers were not washing their own hands with soap and water before feeding their child. Similar type of results is seen in the study of Saleh F et al\textsuperscript{26}. Only 25.6% of mothers were able to provide safe water to their children in the present study.

The study by Sethi V et al\textsuperscript{27} had shown that improvement in feeding practices was possible through proper utilization of existing health services, helping mothers to understand the rationale of good feeding practices.

**Conclusion**

A correct guidance by health workers during their each contact with mothers can bring changes in mothers’ knowledge and feeding practices so that the child gets optimal nutrition. They get an opportunity to guide mothers regarding exclusive breastfeeding and complementary feeding during Post-natal visits and immunization of children. At any cost this opportunity should not be missed and every attempt should be made to realize the mother about correct method of complementary feeding. Maintenance of hygiene during complementary foods preparation, using safe water (at least by boiling) will prevent the child from falling sick frequently. Awareness should be aroused regarding this.

To improve mothers’ knowledge every hospital should have IYCF practices education corner/unit in the pediatric department to demonstrate the correct method of feeding practices to mothers of children having less than two years age. There is a need of counseling services directly to the mother and family in community through gross root level workers. Only the integrated work at all levels help in optimal feeding practices.

Internet of Things based Remote Patients Observatory System Using Biomedical Sensors

S. Ramani¹, L. Ramanathan², S. Rajkumar³, M. Anbarasi¹, N. Prabakaran¹

¹Assistant Professor (Senior), ²Assistant Professor (Selection Grade), ³Associate Professor, School of Computer Science and Engineering, Vellore Institute of Technology, Vellore, Tamilnadu, India

Abstract

In modern health care environment, meliorations of the IoT based information and communication technologies are broadly utilized for the contraption of licensed medical practitioner and patients. The most difficult task is patient’s health issues keying out and unriddling. This is due to weak force and misfortunate mobility of the existing healthcare systems. We propose an IOT based Remote patient’s observatory System using Biomedical Sensor. The biomedical component is inclusive of Temperature Sensor, Heart rate sensors and BP sensors. Here in this work a more proficient machine to machine correspondence is accomplished for medicinal services data. This proposed individuals driven detecting framework is proficient in taking care of the issues looked by patients and doctor by checking human exercises and cooperating with the living condition. In this work, three parameter viz., heart beat rate, temperature and Blood Pressure are checked and transmitted. The medicinal services framework setup is mimicked utilizing Visual Studio programming, and the parameters are seen by remote wellbeing application tolerant observing screen.

Keywords: Health care system, patient remote monitoring system, IoT based healthcare system; body sensor based remote monitoring.

Introduction

Remote Healthcare system Iot is fundamentally an accumulation of lower power and light-weight biomedical sensors that are utilized to screen the human body works and encompassing condition. Subsequently biomedical sensors are utilized to gather sensitive data and may work in unfriendly conditions; likewise, they require strict security devices to forestall malicious association with the framework. The healthcare remote observing framework has turned into a key supporter of the human life quality. The market area of medicinal services remote checking frameworks has expanded altogether because of a few reasons¹. The quantity of elderly individuals is expanding over the time where today in created nations it is very ordinary that elderly individuals generally live freely in their own particular homes. Moreover, Internet of things (IoT) makes these healthcare remote observing frameworks actually plausible (IoT as the idea of a screen capable and modifiable world in which sensors and actuators over living and non-living items) and the notwithstanding diminishing expense of sensors makes it monetarily doable ².

The fundamental vision of the healthcare industry is to give better human services to every one of the general population at anyplace and whenever on the planet. This ought to be done in a more patient benevolent and financial way ³. Consequently to increase the patient care effectiveness, there is a need to enhance the patient observing gadgets. The therapeutic world today faces two issues in understanding checking; right off the bat, the need of social insurance suppliers and overseers to be available at the bedside of the patient and second is that the patient is confined to informal lodging wired to vast machines ⁴. So as to accomplish adaptable and agreeable patient care, the previously mentioned issues ought to be unraveled and as the bioinstrumentation and media communications advances are propelling, it has turned out to be more practical to plan a remote checking framework to accumulate, show, record and transmit the physiological information from a human body to any area ⁵.

The biomedical sensor innovation is a standout amongst the most basic advances utilized as a part of IoT-based current Healthcare framework. It is fundamentally
an accumulation of low-power and lightweight remote sensor hubs that are utilized to screen the human body works and encompassing condition. Since biomedical segments are utilized to gather touchy (life-basic) data and may work in antagonistic conditions, in like manner, they require strict security instruments to counteract pernicious association with the framework.

In this article, at first we address few security necessities in remote checking based present day medicinal services framework. At that point, we propose a protected IoT based healthcare framework utilizing biomedical sensors which can ensure to achieve those prerequisites. Subsequently, whatever is left of the article is sorted out as takes after. In Section 2, we portray a portion of the related works in IoT based human services framework utilizing biomedical sensors. In Section 3, we display our remote patient’s observatory framework and along these lines, in this area, we likewise demonstrate to authorize security in our IOT which accomplishes all the basic security properties. In Section 4, we had demonstrated the exploratory outcomes. At last, a finishing up comment is given in Section 5.

Related Work: As featured in past area IoT innovation, with the utilization of sensors, gives a vital favorable position in the medical field. Numerous related works has been done as of now which are dissected based on their application space, security and effectiveness in this segment. Shrewd health administrations help in observing the patient remotely, some application includes additionally expands the insightfulness and effectiveness of IoT based smart healthcare framework.

A proficient recovery framework proposed by Fan et al is likewise an enhanced framework. Their proposed framework oversees assets by giving semantic data. Philosophy based framework make fast and proficient reconciliation of assets conceivable. Different savvy and remote gadgets impart in the brilliant recovery of framework by utilizing TCP/IP convention suite. Framework can be overseen in three levels chain of command. This includes Management level, improvement level and PC human connection level that builds the productivity of keen wellbeing framework.

Social insurance framework is exhibited by Basanta et al. Creators give the fundamental system to observing of elderly individuals and patients. Typically specialists can’t screen the patient all the time thus; there is a need to screen individual’s particularly elderly patients at their home. Help to you human services framework interfaces heterogeneous sort of processing gadgets together. As elderly patients require constant observing, an extensive variety of sensors can be associated with the collection of patient.

Security Needs in IoT Based Remote Patient Monitoring Systems: Security is a standout amongst the most basic parts of any biomedical framework. Individuals have alternate point of view with respect to security and henceforth it characterized in a few techniques. By and large, security is an idea like Healthcare of the framework as complete data. Particularly medicinal services are for the most part remote in nature.

Authentication: It is a standout amongst the most critical necessities in any IoT based Healthcare framework utilizing biomedical parts, which can proficiently manage the mimicking assaults. In sensor based social insurance framework, all the sensor hubs send their information to a facilitator. At that point the facilitator sends occasional updates of the patient to a server.

Data Privacy: Information protection is thought to be most essential issue in remote medicinal services frameworks. Data ought not to release patient’s vital subtle elements to outer or neighboring systems. In IoT-based human services application, the sensor hubs gather and advances touchy information to an organizer. An enemy can listen in on the correspondence, and can catch basic data. This listening may cause extreme harm to the patient since the foe can utilize the procured information for some, illicit purposes.

Data Integrity: Holding information classified does not shield it from outside alterations. An opponent can simply modify the information by including a few shreds or by controlling the information within a packet. This modified information can be sent to the facilitator. Absence of trustworthiness instrument is now and then exceptionally unsafe particularly if there should be an occurrence of life-basic (when crisis information is adjusted). Information misfortune can likewise happen because of the awful correspondence condition.

Remote Patient Observatory System Using Biomedical Sensor: The solidification of the wise low-price sensor hubs are kept in or close by the human body to screen the body capacities and its condition. The correspondence procedure held in-body organization.
involves embedded gadgets and base station. Conflictingly, the correspondence procedure in on-body arrange contains wearable gadgets and a facilitator. Our proposed system remote care comprises of wearable and implantable sensors. The sensor hubs are related with biomedical gadgets like Temperature, Heart rate Monitoring and Blood Pressure.

**System Implementation:** The microcontroller is fixed with present Threshold value with a specific end goal to recognize the event of the anomalies. At the point when the remote Care server gets information of a man from small scale controller, it bolsters the remote information into its database and breaks down that information. Consequently, in light of the level of variations from the norm, it might associate with the relatives of the individual, neighborhood doctor, or even crisis unit of an adjacent social insurance focus. Unequivocally, considering a man wearing a few bio sensors on his body and the IoT Servers get a periodical updates from these sensors through Microcontroller.

**PIC 16F877A Microcontroller:** The microcontroller is a gadget that can play out a particular capacity as indicated by the coding/program consumed into its program memory. The PIC16F887 is one of the most recent items from Microchip. It includes every one of the segments which current microcontrollers typically have. At its minimal effort, extensive variety of use, high caliber and simple accessibility, it is a perfect arrangement in applications. For example, the control of various procedures in industry, machine control gadgets, estimation of various esteems and so on. Some of its principle highlights are recorded underneath. The 16F877A is a proficient microcontroller that can do numerous errands since it has a sufficiently huge programming memory 8k words and 368 Bytes of RAM.

The 40 pins make it less demanding to utilize the peripherals as the capacities are spread out finished the pins. This makes it less demanding to choose what outside gadgets to join without stressing excessively if there are sufficient pins to carry out the activity. One of the principle preferences is that each stick is just shared between a few capacities so it’s less demanding to choose what the stick work.

**Heart Rate Sensor:** The heartbeat sensor depends on the guideline of plethysmography. It gauges the adjustment in blood volume via any organ of the body which causes an adjustment in the light power through that organ (a vascular locale). If there should be an occurrence of utilizations where heart beat rate is to be observed, the planning of the beats is more vital. The blood stream volume is chosen by the heart beats rate and since light is consumed by blood, the flag beats are comparable to the heart beat beats.

The task of the board is extremely straightforward. Subsequent power of the board is given as a 3-5.5V supply; the Enable (EN) stick must be pulled high to initiate the IR sensor. Next, put the tip of your index finger tenderly around the sensor. Your finger ought to be still and ought not to press too hard on the sensor. Inside a few seconds the circuit balances out and you will see the LED blazing synchronously with your heart beat. You can encourage the yield flag either to an advanced I/O or an ADC input stick of the microcontroller for estimation of the heart beat rate in BPM. The oscilloscope is used to view the waveform of the output voltage.

![Fig. 1. PIC 16F877A IC](image1)

![Fig. 2. Heart rate sensors](image2)
Heart beat sensor deals with an exceptionally fundamental standard of optoelectronics. All it takes to quantify your heart rate in a couple of LED and LDR and a microcontroller. IR LED transmits infrared radiation and surface mirrors the infrared light. Contingent upon reflectivity of the surface, measure of light reflected shifts. This reflected light is made episode on invert one-sided IR sensor which brings about turn around spillage current. Measure of electron-opening sets created relies upon power of episode IR radiation. More exceptional radiation brings about more switch spillage current. This current can be gone through a resistor to get relative voltage.

Temperature Sensor: A temperature sensor is a gadget, ordinarily, a thermocouple or RTD that accommodates temperature estimation via an electrical signal. A thermocouple (T/C) is produced using two different metals that create electrical voltage in guide extent to changes in temperature. The LM35 gadget has preference over direct temperature sensors aligned in Kelvin, as the client isn’t required to subtract an expansive consistent voltage from the output for acquiring helpful scaling of Centigrade.

LM35 is an accuracy IC temperature sensor with its output proportional to the temperature (in °C). The sensor hardware is connected and in this way it isn’t submitted to oxidation and different procedures. With LM35, temperature can be estimated more precisely than with a thermistor. It likewise has low self-warming and does not cause in extra of 0.1 °C temperature ascend in still air. The gadget is utilized with single power supplies, or with in addition to and short supplies. As the LM35 gadget draws just 60 µA from the supply, it has low self-warming of under 0.1°C in still air.

Blood Pressure Sensor: The Blood pressure level Sensor is a non-intrusive sensor intended to gauge human
blood pressure. It gauges systolic, mean blood vessel weight and diastolic with the help of the oscillometric method. Heartbeat rate is additionally revealed. A sphygmomanometer is a gadget that measures pulse. It is made out of an inflatable elastic sleeve, which is cloaked around the arm.

**Proposed Algorithm:**

1. Microcontroller board is connected with the sensors that are connected with the patient.
2. The array form values are obtained and stored.
3. A PC is connected with the Microcontroller by using a Serial to USB Converter.
4. The values that are received are read with the help of Communication Port that is displayed on the Windows PC and the Values are Monitored by Creating a GUI
5. Restoring the sensor values are done by typecasting from ASCII to normal.
6. The abnormal condition is indicated by comparing the values with threshold values.
7. The front panel displays the vital parameters.
8. A file stores the obtained values and also for further assistance in the patient treatment.
9. Using web publishing tools created in Visual studio 2010 the front panel can be seen remotely.

The different sensors are placed at the respective locations on the body of human and are connected to the microcontroller board. The output of the temperature sensor from LM35 is converted to digital form with the help of ADC pins of microcontroller board. For the pulse rate sensor when the heart pumps blood through the blood vessels, the finger becomes slightly opaque and so less light reaches the detector. With each heart beat the detector signal varies and this variation is converted into electrical pulse. The pulse is also indicated by an LED which blinks on each heartbeat.

**Experimental Results**

This part has the description of the results obtained from testing the device.

**Conclusion and Future Work:** In this article, remote checking application is introduced which enables the specialist to see the patient’s biomedical parameters remotely and powerfully in a Web page continuously and doesn’t need any exceptional prerequisite on the PC. All he needs is an Internet to go. For the patient side, a locally established VB application which is inserted in home PC is required. Finally it is concluded that we have implemented Remote patient monitoring system utilizing the propel advancements and sensors which screens the biomedical parameters. This model was done and tried on single individual’s information accumulation and in future this can be reached out to different individuals.

Methicillin Resistant Staphylococcus Aureus (MRSA) Infection: Knowledge, Preventive Practices and Colonisation among Healthcare Professionals of Surgical Units

Diana D. Mello¹, Latha T.², Janet Alva³, Barnini Banarjee⁴, Vandana K.E.⁵

¹M.Sc. Nursing, MCON Manipal, MAHE Manipal, ²Assistant Professor-Senior Scale, MCON Manipal, MAHE Manipal, Karnataka, India, ³Assistant Professor, MCON Manipal, MAHE Manipal, Karnataka, India, ⁴Associate Professor, Department of Microbiology, Kasturba Medical College Manipal, MAHE Manipal, ⁵Professor, Department of Microbiology, Chairperson, Infection Control Committee, Kasturba Hospital Manipal, MAHE Manipal

Abstract

*Staphylococcus aureus* is the most prevalent pathogen in hospitals and Methicillin Resistant *Staphylococcus aureus* (MRSA) is one of the major drug resistant strain. The severity may range from a minor skin infection to major life threatening septic shock. The objective of the study were to assess the knowledge of healthcare professionals (HCPs) on MRSA infection, to observe and to screen HCPs to detect MRSA colonization and decolonize them appropriately.

**Method:** A cross sectional descriptive survey was conducted in surgical units of a tertiary care hospital, Southern India among 101 HCPs. The concealed observation of the infection control practices was done using observational checklist followed by which the HCPs were screened (anterior nares, throat and axilla or web spaces) to detect MRSA carrier status. Knowledge on MRSA infection and prevention was assessed through structured knowledge questionnaire.

**Results:** Among 101 HCPs, 42% had excellent knowledge on transmission and prevention of MRSA. Observation of infection control practices revealed that there was good compliance in waste disposal and specimen collection but the compliance was low in hand hygiene, use of personal protective equipment and dressing. Out of 101 HCPs, 2.97% were found to be the carriers.

**Conclusion:** Increase in the compliance towards hand hygiene and infection control practices would reduce the infection rate and also motivating the HCPs to follow standard precautions would contribute towards prevention of hospital acquired infections.

**Keywords:** Carrier status, Methicillin Resistant *Staphylococcus aureus* (MRSA), Infection control practices, Healthcare Professionals, Surgical units, Hand hygiene.

Introduction

*Staphylococcus aureus* is one of the prevalent and clinically significant hospital acquired pathogens worldwide¹. The incidence of *staphylococcus aureus* infections is been raising. Infections caused by MRSA are associated with worse outcomes leading to prolonged hospital stays, increasing cost of treatment and poor prognosis¹. Healthcare workers are traditionally considered to be the vectors of nosocomial infections.
including MRSA\textsuperscript{2}. The screening and decolonising the healthcare workers is reflected to be the important component in controlling spread of MRSA infection in health care setting\textsuperscript{3}. Studies reported that 33\% people carry \textit{Staphylococcus} in their nose, usually without any illness whereas two in 100 people were found to be the carriers of MRSA with manifestations of illness\textsuperscript{4}.

Healthcare workers may transmit MRSA infection to the patients and others through their daily patient care activities. Screening the HCPs identifies the carriers and decolonizing them reduces the risk of transmission. Knowledge of MRSA can reduce the infection rate in the hospital\textsuperscript{5}. There is scarce of evidence on assessing the knowledge of MRSA infection in India. Hence, we aimed at observing the infection control practices, assessing the knowledge of HCPs on MRSA infection, identifying the MRSA carrier and recommending the HCPs for the decolonization with the aim to reduce MRSA infection in the hospital.

**Method**

The cross – sectional descriptive survey design was used with quantitative approach. The study was conducted in the surgical units of a tertiary care, multispecialty teaching hospital, Southern India. The hospital has more than 2000 beds with 240 beds for surgery department. Data were collected by total enumerative sampling for detecting MRSA carrier status and to assess their knowledge and event sampling for observation of infection control practices. The data were collected by using demographic proforma, structured knowledge questionnaire on MRSA infection and its prevention and observation checklist on infection control practices.

Knowledge on MRSA infection and prevention: Structured knowledge questionnaire consisted of 28 multiple choice questions. The items in the questionnaire was based on the diagnosis, management and preventive aspects of MRSA infection. It was validated by seven experts. The reliability was found by split half method \((r = 0.80)\). The questionnaire was administered to HCPs after obtaining written consent from them.

Concealed Observation of Practices: The infection control practices were observed using observation checklist during patient care activities and the participants were not aware of being observed. The observation checklist had infection control practices distributed under different domains namely hand hygiene, use of personal protective equipment (PPE), personal factors and dressing. The reliability was found by inter-rater method. Tool was found to be reliable \((r = 0.9)\). The numbers of events to be observed were calculated using ‘estimate of proportion’. The calculated event size for hand hygiene was 200 observations, use of PPE was 80, personal factors was 70 and dressing was 74. Consent was taken from the participants after the observations.

Screening for MRSA carrier status: Pre-moistened swabs were collected from anterior nares, throat and axilla of HCPs. Different swabs were used for different location. Swabs were sent for microbiology department immediately after collection for further analysis. A total of 303 swabs were collected from 101 participants and analysed according to guidelines of Clinical and Laboratory Standards Institute (CLSI) using Cefoxitin \((30 \mu g)\) disc diffusion method\textsuperscript{5}.

The data collected was coded and analysed using a software, Statistical Package for the Social Sciences (SPSS16.0).

**Ethical Consideration:** Permission was obtained from Institutional Research Committee and Institutional Ethical Committee (IEC No: 754/2016). The project was registered in Clinical Trials Registry-India (CTRI/2017/05/008706). Participant consent was obtained.

**Findings**

Sample characteristics: The demographic data was collected from 101 HCPs working surgery ward. The sample consisted of 21 doctors and 80 nurses working in the surgical units. Majority of the study participants were female (94.1\%) and the 50\% of participant were ranging from 20-24 years of age. Majority of the participants (51.5\%) had 2-5 years of experience. Most of them had multiple source of information (40\%) on MRSA infection and its prevention.

Distribution of knowledge scores: The knowledge on MRSA infection and its prevention was collected using a structured knowledge questionnaire. Participants who scored less than 50\% were categorized as needs improvement, between 51\%-64\% as satisfactory, between 65\%-75\% as good and 75\% and above as having excellent knowledge. Out of the 101 sample, 43\% of the participants had excellent knowledge. The description is represented in figure 1.
Description of infection control practices:
Infection control practices were observed using observation checklist on different domains. The result is given in table 1.

</tbody>
</table>
Out of 200 observations on hand hygiene, 74% of the participants washed hands before the activity and 71% washed hands after the care activity. In 80 events observed for use of PPE, 53% used gloves during the procedures. Only 6.2% of the participants wore masks when changing linen.

Among the events observed for personal factors, 95.7% of the participants wore clean clothing, majority (95%) of the participant maintained good personal hygiene. Observations on wound dressing showed, 68.9% had washed their hands before the dressings. The soiled dressing was discarded into the appropriate bin was in 96.3% event and 89.2% of times dressing was done using sterile gloves.

**Screening of MRSA carrier status:** Out of 101 HCPs screened for MRSA carrier status, 2.97% (three HCPs) were found to be the MRSA nasal carriers and one among the three nasal carrier (0.9%) was found to be carrier in the throat also. No colonization was detected in axilla of screened HCPs.

**Discussion and Conclusion**

Hospital acquired infections are threat to the patients and also to the employees. Healthcare professionals are considered to be the vectors in transmitting the infections in the hospital\(^2\). Attention to certain preventive aspects such as hand hygiene, proper waste disposal must be practices, use of gloves, gown and masks play a vital role in prevention of transmission.

In the present study, most of the participants were in the age group of 20 to 24 years and 72.3% were staff nurses with two to five years of experience. The study findings revealed that out of 101 participants, the mean knowledge score was 20.29 ± 4.08 and 42% of the participants had excellent knowledge and 29% of the participants had good knowledge on MRSA infection. A similar cross sectional survey was conducted in Albania among 251 HCPS. The results demonstrated a moderate knowledge of nosocomial infection and isolation precautions among HCPs\(^6\). A study from Palestine supports the present study where knowledge of 331 healthcare workers was assessed in which 85% of the participants had good knowledge on MRSA infection and transmission\(^7\).

Awareness on infection prevention is essential to reduce hospital related infection. Compliance to infection control practices is equally important. The present study states that the good practice of hand hygiene was found in 54.7% event. The appropriate use of PPE is seen in 43.25% of events. In 80.4% of events wound dressing were done by following all the infection control practices. Self-reported compliance to infection control is higher (89%) than actual observation (77%)\(^8\), indicating that periodic observation of infection practices of HCP assist them in understanding the compliance level and improve the practices.

Educating HCPs and patient care givers on safe and clean environment, decontaminating equipment and importance of decolonization also play a vital role. It was reported that suitably sited wash basins and rubs motivate the healthcare workers to wash hands at the appropriate time\(^9\).

The study also found that 2.97% of the healthcare professionals in the surgical unit were the nasal carriers of MRSA, and 0.9% were the throat carriers. However, none had positive culture in the sample obtained from axilla. The rate of MRSA carrier is not homogenous across the globe\(^10,11,12,13,14\). The rate of MRSA colonisation in Iran shows 32.8% (95% CI: 26.0-40.4), in Egypt 58.8% *Staphylococcus aureus* was MRSA, in Ethiopia 44% was MRSA, in China 4.7% of *Staphylococcus aureus* was MRSA, in Ireland 8.9% and in Europe and the United States the lowest, 1.8% are reported\(^14\). However, the global prevalence was 4.6% in 2008\(^2\).

The causes for the low compliance to infection control practices must be researched. The carrier status was comparatively low among healthcare professions and use of barrier precautions could be the factor leading towards low carrier rates. Continuous nursing education and training programs on hospital infection and prevention in the present setting must have been effective as majority of the healthcare professionals had good knowledge on MRSA infection and prevention of transmission.

The study concludes that educating the professionals on prevention strategies create awareness among the healthcare professionals. In this study majority of the participants had adequate knowledge on MRSA infection and the prevention strategies but the compliance to practice was comparatively low. This provided a base towards assessing the compliance of the healthcare professionals and also the carrier status of MRSA. The study recommends screening of the healthcare workers in high risk and critical units. Further recommendations.
includes creating awareness among staffs towards importance of adherence to infection control practices.

Abstract

The study of cervical cancer epidemiology is an ongoing crucial research as the disease is region dependent. Attempt at awareness measures have curbed the disease to an extent but more regional studies are required to explain the association of pathologic findings with region-dependent risk factors. This study attempts to study the prevalence of cervical dysplasia amongst women in Guwahati, Assam and to interpret the associated risk factors. Data is collected from the Out Patient Department (OPD) of the Obstetrics & Gynaecology (O & G) Department of Guwahati Medical College and Hospital, the most prominent super-specialty public hospital of the region. The sampling procedure was systematic random sampling with patients being selected as and when they arrive. Out of 496 women who visited the hospital over a period of eighteen months the study is conducted with 366, based on successful reports from Pap smears evaluated using Liquid Based Cytology technology(LBC). Chi-square test is used for statistical analysis of association. 11.7% of the respondents had precancerous symptoms. Eleven factors showed significant association with the smear status of the respondents.

Keywords: Cervical cancer; Epidemiology; Pathological findings; Precancerous.

Introduction

Cervical cancer is a common cancer among women after breast cancer. There has been regular campaign against cervical cancer for the last 30 years in India, but this has had little impact on the morbidity and mortality of the disease, with India now ranking fourth worldwide⁶,¹³. Government of India has undertaken several cancer control programs, but these measures have not been much effective for women of poor to modest background due to untrained manpower, lack of infrastructure and lack of awareness¹⁰. The growing risk of cervical cancer in women (aged 15-64 years) is 2.4% in India compared to 1.3% for the world⁷. So, early detection of cervical cancer may take a very precious role in preventing this disease. Pap smear screening test is a painless screening test for early detection of cervical cancer and has made cervical cancer one of the most preventable cancer⁵.

In order to achieve success in this fight against cervical cancer it is very important to know the risk factors the women of the region are most exposed to. Several regional, national and worldwide studies have been made on the study of epidemiology and risk factors of the disease to understand the entire range of risk factors¹¹,¹⁷,²⁰,²². It is well known that cervical cancer presents very little early symptoms¹⁶,²³ and hence the disease remains in dormant stage for a long time until it manifests itself. Early detection of the disease would entail recognizing its onstage from Pap smear tests¹⁴. Cervical cells may be observed to be in several states
of dysplasia before progressing to carcinoma. Even inflammatory cells, although considered as normal, signify a difference since it is part of a response of the biological system to harmful stimuli, one of which may be carcinogen. The evaluation of cervical specimen to categorize dysplasia into mild, moderate, severe or cancer in-situ is performed by The Bethesda System (TBS)\textsuperscript{15} of classification. These minor changes in the states of dysplasia may well be affected by risk factors associated with the disease.

**With this motivation the present study was conducted to:**

1. To make a complete epidemiological study of the women of the region and
2. To identify the risk factors of the women with dysplasia.

**Materials and Method**

**Study setting and study design:** The study was conducted over a period of 18 months from December 2016 to June 2017 in the OPD of the O & G Department of Guwahati Medical College and Hospital (GMCH), the most prominent super-specialty public hospital of the region. The patients were checked by the clinician and enrolled to take part in the survey, following consent norms. The survey consisted of two parts: answering the questionnaire and taking the LBC Pap smear test.

**Study questionnaire:** A well laid out questionnaire was prepared and tested on 15 patients as a pilot study for clarity, suitability and completion of the study being conducted\textsuperscript{21}. The questionnaire consisted of 44 questions, ranging from socio-economic and demographic background of the patients to different questions related to sexual and childbirth (age, place) activities. The questionnaire also included family history of cancer, inflicting medical conditions, dietary habits, etc. **Figure 1** gives a glimpse of the respondents answering the questions of the questionnaire.

**Cervical Sample collection & slide preparation using LBC Unit:** The method of Pap smears taken for the study was LBC technique as it provides several advantages over conventional smears\textsuperscript{19}. The collection was done by trained technician of GMCH who also interviewed each patient and filled the questionnaire. The stained slides, ready for microscopic diagnosis by pathologist, were then sent to the Department of Pathology of the same hospital for diagnosis. **Figure 2** shows the collection of the samples and their subsequent analysis on the LBC unit.
Sample size determination and sampling procedure: The hospital faces a heavy footfall of patients from inside and outside the state, due to the fact it is freely run and due to its geographic location. Hence, it was not possible to include all patients who visit the O & G department. Moreover, it is not viable to estimate the population size of women due to multi-state involvement. When the population is unknown and unlimited, the sample size can be derived by computing the minimum sample size required for accuracy in estimating proportions by considering the formula:

\[ n = \frac{z^2(p)(1-p)}{c^2} \]  \hspace{1cm} (1)

Where: \( z \) = standard normal deviation set at 95% confidence level, \( p \) = percentage picking a choice or response, \( c \) = confidence interval

Setting standard normal deviation at 95% confidence level (1.96), percentage picking a choice or response (50% = 0.5) and the confidence interval (0.044 = ±4.4), a sample size of 496 was decided on. The sampling procedure was systematic random sampling with patients being selected as and when the previous one gets over. SPSS software is used to calculate the number and percentages, and also to find out the contingency tables and degree of association between the factors vide chi-square analysis.

Exclusion criteria of objective 2: Out of the 496 slides sent to the Department of Pathology, 130 slides were found to be inadequate or unsatisfactory due to several reasons like low cell count etc. These slides would not give conclusive result for association of pathological status with risk factors and were excluded from the analysis. Hence 366 slides were considered for analysis of the objective 2.

Findings: The study revealed that respondents were largely normal. Out of the 366 cases for which smears could be taken adequately 280(77%) were normal and the remaining 86(23%) were in precancerous states. Figure 3 illustrates the same pictorially.

Figure 3: Pathological findings of the study (figures in percent)

India has populations divided by many caste and tribes\(^9\). It was revealed in this study that maximum respondents were General caste (73.19%) and 93.15% were of local mother tongue (assamese). 57.1% respondents had family members 2-5 (i.e. medium size family) and that almost all (96.8%) were homemakers and married (97.4%). 72.6% and 24.4% of the women reported nil and single abortion(s) respectively and maximum women had two children (41.7%). The ages at childbirth were mostly 20-25 for first two births, with normal delivery in hospitals leading the location of delivery. 82.66% said they did not use any contraceptive method for birth control and 64.11% had regular menstruation. Of the remaining, 21.17% had irregular menses and 14.7% fluctuated between the two statuses. It was found that almost all(94.35%) women did not use pills to postpone menstrual cycle. 45.77% were betel nut chewers. For the next objective we conducted chi-square test for analysis of association of pathological findings with different risk factor. Eleven factors showed significant association with smear status of the respondents. The results of the same are given below (Table 1).
Table 1: Significant factors of the study and association of the factors with pathological findings

Mother tongue (highly associated with p < .01) reflects the race and ethnicity of the population. A previous study too reported association of cervical cancer with this socio-demographic feature\textsuperscript{12}. North-East India has at all times been a hotspot for population geneticists owing to the existence of linguistically, culturally and demographically varied population\textsuperscript{1}. Hence, this finding indicates the need for a detailed study in this direction. Type of occupation of the family is mildly associated\textsuperscript{(p<.1)} with the occurrence of the disease. Although the highest reported occupation is business (55.7%), it does not provide adequate stability to economic and lifestyle status. Socio-economic status reflects a high degree of association\textsuperscript{(p<.05)} in our study\textsuperscript{8}.

It is revealed that all the patients belong either to poor or middle class, which is understandable as this hospital is a public one. But what is revealing is that most patients with dysplastic symptoms were found to belong to middle class. A look at their education profiles show that most of them were educated up to primary level (35.7%), followed by uneducated (25.8%). Further the highest number of occurrence of ASCUS (17 each) were from these two categories. In fact the 4 numbers of LSIL patients and 1 HSIL patient also belonged to Primary educated category.

So we can conclude that, in this region, economic wellness, as well as education, is not an awareness factor.

Further, type of delivery of third child has a mild association (p<0.1) with the occurrence of the disease. So, although the number of children or parity, which is a common risk factor, did not reveal any risk factor, women who gave normal delivery for their third child in hospitals (16.8%) were found to be more affected by ASCUS and LSIL than women who gave normal birth at homes (11.1%). Previously no study had been conducted for considering type of delivery as a risk factor for cervix cancer. However, since in India there are numerous pockets where health care system is very weak and traditional belief system still rampant, it is felt that it is an important factor to be considered.

Again, contraceptive method displayed a mild association\textsuperscript{(p<.1)}. Previous studies have revealed that oral contraceptives is a risk factor for the disease\textsuperscript{4,24} although the exact reason for so is yet to be defined.

An important risk factor, age at menopause was found to be highly associated (p<0.05) in our study. 25.5% and 47.4% of menopausal women were affected with ASCUS and inflammatory cell conditions respectively while 13.11% and 8.2% non-menopausal(either premenopausal or post-menopausal) women reported the same respectively. Here all the patients with LSIL cells belonged to non-menopausal group and the lone HSIL patient was menopausal.

Further, family history of cancer and pain in abdomen were revealed to be very highly associated (p<0.01) with the pathological status of the respondents. 15.8% and 14.5% of patients who had pain were found to have ASCUS and inflammatory cells present as compared to 13.6% and 2.34% women with the same status respectively, who did not report of any pain.

Few studies\textsuperscript{6,7} have reported that manifestation age of the disease is after 40 years. In our study maximum number of patients were found to have ASCUS, i.e.
precancerous, symptoms for both the age groups 21-40 and 41-60. Further, out of 53, 27, 4 and 1 patient(s) showing ASCUS, inflammatory, LSIL and HSIL status 34(64%), 14(52%), 1(25%) and 1(100%) patient belonged to the age group 16-20 for ‘Age at marriage’. It is clear from the bar graph that maximum patients belonged to this group not only for ‘Age at marriage’ but ‘Age at menarche’, ‘Age at first sexual intercourse’ and ‘Age at first pregnancy’ too. Early menarche(at age <=12) is significantly prevalent in this region\cite{18,23}. Hence marriage, sexual life and child birth at tender age is common, particularly amongst the economically weak, as the sooner a girl child is wed off, the better. Although the association of this factor with pre-cancerous symptoms are not significant in this study the high percentage of occurrence is not a good sign. In consistence with the correlation between chance of occurrence of carcinoma cervix and the age of marriage, similar relation was also observed with the age at first pregnancy by J.T. Boyd\cite{3} and co-workers who showed similar result with increased risk of developing carcinoma cervix in women who got pregnant before the age of 18 years\cite{2}.

Poor genital hygiene is a risk factor of the disease\cite{6}. Non-use of sanitary napkins is one amongst them. 56.9% patients in the study reported non-use of napkins. Although higher than the proportion of users, it is satisfactory trend considering the economic status of the women. Also, since a larger number of women reported of white discharge(258 out of 366), out of them 196 were having normal status. Hence this factor was not indicative of any risk in our study.

The nutrition intake of women has been reported\cite{6} as an important risk factor for cervical cancer. Here it was observed that intake of vegetables grown in own garden or plantation and source of drinking water were found to have high and mild significant association respectively, with the cervical status of the women.

**Conclusion**

The fight against cervical cancer is an ongoing vital public health problem. In order to arrest the disease it is important to know the regional factors contributing to the cause of dysplasia. The significant factors revealed are location of residence(last 3 years), mother tongue, type of occupation of family, socio-economic status, type of 3rd delivery, type of contraceptive method, age at menopause, source of drinking water, consumption of vegetables from own plantation, family history of cancer and pain in abdomen. Residence indicates there may be some environmental(air, water and soil) factors contributing to the cause. All the manipulatable factors are important for sensitizing women of the region for better prevention of the disease.

Abstract

Objective: Examine the trends and evolution of telemedicine research based on a bibliometric approach.

Materials and Method: A bibliometric study was developed taking into account the SCOPUS database. For the analysis of results, a search equation was previously developed and quantity, quality and structure indicators were analyzed.

Results: There has been a significant increase in telemedicine research in recent years. The institutions with the highest production are Medical Center and University of Washington, and the main countries where production is concentrated in the United States, the United Kingdom and Australia.

Conclusions: The academic production is concentrated in high income countries, dividing itself into several sub-areas such as medicine, psychology and engineering.

Keywords: Bibliometrics, Telemedicine, Health Care Delivery, Bibliometric Approach.

Introduction

The Telemedicine1 is conceived as a remote delivery of services such as medical care and clinical information, used through the Information and Communication Technologies (ICT) like internet, satellite, telephone, among others. This tries to improve a patient’s health; in fact, this is one of the most important branches of telehealth. However, Darkins & Ann Cary2 choose to use the term telehealth since it encompasses telemedicine and additionally it is not associated only with direct contact between doctor and patient.

The acceptance of telemedicine is also observed from the perspective of technological adoption, understood as the acceptance and incorporation of technology in people’s daily lives3. To this end, some technology adoption models have also been defined, such as the Unified Theory of Acceptance and Use of Technology (UTAUT)4. For the specific case of telemedicine, social influence and ease of use are key factors for adoption5, 6.

Currently, telemedicine has led to great advances in terms of efficiency and improvement of patient quality7. Studies have found that teleconsultations are a benefit for people who are in the last stages of the Human Immunodeficiency Virus (HIV), due to social stigma, the severity of the disease and the fact that it supposes little physical contact8.

However, telemedicine must deal with challenges, in fact, a study reported in Nigeria, carried out with health personnel (doctors and nurses), showed that health service providers perceive it as a double responsibility that requires a great effort9. However, it should be borne in mind that there are also limitations for patients. One of them is the one associated with the socioeconomic stratum, because lower strata have less access to these
This is how telemedicine, recognized as such from the formal point of view in the processes of health care, has been accepted by communities and by those who should guarantee care to patients. However, there are still challenges and fears in the execution of this type of strategies, which is why it was intended to examine the trends and evolution of research based on a bibliometric approach in order to strengthen knowledge in this type of care and that allows to generate bases for the planning and improvement in this type of care in health.

**Methodology**

A bibliometric study was carried out in which necessary information was obtained by means of a database and the search equation was also structured. Then, bibliometric indicators were calculated. Carrying out these studies requires carefully choosing the database records that represent the studies. Criteria of coverage, accessibility and flexibility of the search engines were taken into account. The databases favored were ISI, SCOPUS and Google Scholar. In this sense, SCOPUS was chosen since it offers access to interdisciplinary databases, provides tools to manage the information and for its quantity of citations.

Then, the search equation was defined taking into account the best journals in the area of telemedicine, according to SCIMAGO indicators and verifying that by publishing policies they had direct affinity with telemedicine, resulting in the following: (TITLE ((telemedicine OR telehealth*) AND (patient* OR user) AND (accept*))) OR KEY ((telemedicine OR telehealth*) AND (patient* OR user) AND (accept*))

When the definitive matrix was obtained, it was found that the results referred to the subject of study and proceeded to make a database to analyze the variables required for the treatment of the information, and later calculate and study the bibliometric indicators of quantity, quality and structure.

**Findings**

**Annual Productivity:** In Figure 1, it can be seen that there has been a growing trend in the research of the subject, reaching its point of greatest productivity in the year 2017 with 79 publications, followed by 2016 with 78. This shows a representative increase if compared to the amount of production in previous years, meaning that telemedicine has become a topic of interest in research by the academic community.

![Fig 1. Number of publications in the field per year. Source: Authors, based on Scopus information.](image)

**Productivity of Institutions:** Publications on this topic have been carried out by 160 institutions, where the first 10 participate in 18% of the publications. VA Medical Center leads the list with 22 publications, followed by the University of Washington with 16 publications (see Figure 2). Of these 10 institutions, 5 are in the United States, 3 in Australia, 1 in England and 1 in Canada.
Productivity by countries: The countries responsible for the contributions in the field are 57, of which the 10 that produce the most contribute with more than 75% of the publications. The country that stands out the most is the United States with 216 (46%) publications, followed by the United Kingdom with 67 (14%) and Australia with 62 (13%). 26% of the remaining publications are distributed among the countries Germany, Netherlands, Canada, Spain, Italy, China and Denmark. This shows that academic production is reflected in countries with a high level of development and even though they have different health systems models, they have promoted telemedicine as a way to shorten access barriers to health services, from which experiences for implementation in countries that are delving into this new model of care can be seen.

Cross-cutting research areas: There is a great interest in a sub-area of telemedicine. Medicine is the one about which 60% of the research has been published, while Health and Nursing Professions correspond to 10% and 7% of publications, respectively. Engineering (6%), Psychology (5%), Computer Science (4%), Biochemistry, Genetics and Molecular Biology (3%), Social Sciences (3%), Chemical Engineering (1%) and Neuroscience (1%), are other relevant sub-areas of interest. This shows that telemedicine is not an activity of exclusive interest for health care, but that other areas can also support this process, such as engineering and computational sciences, which are important disciplines for the design of this strategy.

Magazines with publications on the subject: Referring to the journals that have been published on the subject, it was found that Journal of Telemedicine and Telecare is the main one with 44 publications, followed by Telemedicine and E-Health with 25, and Studies in Health Technology and Informatics with 21 (see Figure 3).
**Discussion of topics emerging from the study of telemedicine:** When analyzing the trend of the topics in the area since their research began, it can be shown that Telemedicine is the most researched topic with 90 publications, followed by Telehealth and mHealth with 51 and 31 publications respectively, eHealth is in the same order with 24 publications, Systems thinking (24), Technology acceptance, Acceptance, Internet with 16 publications respectively and mobile health (14).

Over the last few years, there has been a significant change in the topics researched while others are emerging (see Figure 4). Thus, it is observed that telemedicine is the most researched topic with an increasing tendency in the consulted periods, that is, the studied field turns out to be the one of greater interest of researchers, dealing with topics such as the use of mobile applications in diseases like diabetes, which according to Torbjörnsen, Smastuen, Jenum, Arsand & Ribu, telemedicine through mobile applications can improve the quality of life of these patients and help control and monitor the process.

Telehealth is the second topic of greatest interest among researchers, also with a growing trend, defined as the system that makes use of ICT to provide health services, medical care and information, regardless of distance, focusing on prevention. It is a great tool for the dissemination of information on the care and prevention of chronic diseases such as cardiovascular, respiratory and also epidemics.

Emerging themes such as mHealth, mobile health and eHealth have been of significant relevance in recent years, with mobile devices being increasingly used for the prevention, control and monitoring of different common chronic pathologies.

Technological acceptance, Systemic Thinking and Internet have been themes that have been constant in the research production of the area.

**Fig. 4. Emerging and growing issues in Telemedicine. Source: Authors, based on information by Scopus.**

**Discussion**

Below are the keywords that have shown greater growth in the period of time analyzed, of which the most relevant will be discussed.

**Telehealth:** As observed in this study, although telehealth services improve the health outcomes of patients with heart failure or other chronic diseases, patients’ acceptance of this service is low. In this regard, some authors find that the factors that can affect the adoption of telehealth include concerns about equipment or technology, the change of service, ignorance of the benefits of telehealth, limited access to care, cost and privacy. On the other hand, the study conducted by Shen, and Naeim to small groups of adult populations in the United States, shows promising results in the implementation of telehealth tools. However, it shows that for implementation on a larger scale, it is necessary for older adults to accept and adapt them to routine medical care and that smart homes are formed for the
interaction between patients and professionals since this service is favorable, for example by avoiding the transfer to care centers, which is reflected in less stress and more comfortable interactions for patients\textsuperscript{18}.

**Mobile health (mHealth):** MHealth, or the use of mobile technology in healthcare, is becoming more common\textsuperscript{19}. An example of this is what was done by Jonathan, Pivaral and Ben-Zeev\textsuperscript{20}, where the activities of two mHealth specialists are described, who endorsed a mobile phone application for people with severe mental illness and find that it offers different opportunities for the treatment of these patients. On the other hand, other authors investigate the use of mHealth in the prevention of HIV, for which they study a population with a high level of exposure, finding that participants expressed interest in using mHealth for medication reminders, evaluating its effects and receiving information on HIV\textsuperscript{21}.

**Technology acceptance:** Technological acceptance in telemedicine is associated with how viable a person sees the use of electronic services in aspects related to their health. Over time, different approaches have been given to this topic, which are based on the Technological Acceptance Model (TAM). This can be seen in the study carried out by Campbell where, in the search to implement mHealth in limited resources environments, technological acceptance is resorted to, in which the creation of a Model in Limited Resources Environments (TAM-RLS) is proposed. Part of the characteristics established in the TAM, such as perceived ease of use, perceived utility and new factors, affect the use in this environment\textsuperscript{22}.

**Conclusions**

Telemedicine is a subject of great interest that has been positioned in the field of academic production. Its tendency is to grow, for knowledge is required to improve the experience and the satisfaction of users in this modality of care because it allows the system to reach all places, which is a priority for the States. Its good implementation will require conceptual bases, resources, demystification by the community and continuous evaluation.

On the other hand, the concentration of academic production in high-income countries was observed, which implies a great challenge for researchers from low and middle income countries to begin to strengthen the generation of knowledge in this new area, so that it provides the necessary tools to the health authorities for construction and planning this new form of care.

**Conflict of Interest:** The study does not present conflicts of interest with other authors or entities, it is an original production and it is approved by the authors of the article.

Abstract

Human resource development has been acknowledged to be a key factor in the process of economic growth, as the character and pace of economic and social development of any country are ultimately determined not by its capital of its material resources but by human resources. The abundant physical resources alone cannot benefit the growth of the country without human resources component, which transforms physical resources into productive resources. Human resource should also be looked after properly and continuously regarding various aspects like development and economic, social and psychological aspects. Public health facilities are allocated on the basis of primary health centers dispensaries through which preventive and primitive care is provided. India spends about 4.9 per cent of its GDP on health with the share of public expenditure fixed at 0.9 per cent compared to private is 4 per cent of private expenditure. The private healthcare is much larger and widespread than public health services. The improvement people in the health status been one of the major thrust areas for the social development programs of the country. Over the last five decades, India has built up vast health infrastructure and manpower at primary, secondary and tertiary care in government, voluntary and private sectors.

Keywords: Human Development, Health Care, Communicable Diseases, health status, Life Expectancy, Nutrition and Health Expenditures.

Introduction

Human resource development has been acknowledged to be a key factor in the process of economic growth, as the character and pace of economic and social development of any country are ultimately determined not by its capital of its material resources but by human resources. The abundant physical resources alone cannot benefit the growth of the country without human resources component, which transforms physical resources into productive resources. Human resource should also be looked after properly and continuously regarding various aspects like development and economic, social and psychological aspects. Public health facilities are allocated on the basis of primary health centers dispensaries through which preventive and primitive care is provided. India spends about 4.9 per cent of its GDP on health with the share of public expenditure fixed at 0.9 per cent compared to private is 4 per cent of private expenditure. The private healthcare is much larger and widespread than public health services. The private sector is dominant sector with 50 per cent of people seeking indoor care and 50 per cent seeking ambulatory care (out-patient care) from private health facilities. All functions and facilities necessary to diagnose and treat patients aim at reducing margin of errors as well as the patient’s stress levels. Although the urban areas provide ample economic opportunities, they, however, grossly fail in providing a basic minimum standard of living, especially to the poor. Over the last six decades, India has built up vast health infrastructure and manpower at primary, secondary and tertiary care in Government, Private and Voluntary sectors. The people keep abreast of the myriad benefits of health-related technologies for prevention, early diagnosis, and effective treatment as well as rehabilitation for a wide variety of illnesses. On one side, there are communicable diseases, which have become more difficult to combat. While on the other increasing longevity and the changes in life style have resulted in the widespread prevalence of non-communicable diseases. The obvious conundrum is that the improvement of health care system has not kept pace with the needs of a vast majority of people.
Importance of Health: The improvement in the health status has been one of the major thrust areas for the social development programs of the country. Over the last five decades, India has built up vast health infrastructure and manpower at primary, secondary and tertiary care in government, voluntary and private sectors. The population has become aware of the benefits of health-related technologies for prevention, early diagnosis, and effective treatment as well as rehabilitation for a wide variety of illnesses. The extent of access and utilization of health care varied substantially between states, districts and different segments of society.

Dimensions of Human Development: Human development is broadly defined as a process of enlarging people’s choices, as well as raising the level of their well-being. Among these, the choice to acquire knowledge and to be educated; and to have access to resources needed for a decent level of living are identified as three most critical and socially valuable indicators (Human Development Reports, UNDP and National Human Development Report 2001. Government of India). Therefore, the development process is being viewed in terms of efficiency with which it uses an economy’s productive capacities, involving both physical and human resources, as a means to attain the desired social ends and not just material attainments and, on the other hand, to see the extent to which the outcome to this process generates a buildup of the economy’s productive potential so as to put development on a path of sustainable improvement in well-being. With the broadening in the conceptualization of well-being of individuals and societies, there has been, in recent times, a renewed focus on the importance of development of social service sector followed by the economic service sectors, more particularly the need to obtain desirable socio-economic outcomes in the course of development. Development is potentially a powerful instrument for fighting poverty, improving the health conditions, promoting literacy and quality education among masses.

Human development (HD) that encompasses quality of life, the level of well-being and access to basic social services, is an input as well as a key ingredient in the development process. Human Development is development that not only generates economic growth but, distributes its benefits equitably; regenerates the environment rather than destroying it; empowers people rather than marginalizing them (UNDP, 1994. Thus, the basic objective of the development process is to enlarge the range of choices available to the people who should include in addition to income and employment aspects such as health, education, physical environment, human dignity and freedom.

The principal indicators of human development may be identified as; Average Life Expectancy, which in turn is the resultant of general availability of and access to subsistence, nutritional food, medical and health facilities, and of immunity from internal disorders, wars, environmental, natural and other hazards to life. Educational status of population broadly related to by the proportion of literate adult population above fifteen and the man-years of schooling of children (below fifteen) Capacity to purchase consumption goods and services.

Selected Health Indicators of Human Development for Major States: The Table 2 represents the selected health indicators of human development for major states of India. The major components are Life expectancy at birth, infant mortality rate, Birth rate and death rate. The most vital component of human development the health of a population it envisages nation’s economic growth and stability. Good health result in disease control and nutrition, and an efficient medical care in turn leads to better health. In fact, while health is a state subject, population stabilisation and control are on the Concurrent List. The following table clearly explain the indicators of human development in different states.

**The Structure of Health Care System:** The health care system in any society can be separated into two components: the disease theory system and the service delivery system. The disease theory system involves the underlying explanatory framework that provides meaning to the system. This component is unique to each society and reflects the particular society’s worldview. The disease theory system addresses such issues as the nature of health and illness, the meaning of life and death, the appropriateness of intervening in the face of sickness, and/or the prolongation of life for the terminally ill. In effect, it encompasses the assumptions that underlie the system and provides the basis for the creation of health care delivery mechanisms. It should be noted that the underlying paradigm is both a consequence and a determinant of the demographic attributes of the population. Most observers, in fact, argue that the US health care system has experienced a paradigm shift involving the disease theory system during the last years of the twentieth century. The second component, the health care delivery system itself, is our main concern. The delivery system is the mechanism through which society discharges its responsibility for providing for the health and welfare of its members. As such, it involves both structural aspects such as facilities, organizational arrangements, and role relationships and functional aspects such as treatment, research, and education. Hence, the responsibilities entrusted upon good governance is much more in terms of providing quality health care services to its citizen. In fact, in India, several policy initiatives have been taken up from time to time in this direction to deal with various aspects of delivery of health care and family welfare.

**Investment on Health Under Five Year Plans:** Table 3 illustrates the pattern of investment on health, family welfare and Indian system of medicine and homeopathy/AYUSH in different plan period in India.

**Health Care Planning in India:** A drastic change and a major transformation in health was witnessed with the improvement in the health indices showing major achievements in disease control. Once planning process commenced in India, special emphasis in the preventive, promotive and rehabilitation health services were laid with the formal adoption of the National Health Policy by the Indian Parliament in the year 1983.

Thereafter comprehensive network of primary health center services creation of an army of health volunteers and effective community participation have also been some of the highlights. Moreover, training facilities for medical and paramedical personal in various system have been increased which all laid a solid foundation for making an intensive medical research in formulating new alternative drugs for dreadful diseases. In India, doctors are produced in plenty but their services do not reach people who really deserve them. The concentration of doctors is more in the urban areas. And the “goal” of a doctor is considered more to be a business, than a service as the parents spend much money in the training and they expect to get ransom money while practicing medicine.

**Health Status in Tamil Nadu:** Social security assumes special importance on account of the recent economic reforms which insists on fiscal compression. Social provisions such as health care, education, housing and old age security have nowhere in the world been able to make an effective contribution without the active participation of the state. The need for enhancing such support has been compelling in the context of India where a substantial proportion of the population lives below the poverty line.

Tamil Nadu has been in the forefront in formulating and implementing a wide range of welfare measures to the old, infirm and destitute sections of the population. The nutrition programmes implemented by the state have provided an additional layer of support to the malnutritional and weak. In Tamil Nadu the social security schemes have shifted in favour of nutrition schemes towards the welfare of children and expectant and nursing mothers. These schemes have an important role to play in ensuring minimum security for the rural poor; however, no single measure can fully ameliorate...
the living conditions of the rural poor. The need of hour is a package of measures.

**Conclusion**

Health is a multi-dimensional and multi-causal variable. Health transition is a complex process involving cumulative institutional shifts requiring fundamental changes in the configuration of population’s health profile. One of the unsolved conundrums in our country is the inability to provide for universal health care coverage, despite economic growth and development. Any policy that aims at providing basic, affordable health care requires the integration of provision and payment of primary and preventive health care calling for a lead role by governments and an institutionally separate agency in our country.

Residents of Madurai city enjoy easy and better access to private health care service providers thanks to the inter-play of intervening variables such as education, income, employment, housing, nutrition and health expenditures, though the poor and the unskilled still depend on the enviable position of public health care providers in the form of referrals and statutory requirements. Health care contains a component of prevention in its very conception. Care and attention should be focused on leading a healthy life style in terms of physical activities pattern and dietary modifications. Health policy makers must put in place better-developed, spatially-spread and people-friendly health care services.

A Study on Welfare Measure of LIC Employees with Special Reference to Salem Division of Tamilnadu

K. Kalaiselvi\textsuperscript{1}, P. Jagadeesan\textsuperscript{2}, M. Ramesh\textsuperscript{3}

\textsuperscript{1}Assistant Professor, Department of Commerce, \textsuperscript{2}Professor & Head, Department of Commerce, \textsuperscript{3}Assistant Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, (Deemed to be University) Chennai

Abstract

The present research is an inquiry into the welfare facilities provided and the job satisfaction experienced in LIC Corporation Salem Division. The study seeks to find out which dimensions in the welfare Measure inventory significantly influence the level of job satisfaction in LIC employees of the Salem Division. This article undertaken 300 samples and adopted disproportionate random sampling method & reviews the meaning of Welfare Measure, various determinant of Welfare measure. It is an important feature of industrial relations and is a vital ingredient in smooth employer-employee relations. The research will analyses the influence of personal variables such as age, education and experience on the job satisfaction of employees in LIC. The main objectives of the study are to evaluate the welfare activity practices in the public sector organization. Employers offer extra incentives in the form of employee welfare schemes on order to increase employee welfare and to make it possible to persuade workers to accept mechanization.

Keywords: Employee welfare, Fringe Benefits, Organizational Performance, Welfare Measures Adequate Infrastructure.

Introduction

Employee welfare is a dynamic concept. Welfare measures relating to employees are also known as fringe benefits and services.\textsuperscript{1} Welfare measures help to improve the goodwill, public image of the enterprise and to improve industrial relations as well. It also improves the employee productivity. Welfare of labour definitely augment the physical and mental conditions of employees.\textsuperscript{2} Labour welfare consist of better housing, improved medical facilities, educational, rest rooms, canteen, sports club facilities, adequate wages, insurance etc. increase the efficiency of employees considerably. These facilities create confidence in the worker; he feels happy and thus takes more interest in the work. Its main objective is to acquire a better standard of living for the employees, which have the effects on the workers psychology and it leads to an increase in their productive capacities. Welfare basically means wellness, health, happiness, cordial relations, prosperity, which are prerequisite for the physical, mental, moral and emotional stability.\textsuperscript{3} The welfare of the labour must be a voluntary effort made by the management in all the institution.

Statement of the Problem: Service organizations play a crucial role in any economy. In our country, it is backbone in terms of creation of employment potential and contribution to the National Income. The study of Welfare measure was considered to be important and critical area in management and organizational performance for past several years especially in the LIC. Work as an integral part of our everyday life, in our livelihood or career or business. On an average the time spends around twelve hours daily in the work place i.e., one third of our entire life. This study was undertaken in order to find out the perception of the employees about influence the overall welfare measure.

Objectives:

1. To study the socio-economic and organizational profile of the employees in LIC of India, Salem Division.
2. To analyze the factors influencing Welfare measure among the employees in the study area.

Research design: The research design is the basic framework or a plan for a study that guides the collection
of data and analysis of data. Employee satisfaction and opinion about this study was used Descriptive Research Design in nature.

Method of Data Collection

Primary data: Primary data are those which are collected afresh and for the first time, and thus happen to be original in character. For collecting primary data OBSERVATION and QUESTIONNAIRE method are used.

Sampling Unit: The respondents of the study are part of population of employees of Life Insurance Corporation of India, Salem Division. Each employee is considered to be the sampling unit. For this purpose of study was conducted with 300 sample respondents of Life Insurance Corporation of India, Salem Division.

Sampling Method: Disproportionate Stratified random sampling is adopted to get insight about the study.

Descriptive analysis: Descriptive analysis also termed as percentage analysis were performed for each question contained in the interview schedule mainly to ascertain the distribution of respondents in the Life Insurance Corporation of India, Salem Division under each category.

Factor analysis: Factor analysis is an increasingly popular tool of the practicing business and research. It is two primary applications are (i) Simplifying a set of data by reducing the number of variables, and (ii) Identifying the underlying structure of dimensionality of the data.

Table 1: Age of the Respondents

Source: Primary Data

Welfare measures help to improve the Good will and public image of the LIC employees. It helps to improve employee productivity. Labor welfare includes various facilities, services and amenities provided to workers for improving their health, efficiency, economic betterment and social status.

Findings: In any institutions or organization, it was first and foremost to see the Welfare Measures taken. This factor when put forth among the selected respondents they revealed that they were satisfied with the welfare measures like satisfaction of education facilities, sanitary facilities, Drinking water facilities, recreational facilities, Canteen facilities, Housing facilities and Medical facilities. Sufficient and adequate infrastructure and work space should be provided to the employees in various branches in Salem Division. Improve the welfare measure & working environment in the LIC which in turn would increase the productivity among the employees.

Conclusion

Human Resource Management function today is much integrated and strategically involved. The most important task of the Human Resources Department is to make sure that the people working in the organization.
There are three basic needs of a man i.e. food, clothing and shelter. In order to fulfil their basic needs man has to work. Food, clothing and shelter could only be purchased by money and money could be earned by doing work. It improves the moral and mental conditions of the workers by providing facilities like games, cultural activities and recreation etc. By providing all these facilities, workers feel happy and become enthusiastic. Thus, worker starts taking much interest in his work, which leads to greater efficiency. To increase efficiency and productivity among workers. To earn goodwill and enhance public image.

A Study on Quality of Work of Life Practice in Chemical Industrial Units Sipcot in Cuddalore

M. Vetrivel¹, N. Manivanan¹

¹Assistant Professor, Department of Commerce, School of Management Studies & Commerce, VELS University, Chennai

Abstract

This study examines the relation between employees perceived Quality of Work Life (QWL) with life domains using spillover theory. For this study the subjects were employees from chemical industries at Cuddalore (SIPCOT). The QWL was measured using need satisfaction variables. The questionnaire was developed as to capture the needed information of the study variables. The sample size for this study was 227. The questionnaire was administered and reliability test was used to validate it. The regression analysis was done to find the level of influence on the dependent variables. The results showed that the employees who sensing higher level of QWL were sensing high level of job satisfaction, life satisfaction and general well-being. Fulfilling the needs of the employees by the organization can achieve higher level of QWL and organizational commitment from the employees.

Keywords: Quality of work Life (QWL), Job Satisfaction, Life Satisfaction, General Well-being, spill over.

Introduction

In the fast changing global market, all organizations have to face challenges and able to grab the opportunities; the dynamic organizations are surviving in the competition by making necessary changes in the working environment and policies.¹ The organizations need to have competent work force for constant improvement for achieving higher productivity. For any organization the success depends upon recruitment of individual, motivating and retaining of current workforce to maintain the organizational status in the competitive environment. Quality of Work Life (QWL) is the favorable working conditions and workplace environment that enhance employee satisfaction by providing growth opportunity, job security and with rewards.² QWL can be defined as the process of employees needs were addressed by an organization and the employees were included in the decision making process.

QWL can be expressed as the degree to which organizational members able to satisfy their important needs through with their experiences in the organization. QWL emphasizes to identify and to improve the quality of professional and personal life of the employees. QWL can be viewed as an individual’s evaluation of working life. When the employees has positive feelings towards the job and his prospects, is motivated and performs well. Many researchers experienced and demonstrated that improvement in quality of work life will increase in productivity and overall organizational effectiveness as also reducing absenteeism, grievances and industrial accidents.³

Research Methodology: In this study Spill Over theory was adopted and the Research Hypothesis were.

Hypothesis 1: Perceived high level of QWL is higher the job satisfaction level

Hypothesis 2: Perceived high level of QWL is higher the life satisfaction.

Hypothesis 3: Perceived high level of QWL is higher the well-being.

Hypothesis 4: Perceived high level of QWL is higher level of organizational commitment.

The six major contributing needs towards QWL was taken in to this study to measure QWL. The six needs were health & safety, family need, social need, esteem need, actualization need and knowledge need.⁴ The employees were requested to respond each item by 5 point Likert scale ranging 1 be the strongly disagree to
The employees were requested to respond each item by 5 point Likert scale ranging 1 be the strongly disagree to 5 be the strongly agree. The employees were requested to respond which they experienced during the previous two months by 5 point Likert scale ranging 1 be the strongly disagree to 5 be the strongly agree. The employees were requested to respond each item by 5 point Likert scale ranging 1 be the strongly disagree to 5 be the strongly agree. A total of 227 subjects from chemical industries SIPCOT from cuddalore were participated in this study.

A covering letter was attached with the questionnaire stating the confidentiality of their response and mentioned the objectives of the study. The participation in this study was made as voluntary. The questionnaire were distributed and collected personally.

**Data Analysis and Interpretations:** There were 18 percent of respondents age were less than 25 years, 22 percent of respondents belong to 25-30 age groups, 32 percent of respondents belong to 31-40 age groups, 17 percent of respondents belong to 41-50 age groups and 11 percent of respondents belong to 51 years and above. 13 percent of respondent’s education was ITI, 34 percent of respondents were Diploma holders, 32 percent of respondents were Undergraduates and 21 percent of respondents were Master’s degree holders. The sample respondents were considered as fairly educated. 15 percent of the respondents were working in the current organization for less than one year, 31 percent of respondents were working in the current organization for the period of 1-3 years, 23 percent of respondents were working in the current organization for the period of 4-6 years, 13 percent of respondents were working in the current organization for the period of 7-9 years, 18 percent of respondents were working in the current organization for 10 years and above.

Table 1 presents the mean value, standard deviation and the reliability alpha value for the study variables. Among the six needs, Health and Safety need was highest on 5 point scale. Knowledge need was at the second position and Social need was at the third position. The standardized alpha values showing that the questionnaire was reliable and it has the ability to capture data for the study. The mean values for Job Satisfaction, Life satisfaction and General well-being are showing that all the companies were providing similar facilities and maintaining above average. It is a positive sign for the human resource practices in the industries.

</tbody>
</table>

** Significant at 0.01 Level (2-tailed) N=227

The multiple regression analysis were present in the table 3. The six need as measures of QWL were taken as dependent variables, job satisfaction, general well-being and organization commitment were taken as dependent variables.

From the regression analysis, the significant predictors for job satisfaction were family need, health and safety need and knowledge need. A high level of satisfaction on known need was a strong predictor for job satisfaction. The ability to develop professional skills is an important elements for employees to feel the job satisfaction. Job security, higher level of wages and family needs were strongly related to job satisfaction. The results was showing that the stated relationship, perceived higher level of quality of work life is higher the job satisfaction level is significant.

From the table 3 using spillover theories the hypothesis was stated as perceived higher level of quality of work life higher the life satisfaction. This hypothesis was accepted and the individual who perceiving higher QWL tend to experience life satisfaction. The results shows that esteem need was the prime predictor for life satisfaction.

Result from the regression analyses support the stated hypothesis, perceived high level of QWL is higher the well-being. The satisfaction on needs spill over in to employees sense of well-being. The major predictor’s health and safety need is positively associated with general well-being. But the two major predictors, family need and actualization need are negatively associated with general well-being. This negative relationship is explained by equity theory.

The regression result supports the hypothesis of perceived high level of quality of work life is higher level of organizational commitment. From the table 3 knowledge need predicts most of the variance in the organization commitment. The organization has to fill the learning and knowledge needs to get higher level of organization commitment.

### Conclusion

The analyses were supporting the stated hypothesis. It supports the spill over theory as employees satisfaction in one life domain is positively influence in other life domains. The needs are major contributor in quality of work life, sensing of QWL leads to sense job satisfaction, the satisfaction and general well-being.\(^5\) Fulfilling the needs of the employees by the organization can achieve higher level of quality of work life and organizational commitment the employees.

A Study on Role of Industrialization for Sustainable Development and Poverty Eradication

N. Manivannan¹, M.Vetrivel¹, A.G. Vijayanarayanan²

¹Assistant Professor, ²Associate Professor, Department of Commerce (CA), VELS Institute of Science, Technology and Advanced Studies (VISTAS), Pallavaram, Chennai

Abstract

This study is a role of industrialization for sustainable development and poverty eradication, this study is related for how to promote the organizational performance from the lower level to higher level. The level of promotion is based on human resources and also the efforts of organizational authority. The authorized persons has the ideas for long term growth with the sustainable development, the developmental process must to eradicate the poverty form the society. Initially, a pilot study was conducted among few respondents and changes were brought in the questionnaire. Analysis and Interpretation is done using Chi-square method. It was found out that people gives his opinion about the industrialization is for sustainable development and poverty eradication are from the personal thoughts. Based on the findings, appropriate suggestions have been made for increasing the number of users.

Keywords: Industrialization, Poverty Eradication, Growth of Economic.

Introduction

Indian country is an industrially developing one; so many industries are working on the basis of human resources only. The human resources are incomparable and also unbeatable one. Which country is giving priority to the industries they are developed easy to the world level? The industrially developing country concentrates for sustainable development and also eradication of poverty to the general people.¹ The emerging development of job opportunities is given only by the reason of industrialization. The industrially developed countries are ready to compete with globally. The global level competition is basically related for the knowing factors of promotion. The educational motivation has to give a good result of the industries development. This type of development is concentrating the reduction of poverty of the people.²

Industrialization for Sustainable Development:

Industrialization enables mankind to do more with less. Instead of one man taking days to plow his field with one horse, he can do it in a couple of hours with the help a tractor that has the power of hundreds of horses. That frees up his time to do more work around the farm, and maybe even take a vacation, and it frees up his family so his kids can go to college and work in professions that require less backbreaking work than he had to do. sustainable development’ Its definition of “development which meets the needs of the present without compromising the ability of future generations to meet their own needs” still provides the broad underpinning for current thinking and practice, based on balancing people’s economic and social needs with the preservation and enhancement of natural resources and ecosystems.³

Institutional Change and Technology:

The main institution for industrialization is GATT (General Agreement on Tariffs and Trade) was a legal overall purpose was to promote international trade by reducing or eliminating trade barriers such as tariffs or quotas. According to its preamble, its purpose was the “sustainable reduction of tariffs and other barriers and the elimination of preference on a reciprocal and mutually advantageous basis.”³ The TRIMs (Trade-
Related Investment Measures) and TRIPS (Trade-Related Aspects of Intellectual Property Rights) are participating higher level of industrialization. The technological development in India is also a reason for promotion industries and also the eradication poverty. The industrial technology is the use of faster production, simple and efficient. The technological advancement helps a company achieve efficient and profitable productivity. The modernization of technology, machine and tools also going to give good result of industrialization.5

**How to Eradicate the Poverty:** This year’s theme for the International Day for the Eradication of Poverty, “Answering the Call to End Poverty: A path toward peaceful and inclusive societies”, celebrates the 25 year anniversary of the creation of this international day and the idea behind it: that hunger, lack of education, and violence are not inevitable. That extreme poverty must be something we all strive to eradicate. The first and foremost step of the industrialization is eradication of poverty in the society.6 The recent development of employment opportunities all are to be followed by the family situation and also personal like. The earning of individual income or per capita income is basic for economic development of the nation. The national income is basically fix a target for removed poverty from the society.7

**Challenges of Future Industrialization:** In the modern society technology advancement is a developing one because of number of industries are followed a recent technology in his business. The financially developed organisation are utilized a technology in a perfect way. But most of the organisation not having a enough money to modernization of technology. Most of the organisation are ready to adopt an upgradation technology in future days. So all the organisation must try to know about what are the updated technology available in the society and also the how to handle the technology8. The human efficiency about the handling of technology without wasting of time and also the energy. The energy saving actions also gives a good result about the upgradation of organisation. The challenges of future are fully based on the effective utilization full resources into his organisation.

**Objectives of the Study:**

- The main theme of the study is updating of recently developed technology.
- The organisation development is to give priority to the eradication of poverty.
- To find out the kinds of human resources and technical source are to be needed in the organisation.

**Sampling Method:** Since the population is large in number, the researcher undertook a sample survey. Convenient sampling method has been adopted to collect data from customers. The sample size 500 respondents.

**Scope of the Study:**

- The promotional activities are never to disturb the other organisational activities.
- The industrial development is only based adoptability of the individual capability.
- The promotional activities are to be concentrated for the growth of organisation not for the individual growth.

**Limitations of the Study**

- To frame certain rules and regulations are followed effectively not for namely.
- To convey the real result into the society, so we are observe the daily activity of the organisation.
- The organisation should be implemented by assessing the training and development requirements of employees
- The organisation needs implementation of programmes by the way of gradually not for suddenly.

</table>
Since the calculated value of Chi Square is greater than the table value of $X^2$, $H_0$ is rejected. So the employees’ age group is influenced by the package system in the form of industrialization. Hence there is evidence of association between age group of the respondent and Salary package system in the form of industrialisation.

Findings:

- Most of the respondents are too participated in the newly adopted rules and regulation related for upgradation.
- The study is finding a real result of salary and also wage is reasonable in the present situation.
- Most of them need for eradicate the poverty in his life with the satisfied working conditions.
- Most of the employees are in the age group of middle, because of all are understand the importance industrial development in the society.

Suggestions:
The human resources are effectively utilised for the industrial development with the available nature of working areas. Most of the people want to introduce a newly developed technology without delay. The duration of time period is no longer for changing of ownership, because of the changes of ownership is create a zero percentage of interest from the working people. This type of study is creating a favor about the technology development and also the sustainable growth of the organisation. The training and developmental process are too framed in correct manner and utilized in time, it gives a role model of the followed organisation. The organisation must have a rights to coordinate the people and also discuss with them getting further movement by the management. The further step of the management is give part and partial portion of their employees because of this industrialisation is to eliminate the poverty. The organisation must to create an employment opportunities to general public and the awareness about the industrialization.
Conclusion

Finally the sustainable growth of the organisation gives a way of globalization of the organisation. The organisational performance in the hands of human empowerment. The human efforts give a result of the industrial growth, these kinds of activity is based on transfer a business from one stage to next stage. The stages of organizational development must to provide a suitable way for modernisation. The poverty of the general public can be eliminated very easily with help of industrialisation.

A Study on Occupational Health Hazards among IT Sector Women Employees in Tamil Nadu

R. Lakshmi¹, M. Vetrivel¹, R.V. Suganya²

¹Associate Professor, ²Assistant Professor, Department of Commerce, School of Management Studies & Commerce, VELS University, Chennai

Abstract

In view of this healthcare importance, the real economic growth rate depends on the quality of human life especially in improving the women’s standard of living around the world. At present, a large number of women are working in all sectors viz., primary sector, secondary sector and service sector in both the rural and urban areas. Further, they are actively participating in each and every job and express their knowledge and capacity to the society. However, most of the women are dominated by men and are affected psychologically and are under pressure in their work places. The term occupational hazards refer to a risk accepted as a consequence of a particular occupation. Regarding the occupational problems, the women employees in IT sector are facing health hazards like eye fatigue, headache, thyroid problem and others. It could be seen that over a past decade, a large number of women employees in IT sector suffer from heart related diseases. Moreover, the Poor health creates huge strain on physical and mental pressure in working places. At present, the large numbers of women employees also face many social, cultural and economic challenges. Hence, this study is an attempt to identify and analyse the reasons that affects the health of IT sector women employee respondents and give suitable measures to reduce the work related stress in IT sector among women employee respondents. Further, this study focused on primary data and the tools of analyses with using statistical techniques like percentages, t-test and rank value method. As a result found that, the urban area women respondents are highly affected as compared to that of rural area women respondents among the IT sector field. By and large, the study suggested that spiritual meditation is a way to help the reducing stress in psychologically and work related stress reduced through improving communication and technical skill.

Keywords: Women empowerment, health, IT sector, stress, economic development, communication skill, spiritual meditation.

Introduction

In view of this healthcare importance, the real economic growth rate is based on to develop the quality of human life and especially to improve the women’s standard of living around the world. The human development report (1995) stated that the basic capability for human development are living a long and healthy life, being educated and better standard of living in a society.¹ At present, a large number of women are working in all sectors like primary sector, secondary sector and service sector in which both rural and urban areas. Further, they are actively participating in each and every job and exposure their knowledge and capacity to the society. However, most of them women are conquered by men and they are affected in both psychology and mental pressure in working places.² The term occupational hazards refers to the stress related to the works require to be addressed without any delay. Regarding the occupational problems, the software women employees are facing continuously like eye fatigue, headache, thyroid problem and others. It could be seen that over a past decade, a huge number of software women employees are suffered due to heart diseases. Moreover, the Poor health creates huge strain on physical and mental pressure in working places. The term occupational hazards refer to a risk accepted as a consequence of a particular occupation. Regarding the occupational problems, the software women employees are facing health hazards like eye fatigue, headache, thyroid problem and others. It could be seen that over a past decade, a large number of software women employees suffer from heart related diseases. Moreover, the Poor health creates huge strain on physical and mental pressure in working places. At present, the large numbers of software employees also face many social, cultural and economic challenges. Hence, this study is an attempt to identify and analyse the reasons that affects the health of software women employee respondents and give suitable measures to reduce the work related stress in software sector among software employee respondents. Further, this study focused on primary data and the tools of analyses with using statistical techniques like percentages, t-test and rank value method. As a result found that, the urban area software respondents are highly affected as compared to that of rural area software respondents among the software sector field. By and large, the study suggested that spiritual meditation is a way to help the reducing stress in psychologically and work related stress reduced through improving communication and technical skill.

mental pressure in working places. At present, the large numbers of women employees are facing many problems from different directions like social problems, cultural problems, and economic problems. More specifically, women are not only facing problems in working places and from her homes also. But some of them are actively participated in domestic work like cooking, washing, drawing water, preparing food and so on. Additionally, the physical health was majorly suffered due to that insufficient sleep as regularly. Meantime, without yoga activity may be disturbed their psychological feelings also. The adverse impact of health is one of the major problems to makes gender equities in the society. In view of these all problems, maintaining health nutrition, and yoga and exercises, proper training and improving knowledge, good sleeping, and air conditioner facilities are the major solution to reduce their stress in software industries. Hence, the present study makes an attempt to analyze the health hazards among IT sector women employees in Tamil Nadu.

Objectives:
1. To analyse the reasons for health affect in IT sector women employee respondents in selected region.
2. To suggest the suitable measures to prevent the work related stress in IT sector.

Hypothesis: Rural area women employees are majorly affected as compared to urban area women employees in IT sector.

Methodology

Drawn from the present study has been focused on primary data and it involves a multi-stage sampling method. Further, the present study is covered four stages and the accurate information is derived from the field of inquiry in IT sector, Chennai city, Tamil Nadu: (i) Selection of Chennai district in Tamil Nadu, (ii) Selection of major towns’ viz., Ambattur, Thiyagarayanagar, Kodambakkam and Nungambakkam in Chennai district (iii) Selection of few software industries in selected areas, (iv) Selection of rural area and urban area women employee respondents according to Tamil Nadu state and Other States in software sector. Among these four stages of investigation, 115 sample respondents are selected for the present study. In which, 63 respondents are collected from Tamil Nadu state and the remaining 52 respondents are collected from other states viz., Kerala, Bangalore, Sikkim, etc. Out of these 63 women respondents in Tamil Nadu, 27 respondents belonging to rural areas and the remaining 36 respondents are belonging to urban areas. On the other hand, out of 52 respondents in other states women respondents, 23 respondents are belonging to rural areas and the remaining 29 respondents are belonging to urban areas. In whole, 50 respondents are from rural area respondents and the remaining 65 respondents are from urban area respondents. Moreover, the present study is used by the convenient sampling method and the period covers from 2017-2018.

Tools for Data Analysis:
1. To analyse the reasons for health affect in IT sector women employee respondents, rank analysis and t-test analysis have been applied.
2. To identify the major factors to prevent the work related stress in IT sector, the percentage analysis has been employed.

Table 1 analyzes the causes of work related stress with the help of utilizing the rank analysis method. Among the ranking method and estimating the mean value in rural area, most of the respondents are highly suffered by health issues under working in software sector which constitute the mean value at 8.98, followed by poor working places (8.30), problems with co-workers (8.23), family issues (7.98), gender discrimination (7.70), Heavy workload (7.64), age discrimination (7.23), could not provide maternity leave (7.18), sexual harassment (6.99), wage discrimination (6.92), working in night shift (6.78), and the remaining unable to achieve their target (5.78). In the case of urban area by using the mean value with the help of ranking method, the mean value is highly recorded in health issues (9.94), followed by the family issues (8.90), problem with co-workers (8.89), working in night shift (8.01), poor working places (7.80), heavy workload pressure (7.23), unable to achieve their target (7.20), wage discrimination (6.94), gender discrimination (6.89), age discrimination (6.80), could not provide maternity leave (6.78) and the remaining sexual harassment (6.21). As a result found that both rural and urban areas women respondents, health issues and health problems are mainly dominated the job related stress in the study area.

Table 2 examines the job related stress with testing of t-test analysis. The null hypothesis is based on “rural area women respondents are highly affected in work related stress with compared to urban area women respondents”. The following results are mentioned the rural area respondents are highly suffered in job related stress with compared to urban area respondents. Age discrimination is found to statistically significant at 1% level, and the remaining factors are statistically significant at 5% level viz., heavy workload pressure, family issues, health problems, problem with co-worker, sexual harassment and working in night shift are found to be highly affected in rural area as compared to urban area respondents. Hence, accept the null hypothesis for the above mentioned factors. Rests of them, wage discrimination, gender discrimination, unable to achieve their target, could not provide maternity leave and the remaining poor working places are not significant. As a result found that, the urban area respondents are highly affected in these mentioned factors as compared to that of rural area women respondents. Hence, reject the null hypothesis for above the mentioned factors and accepted alternative hypothesis.

Source: Computed  
Table 3 interprets the impact on personal stress among IT sector women employees. It is seen that the rural area women respondents are highly affected due to the personal stress as compared to urban area respondents. The personal stress factors such as child care, family issues, and personal financial burden are statistically not significant at 5% or 1% level. Thus it leads to accept the alternative hypothesis i.e., urban area women respondents are highly affected in personal stress as compared to rural area respondents.

</table>
Source: Computed; Figures in Parentheses denote percentages

Table 4 exhibits the factors attributing to prevent the work related stress among IT sector women employees in selected region. It is seen that more than three fourth of the respondents are stated that agree with spiritual meditation may reduce the work related stress which constitute 86.1 percent, followed by 83.5 percent of them where recorded group discussion with other employees, nearly three fourth of the respondents (72.2 %) are agree with yoga and/or exercises may reduce the work related stress, 71.3 percent of them recorded that improving communication and technical skills and the least recorded by the proper training method at 67.8 percent in selected region. It is noticed that on the table, spiritual meditation and group discussion may reduce the work related stress among IT sector women employees.

Policy Suggestions:

1. Protecting the women employees for the long hours of work in the software sector. Because the long hours of work due to increase the physical stresses and psychological stresses. Hence, all the software institutional should banned the long hours of work.
2. Improve the gender sensitive related and monitor progress about regulatory framework, software technologies and labour policies, and create infrastructural facilities are drawn it by the regulatory information as follow the ICT policies.
3. Improve the software mechanisms monitor the progress and to encourage gender development in IT field.
4. All the software institutions should strengthen their capacity through technical support, gender equality and ICT.
5. All the software institutions should provide the training facilities to the employees for improving the technical and communication skills and create more employment opportunities.
6. Government should promote software technologies, because it gives more taxation to the central and state Governments.
7. Government should collaborate with ICT sector. Because recently number of people depend on the software technologies. If the Government...
undertakes the ICT, it will helpful to increase the most employment opportunities.

Verrucous Carcinoma: A Case Report

Malathi L.1, Masthan K.M.K.2, Sudha Jimson3, Hemasri V.4

1Reader, 2Professor & Head, 3Associate Professor, 4Tutor, Dept of Oral Pathology
Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education and Research

Abstract

Verrucous carcinoma is a variant of squamous cell carcinoma. It most typically affects the mouth with buccal mucous membrane being the most typical site affected. Clinically its proliferative finger like projections or a cauliflower like growth could be a typical feature towards diagnosis. It’s more common in tobacco user and more predilection in males. The histopathological diagnosis of verrucous carcinoma is quite difficult and need immense expertise to report a case of verrucous carcinoma. Though verrucous carcinoma is a benign lesion with minimum aggressive potential however long standing cases shows transformation into squamous cell carcinoma. Here in we discuss the clinical and histopathological finding of the case of 80 year old male patient with oral verrucous carcinoma on buccal sulcus as a differential diagnosis with possible etiology, management of the lesion.

Keywords: Verrucous carcinoma, buccal mucosa, incisional biopsy, cauliflower like growth.

Introduction

Oral Verrucous carcinoma is a variant of squamous cell carcinomawhich was 1st delineated by Lauren V Ackermann in 1948 therefore it was called ‘Verrucous malignant neoplastic disease of Ackermann” or “Ackermann’s Tumor”1. Different names utilized in literature are Buschke-Loewenstein tumour, florid oral papillomatosis, epitheliomacuniculatum, and carcinoma cuniculatum2. Common site of incidence is mouth, other sites being pyriform sinus, larynx, nasal cavity, esophagus, external auditory canal, paranasal sinuses, legs, scrotum, skin, perineum, penis, vulva, vagina, and uterine cervix3, 4. Oral verrucous carcinoma features a predilection for male in sixth decade with a slow growing rate and becomes regionally invasive if not treated properly. But, there is a rare distant metastasis6. Clinically, it is featured as a plaque like lesion with finger like projections resembling cauliflower5. Any type of Tobacco as smoking and smokeless type, alcohol and opportunist infective agent, infections are the foremost associated etiologies with Oral Verrucous Carcinoma6, 7. So early diagnosis and surgical excision of the lesion is the most appropriate treatment modality of verrucous carcinoma.

Case Report: An 80 year old male patient reported with a painful growth in the right buccal mucosa for the past 3 months. Patient had a habit of betel nut chewing since 40 years, 5-6 times/day. On general examination patient had normal gait posture, well oriented, moderately built and conscious. No evidence of icterus, pallor, cyanosis, clubbing was present. Single left submandibular lymph node was palpable and was firm, mobile and tender on palpation. Clinical intra oral examination revealed a soft growth of 2x1.5 cm in size, well defined with irregular margins pedunculated, irregular surface with finger like projections in the center, color was erythematous in the periphery and white in the center. On palpation, the growth was elevated from adjacent mucosa and tender. Based on the clinical examination a provisional diagnosis of erythroleukoplakia and verrucous leukoplakia was given and Differential diagnosis of verrucous hyperplasia and verrucous carcinoma, was considered. To confirm the diagnosis, an incisional biopsy was taken, The histological cut was performed

and stained in hematoxylin and eosin. The hematoxylin and eosin stained histopathological section of the given specimen showed hyperplastic parakeratinized stratified squamous epithelium with underlying connective tissue stroma. Wide elongated reteridges are seen with pushing margins. Parakeratin plugging was seen (fig-1). Pseudoepitheliomatous hyperplasia was noticed (fig-2). The fibrous connective shows moderate cellularity and diffuse mild chronic inflammatory cell infiltrate with increased vascularity. Therefore, the histopathology diagnosis confirmed the diagnosis of verrucous carcinoma.

Fig 1: Histopathology image showing parakeratin plugging

Fig 2: Histopathology image showing pseudoepitheliomatous hyperplasia

Discussion

Verrucous carcinoma, as mentioned most typically affects older male with adverse habits of tobacco and alcohol6. Lesions usually develop at the location wherever the tobacco is placed habitually8. In Ackerman’s study, eleven out of eighteen patients (61%) with squamous cell carcinoma of buccal mucosa were tobacco chewers. Other etiologic factors like poor dental hygiene, ill-fitting dentures, low socioeconomic status, tobacco chew, snuff, alcohol use, and smoking also causes verrucous carcinoma6,8,10. Some of the similar factors that predispose people to the event of premalignant lesions like, submucous fibrosis (SMF), erythroplakia and leukoplakia1. Untreated long standing leukoplakia has been reported to transform into Verrucous Carcinoma12. Oral verrucous carcinoma are largely massive, exophytic, soft, and fungating growth with pebbly surface having regionally aggressive nature, Enlarge lymph nodes are typically palpable.9 Diagnosis of verrucous carcinoma histopathologically is quite difficult and needs expertise to diagnose.

The term “ verrucous” was applied for lesions showing a exophytic keratotic surface composed of blunt or sharp epithelial projections with keratin-filled invaginations (plugging). The microscopic anatomy of Verrucous Carcinoma, for instance, verrucous surface and “elephant feet” like down growth superficial to compress the underlying connective tissue and usually showing least or absent cytologic atypia is seen12. By flow cytometry, Verrucous Carcinoma could be a diploid lesion; on the contrary, the traditional squamous cell cancer typically shows genomic instability and aneuploidy16. As a result of its benign cytological features, besides the focal basal cell nuclear hyperchromatism, distinction from Verrucous carcinoma and verrucous hyperplasia (VH) can’t be primarily based solely on microscopic anatomy features17,18. Differential diagnosis of verrucous carcinoma includes: (i) Proliferative verrucous leukoplakia, (ii) squamous cell carcinoma showing verrucoid feature (iii) verruca vulgaris (iv) keratoacanthoma. (v) Pseudoepitheliomatous hyperplasia19. The simplest treatment modality of Verrucous Carcinoma is surgical resection20. So, the patient is additionally suggested for surgical removal of the lesion and regular follow up. Although Verrucous Carcinoma doesn’t show distant metastasis, supra omohyoid neck dissection is usually considered20. Recurrence of lesion is because of improper section, false negative frozen section report and generally as a result of the slow growth pattern surgical margins are compromised9,13,22. The presence of carcinoma in place of clinically improper resections will lead to the development of recurrence of invasive cancer in apparently traditional epithelial tissue or previous excision sites21. Radiation therapy is contraindicated in treatment of Verrucous Carcinoma as radiation induced anaplastic transformation.
Conclusion

In most of the cases verrucous hyperplasia, verrucous carcinoma, verrucous keratosis are clinically indistinguishable from each other. Thus histopathological proof is important to allow an acceptable diagnosis. Verrucous carcinoma presents as thick verrucous keratotic lesion that is additional common in males and is typically painless. Verrucous Carcinoma related to leukoplakia or submucous fibrosis is also a sign of “field cancerization” and might cause multiple recurrences, therefore it’s extremely suggestive, that such patients should be kept under regular follow up.

Evaluation of Degree of Relationship of Insulin to LH, Testosterone and SHBG in Various PCOS Groups Categorized on the Basis of Altered LH: FSH Ratios

Malini N.A.1, Roy George K.2

1Research Scholar in Zoology, 2Assistant Professor, Head, & Research Guide, Post-Graduate and Research Department of Zoology, St. Thomas College Kozhencherry, Kerala, India

Abstract

Context: Polycystic ovary syndrome (PCOS) is a highly prevalent cause of female infertility.

Objective: This study aimed to detect effect of insulin on LH, testosterone and SHBG of various PCOS groups. Experimental design: A total of 745 women who were subjected to infertility treatment at infertility clinics were selected. About 50 healthy females with regular menstrual cycles were considered as control. The data were collected from hospital records using subject’s written informed consent.

Results: Relationship of insulin to LH and testosterone was positive and significant only in (p<0.05) in entire PCOD group and PCO subgroups with LH: FSH ratios 1.1-1.5, 1.6-2.5, 2.6-3.5, 3.6-4.5 and 4.6-5.5. The degree of relationship was strong and showed a gradation from lower to higher ranges of LH: FSH ratios. Correlation between insulin and SHBG was inverse and significant (p<0.05) in all PCOD subgroups except in subgroups with LH: FSH ratios <1 and 1. A strong positive relationship was observed between insulin and SHBG in control group. The degree of inverse relationship was strong in PCOD subgroups with higher ranges of LH: FSH ratios.

Conclusion: This study concluded effect of insulin on LH, testosterone and SHBG of various PCOS groups in terms of degree of relationship.

Keywords: Insulin resistance; hyperinsulinemia; hyperandrogenism; body mass index; SHBG.

Introduction

Polycystic ovary syndrome (PCOS) is one of the most common causes of female infertility affecting 6-8% of reproductive age women and is represented by hyperandrogenism, oligo-anovulation, and polycystic ovarian morphology on ultra sound1,2. This syndrome is also associated with insulin resistance, obesity, hyperinsulinemia, diabetes mellitus and cardio vascular disease.

Severe insulin resistance depicts up to 90% of women with PCOS further than that expected by their body mass index (BMI)3. In fact, even lean women with PCOS have increased insulin resistance in comparison to BMI-matched controls4. Regarding insulin secretion, numerous studies have assessed β-cell function in PCOS, yet the results are ambiguous. Researchers reported that there is a defect in the glucose-stimulated insulin secretion5, but other studies have found that insulin response is increased in PCOS women, probable as a compensation for the peripheral insulin resistance6. The present study aimed to evaluate the degree of relationship of insulin to LH, testosterone and SHBG in control and various PCOS groups.

Study design: It was a hospital data-based cross-sectional study done in specialist infertility clinics in central Travancore region of Kerala. A total of 745
consecutive subjects (aged 28.11 ± 0.2) with complaints and symptoms suggestive of PCOS participated in the study. They were categorized into seven subgroups on the basis of different ranges of LH: FSH ratios. The control subjects (Group I) consisted of 50 healthy volunteer females with regular menstrual cycles aged 27.58 ± 0.4. The subgroups of PCOD were PCOD with LH: FSH ratio 1 (Group II), PCOD with LH: FSH ratio < 1 (Group III), PCOD with LH: FSH ratio 1.1-1.5 (Group IV), PCOD with LH: FSH ratio 1.6-2.5 (Group V), PCOD with LH: FSH ratio 2.6-3.5 (Group VI), PCOD with LH: FSH ratio 3.6-4.5 (Group VII) and PCOD with LH: FSH ratio 4.6-5.5 (Group-VIII). Control subjects had regular ovulatory cycles and no signs of polycystic ovaries on ultrasound. All women participated in the study provided written informed consent for collecting their reports from medical records. The data regarding endocrine parameters of PCOS subjects and control were collected.

**Statistical Analysis:** The statistical Package for Social Sciences (SPSS 16.0 version for windows) was used for all data analysis. Pearson correlation and Fisher’s Z transformation test were conducted to interpret the effect of insulin on LH, testosterone and SHBG in various PCOS subgroups and control subjects. Statistical significance was accepted at p<0.05.

*significant (p<0.05)

The relationship between insulin and LH was not significant in control (Group I) and two PCOS sub groups namely PCOD with LH: FSH ratio 1 (Group II) and PCOD with LH: FSH ratio < 1 (Group III). Conversely a significant (p<0.05) positive correlation was observed between insulin and LH in PCOD with LH:FSH ratio 1.1-1.5 (Group IV), PCOD with LH:FSH ratio 1.6-2.5 (Group V), PCOD with LH:FSH ratio 2.6-3.5 (Group VI), PCOD with LH:FSH ratio 3.6-4.5 (Group VII), PCOD with LH:FSH ratio 4.6-5.5 (Group VIII) and whole PCOS groups. Moreover, the degree of positive relationship between insulin and LH showed a gradation pattern from group IV to group VIII (.547, .594, .602, .626 and .695) of these PCOS subgroups with increase in LH: FSH ratio (Table 1). Similarly, the relationship of insulin to testosterone and SHBG was not significant in control (Group I) and PCO subgroups including PCOD with LH: FSH ratio 1 (Group II) and PCOD with LH: FSH ratio < 1 (Group III) and significant in the remaining PCOD sub groups and whole PCOS group (Table1). Also, the correlation between insulin and testosterone was positive and showed the similar increasing pattern (.664, .767, .805, .808 and .830) from group IV to group VIII as in the case of correlation between insulin and LH. However, the relationship between insulin and SHBG was inverse in PCO subgroups except in PCOD with LH: FSH ratio < 1 (Group III). The degree of inverse relationship also exhibited a progression (-.658, -.747, and -.830) from group VI to group VIII (Table 1).
Table 2. Comparison of significance of difference between control and various PCOS groups with respect to correlation coefficients (regarding insulin to LH, testosterone and SHBG) using Fisher’s Z transformation test.

*significant (p<0.05)

The effect of insulin on LH and testosterone was significantly (p<0.05) higher in PCO sub groups comprising PCOD with LH: FSH ratio 1.1-1.5 (Gp IV), PCOD with LH: FSH ratio 1.6-2.5 (Gp V), PCOD with LH: FSH ratio 2.6-3.5 (Gp VI), PCOD with LH: FSH ratio 3.6-4.5 (Gp VII), PCOD with LH: FSH ratio 4.6-5.5 (Gp VIII) and whole PCOS group (Table 2) when compared to control. However, the effect of insulin on SHBG was significant (p<0.05) in all PCO subgroups except Gp II comprises PCOD with LH: FSH ratio 1, when compared to control. The effect was also significant (p<0.05) in whole PCOS group in comparison to control.

**Discussion**

The aim of this prospective study was to assess the influence of insulin on LH, testosterone and SHBG in various PCOS groups differentiated on the basis of LH: FSH ratios, which were not done in earlier studies. We hypothesized that elevated insulin levels exert their effect on other hormones to develop hormonal imbalances in PCOS. In our study insulin influences LH and testosterone levels which are markedly higher in these PCOS subgroups with elevated LH: FSH ratios. LH and testosterone levels increase with increase in the level of insulin in PCOS subjects when compared to control. Moreover, the degree of positive relationship of insulin to LH and testosterone showed a gradation from group IV to group VIII of PCO subgroups i.e. this study showed that higher the LH: FSH ratio, higher will be the degree of relationship. Also degree of relationship was feeble in PCO sub groups having LH: FSH ratios 1 and <1 i.e. lower the LH: FSH ratio lower will be the degree of relationship. The amount of relationship is associated with increase in the range of LH: FSH ratios and PCO subgroups were categorized on that basis. When considering PCOS as a heterogeneous group, the degree of relationship was not higher as in PCO subgroups with identical and elevated LH: FSH ratios.

Insulin and intraovarian insulin-like growth factor type I (IGF-I) may enhance the activities of both follicle stimulating hormone (FSH) and luteinizing hormone (LH) in triggering biochemical luteinization and enhancing steroidogenesis. Insulin may act a role in the occurrence of the usual augmented amplitude and frequency of GnRH and LH pulse secretion found in PCOS. Undoubtedly, increase of LH and GnRH secretion as a consequence of insulin infusion has been detected in vitro, together in dose dependent and time-dependent modes. This influence may be intervened by insulin in GnRH-secreting cells of the hypothalamus, by stimulating GnRH gene transcription through the MAPK pathway. Accordingly, elevated GnRH synthesis and secretion bring about later increase of LH levels. This constant stimulation would decipher into amplified synthesis of ovarian steroid hormones, mainly androgens. Likewise, insulin enhances testosterone levels of PCOS subjects in this study. Thus increase in the level of testosterone is associated with increasing insulin levels and consequent increase in LH levels observed in this study. In this case also, the amount of relationship between insulin and testosterone was higher in groups consisting of PCOD with LH: FSH ratios 1.6-2.5, 2.6-3.5, 3.6-4.5 and 4.6-5.5 than the entire PCOD group.
Researchers\textsuperscript{10} reported a steady increase in the mean levels of insulin and testosterone with the corresponding increase in LH: FSH ratios in various PCO subgroups. This study has prompted our conclusion that insulin definitely played a putative role in generating gonadotropin dysfunction and steroid hormone imbalance in PCOS. Insulin seems to play in collaboration with LH to raise intracellular concentration of cAMP, which triggers steroidogenic acute regulatory (STAR) protein, stimulating steroidogenic action. Though this influence may be straight via the PI3K pathway, the demand of cAMP for this process implies deviation from the normal insulin cascade; however the discrepancies in molecular interactions are unidentified\textsuperscript{11}. Likewise, the combined action of insulin and LH elevate transcription of LDL-C receptors in GC by means of the PKA, PI3K, and MAPK pathways. Conversely, insulin may also increase steroid synthesis through aromatase up regulation in GC, which would serve as substrates for theca cells for further conversion into androgens\textsuperscript{12}.

In accord with earlier findings we observed an inverse relationship between insulin and SHBG concentration\textsuperscript{13}. Also the degree of negative relationship is very higher in PCO subgroups consisting of subjects with same and elevated ranges of LH: FSH ratios than the entire PCOD group with different ranges of LH: FSH ratios. However, a moderate inverse relationship (-.437) was observed in PCOD with LH: FSH ratio 1 and very lower positive relationship was established in PCOS subgroup with LH: FSH ratio<1. Strong positive relationship between insulin and SHBG was detected in control subjects.

The decrease in the level of SHBG can be attributed to increased insulin levels and the resultant increase in LH and testosterone levels. Insulin seems to suppress sex hormone binding globulin (SHBG) levels of PCOS subjects. Lower SHBG concentration was observed in PCOS with elevated insulin, in comparison to the control subjects. Correlations between lower SHBG concentrations and hyperinsulinemia have reported mutually in health and hyperinsulinemic conditions such as PCOS and type 2 diabetes\textsuperscript{14}. This strong relationship has incited inferences that a low level of SHBG could be used as an indicator to recognize individuals with insulin resistance\textsuperscript{15}.

**Conclusion**

The present study concluded that insulin may influence LH, testosterone and SHBG levels in PCOS subjects of this study. The effect of insulin on these hormones in terms of degree of relationship was more noticeable and higher in PCO subgroups having identical increased ranges of LH: FSH ratios than the heterogeneous whole PCO group with diverse ranges of LH: FSH ratios.

Abstract

Non-communicable diseases (NCDs) are defined as diseases of long duration, and are generally slow in progression. NCDs kill more than 36 million people each year. Nearly 80% of NCD deaths-29 million-occur in low-and middle-income countries. They share four risk factors: tobacco use, physical inactivity, the harmful use of alcohol and unhealthy diets. This study aims on NCDs and its risk factors with special focus on CVDs and Diabetes among the employees of aviation sector at NSCBI Airport, Kolkata. Obesity, Hypertension, Diabetes and Metabolic syndrome are predominant among the employees in the age group of 35 and above. Four risk factors such as tobacco use, physical inactivity, the harmful use of alcohol and unhealthy diet were found predominant among the employees. There is an urgent need of health awareness and health promotion activities at employee level and workplace level with special focus on health diet, physical activities and behavioural risk factors.

Keywords: Non-communicable diseases, Obesity, Hypertension, Diabetes, Metabolic syndrome.

Introduction

Non-communicable diseases (NCDs) are defined as diseases of long duration, and are generally slow in progression. NCDs kill more than 36 million people each year. Nearly 80% of NCD deaths-29 million-occur in low-and middle-income countries. More than nine million of all deaths attributed to NCDs occur before the age of 60; 90% of these “premature” deaths occurred in low-and middle-income countries. Cardiovascular diseases account for most NCD deaths, or 17.3 million people annually, followed by cancers (7.6 million), respiratory diseases (4.2 million), and diabetes (1.3 million). These four groups of diseases account for around 80% of all NCD deaths. They share four risk factors: tobacco use, physical inactivity, the harmful use of alcohol and unhealthy diets.

- Non-communicable diseases (NCDs) kill 41 million people each year, equivalent to 71% of all deaths globally.
- Each year, 15 million people die from a NCD between the ages of 30 and 69 years; over 85% of these “premature” deaths occur in low-and middle-income countries.
- Cardiovascular diseases account for most NCD deaths, or 17.9 million people annually, followed by cancers (9.0 million), respiratory diseases (3.9 million), and diabetes (1.6 million).
- These 4 groups of diseases account for over 80% of all premature NCD deaths.
- Tobacco use, physical inactivity, the harmful use of alcohol and unhealthy diets all increase the risk of
dying from a NCD.

- Detection, screening and treatment of NCDs, as well as palliative care, are key components of the response to NCDs.2

The prevalence of NCDs is showing an upward trend in most countries and for several reason this trend is likely to increase. Of the 57 million global deaths in 2008, 36 million, or 63%, were due to NCDs, principally cardiovascular diseases, diabetes, cancers and chronic respiratory diseases.3 An epidemiological transition is taking place in most of the states in India with a decline in communicable diseases and an increase in chronic NCDs that has resulted in more than 50 per cent of total deaths in India in 2005 due to chronic diseases.4 The four leading chronic diseases in India, as measured by their prevalence, are in descending order: cardiovascular diseases (CVDs), diabetes mellitus, chronic obstructive pulmonary disease (COPD) and cancer. All four of these diseases are projected to continue to increase in prevalence in the near future. The projected cumulative loss of national income for India due to non-communicable disease mortality for 2006–2015 is expected to be USD237 billion. By 2030, this productivity loss is expected to double to 17.9 million years lost.5 India is the first country to develop specific national targets and indicators aimed at reducing the number of global premature deaths from NCDs by 25% by 2025. The Central Govt. proposes to supplement their efforts by providing technical and financial support through National Program for Prevention and Control of Cancer, Diabetes, CVD and Stroke (NPCDCS). The NPCDCS program has two components viz. (i) Cancer and (ii) Diabetes, CVDs and Stroke. These two components have been integrated at different levels as far as possible for optimal utilization of the resources. The activities at State, Districts, CHC and Sub Centre level have been planned under the programme and will be closely monitored through NCD cell at different levels. 6 New scientific strategies, alternate systems of medicine, holistic life sciences, etc. (which are exceptionally cost-effective also), may be considered seriously for control and prevention of diabetes and other NCDs. The impact of NCDs will rapidly increase in countries in view of the rapid health and demographic transition. Public health experts have predicted a global epidemic of cardiovascular and other chronic diseases in the developing world by 2020.7 With the enormous number of diabetes cases, India is considered as the ‘Diabetes Capital’ of the world.8 Evidence from clinical practice and literature suggests that approximately half of most chronic diseases are undetected, and that half of that detected are not treated, and that half of those treated are not controlled. The primary care work load would increase if all the common and important chronic disorders were fully detected, treated and followed up.9 The World Health Organization has stressed on this imperative surveillance mechanism, focusing on the collection of data and statistics on key NCD risk factors continuously in order to design community based interventions targeted at the reduction of these risk factors and for monitoring the effectiveness of such interventions and its sequential phases and results.10 In macroeconomic term, most of the estimates suggest that the NCDs in India account for an economic burden in the range of 5–10% of GDP, which is significant and slowing down GDP thus hampering development. Since health sector alone cannot deal with the “chronic emergency” of NCDs, a multi-sectoral action addressing the social determinants and strengthening of health systems for universal coverage to population and individual services is required.11

**Objectives of the Study**

a) To study the distribution Non Communicable Diseases (NCDs) and its risk factors with special focus on CVDs and Diabetes among the employees of aviation sector at NSCBI Airport, Kolkata.

b) To study the socio-demographic correlates associated with NCDs and its risk factors in the study population.

c) To suggest appropriate recommendations regarding modifiable risk factors of NCDs in the study population.

**Material and Method**

This is an institution based cross-sectional study carried in NSCBI Airport, Kolkata. After fixing the objective of NCDs and risk factors among the employee of NSCBI Airport, Kolkata this study was conducted. Pre-designed questionnaire, Weighing machine, Stethoscope, measuring tapes were used for necessary measurement to obtain data with special focus on Hypertension, Obesity, Diabetes, Dyslipidemia, Metabolic Syndrome, Coronary Artery Diseases.

**Sample size:** was calculated by the formula: \(Z^2(p) (q) / d^2\), where \(Z=\) statistic for a level of confidence. For the level of confidence of 95%, the conventional \(Z\) value
is 1.96 \{2 SD\}, p= prevalence or proportion of the aspect being studied in the population, q= (100-p) d= relative error of the estimated prevalence.

**Study subjects:** 750 employees were selected on systematic random basis in various categories of employees of Kolkata Airport for the study. Persons who were working in the study area for more than 6 months and give their voluntary consent to participate were included in the study. Critically ill patients, pregnant women, and patients with as cites, not willing o give consent or not available even after three visits, were excluded from the study.

**Sampling technique:** Systematic random sampling technique was used. Study Tools: Pre-structured and pre-tested questionnaire: was adopted based on STEPS instrument for NCD risk factor surveillance. Modifications to suit the local requirements were done to generate data, Sphygmomanometer, Stethoscope, Weighing machine and measuring tape etc. Standard Operational Definitions were used in the study.

**Results and Discussion**

This is an Observational study conducted on employees of NSCBI Airport, Kolkata. We have collected data from 750 employees. We have tried to find out association of the factors such Obesity, Diabetes, Hypertension, Dyslipidemia, Metabolic Syndrome, Coronary Arterial Diseases with other variables like age, sex, marital status, job status, physical activity, drinking, smoking and other addiction habits.

| Table 1: Distribution of General Obesity (as per BMI) among Employees (n= 750) |
|---------------------------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| Age Group (Yrs) | Obese | % | Over-weight | % | Normal | % | Under-weight | % | Total |
| 20-24 | 4 | 10.26 | 13 | 33.33 | 21 | 53.85 | 1 | 2.56 | 39 |
| 25-29 | 27 | 12.68 | 72 | 33.80 | 107 | 50.23 | 7 | 3.29 | 213 |
| 30-34 | 35 | 16.43 | 73 | 34.27 | 99 | 46.48 | 6 | 2.82 | 213 |
| 35-39 | 30 | 19.74 | 56 | 36.84 | 56 | 36.84 | 10 | 6.58 | 152 |
| 40 & above | 22 | 16.54 | 49 | 36.84 | 53 | 39.85 | 9 | 6.77 | 133 |
| Total | 118 | 15.73 | 263 | 35.07 | 336 | 44.80 | 33 | 4.40 | 750 |

This study shows that the distribution of Obesity is maximum in the age group of 35-39 years (19.74%). It is observed that 15.73 % of the populations are obese, while 35.07% & 4.40% are overweight and underweight, respectively.

This study also shows that the percentage of Abdominal Obesity is maximum (59.87%) in the age group of 35-39. It is also observed that 54.8 % of the populations are having abdominal obesity.

| Table 2: Distribution of Abdominal obesity (WC ≥90cm in males and ≥80cm in females) among employees |
|---------------------------------|-------------|-------------|-------------|-------------|-------------|-------------|
| Age Group (Yrs) | Abdominal obesity | % among specific age group | Total |
| 20-24 | 20 | 51.28 | 39 |
| 25-29 | 111 | 52.11 | 213 |
| 30-34 | 112 | 52.58 | 213 |
| 35-39 | 91 | 59.87 | 152 |
| 40 & above | 77 | 57.89 | 133 |
| Total | 411 | 54.80 | 750 |

| Table 3: Distribution of Hypertension among employees (n= 750) |
|---------------------------------|-------------|-------------|-------------|-------------|-------------|-------------|
| Age group (Yrs) | Pre-hypertension | % | Hypertension | % | No Hypertension | % | Total |
| 20-24 | 7 | 17.95 | 2 | 5.13 | 30 | 76.92 | 39 |
| 25-29 | 47 | 22.07 | 18 | 8.45 | 148 | 69.48 | 213 |
| 30-34 | 65 | 30.52 | 12 | 5.63 | 136 | 63.85 | 213 |
| 35-39 | 56 | 36.84 | 34 | 22.37 | 62 | 40.79 | 152 |
| 40 & above | 44 | 33.08 | 26 | 19.55 | 63 | 47.37 | 133 |
| Total | 219 | 29.20 | 92 | 12.27 | 439 | 58.53 | 750 |
This study shows that the distribution of Hypertension is maximum in the age group of 35-39. It is also observed that 12.27% of the populations are hypertensive while 29.20% populations are pre-hypertensive.

The study shows that Diabetes and Pre-Diabetes is maximum in the age group above 40 and above. It is also observed that 10.93% of the populations are Diabetic and 9.87% are Pre-Diabetic.

IFG Impaired Fasting Glucose, IGT-Impaired Glucose Tolerance, IFG+ IGT-Both IFG+IGT

**This study also shows that:**

- Dyslipidemia is maximum in the age group 40 & above. It is also observed that 17.9% of the populations are having Dyslipidemia.
- Metabolic Syndrome (including Diabetes) is maximum in the age group 40 & above. It is also observed that 19.6% of the population is having Metabolic Syndrome (including Diabetes). Metabolic Syndrome (excluding Diabetes) is maximum in the age group 40 & above. It is also observed that 19.6% of the populations are having Metabolic Syndrome (excluding Diabetes).
- Coronary Artery Diseases is maximum in the age group 40 & above.
- Obesity among female (21.26%) is more than Obesity among male (12.90%)
- Hypertension among male (14.31%) is more than among female 8.27%
- Pre-Diabetes and Diabetes is more in Male (10.89% & 12.30%) than Female (7.87% & 8.27%).
- Dyslipidemia is slightly more in female (18.5%) than male (17.54%)
- Metabolic Syndrome (including Diabetes) is slightly more in male (8.67%) than Female (7.48%)
- Obesity is more in married (17.38%) than in single (10.94%).
- Hypertension is more in Married (14.87%) than in Single (4.69%)
- Diabetes is more in Married (14.7%) than in Single (0%)
- Dyslipidemia is more (23.30%) in Married than Single (2.08%)
- Metabolic Syndrome (without Diabetes) is high in Married (10.57%) than in Single (1.56%)
- Obesity is high in Top Level (40%) in comparison to Mid Level (15.4%) and First Level (6.9%)
- Hypertension is high in Top Level (15.2%) of Employment in comparison to Mid Level (13.6%) and First Level (9.4%)
- Diabetes in high in Top level (14.3%) in comparison to Mid Level (11.4%) or First Level (9.1%) employment
- Dyslipidemia is high in To Level (21.9%) in comparison to Mid Level (19.8%) and First Level (13.8%)
- Metabolic Syndrome (including Diabetes) is high in Top level (19%) and Mid level (18.2%) of employment in comparison to First level (15.9%) of employment
- Metabolic Syndrome (excluding Diabetes) is high in Top level (9.5%) and Mid Level (9.2%) in comparison to First Level (6.5%) of employment.

**Conclusion**

Obesity, Hypertension, Diabetes and Metabolic syndrome are predominant among the employees in the age group of 35 and above. Risk factors such as smoking, smokeless tobacco, alcohol are more in male whereas unhealthy diet, low physical activity, Dyslipidemia, high BMI, abdominal obesity are more in female. Obesity, Hypertension, Diabetes, Dyslipidemia, Metabolic Syndrome are more in Top level and Mid level management in comparison to First Level management. There is an urgent need of health awareness and health promotion activities at employee level with special focus on health diet, physical activities and behavioural risk factors. At airport level there is a need of creating an environment that promotes the adoption of positive health behaviour.

Verbal Autopsy: An Adjunct to Medico-Legal Autopsy

Manoj Kumar Pathak¹, Rohini², Madhu Kumari Upadhyay³

¹Professor and Head, Department of Forensic Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, U.P., ²Research Scholar, Department of Forensic Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, U.P., ³Associate Professor, Department of Community Medicine, University College of Medical Sciences & GTB hospital, Dilshad Garden, New Delhi, India

Abstract

Introduction: Verbal autopsy is a method, used to ascertain the cause of death based on an interview with caregivers or family members. In India, first autopsy was performed by Edward Buckley on 10ᵗʰ August 1714 in Madras.

Material and Method: A thorough study was made from the available online resources and books.

Result: It is worth mentioning that in spite of the advancements and developments in this field, still the users thrive on old standards and are unaware of the newer method of autopsy.

Conclusion: In cases, where the corpse is not available, Verbal autopsy is the only way of ascertaining the cause of death.

Keywords: VA-Verbal Autopsy, Cods-Causes of Death, Low and Middle Income Countries (LMICS), Civil Registration and Vital Statistics (CRVS).

Introduction

Autopsy, also known as necropsy, refers to the examination of the dead body, and with a view to primarily searching the cause of death. It refers to the systematic examination of a dead person for medical, legal, and/or scientific purposes. [1]

Autopsy is of three types:

Academic autopsy: Dissection carried by students of anatomy.

Medico-legal autopsy: It is done when some legal issue is involved (homicide, accident, suicide any other suspicious death). In India it is conducted by any registered medical practitioner, on the request of the investigating officer. Seeking permission of relatives is not required.

Hospital autopsy: It is done for academic purposes, research. No legal issue is involved. Permission of relatives is required.[1][2]

Besides, some other forms of autopsy are:

Virtopsy, combination of ‘virtual’ and ‘autopsy’ is a bloodless and minimal invasive procedure to examine a body for cause of death. It utilizes imaging techniques, photogrammetry and 3-D optical measuring techniques to get a reliable, accurate geometric presentation of all findings, the body surface as well as interior.

Endoscopic autopsy: It is also known as keyhole autopsy. Organs are seen through endoscopes and laparoscopes. It is conventional form of Autopsy performed for religious or other reasons. It has proven to be more rapid than conventional autopsy and left the body virtually intact.

Needle autopsy-a biopsy needle is used to take the samples of tissues and examined microscopically.
only. Virtopsy, endoscopic autopsy and needle autopsy are examples of limited autopsy (anything less than a complete autopsy).

**Psychological autopsy**: It is an investigative procedure of reconstructing a person’s state of mind prior to death. This is based upon information gathered from personal documents, police and medical records and interviews with survivors of the deceased-families, friends and others who had contact with the person.

**Verbal autopsy**: It is a protocolled procedure that allows the classification of the causes of death through analysis of data derived from structured interviewers with the family, friends and caregivers.

**Aims of Autopsy:**

- Identification of the deceased in case of decomposed, burnt, mutilated or an unidentified body.
- Cause of death, whether natural or unnatural and to interpret the significance and effect of the disease present in the case of natural death.
- Approximate time of death, mode of death, age of injuries and place of death.
- Ascertaining manner of death, poison or weapons responsible for death, extent of injuries present, any treatment received by the deceased before death.[1]

Verbal autopsy is a method, used to ascertain the cause of a death based on an interview with caregivers or family members. Information is elicited on the basis of prepared questionnaire. For building the basis of health policy, the causes of mortality prove to be of prime importance. In this regards, its planning, monitoring and evaluation of data as well as its reliability is of prime importance. Verbal Autopsy is a milestone in settings, where the majority of deaths occur at residence or away from clinical set ups or health systems. At places, where civil registration systems do not function, there is a little chance that deaths occurring away from health services will be available assuring the cause of death. In such cases, Verbal Autopsy remains of prime importance in obtaining a directional estimation of mortality at a community or population level.[7]

**Material and Method**

A thorough search related to Autopsy and Verbal Autopsy was done from various sources including online resources, various journals, and books including this topic and WHO Verbal Autopsy standards and ICDs. A thorough interviewing of police personnel (I.O.), relative of the deceased and the inquest papers were properly reviewed and incorporated in this study.

**Result and Discussion**

**History**: Egyptians in 300 BC, used to practice the removal and examination of internal organs of humans. Notable Greek autopsists were Galen, Erasistrates and Herophilus of Chalcedon.

The history of verbal autopsy is rooted deep before 19th century, in Europe, when designated death searchers used to visit the households of deceased in order to assess the nature of deaths. Systematic interviews were then used to determine the cause of death as an alternative in Asia and Africa in 1950s and 1960s and it was termed as Verbal Autopsy by workers at Narangwal project in India.

The interest of WHO in verbal autopsy of health data was first demonstrated in a publication by Dr. Yves Biraud in 1956. During the 1970s, WHO encouraged the use of lay reporting of health information by people with no medical information, leading to development in 1975 of lay reporting form. Since the late 1970s and 80s when the Reproductive Age Mortality Studies (RAMOS), Matlab and Niakhar questionnaires first emerged,
several other questionnaires have been developed for use in research settings and in national or large-scale regional surveys.

**Aims of Verbal Autopsy:** The main objective of Verbal Autopsy is to describe the cause of death at the community level or population level, where civil registrations and death certification systems are weak and people die without having any connection with the health systems or clinical set-ups. In cases, where the corpse is not available, and ascertaining the cause and manner of death is required, Verbal autopsy is the only way of ascertaining the cause of death.

**Ways of using Verbal Autopsy:** According to Development of Verbal autopsy standards, Verbal Autopsy is mainly used in three ways:

Primary use of verbal autopsy is in the field of research, as a tool. It is applicable in a number of contexts mainly in cases of children or ascertaining the maternal causes of death. It is also applicable in the cases of longitudinal population studies and intervention research programs. It is of prime importance in cases of epidemiological studies.

It has emerged as a source of cause of death statistics to meet the demand for population level estimates. It is used for estimating disease-burden, policy and priority-setting.

The third way of using Verbal autopsy is in the form of data derived from it. It is utilized as a source death statistics.

**Verbal autopsy method:** It can be Physician-certified Verbal Autopsy(PCVA) or Computer-coded Verbal Autopsy(CCVA).

PCVA-involves at least two physicians. It takes into account each record, followed by consensus review or by a third physician.

CCVA—there has been an increasing use of verbal autopsy by this method. It improves consistency and comparability. It also adds up to inter-observer agreement. The worth mentioning here is that it is faster and cheaper.

**Questionnaires:** It should utilize all available information. Query is made from police personnel about the crime scene, if a visit to crime-scene has been made. Also, the inquest papers are thoroughly scrutinized. Query should include the hospital and health records. The packets of old medicines should be taken into account. Listing some of the causes occurring frequently and age wise should be mentioned. The questionnaire should vary in cases of neonatal, child, maternal and adult health issues. A number of Questionnaire formats exist. More common are open-ended and High structured Questionnaires. Open-handed questionnaires focus on time sequence, severity and duration of symptoms while High structured questionnaires. Highly ended questionnaires include what is not salient to the respondent.

**Challenges:** At places having consistent medical records, health records are better used for the purpose. There have been some attempts to publish, document and advocate for standardized approaches to cause of death assignment. The limitations lies attributed to the facts like lack of standard data collection and thus cause of death attribution. Also, the improper tabulation leads to improper comparisons, making the things more complex. One of such factors is reliability of data which is constrained by lack of public availability of data. Further, the selection of small and non-representative samples affects the analysis. Above all these factors, lack of appropriate validation is a big hurdle in the assessment procedure.

Once captured, Verbal autopsy data should be interpreted and processed to mimic as close as possible. In international standard death certificates, there is a demand of a single underlying cause of death. In multiethnic populations, conducting Verbal Autopsy gives rise to linguistic and conceptual challenges. Also, identification of appropriate respondents is needed to be standardized. They should be close relatives, possibly present at the time of death.

**Need for standardization:** According to Applying ICD-10 to verbal autopsy, it is worth noticing that in spite of the advancements and developments in this field, still the users thrive on old standards and are unaware of the new method. The reason behind this lies in coordination gap between the users and the developers of the program. First and second generation questionnaires have been developed and stresses upon the need of researchers. Emphasis has been laid upon the type of questions needed to be put for the purpose. There are some factors acting behind the lack of standardization. The foremost factor lies in the costs of verbal autopsy. The method is easily adoptable if affordable. The other factor is
the complexity of verbal autopsy validation. Complex processes are not easily understandable and thus not easily adoptable. One such factor adding to the cause is the scarcity of comparative studies and its validation in multiple countries. Cannibalizing from previous forms is also a factor.

The WHO Verbal Autopsy standards: It has been designed for routine use. Compared to the previous standards of 2007, number of questions has been reduced. Questions have been reformed to suit the simple Yes-No question.

It includes all age groups, maternal and perinatal deaths and also death caused by injuries. It is intended to allow for simple and inexpensive identification of causes of death in places where no other routine system is in place and will serve the needs of countries’ civil registration and vital statistics (CRVS). In recent years, there has been growing interest in strengthening countries’ CRVS systems leading to demand for a more simplified and practical Verbal Autopsy instrument associated with IT applications for data collection and analysis.

The WHO Verbal Autopsy instrument has been designed for software use. It has a skip pattern embedded that takes into account all the age groups and special cases in one big questionnaire. Sample questionnaires are provided for three age groups (under four weeks, four weeks to fourteen years, fifteen years and above). The notes for translators and interviewers along with unique variable identifiers enable the translation of the instrument in the desired language. Software for interpreting verbal autopsy indicators into causes of death without the use of physician can be used in majority of cases.

Deriving causes of death from Verbal autopsy data: According to Verbal Autopsy : Method in Transition, by Fottrell E, Byass P, ascertaining cause of death at the interview stage itself has a poor validity as the information is yet to be elicited. Diagnosis is to be made at later stage by using one of the four method of interpretation: physician review without algorithmic diagnostic criteria, physician review using algorithms, computer algorithms the most recent probabilistic approaches.

Physician review-Questionnaires’ analysis by two physicians is customary as it requires subjectivity and judgement. In the case of disagreement, additional review is required and a consensus diagnosis is given. Physician review using Algorithms-These approaches are based on labeling the process of physicians review into standardized rules.

Computer algorithms-These are closely linked to the questionnaire design and field procedures. Algorithms can be developed from textbook descriptions, existing clinical algorithms, local experience or a combination of all the three.

Probabilistic approaches-Automated method applying probability and reasoning result in a range of simultaneous outcomes in contrast to algorithmic method assessing the presence or absence of a single cause.

Factors Affecting Verbal autopsy: The verbal autopsy is the outcome of thorough questionnaires. It is influenced by educational background and gender of interviewers. Proper questions need to be put for ascertaining the cause of death, which requires an elaborate knowledge of things. Any one new in the field or not well educated can’t take it properly when it comes to what is to be asked? The gender affects in a way of asking questions relevant to the gender of the interviewer. Well-trained lay men can obtain accurate information. The ultimate option of this is assigning medically trained interviewers or health professionals. A number of interviewers can be assigned but this can lead to controversies. So, in cases more than one interviewer is assigned, it is ensured that they belong to same ethnic groups as respondents in order match the words corresponding to the disease.

Validity: The validity of Verbal autopsy is attributed to a number of factors. Depending on the questions asked, respondents chosen, and the field procedures taken, VA varies. It is also affected by cause of deaths assigned by the physician. For quality studies, only those studies are included which fit our eligibility criteria. It further improves comparability of the data. It needs to be taken care of while conducting VA, that its validity thrives on questions asked. So, only studies using most validated questionnaires are eligible for it. These include a number of VA questionnaires developed: VA tools, INDEPTH, London School of Hygiene and Tropical Medicine VA, Sample Vital Registration with Verbal Autopsy. Other such tools are Routine, Reliable, Representative and Resampled Household Investigation of Mortality with Medical Evaluations (MDS) or questionnaires used in the mortality surveillance system of Tanzania and
These tools were developed under the guidelines of WHO review meeting on formulation of standard guidelines for its Verbal Autopsy tools. Second thing is that Physician Certified Verbal Autopsy coding must have been specifically carried out by Physicians himself, not other health professionals.

It necessitates the standardization of all the approaches to verbal autopsy. The methodologies are still evolving. Removing human bias is also a necessary factor for ensuring better results. It can be achieved by emphasizing on questionnaires and statistical analysis. In order to make the data better utilized by those producing it, and those utilizing it, it becomes necessary to use the standardized data..

Conclusion

Still there are questions about the accuracy of Verbal Autopsy. In countries, where inadequate registration systems are there, the accuracy of verbal autopsy means a lot. It is necessary to mention that research and development in data collection has been focused upon and has developed a lot, but the whole effort is futile without standardization of further steps. This is because variation in cause of death and proportionate mortality pattern still exists.

Pitiable and Painful Life of Indian Call Girls

Manoj Kumar Pathak1, Rohini2

1Professor and Head, 2Research Scholar, Department of Forensic Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, U.P., India

Abstract

The history of prostitution is not new. It is one of the oldest known professions. Vedas, the most ancient literature have reference of organised and established institution of prostitution., millions of Indian Citizens are bound to live their lives devoid even of fundamental and constitutional rights of living. The Immoral Traffic (Suppression) Act passed in 1956 defines the base of sex workers’ status and was passed in 1956. The remedy does not lie in its legalisation alone or criminalisation or decriminalisation.

Keywords: Prostitution, Call-girls, Trafficking, Abduction, Incest.

Introduction

We as human beings just Love to Judge. We live in a society that judges people by their profession. And, when the focal point of judgments gets centred on any Woman, then our notions become even more brutal. If a girl is comfortable in talking to only a single person of opposite sex, then she is assumed to be having physical intimacy with the same person; and if a girl is comfortable with every person of opposite sex, then our society doesn’t even bat a lid to type-cast her as a slut, whore and what not!!![1] The history of prostitution is not new. It is one of the oldest known professions. Vedas, the most ancient literature have reference of organised and established institution of prostitution. The references of celestial demigods referred as Menka, Rambha, Urvashi and Thilothamma is also available. Accomplished in the art of music and dance, they were known for their unsurpassed beauty and perfect embodiments in the court of Hindu God Indra.[2]

Hindu mythology mark the culture of Devdasis, the girls married to the temple deity, and employed as goods of amusement for the priests and rich class of the society. In the Mughal era, prostitution was a recognised profession and flourished under royal patronage, except the reign of Aurangzeb. Tawaif became popular during this period. With the downfall of the Mughals, they were bound to get out and recourse to this profession as they were not skilled in any profession and the society had no job opportunities for them.

During British rule, the Indian classical dance form was taken as “prostitute dance”. The “mujras” at kothas were also of the same class and the thumri form of local song was associated with court courtesans and prostitutes.[3]

The first known registration of prostitutes took place in Rome. They were taxed and the earnings contributed to city coffers. In the fifth century BC, with the spark of Pndora’s box women were associated with evil, worsening the condition of prostitutes. Sex began being considered as “fall of humankind”. Sexual enjoyment started being considered as a way towards hell and Men started blaming women for their own desires.[4]

The religious aspect: Prostitution is an extension of the concept of reciprocity, whereby certain women become public property and their sexuality is used by more than one man. Prostitutes may be found in every strata of ancient society, regardless of religion. In general, prostitutes were accepted as a part of the society. Since time immemorial the sexual freedom has been fantasized but in public the presence of such females has been decried. [4]
Social aspect: Women who have had sexual experience earlier are treated as “used goods”. They are considered as a commodity in the society. The existence of a woman without her husband is nothing and so the widowed and divorced women have a social stigma of being “used goods”. They are not acceptable as a spouse, except few who face a lot in doing so but are on the verge of being tried for “services”.\(^2\)

The legal perspective: According to Indian penal code, acts of soliciting such services at public places, carrying out such activities in hotels, kerb crawling, pandering, being an owner of a brothel or even running one such, pimping are contraventions of the law. Here what needs to be pondered upon is that the above mentioned things are indifferent from prostitution itself. Merely out casting these things won’t make much difference.\(^5\)

The Flip Side: In striking contrast to what elaborated above, there are also a plenty of cases when females coming from a relatively better background turn out as Call Girls. Though, their circumstances might not have forced them into prostitution but again, who are we to question their choices and their chosen way of living per se. More so, why don’t we question the people who take their services in the first place. In the times we are living, ogling at girls and passing crass comments is a normality for males in cities, towns and even villages in general. Not only this, at many workplaces and offices, very often women employees are forced to sleep their way up to the ladders of success. These are some silent truths which are known by all, but acknowledged by few. Truth is not always pleasant. It is somewhat a bitter pill which we fail to engulf unless we are forced to. Similar is the case of Call Girls too. If we are not questioning their market, we don’t have a right to point fingers at them. Instead of beating the stick at problems, we should rather focus on removal of their causes. Striving for a society having a genuine respect for women may be the actual solution for resolving this problem in hand.\(^6\)

According Human Rights survey, most of the prostitutes in Mumbai are indentured from Nepal, at a tender age between 10-20 years. They are not what they are by their choice. Girls in the profession are mostly from low socio-economic background and lower educational status. Teenage girls turn towards this profession in a need of money to feed their starved stomach, get out of a debt of family or husband. One-third of the prostitutes are there in the profession because of poverty and more than a fourth due to marital problems. Sometimes they are forced into the profession by gang members and sometimes by false promises of job and employment and love-betrayals.\(^3\)

The flesh trade goes on in almost every city and society with Mumbai and Kolkata being the hotspots. In Mumbai, commercial sex district is actually two interconnected neighbourhoods in the South-Central part of the city, approximately three kilometres from the city, between the immense Muslim and Hindu slums. The city inhabits more than 2 lakh female sex workers and is known to be Asia’s largest sex bazaar. Kolkata inhabits more than 50,000 prostitutes in the red light areas. Of these, the largest Sonagachhi is run by landlords, pimps and madams.\(^3\)

They say they are addicted to the things happening to them, but psychology says that we get addicted to the things which give us pleasure and satisfaction, but if it remains a mechanical process it can’t make the things enjoyable.

Those involved in the profession get older earlier. With time there are changes in the body, gain in weight, vaginal infections with an equal chance of uterine infection and AIDS. Such burdens make the girls matured both physically and mentally before time. Hiding things from friends and family along with a compulsion to do it make them suffer from depression.\(^7\)

The things go more pathetic because the clients who find a way out in those girls do not pay any heed to the girls and their situations, they are least interested in getting involved into the things. Merely talking with them can make the things a bit comfortable but they are in a hurry to do for what they are there and get out of the place.\(^8\)

In addition to this, the most alarming is the child prostitution. According to data, one of the five sex-workers in Mumbai are under age 18 and the problem has been ignored by the government. Sex-workers of this tender age are auctioned and wealthy Arabs compete with wealthy Indian males and others in the same. Since, the virgins are far away from AIDS and other STDs, they bring a huge amount in bidding.\(^9\)

Nobody is born as a “CALL GIRL”, but the human beings make them call girls, because they are unsatisfied by their own wives or other matters of their life and most pathetic and painful thing is that sometimes parents push
their daughter into such a society only because this is the easiest way of earning money.[10]

Material and Method

A thorough search related to Prostitution and Call-Girls was done from various sources including online resources various journals, books available on this topic and various acts passed by parliament of India one of them is the Immoral Traffic (Suppression) Act passed in 1956.

Result & Discussion

Prevalence of Prostitution

History: India is one of the oldest countries having the history of prostitution.

Vedas, the earliest known Indian literature refer prostitution as an established institution. In the Hindu mythology, Menka, Rambha, Urvashi were prominent names in the court of Indradev and were known for their unsurpassed beauty and accomplishment in the field of music and dance. In the period of Aryans, well accomplished maiden were presented as token of friendship and is marked by good position of the clan. Vishkanyas were one of the kind in this field fed on poisons from infancy and used to kill the enemies of king using their beauty. The period of Pandavas and Kauravas also has a reference of prostitutes. Kautilya’s Arthshastra defines concubines and rules made during the time for prostitutes. Kamasutra by Vatsyayan also gives an account of prostitutes and their prototypes.

The third century AD witnesses religious belief of attaching girls to temples, who were known as Devdasis in South India and Mukhies in North India. They used to offer prayers to the temple God by their dance, but later on due to immorality of priests they were forced into prostitution. The Mughal era gave a great importance to women and wine and except Aurangzeb, the period shows the flourish of this profession. The words “Tawaif” and “Mujra” became popular and were associated with performing arts. After downfall of Mughal kingdom, the prostitutes in harem of the kings came out of the royal palaces and took to the same profession again as they were not skilled in any other profession and the society had no employment opportunities for them. The British rule did not show any improvement in the status of women, rather it worsened.

Sometimes the flesh-trade is used as a source of money by female folk entertainers. Qalanders and Kanjars are few in this category.

Prostitution as a tradition: In India there are places, where prostitution is the only source of income and the entire family supports in the same. One such place is Wadia in Gujrat, where men use to find suitors for women. Natpurwa in Uttar Pradesh is inhabited mainly by people of Nat caste. They have a 400 year old tradition of Devdasis, marrying young girls to Goddess Yellamma who are forced into the prostitution for rest of their lives. Karnataka also has a tradition of Devdasis at some places. In Bachara tribe of Madhya Pradesh, the eldest most girl of the family is forced into prostitution.

The religious belief: Indian men believe that having sex with a virgin will make them invulnerable to disease. Some believe that that having sex with Indian boys will make them more potent and reduce the risk of Sexually Transmitted Diseases.

Prostitution in Mumbai: Commercially this trade in the city has its hotspot in South-central part of the city, between slums of Hindus and Muslims. On the Faulkland road, lying at the centre of the city’s red light district, women are displayed in 4*6 windows called the pinjara.

The youngest and prettiest girls are displayed at places where they are most visible and can seek the attention of clients, who are mainly there for easy sex. The trade operates in four separate harmonious crime groups, each employed for a particular job. One group controls Police buys off, second controls money lending, the third maintains the districts’ internal law and order. The fourth and the most powerful group manage the procurement of women in vast network.

Prostitution in Kolkata: The brothels of Sonagachhi are run by powerful pimps and landlords. Some of the prostitutes work in the districts’ 362 brothels while the rest walk the streets. About 40,000 customers visit the district every day, which means the average prostitute there services five to six customers a day.

Child prostitution in India: India accounts for about half a million Children prostitutes in brothels. They too suffer from HIV or AIDS. They are victims of run away or child abuse. Some have been sold, abducted or enticed by gifts. Most of these come from Bangladesh and Nepal and provided for clients abroad, mostly in the middle East. Sex tourism is quite common and normal
on the beaches of Goa, Koyalam, Puducherry and Puri, perhaps as a result of decrease in the same in Thailand and Phillipines because of which pedophiles from Europe, Japan and USA turn to India.

**Types of prostitutes**

On the basis of execution, prostitutes are:

- Brothel prostitutes—Operate in brothels, owned by ex-prostitutes and get commission in lieu of the services.
- Call girls—operate generally independently, from her place, may solicit customers through a middle man.
- Street prostitutes—They solicit customers in streets and take them to an assigned place.
- Other types—some forms of prostitution also goes in dance bars, massage parlours, dance clubs, amusement centres.

**Prostitution abroad:** In poor countries like Nepal, this trade of flesh is quite common source of income. About half the prostitutes in Mumbai are Nepalese. India has a strange legal stance when it comes to sex work. We don’t have a progressive system like New Zealand, Austria, Denmark, Ecuador, Germany etc. where sex work is legal. These places have legal brothels and in most of these countries, the workers are provided with health insurance, they have to pay taxes and even receive social benefits. But in India, there is also no blanket ban on sex work like Iran, Afghanistan, Norway, Iceland and Northern Ireland etc.

**The Legislation:** Having said that, existence of some of the Asia’s largest red-light districts in Kolkata, Delhi and Mumbai is also a fact that none can deny. Then, where is the law and where are its implementers? Just because of shear flimsiness of legislation across the sex-workers, millions of Indian Citizens are bound to live their lives devoid even of fundamental and constitutional rights of living. They are left unprotected by the law and this further leads to their exploitation. All this happens because *We as a Society,* have accepted them to be immoral for their ‘choices of lives’ and assumed with our intellectual thinking that immoral should never have rights to voice against exploitation of any nature, and torture of any magnitude.

**Laws related to prostitution in India:** The Immoral Traffic(Suppression) Act passed in 1956 defines the base of sex workers’ status and was passed in 1956. The law says that the prostitutes are allowed to ply their trade in private, but not in open. Indian laws do not consider sex in exchange of money as illegal, but this trade is to be restricted within the boundary wall at distance of 200 yards of a public place.

Immoral traffic prevention act, passed in 1986 is an amendment of The Immoral Traffic(Suppression) Act. According to this law, the call girls are restricted from sharing their phone number in public will be arrested for soliciting their services or for seducing in public. Clients consorting with prostitute within 200 yards of a designated area can be imprisoned for a maximum of 3 months along with financial penalties. If someone involved in such activities is below 18 years, imprisonment of 7-10 years can be conferred. Also the landlords, housekeepers and those living with pimps are liable to be punished if fail to disprove their guilt.

**Legalising prostitution in India:** The problem seems to be inevitable because it’s next to impossible to bring a sudden pause. Legalising prostitution can be a respite to sex and child trafficking. Other things added to this will be protection of women and their rights in this field. The legalisation can provide a protection from criminals and blackmailers who in the name of keeping it a secret exploit them. Also the lawkeepers will no more be able to threaten them for exposing them. There can be a track record of sex-workers, the kind of health issues with them and health services can be made accessible to them. The foremost expectation be an alleviation in the incidences of rape, incest and similar incidences as such desires can be fulfilled with easy access to an assigned place.

**Possible solutions:** The problem has its roots deeply fabricated into the society itself. But when it comes to alleviating the plight of those in the field, it can be done by both preventing the new add ups to the profession and also rehabilitating those already there.

Preventive efforts can prove beneficial as there will be a check to the new addition to this clan. This can be done by creating awareness about the long term consequences of this field. Proper guidance and counselling can be fruitful in this regard. The abduction /abuse related to girl especially should be given prime importance and follow-ups. In order to make the community an active part of such programmes, NGOs should be promoted. The blossoming lives in the brothels should be taken out and proper grooming and education should be ensured.
in order to shape them in a way different from their mothers.

Rehabilitative-to bring a pause to prostitution, rehabilitation is needed to be ensured, both physically and psychologically. Physical rehabilitation can be achieved by taking them out to new habitats away from brothels. Protecting them from the torture and threatening of dalals and brokers should be ensured in order to make them stress free and relieved. Making them aware about their legal rights can imbibe positivity in them. Similarly, ensuring the financial security by engaging them in suitable jobs or small-scale industries can do the needful.

**NGOs working for sex-workers**

Shakti Vahini-Dehi

AAWC-Apne Aap Women Collective, Kamthipura, Mumbai

Indian Women Welfare Foundation, Faridabad

Prajwala, South India

Prerana Anti-trafficking, Mumbai

Katkatha, New Delhi

Pahal welfare society, New Delhi

In Calcutta prostitutes have formed a union-like organizations—the Durbar Mahila Samanvaya Committee (DMSC), or Committee for the Coordination of Unstoppable Women—to fight for their rights.

Recent researches highlight that more than 3 million sex workers are currently operating in our country. More concerning is the fact that majority of them belong to the age group of 15-30 years. A common statistic puts the number of girls and women currently indentured from Nepal into India at 200,000, with approximately 3,000 girls being trafficked out of the country each year, with 20 percent of prostitutes in the country being younger than 16 years old.

**Conclusion**

Many a times, the solution to a problem lies alongside the problem itself. It goes without saying that, Sex-Trading is a reality in India. Time is high we free ourselves from the cage of self-righteous cocoons. While on one hand we should definitely work on strengthening the legal framework related to sex-workers, but at the same time we should never shy from working towards creating a healthier environment at large, where women are not treated as prey for pity satisfactions of intimate fantasies of a male-dominant society; they are subjected to dignity and respect from one and all instead.

Ultimately, it would be better to say that no specific remedy is required for the problem for prostitution in India. The remedy does not lie in its legalisation alone or criminalisation or decriminalisation. The situations force her to be what she is or she chooses it by her choice—it’s only one face of the coin, the other side being a bitter truth that they do exist because of a clan of society, who find their amusement and happiness in them and find them a way to get out of their solitude in the dark, but never forget to point them out in the light.

Healthy Diet and Literature: Representation of Children’s Food in Enid Blyton Stories

Meera Krishnadas

Ph.D. Scholar, Department of English and Languages, Amrita School of Arts and Sciences, Kochi, Kerala

Abstract

Food, an indispensable part of children’s lives and subsequently children’s literature, provides multifaceted dimensions to a narrative. The paper tries to explore the introduction of a healthy western cuisine to the Indian audience through the books of Enid Blyton. As many have noted, Enid Blyton in her books provide a rather healthy diet and also manages to make it appealing to the children. Her characters do not gorge themselves on junk food, but eat balanced, nutritious food. This multidisciplinary dialogue between literature and health shapes the perceptions of the young generation towards a healthier lifestyle. Enid spelt backwards is dine, a happy coincidence to generations upon generations who grew up reading Blyton’s stories. Her books, with an enduring appeal that reigns the bookshelves, is subtly centered around cultural caricatures through culinary delights irrespective of the story. An a la carte of high teas, picnic lunches and midnight feasts-commonplace in the Enid Blyton menu-vivified tastefully, result in traditional British cuisine being synonymous with fine dining. Thus, the food becomes an aspirational motif to young readers, who are attracted to not just the imperial culinary traditions, but also to the British lifestyle, of which the delicious food is only a subset. The paper explores this interplay between food and the literature, paying careful attention to how a healthy diet is prioritised in Blyton’s stories.

Keywords: Food, Health, Enid Blyton, Children’s novels, Diet.

Introduction

“You cannot have adventures on an empty stomach”, reasons Dick, one of the characters in the Blyton Adventure Series. Wendy R. Katz, one of the pioneers in connecting food to children’s literature, in her article “Some Uses of Food in Children’s Literature” argues that “children’s literature is filled with food-related images, notions, and values” because if one “understand[s] the relations between the child and food… [one] understand[s] the workings of the world of the young.” In the Blyton books that range from bedtime tales to school life adventures, food is an indispensable entity. Yet it blends so beautifully with the narrative and does not stand out in any way. It normalizes the world of children’s literature. It is an aspect familiar to children from the time they are born. The characters having food serves as a connector from the reader to the character, a habit that is shared. A normal child cannot expect to go on a picnic and find an adventure awaiting them like the Famous Five characters. The books are colourfully and deliciously packaged as a realistic fantasy to the young audience for whom the real elements of food balance out the unreal.

Materials and Method

This paper attempts a textual analysis of the Blyton books and the various articles that have come up based on them. The main focus here is on the depiction of food in these highly influential children’s stories in which the kids are introduced to healthy western food choices rather than pizza or burgers. An effort is made to look at the successful interplay of literature with food leading to a more effective impact on generations of readers.

Food in Blyton’s Stories: In the introduction to their anthology Critical Approaches to Food in Children’s Literature, Kara Keeling and Scott Pollard argue that if food is fundamental to life and a substance upon which civilizations and cultures have built themselves, then food is also fundamental to the imagination and the imaginary arts. Few authors have ever had as much of a tryst with food in their writings the way Blyton has. Adventures have begun and culminated with feasts.
Picnics have centered around them. School lives were enriched by them. Breakasts, dinners and suppers have dotted the days of our favourite childhood characters incessantly. Even the most common plant in the Enid Blyton stories-honeysuckle-resonates a joyous, jolly and distinctly “foodish” vibe.
